Since 2008, to mainstream the national policy measures in national planning and development, all the states were urged to make their prospective State Action Plans on Climate Change (SAPCCs) to integrate the national goals into their planning measures. At the Conference of State Environment Ministers held on August 18, 2009, the Prime Minister of the country requested all the state governments to prepare their respective SAPCCs. Many states are currently in the process of preparing their respective SAPCCs. "The State Action Plans include strategies and a list of possible sectoral actions that would help the states to achieve their adaptation and mitigation objectives. The common thread that binds all the state actions plan together is the principles of territorial approach to climate change, sub-national planning, building capacities for vulnerability assessment and identifying investment opportunities based on state priorities. This framework provides a broad, systematic, and step-wise process for the preparation of the SAPCCs and advocates for a participatory approach so that the states have ownership of the process and final plan. The major sectors for which adaptation strategies envisaged are agriculture, water, forests, coastal zone and health" (GoI 2013, p. 256).

According to the constitutional agenda of the country, states and centers are collaborators and partners in quasi-federal framework. Pertaining to the resource mobilization and expenditure, while the capacities of both the stakeholders are comparatively similar, the position of the states in effective policy and program implementation is stronger than the central government. Besides implementing central government programs, states implement a range of programs under the state plans to meet the developmental deficits, which are specific to the respective states. For the adaptation measures, hence, the role of the states is significantly paramount as it requires a multipronged targeted and locally contextualized approach to address the specific vulnerabilities prevalent in each state. Since the adaptation measures need to be implemented at the local level within the states, the states themselves can best decide on the prioritization between the various sectors to build the adaptation capacity of the poor and marginalized groups.

The adaptation interventions in India are placed within the broad developmental paradigm. The character of public expenditure till date is to support national policies pertaining to poverty eradication, accelerating the socioeconomic development to meet developmental deficits, and helping the country to build institutional and economic capital. However, mere fulfilling economic growth and poverty reduction are not sufficient to raise the living standards of people to help them adapt to climate change and transforming their lives to adapt to low-carbon lifestyles.

Public expenditure for adaptation strategies requires a new definition. It explains as that expenditure which builds human capacity of the poor, marginalized, and vulnerable groups to meet/cope with the effects of climate change. Developmental budgets are not adaptation budget by itself; it may not be necessarily targeted to build the resilience of the communities. Adaptation expenditure can be viewed as pro-climate developmental interventions at different levels of the economy. It entails improving human conditions and capabilities, enhancing the standard of living for the poor and marginalized groups to prepare themselves to cope with the adverse impacts of climate change. Further it has components of improving sustainability of ecosystem which intends to manage the human dependence on nature and environment, focusing on sustainable use of natural resources, conservation of common property resources and ecosystems, reduction in human-animal conflicts, and creation of buffers against potential natural calamities. It further requires recognizing the multidimensional nature and complexity of the issues involved and necessitates differentiation between programs/schemes that address adaptation to climate change on the lines of their intended outcomes, particularly those that address and augment human capabilities and schemes, which focus on better management of natural resources.

Explaining adaptation expenditure in the overall public expenditure is methodologically a challenging exercise. No such systematic accounting exercise was initiated by the Ministry of Finance (MoF) or Ministry of Environment and Forest (MoEF) to try and assess the public expenditure being spent on addressing the environmental concerns. However, the Union Government for the first time claimed in NAPCC that it spends nearly 2.6 % of GDP toward adaptation expenditure (GoI 2008, p. 19). The basis of such accounting exercise is yet to come in the public domain. But what the policy document NAPCC unveiled was the adaptation policy framework for the country, underlining the focus areas of interventions, viz., crop improvement, drought proofing, forestry, water, coastal region, health, risk financing, and disaster management. In order to demystify the puzzle of adaptation spending in the country, the study by Ganguly and Panda (2010, p. 11) attempted to provide certain classifications of adaptation expenditure in India which was further put into context on the following indicators by Kapoor and Panda (2014) in the analysis of state funding:

- *Land development*, *drought proofing*, *irrigation*, *and flood control* including programs like the Drought-Prone Areas Program and the Integrated Watershed Management Program
- *Agriculture and allied activities* including programs like the National Food Security Mission and Macro Management of Agriculture (MMA), ATMA, National Horticulture Mission, and Dairy Development programs
- *Water resources* including programs like the Desalination Project and Artificial Recharge of Groundwater Through Dug Wells
- *Forestry*, *wildlife*, *and biodiversity* including programs like the Integrated Forest Protection Scheme and the Integrated Development of Wildlife Habitats
- *Poverty alleviation*, *livelihood promotions*, *and food security* including programs like the food subsidy, Antyodaya Anna Yojana and Swarnajayanti Gram Swarozgar Yojana (now changed to National Rural Livelihoods Mission)
- *Risk management* including programs like the National Agriculture Insurance Scheme (NAIS) and Weather-Based Crop Insurance
- *Disaster management* including programs like the National Disaster Management Program and the Tsunami and Storm Surge Warning System

Methodological Boundary

The study of adaptation expenditure necessitates the process of identification of the schemes and programs oriented and enabled with building the resilience of the people and the state against the adverse impacts of climate change. This premise is based on the primary assumption that the certain initiatives undertaken by the government for general development also build resilience of the communities to deal with the adverse impacts of climate change and also induce behavioral changes in use of and access to natural resources. The study of adaptation expenditure of the state budgets through gender lens requires the analysis of financial data that are reported on many levels. Funds for adaptation expenditures are flowing through centrally sponsored schemes (CSS), central sector schemes, state plan schemes, and district sector plans. The study has attempted to capture the funds flowing to these categorizations of programs.

The time period for analysis for estimating expenditure is 4 years from 2009–2010 (actuals) to 2012–2013 (budget estimates). The states identified for the study are Madhya Pradesh, Uttar Pradesh, Uttarakhand, and West Bengal. For the identification of the schemes/programs pertinent to adaptation to climate change, authors have relied extensively upon the SAPCCs, annual reports of the departments, plan documents, and policy guidelines of the ministries and departments to cull out the relevant information about various components within each scheme that aims to build/increase the adaptive capacities of the people and the state. In addition to, for expenditure tracking, extensive and meticulous research of state budgets and plan budget documents of the states has been undertaken to arrive at the quantum of expenditure that state government is spending for adaptation to climate change. Field studies in the study states have become significant instruments to elicit the perspectives of the government officials on adaptation interventions and expenditures, the SAPCCs, impacts of climate change on women, and finally knowing the prospective plan for the future. Centre for Budget and Governance Accountability (CBGA) with the collaboration of Alternative Futures has been part of a series of Interdepartmental Round Table 1 Discussions on climate change, which has been a forum of immense help to capture insights from the multi-stakeholders participation.

Table 1 Estimations of adaptation expenditures of select states in India

State	Public expenditure on adaptation to climate change	2010–2011[a]	2011–2012[b]	2012–2013[c]
Madhya Pradesh (MP)	Total adaptation expenditure (million in US $)	14,848.00 (32.82)	16,822.00 (35.10)	17,884.00 (32.88)
	Total adaptation expenditure as % of total budgetary expenditures (TBE)	22.55	20.86	22.35
	Total adaptation expenditure as % of GSDP at current prices	5.7	5.33	4.36
Uttar Pradesh (UP)	Total adaptation expenditure (million in US $)	24,188.00 (53.47)	23,307.00 (48.64)	32,335.00 (59.44)
	Total adaptation expenditure as % of TBE	17.75	14.1	17.36
	Total adaptation expenditure as % of GSDP at current prices	4.03	3.43	4.2
Uttarakhand (UK)	Total adaptation expenditure (million in US $)	1,158.49 (2.56)	1,402.64 (2.93)	1,489.92 (2.74)
	Total adaptation expenditure as % of TBE	7.87	8.03	6.42
	Total adaptation expenditure as % of GSDP at current prices	1.38	1.49	1.38
West Bengal (WB)[d]	Total adaptation expenditure (million in US $)	8,137.15 (17.99)	11,032.51 (23.02)	13,454.17 (24.73)
	Total adaptation expenditure as % of TBE	**11.15**	12.54	13.4
	Total adaptation expenditure as % of GSDP at current prices	**1.76**	2.07	2.16

[a]Annual average of exchange rate of INR to US $ in FY 2010–2011 (45.24)
[b]Annual average of exchange rate of INR to US $ in FY 2011–2012 (47.92)
[c]Annual average of exchange rate of INR to US $ in FY 2012–2013 (54.40)
[d]The adaptation estimation for West Bengal includes both plan and non-plan expenditures. On the other hand, the adaptation expenditure of other three states includes only plan expenditure components

Analysis of the Budgets of Select States

Following the abovementioned categorization of adaptation program framework, it is observed that there are marked variations in adaptation spending among the four study states due to the extent of developmental interventions. However taking into account the differences in the size of the states and their corresponding economies and total budgetary outlays, it would be misleading to suggest that UP is doing better than the other three states (on the basis of absolute numbers). To make the analysis comparative, the study has computed the total adaptation expenditure (TAE) for each state as a proportion of the gross state domestic product (GSDP), as a proportion of the total budgetary expenditure (TBE), as well as the per capita adaptation expenditure (PCAE).

India is a federal country having 29 states. UP has one of the largest budgets in comparison to any state in India. Its total budget was nearly two crore in 2012–2013 (BE) in which the proportion of developmental and nondevelopmental expenditure was 67 % and 37 %, respectively (RBI 2013). The analysis of adaptation budget for UP revealed that it spent approximately 4.2 % of GSDP (at current prices with 2004–2005 base year) in 2012–2013 (BE) and around 16.2 % as proportion of total budgetary expenditure (TBE),for the same year. MP budget shows similar trend while estimating adaptation expenditure. Its developmental and nondevelopmental compositions of expenditures turned out to be 68 % and 32 %, respectively, during the same year (RBI 2013). However, its share for the adaptation budget was much higher than UP as it constituted nearly 4.8 % of the GSDP (at current prices with 2004–2005 base year) and nearly 22.35 % of its TBE in 2012–2013 (BE). In absolute number, MP spent nearly Rs. 17,000 crore for adaptation-oriented interventions in the FY 2012–2013 (Fig. 1).

West Bengal (WB) and Uttarakhand (UK), as compared to UP and MP, have a small size of adaptation budget. The UK has the smallest state budget under study having a budget of approximately Rs.21,931.77 crore in 2012–2013 (BE), in which the adaptation expenditure is estimated to be merely Rs 1,489 crore in FY 2012–2013. This constitutes nearly 6.8 % of the TBE, and as proportion of GSDP (at current prices with 2004–2005 base year), it is merely 1.38 % (Fig. 1). This reflects the fact that the budget of the UK has placed priority on adaptation measures in the state. The UK is highly vulnerable to climate change impacts due to its geophysical location and because of its almost complete dependence on climate-sensitive natural resources. About 65 % of its area is under forests, and more than half of its population is dependent on agriculture, horticulture, and livestock for their living. Most of the agriculture is rain-fed and so very sensitive to climate vagaries. A whopping 73 % of women workers are engaged in farm-related activities, compared to 40 % of all male workers (Census 2011), but only 10 % of all landholders are women.

The analysis of WB state budget suggests that out of the total budget of approximately Rs. 1 lakh crore, the adaptation budget is nearly 13.40 % of TBE and 2.2 % of the GSDP (at current prices with 2004–2005 base year) in FY 2012–2013 (Figs. 1 and 2). The figure suggests an increasing trend over the

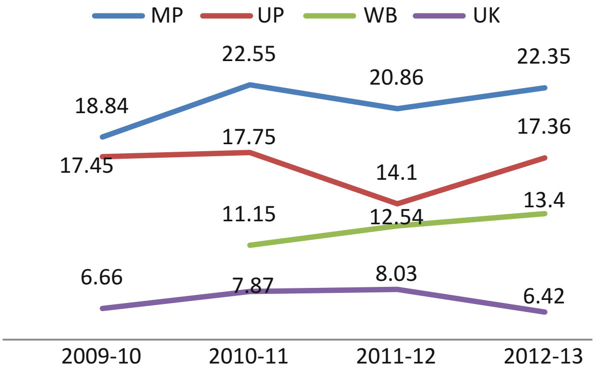

Fig. 1 Adaptation expenditure as proportion to total budget of selected study states

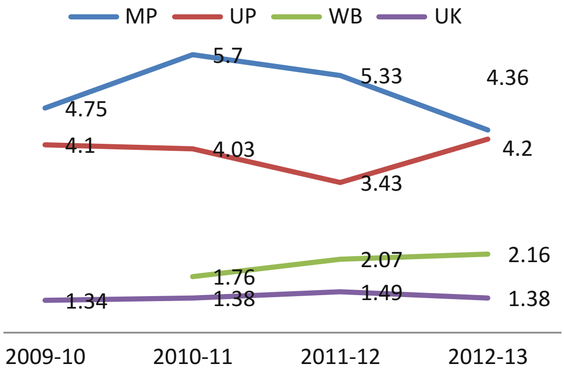

Fig. 2 Adaptation expenditure as proportion to GSDP of selected study states

years. WB being the world's ninth most populated state, with a fifth of its people living below the poverty line (GoI 2013,) has a long history of recurring cyclones and floods. Climate change brings with it the threat of sea-level rise and related disasters. Primary sector workers comprise only 44 % of total workers, but they are extremely resource poor with women comprising only 3.5 % of total land owners.

The total adaptation expenditure by the states has also been computed as per capita adaptation expenditure (PCAE). When one looks at the per capita expenditure on adaptation to climate change (Fig. 3), yet again MP emerges as a better performer as compared to the other three states under analysis. However what is surprising is that in per capita terms, the UK fares better than WB, which is surprising as the outlays for WB are inclusive of the non-plan component as well.

Assessing the Sectoral Prioritization Within the Adaptation Expenditure

While looking into sectoral composition within the adaptation expenditure framework for each state, the study tries to gauge the priority within the adaptation framework and whether adaptation initiatives by the states are more

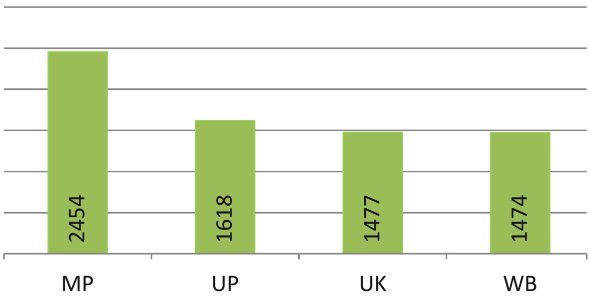

Fig. 3 Per capita state budget expenditure on adaptation to climate change (in Rs.) in 2012–2013 (BE)

pro-developmental or more pro-adaptation in nature. Analysis reveals that in all the four states, poverty alleviation, livelihood, and food security have the highest quantum of allocations, indicative of the high priority accorded to this sector in the states' plan schemes. Also, the allocations under this sector surpass the allocations under other sectors by a huge margin. This is probably owing to the fact that this is one area which is more in the nature of developmental initiative rather than purely adaptation strategies, with many developmental schemes already in place in these states. The adaptation benefits that accrue from this sector are more in the nature of incidental benefits, which nevertheless go a long way in building up the resilience of the people and the state against any adverse condition. In fact, sectoral distribution of adaptation budget in the UK shows that components such as poverty alleviation, livelihood and food security, land development, drought proofing, irrigation and flood control, and agriculture and allied services constitute nearly 80 % of the total adaptation expenditure in the state.

Two areas that need maximum attention are disaster management and risk management. Considering the kinds of threat that climate change portrays, it is important to have adequate mechanisms in place to deal with any natural calamity that may result due to changing climate patterns. The states also need to focus on putting in more effort and thought into how best it can work to alleviate the risk factor that increases with the threat of climate change. Hence both form an important focus area to be given high priority in the overall policy framework for adaptation. Unfortunately, both suffer from lack of adequate prioritization by the government in terms of actual allocations. For example, in Uttar Pradesh, there is no expenditure whatsoever on disaster management, and the forestry sector has been accorded a low priority. Agriculture and allied activities also need greater prioritization, especially in view of the fact that a majority of the population depends on this sector for livelihood as well as for food security. Study reveals that in all the states most of the schemes and programs that make up the adaptation budget in the state are primarily developmental in nature, with adaptation being a secondary incidental benefit. The entire planning approach is focused on "development," and prioritization toward adaptation is missing in all the states. It is quite clear from the analysis that adaptation is yet to be recognized as a policy priority by the government and that most of the adaptation measures are side-along benefits from the mainstream developmental measures (Figs. 4, 5, 6, and 7).

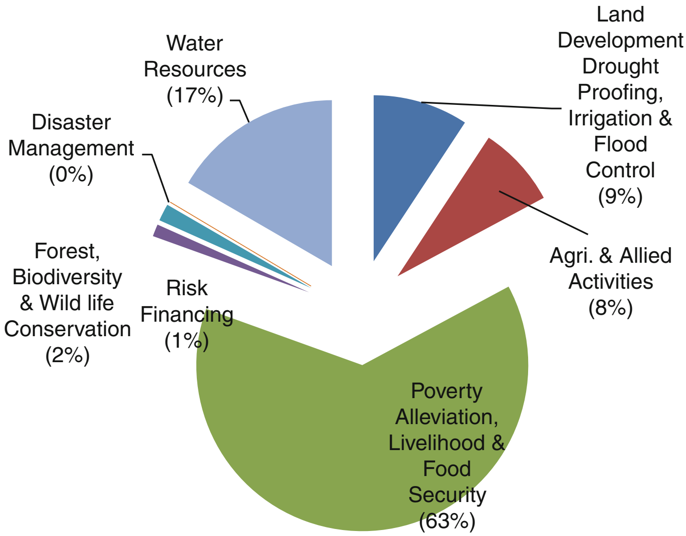

Fig. 4 Adaptation expenditure in FY 2012–2013 in MP

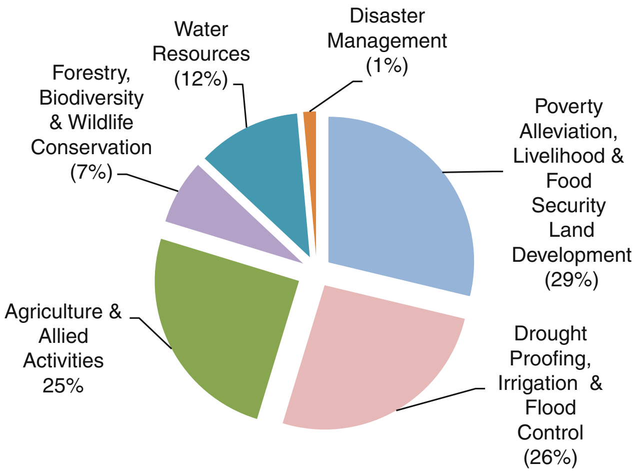

Fig. 5 Adaptation expenditure in FY 2012–2013 in the UK

Engendering Adaptation Budget in Select States

It is important to recognize the fact that in all the categories of adaptation interventions, women are major actors; hence no sector can be viewed as gender neutral. Mainstream developmental programs need to be engendered, taking into account the numerous developmental deficits faced by women and girl children in the

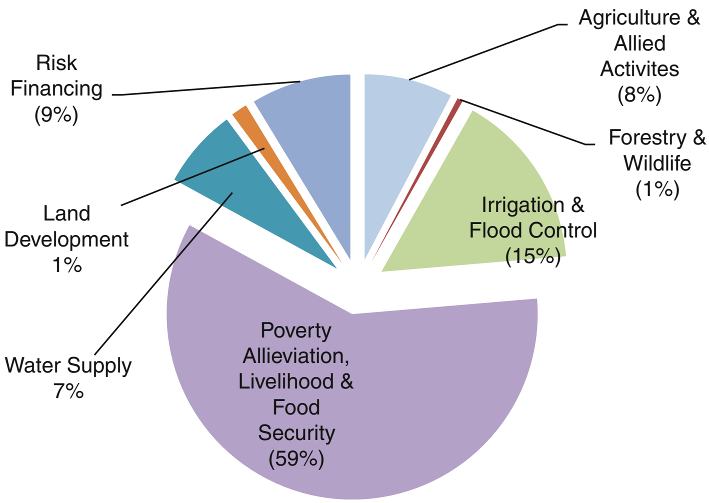

Fig. 6 Adaptation expenditure in FY 2012–2013 in UB

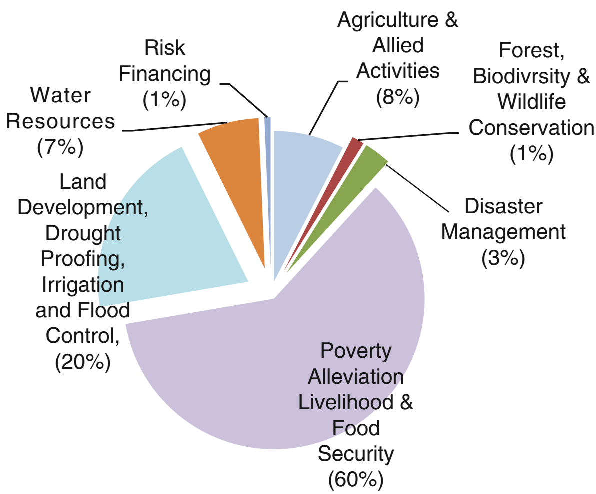

Fig. 7 Adaptation expenditure in FY 2012–2013 in WB

various sectors. Given the scenario with respect to the status of the women in these four states, it is imperative that the gendered concerns in all spheres of development, and particularly with respect to the process of climate change, are recognized by the policy makers and the same addressed in the policies that promote adaptation or mitigation to climate change. To assess the state's endeavors in this regard, the study looked at the gender budget statements/women component plans being compiled in the respective states. Gender budgeting refers to a method of looking at the budget formulation process, budgetary policies, and budget outlays from the gender lens (Das and Mishra 2006). "Gender Budget, with regard to the

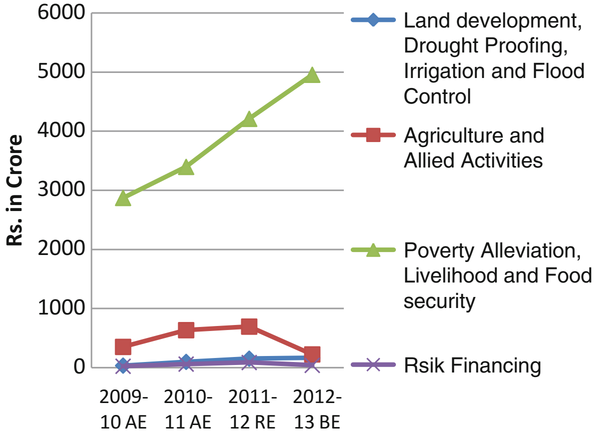
Government at any level, does not refer to a separate budget for women; rather it is an analytical tool which scrutinizes the government budget to reveal its gender-differentiated impact and advocate for greater priorities for programmes and schemes to address the gender-based disadvantages faced by women" (Parvati et al. 2012).

In order to evaluate the priority accorded to women and girl children in the schemes specific to adaptation to climate change, an analysis was carried out of the gender budget statement (GBS)/women component plan (WCP) of the respective states. Schemes reported in the GBS/WCP were identified as adaptation specific or pro-adaptation based on their respective guidelines and policy objectives. The states of MP and the UK have institutionalized gender budgeting and present a gender budget statement as a part of their respective state budgets. However, both the statements suffer from some critical shortcomings which dilute the efforts of the states in this domain. The methodologies followed by both the states are flawed; while MP has been reporting 100 % allocations under various schemes under Part B of the GBS (which is meant to capture at least 30 %, but not entire allocations meant for women/girl children under a scheme), in the UK it is the Finance Department which is single-handedly preparing the GBS without any inputs or consultations with the line departments. Merely reporting higher allocations (the way departments are doing in MP) in the statement has been seen as the final objective by most departments.

There also exist issues with regard to the quality of interventions being reported under the GBS in both the states. Recognizing that the purpose of gender budgeting is to address the concerns being faced by women and girl children, not just in their socioeconomic status but also for their overall empowerment, in most cases, there remain doubts regarding the pertinence of including these interventions under the GBS in both the states. Most of the schemes and programs being reported do not aim to address gender inequity in any way or only continue to reinforce gender stereotypes (Parvati et al. 2012). Moreover, the so-called indivisible sectors remain outside the ambit of the GB statements.

In the sectors identified as crucial for adaptation, departments such as Agriculture and Watershed Management hardly report any schemes under Part A of the GBS in the UK where 100 % of the allocation is for women. Where such schemes are reported, the budgetary allocations under these are miniscule. Moreover, there are some schemes specifically for women that have well-defined guidelines for their benefit, which are not listed in the GBS in the UK. For example, schemes like Mahila Dairy Vikas Yojana and Mahila Dairy schemes being implemented by Dairy Development Department, though exclusively for women, do not find mention in the GB statement. Again, under the GBS, allocations under food security get maximum priority mainly on the account of the centrally sponsored scheme for nutrition. Several key climate change-sensitive sectors like disaster management and risk financing do not report even under Part B of the GBS, where at least 30 % of the total allocation must be for women. In cases where some interventions are reported under the GBS, the allocations under these are fairly low. Above all, interventions being reported under the GBS in these five categories are mainly

Fig. 8 Adaptation to climate change under the GB statement in MP



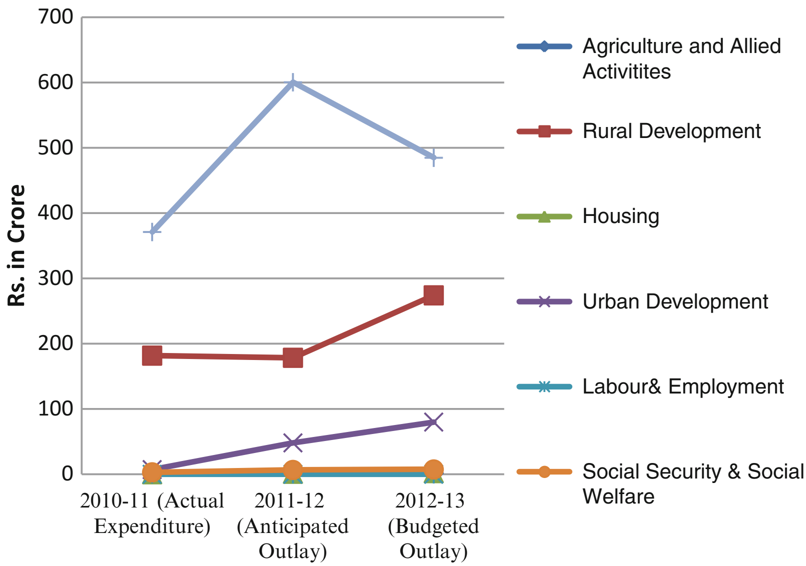


Fig. 9 Adaptation to climate change under the women component plan in WB

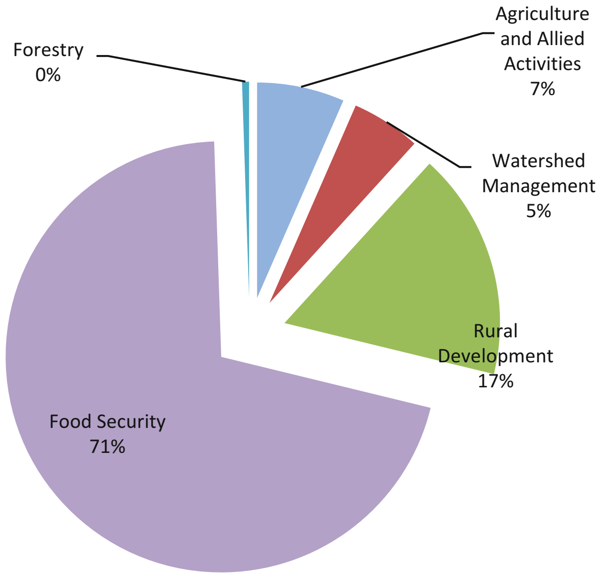
welfare oriented; they do not empower people by building their capacities and resilience to various shocks, including climate change (see Figs. 8, 9, 10, and 11).

The analysis of the GBS in MP reveals that very few departments have all-women schemes, and these too have miniscule allocations. Most sectors remain outside the ambit of gender budgeting. In the sectors which do have a component of gender, the bulk of the allocations are concentrated in the poverty alleviation category. Sectors like disaster management and forestry do not report under GBS. Allocations under agriculture sector remain low and have witnessed a falling trend over the last few years. This is a concern, especially in view of increased

Fig. 10 Adaptation to climate change under GB statement in the UK for 2012–2013 (%)



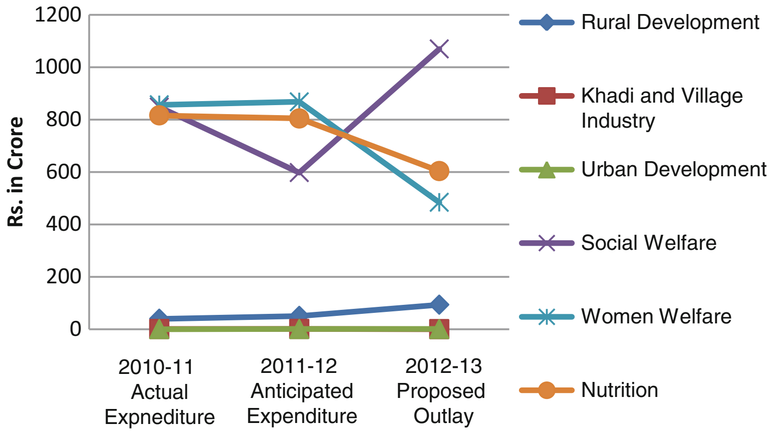


Fig. 11 Adaptation to climate change under WCP in UP

feminization of agriculture. Planning for gender concerns in the budget process is missing with most interventions remaining an ex post exercise by the relevant departments (see Figs. 8, 9, 10, and 11).

The states of UP and WB are still carrying forward the WCP, presented as an annex in their state annual plans. WCP is restricted to the plan budget of the government. Moreover, only select departments, which are considered as women specific and beneficiary oriented, have been reporting under the WCP. Further, even the reporting under this seems more like an ad hoc exercise, rather than a planned, deliberated task. The states in formulating the WCP, have not adopted an "engendering" approach to planning. Many schemes, which have clear policy guidelines benefitting women and are being implemented in the states, do not find mention in the WCP. Uttar Pradesh has still not moved on to adopting gender budgeting as a tool for women's empowerment. The state has in place, since 2005–2006, a WCP which, under plan allocations, reported an outlay of Rs. 2,253.09 crore during 2012–2013 (see Figs. 8, 9, 10, and 11).

The WCP witnessed an increase in the quantum of funds being reported over the recent years. However, no schemes under agriculture and allied activities, which are a core sector with respect to both climate change and the participation of women in the sector, are reported under WCP. In fact the coverage of sectors under the WCP is very restricted, leaving out a bulk of the core sectors that have a direct bearing on the welfare of women. The entire approach poses a question on the seriousness with which the exercise of WCP is being carried out by the planning department. Nutrition and women welfare, critical to cushion the impact of low food production in the wake of climate vagaries, witnessed a sharp fall in 2012–2013 compared to 2011–2012. A reverse trend was witnessed in the allocations under social welfare. In fact, most schemes reported do not address specific gender concerns but seem a procedural ex post accounting exercise. Again, reported schemes are welfare oriented, not empowering. Also, any adaptation benefits that accrue from these are merely side-along benefits.

West Bengal too has not adopted gender budgeting yet. The state presents a WCP which has witnessed a marginal increase in allocations over the last 3 last years (2010–2011 to 2012–2013). Very few departments report under the WCP, and key adaptation-centric sectors remain outside the ambit of the WCP. Reporting under the WCP is not robust with many interventions that benefit women are not being included under the WCP. One disturbing observation that emerges from this analysis is that none of the schemes can be termed as purely adaptation schemes. All of them fall under the head of developmental interventions. Even allowing for the fact that all interventions are not being captured in the WCP, it is quite disconcerting that the mainstream adaptation strategies of the state have not found a place for women and their needs in their planning and budgets.

Finally, it is observed from the field that the whole approach of integrating the gender concerns in the entire planning and budgeting process is missing. There has not been an attempt to think through the challenges that women and girl children face in the context of climate change and the adaptation framework and thereby address them. The recognition of the interlinkage between process of climate change, adaptation to climate change, and the inherent gender concerns is absent. Thus both GBS and WCP have remained fairly limited exercises in these states, each fraught with its own set of anomalies. Moreover, as observed earlier, the interlinkage of gender, climate change, and hence adaptation to climate change is yet to be recognized in the planning framework by all the states. Most of the adaptation benefits remain mainly a spillover from the main developmental initiatives of the states, and at the same time prevalent gender concerns within it have not been integrated in the overall planning in the states.

Box 1: Gender Budgeting in India

Gender responsive budgeting (GRB) has been endorsed as an important tool for advancing gender equity. The latest count shows that around 90 countries have integrated GRB practices and processes. Gender budgeting is based on the premise that there are specific gender-based disadvantages confronting women and girls due to which they are able to derive much less benefit from a given policy as compared to men and boys. A gender-responsive budget thus ensures that such disadvantages are recognized and special measures are taken to address the gender-based disadvantages. Diane Elson has proposed a set of six tools of GRB:

1. Gender-aware policy appraisal
2. *Beneficiary assessments*
3. Gender-disaggregated public expenditure incidence analysis
4. Gender-disaggregated analysis of the impact of the budget on time use
5. Gender-aware medium-term economic policy framework
6. Gender-responsive budget statement

In India, the first attempt to ensure a definite flow of funds to women was with the introduction of Women's Component Plan (WCP) in the Ninth Five-Year Plan. However, noting its sluggish growth and given fundamental shortcomings in its approach, the government discontinued WCP and adopted gender budgeting.

Since 2005–2006, a separate statement "gender budget" (Statement 20, Expenditure Budget Volume I) is presented every year as part of the union budget that tries to capture all those budgetary resources, which, according to the Union Ministries/Departments, are earmarked for women and girls. The schemes with 100 % funds meant for women and girls are reported in Part A of the GB statement, while those with at least 30 % funds but not the entire sum are slated under Part B. A total of 33 demands for grants under 27 ministries/departments and five union territories are covered in the GB statement of 2012–2013.

Conclusion

The chapter focuses on the "priority accorded to gender" in adaptation-responsive programs and public budgeting in select states. The developmental planning and policies pursued by the study states fail to empower women to meet the vulnerabilities emanating from climate change. Policies followed by these states are largely gender blind and gender neutral. State-specific action plans on climate change were formulated to integrate that climate change concerns also do not address gender concerns in climate change policies and developmental interventions.

The character of public expenditure in study states is largely developmental and not oriented toward adaptation to climate change. Even within the framework of adaptation expenditure, the focus is largely on interventions toward poverty alleviation, livelihood, and food security. Huge gaps are observed between expenditure for the abovementioned area and climate-sensitive sectors like agriculture and allied activities, water resources, disaster management, forestry, etc. These gaps reveal that India has consistently neglected investing in natural resources which are now vulnerable to climate change impacts. Women, poor and marginalized, are disproportionately dependent on natural resources for their livelihood sustenance. In sum, the gender status quo should be reversed in local planning and budgeting.

For effective assimilation of gender concerns in climate change discourse, policy departure should focus on integrating gender concerns policy planning itself. Mere bringing out of a gender budget statement is hardly effective unless gender budgeting is implemented in its true spirit at all levels of governance, especially in the wake of climate change threats. Further, all states are at the nascent stage of implementing gender budgeting, and often this is an eyewash. It is mostly a mere reporting exercise.

The implementation of NAPCC and state action plans is yet to happen. However without putting gender and poor and marginalized (vulnerable) people at the center of inclusive economic development and adaptation, the challenges of climate change and economic growth can never be addressed.

Climate Change Mitigation: From Carbon-Intensive Sprawl Toward Low Carbon Urbanization: Progress and Prospects for Istanbul

Arzu Kocabas, Michael S. Gibson, and Murat Diren

Contents

Abstract

This chapter assesses the prospects for progress toward sustainable urban development in Istanbul/Turkey, as an outcome of interrelated innovative policies for climate change mitigation which reduces carbon emissions from cities/towns and earthquake mitigation-led urban regeneration. It first provides a generic model of planning for low carbon cities which integrates "top-down" and "bottom-up" components. This model structures the subsequent analysis of the experience of planning for eco-settlements in EU countries, with particular reference to the UK. Lessons from this experience then inform an analysis of policy development in Turkey at national/local levels, which focuses on climate

change mitigation action and earthquake mitigation-led neighborhood regeneration programs. A case study of Kartal, Istanbul, demonstrates the application of these policies which have the potential for reducing carbon emissions from Turkish cities through the redevelopment of earthquake-vulnerable, poor-quality, carbon-intensive housing areas and replacing them with low carbon neighborhoods. As the housing stock in Turkish cities contributes over a quarter of national carbon emissions, this will make a major contribution to national carbon reduction targets and help make urban areas earthquake resilient. This assessment has implications for earthquake-threatened cities elsewhere in the world.

Introduction

In July 2011, the Turkish government published the country's national climate change action plan (NCCAP), the product of international collaboration which had enabled Turkish government policy makers to draw on the experience of EU countries, particularly the UK. In common with the national plans of many other countries, the Turkish NCCAP specifies that local municipalities will play a major role in implementation. The UK national climate strategy and action plan is widely regarded as one of the most sophisticated in the EU. The coastal city of Brighton and Hove, 1 hour by train from London, has the national leader of the Green Party as one of its MPs and has the country's only Green Party-led municipal administration. The city's experience illustrates best practice in planning for low carbon cities in the UK. As one of the 32 district municipalities of Istanbul, Kartal is on the Marmara Sea coast, somewhat less than an hour from Istanbul city center. Like Brighton and Hove, Kartal's urban area is between the sea and green hills behind, but green planning is in an embryonic state. In the context of the two countries' evolving national policies, this chapter draws on the experience of Brighton and Hove to discuss how Kartal can develop its climate change and action plan and move further toward planning for low carbon urban development and regeneration.

Toward Low Carbon Urbanization: An Analytical Framework

Since the early 1990s, the growing understanding of the contribution of cities to climate change has stimulated the emergence of the (still contested) concept of "sustainable urban development" (Jenks and Dempsey 2005). This concept has underpinned a variety of normative models of eco-settlements at all levels. For example, the ECOCITY model (Coplack 2003) comprises of compact, pedestrian-oriented, residential, and mixed-use neighborhoods, composed of solar-oriented buildings, and integrated into a polycentric urban system through a low carbon public transport system. But the challenge is how governments can modify market-driven urbanization processes to deliver sustainable urban development.

In the run-up to the 2009 Copenhagen Summit, methods of calculating the sources of carbon emissions improved, prompting growing awareness that cities produce 70 % of global CO2 emissions including 40 % from buildings. Across the EU, some 28 % of carbon emissions come from the housing sector, with slightly less from transport. Planning for low carbon new and extended settlements and neighborhood regeneration is developing in the context of evolving climate change action plans which establish carbon reduction targets as key priorities across a wide range of sector policies, particularly in energy, housing/buildings, and transport – a process known as "mainstreaming." Thus Wilson and Piper's (2010) review of climate change policy frameworks at international, EU, and national levels identified a range of increasingly standard components, many of which relate to the promotion of low carbon urban development, including mitigation through emission reduction, building resilience/reducing vulnerability (related to buildings, communities, infrastructure, and habitats), adaptation programs, legislation/regulation/guidance, mainstreaming, and cross-sectoral policy integration, together with public awareness raising and monitoring the impact of action programs.

But it is increasingly acknowledged that planning for low carbon cities will require a combination of a top-down national framework of policy, law, and finance with a bottom-up capacity for program development and delivery by local municipalities working in partnership with NGOs, the private sector, and increasingly "carbon-conscious" households. In particular, it will be critical to deliver carbon-neutral neighborhoods (CNNs), which can be defined as those in which "... over a year, net carbon emissions from energy use within the neighbourhood and from vehicles based in the neighbourhood, would be neutral" (Gibson 2007, p. 15). Figure 1 illustrates a conceptual process model which integrates top-down and bottom-up action to deliver CNNs, as building blocks of low carbon urban planning. The matrix in Fig. 2 illustrates the key parameters of action planning for CNNs.

The vertical axis of the matrix sets out a range of interlinked neighborhood planning objectives, and the horizontal axis illustrates a range of possible actions to achieve each objective.

Brighton and Hove in its National Context: Toward a Low Carbon City

In England, as in many EU countries, planning for climate change has gathered momentum as it has become increasingly focused on the reduction of carbon emissions from cities and towns, particularly from buildings and transport systems. National government is providing an evolving framework of targets, policies, and resources which are cascaded down to municipal and eventually neighborhood level, as carbon reduction becomes a key dimension of multi-level and

multi-agency planning. However, it increasingly understood that success will need a combination of both "top-down" and "bottom-up" innovations in multi-sector working. At neighborhood level, local municipalities with their private sector and community partnerships are pioneering low carbon new housing development, neighborhood retrofitting, and community renewable energy schemes. Upscaling these "local success stories" is essential for meeting carbon reduction targets.

The headline target for mitigation is to reduce the national total of carbon emissions by 18 % on 2008 levels by 2020, as a major step toward achieving the legally binding target of cutting emissions by 30 % by 2050, which was embodied in the *Climate Change Act 2009*. The UK was the first (and is still the only country) to pass a law which imposes a legal obligation on government to achieve a specified carbon reduction target by a specific date. The *UK Low Carbon Transition Plan* (DECC 2009) is a cross-sector plan which provides the integrating framework for action by government, the private sector, and NGOs/community organizations. It was developed by the Labour government in the run-up to the 2009 Copenhagen Summit and is now being taken forward by the new center-right coalition government which has pledged itself to be "the greenest government ever." In common with other national plans, this plan emphasizes climate change mitigation focused on reducing carbon emissions especially from the built environment and transport. It aims to cut emissions from homes by 29 % on 2008 levels by 2030. Three key action programs are now underway to achieve these targets.

The first is a phased move toward zero carbon new housing and, eventually, zero carbon new communities, in order to slow down/halt the increase in energy demand from new construction. In 2006, the UK government announced that it would ramp up the environmental component of the building regulations in 2008, 2010, 2013, and finally to zero carbon in 2016, using the new Code for Sustainable Homes. The Code covers nine areas: energy, water, materials, surface water run-off and waste, pollution, health and well-being, management, and ecology. The Code Levels are 1–6. The highest standard is Level 6 – a zero carbon development emissions achieved through energy conservation and the use of renewable energy. All new social housing construction had to achieve Code Level 3 from April 2009, as a condition of government funding. Thus social housing associations and their contractors are tasked with spearheading the move toward zero carbon housing.

The second is to secure the retrofitting of existing energy-inefficient housing, through a new Energy Company Obligation (ECO), requiring energy companies to participate in the *Green Deal*. This is a "pay-as-you-save system" which came into operation in spring 2013. The capital cost of the energy efficiency measures is paid to back to "green deal providers" by users of dwelling from the reduction in their energy bills. The third program aims to increase the proportion of energy from renewable sources 4–30 % by 2020. This requires the electricity supply companies to sell electricity generated from large-scale renewable sources, including wind, solar, and nuclear. But it requires incentives and standards to dramatically increase microgeneration from renewable sources. Taken together, these measures have the potential to deliver the key component of carbon-neutral neighborhoods, by ensuring that the levels of energy efficiency of neighborhood buildings are so high that the neighborhood's microgeneration capacity can meet its minimal energy requirements.

Policy makers developing the UK national climate change action plan were able to draw on the experience of a significant number of pioneering local authorities, both at home and abroad (Allman, et al. 2004; Granberg and Elander 2007). The national plan now provides a framework within which there is the potential for this innovative work to be progressively mainstreamed. In this context, the city of ***Brighton and Hove*** has recently revised the city's climate change strategy to meet the overall objective of "living within environmental limits" (see Fig. 3; Brighton and Hove City Sustainability Partnership 2011). The city has signed up to Nottingham Declaration commitment to "develop our plans with our partners and communities to progressively address the causes and impacts of climate change." This is the main UK network of local authorities which promotes and shares good practice.

The climate change strategy is managed by Brighton and Hove City Sustainability Partnership, a multi-sector and multi-agency partnership organization, led by the city council and covering all the key sectors. Data provided by central

Fig. 3 The city of Brighton and Hove on the south coast of England; between the South Downs and the English Channel (Source: *1*. www.smoothhound.co.uk; *2*. ww3.brighton-hove.gov.uk/index.cfm?request=b1120082&node=1576; *3*. www.ordnancesurvey.co.uk/shop/explorer-map-brighton-hove.html; and *4*. www.takethefamily.com/)

government gives the city's annual CO2 emissions as 1.2 m tonnes, which is 4.8 tonnes per person. By sector, 42 % of emissions are from housing, 32 % industrial and commercial, and 26 % transport. The partnership has agreed the city's targets as its contribution to the national target: from a 2005 baseline, a 42 % reduction in emissions by 2020 and an 80 % reduction by 2050. The strategy to achieve these targets uses an approach based on five high-level outcomes to provide a clear but flexible framework. For each outcome, the strategy promotes an understanding of the issue and provides a structure for actions. The outcomes are a low carbon economy, low carbon buildings, low carbon transport, and renewable and sustainable energy. Each of these areas is led by a senior city councilor and is broken down into sub-outcomes (manageable pieces), which have an implementation plan that identifies actions needed to meet targets, and clear processes for monitoring and review, resourcing and investment, and community engagement. For example, the *Low Carbon Homes and Buildings* section of the strategy sets out the issue in terms of the fact that buildings account for 42 % of the city's carbon footprint but that this can be drastically reduced by increasing the energy efficiency of buildings and by using low and zero carbon technologies (microgeneration) and district heating and power systems. Moreover, individual citizens can contribute by adapting their behavior in relation to water and space heating and use of electric appliances. A profile of the characteristics of housing explains that different house types have different carbon footprints and opportunities for energy efficiency improvements.

The strategy then sets out what the council is doing to promote energy efficiency improvements in existing housing, taking advantage of government grants and the subsidies which energy companies have to provide under the Energy Company Obligation. At present, the program is not targeted to particular areas as the volume of action is not large enough. However, it is likely that this will change when the Green Deal comes into operation, as the volume of activity will increase to the point where a neighborhood approach will achieve scale economies, and it may be appropriate to apply the CNN model. The strategy explains how the city is promoting low carbon construction of new housing through its sustainable building design code. Its provisions have to be complied with before planning approval is given. This requires energy-efficient design which maximizes the use of passive solar gains, natural ventilation, super insulation of walls, roofs, and floors, advanced glazing systems, high-efficiency condensing boilers, energy-efficient lighting, and energy-labeled white goods. The resultant reduced energy demand is substantially met by on-site or "near-to-site" renewable wind, solar, and geothermal sources and the use of biofuels. The award-winning New England Quarter is the city's exemplar carbon-neutral neighborhood, designed to Code for Sustainable Homes Level 5 on a redeveloped brownfield site close to the railway station and bus services.

Turkey National Climate Change Action Plan (NCCAP)

During the last three decades of the twentieth century, the explosive growth of Turkish cities has been dominated by illegal development. Initially, this took the form of squatter constructed *gecekondu* neighborhoods of single-story dwellings. This was succeeded by poor-quality, steel-reinforced concrete-frame construction apartment blocks with low levels of insulation – characteristically 5–8 stories high. The recent building boom has been dominated by the construction of large peripheral estates of high-rise blocks, often built on public sector-owned greenfield sites, creating vast car-dependent suburbs. Overall, these carbon-intensive processes have been the antithesis of sustainable urban development as demonstrated by the illustrative outcomes in Table 1.

However, another major outcome of this very rapid but weakly regulated urbanization process is that vast numbers of the poor-quality apartments were built on earthquake-vulnerable land. The deaths of more than 18,000 people in the 1999 Marmara earthquake brought an end to "earthquake amnesia" and tragically demonstrated the need for a major, earthquake mitigation-led neighborhood regeneration program.

The future of Turkish cities will be significantly shaped by the response to the dual challenge of carbon-intensive urban development and earthquake-vulnerable neighborhoods. In July 2011, the Turkish government published the National Climate Change Action Plan 2011–2023 (Republic of Turkey 2011). This plan includes a landmark commitment to reduce carbon emissions from Turkish cities. It was the culmination of a national-level policy development process that was

Table 1 Carbon-intensive Turkish urbanization

The building sector accounts for 36 % of energy consumption and 32 % of the total energy-related CO2 emissions, and on a "business-as-usual scenario," these emissions will double by 2020
Many of Turkey's new buildings (built post-2000) are energy inefficient compared with new buildings in the EU countries which have similar degree-days
Comparisons of Turkey's new buildings alongside EU countries' energy use standards reveals that even building regulation-compliant buildings require at least 50 % more energy for heating than their EU counterparts
Only 20–30 % of new buildings comply fully with the building and other regulations
There are huge opportunities for reducing CO_2 emissions by 30–50 % of current levels, including enormous scope for low-cost improvement in energy efficiency
Only 16 % of buildings have roof insulation
The use of insulation materials per person is one-tenth of the average use per person in the EU

Source: Adapted from Kocabas (2012)

structured by supranational policy drivers. Kocabas (2012) has identified the key stages in this process. In common with many other countries, the energy sector was the first to incorporate a climate change dimension. The EU harmonization process included a major technical assistance project that provided the basis for new legislation to increase building regulation minimum energy standards and incentivize increased investment in renewable energy sources through a feed-in tariff.

The implementation of the EU's Building Energy Performance Directive in 2011 made the energy efficiency levels of all new buildings transparent by introducing energy identity documents (EIDs). Moreover, by 2017, all existing buildings will require EIDs which will specify how energy efficiency can be improved. The EU harmonization processes also positively influenced the Turkish government's decision to sign the Kyoto Treaty in February 2009. In turn, this gave impetus to the implementation of legislation to enable the government to adopt the target of moving toward 30 % of total energy production from renewable sources by 2023. In parallel, a UNDP-funded research and development project demonstrated the enormity of the challenge of reducing the negative impact of the building stock on levels of carbon emissions.

The Turkish National Climate Change Action Plan (NCCAP) was a result of international collaboration between the UNDP, the British Foreign and Commonwealth Office, and the Turkish government. For each sector, the plan sets out objectives and (at this stage) modest targets for short, medium, and long terms, together with the responsible organizations in public, private, and NGO sectors. The targets for the energy and buildings sectors establish new parameters for Turkish urbanization and are summarized in Table 2.

They constitute a commitment to move toward climate-sensitive physical development planning, as part of a wider process of climate change mitigation. This overall approach is recognizably similar to that adopted by other governments, as is the expectation of a significant role for local municipalities in the further development and implementation of the national strategy.

Table 2 The NCCAP's new parameters for Turkish urban development

Buildings and energy
Increasing energy efficiency in commercial and public buildings over 10 k sq m floor
Increasing energy efficiency in at least one million (out of a national total of 8.5 million) residential buildings by 2023
Developing financial incentives for energy efficiency and renewable energy by the end of 2013
Decreasing energy consumption in public buildings by 10 % by 2015 and 20 % by 2023
At least 20 % of energy in new buildings to be from renewable sources by 2017, including on-site microgeneration in major housing developments
Settlements and carbon emissions
Reducing carbon emissions in new pilot project settlements by 10 % by 2015
Reducing carbon emissions from all new settlements by 10 % by 2023

Source: Adapted from Kocabas (2012) and Republic of Turkey Ministry of Environment and Urbanisation (2011)

> In order to combat climate change more effectively... it is very important for the local administrations to integrate the issue of climate change into their own strategic plans and programmes and to prepare Local Climate Change Action Plans. (Ministry of Environment and Urbanisation 2011, p. 2)

This proposal that local authorities should integrate climate change into their strategic plans and programs, in the context of an overarching climate change strategy, is consistent with the general approach which continues to evolve in EU countries, as discussed above. However, it has emerged at a time when there is about to be a major development of new strategic plans and programs for earthquake-led neighborhood regeneration. After more than a decade of debate and pilot studies, the new Ministry of Urbanisation and Environment (2011) now also have responsibility for implementing new urban regeneration legislation (Law no: 6306, May 2012). This is an important milestone on the road to the major and long-term demolition and rebuilding program that is needed to avoid a humanitarian disaster in the next earthquake. But a major neighborhood regeneration program is also an opportunity to significantly reduce carbon emissions from housing in Turkish cities, by replacing energy-inefficient housing with carbon-neutral neighborhoods.

Local Climate Change Action Plans: Prospects for Kartal

The policy makers developing the UK national climate change action plan were able to draw on the experience of a significant number of pioneering local authorities to produce a national plan which now provides an integrated framework within which there is the potential for this innovative work to be progressively mainstreamed. The Turkish national plan was published only 2 years later, but in sharp contrast, it emerged from a context in which no local authority had established a climate change action plan and the limited "bottom-up" experience was restricted to the environmental projects of a few municipalities together with

NGO campaigns and associated small-scale exemplar projects. In the context of the review of UK experience, the prospects of local municipalities developing a significant role de novo will now be assessed with reference to the Kartal municipality (see Fig. 4).

The Regional Environment Center (REC) is the leading NGO in the field. Within a few months of the publication of the NCCAP, REC jointly organized a conference with the French Development Agency (AFD) entitled “Sustainable Cities in Turkey.” This initiative was designed to focus attention on the question of how to manage the transition to a low carbon era. The mayor of Kartal, Dr. Oz, was a keynote speaker. His election manifesto had the stated aim of moving Kartal toward becoming a “sustainable ecological town,” which was shared with the public and council employees through subsequent vision and mission statements. He outlined some of the results of the work that Kartal had been undertaking over the previous 2 years, which are summarized in Table 3.

He argued that all municipalities should develop action plans but warned that generating public support would be very challenging as “the public are not ready yet,” illustrating his point by reference to the difficulties of improving domestic waste recycling rates. At the strategic level, he drew attention to the potential of the municipality working in partnership with the Greater Istanbul Metropolitan municipality to realize the potential of urban regeneration for saving energy and saving water. Such a partnership could draw Kocabas’ (2010) scenario for sustainable urban regeneration. EU experience has shown that international and intranational networking is an important element in the dynamic of developing local climate change action plans.

Kartal is one of the few Turkish municipalities which are a participating member of the International Council for Local Environmental Initiatives (ICLEI), and the mayor stressed the value of international networking in supporting the development of local initiatives. Importantly, the conference signified the beginning of intranational networking between Turkish local municipalities. In a move which echoed the Nottingham Declaration in England and similar initiatives in other EU countries, municipalities were given the opportunity to join a website which would be developed as a forum for sharing experience and promoting good practice. Thus, Kartal is in a good position to build on its portfolio of environmental projects to develop a local climate change strategy and action plan, within the new national climate change action framework and new urban regeneration laws.

Drawing on the contemporary experience of EU cities, illustrated by Brighton, this process could include:

- Carrying out an audit and evaluation of recent and ongoing local environmental projects to assess potential for development and replication
- Creating a Kartal Environmental Partnership to facilitate coordinated interagency working
- Establishing a municipality carbon emission baseline, such as that recently completed in the nearby municipality of Kadıkoy, as a basis for monitoring and evaluating the impact of local action

Fig. 4 Kartal District Municipality on the Anatolian side of the Bosphorus; between the Aydos Hills and the Sea of Marmara (Source: *1*.www.avrasyanakliyat.com; *2*. www.webrehberi.net; *3*. www.panoramio.com; *4*. http://upload.wikimedia.org/ and *5*. www.emlakwebtv.com)

Table 3 Environmental initiatives in Kartal district

Leading by example: The municipality is converting a multistory car park into a green municipal building to provide accommodation for council departments which will replace an earthquake-vulnerable building which will be demolished
Lighting public parks: Eight public parks in Kartal are now lit by renewable energy from photovoltaic panels installed in the park, reducing emissions and providing a symbol of the council's intent
Improving water management: The municipality construction directorate now requires all residential developments to include facilities for rainwater harvesting which can be used for gardens rather than periodically flooding the streets; automated irrigation systems for parks and gardens have replaced tankers, reducing both operation costs and carbon emissions
Local sourcing of sustainable organic food: The municipality has established the first 100 % organic market on the Anatolian side of Istanbul and is promoting organic farming in the Aydos Hills which run parallel to the coast

Source: Authors' research

- Setting targets for carbon emission reductions from the municipal area
- Systematically identifying ways in which sector plans and projects could contribute to meeting carbon reduction targets, particularly by building on recent initiatives, e.g., further carbon reductions from public buildings
- A Kartal code of sustainable construction to be used to incrementally increase building standards, in both new neighborhoods and neighborhood regeneration areas
- A local energy policy to promote domestic energy efficiency and the enhanced use of renewable energy in existing homes
- A food strategy to enhance local access to healthy food
- A systematic capacity-building program for public, private, and NGO sectors

Conclusion

Planning for low carbon cities in Turkey has now started. Overall, the current state of local climate change action in Turkey is evocative of the experience of that in EU cities in the early 2000s. However, the key difference is that initial experience in Turkey will develop within the framework of an approved national climate change action plan which provides a basic policy framework and incentives for local action. Moreover, the government is now recognizing the potential of developing local climate change action plans and local urban regeneration programs in tandem. These conditions enhance the prospects of the more enterprising municipalities developing climate change action plans relatively quickly. However, national government has yet to allocate significant additional resources to incentivize municipalities, so at this early stage, much will depend on local initiative. This will require substantial capacity building, and this chapter has shown that just as international collaboration has had a positive influence at national level, so it is now appropriate for Turkish municipalities, like Kartal, to systematically draw on the experience of contemporary local climate change action plans from cities like Brighton.

Climate Change: Safeguarding Indigenous Peoples through "Land Sensitive" Adaptation Policy in Africa

Ademola Oluborode Jegede

Contents

Abstract

While, generally, climate change affects Africa negatively, indigenous peoples will suffer more, considering their lifestyle which is intricately attached to land. On three grounds, this chapter argues the importance of safeguarding indigenous peoples through "land-sensitive" adaptation policy at the national level in Africa. First, this is based on the evidence of existing forms of "land-sensitive"

A.O. Jegede (✉)

adaptation practices among indigenous peoples in the face of climate variability over time in Africa. Second, the current emerging range of climatic variation in Africa, however, challenges these "land-sensitive" adaptation practices of indigenous peoples. Finally, although international climate adaptation policy requires the protection of indigenous peoples in its processes, states in Africa hardly comply with this prescription while engaging with these processes at the domestic level. The chapter concludes by suggesting what a "land-sensitive" adaptation policy at national level should embody for indigenous peoples in Africa.

Keywords

Africa • Climate change • Adaptation policy • Adaptation practices • Indigenous peoples' land use and tenure

Introduction

The contributions of Working Group 1 to the Assessment Reports of the Intergovernmental Panel on Climate Change (IPCC) in 1990 (Watson et al. 1990), 1995 (Houghton et al. 1995), 2001 (Baede et al. 2001), 2007 (Le Treut et al. 2007), and 2013 (Stocker et al. 2013) have overwhelmingly explained the scientific and factual basis of climate change. According to these contributions, human activities are substantially increasing the concentration of greenhouse gases in the atmosphere, thus enhancing greenhouse effect, which has in turn led to increased warming of the earth's surface resulting in climate change (Le Treut et al. 2007; Baede et al. 2001; Houghton et al. 1995; Watson et al. 1990). With an economy largely agrarian and limited adaptation capacity, populations in Africa are and will be seriously affected by climate change (Toulmin 2009; Wold et al. 2009, pp. 1–47; Collier et al. 2008, p. 337; Boko et al. 2007). Although, there is no Africa-wide climate homogenous effect (Collier et al. 2008, p. 338), in general terms, climate change's negative impacts for Africa, actual and projected, is expected on areas such as water resources, food security, natural resource management and biodiversity, human health, settlements and infrastructure, and desertification (Toulmin 2009, pp. 15–87; Boko et al. 2007, pp. 10.2–10.6).

Even though indigenous peoples have contributed least to climate change, according to the United Nations Development Group's Guidelines on Indigenous Peoples' Issues (UNGGIPI 2008, p. 8), "they are the first to face its impact." Indeed, indigenous peoples will be disproportionately affected by climate change (Crippa 2013, p. 124; UNHRC 2009 Resolution 10/4; Salick and Byg 2007, p. 4; Stern 2006, p. 95). Through a review of literature, using a descriptive and analytical approach, this chapter contends that safeguarding indigenous peoples through "land-sensitive" adaptation policy is important at the national level in Africa for three reasons. First, there are existing forms of "land-sensitive" adaptation practices among indigenous peoples in Africa based on their experience of climate variability. Second, given the emerging range of climatic variation in Africa, these "land-sensitive" adaptation practices of indigenous peoples are under threat.

Finally, despite the requirement in international climate adaptation policy for the protection of indigenous peoples in its processes, states in Africa do not specifically attend to the adaptive concerns and practices of indigenous peoples while engaging with international adaptation policy requirement.

Understanding Terms: "Indigenous Peoples" in Africa, "Land-Sensitive" and "Adaptation"

In the interest of clarity, there are key terms which are employed in this chapter that merit brief explanation.

"Indigenous Peoples" in Africa

Although the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) was adopted in 2007 with the participation of states in Africa, the concept of indigenous peoples is disputed in Africa (Viljoen 2012, p. 230; Ndahinda 2011, pp. 1–13; Bojosi 2010; ACHPR and IWGIA 2005). The argument questioning their status stems from the difference in historical encounter with colonialism which, unlike in the Americas and Australasia, did not come with significant displacement of any population in Africa. In those parts of the world, the concept of indigenous peoples is understood as describing the identity of people who were the first to settle on the land from which they were displaced by European colonizers (Anaya 2010, pp. 23–42). In this context of displacement by colonialism, political leadership in Africa has generally argued that every "African is indigenous to Africa" (Viljoen 2012, p. 230; Barume 2010, p. 20; ACHPR and IWGIA 2005, pp. 86–89). However, this position, as it has been validly argued, ignores the situations of hunters and gatherers as well as pastoralists whose peculiar nature of land tenure and use had been disrupted due to internal suppression by dominant groups which existed in pre-colonial Africa and thereafter (ACHPR and IWGIA 2005, p. 92).

Hence, scholarly writings, including Kidd and Kenrick (2009, pp. 8–9) and Wachira (2010, p. 313), and indeed the regional commissioned reports such as the Report of the African Commission's Working Group of Experts on Indigenous Populations/Communities (ACHPR and IWGIA 2005) and the Advisory Opinion of the African Commission on Human and Peoples' Rights on the United Nations Declaration on the Rights of Indigenous Peoples (AU and ACHPR 2007), recognize the presence of indigenous peoples in Africa. According to the ACHPR and IWGIA (2005), the report of the Working Group prescribes the criteria for identifying indigenous peoples/populations in Africa and argues that the African Charter on Human and Peoples' Rights (African Charter) protects their collective rights. These are, namely, (1) the occupation and use of a specific land; (2) voluntary perpetuation of cultural distinctiveness; (3) self-identification, as well as recognition by other groups, as a distinct collectivity; and (4) an experience of subjugation, marginalization, dispossession, exclusion, or discrimination (ACHPR and IWGIA 2005, p. 93).

While there is no requirement that all the four elements should be present for a given population to constitute indigenous peoples in Africa (ACHPR and IWGIA 2005, p. 93), the literature has stressed the importance of these criteria. Kidd and Kenrick (2009), Wachira (2010, p. 313), and ACHPR and IWGIA (2005, p. 93) emphasize the peculiar cultural lifestyle of indigenous peoples which is evidenced in a number of ways including language, social organization, religion and spiritual values, modes of production, laws, and institutions. Also, the writings of Daes (2011, p. 465, 2010, p. 18) and Anaya (2010, pp. 23–42) identify self-identification, marginalization, and collective cultural and physical dependence on land as some of the markers of their identity. More importantly, the report of the Working Group offers extensive examples of these groups in Africa, noting however that the list is not exhaustive (ACHPR and IWGIA 2005, pp. 15–19). According to the report of the Working Group, those whose lifestyle defines these criteria in Africa are the hunters and gatherers as well as the pastoralists (ACHPR and IWGIA 2005, pp. 14–61).

"Land-Sensitive"

Generally, considered from the lens of "indigenous peoples' knowledge" or "indigenous peoples' land ethics," the worldview of indigenous peoples toward the environment has been robustly debated (Raygorodetsky 2013; CHARAPA et al. 2012; Desmet 2011; Heinämäki 2010; Nelson 2010; Jaska 2006; Berkes et al. 2005; Johannes 2002; O'Connor 1994; Tsosie 1996; Asiemat and Situmatt 1994; Durning 1992; Doubleday 1989). Particularly, in the context of climate change, the centrality of indigenous knowledge about their environment as a resource for adaptation has been well explored in climate-related literature (Raygorodetsky 2013; Burket and Davidson 2012; Macchi et al. 2008; Salick and Byg 2007). However, while this approach is useful, it should be embraced with caution in discussing climate change impacts on indigenous peoples in Africa. The exercise of caution is necessary because such an approach can potentially obscure the reality that adaptive challenges and practices of indigenous peoples are not isolated but dependent on a unique attachment to land. Also, while the focus on indigenous peoples' knowledge may be helpful in addressing the scourge of climate change, this may be overrated and counterproductive. This is in the sense that the focus on indigenous peoples' knowledge by policy makers may divert attention from the urgent need to address more fundamental issues such as land tenure and access that are central to the strengthening of indigenous peoples' adaptive practices.

Additionally, the land of indigenous peoples forms part of their worldview and so they are culturally dependent on the land (Asiemat and Situmatt 1994, p. 151). Hence, any change within the environment of indigenous peoples is best discussed in the context of changes "to and in the community's right to land" (Asiemat and Situmatt 1994, p. 159). More importantly, a focus on land is crucial considering that the UNDRIP holds land as central in the protection of indigenous peoples (UNDRIP 2007, arts 25 and 26). Accordingly, "land-sensitive" connotes an adaptation policy approach that includes respects and enhances the land use and tenure of indigenous peoples in the light of climate change challenge in Africa.

Adaptation

Adaptation has been a central part of international climate negotiation. Initially, it was thought of as a "taboo" to discuss adaptation in the climate change negotiation as advocates for climate mitigation feared that politicians were likely to lose interest in mitigation if adaptation options become the focus of discussion (Pielke et al. 2007, p. 598). However, for developing states and vulnerable populations, it has been argued that it will amount to playacting to imagine that adaptation is not urgent (Burney et al. 2013, p. 52).

Adaptation is understood as measures that can be used in coping with the "ill-effects of climate change" (Caney 2009, p. 203) or activities geared toward the prevention of impacts of climate change from being harmful (Paavola and Adger 2006, pp. 594–609). The IPCC defines adaptation as an alteration in the natural or human systems in response to actual or expected impacts of climate change with the aim of moderating the harm in climate change or exploiting its beneficial opportunities (Watson et al. 1990, p. 398). Adaptation also connotes the adjustments to reduce vulnerability or improve flexibility to the observed or expected changes in climate, involving a range of options such as processes, perceptions, practices, and functions (Boko et al. 2007).

The potentials and options for adapting to climate change at the domestic and regional levels have been given considerable attention in climate change literature. Adaptation, explains Goklany (2005, p. 675), can take advantage of positive impacts and reduce negative impacts of climate change. According to Solomon et al. (2009, p. 1708), some impacts of climate change, such as sea level rise, can be addressed by constructing sea walls. Also, as it has been generally shown, in some regions, an appropriate adaptive strategy might entail swapping from negatively impacted products to less impacted crops (Lobell et al. 2008, p. 610) or the use of new crop varieties and livestock species better suited for drier conditions, as well as the use of irrigation, crop diversification, adoption of mixed-crop and livestock farming systems, and alternating planting dates (Kurukulasuriya and Mendelsohn 2008, p. 6; Nhemachena and Hassan 2007).

Having described the key concepts used in this chapter, three arguments proposed in favor of safeguarding indigenous peoples through "land-sensitive" adaptation policy in Africa are discussed in the next sections.

Indigenous Peoples' Existing "Land-Sensitive" Adaptive Practices

From the outset, it should be stated that there are arguments suggesting that indigenous peoples' relationship with land is not harmonious or any different from the approach by mainstream society. For instance, Lüdert (2009, pp. 7, 20), citing the economic benefits derived by the Bayei in Northern Botswana from ecotourism projects in their territory, is of the view that indigenous peoples are involved in the commodification of nature. Also, attempting to show that the relationship of indigenous peoples' with their land is not necessarily harmonious, The Economist (2012) and D'Amato and Chopra (1991) note that the activities of the Inuit, indigenous peoples of arctic Canada, Alaska, Greenland, and Siberia, are injurious to whales and should not be exempted if an international norm should emerge granting the whale a right to life. Maragia (2006, p. 219), Berkes et al. (2005, p. 1252), and Tsosie (1996, p. 268) equally demonstrate that not all traditional perception of the indigenous peoples in relation to their land is ecologically adaptive. According to Neely et al. (2009, pp. 9–10), herding of cattle may result in overgrazing and, in effect, land degradation, a major factor in climate change. As explained by Adeloye and Okukpe (2011, p. 56), the manure of herds, except if properly handled, is a major source of greenhouse gas emission which brings about global warming.

However, the validity of these arguments is disputed. Although the activities of indigenous peoples may negatively impact their land, this is only minimal. More than any other populations, the indigenous peoples have reasons to be friendly with their land. Foremost, and according to West and Brockington (2006, pp. 609–616), indigenous peoples view their land as a divine gift or heritage and themselves as its guardian or protectors. Having lived in this land for long, indigenous peoples hold their land in great respect (Woodliffe 1996, p. 256, Durning 1992, p. 112). Sensitivity to land is evidenced in the understanding that land is significant for their cultural preservation (Woodliffe 1996; Cohen 1993, p. 195). The land of indigenous peoples is a site of several items they hold dear to culture and spirituality such as sacred mountains, rivers, lakes, caves, single trees or forest groves, and coastal waters (McLean 2010). As Anaya (2000, p. 2) observes, indigenous peoples living in forested areas consider the survival of the forest as essential to the survival of human life.

This is in fact generally the case with indigenous peoples in Africa. Among the San peoples of the Kalahari in Southern Africa, according to Lee (2000), land represents a "sense of place" and the means through which they display a sense of harmony with nature. The San peoples, as Chennells (2003, pp. 278–279) reports, "know what to do with the land" and "every plant, beetle, animal" in the Kalahari. Generally, the protection of the indigenous peoples' land and its biological communities are therefore viewed as a prerequisite for survival (Suagee 1999, pp. 48–50). Findings also show that among the Mbendjele (pygmies) of Congo-Brazzaville, forests fulfill the cultural role including serving as places where pregnant women give birth to children, for finding indigenous foods, and for sharing stories relating to traditional practices such as "past hunting, fishing, or gathering trips" and eternal abode after death (Lewis 2001, p. 7). According to Asiemat and Situmatt (1994, p. 149), the Maasai of eastern Africa, particularly Kenya, conceive land as an important host not only of themselves as a people but of the plants, animals, trees, and fish which, among other things, all constitute their cultural and environmental universe.

It is the foregoing worldview about land that supports several forms of adaptive practices among indigenous peoples in different parts of Africa in the face of adverse impacts of climate change over time. While these adaptive practices vary, a common trend is that these practices portray indigenous peoples' resilient adjustment to the use of land, despite the harsh reality of climate change. This pattern of adjustment, as it is illustrated in the next section, cuts across different scenarios of climate impacts including prediction of weather, water scarcity, drought, land degradation, and food insecurity.

Prediction of Weather

Indigenous peoples in Africa have devised diverse means of predicting the weather. Environmental conditions, such as rainfall, thunderstorms, windstorms, and dusty winds, have been reportedly used by indigenous peoples in preparing for future use of land and weather forecast in West Africa (Ajani et al. 2013; Ajibade and Shokemi 2003). More particularly, the Maasai in the eastern part of Africa do predict droughts by observing the movement of celestial bodies and combining such with watching the development of certain plants. This has been reported as useful in serving as an early warning signal of an approaching environmental disaster as well as an early indication of "the condition of the range of land and its likely changes" (UNFCCC Adaptation Case Study 2013a). Other forecasting approaches, according to Roncoli et al. (2001), include the timing of fruiting by certain local trees, the water level in streams and ponds, the nesting behavior of small quail-like birds, and the insect behavior in rubbish heaps outside compound walls.

The foregoing has adaptive utility. Outcome of weather prediction enables indigenous peoples in Kenya to understand storm routes and wind patterns and, hence, to design local disaster management practices in advance. This is achieved by constructing appropriate shelters, windbreak structures, walls, and homestead fences (UNU-IAS-TKI 2009, p. 55). Also, as a result of prediction of weather, indigenous peoples are able to plan daily economic life and social activities with foresight. This possibility further results in adaptive strategy such as planting appropriate crops that suit a particular season (UNU-IAS-TKI 2009, p. 55). Generally in East Africa, knowledge about weather condition enables the pastoral Maasai to prepare for drought and make decisions about where to graze and which grasses recover faster than others (UNU-IAS-TKI 2009, p. 55).

Water Scarcity Coping Approach

A range of adaptive measures is also being taken by indigenous peoples in conditions of scarcity of water. The Maasai accurately assess the water-holding capacity of distant pastures to plan transhumance activities. Generally, pastoral communities living in the water-deficient areas engage in rainwater harvesting which is conserved for all their needs. Other approaches include the construction of "sand dams" which slows down flash floods and holds the water in the sand of the riverbed (UNFCCC Adaptation Case Study 2013b). Shallow wells may also be provided with sanitary seals to protect them from contamination and unnecessary siltation after floods. This, in essence, helps in reducing the caving in of wells during the floods thus making water available for a longer period and reducing human stress (UNFCCC Adaptation Case Study 2013b).

Drought and Land Degradation Management Skills

Among the Tuaregs in North Africa as well as in the south of the Sahara, adaptive practices of coping with drought and land degradation have been documented. “Fixation sites” are constructed since 1990 to assist in coping with spread of desertification (Woodke 2007, pp. 10–11; Harris 2007). Also, during drought periods, the pastoralists in this region change from cattle to sheep and goat husbandry (Seo and Mendelsohn 2006) or move from the dry northern areas to the wetter southern areas of the Sahel (McLean 2010, p. 60). Additionally, the Sukuma people of the north of Tanzania engage in soil conservation through which animal fodders are prepared and made available to very young, old, or sick animals unable to follow other animals to grazing lands. The process encourages the conservation of grazing and fodder lands by encouraging vegetation regeneration and tree planting (UNFCCC Adaptation Case Study 2013c).

Food Preservation

To cope with loss of crops and food insecurity, fodder is of huge importance to nomadic people whose livestock is often the only source of income. Among the Tuaregs, there is evidence of enclosures designed to protect and safeguard pastures (Woodke 2007). Preservation of items such as fruits, vegetables, and edible insects is demonstrated in two ways: for vegetables, it is usually to immerse the fresh vegetables in salty boiling water and spread for drying after boiling for a few minutes to avoid loss of nutrient, and for drying caterpillars, termites, white ants, and other edible insects, this may be directly spread in the sun (UNFCCC Adaptation Case Study 2013d). The practice of sun drying among indigenous peoples is a coping mechanism found in several states in Africa including Ethiopia, Kenya, Niger, Tanzania, Senegal, and Democratic Republic of the Congo (FAO 1985).

Notwithstanding these existing forms of adaptation among indigenous peoples, the “land-sensitive” adaptation practices of indigenous peoples in Africa are threatened by a new emerging range of climatic variations requiring urgent policy attention by states in Africa.

Increasing Climate Variation as a Threat

Climate variation is increasing with peculiar adverse impacts on indigenous peoples’ land in different regions of Africa (IPACC Web; IWGIA 2011; Mclean 2010; Tebtebba 2010). This arguably threatens the existing adaptive capacity of indigenous peoples in Africa. Although the experiences of indigenous peoples throughout Africa are not the same, they share common experience of vulnerability to climate change, notwithstanding adaptive practices.

According to the ACHPR and IWGIA (2005, p. 18), among indigenous peoples in West Africa are the Baka, Mbororo, and Tuareg. In the territories of these groups, there is reported evidence that the consequence of climate change is typified by destruction of grazing lands, drought, reduced access to safe water, and destruction of plants and animals (IPACC Web; Mclean 2010, p. 42; Woodke 2007, pp. 10–11). In East Africa, there are several indigenous peoples' groups, among which are the Maasai, Ogiek, Endorois, and Yaaku in Kenya (CHARAPA et al. 2012, pp. 29–39; Tebtebba Foundation 2010, p. 440). These peoples experience several negative conditions as a result of a changing climate, including land degradation, drought, flood, famine, and displacement (UNFCCC 2013; CHARAPA et al. 2012, pp. 35–37; IWGIA 2011, p. 410).

The Batwas in Rwanda, Burundi, Uganda, and Democratic Republic of the Congo (DRC), also known as Baka in Central African Republic (CAR) and Gabon, Baka, and Bagyeli in Cameroon, are in the Central Africa and Great Lakes region (ACHPR and IWGIA 2005, p. 16). The recent experiences of these peoples include a lengthy dry season and unpredictable weather conditions, which are affecting the agricultural calendar and bringing scarcity of forest products such as fruits and tubers, thereby disturbing their cultural lifestyle (Baka People Video 2013; Tebtebba 2010, p. 481; Mclean 2010, p. 44; CWE 2009, p. 2). More frequently, to the Mbororo and other pastoralists in the same region, transhumance calendars are being altered from January to late October due to a shift in the start of the dry season (Tebtebba 2010, p. 481; Mclean 2010, p. 44).

In the north of Africa are indigenous peoples known as the Amazigh (or Imazighen), also referred to as the Berbers or Tuaregs (ACHPR and IWGIA 2005, pp. 18–19). Evidence of climate impacts on their land includes scarcity of water, degradation, desertification, overgrazing, and salinization, in a changing climate (McLean 2010, p. 42; IISD 2001). In the southern part of Africa, the San, or Basarwa, peoples of the Kalahari (ACHPR and IWGIA 2005, p. 17) face increasing dune expansion and increased wind speeds which have resulted in a loss of vegetation and negatively impacted traditional cattle and goat farming practices (UNPFII 2008). In the Horn of Africa, the Doko, Ezo, Zozo, and Daro Malo in the Gamo Highlands experience increasing pressures on local resources and great hardship through increase in temperature, scarcity of water, dying animals, and fewer grazing land (Gamo Video Report 2013). The “Outsa” leaf which is used for shelter, animal grazing, and food and hence crucial to the survival of these peoples is fast disappearing (Gamo Video Report 2013). The situation is not different with the Afar people to the northeast of Ethiopia. Living in an extremely fragile environment worsened by climate change, the Afar suffer damage of flash flooding, change in river courses, increased desertification, herd loss, hunger, thirst, and famine (Gardo 2008).

In sum, across Africa, the foregoing emerging and increasing impacts of climate change are overwhelming and beyond the capability of existing adaptive measures being used by indigenous peoples in the face of droughts, flooding, famine, and loss of grazing land and livestock. This is largely because increasing variations of climate impact disrupt the land use and result into displacement of indigenous peoples from the land which is crucial to their adaptive practices.

Generally, land degradation reduces the availability of ecosystem goods to these populations for adaptation purposes (Nkem et al. 2010; Tobey et al. 2010). More specifically, insecurity of land tenure and use has been found to constrain adaptation practices among indigenous peoples in states including Mali (Ebi et al. 2011) and Uganda (Hisali et al. 2011) and generally in the Congo Basin region (Nkem et al. 2010). Even where partial communal tenure is recognized as in Kenya, Namibia, and DRC, discrimination against traditional land use and livelihood strategies, logging concessions, commercial farms, and large-scale development projects (dams, oil exploitation, floriculture) are major constraint to local adaptation practices (CHARAPA et al. 2012, p. 87). Insecurity of land tenure and use and the resultant changing livelihood are a driver of declining traditional relationship with the land, a major source of adaptation information and knowledge (Pearce et al. 2011, 16.3.2.1; CHARAPA et al. 2012, p. 88).

Besides, the emerging range of climate variation requires long-term adaptation strategies, which the existing adaptive practices of indigenous peoples cannot achieve on their own without nontraditional technology and resources as complements (CHARAPA et al. 2012, p. 87). The nontraditional measures refer to the transfer of modern technology and resources that most indigenous peoples do not possess. The need for technology and resources cannot be overemphasized considering that indigenous populations live in remote places of a country, characterized by poor infrastructure, limited basic services, and poor government presence (Macchi et al. 2008, pp. 49–50). Technology can help in complementing or improving existing adaptive strategies linked with their land in coping with increasing impacts of climate change resulting from the emerging range of climate variation (Fleischer et al. 2011). Also, availability of funds is a good resource that may improve traditional or indigenous adaptation practices (Peters et al. 2013, p. 16.6; Nakhooda et al. 2011, p. 7).

Yet, while the existing climate variability challenges the adaptive capacities of indigenous peoples, the approach by states in Africa to this reality does not show an effective implementation of international processes for adaptation measures in such manner that addresses the adaptive challenges of indigenous peoples.

Weak States' Role in Engaging Adaptive Processes

Although the pillar instruments of climate change at the international level, the United Nations Framework Convention on Climate Change (UNFCCC), the Kyoto Protocol, and a range of decisions by the Conference of the Parties (COP) and Meeting of the Parties (MOP) under the Kyoto Protocol, require states to follow certain processes in responding to adaptation concerns, indigenous peoples' adaptive concerns and capacities are hardly specifically addressed in the framing of adaptive challenges by states in Africa.

International Climate Change Adaptation Processes

The pillar instruments of the climate change, the UNFCCC, the Kyoto Protocol, and a range of decisions by the COP under the UNFCCC and the MOP under the Kyoto Protocol, set out the standard processes for international adaptation measures. Article 4 (1) (b) of the UNFCCC enjoins all parties to "formulate, implement, publish and regularly update national. . .programmes containing measures to facilitate adequate adaptation to climate change. . .." Also, article 4 (1) (e) requires parties to the UNFCCC to cooperate "in preparing for adaptation to the impacts of climate change" as well as plan for "coastal zone management, water resources and agriculture, and for the protection and rehabilitation of areas, particularly in Africa, affected by drought and desertification, as well as floods." Under the Kyoto Protocol, it is similarly evident that the national level has the directing policy role to play in documenting and implementing adaptation measures. Article 10 (b) (ii) of the Kyoto Protocol enjoins parties to "include in their national communications as appropriate, information on programmes which contain measures. . ." which may be helpful in "addressing climate change and its adverse impacts, including. . .adaptation measures."

In the decisions of the COP or the MOP under the Kyoto Protocol, there is equally a requirement on the state government for the facilitation of adaptation process. This began to feature prominently since the COP 7 held in 2001, which acknowledged the specific needs and concerns of developing countries, including the least developing countries (LDC), and emphasized the unique role of states in addressing adaptation issues. It insisted that adaptation actions should follow a review process based on national communications and/or other relevant information (Decision 5/CP.7/2001, p. 2). It was equally stressed that support be given to the states in the preparation of the national adaptation programmes of action (NAPAs) (Decision 5/CP.7/2001, p. 15). Furthermore, the decision acknowledges the importance of indigenous resources and urges parties to take these resources into consideration as part of options for addressing the impacts of climate change (Decision 5/CP.72002, p. 24). It also formulates guidelines to facilitate preparation for NAPA (Decision 28/CP.7/2001).

The NAPA guidelines in its paragraphs 6 (a) and (c) affirm that it will be "action oriented." Paragraph 7 (f) of the NAPA guidelines reiterates that it is "a country-driven approach." While no specific mention is made of indigenous peoples, in paragraph 7 (a), it is pointed out that NAPA is "a participatory process involving stakeholders, particularly local communities," while paragraph 7 (j) assures that the process will ensure "flexibility of procedures based on individual country circumstances." The use of the term "local populations" arguably involves the indigenous peoples particularly when it is read together with paragraphs 16 (a), (f), and (h) which, respectively, require "loss of life and livelihood," "cultural heritage," and "land use management and forestry" as part of the criteria for prioritizing adaptation activities at the national level. These required items are core issues to the adaptive practices of indigenous peoples in Africa. Guidelines in relation to national adaptation plan of action were subsequently endorsed at COP 8 (Decision 9/CP.8/2002, p. 1), COP 9 (Decision 8/CP.9/2003, p. 1), and COP 10

(Decision 1/CP.10/2004, p. 4), for the developing countries in the LDC and non-LDC to document their adaptive concerns and need for funds.

Furthermore, the COP 12 in Nairobi indicates that activities to be funded under climate funds may consider national communications or national adaptation programs of action and other relevant information from the applicant party (Decision 1/CP.12/2006). At COP 13 held at Bali, an “enhanced action on adaptation” was conceived as consisting of elements including international cooperation in order to support developing states in their vulnerability assessment and integration of actions into “national planning, specific projects and programmes” (Decision 1/CP.13/2007). This was also reinforced at the Cancun meeting of COP 16 (Decision 1/CP.16/2010, pp. 11–14) which highlighted the human rights implications for adverse impacts of climate change and the need to engage with stakeholders including indigenous peoples when developing and implementing their national action plans (Decision 1/CP.16/2010, p. 12).

At a subsequent meeting in Durban, parties were urged to include in their national communications and other channels the steps they have taken in actualizing NAPA (Decision 5/CP.17/2011, p. 33), as well as indigenous and traditional knowledge and practices in adaptation strategies (Decision 6/CP.172011, p. 4). These requirements are also evident in the key decisions dealing with the access of the state to adaptation funds (Decision 28/CP.7/2001, p. 4; Decision 8/CP.5/1999). Different categories of funds in relation to adaptation are mainly the Least Developed Countries Fund (LDCF) and the Special Climate Change Fund (SCCF) established at COP 7, respectively, under Decisions 5/CP.7/2001 (p. 12) and 7/CP.7/2001 (p. 6) and Decision 7/CP.7/2001 (p. 2). Adaptation Fund (AF) was established pursuant to article 12 (8) of the Kyoto Protocol at COP 7 (Decision 10/CP.7/2001, p. 1), while a Green Climate Fund (GCF) was established pursuant to article 11 of the UNFCCC at COP16 held at Cancun (Decision 1/CP.16/2010, p. 102). The funds under the LDCF and SCCF are voluntary contributions from developed country parties to the UNFCCC (Muyungi 2013; O’Sullivan et al. 2011, p. 15) and managed by the Global Environment Facility (GEF) (Decision 7/CP.7/2001, p. 6). The GCF is managed by the GCF Board (Decision 1/CP.16/2010, p. 103), while the AF is managed by the Adaptation Fund Board (Decision 1/CMP.3/2007, p. 3). All of these funds, namely, AF (Decision 1/CMP.4/2008, p. 11), GCF (Decision 3/CP.17/2011, p. 31), LDCF, and SCCF (Xing and Fröde 2012; Bird et al. 2011), support direct access.

The guidelines relating to the operationalization of these decisions at the national level emphasize the need to safeguard indigenous peoples’ adaptive concerns and experiences in national adaptation programs. For instance, GEF Principles and Guidelines for Engagement with Indigenous Peoples set out a minimum standard relating to indigenous peoples which is expected to be complied with by partner agencies seeking to implement projects under GEF auspices in response to NAPA proposal (GEF 2012, pp. 22–29). Also the negotiation around the GCF indicates that the participation of indigenous peoples from “the local to the national to the Board level” and inclusion of their knowledge are critical to the implementation of the GCF (Martone and Rubis 2012).

Notwithstanding the foregoing, the effectiveness of the approach by states in Africa in engaging with these international adaptation processes to strengthen indigenous peoples' adaptive practices and concerns is doubtful.

Weak Approach by States

In order to comply with the requirement for adaptation funds, each of the 33 African states belonging to LDC has filed a NAPA (UNFCCC 2013b), while the developing states in Africa which are non-LDC have at least filed a national communication. The ensuing subsection demonstrates that the concerns of indigenous peoples in relation to their adaptive experiences are obscured in the official processes for capturing adaptation needs and funds. This is achieved by examining processes from Uganda, Tanzania, and Nigeria.

Uganda

The Uganda National Adaptation Programmes of Action (Uganda NAPA) was compiled in 2007. The formulation of Uganda's NAPA claims to have been guided by the principle of participatory approach and benefited from the views of the vulnerable communities and their knowledge on coping mechanisms (Uganda NAPA 2007, VII). It describes the impacts of climate change on sample districts as destruction of infrastructure, deforestation, loss of lives, famine, poverty, water shortage and drying up, erratic seasons and rains, destruction of biodiversity, and epidemics of pests and diseases (Uganda NAPA 2007, p. 27). It notes that indigenous knowledge has been employed by communities in Uganda to cope with climate events. As part of its adaptive strategies for funding, it suggests projects such as "Community Tree Growing Project" (Uganda NAPA 2007, p. 51), "Land Degradation Management" (Uganda NAPA 2007, p. 53), and "Indigenous Knowledge (IK) and Natural Resources Management Project" (Uganda NAPA 2007, p. 63).

In the document, however, impact scenarios of climate change in Uganda are discussed as though it is proportionately borne by all. It neither discloses the identity of the communities it identifies as "vulnerable" nor profiles as adaptation challenge the lack of protection of the land use and tenure of communities, such as the Batwas, who are indigenous and forest dependent in Uganda (ACHPR and IWGIA 2005, p. 17). While it uses the word "indigenous" in describing "indigenous knowledge," it is used to refer to every citizen of Uganda. This is the logical inference that can be drawn when the term "indigenous" is examined in the sense that it is used in the Uganda 2005 Constitution. According to article 10 (a) of the constitution of Uganda, all the communities found in Uganda as on February 1, 1926, are indigenous. The NAPA employs the concept of "vulnerability" and "indigenous" in referring to all the communities in Uganda without paying attention to the peculiar situations or circumstances of specific groups such as the Batwas who are understood under international human rights law as "indigenous" in Uganda (ACHPR and IWGIA 2005, p. 17).

Tanzania

There is a similar trend in the NAPA of Tanzania, which was submitted in 2007 (Tanzania NAPA). The document indicates the adaptation concerns in Tanzania as including "loss of human, natural, financial, social and physical capital, caused by the adverse impacts of climate change." It also documents "severe droughts and floods, among many other disasters" (Tanzania NAPA 2007, VI). It is further mentioned in the NAPA that climate change is expected to further shrink the rangelands which are significant for livestock-keeping communities in Tanzania (Tanzania NAPA 2007, p. 7). While this may be argued as embodying some of the concerns of indigenous peoples in Tanzania such as the Maasai and Barabaig (ACHPR and IWGIA 2005, p. 17), it is not certain. This is because it proposes as adaptation measures the inclusion of some activities such as relocation of people living in wildlife corridors, zero grazing, and development of alternative means of income for communities in tourist areas (Tanzania NAPA 2007, pp. 29–31). These activities will disrupt the culture and lead to the displacement of indigenous peoples such as the Maasai and Barabaig in Tanzania and hence threaten their land use and local adaptive practices.

Nigeria

Nigeria is a non-LDC state and has shown no interest yet in filing a NAPA as a non-LDC. It has, however, filed a national communication which devotes a substantial attention to issues of adaptation in the country. In the communication which is the first and only national communication it has so far lodged under the UNFCCC, peculiar consequences resulting from climate change, and which require adaptive measures, include soil erosion and flooding in the southeastern part of the country. The impacts of climate change on agriculture are assessed as including the effects of changes in temperature and rainfall on plants and animals as well as sea level rise on agricultural land (Nigeria First National Communication 2003, p. 73). Livestock production also suffers due to a decrease in rainfall which has led to a decline of pastureland and water resources (Nigeria First National Communication 2003, p. 75). Sea level rise is also cited as an event likely to lead to considerable losses in the oil investments and developments in the Niger Delta zone. General reference is made to "the people in the coastal areas" as being impacted by challenges such as flooding and erosion in the Niger Delta and leading to the emergence of "environmental refugees" (Nigeria First National Communication 2003, p. 82).

Nonetheless, the Nigeria's national communication largely focuses on the environmental impacts of climate change, relying "heavily on. . .existing records and documentation in various forms including socio-economic statistics, photographs, satellite imageries, geologic and oceanographic data, biological and fisheries data. . ." (Nigeria First National Communication 2003, p. 70). Generally, communities affected by these impacts are not mentioned nor are the pertinent issues such as land use, land tenure, and resource rights relating to these communities discussed. For instance, a decline in pastureland as a result of climate change will not only affect the production of livestock, but it will negatively impact the peoples such as the Mbororo whose lifestyle is traditionally connected to the use of land for cattle rearing. Also, the passing reference to the people living in coastal areas as likely to experience flooding and erosion does not capture the larger problems which the peoples of this region, particularly the Ogoni, have for long faced and fought in terms of oil spillage, environmental protection, and compensation for environmental losses and land degradation on their land (Nzeadibe et al. 2011). It is difficult to anticipate that a national communication which fails to reflect key issues peculiar to these indigenous peoples will, even if allocated, apply adaptation funds for the purpose of supporting their adaptive practices and concerns.

What emerges from the foregoing discussion are therefore the reasons why states in Africa neglect indigenous peoples' concerns and land-based experiences in framing adaptation processes at national level.

Basis for State's Exclusion

The approach by states of Africa in engaging adaptive processes in a way that strengthens adaptive practices and addresses the adaptive concerns of indigenous peoples is arguably shaped by two factors. These are the state-centered nature of the processes and the overriding claim to ownership of land and disposition to use same in accordance with its priority.

State-Centered Process

The UNFCCC and the Kyoto Protocol and indeed decisions of the COP and MOP, respectively, are state centered. In line with article 2 (1) (a) of the Vienna Convention which describes a treaty as an agreement concluded between states (UN 2005), the parties to the international negotiation of climate change instruments such as the UNFCCC and the Kyoto Protocol are states and not community or group of people. Also, the Conference of the Parties (COP) which is the key decision-making body under the UNFCCC or the Meeting of the Parties (MOP) to the Kyoto Protocol which makes the ultimate decisions in respect of climate change and response mechanisms is state based representing the interest of different negotiation blocs and states.

The decisions of these bodies emphasize the "country-driven" nature of adaptation measures. For instance, the Cancun Agreement which serves as the basis for enhanced action on adaptation involving the developing country parties endorses this approach. It urges parties to strengthen and, in applicable circumstances, establish centers and networks to facilitate and enhance national and regional adaptation actions, in a manner that is country driven and with support from developed countries (Decision 1/CP.16/2010, p. 30).

This state-centered nature of adaptation processes also applies to funds relating to adaptation. For instance, the AF (Decision 1/CMP.4/2008, p. 11), GCF (Decision 3/CP.17/2011, p. 31), LDCF, and SCCF (Xing and Fröde 2012; Bird et al. 2011) support direct access to adaptation funds. By "direct access," it is meant that these funds allow recipient countries to access financial resources, unlike the indirect access, where funding is channeled through a third-party implementing agency (Xing and Fröde 2012). However, this challenges the adaptation potentials of land use by the indigenous peoples in Africa. This is because the notion of direct access is understood in terms of the ownership of these funds by the state. This is clear, for instance, in the recommendations made by the African Development Bank (AfDB) on GCF where it employs the term "direct access" to fund largely as accessibility by national governments (AfDB 2012, p. 3). Also, according to the *Operational Policies and Guidelines for Parties to Access Resources from the Adaptation Fund* (AF Guidelines 2013), projects may only be submitted and funds received directly by the national implementing entity (NIE) which may consist of government ministries and government cooperation agencies (AF Guidelines 2013, para 27).

The implication of state-centered focus of adaptation process is that it is coordinated by the states as has been shown and thus compromises ownership of process by indigenous peoples in Africa. Also, the lack of direct access to funds is that it undermines the utility of indigenous peoples' adaptive practices and may, as climate change worsens, compromise their opportunity to strengthen capacity. Yet, an arrangement enabling indigenous peoples a direct access to funds is not unknown to the operation of some financial institutions. For instance, models on direct access to funds for indigenous peoples exist under the International Fund for Agricultural Development (IFAD); Indigenous Peoples Assistance Facility (IPAF), a former World Bank Facility for Indigenous Peoples; and the Forest Carbon Partnership Facility (FCPF) which has a Capacity Building Program for Forest-Dependent People, all of which are dedicated indigenous funds (Martone and Rubis 2012).

National Legal Framework

In addition to the above, in Africa, key legal and policy framework relating to land use and tenure of indigenous peoples generally vests ownership of land in the state. For instance, article 44 of the Uganda Land Act (1998), articles 1 and 2 of Nigeria Land Use Act (1990), article 3 of Zambia Lands Act (1995), and Tanzania Land Act (1999) vest in the state the power to own and use land in accordance with its priority. This is similarly the case with the Forest Act of states in Africa which assumes the forests as "common goods." Accordingly, articles 3, 10, and 11 of the Forests Act of Zambia (1999), respectively, vest the ownership of every tree and its produce in the presidency, which enjoys the power to compulsorily acquire any land for the purpose of national forests and restricts the activities of peoples dependent on land such as fishing and hunting from compensation. Article 26 of the Tanzania Forest Act prohibits every action of indigenous peoples that can be regarded as of adaptation relevance such as grazing, hunting and fishing, and erection of any buildings or other structures except with the permission of the minister or a local authority. According to article 5 (1) of the Uganda's National Forestry and Tree Planting Act (2003), the state at different levels of governance is empowered to hold the forests in trust for the common good of Uganda. Also, according to the National Forest Policy of Nigeria (2006, p. 68), the government is empowered to hold in trust the forest set aside as reserve lands.

While there are few exceptions within the legal framework on state ownership and control of land, this is often rendered redundant in the face of overriding public interest. Hence, the general implication of this land and forest regime is that government can legally own and use land for different priorities other than the strengthening of adaptive practices of indigenous peoples. For instance, this enables the state to pursue interests such as large-scale agricultural plantations, mining and logging, construction of roads and dams, as well as conservation which are often at cross-purposes with indigenous peoples' adaptive practices. In addition to land degradation, the consequence of these activities for indigenous peoples is displacement from the land or territories to which they are culturally attached. This can be buttressed by the presence and consequences of such projects on indigenous peoples' land in Africa.

Large-scale agricultural plantations in several states of Africa including Benin, Ghana, Cameroon, Kenya, Tanzania, Mozambique, Namibia, and Ethiopia do not only disrupt the land use of indigenous peoples but also compromise their tenure rights (Vermeulen and Cotula 2010). In particular, according to Laltaika (2009), massive Jatropha plantations are a new threat to the survival and livelihood of the Maasai in Tanzania. Through concession to private or public business, including logging and mining companies, the land regime also allows mining and logging activities on indigenous peoples' lands (Barume 2010, p. 70). In the Niger Delta region of Nigeria, which is rich in crude oil, oil exploration on the land of indigenous peoples such as the Ogoni, Efik, and Ijaw (ACHPR and IWGIA 2005, p. 18) has occasioned environmental degradation resulting from activities including gas flaring and deforestation (Oruonye 2012). Kidd and Kenrick (2009, p. 21) found that the Exxon's World Bank oil pipeline project backed by the government in Chad and Cameroon which crossed Bagyéli land at least five times in the Bipindi area has severe impacts on these communities. These include their displacement and destruction of sacred sites and way of life.

Roads and dam constructions have all played a part in the destruction of forests (rainforest deforestation), which are crucial to the shelter, survival, and livelihood of some indigenous peoples. In Namibia, the construction of dam at Epupa was considered environmentally and socially attractive but would displace 1,100 Himba and affect 5,000 occasional users of the grazing areas on the river bank, in addition to the loss of their cultural and religious sites (World Rainforest Movement 2013, p. 28). Conservation efforts in Central Africa have equally led to the dispossession and poverty of indigenous peoples such as the Batwas in that part of Africa. According to Cernea and Schmidt-Soltau (2006), the trend in this regard has been ongoing for long, taking place without due regard for consultation and compensation for forced removal.

Essentially, this land regime allows the states in Africa to deflate their responsibilities toward indigenous peoples' immediate adaptation concerns in the guise of accessing, using, and controlling land for public good. It is thus no surprise that, at international climate forum, indigenous peoples have made the claim for protection of land as key in climate change responses including adaptation. At Nakuru, Kenya, indigenous peoples, particularly of Africa, urge intergovernmental organizations, UN agencies, and international organizations and foundations to ensure that the principles of the UNDRIP are mainstreamed in the design and implementation of any program or project in their land (Nakuru Declaration 2009). At Anchorage, in addition to emphasizing the need for security of land of indigenous peoples as critical to climate programs, indigenous peoples call for adequate and direct funding to enable them to participate effectively in all projects or programs including adaptation (The Anchorage Declaration 2009, pp. 5–7). Also, the International Indigenous Peoples' Forum on Climate Change (IIPFCC) in its closing statement before the 2012 SBSTA Working Group meeting calls for the strengthening of the adaptive strategies of indigenous peoples with appropriate policy framework which respect their rights to land and traditional practices (UNFCCC 2012).

Conclusions

This chapter makes a case for the necessity for states to have in place adaptation policy in Africa. It bases this proposition on three premises. The first foundation is that there are existent adaptive practices of indigenous peoples which had been useful in coping with adverse range of climate conditions. These adaptive practices which are closely linked to the cultural relationship of indigenous peoples with their land include approaches in form of prediction of weather, water security, drought and land degradation management skills, and food preservation. The second premise is that indigenous peoples in Africa now face a new range of climatic variations beyond their coping adaptive capability. As the final basis of the argument, the chapter demonstrates that rather than addressing this situation, in engaging with international adaptation processes, states in Africa do not facilitate the profiling of indigenous peoples' adaptive challenges and the development of their land-related adaptive practices. Thus, the foregoing premises justify the necessity of formulating appropriate policy to safeguard indigenous peoples through "land-sensitive" adaptation policy in different states in Africa.

Basic policy framework should include the recognition of indigenous peoples' identity, land use, and land tenure as critical to adaptation approach. In line with UNDRIP principles of participation and benefit sharing and protection of land rights (UNDRIP 2007, art 26), it should reflect the vulnerability of indigenous peoples while engaging with international adaptation processes. Along similar line, it should include indigenous peoples in the framework for implementation of adaptation policy, grant them direct access to funds and culturally acceptable technology, address climate threats to their land, and commit funds for successful design and/or implementation of programs and projects under NAPA and national communications. Adaptation policy measure at the national level should include the recognition of indigenous peoples' traditional institution structure in accessing funds for the implementation of adaptation projects and secure their land access and tenure. All this is important, not only for the purpose of giving hope to indigenous peoples who may yet face a somber future of difficult climate variability but because it will help states in Africa in investing time and resources into where they are needed most.

Climate Migration Governance

Benoît Mayer

Contents

Abstract

This chapter engages with the current political and academic debate on the governance of "climate migration." It highlights the difficulties of ascribing a unique cause to migration and questions the relevance of distinguishing "climate migration" from other forms of migration. It then exposes the opportunities and challenges of this concept for international cooperation. Finally, it assesses the potential of different policy options. Despite the difficulties related to the attribution of migration to a unique driver, the concept of "climate migration" appears as a powerful communicative strategy to trigger important international and domestic actions with regard to climate change adaptation and to the protection of the rights of migrants, even though a specific legal regime remains unlikely and perhaps undesirable.

Keywords
Climate migration • Governance • Multicausality • Norm entrepreneurship

Introduction

Every society comprises migrants. Individuals migrate in response to a multitude of factors – political, economic, social, cultural, demographic, or environmental. The impacts of climate change on the environment and societies are therefore likely to have consequences on the way people migrate or do not migrate.

Since the late 1980s, a literature has developed on a new issue, first labeled "environmental migration" (i.e., migration attributed to environmental factors) but soon refurbished as "climate migration" (i.e., environmental migration that can be attributed to climate change) as climate change was attracting an increasing amount of public attention. Norman Myers ventured to predict the number of "environmental refugees" in the coming decades: 150 millions (Myers 1993), 200 millions (Myers 2002), or 250 millions (Myers 2007). Climate change affects the probability of slow-onset environmental changes (desertification, land degradation, sea-level rise) and sudden-onset events (cyclone, storm surge, etc.), and both of them may have an impact on migration. Walter Kälin distinguished between five scenarios leading to environmental migration: (1) "*sudden-onset disasters*, such as flooding, windstorms [. . .] or mudslides caused by heavy rainfalls"; (2) "*slow-onset environmental degradation* caused, inter alia, by rising sea levels, increased salinisation of groundwater and soil, long-term effects of recurrent flooding, thawing of permafrost, as well as droughts and desertification"; (3) "so-called '*sinking*' *small island states*"; (4) areas designated by governments as "*high-risk zones* too dangerous for human habitation on account of environmental dangers"; and (5) displacement following "unrest seriously disturbing public order, violence or even armed conflict" that "may be triggered, at least partially, by a decrease in essential resources due to climate change" (Kälin 2010). The concept of "climate migration," more specifically, reflects a growing understanding that, climate change affecting a large array of human activities, climate change governance needs to expand beyond, in particular beyond in situ adaptation.

On this understanding of climate change-induced migration, political scientists and lawyers suggested solutions directed to address the vulnerability of "climate migrants," mostly conceived as forced and international migrants. By analogy to the Convention relating to the Status of Refugees adopted in Geneva in 1951 (Refugee Convention), Biermann and Boas proposed an international "climate refugee" convention to "prepar[e] for a warmer world" (Biermann and Boas 2010). A group of French lawyers even designed a ready-to-sign project of convention (CRIDEAU 2008). Discussions were initiated in multiple domestic or regional political constituencies, although the adoption of a multilateral treaty never really appeared as a realistic option (Mayer 2011; McAdam 2011).

A more cautious, "skeptical" school came to dominate the literature (Morrissey 2009). This school has three main credos. Firstly, it insists on the diversity of the migration strategies that are affected by climate change. In particular, internal migration (i.e., within a state) must be distinguished from international migration (i.e., across international borders). Both raise significantly different legal issues, as internal migrants remain within the jurisdiction of a same state responsible for the realization of their human rights, whereas international migrants need to be admitted to a third country. In most circumstances, the effects of climate change are limited to internal migration (EACH-FOR 2009; UNU 2012), and they are particularly unlikely to trigger significant long-distance migration flows. The exception relates to the hypothesis that small, low-lying island developing states such as the Maldives or Tuvalu may become uninhabitable because of sea-level rise, drought, more extreme and frequent weather events, and the impact of the acidification of the ocean.

Secondly, this “skeptical” school rejects a simple and direct causal link through which climate change would force individuals to migrate. In 2001, Richard Black already opposed the “multiple and overlapping causes of most migration streams” to Myer’s alarmist predictions (Black 2001). Just as there is no purely “natural” disaster, the impacts of climate change depend on the social, political, economic, demographic, and cultural factors that define a society’s vulnerability. Nor does any more or less “natural” disaster determine a migratory behavior: different societies and different individuals react in various ways to the same events. Rather than the driver of a specific form of migration, the impact of climate change appears now as one in a cluster of causes; rather than purely “forced migration,” climate migration may range on a continuum between voluntary and forced migration (Hugo 1996).

Thirdly, and largely as a consequence of this, the “skeptical” school questions our capacity to identify individual “climate migrants,” as would be necessary if a personal status was to be granted. An influential report to the British Foresight agency concludes that “the range and complexity of the interactions between the [multiple economic, social and demographic] drivers means that it will rarely be possible to distinguish individuals for whom environmental factors are the sole driver (‘environmental migrants’)” (Foresight 2011).

This credo makes it virtually impossible to conceive the governance of climate migration by analogy with that of international protection of refugees through the conference of an individual status. Under the Refugee Convention, a refugee is a person who (1) “is outside the country of his nationality” or habitual residence and (2) “owing to well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, . . . is unable or . . . unwilling to avail himself of the protection of that country” (1951 art. 1(A)(2)). Climate migrants do not normally qualify, even the few who cross an international border, because it is difficult to conceive climate change as a form of persecution and if this was the case, such “persecution” could not be related to one of the five grounds enumerated in the Convention (McAdam 2012), and in most cases there would likely be reasonable internal flight alternatives. The legal definition of a “refugee” can however be extended to other individuals, fleeing for instance situations of generalized violence, as has been done regionally in particular in Africa, Latin America, and Europe (McAdam 2007); a further extension to other forced migrants could certainly be considered – but this would only address a small part of the issue, letting aside the vast majority of internal migrants affected by the impacts of climate change.

In what follows, I question the possible responses that international governance can realistically bring to address climate migration. This requires a more thorough look at certain difficulties that relate to "climate migration," a concept that appears as impractical, arbitrary, yet promising.

Conceiving Climate Migration: From Ethics to Norm Entrepreneurship

Practical and Conceptual Difficulties

It is difficult to reconcile the concept of "climate migration" with the understanding that migrations result from a multitude of factors (Lee 1966). The abovementioned report to the Foresight agency concluded that "[e]nvironmental change is equally likely to make migration less possible as more probable" (Foresight 2011), in particular because environmental stress may decrease the resources available to a population and consequently deprive individuals from the capacity to invest in the costs of migrating – including travel expenses, dangers, and temporary unavailability of income (Brown 2007). On the other hand, the same environmental stress may increase the need for income diversification. Which tendency will prevail – less migration because of resource deprivation or more migration for resource diversification – depends on the complex circumstances that define each case at the domestic, local, and individual scale. Similarly, insecurity may be a factor of migration in some cases, but the fear of land-grabbing or theft may also force individuals to remain or rapidly return in the vicinity of their property after an environmental disaster. More generally, the ability and propensity of individuals displaced by a disaster to return to their place of origin depends, among others, on social resilience (e.g., the reconstruction of infrastructures in the place of origin) and on the capacity of the displaced individuals to integrate in the place of destination.

Following the earthquake that struck Lisbon in the mid-eighteenth century, French philosopher Rousseau (1756) disputed Voltaire's blame of the Providence; accordingly, "it was hardly nature who assembled there twenty-thousand houses of six or seven stories." Natural disasters result from a combination of physical elements on which humans have no direct control (although they have an indirect control on global anthropogenic climate change) and social elements that define the vulnerability of a society. Future numbers of migrants who can be attributed to climate change depend on many political, economic, social, cultural, and demographic factors. In particular, demographic growth will have an influence on the number of persons affected by any environmental change and so will also any policies that have an impact on the distribution of a population within a territory (Hugo 2011). Development also plays an important role: a country such as Bangladesh is vulnerable to sea-level rise because of its exposure (low altitude of most of its territory) but also because it does not have financial capacities comparable to the Netherlands to build dikes and seawalls. In some countries, the adverse effects of climate change may significantly impact the economy, thus further increasing the country's vulnerability to climate change.

Nonetheless, there are some estimates of the numbers of individuals displaced by sudden-onset natural disasters. The Internal Displacement Monitoring Centre (IDMC) estimates that between 2008 and 2012, an average of 29 million persons had been displaced each year (143.9 million persons in 5 years) by such rapid-onset natural disasters, although not all countries reported (Yonetani 2013). Eighty-two percent of these persons were in Asia, 9 % in the Americas, and another 9 % in Africa. Moreover, 16.7 % were displaced due to geophysical disasters (e.g., earthquakes, tsunamis) that are not a priori related to the climate, while the remaining 83.3 % were displaced by weather-related disasters, comprising 62.4 % displaced by hydrological disasters (e.g., floods, wet mass movements), 20.2 % by meteorological disasters (e.g., storms), and 0.7 % by climatological disasters (e.g., extreme winter conditions, heat waves, etc.) (Yonetani 2013). These statistics are produced by estimating the number of persons displaced following a disaster, thus ignoring the contribution of different factors in creating a “natural disaster.”

On the other hand, however, this approach cannot readily be applied to measure the consequences of the diffuse economic impact of slow-onset environmental disasters such as sea-level rise, land degradation, desertification, or droughts. If some contend that environmental degradation may have consequences on security, possibly making conflict escalation more likely through increased competition for essential resources, the number of additional migrants that can be attributed to environmental degradation would also be particularly difficult to measure – and identifying individual migrants would be virtually impossible. Often, the migratory impact of environmental changes is statistical (increased numbers) but cannot be established at the individual level through an individual status determination procedure.

Beside the difficulty of attributing individual migrants to a “natural disaster,” there is a difficulty in attributing a “natural disaster” to climate change. A media and political discourse has attributed super typhoon Haiyan that struck the Philippines in November 2013 to climate change, although scientific evidence only suggests that cyclones might become less frequent but more violent (IPCC 2014, 216–217 (Sect. 2.6.3), 913–614 (Sect. 10.6.1.5)). Nor can climate change be considered as the cause of the 2010 monsoon floods in affected China that IDMC identifies as the greatest displacement (15.2 million persons) between 2008 and 2012 (Yonetani 2013). Besides the inevitable element of scientific uncertainty of the climate models, the scientific community only asserts that “global monsoon precipitation will likely strengthen” (IPCC 2014, 1234 Sect. 14.2.5), saying that the *probability* of such floods increasing does not mean that a specific flood is *caused* by climate change. In other words, the statistical concept of climate (change) does not allow for the binary determination of whether or not a disaster is caused by climate change and, even less, whether or not an individual is a “climate migrant.”

Therefore, “climate migration,” as individuals displaced because of climate change and who can be distinguished from economic migrants and treated differently, is an impractical concept. Dramatic but controversial forecasts of small island developing states being submerged by sea-level rise draw a wrong picture of environmental changes as direct, isolable factors of migration, letting little to no place for human agency (Farbotko 2005; Gemenne 2010; Kälin 2010). Whereas refugees are often opposed to "voluntary" economic migrants, environmentally induced displacement is not distinct from economic migration: most "climate migrants" *are*, indeed, economic migrants, as economic factors are the most proximate cause of their flight. This should not, however, mean that environmental change does not "force" people to move, but rather that the dichotomy between "voluntary" economic migrants and "forced" refugees is artificial: economic conditions leading to migration, be they triggered by an environmental change or not, can be and often are tragic.

Discourse Inconsistencies

The concept of climate migration is not only impractical: it is also arbitrary. No valid ethical discourse seems able to plead for a governance of climate migration rather than for responses to larger issues. To support this claim, three narratives can be identified: one on the protection of the rights of climate migrants as migrants (rights narrative), another one on the responsibility of polluting states for the adverse impacts of climate migration (responsibility narrative), and the last one on conceiving climate migration as a security issue (security narrative) (Mayer 2012a). Each of these three narratives is rooted in a different disciplinary background and leads to a different justification for an engagement of the international community, but none of them identify climate migration as a unique issue needing a specific form of governance.

Firstly, the rights narrative often relates to a broader humanitarian discourse, conceiving the governance of climate migration as essentially a question of international solidarity. It puts forward the need for the protection of climate migrants. It proposes in particular an analogy between refugees and climate migrants, suggesting either to expand to the latter the protection that benefits many of the former or to create an alternative system of protection. Many such works call for an ambitious engagement of the international community to protect environmental migrants (Bell 2004; Brindal 2007). However, what this narrative really looks at is not climate migrants, but forced migrants. Limiting a new instrument to "climate migrants" (besides being impractical) would reproduce the arbitrary distinction between refugees and other forced migrants. The rights narrative addresses vulnerability, but the cause of vulnerability is irrelevant. If this narrative focuses on international migration, then Betts' argument for a protection of "survival migrants" is more coherent (Betts 2013); if it turns to internal migration, then it should propose mechanisms to reinforce the protection of internal migrants. Furthermore, the rights narrative cannot ignore that migrants are generally *not* the most vulnerable in a society, as the poorer often lack the resources necessary to move (Foresight 2011) – this issue of the "invisibility" of more vulnerable nonmigrants is well known in other situations of forced migration (Lubkemann 2008). In a humanitarian perspective, many climate migrants should certainly be of concern, but any governance endeavor limited to climate migrants would be arbitrary: other migrants in a similar situation of vulnerability and arguably, even more, those "trapped in place" should also be of concern.

Secondly, the responsibility narrative highlights the inequity that results from the poor, who benefit the less from greenhouse gas emissions, being the most severely affected by anthropogenic climate change. There are multiple technical hurdles to the legal argument that Tuvalu and Palau considered to bring to the International Court of Justice and that the inhabitants of Kivalina, an Alaskan village displaced because of the melting of a natural seawall, brought before American courts against multinational companies (Ielemia 2007; Kysar 2011). The ethical argument, however, is relatively straightforward, even through its modalities such as the discounting of past emissions, the possible excuse of ignorance, or the level of excusable emissions are subject to debates (Shue 1999; Caney 2005). Migration might be one of the adverse effects of climate change, and it was identified as such during recent international negotiations on loss and damage associated with the adverse impacts of climate change (UNFCCC 2012). Yet arguments for the responsibility of greenhouse gas emitters do not lead specifically to the governance of climate migration. The responsible parties ought arguably to cease their wrongful conduct and to repair the harm they already caused (see by analogy ILC 2001), but responsibility can in no case justify the imposition of specific norms on the injured parties. How to respond to migration through climate change adaptation policies should be within the sovereign prerogatives of each state, as long as this state complies with its general international obligations such as under international human rights law. Specific humanitarian standards may be desirable, as the rights narrative suggests, but they should not be specific to climate migration, as mentioned above.

Thirdly, the security narrative, constructed by military and intelligence research, approaches climate migration in a very different way by putting forward the interests of powerful actors (generally states, but also possibly corporations) rather than their ethical duties. This narrative contends in particular that states should act early in order to prevent future political instability and that they should cooperate in order to avoid illegal migration and the concomitant development of issues such as drug or human trafficking, failing states and wars affecting commercial interests overseas, and international terrorism (e.g., Söderblom 2008). In other words, states should cooperate because this is in their own, well-understood interests. This narrative may come along with an incentive to militarization, although some have tried to reframe climate migration as rather a "human security" issue (Elliott 2010). Here again, however, it is not evident how climate migration appears as a different sort of issue from other humanitarian situations leading to migration, most obviously in cases of non-climate-related environmental disasters. When a state goes through a spiral of environmental, economic, political, and military issues leading to its failure to protect its population, the contribution of climate change to this spiral is irrelevant in terms of international security. At most, by possibly making such scenarios more likely, climate change calls for more attention to larger security issues.

Momentum for Change

Because the concept of climate migration is both impractical and arbitrary, Betts (2013) and Nicholson (2014) have suggested abandoning it altogether. Consistency would dictate the definition of different issues: the rights narrative suggests a governance of migration or forced migration; the responsibility narrative calls for a commitment of greenhouse gas emitters toward mitigation and compensation, arguably not only through adaptation but also through a substantial loss and damage mechanism; and the security narrative calls for international cooperation reflective of our growing complex interdependence.

The problem is that neither the rights nor the responsibility narratives are very effective on their own as both are ethical arguments about what actors *should* do – and actors do not always do what they should. In particular, these two narratives are grounded in cosmopolitan ethics or "global justice" theories that are yet to be fully endorsed by sovereign states: international governance remains grounded on the concept of sovereign states pursuing their own interests, the rebirth of autocratic monarchs "owing" their country. Within the climate regime, for instance, the responsibility narrative is less influential than the interests of each state (Posner and Weisbach 2010); it is in particular on a purely voluntary basis that states commit (or not) to contribute to mitigation, only vaguely guided by the UN Framework Convention on Climate Change's ambiguous references to principles of "equity" and "common but differentiated responsibilities and respective capabilities" (art. 3.1). The recent negotiations on a loss and damage mechanism show the fierce opposition of developed states to anything approaching compensation, despite compelling ethical arguments.

On the other hand, the security narrative is able to create a political momentum by "speaking to states' interests," that is, by explaining why states could be motivated in doing something that happens also to be ethically sound. James Hathaway (1990) demonstrated that the international refugee regime was not developed out of pure generosity (how could the limitation of the definition of a refugee to persons persecuted on a specific ground be explained?), but rather because of the conjunction of a humanitarian narrative with a persuasive interpretation of states' interests, generating a shared willingness to "govern disruptions of regulated international migration in accordance with the interests of states," "a compromise between the sovereign prerogative of states to control immigration and the reality of coerced movements of persons at risk." Hathaway's conception of the rationale of the refugee regime suggests an alternative analogy with climate migration, not on the substance by pleading for the expansion of a regime already running out of political support but rather on the method of constructing a political support, a momentum for change, by joining ethical arguments with an interpretation of the states' own interests.

Despite its logical inconsistencies, the case for climate migration appears as a magical recipe for norm entrepreneurs (Mayer 2014). There is no essential reason why migrants should be protected rather than other vulnerable people, but migrants attract more attention, if only because of the fear that they may be approaching "us." Nor is there any reason to focus on climate migrants specifically – other environmental migrants are most obviously in a similar situation of human suffering – but anything related to climate change attracts a unique degree of public attention and, possibly, of engagement. By joining the deep-rooted fears of migration with the existential uncertainties raised by climate change, climate migration has an immense marketing potential.

Climate change fuels fears that, if well directed by skillful norm entrepreneurs, may be overcome through fair international cooperation. Similar moments of doubt, such as the end of the Second World War, led to great progress for international governance – including the formalization of the international refugee regime. The same could be done today, in response to climate change, with regard to larger populations of unprotected migrants or other vulnerable individuals throughout the world. Climate migration might not be a practical or consistent concept, but it is a popular one – it is a concept that may trigger a first step toward fairer international cooperation.

The Challenges of Governing Climate Migration

Reconciling the Fair and the Realistic

Governing climate migration poses a broad challenge: how to reconcile the sovereign rights of states with the human rights of climate migrants or, more broadly, of any migrants or anyone affected by climate change? Meaningful preliminary steps have been made to realize the rights of all migrants and to promote cooperation with regard to climate change, but new steps need to be conceived.

The control of migration has generally been conceived as the preserve of states, despite some ethical arguments for an opening of international borders (Carens 1987). A report of the UN High Commissioner for Human Rights on the relationship between climate change and human rights clearly recognized that persons affected by climate change "would often not have a right of entry" to another state (OHCHR 2009). As noted before, the refugee regime has arguably been developed as the exception that reinforces the rule. The Universal Declaration of Human Rights (1948), however, confers to everyone "the right to freedom of movement and residence within the borders of each State," although the International Covenant on Civil and Political Rights (1966) allowed for restrictions of this right "which are provided by law [and] are necessary to protect national security, public order . . ., public health or morals or the rights and freedoms of others."

More than the right to move, however, it is often the many other rights of the migrants that are at issue: right to health, education, decent conditions of living, certain economic opportunities, etc. Both the UN Human Rights Council and the Conference of the Parties (COP) to the UN Framework Convention on Climate Change recognized that the adverse effects of climate change have a range of direct and indirect implications for the effective enjoyment of human rights (HRC 2008, 2009, 2011; UNFCCC 2010). Migrants, as human beings, are protected under international human rights law like anyone else; foreigners benefit from all human rights with the sole exceptions of the right to vote and to be elected and the right to enter a country (OHCHR 2009). The International Convention on the Protection of the Rights of All Migrant Workers and Members of their Families was adopted in 1990 in order to emphasize the human rights of all migrants, including those who lack regular documentation. It is significant that, after 23 years, no more than 47 states ratified this convention (as of January 2014). Regarding internal migrants, the Guiding Principles on Internal Displacement adopted by the UN Commission on Human Rights in 1998 clarified and promoted state human rights obligations, and the African Union Convention for the Protection and Assistance of Internally Displaced Persons in Africa adopted in Kampala in 2009 and entered into force on 6 December 2012 (Kampala Convention) is an important development in a regional context.

The lack of capacities of local governments may however significantly hinder the realization of human rights, in particular by limiting the implementation of programs of humanitarian assistance that are costly but indispensable. This might be specifically the case for developing states that are particularly vulnerable to the adverse effects of climate change, whose capacities may shrink while needs expand. The general reliance of international human rights law on the obligation of each state to protect the persons within its jurisdiction is inadequate to address the circumstances where the impacts of climate change may affect a state as a whole. Existing mechanisms of humanitarian assistance and aid to development are of paramount importance, but they are also strikingly insufficient, attached with detrimental conditions and extraneous political priorities, and contingent to inconsistent levels of public attention (Fassin 2012; GHA 2013).

Linking migration with climate change, however, suggests that the human rights of migrants could more efficiently be implemented through international cooperation. Climate change is by essence a global issue, the substantiation of our growing complex interdependence (Singer 2004). It is also by essence a moral issue, through which the action of some causes harm to others, although in a complex manner (Gardiner 2011). The wide gap between the "haves" and the "have-nots" in terms of historical or present emissions and the concentration of most of the physical and social impacts on the "have-nots" ground a compelling case for not only a form of international solidarity but also for a full-fledged causal (tort-like) responsibility. The ethical responsibility of greenhouse gas emitters substantiates demands for international cooperation in the realization of human rights, not as a "soft duty" of humanitarian assistance but as a "hard duty" of compensation: aid is a due, not a charity.

Yet such ethical arguments are unlikely to have a substantial political impact on their own. NGOs, intellectuals, and some politicians play an important role in raising public awareness, and public opinions may contribute to frame international politics. The success of the International Campaign to Ban Landmines in the 1990s, despite the economic interests of weapon-exporting developed states, evidences the ability of relatively powerless actors, as "norm entrepreneurs," to impact public opinion and thus to shape international relations (Wexler 2003). Yet the interests at stake with regard to climate change far exceed the concessions that some developed states made with regard to the exportation of landmines. Ethical arguments, even if accompanied with a high degree of pathos, will not suffice to convince any democratic government to make the economic sacrifices necessary to fully compensate affected countries. An advocacy that is solely based on the rights of climate migrants and the ethical obligations of other states toward them is unlikely to lead to anything else than an increase in humanitarian assistance. Some American scholars argue that ethical arguments impede international negotiations and should be avoided: rather, states should openly seek their own interests (Posner and Weisbach 2010). This is a dead end, for rational, profit-seeking states are likely *not* to participate in a climate treaty, preferring to free ride over the sacrifices of other states.

The flaw in the arguments based on states' interests is that these "interests" are assumed to be known, uncontroversial givens. There is in particular a tendency to equate "interests" with "rational economic interests" that economists can calculate. Yet the economic value of avoiding climate change is difficult to evaluate, not only because of scientific uncertainty and contingence to a range of other processes such as development but also because there is no agreement as to how future costs should be discounted (Nordhaus 2007). Furthermore, states are also prone to take noneconomic interests into account, especially when discussing an issue such as climate change with potential tremendous security consequences. Unaddressed disasters may conceivably contribute to induce famines, extreme poverty, epidemics, failing states, conflicts, and terrorism, which will have consequences in the whole of an interdependent world. Just like there is no one rational magical formula to discount future events, there is also no such formula to measure existential risks. How much a state is willing to invest today in order to address such undefined future security risks depends on a complex process of political deliberation, in particular social and cultural settings. The current divergence between the European Union and the United States in climate negotiations reflects different political deliberation rather than radically different economic interests.

As long as states' interests are opposed to their ethical obligations, these ethical obligations will be left behind. It may therefore be advisable for norm entrepreneurs to focus on reinterpreting the interests of states in terms that are at least *roughly* ethical. Linking climate migration to security may appear as a promising strategy to trigger change. Under the influence of this discourse, the UN Security Council has already discussed the impact of climate change on international peace and security and requested a report of the Secretary-General on this topic (UN Secretary General 2009). The same discourse, however, has also been used to justify US military investments in Africa (Hartmann 2010) or India to fence part of its border with Bangladesh – but containment is not a sustainable response to humanitarian crises. Contemporary history shows that no crisis is set to remain purely domestic. The neglecting of the Afghan humanitarian crisis by the rest of the world over the last decades of the twentieth century allowed the development of a terrorist movement that led to the worst terrorist attacks in the United States. It is rather through an intense and responsible investment in human development that the international community may reduce threats to international peace and security.

Possible Steps Forward

Some form of international governance might be both realistic and desirable and, indeed, is already being discussed. Proposals for an international treaty that would be inspired by the Refugee Convention and would establish an individual status for international climate migrants, or forced migrants more generally, are not among such realistic and desirable steps. It is unlikely that states will agree to bind themselves to provide international protection to an unknown number of future migrants. Many states that have ratified the Refugee Convention are increasingly reluctant to comply with the specific obligations that it defines. Furthermore, whereas it is in Asia that climate change has the impact on migration, few Asian states are party to the Refugee Convention – even fewer would possibly ratify a convention protecting any broader categories of migrants (Mayer 2012b).

The adoption of a treaty promoting the rights of internal migrants is less unlikely, as the recent entry into force of the Kampala Convention shows, and it might be desirable. As it would be impossible and arbitrary to distinguish "climate migrants" within the flow of internal migrants, such a treaty should extend to all internal migrants. Such a treaty would essentially interpret and repeat the existing obligations of states under treaty and customary international human rights law rather than create brand new rights and obligations – for it is common ground that international human rights law lays down the basic principles that should be implemented while addressing climate migration (Crépeau 2012). A new treaty could play an important role in setting the agenda or advocating for domestic policies, but "soft law" instruments (like a resolution of the UN Human Rights Council or of the UN General Assembly) could play the same role without requiring the long and difficult process of signature and ratification by states (Mayer 2011). Indeed, the "Nansen initiative towards a protection agenda for people displaced across borders due to natural disasters and the adverse effects of climate change," established by a few states in October 2012 as a consultative process, may be taking the direction of promoting some sort of guiding principles on disaster-induced migration (Kälin 2012).

While the adoption of such instruments may be promising, a word of caution is necessary. As explained above, the concept of "climate migration" is essentially arbitrary. Following the rights narrative, it would be arbitrary to limit protection to migrants attributed to climate change, as the cause of migration should be indifferent, or to limit protection to migrants, as the most vulnerable are often unable to migrate. Following the responsibility narrative, the international community should certainly organize a form of reparation for states and individuals affected by climate change, but this reparation does not justify an interference with the way a state decides to adapt to climate change. There is something profoundly disturbing in the possibility that the international community may impose arbitrary humanitarian priorities upon developing countries. There would in particular be important costs of opportunity if scarce domestic resources were focused on climate migrants rather than being more equitably distributed among all of those who need assistance within the state (migrants and nonmigrants), or if these resources were all diverted to address present humanitarian crises rather than dedicating some resources to promote long-term sustainable development and resilience to climate change.

The advocacy for international regulation often lies on two assumptions, according to which, firstly, the states affected are reluctant to protect climate migrants within their jurisdiction and, secondly, that international law can do something about it. Both assumptions are questionable. On the one hand, the need for protection of climate migrants often results from the lack of capacities rather than from the unwillingness of a state to protect its population. It must be kept in mind that the impacts of climate change in developing states such as the Maldives, Bangladesh, and Nigeria do not only affect individuals: they considerably diminish the capacities of states, some of which already face many other severe issues such as poverty, violence, and corruption. On the other hand, it is also uncertain that international law can curb the conduct of those states that are able but unwilling to act in a certain way. There is no direct way to enforce international law (like police does in domestic contexts). The international trade sanctions that are often used against pariah states affect the population more than their leaders. In any case, a treaty only obligates those states that have decided to ratify it. Most of the norms that an instrument on the protection of climate migrants would contain are already norms of international law, and simply rehearsing those norms will not automatically lead to a change of conduct, although it may contribute to different political, social, and cultural processes through which the international community influences domestic politics.

Rather than international regulation, attention should be given to institutional governance as a possible element to promote international cooperation with regard to climate migration and other forms of migration. In the many states that show willingness but are unable to provide protection, cooperation is essential to supplement the capacities that a country needs, among others, through international assistance and capacity building. In those other countries that would be able but are unwilling to comply with their obligations, international socialization would help to prompt compliance. Rather than state-to-state discussions, an international organization would provide a greater authority as a unique voice, relatively independent from global day-to-day politics, established on a solid expertise.

Therefore, perhaps the most worrisome issue raised by the debate on climate migration is the absence of an international institution with a specific mandate of protecting migrants. On the one hand, the UN High Commissioner for Refugees, which is the "UN refugee agency," has developed significant expertise on assistance and protection, but its mandate is narrowly conceived. The agency's initial focus on refugees has been extended to other persons of concern, such as stateless persons, returnees, asylum seekers, and some internally displaced persons, and it has provided some assistance in responding to natural disasters. Yet the UNHCR has no general mandate covering generally all migrants or climate migrants. On the other hand, the International Organization for Migration (IOM) is a self-standing international organization, outside of the United Nations system, which has significantly expanded its membership since the end of the Cold War, reaching 155 parties in January 2014, but has no proper protection mandate. The IOM provides logistical assistance as requested by states, for instance with regard to the control of migration and to the recruitment, transfer, and voluntary return of migrants. As the UN Special Rapporteur on the Human Rights of Migrants recently noted, "the mandate and funding of IOM pose structural problems with regard to fully adopting a human rights framework for its work: both would need to be revised if the organization is to become a key player in the promotion and protection of the human rights of migrants" (Crépeau 2013). The Special Rapporteur considered new institutional arrangements, such as a new UN agency, the expansion of the mandate of the

UNHCR or the transformation of that of the IOM, or, on a shorter term, a set of measures to strengthen the current institutional framework such as through increasing the frequency of High-Level Dialogues on Migration and Development within the UN General Assembly. Such options suggest relevant responses to many of the questions raised by the debate on climate migration.

Other institutional questions relate to the ability of today's international institutions to channel efficient international funding to support development and capacity building, in particular in countries affected by climate change. Important discussions are ongoing, within the climate regime, on international funding for climate change adaptation as well as loss and damage mechanisms that may support countries affected by climate change. The voluntary nature of states' contributions and the limited amounts proposed so far fail however to respond to the constant calls for the responsibility of greenhouse gas emitters.

Conclusion

Social progress rarely comes straightforwardly from fully reasoned ethical arguments. Rather, biased representation and emotions are some of the factors that allow the success of certain arguments instead of others in public deliberation (Crawford 2006). That the concept of climate migration is essentially flawed and virtually impossible to implement should accordingly not be the end of our discussion: because of its ability to generate momentum for change, the concept appears as a rare opportunity for meaningful progress toward fairer international governance. The refugee regime succeeded in the post-Second World War, thanks to its ability to reconcile individuals' rights with states' "enlightened self-interests" (Hathaway 2005), thus fostering an important step toward what was to become international human rights law.

The concept of climate migration is a powerful one as it calls to two of our deepest contemporary fears: climate change and migration. Doing nothing in front of such fears is politically impossible, while granting an individual status to "climate migrants" is practically impossible. It belongs to us to foster advocacy and create institutions that are able to direct the momentum for change toward meaningful progress toward the protection of the rights of migrants and the responsibility of greenhouse gas emitters. There are major risks, however, that such fears may rather fuel xenophobia and tense the relations between developed and developing countries or at least impose inappropriate policy priorities on resource-constrained states.

Climbing the Adaptation Planning Ladder: Barriers and Enablers in Municipal Planning

Elisabeth Hamin and Nicole Gurran

Contents

Abstract

Local municipal governments have a crucial role in helping communities adapt to climate change. Recognizing different levels of climate preparedness, this chapter analyzes what steps communities tend to follow when they move forward on climate adaptation, including prerequisites for planning and the selection of policies. Drawing on content analyses of local climate adaptation plans from the USA and Australia, as well as interviews with municipal planners

in both nations, the chapter explores the adaptation policy choices communities are making and explains the range of strategies local governments have used to move forward on a "ladder" of climate adaptation, proceeding from awareness and constituency building activities through formal risk analyses and strategic planning for climate adaptation, through implementation through specific changes to land-use planning and infrastructure investment. Factors found to support or hinder these efforts relate to political will, staff resources, technical information, and training in potential policy responses. Significant barriers include issues of property rights and sunk investment in vulnerable locations (particularly along the coast), as well as shifting community and political views about the reality of climate change. Overall, progress in municipal climate adaptation planning is patchy and affected by wider policy frameworks and access to state- or national-level support. However, this chapter highlights opportunities for municipalities to move forward on climate adaption planning, despite local barriers to action.

Keywords

Municipal responses • Adaptation barriers • Local planning

Introduction

Adapting to climate change is, in many ways, a local issue. The interaction of climate with specific local geographies and populations means that each place has unique issues and opportunities, and planning to increase resilience has to occur at this local level to accommodate that variability. Improving local governance, infrastructure, and built form in urban areas provides great potential to increase the safety of the world's majority-urban population while improving quality of life. However, urban policy frameworks and technical expertise among planning practitioners remain in a state of evolution, two decades since the passage of the United Nations Framework Convention on Climate Change (1992). Early urban policy action focused on reducing greenhouse gas emissions through policies to limit sprawl and reliance on private automobiles and to shift patterns of energy use in the built environment – termed "mitigation planning." "Adaptation" approaches have the goal of reducing the vulnerability of communities and the built and natural environment to the impacts of now-unavoidable climate change. Appropriately, in developed countries, the first attention went to mitigation, and only recently has there been much uptake of local policies for adaptation. Research on climate change adaptation (CCA) planning emphasizes a number of barriers impeding local response, such as insufficient data on potential climate risks, a lack of political will to change, and a lack of state- or national-level mandate for action. Nevertheless, some communities have made important progress in addressing climate risk within their local planning frameworks.

Organized local action on climate change really commenced with the implementation of *Local Agenda* 21 (LA21), a set of commitments for local engagement in sustainability planning, agreed by municipalities from throughout the world, at the 1992 United Nations meeting just described. At the subsequent 2002 World

Summit held in Johannesburg, emphasis moved more explicitly to local sustainability "action." Since this time, climate change has become an increasing theme in local environmental initiatives. The Cities for Climate Protection (CCP) campaign, spearheaded by ICLEI, has resourced and encouraged many of the municipal actions around greenhouse gas reduction, with more than 1,000 cities, towns, counties, and associations' worldwide members of ICLEI by 2013 (ICLEI: Local Governments for Sustainability 2014). However, overall, municipal actions have related to climate change mitigation, rather than adaptation (Measham et al. 2011; Castán Broto and Bulkeley 2013).

Many of the world's global cities, particularly within the developed world, have demonstrated significant leadership, with cities such as London, New York, Amsterdam, and Sydney all developing landmark plans and programs across a spectrum of carbon reduction and climate adaption approaches, particularly in relation to energy, water, waste, and, increasingly, risk reduction planning (EEA 2012). However, smaller municipalities and those in the global south have made more varied progress, particularly in relation to considering potential increased climate risk within their land-use planning framework (Baker et al. 2012; Carmin et al. 2012; Romero-Lankao 2012; Bierbaum et al. 2013). Given that the effects of climate change seem to be consistently "ahead of schedule" (Betts et al. 2011; McKibben 2011) and the long-time horizon for built form to change in response to changes in policies and plans, this is a significant problem.

To give a sense of what sorts of actions are possible at the municipal level, the chapter begins by identifying the policies and practices that first-adopter communities are undertaking. Following that, the chapter focuses in on the process that these communities are using to reach those policies and the conditions and actions that enable or disable progress particularly in relation to land-use planning for climate adaptation. The empirical data suggests that the steps undertaken by communities lie along an adaptation "ladder." In conclusion, policy interventions and other forms of support needed to help local communities move forward on the adaptation ladder are proposed.

Research Method

Three empirical studies of adaptation practice by the authors, plus insights from the research and practice literature, are synthesized to inform this chapter. Hamin and Gurran (2011) examined the small number of climate change adaptation plans that had been prepared by communities as early as 2010, comparing practice in two nations – the USA and Australia, which both have similar governance and land-use planning systems. Both nations have three-tier federal, state, and local governments, with planning law defined by the states but implemented by municipalities who show varying levels of heterogeneity in their policy approaches and priorities. This means that even when strong state policy exists, very different local planning frameworks and outcomes are typical in both nations. We identified stand-alone climate adaptation plans and separate adaptation chapters in wider municipal documents from two sources. One was the American Planning Association's (APA) list of cities and towns that had undertaken climate planning (APA's Green Communities Research Center 2010); the second was Australia's local government database Commonwealth Government's Local Adaptation Pathways Program, which provided financial support for local adaptation between 2009 and 2011. Despite this wide net, only eight municipalities were identified to have full adaptation plans in place or exhibited drafts with specific spatial or land-use policies as of November 2010. Each climate plan was analyzed in relation to climate threats and impacts, key goals and recommendations, and the relationship between the adaptation plan and other local climate change mitigation strategies or plans. The analysis provided a suite of local options for addressing climate change in municipal planning, as discussed below.

Two next-phase studies sought to understand the issues and barriers facing other municipalities, and steps taken to move forward. Primary research was carried out in Australian coastal councils between 2010 and 2011 (Gurran et al. 2012a) and in coastal Massachusetts of the USA between 2011 and 2012 (Hamin and Gurran 2013). The focus on coastal locations reflects the particular issues arising from climate risk in coastal areas, and the likelihood that community sentiment toward climate risk is heightened in these contexts, thus providing an important political impetus for action. For Gurran et al. (2012a), 55 local government areas (just under 10 % of Australia's total local municipalities) were surveyed, representing coastal areas with identified common issues arising from population growth and change, inadequate or declining infrastructure, and economic instability. The companion study undertaken in coastal Massachusetts in the USA involved 15 interviews with 15 cities and towns, conducted in 2011. The results presented below represent a synthesis of the findings of these three studies as well as the broader literature.

Climate Change, Spatial Planning, and Municipal Action

Planning Processes

The impacts of climate change are already being observed many parts of the world, as documented elsewhere in this book. Rising temperatures, more frequent and intense heat waves, water shortages, rain events, and changes in the spatial range of bushfire risk all have implications for the siting and design of new development and for the ongoing utility of existing homes and infrastructure. Global sea level rise represents a particular threat to coastal ecosystems and settlements. Social and economic implications of increased climate changes are also significant and will vary across geographic areas and community groups. In the major cities, hotter temperatures and more frequent storms or flooding cause major disruption due to the density of people and major infrastructure affected. However, in many regional areas, drought, inundation, and storm events can ravage the economic base of small settlements, while providing or restoring services and infrastructure to rural and isolated communities can be much more difficult (IPCC 2012).

Although future impacts of climate change are uncertain, decisions regarding settlement patterns and building design will have lasting impacts – with most buildings and infrastructure designed to a 50–70-year life span. Current planning frameworks must neither exacerbate contributions to greenhouse gas emissions nor increase community exposure to climate threats (Hamin 2011). Rather, strategic planning decisions should actively facilitate climate change mitigation and adaptation opportunities. Overall then, climate change represents multifaceted challenges for spatial planning – the decision-making framework governing the location and design of development and infrastructure. Given that climate impacts will differ markedly between places, local planning is particularly important.

The following principles have been identified to guide local planners in developing adaptation responses to climate change for their communities:

1. Adaptation energies should complement strategies for greenhouse gas reduction. Climate change mitigation should be seen as long range adaptation, and adaptation approaches that might increase carbon pollution or have other negative environmental effects should be avoided.
2. Secondly, because decisions about the built environment will have lasting impacts, planners must be ready now to prevent further risks associated with climate change and to support rapid adoption of new approaches if and when required (Gurran et al. 2008).
3. Social equity considerations in climate change adaptation are also important, and planners must recognize that vulnerability is not evenly spread across a community. Poorer and minority constituents are more likely to be located in geographically vulnerable areas to start with. As harms occur, less-resourced groups will tend to be disadvantaged by costs needed to cope with increased climate volatility and have less capacity to enact dwelling modifications for climate safety or comfort.
4. In deciding whether or not to move forward, it is worth prioritizing actions with multiple benefits for the environment or community (like enhancing natural ecosystems to improve resilience to climate impacts, or providing more opportunities for non-motorized transport) (Gurran et al. 2012a).

It is important to recognize that the techniques and processes of planning practice must also respond to new pressures and challenges associated with climate change. Traditional planning practice draws heavily on research and data based on past trends and generally assumes a stable framework of a predictable future. However, unpredictability is one of the major challenges associated with climate change. Faced with uncertainty as to the timing, nature, and magnitude of risks, planning needs to include adaptive management, where decision and response frameworks are designed to adjust to changing circumstances and information. Such approaches can be designed into statutory planning documents through controls that are triggered when a particular "threshold" is reached or when new information comes to light (Folke 2006; Abunaser et al. 2013). A second approach is that of scenario building, whereby potential story lines about the future are developed as a way of exploring or testing different possible approaches in a more creative way (Wilson 2009).

One of the major differences between local climate mitigation strategies and the commencement of adaptation efforts is the need to understand potential local climate change risk. Climate vulnerability assessments generally provide the basis for informing strategic land-use planning decisions on levels of risk in relation to an entire local area, site, or development proposal (National Research Council 2010). In drafting planning instruments and criteria for development assessment, existing information used to support land-use planning decisions – including floodplain and bushfire protection thresholds or models – may need updating or reconsideration over time as new data becomes available, particularly in relation to likely increases in the intensity or frequency of these events and projected new geographical range. It may be necessary to reorient natural hazard assessment methodologies from historical events to forecasted impacts associated with climate change scenarios.

Policy Responses

There are quite a variety of possible policies to respond to climate change at the municipal level. As noted above, all policies should seek to achieve dual goals to adapt to climate change impacts and promote long-term mitigation (reductions) of greenhouse gas emissions. Infrastructure examples include establishing new, decentralized energy, water, or waste management plants that reduce the carbon impact of settlements while contributing to resilience of the entire network in case of natural hazards. Self-provision of distributed and smaller-scale key infrastructure services – like energy, water, and waste management, through technologies for micro-energy generation, water retention, reduction technologies, and waste minimization, reuse, and recycling – tends to create a more disaster-resilient community. Part of resilience is assuring that new facilities can be retrofitted for more sustainable technologies as they become financially feasible. For instance, solar access should be protected to ensure future capacity for onsite solar generation. Regulatory burdens to require proposals for renewable energy infrastructure should be minimized, and where possible, the planning policy should be shifted to favor renewable energy projects (Department of Communities and Local Government (DCLG) 2007).

Similarly, there are a number of basic approaches to reducing the carbon impact of transportation systems and improving resilience to future climate impacts and potential oil scarcity. New and existing settlements should be designed or reconfigured to reduce trip generation and to encourage public transport use and active transportation such as walking and cycling. Safe, naturally vegetated walkways and cycle paths should connect residential, retail, employment, and recreational areas. Proposals for new development should include travel plans which include a range of sustainable transport options – walking, cycling, public transport, and only lastly the private motor car (Newman et al. 2009).

Urban design guidelines and building codes for public and private buildings should be designed for future climate scenarios. While much has been written about sea level rise, addressing potential urban heat island effects arising from hotter temperature and heat waves is also an important consideration when preparing urban design guidelines and assessing public and private buildings in built-up areas (Stone 2012). Requirements for urban vegetation, "green" (planted) roofs, and specific colors for building and paving materials can be considered. Public space designs must anticipate more severe local climatic conditions, with shading, shelter, and appropriate vegetation to cool areas of open space and walkways or cycle paths, as well as designing public amenities for safety and storage during disaster events.

In planning for areas where risk is found to be high, decisions fall roughly into three categories: to protect infrastructure through engineered fortification, such as a sea wall; to accommodate threat through planning and design modifications; or to retreat, by relocating infrastructure and activities. Such decisions often need to be made at a local scale, responding and adapting to specific circumstances as they unfold (de Vries and Wolsink 2009). In planning for new settlements, or for new development within existing areas, it is important to reserve space for emergency access, congregation, shelter, and evacuation. In particularly vulnerable areas, locations for intermediate post-emergency recovery, such as temporary housing, should be identified. Long-term planning ensures that intermediate land-use decisions do not compromise future opportunities (Meck and Schwab 2005).

Climate Adaptation Plans: Policies Actually Chosen

The literature described above outlines potential policies for CCA. But what steps are communities actually choosing? Table 1 identifies the actions taken by eight early-adopting communities in Australia and in the USA who prepared specific plans for adaptation.

As shown in Table 1, the full suite of potential policy responses is being attempted across the plans reviewed, although not necessarily within the one local area. The most comprehensive adaptation planning frameworks (for instance, plans for Keene, Olympia, and King County in the USA and Brisbane and the Gold and Sunshine coasts in Australia) cover land-use allocation, development and design controls, infrastructure provision, urban transport, and even the ongoing resilience of food supplies. By contrast, more targeted frameworks focus more on direct climate risks (e.g., Chicago, Hornsby, Melbourne, Mandurah).

Climbing the Adaptation Ladder

As the literature has progressed, a general perspective on the process of adaptation has emerged. Moser and Eckstrom (2010) suggest that adaptation occurs in these phases:

Table 1 Policies recommended in climate adaptation plans, USA and Australia (Adapted from Hamin and Gurran 2011)

Local authority	Plan name	State	Population category	Location	Key land-use planning actions
Keene	Adapting to Climate Change: Planning A Resilient Community 2007	New Hampshire	0–50 K	Inland	Scientific staff to provide climate change information to policymakers for consideration in regulation and decisions; review comprehensive plan; hazard mitigation; and relevant building ordinances/design standards in light of potential climate change impacts; create flood control zone; protect and rehabilitate historic and cultural resources to reduce vulnerability; code and plan revisions for water quality protection
Olympia	Olympia's Response to the Challenge of Climate Change 2007	Washington	0–50 K	Inland	Develop new sustainability design standards (green building materials, energy conservation principles); design standards for greater resilience to severe weather, floodplain identification; identify alternative route options for movements of goods and people; sustainable transportation mode choices; promote locally generated; secure energy sources; increase protection of existing/future wetlands to enhance resilience of ecology and hydrology; increase water-storage capacity; increase food security – identifying and protecting prime agricultural soils
Berkeley	Berkeley Climate Action Plan 2009	California	50–300 k	Coastal	Encourage water efficiency; expand and diversify water supply; increase urban tree cover
Chicago	Chicago Climate Action Plan 2008, Especially Chapter 5: Adaptation	Illinois	1–3 M	Inland	Refers to previous efforts in encouraging denser less car dependent development; introduction of stormwater regulations
King County	King County Climate Plan 2007, Especially Section 6B On Adaptation	Washington	1–3 M	Inland	Update heat response plan – research into urban heat island effect; encouragements for innovative cooling/energy efficiency in properties; "Green Urban Design Plan" (permeable pavements; rooftop gardens; green alleys; onsite mechanisms to prevent flooding); amendment of landscape ordinance for climate tolerant plants

Hornsby	Climate Change Adaptation Strategic Plan 2009	New South Wales	50–300 K	Coastal	Review planning controls to strengthen requirements in locations of increased vulnerability
Gold Coast	Gold Coast Climate Strategy 2009	Queensland	300 K–1 M	Coastal	Designate climate sinks in local planning scheme; scope local food production opportunities and requirements; implement coastal planning measures
Sunshine Coast	Sunshine Coast Climate Change and Peak Oil Strategy 2010	Queensland	300 K–1 M	Coastal	Revised sea level rise projections; planning controls to improve resilience of natural systems; risk assessments in planning decisions; planning controls to encourage localization
Brisbane	Brisbane's Plan for Action on Climate Change and Energy 2007	Queensland	1–3 M	Inland	Planning controls to prevent flood/storm surge exposure; shade and weather protection; transit-oriented development to reduce emissions; reducing barriers to urban food production; improve resilience of natural systems – no net loss of natural vegetation
Darebin	Climate Change and Peak Oil Adaptation Plan 2009	Victoria	0–50 K	Inland	Zoning flexibility – provision for local food production; assessing planning controls to remove impediments to resilience strategies; appropriate development in areas subject to climate risks
Melbourne	Climate Change Adaptation Strategy 2009	Victoria	0–50 K	Coastal	Revised planning controls for sea level rise; new building standards to manage heat island effect
City of Port Phillip	Draft Climate Adaptation Plan 2010	Victoria	0–50 K	Coastal	Revise planning controls to restrict building in areas of coastal vulnerability; require climate adaptive building design and vulnerability to be considered in planning decisions; amend planning controls and permit requirements accordingly
Mandurah	Coastal Zone Climate Change Risk Assessment and Adaptation Plan 2009	Western Australia	0–50 K	Coastal	Modifying planning process; amending standards; reviewing information requirements for decision-making

- Understanding the problem (detect the problem, gather and use information, re-/define problem)
- Planning phase (develop options, assess options)
- Managing stage (implement options, monitor outcomes and environment, evaluate effectiveness of option) (see also Arnell and Delaney 2006; National Research Council 2010)

This of course mirrors the general comprehensive planning process. One key difference is that built into the "understanding the problem" phase are forecasts of climate change and analysis of who and where is most vulnerable to those changes.

More precisely, our empirical research suggests a continuum of stages in developing climate adaptation responses within local areas, beginning with risk analysis moving through the preparation of an adaptation strategy to changing planning controls. This pattern is consistent with previous research identifying a climate risk analysis as a precondition for further adaptation action in Australian public and private sector organizations (Gardner et al. 2010). This risk analysis informs the development of a framework for strategic adaptation action across the many responsibilities of local government and might include actions ranging from community education through to developing applications for external funding and resources.

With a risk analysis in place, communities' next typical step was to change the planning and regulatory framework governing future development, so that such development enhances resilience to climate risks, rather than furthering exposure. Subsequent actions involve rethinking the ways in which local infrastructure (both public and private) is designed and delivered, before finally establishing a funding strategy to resource ongoing intervention. These last two stages have as yet been undertaken by only a few of the municipalities or councils involved in our study, but the vast majority of responding agencies indicated that they intended to commence such work in the near future. In doing so, a strong evidence base will be needed with detailed local-level information, including costings on necessary adaptation expenses over time. Strategic assistance to help councils overcome barriers to the adoption of more resilient forms of infrastructure design and delivery will also be needed. Note that the actions above are being taken in regard to new development permits and infrastructure. The literature may suggest substantial changes to existing property such as retreat, but that is much harder to accomplish for obvious reasons. Absent a major loss or disaster, our survey respondents were not attempting to force change to existing properties.

Taken together, these series of actions suggest a ladder of adaptation that communities are tending to follow, at least in coastal Australia (Fig. 1).

The ladder begins with institutional awareness of climate change issues through to developing an information base (risk analysis) and to preparing an umbrella framework for adaptation action. Subsequent implementation stages typically include amendments to land-use planning controls and, finally, investment in infrastructure augmentation or change (see also Tompkins et al. 2010). Although regulatory change itself is time-consuming and costly, involving consultant studies, legal opinions, local

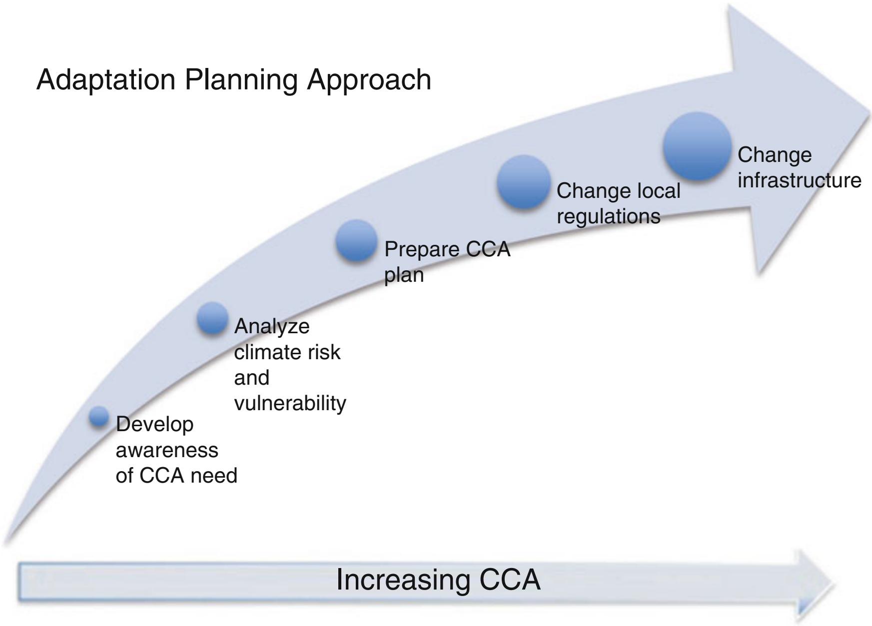

Fig. 1 Adaptation ladder (Adapted from Gurran et al. 2012b)

politics, and potentially, litigation, these costs are far less than those anticipated for key municipal infrastructure upgrade or relocation. Retrospective adaptation action for existing infrastructure will likely be delayed until the infrastructure requires replacement, resources are available, and/or the risk becomes quite urgent.

Barriers to Adaptation Action

The sections above have identified what typical actions are and the steps through which communities tend to move. This section discusses the process itself – what has enabled governments to move forward, what tends to slow them down, and the processes that are most appropriate.

Barriers can cover a wide range of issues, but, following Adger (2009), they are socially constructed and thus not insurmountable. Moser and Ekstrom (2010), building from the wide range of research identifying barriers to adaptation planning (Mukheibir and Ziervogel 2007; Amundsen et al. 2010; Nielsen and Reenberg 2010; Measham et al. 2011; Mozumder et al. 2011; Rosenzweig et al. 2011), explain the necessary conditions for CCA as the following:

- *Leadership*, whether in the government or grassroots-level activism. Leadership is particularly essential when there is no regulatory mandate or local public demand for action.

- *Resources*, including technical information such as regional climate forecasts as well as staff time and expertise.
- *Communication and information* , which is particularly understood to be public participation and the flow of communication among those responsible for action; there is a sense in the article that this is a top-down flow of information from agencies to the public as well as cross-flow among members engaged in a CCA planning process. Note that in this formation, technical information needs are included in the resources category above.
- *Values and beliefs*, especially regarding risk and how it should be managed and what concerns have standing. Although not explicit in the original framework, for our purposes, belief (or lack thereof) in the anthropogenic causes of climate change would be categorized here (Moser and Ekstrom 2010; Hamin and Gurran 2013).

Adaptation barriers thus arise when deficiencies across any of these elements occur during any stage of the adaptation planning process. For instance, Arnell and Delaney (2006) characterize barriers in relation to *missing operators*, arising from a lack of awareness by leadership of the need for adaptation, and *missing means* – that is, limited institutional capacity, budgetary constraints, and lack of regulatory authority (see also Gupta et al. 2010; Berkhout 2012). They also point to the problem of *unemployed means*, where because of misallocation of costs and benefits, actions are not taken. A relevant example would be homeowners not moving because low-priced nationally subsidized flood insurance will reimburse their losses or local government officials prioritizing other budgetary items – such as short-term infrastructure upgrading (Measham et al. 2011).

Empirical studies generally support these theoretical frameworks. Among the most basic needs are climate change awareness and technical knowledge of how to proceed; Australian research has found that planners express uncertainty about how to begin CCA planning, despite evident awareness and conviction about the need for action (Measham et al. 2011; Baker et al. 2012; Gurran et al. 2012a). Consistently, if regulatory authority or mandates to support adaptation efforts are absent, it is much more difficult for planners overcome local barriers arising from insufficient information and capacity constraints (Few et al. 2007; Funfgeld 2010; Tang et al. 2010). State mandates, while sometimes viewed by local officials as intrusive and controlling without the benefit of additional funding, can provide both an alignment of values and the political cover needed when facing opposition from constituents (Bedsworth and Hanak 2010; Dalton and Burby 1994). Guidance from the state or region should present the best available science in order to influence beliefs while considering financial compensation to constituents adversely affected by the policies (Bedsworth and Hanak 2010). By implication, a state mandate would overcome concerns about the legal basis for changing zones or ordinances in relation to climate adaptation. For other activities, such as provision of water infrastructure, specific state regulations need to change for local authorities to modify their own systems.

Previous research and policy development work has emphasized the importance of access to additional resources in helping local governments build capacity for climate change adaptation, particularly in local government areas already struggling with resource constraints (Baker et al. 2012; Bierbaum et al. 2013). This is similar to many topics – a study of 100 cities in California's Central Valley found a link between the cities' fiscal means and the occurrence of sustainability policies (Lubell et al. 2009). In well-resourced communities, addressing barriers tends to be more an issue of facilitating effective use of resources rather than a need to create capacity per se (Burch 2010). But this requires political leadership to push adaptation to the top of the priority list. As Measham et al. (2011) have suggested, because climate change adaptation is not embedded within local planning practice, it is easily displaced by the context of routine demands.

Case Study: Barriers to Action in Massachusetts Coastal Communities

To ground this discussion of barriers and enablers of CCA, it may be helpful to provide two case studies, one focusing on what prevents forward movement and one on what enables it. These are of course closely interrelated, but not exact mirror opposites.

In Massachusetts, cities and towns update their master (comprehensive) plans when they wish to – there is no legal requirement for updates. There is no state or national mandate or funding for CCA; there are not even any accepted projections for climate change upon which towns can rely. Consequently, local CCA planning can only happen through very conscious effort to undergo dedicated CCA planning process, or if a town happens to be updating their master plan. Unsurprisingly, forward movement on adaptation at the local level has been quite slow. In reviewing all 351 cities and towns of the Commonwealth, only Boston had prepared a dedicated CCA plan as of 2012. One town is including a CCA chapter in their new master plan, which is now underway. Despite this, most of the planners in our 15 case study communities saw value in including CCA in their comprehensive or capital improvement plans. Many of the responses resonate with previous research: the three most common barriers to taking action reported were resources (staff and money), the sense that climate projections or climate science remains uncertain, and concern over politics or lack of leadership (Hamin and Gurran 2013).

Less reported previously is the impact of high private property values in motivating opposition to policy changes involving retreat options and in stimulating pressure to enable hard shoreline defense. After this, a range of barriers are mentioned: challenges from existing land-use patterns (which limit adaptation options), lack of public support or contrary local values, and the distant time frame of adaptive need. Various institutional constraints were occasionally mentioned: the lack of regional planning in the state, the lack of federal or state mandates for action, and difficulty in finding a legal basis for including adaptation in regulations. Planners also reported political unwillingness to threaten property interests in expensive coastal land. In coastal Massachusetts as well as many beach areas, the residents most likely to be affected by sea change policies tend to be quite wealthy and have the ability to concentrate resources to prevent change they consider undesirable (Hamin and Gurran 2013). This is evident in the Australian case study as well, discussed below.

Case Study: Planning, Property Values, and Community "Pushback" in Australia

Local values can provide an atmosphere of support for climate change adaptation or, alternately, can act as a barrier to that process (Wolf et al. 2013). The politics of risk are a major concern for Australian local governments. Councils that had reasonable success in making general plans for adaptation found it much harder to move to implementing regulatory policy (Gurran et al. 2012b). Vague comments regarding the need to adapt are one thing; plans and regulations that identify the affected properties are quite another. It did not seem to make much difference whether the property owner was a long-term owner or a "wash-ashore" who was just thinking about buying land. Several participants described pressure from affluent newcomers who had purchased sites in vulnerable locations and now sought to secure approval for new development, despite climate risk. These conflicting pressures arising from various stakeholder groups are a major concern for local councilors and professional staff. Respondents described a growing community "pushback" against climate change, driven by concern that identifying areas of climate risk and imposing exposure-reducing development controls would lower private property values, that has strong potential to erode local political support for adaptation measures. Given that the benefits of adaptation occur in the distant and uncertain future and that there is no obvious constituency for adaptation action, it has proven difficult even for local communities that started a solid CCA process with state funding to move into the implementation stage. The public – and often the planners – perceives climate change as part of the distant future, and it is difficult to care about that when there are pressing issues at hand.

Overcoming Barriers Through Alternative Processes

In general, the literature and discussions on climate adaptation tend to propose two basic approaches to forward movement of CCA policies. The first is overt adaptation planning (Adger et al. 2005), in which the city or town prepares a comprehensive strategic framework based on climate forecasts and vulnerability analyses. The advantages here include the comprehensive nature of the method, which should assist in preventing maladaptation, the ability to include the public through regular participatory processes, and having as one product of the process an agreed-upon climate projection or set of scenarios (Preston et al. 2011). It appears that the comprehensive planning approach may overcome several barriers: it provides the ability to request resources for CCA, to develop an accepted climate projection for use in guiding policy, and to generate public support through participatory processes.

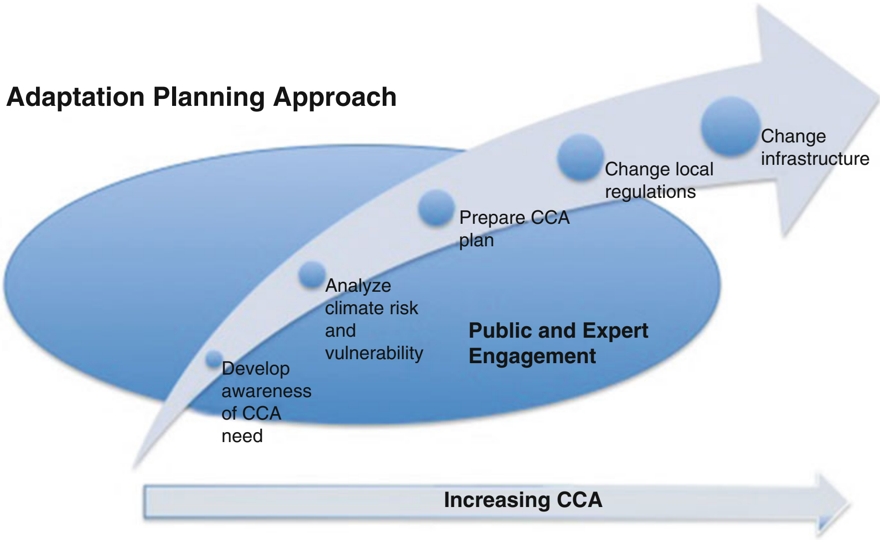

Fig. 2 CCA planning approach

Figure 2 reprises the ladder of adaptation as a planning process, with a focus on the potential to engage the public throughout many steps of the process, thereby bringing in better transparency and potentially building political support.

The second approach is often termed “mainstreaming” and implies moving directly from climate forecast to changing technical specifications and regulations without going through a full, stand-alone climate planning process (Klein et al. 2005; Sharma and Tomar 2010). In this approach, officials can avoid discussion with the public or formal planning processes and instead focus on changing regulations and technical specifications and including future climate as a normal variable in municipal management decisions. For example, at the urging of their regional planning body, several Massachusetts towns are including climate change projections in the vulnerability analyses for their, mandatory multi-hazard mitigation plans.

The advantages here include speed, as climate becomes a normal part of the municipal processes quite directly; implementation, as the goal is to bypass a long planning process and go directly to changing policy; and integration, as climate adaptation is situated within existing cross-sectoral plans and activities. The disadvantage is that there is little ability to engage the public and minimal ability to coordinate policies or undertake a proper risk analysis. Given this, mainstreaming may lead to more maladaptation over time, as there is little chance to consider action in its fuller environment or compare actions to assure they work together. But it does allow quicker forward movement and may be a good response when the issues are primarily technical, when upper-level political support is weak but department-level support is strong, or when too much publicity is likely to lead to community pushback. The general steps are demonstrated in Fig. 3.

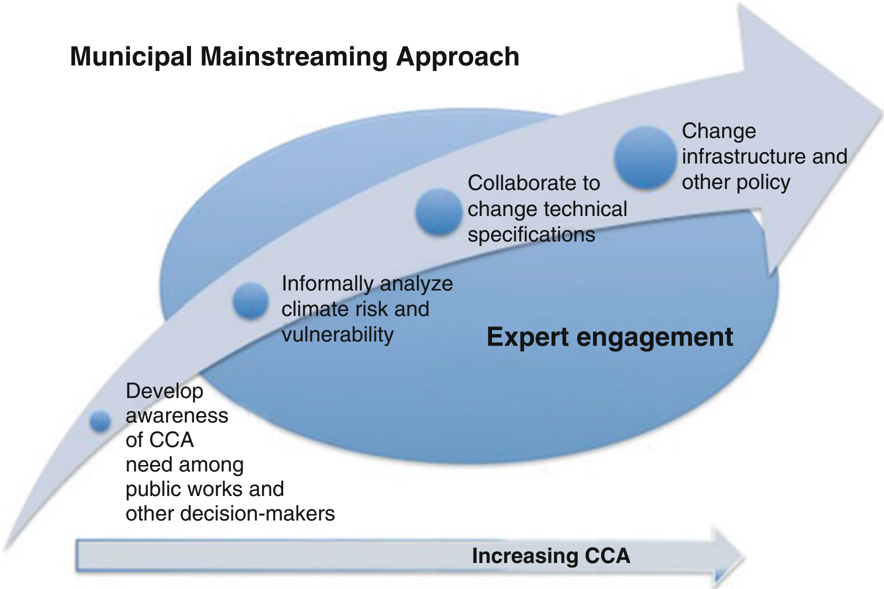

Fig. 3 Municipal mainstreaming approach

There is in addition a third potential approach which can be thought of as "stealth," but might be less controversially be described as the "no regrets + co-benefits, no discussion" approach. The idea here is to achieve some climate adaptation goals without identifying the actions as adaptation. Instead, the focus is on the other or "co-benefits" of a policy (United Nations Human Settlements Programme (UN-Habitat) 2011). Indeed, research suggests that at the national level at least, climate change is rarely the primary or stated motivation for adaptive action (Berrang-Ford et al. 2011), but the extent of incorporation of climate adaptation measures within other policy frameworks is largely unknown. With anticipated increases in sea level, floods, and stormwater intrusion (Frumhoff et al. 2007), most planners know there is pressing need for policy, but remain largely unable to publically frame the problem as one of climate change (Ruth and Coelho 2007). It may even be that adaptation actions situated within established policy areas, such as natural hazards frameworks, are more likely to endure changing political cycles (Gurran et al. 2012a). This approach had been used in the Australian context, with some local council professionals addressing skepticism by using a language of climate "variability" rather than climate "change," which they felt helped counter-act the growing political pushback against climate change. Even more so than mainstreaming, this approach lacks the advantages that a public process can bring and cannot achieve the perspective of a planning process. It works hit or miss. But in the hardest situations, it may be the way to start. Illustrative steps are identified in Fig. 4.

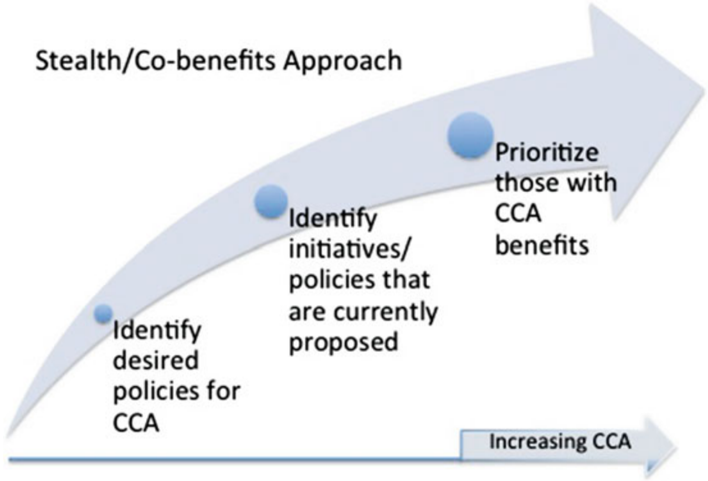

Fig. 4 Stealth approach

Choosing Your Approach/Overcoming Barriers and Engaging Enablers

The short story is, not surprisingly, that undertaking a proper plan enables engaging the public and thus can build political support and create long-lasting credibility. A plan can also assist in requests for funding and enable a more comprehensive view that may help in overcoming limits from lack of information and technical knowledge. Both the quality of the plan (clarity of goals, policies, and regulation (Neuman 1998)) and the quality of the process (participation, community education, and support (Baer 1997; Laurian et al. 2004; Burby 2003)) are important, and the plan can provide a bottom-up, participatory approach. Mainstreaming, in contrast, encourages the technical uptake and integration of CCA into a range of municipal decision-making, which can address important infrastructure issues such as how high a bridge should be, or how large a water reservoir may be needed under changed climate. But mainstreaming is unlikely to build political support. Both mainstreaming and stealth may be efficient in getting movement quickly – for instance, in assembling data and undertaking basic changes to local strategies, guidelines, and, perhaps, regulations, without inflaming climate change debate. However, stealth is unlikely to be able to move CCA very far along given the need to gain political support for increased expenditure, when actions need implementing, or for the exercise of unpopular decisions, both of which depend on leadership- and community-endorsed policy (Rosenzweig et al. 2011; Brody and Highfield 2005).

A logical approach then could engage all three: beginning with overt CCA builds constituency, mainstreaming achieves integration, and stealth is an option if political change threatens policy commitment. If politics are an initial barrier, start with a stealth approach, seeking co-benefits policies first while laying political ground work for a comprehensive CCA planning process and mainstreaming into a range of policies. Further work is needed to know whether, in the case of climate adaptation, an explicit process, including community engagement, delivers better outcomes (in which case actions by stealth are best used as a last resort) and whether explicit climate adaptation strategies are more, or less, effective than those incorporated within other frameworks ("mainstreaming"), over the long term. Then, there are the questions of ethics and process, which are conveniently ignored here but must be part of the considerations when actually selecting actions.

Conclusions: Connecting the Dots Between Barriers and Approaches

CCA action in the communities studied is at too early a phase for strong conclusions. But some strategies for overcoming typical barriers nevertheless emerge.

Even without a strong legal framework, local governments have the potential to embed climate change considerations across all aspects of strategic planning and development assessment, as well as their wider operational, environmental management, and natural hazard activities, as outlined in this chapter. The strategies for low carbon development, which emphasize local and decentralized approaches to food, energy, water, waste, and transportation and preserving and enhancing biodiversity and natural processes, provide a blueprint for the wider sustainable community agenda, emphasizing resilience not only to future climate impacts but also to many of the other economic and social challenges likely to arise during the twenty-first century.

Adaptation, by improving resilience to extreme events as well as the increasing hardships of climate, provides local benefits. But getting that message across requires overcoming the typically short time frame of politics and budgets and considering instead a longer investment that matches investments and built form to the climate that is to come, rather than climates past. Some cities and towns have taken a leadership role and undergone adaptation planning without significant support from upper government levels. However, having state support through an existing state-level adaptation plan appears a far more reliable way to encourage local governments to make local adaptation plans.

Ultimately, this analysis of early generation local adaptation planning suggests that more sophisticated and detailed policy and practice innovation is needed to allow municipalities to translate climate vulnerabilities into a concrete response framework, particularly in relation to land-use planning. That adaptation actions are arising within the context of larger mitigation planning efforts suggests strong potential for synergistic solutions to be devised. Nevertheless, when new information about likely sea levels, flooding, and fire risks comes to light, difficult decisions regarding land-based adaptation measures will be needed, potentially including identifying new areas as no-build zones. This implies a need for specific planning tools – such as planned retreat and transferrable development rights (enabling historical development entitlement to shift to more appropriate locations) – to provide a basis for offsetting some of the inevitable costs to individuals associated with such decisions. Vulnerability analyses need to become more common to assure that the least resourced are not the most affected. There is also a danger that in failing to clearly connect mitigation and adaptation decisions in new generation plans, misalignment may seep into the ellipsis. But as more examples, technical/policy guidance, and nongovernmental support become available, in part building from the experiences of these early adopters, it appears reasonable to expect adaptation planning to spread, particularly with more explicit state and federal encouragement.

Overall, there is an urgent need to move beyond vulnerability analysis and into implementation of adaptation action. While "global" cities have been able to move forward, smaller cities are falling behind. Aid agencies have tended to prioritize rapid mainstreaming, while planners and policymakers want a comprehensive analysis of the adaptation situation. The frameworks presented here could encourage a more place-sensitive approach that matches barriers to approaches, encourages a more *realpolitik* awareness of the local challenges of adaptation implementation, and thereby assists smaller cities in making on-the-ground progress in implementation.

Designing an Adaptation Strategy in a Complex Socioecosystem: Case of Territorial Climate and Energy Plans in France

Stéphane La Branche

Contents

Abstract

Adaptation has become an obligatory part of larger Territorial Climate and Energy Plans, mandatory by law for all communities over 50,000 in France. This chapter first described these TCEPs and then analyzes the elaboration process of two different approaches for an adaptation strategy. The first one is incremental, sector specific in an urban setting, and tightly associated to urban planning in the city of Dijon. The other is holistic, multisectorial, and multi-issue, in a semi-urbanized area that includes agriculture, very high-tech production, valleys, and high mountain areas. We then offer an evaluation of both approaches, with respective strengths, weaknesses, and potentials.

Keywords

Adaptation policies • Strategy • Design • Formulation construction

---

The material from case studies comes from projects undertaken with Patricia Dubois and the Equineo team (www.equineo.com). I deeply thank her for her as-always pertinent comments.

> Limits of survival are set by climate, those long drifts of change which a generation may fail to notice. And it is the extremes of climate which set the pattern. Lonely finite humans may observe climatic provinces, fluctuations of annual weather and occasionally may observe such things as ‘this is a colder year than I’ve ever known’. Such things are sensible. But humans are seldom alerted to the shifting average through a great span of years. And it is precisely in this alerting that humans learn how to survive. . .They must learn climate. (Frank Herbert 1976: 350)

For the first time in human history, even since the first great human revolution, the Neolithic, and then the sedentarization of the human species, not only are we facing a truly global crisis due to climate change (CC) and its impacts, but more importantly, for the first time, we are *aware* of this crisis and are trying consciously to create planned solutions and apply them. This can be termed climate energy governance, or even meta-governance. But we have never attempted such an effort and thus have no real past experience to draw from. In the past few years, efforts at decreasing greenhouse gases – mitigation – have increased and improved in terms of efficiency and diversity. While much work remains to be done on mitigation measures, adaptation strategies to climate change are far from being as well understood and developed. Different countries have different methods, but to our knowledge, France remains unique in that adaptation is part of a legally binding territorial-level climate and energy package called Territorial Climate and Energy Territorial Plans (TCEPs).

Indeed, in 2012, the French central government imposed TCEPs on all communities or “community of communities” with over 50,000 people, attempting to implement national climate and energy governance measures at the territorial level, including both mitigation and adaptation measures. This followed several years of voluntary experimentations on the part of a few cities (Lyon, Grenoble, and Paris were leaders among them) starting in 2006 with Grenoble launching the country’s first territorial climate plan (a medium-size city of about 300,000 pop). Then, a national-wide multi-actor participatory procedure was conducted (the Grenelle de l’environnement), whose purpose was to design a national strategy related to energy, the environment, water, climate, and other related issues(?). The general conclusions of this multi-stakeholder process then led to a law project, linked to the Environmental Code. Several laws were indeed passed, but we focus on the now legally mandatory TCEP.

Three fundamental differences can be noted between the previous Plans and the new, binding, ones. First, previous ones were strictly voluntary. Efforts, experimentations, and measures were entirely left to the will of collectivities, with some state financial and expertise support. Second, these plans focused very strongly on the climate question and worked on the energy issue as a corollary of climate change. The new Plans put energy on the same level. And indeed, 2013 has seen a real turn with a strong focus on the energy dimension. Finally, the previously great ignored child of climate governance, adaptation, has become the third pillar of the new TCEPs.

One of the issues in this process is that the national-level efforts at designing a new national climate and energy governance remain on the level of a general strategy. Some actual exemplary measures and methods are proposed by the national administration, but these apply better to mitigation measures than to adaptation ones.

While mitigation policies are beginning to be well understood and tried, the "real," operational, adaptation policies still need to be designed and implemented, and even sometimes invented, at the territorial level. More than mitigation, adaptation is indeed a territorial-level, local, issue. As such, it is difficult to offer exemplary measures that would work on all territories. This explains in part why the national adaptation strategy guidelines and measures are so little consulted by local policy makers. They do not feel that these recommendations apply well to *their* territory and *their* local situation (both natural and socioeconomic and political).

The first part of this paper will quickly present some of the common points and differences between mitigation and adaptation policies in general. Then, we will analyze two case studies, focusing on adaptation: one city (Dijon) and a semi-urbanized rural and mountainous territory, the Gresivaudan Valley. Ambition and breadth vary but it is on the construction process of the adaptation strategy that we will focus on. Lessons for the operational dimensions of designing adaptation policy will then be drawn out.

One of the difficulties is that neither mitigation nor adaptation is sector specific: they are multi- and cross-sectorial. In addition, in France, TCEPs are supposed to give direction and a framework for other territorial planning documents: urban planning, mobility, housing, and other planning documents have to conform to TCEPs. This has direct consequences on agenda setting, institutional arrangement, and policy design, since traditionally separated sectors must now be harmonized toward general climate and energy goals. But adaptation presents additional challenges which I will expand on later.

Differences Between Mitigation and Adaptation for Policy Design

Mitigation aims at reducing GHG emitted on a territory and TCEPs give a clear numbered mitigation objective, the EU's 20 % reduction in GHG emissions, 20 % reduction in overall energy consumption, and 20 % renewable energy in the territorial energy structure, by 2020. Territorial policy design in the case of mitigation does not require anything really revolutionary. First, a carbon evaluation is undertaken – akin to the work and analyses preceding any type of policy. While the ADEME (a state energy and environmental agency) offers a method (which needs to be paid for), territorial collectivities may use any method deemed appropriate. The carbon analysis offers numbered data on emissions by sector, and thereby, a baseline from which to reach the 20/20/20 objective. In an urban setting, we find the same three main sources in France, but in different proportion, depending on the territory: transports, housing, and industry. In rural areas, of course, the agricultural sector takes more importance. There is no need to expand on mitigation measures here aside from a few precisions. In France (and this is akin to the rest of the world), mitigation measures are rather well known and well developed in the transport and housing sector (and by extension but to a lesser extent, urban management and land use) and do not represent much of an issue in terms of policy design. While the translation phase from policy formulation to implementation (e.g., the reduction of the share of car mobility and urban management – multifunctional polycentric, semi-dense urban development seems to be the general direction) still represents challenges (types of incitement, control, constraints, social acceptability, costs, training, etc.), the design phase of mitigation policies is "classical." Finally, while mitigation measures can be implemented immediately and be evaluated in the very short term (diminution of CO_2 emissions due to personal vehicles, number of buildings respecting energy consumption targets, etc.), adaptation requires a different approach. But before touching on this at the territorial level, it is important to remind why and how adaptation has been emerging in the last few years as an inescapable issue in climate governance.

Adaptation and Climate Change as Meta-risk

Climate change is now seen by the international scientific and institutional community as both the number one accelerator and amplifier of natural risks and the single most important obstacle to development efforts in the third world. In wealthy countries, it raises issues about the deep economic structure of our society and discussions about post-carbon or non-carbon-based production and consumption – or the green economy – emerging. In fact, the impacts of climate change and its origins linked to the very fundamental energy structure of our society mean that CC is slowly inserting themselves into every aspect of our societies. This also raises issues regarding the impacts of mitigation and adaptation efforts on other policies and on policy design itself. The underlying hypothesis that climate governance is *emerging* as a new type of *total* governance through four different means (La Branche 2013):

(i) It is inserting itself in the issue-specific or sector-specific governance (water, energy, security, housing, transports, research, development, public policies, health, economic development), as well as individual values and legal international, national, and local norms.
(ii) It tends to redefine these types of governance, *from above*, as an overarching framework.
(iii) It is also *diffusing through* sectors in a transversal (and multidisciplinary) manner.
(iv) It is emerging from below, from local actors, territorial communities, etc.

As such, climate and energy governance is emerging as a *meta*-governance that tends to restructure and redefine other forms and types of governance. In other words, it is increasingly offering a general framework and even a regime of truth in Foucault's sense (1980), in which policy design and implementation are taking place. Indeed, the challenge is total and global in the sense that it involves all human activities. In this sense, climate change is not only a phenomenon; it is an epiphenomenon (Olivier 2005), affecting the way we think and perceive the world as a globality.

Indeed, since 2006, climate and energy issues have been explicitly and increasingly integrated in different international programs and norms, such as the UN's Millennium Development Goals, water management and risks, insurance policies, construction norms, agriculture, local urbanism, etc. These are all slowly being redefined, reworked, reconceptualized, re-practiced, and even retaught in our teaching institutions with climate and energy objectives in mind. All these issues are both affected by the "objective" reality of CC and by the "subjective" efforts at dealing with it and managing it – i.e., governance. Our different field researches explore the impacts of efforts at climate governance on our institutions' structures, identities, strategies, policy formulation, and daily operations. This change does not occur without obstacles linked to a carbon-based path dependency (Pierson 2000) or to Young's arguments (2002a) regarding how an institution's structure and identity may prevent it from reaching its own environmental objectives.

Developing efficient and cogent adaptation strategies is thus framed by this emerging understanding of CC as a "meta-risk" (notion derived from Braithwaite and Williams 2001). My argument, derived from a social science framework of CC, puts forward that CC does not only amplify and modify existing risk, it also tends to modify our classical ways to manage and understand it. Not only does CC change the physical aspects of a risk, it also tends to redefine what is deemed to be a significant risk or not, "a risk that is worth trying to manage or not" because it may or may not increase vulnerability or decrease resilience. The objective of a climate adaptation strategy is not to adapt once the impact has taken place: it is to predict what the potential natural impacts might be in order then, to prepare for them before they happen, so as to reduce vulnerability and increase climate change resilience. But this depends greatly on social, organizational, cultural, and economic factors. Indeed, most recent studies on adaptation put forward the idea that the most important factors playing a role in resilience (the capacity of a society to adapt to change) are not natural but rather, those that play a role in a society's capacity at preparing for climate-induced changes.[1]

In the case of adaptation, policy building needs to take a new form because of adaptation's very nature. First, because climate as risk is redefining the perception of risk as such, from punctual and extreme events to recurrent, permanent pressure. Secondly, this is why the approach to adaptation policy design must change: it requires self-adjusting policies to constant yet uncertain change uncovered by science, territorialized observations. This needs to be combined with analyses at different and changing probability and uncertainty levels and thus varying (and uncertain) levels of success. These all meet at the intersection between vulnerability and more importantly, capacities. But how is this perceived and practiced at the local level by local administrations?

[1]At last, the international scientific community has recognized the importance of social issues: the fifth IPCC Assessment Report will specifically focus on the social dimensions of climate change for both mitigation and adaptation. Hence, the idea now largely recognized that climate change is only secondarily a hard science issue: it is far more a social science one.

Adaptation in French TCEPs

Adaptation became, in 2012, an obligatory sector of the new French TCEPs, but its application and the diffusion of this issue through different administrative levels differs from mitigation in several ways. First, adaptation has yet to enter most actors' awareness, aside from specialists. Its necessity is not perceived in large part because CC's impacts are not being felt nor experienced by actors living in developed countries. Second, adaptation is much less well scientifically understood. Indeed, projection and computer simulations of present and future impacts rarely go below a 100 km^2 area. Thus, the level of scientific and political uncertainty is much greater than with mitigation policies and makes both decision making and policy design more difficult. Third, adaptation is a far more complex issue than mitigation: understanding the natural impacts is only the first part of the process. Indeed, these impacts are not limited to the "objective," natural, biological, and morphological levels – whose frontiers do not often coincide with political-territorial boundaries but also require an understanding of the natural impacts' effects on human activities at the territorial level. Thus, natural sciences link to specific interests, administrative services, and economic activities come into contact with human activity and the social sciences. A third phase is thus required: evaluating a society's capacity at organizing itself to impacts, i.e., its resilience. Only then can we have a relatively good idea of a territory's vulnerability in the full sense of the word and only then can potentially cogent adaptation strategies be developed.

For political scientists, policy design extends to both the mechanisms through which policy goals are given effect, and to the goals themselves, since goal articulation involves considerations of *feasibility* (what is practical or possible to achieve in given circumstances given the means at hand). Adaptation thus represents a real challenge, far greater than mitigation in part because designing adaptation policies requires steps that include a high level of uncertainty and unknowns and thus lower potential of feasibility. How is one to about then? The following steps proposed here are "ideal" and rarely to be found in actual policy settings and framing, but they seem to be the goal to be attained:

(i) Identify what the *probable* increase in temperature might be at a *chosen* time frame (2030, 2050).
(ii) Identify the probability level of natural impacts (rainfall, heat, cold, avalanche, landslides, as well as impacts on living beings – plants and animals – such as reproduction cycles, migration, feeding areas, and growth rate).
(iii) Identify the impacts of these changes on human activities and population.
(iv) This is where resilience, both collective and individual, plays a key role: a younger population (aside from newborns) suffers less from a heat wave than an aging one; a ski-dependent local economy will be more vulnerable to a decline in snowfall, a semiarid-based agriculture will have to face even more arid conditions, etc. Generally, poorer, less educated populations are more vulnerable to climate change than wealthier, more educated ones.

Designing an adaptation strategy thus requires not only a relatively high level of natural scientific input but also an association with social sciences and economic territorialized analyses of what these impacts may mean in the future. But it also requires a different view of what the foundation for policy design and decision are: a backward management approach is necessary with, for example, a prediction for what these impacts might be in 2050 and then backtracking to what should be done in the short term in order to reduce the social and economic effects of future climate change. Adaptation is not a reaction; it is preparation to a specific, given, constraint based on as yet uncertain impacts in the future. The problem is that this constraint remains often uncertain. In order to reduce the high level of uncertainty of these impacts, a significant input of scientific expertise is often asked in the development of climate adaptation policy. But this expertise meets policy and institutional logics that may or may not favor its development (Young 2002a, b).

As an example, hydroelectric dams will be directly affected by variations in water quantity (either not enough or too much) as well as regularity. Indeed, in France, dams are in many regions used as equalizers of peaks in electricity demand, but they may start to fail filling this role if water is insufficient. As for water temperature, which has increased by a couple of degrees on average in most European countries in the last decade, it cannot go beyond 28° to cool nuclear power plants. Over this limit, a plant has to be shut down. In 2011, an energy crisis in France was very closely averted, when after over 2 months of high temperature and little rainfall, it finally started raining, avoiding the shutdown of a nuclear power plant. This raises the following very hard question: how is one to design a policy or a set of policies that can take these types of effects into account? Is a new approach to policy design necessary? The next section develops this section through two case studies: Dijon and the Gresivaudan. We will see that while the Gresivaudan offers a real example of our argument that adaptation necessitates a different model of designing policy, the Dijon case is more classical. This points to the importance of political decision framed by institutional constraints and experience. We then draw conclusions on the weaknesses and strengths of each.

Adaptation in the City of Dijon: Integration in Urban Planning

Dijon is a large city, with an extensive, mineralized historical center. Already vulnerable to urban heat island effects, the population suffered during the 2003 heat waves. Recent local studies show an important disparity in terms of heat vulnerability between the center (with little vegetation and parks) and the periphery. The city of Dijon launched its Climate Plan 2 years before the 2012 deadline. Dijon had been, several years before, well known for its environmental approaches in an urban setting but had lost this image in the last few years, surpassed by a few cities ambitious on climate and energy objectives. Dijon wanted to "catch up" and go beyond by implementing an ambitious climate plan, to coincide with a new tram network. Indeed, there is a strong multiparty political program called "Dijon ville écologiste" (Dijon, an ecological city) that aims at giving an ecological direction to all urban policies.

At the institutional level, the city's urbanism service is quite active and important in the political and budgetary landscape of the city's administration. It is also highly sensitive to ecological questions and, more specifically, to climate change issues. The work aimed at developing an adaptation strategy was headed by the urban ecology service, in coordination with the urbanism department. This department is closely linked to the city's urban developer agency which developed an ecodistrict standard (with several criteria taken into account such as water, energy, vegetation, energy standards, etc.). Urban projects had to follow these standards in order to be accepted by the city urban planning council. But the adaptation issue was largely unknown. More at issue, while there were individuals who knew about CC's potential impacts and adaptation, measures to address these impacts were not integrated in the services as practices or norms. To be noted: while the urbanism department was very present in the adaptation strategy development process, the elected official in charge of urbanism was not in charge of the TCEP. They did not share the same vision of urbanism nor of climate adaptation nor of its urban aspects. Indeed, economic arguments were more important to the first: What would be the impacts of costs of integrating adaptation measures in urban projects? What would be the benefits and for whom and when? Nevertheless, they agreed on the importance of developing an ecological urbanism.

Indeed, the city implemented an ambitious ecodistrict development policy, strong on energy efficiency – and mitigation – but weaker on other climate issues. Our task was to develop an adaptation framework and criteria for these new projects. Indeed, while planning and integration of mitigation measures in urban projects was well under way, adaptation appeared far more difficult, less well-known issue, filled with uncertainties in terms of likelihood of occurrence and impacts as well as time frame. In addition, an earlier multisectorial strategy had been proposed but had failed for several reasons, among which, it was judged to be too general, nonoperational, and not tied enough to its territorial setting and issues. While territorial data did exist on urban climate change vulnerability, those had not been translated into an operational approach. Thus, the decision was, first, to address urban adaptation issues. But the question was: Which ones?

The weakness of the previous approach, coupled with the political project (Dijon, an ecological city), and the desire to develop an operational adaptation strategy led to the adoption of a new approach: less ambitious, but more cautious and more gradual, and more sectorial, over a 3-year period, with two or three specific adaptation issues per year to be co-defined with elected officials and appropriate administrative services. In order to select the issues to be worked on, we first organized a series of multi-stakeholders' meetings (with semi-directive interviews, either individually or in small groups) in order to:

1. Understand administrative actors' level of knowledge of the adaptation issue in general.
2. Understand the level of knowledge of the adaptation issue on Dijon's territory specifically. This also allowed us to:

3. Identify key actors and resources that could produce or offer already produced knowledge and data. To be noted: the information produced was not always recognized by those who produced it as useful for adaptation, yet it was. Key actors were University of Bourgogne, Alterre Bourgogne – an ecological association – Météo France, the Regional authorities, and two national government regionalized bodies.
4. Identify potential issues to be developed in the first phase of the adaptation strategy.
5. Develop operational adaptation indicators and measures in urban projects.

But again, this raises the question: Which ones specifically? We then met again with these different actors in order to select the issues to be dealt with in priority. Several selection criteria were applied: political (the public image an issue would get, including the Dijon's ecological vision); a previous vulnerability study confirmed the risk of urban floods due to water overflow and very insufficient infrastructure; and the emergence of a new issue in the different discussions, and proposed by the project team – urban heat effects and measures to counteract it, including district and building conception approaches and vegetalization. This concurred with a previous study on CC's potential impacts on average rainfall and average urban temperature (associated with an aging population, also important to the actors involved). But even once identified, these issues can only remain nonoperational if a temperature increase scenario is not chosen.

Indeed, an increase of +2° would have only small effects, but climate studies' impacts on vegetation and rainfall and temperature show that an increase of +3° would, *probably*, have a *significant* impact. This raised a real debate among some of the actors: Why a +3° scenario rather than a +2°? National mitigation targets were defined (in 2010) according to a +2° scenario. And national climate change mitigation information campaigns were entirely based on a +2° scenario. The discussion mainly revolved around scientific arguments being thrown against institutional ones. Finally, the +3° scenario was *politically* chosen, the elected official in charge of the TCEPs using his decision power to resolve the issue, as he felt that the scientific arguments but also the precautionary (if one is ready for a +3°, then one is also ready for a +2°, but the opposite does not hold) one were valid.

The scenario chosen led to a few specific adaptation issues emerging, deemed to be both more important in terms of impacts and more likely to occur. Two of these could be associated closely under the same general theme – and associated to the importance of the urban setting: the fight against urban heat effects. Indeed, IPCC +3° projections show that before 2050, 2 years out of 3 would have the same mean temperature as the European 2003 heat waves (which killed 50,000 people), with the additional issue of an even older population by 2050. Two different approaches were co-defined in part because our benchmark of international studies showed that two main sources of the urban heat effect were bad spatial planning and lack of vegetation. In addition to this, another factor was interesting to the responsible elected officials: it would improve citizens' urban daily quality of life. In other words, improving spatial planning and increasing vegetation cover in an urban setting were no regret measures and were relatively certain to produce the effects expected.

A second benchmark of good urban adaptation and vegetalization practices in cities was undertaken. Results and evaluation of these measures for the Dijon contact were produced and diffused in different services and applied to a new urban construction project. A method by which these issues could be integrated in urban planning documents, in services' practices, and in the first phases of urban projects was also developed. Special attention was paid to the different phases of urban projects: measures to be integrated in the conception phase, those that could be integrated during construction, and finally, those that could be added to an already built project. For example, building orientation (north-south) and height need to be included in the conception phase (Is the aim to increase or to decrease exposure to the sun? Where can one integrate a pond for runoff water, which can also be used to increase cooling in the summer?), while planting specific species of trees (high and narrow or short but wide, and where? Is vegetalization on walls or rooftops possible?) can be done in the construction phase. Another issue emerged, strongly in this context: national historical building protection legislation narrows very much the scope of measures possible in the historical center and may even, in some cases, forbid vegetalization. This issue was still not entirely resolved at time of writing. While interesting, the final result falls outside the scope of this paper. More to the point, there are the lessons to be learned from the Dijon case for reflections on policy designs, and we develop those in the last section. It is now interesting to turn, as a counterpoint to the strategy developed in Dion, to the Gresivaudan case.

The Gresivaudan Case

The Gresivaudan is a semi-urban, complex geographic territory, with three main economic activities partly linked to its geographical diversity: the territory is made of a wide valley encased in high mountains. The third economic activity, in terms of economic revenue generated, is high mountain winter tourism – skiing and thus, highly dependent on snow fall. Low-altitude ski stations are already negatively affected by CC, with reactive "adaptive" actions such as artificial snow and attempts at diversifying activities toward summer tourism only being slowly put into place. The second economic activity lies in the valley, with the production of high-yield, very high-quality, low inputs, high revenue generating corn production for oil dedicated to high-tech processes. The first activity is nanomicrotechnologies, with the world's third most important research site, also in the valley.

CC impacts on these different sectors (as well as others, such as forest exploitation and pastoralism) and urban areas were thus highly complex and potentially key to wealth generation, employment, choice of housing, quality of life, and modes of living. It thus raised very sensitive issues for the majority of the population as well as for elected officials and heads of services. The adaptation strategy proposed was both experimental and ambitious: an integrated, holistic, multi-actors multi-issue adaptation comprehensive strategy. The method with which this strategy was designed was thus deeply different from the one used in Dijon. So were the results. Our choice of approach in assisting the territorial administration in designing its adaptation strategy was due to several factors, both natural and human.

The natural set of factors was the geomorphological diversity, with a valley between two mountain chains with different rock formation, one retaining water more than the other, with different vegetal species associated. These three geographical zones were linked to each other by a fourth, the mountain slopes flanking the valley on both sides, with different levels of access and economic activity, and peopled with sparse small villages, on the way to ski stations. The adaptation strategy development team and the administration were very keen on understanding the impacts of CC on these different natural (and human) zones, associated to different economic activities (especially winter sports on one mountain chain), corn production, and nanomicrotechnologies. Note as well that the valley is far more urbanized than the other zones and at risk of flood, due to a river running through it. Note that in this phase of the process, we use notions and terms that are very close to social geography.

The second set of factors was institutional. The Gresivaudan administration had decided to be ambitious and experimental in their adaptation approach but also insisted on being operational. They also possess a rather strong territorial identity that they wish to put forward. Thus, they felt that operational recommendations on our part had to be based on a clear understanding of their territory's specific issues and form. Territorial-based data needs to be accumulated, to which the team could only concur since adaptation is first and foremost a local issue that needs to be developed from that level. But the Gresivaudan administration was also more ambitious on another level: the development of a holistic adaptation strategy was to be the first step in the development of a permanent program that had to include the development of territorial multi-issue multi-stakeholder knowledge for CC adaptation, made possible by the permanent integration of scientists and studies in the adaptation process. Thus, knowledge development was seen as an essential part of a successful adaptation strategy. This is important: usually, public policy is seen as a closed process, where the implementation of a policy is seen as the last phase. Sometimes, an evaluation is undertaken but this is more the exception than the rule. Not in the Gresivaudan's case: evaluation and reformulation of issues, their importance, and impact evaluation are seen to be as a continuous process, to be adjusted according to new knowledge, real and predicted temperature increases. Thus, the administration saw its adaptation strategy not only as an end (be adapted to future climate change impacts) but also as a means, an experimental laboratory by which understanding of all phases of adaptation would be improved.

This was greatly helped by the fact that the elected official in charge of the emerging TCEP was a climatologist working for a national agency (Météo France). As a scientist, he was thus very well informed and up to date on climate issues (as well as aware of the uncertainties linked to adaptation). And, as an elected official, he was also "politically savvy" and sensitive to both internal political dynamics and to the population. He was also very insistent that the recommendations be understandable, operational, and *potentially* (he was also aware that one could not ask hard results from an adaptation strategy) effective for his territory. But faced with such a complexity, how were we to proceed? This is where a third set of factors needs to be taken into account: the role of science. Indeed, one may wish to develop scientific knowledge but there has to be the means to do this.

The Gresivaudan territory is located near Grenoble, a midsize university city, with a highly active scientific, and very diverse in terms of disciplines, community working on climate change. This represented a real opportunity: use this scientific community to gather information and data on the potential impacts of a +3° scenario on the territory. Rather than overlooking the uncertainty issue, and pretend to offer hard answers, we opted for the following approach: identify with these scientists through collective work what the impacts of a +3° scenario would be on that territory according to a 4-level scale: high, mid, low, and unknown probability. This was then coupled with a 4-scale potential severity of CC impacts on, first, the "natural" world.

Our diagnostic of the territorial vulnerability, through multipartenarial working sessions, included the following sectors, with a map that offered a visualization of the areas and their vulnerability:

- Water resources: impacts on water quality and availability
- Natural risk: floods, storm flashfloods, etc.
- Biodiversity
- Agricultural and forest activities
- Mountain tourism: especially snow levels for ski stations and CC's economic impacts
- Energy and economic activity energy production for dams and impacts on tertiary activities and industrial zones (including water management and runoff)
- Urban planning and buildings, including impact on behaviors and uses (i.e., air-conditioning in the summer and its impacts on energy demands)

Local nonscientific and nonadministrative actors were also involved, such as forest managers, owners and exploiters, industrialists, farmers, etc.

The second phase of working sessions aimed at building an integrated adaptation strategy, composed of different policy sectors. It included both scientific actors and institutional actors (forestry, agriculture, industries, urbanism, mobility, and others) working together on the probable effects these impacts could have on activities. The goal was to move from natural vulnerability to socioeconomic vulnerability of natural impacts, with two other, policy-oriented, goals in mind. First, we were able to define levels of priorities to the different issues in the short, middle, and long term. Then, discussions and policy-setting, policy-building, and actions were co-constructed between the adaptation team and the different heads of the territorial administration. This was also used to improve knowledge of administrative actors, so that they would start integrating the adaptation issue in their specific areas of competence and actions.

Conclusion: Lessons from Both Case Studies

Different lessons can be learned from these two case studies, in terms of internal and external factors in how adaptation policies were constructed. Note that while population density or urbanization levels played a role on specific actions and policies that are to be built, this did not play a role in *how* the strategies were built, and only a minor role on the issues chosen: organizational framework and local scientific resources were clearly more important.

In both cases, probable and high-impact territorial natural vulnerabilities were first identified, and then, "social" vulnerabilities were declined. In both cases, a collective (institutional) decision was made regarding which issue was to receive priority, based on the previous more scientific and technical assessments. In Dijon's urban setting, the urban heat island phenomenon and vegetalization were chosen, whereas in the Gresivaudan, an identification of all possible impacts was made, and then priorities defined. The urban heat effect was not a priority, in large part due to the fact that it is a semi-urban setting. But more significant differences, in terms of policy design, can be identified.

In Dijon, the adaptation strategy is being built piece by piece, two issues per year over several years, whereas in the Gresivaudan, the aim was to build in about 1 year an integrated, multisectorial adaptation strategy from the very first phase of the TCEP's construction. The aim to create a permanent scientific knowledge development was also decided from the onset. The differences between the two cases were due to several reasons. In Dijon, a previous "failure" in building the adaptation strategy had led to an attitude of precaution on the part of the administration, who wanted to avoid another failure, so close to the legislative 2012 December 31st deadline. But also, and perhaps more importantly, this failure ran against the city's political vision "Dijon, an ecological city." Dijon's step-by-step strategy offers clear advantages: each step is more likely to succeed in terms of integration by services and operational measures, since it requires less change at once and less human power. It also is less disrupting of everyday work habits, skills, and networks. It is also much easier to correct if need be.

Another factor was internal, in the administration itself, which offers a few reflections on Young's work regarding internal institutional obstacles (2002a, b). The different visions between Dijon's elected official in charge of the climate plan and the official in charge of urbanism meant that issues interesting to both had to be defined. The debates did not prevent the development of a strategy, on which both essentially agreed. In the Gresivaudan, the elected official was a climatologist who not only understood the scientific aspects of climate change but also the potential risks and social and economic and political impacts. He had an integrated and holistic conception and expected, explicitly and from the start, a corresponding adaptation strategy, which had to be *operational*, on which both cases agreed.

Another difference was the territorial scientific resource. As pointed out earlier, the Gresivaudan Valley is located near a Grenoble where, by a series of historical coincidence and scientific laboratories' strategies, research on climate change and its impacts has been developed for several years and in many disciplines, and this is important, *including in the social sciences*: technologies, urbanism, sociology, political science, natural and social geography, economics, etc. This is coupled with a high level of interest, knowledge, and policy development in the field of energy and climate change on the part of the territorial administration. Hence, it was relatively easy for the team to gather different resources to help identify the natural and social impacts, their probability of occurrence as well of probable level of severity. The social and institutional resilience aspects were explored through a social science and economics perspective.

Both methods for building an adaptation strategy have pros and cons. The Dijon strategy requires less effort during the initial phases and may well be easier to internalize and apply by services, as well as conditions in urban projects imposed on constructors or architects. Initial successes in specific sectors then help diffuse the approach to other services, even though this may take more time. In the second phase, the project is to take the previous year's work and integrate the recommendations in daily work routines and institutional texts, in the urban development services, by integrating new adaptation (urban heat effects and vegetalization, as well as the use of water) norms and methods in urban projects. The risk is that the strategy could remain sectorial and not be integrated transversally in the different structures and services. It could eventually lose in efficiency and, or even, face contradictions and tensions between services that could slow down or even block adaptation strategy's diffusion to other departments.

As for the Gresivaudan, it is too early yet to say whether its integrated holistic strategy will not be too complex and heavy to handle for a rather small administration. But if the transversal work is done, it fares a better chance at being efficient and cost effective in more areas at the same time. Its drawback is its potential (un) replicability to other territories. Indeed, not all elected officials (who give the political leadership and general direction and level of ambition of the TCEP) in charge are climatologists and thus understand as well the climate change issue and its link to impacts and social vulnerability. Nor do most territories have such a wealth of scientific expertise on adaptation at its disposal. Taken together, the opportunities for scientific input to the territorial agenda setting, policy objectives, and design were quite specific to the Gresivaudan. Perhaps, too specific for replicability?

Our adaptation strategy development approach was indeed developed so as to be replicable: evaluation of potential impacts on the natural milieu, then on the social one, and finally, evaluation of the territorial vulnerability and resilience. Efforts at improving resilience are an integral part of the Gresivaudan's strategy at developing scientific knowledge on a permanent basis.

A last point needs to be addressed here. Organizational framework and local scientific resources were identified as being clearly significant factors in the elaboration of the adaptation strategies. But one can wonder whether the natural factors did not also play a role, even if indirect. Dijon is a "typical" city with typical functions and services associated to urbanization. It is located in a homogeneous geomorphological (flat, with a few rivers) and climate milieu. But the Gresivaudan territory is made up of two different mountain chains and a valley, with different significant economic activities associated to each, to which we can add high-tech research and development, with different milieus, interconnected by population movements and activities, with related social and economic issues. It may be that these natural characteristics are more conducive to a multisectorial and holistic approach, i.e., a more complex socioeconomic system requires a more complex and holistic adaptation strategy. Further research, comparative as well, is necessary on this point. This also raises a more anthropological and ecopolitical theory question: How much does natural territory affects policy, its design, and its implementation?

Abstract

This chapter attempts to have an in-depth understanding of the climate change policy context of Bangladesh with regard to the notion of disaster vulnerability as a policy concern. The chapter reviews the policy from a social vulnerability perspective. With regard to the socioeconomic and environmental context of Bangladesh, it develops an analytical framework to examine the climate change policy. There is a lack of conceptualizing disaster vulnerability in policy formulation that makes it biased towards "physical adaptation" measures to reduce disaster risk. The political economy of climate change initiatives in Bangladesh leaves little scope to address vulnerability of grassroots communities. The chapter argues that in a country like Bangladesh where lack-of-development-led problems are persistent, there is an urgent need to develop context-responsive policies and action plans that should address the causes and dynamic processes of disaster vulnerability and lack-of-development issues in an integrated manner. Existing climate change policies do not address the structural dynamics of disaster vulnerability adequately. To this end, the chapter suggests policy-relevant insights towards the formulation of people-centered policies and strategies for Bangladesh.

Keywords

Climate change • Disaster • Vulnerability • Political economy • Policy

Introduction

Bangladesh is recognized worldwide as one of the countries most vulnerable to the impacts of climate change (WB 2012). This is due to its unique geographic location, dominance of floodplains, low elevation from the sea, high population density, high levels of poverty, and overwhelming dependence on nature (CCC 2007). Global warming has affected weather patterns and disrupted variability and trends in climate. This is resulting in an increase in climate-related extreme events like heavy rainfall, flood, cyclone, storm surge, etc. (Alam 2004; Alam and Murry 2005; Mahtab 1989). These extreme events claim thousands of lives, destroy assets and properties, and disrupt livelihoods of hundreds of millions of people. Because of sea level rise, coastal Bangladesh has already been experiencing the worst impacts especially in terms of coastal inundation and erosion, saline intrusion, deforestation, and loss of biodiversity (BCAS et al. 1996; BCAS and BUP 1994; BIDS 1994). More than 40 million people of Bangladesh still live in poverty. Many of these people live in remote or ecologically fragile parts of the country, such as river islands (*chars*) and cyclone-prone coastal belts, which are especially vulnerable to natural disasters. In the recently released Poverty Reduction Strategy Paper (2009–2011) and the Sixth Five-Year Plan (2011–2015) (GOB 2012), the government has reaffirmed its commitment to the Millennium Development Goals (MDGs) targets, including halving poverty and hunger by the year 2015, through a strategy of pro-poor growth and climate-resilient development.

Climate change will severely challenge the country's ability to achieve the high rates of economic growth needed to sustain these reductions in poverty. The government has recognized climate change as an important issue and attempts are being made to incorporate potential response measures for reducing impacts of climate change into overall development planning process. Many sectoral policies have recognized the issues of climate change and highlighted the importance of integration of environment and resource management for achieving sustainable development of the nation (Parvin and Johnson 2012; MOEF 1995; GOB 2003). However, until 2005 the government of Bangladesh did not have any climate change policy to address anticipated impacts of climate change. The National Adaptation Program of Action 2005 (NAPA) (MOEF 2005) is the first policy document in this line. In 2009, Bangladesh government has prepared the Bangladesh Climate Change Strategy and Action Plan (BCCSAP) (MOEF 2009). Both policy documents have recognized disaster threats and emphasized on the institutional and functional arrangements required to prepare responses to and recover from disaster events. However, the policies conceived disaster risk and vulnerability from a hazard-centric technocratic approach where the physical impacts of climate change are considered as indicators of disaster vulnerability with little or no consideration of the underlying structural systems, i.e., the social, economic, and political systems that make people vulnerable to natural hazards. The policy context is yet to conceptualize the notion of disaster vulnerability with regard to the structural factors and dynamic processes shaping it. This policy lag is reflected explicitly in the domination of physical intervention-biased adaptation and mitigation strategies outlined in the said documents.

Conceptualizing Disaster Vulnerability as a Policy Concern

An increasing number of devastating disaster events all over the world has caused disaster researchers to rethink the nature and causes of disaster vulnerability. Instead of regarding disaster as a purely physical occurrence, requiring largely technological solutions, as was widespread until the 1970s, scholars have attempted to unmask the naturalness of disasters since 1980s. The dominance of technical interventions focused on predicting hazards or modifying their impacts have been increasingly challenged by alternative approaches that examine disasters through the lens of vulnerability, primarily viewed as the result of human actions. This advancement in disaster studies can be understood in terms of two competing paradigms – the technocratic or hazard-centered paradigm and the constructivist or structural paradigm (Hilhorst 2004; Smith et al. 1999; Oliver-Smith 1996). The technocratic paradigm is dominated by behavioral approach, focused on geophysical processes to monitor and predict hazards, where social scientist is brought in to explain people's behavior to risk and disaster and to develop early warning mechanisms and disaster preparedness schemes (Oliver-Smith 1996). This hazard-centered approach was challenged by the researchers from social sciences and applied sciences arguing that disasters are not primarily the outcome of geographical processes but rather should be understood as the interaction between hazard and vulnerability (Hewitt 1983).

In the structural paradigm social vulnerability is the key to the understanding of disaster risk based on the premise that while hazards are natural, disasters are not (Cannon 1994). Structural forces, such as social, economic, and political processes, generate unequal exposure to risk making some people more vulnerable to disaster than others, and these inequalities are largely a function of the power relations operative in every society (Cannon 1994; Hilhorst and Bankoff 2004; Wisner et al. 2003). Thus, vulnerability is socially constructed and is the result of structural processes (Susman et al. 1983; Lewis 1999). For a particular community, vulnerability to disaster is shaped by the multidimensionality of disaster impacts by combining both the structural and environmental dimensions of disasters (Blaikie et al. 1994). Therefore, during climate change policy formulation, it needs to be understood in the context of social, political, and economic systems that operate on national and even international scales: it is these which decide how groups of people vary in relation to health, income, building safety, location of work and home, and so on (Wisner et al. 2003).

In the structural paradigm of disaster research, the root causes of disaster vulnerability are expressed in terms of various social, economic, political, and physical aspects. Blaikie et al. (1994) expressed the underlying factors shaping vulnerability in terms of ideological root causes, dynamic processes, and unsafe conditions into causal chains. In the "pressure and release model," the notion of vulnerability is explained in terms of social pressures and relations from a global to local level. At the global level different forms of relationship between society and nature, i.e., the social, political, and economic structures, are identified as the ideological root causes of disaster vulnerability. At an intermediate level, the dynamic processes include population growth, urban development and population pressure, environmental conditions, loss of ethics, etc., while at a local level the unsafe conditions include social fragility, potential harm to natural and built environments, poverty, etc. In this approach, disaster prevention and mitigation is conceived of as releasing the pressure of what is global over what is local and signifies intervention at each level (Wisner et al. 2003; Wisner 1993; Cannon 1994; Blaikie et al. 1994). Unsafe condition at local level is shaped by the baseline status (i.e., the basic needs such as income, food, health, education, and shelter) and degree of exposure of individuals to hazards. Irrespective of hazard circumstances, degree of individual's accessibility and reliance on resources determine the first layer of vulnerability, i.e., the baseline vulnerability. Disaster risk is generated as a result of the difficulties that some social groups or households have in accessing resources and facilities which are important to build capacity to face potential disaster (Sen 1981; Chambers 1989; Winchester 1992). Thus, baseline vulnerabilities change over time through changes in one's institutional and economic position, condition of shelter, food, and health, and these changes are affected by environmental changes (Adger and Kelly 1999).

Increased attention to environmental processes and human-induced climate change has marked the emergence of another paradigm – complexity paradigm in the 1990s that takes the constructivist paradigms of disaster a step further (Hilhorst 2004). This paradigm was based on systems theory related to the theories of complexity, chaos, cybernetics, and complex adaptive systems. In system approach, disaster vulnerability is shaped by the complex interaction among three major systems – (1) environmental systems, which include the physical dimensions of earth's hazardous events; (2) social systems, which include the structural and demographic characteristics of the communities that experience disasters; and (3) constructed systems, which include the components of man-made built environment (Mileti 1999). This approach offers a venue for understanding vulnerability and disaster in terms of multiple realities. Instead of capturing and controlling complexity, the challenge then becomes to acknowledge multiple realities shaped by culturally and politically informed selections and to embody the realization of complexity in developing institutional relations, mediations, and identities (Shackley et al. 1996). Regarding response to risk and disaster, Hilhorst (2004) interprets the complexity theory in terms of three main social domains – the domain of "science and disaster management," the domain of "disaster governance," and the domain of "local responses." They are the respective domains of scientists and managers, bureaucrats and politicians, and local producers and vulnerable people. Disaster responses come about through the interaction of science, governance, and local practices, and they are defined and defended in relation to one another (Hilhorst 2004).

The Analytical Framework for Policy Review

Despite the noteworthy advances in conceptualizing disasters, there is yet to develop a consistent and coherent theory of disaster vulnerability. This is mainly due to the inherent complexity and multiple realities of disaster impact and vulnerability. However, real-life disaster response requires a consistent and coherent conceptual framework to help formulate policies responsive to a given social, political, and environmental context. With an aim to understand the climate change policy context of Bangladesh, disaster vulnerability in this chapter is conceived as the societal condition of grassroots community created by the particular social systems and power relations in which the state apportions risk unevenly among its people and in which society places differing demands on the physical and natural environment. As suggested by Blaikie, Wisner, and Cannon (Wisner et al. 2003; Wisner 1993; Cannon 1994; Blaikie et al. 1994), this societal condition stretches along the three-tier vulnerability continuum from local to global level, where the condition is shaped by the dynamic interaction of ideological root causes at global level, dynamic processes at intermediate level, and unsafe condition at local level. Ensuring "safe conditions" at household level is fundamental to reduce local baseline vulnerability and enable the household to move onto the intermediate level of vulnerability continuum. The dynamic processes at intermediate level involve development needs such as basic infrastructure and services, population pressure, livelihood opportunity, natural resource base, environmental conditions, social capital, and so on. These processes are attributed to the structural forces interacting at global level – such as social deprivation, economic disparity, unequal distribution of wealth, global warming, power relations, and so on. Climate change policy should address these interacting dynamics as a strategic focus for adaptation through disaster risk reduction.

Underpinned by this notion of disaster vulnerability, this chapter attempts to examine the climate change policy context of Bangladesh in light of the analytical framework shown in Fig. 1. The framework comprises two major components to analyze climate change policy in Bangladesh. First is the climate change context; it examines the conceptual focus and contextual brief of the policy document.

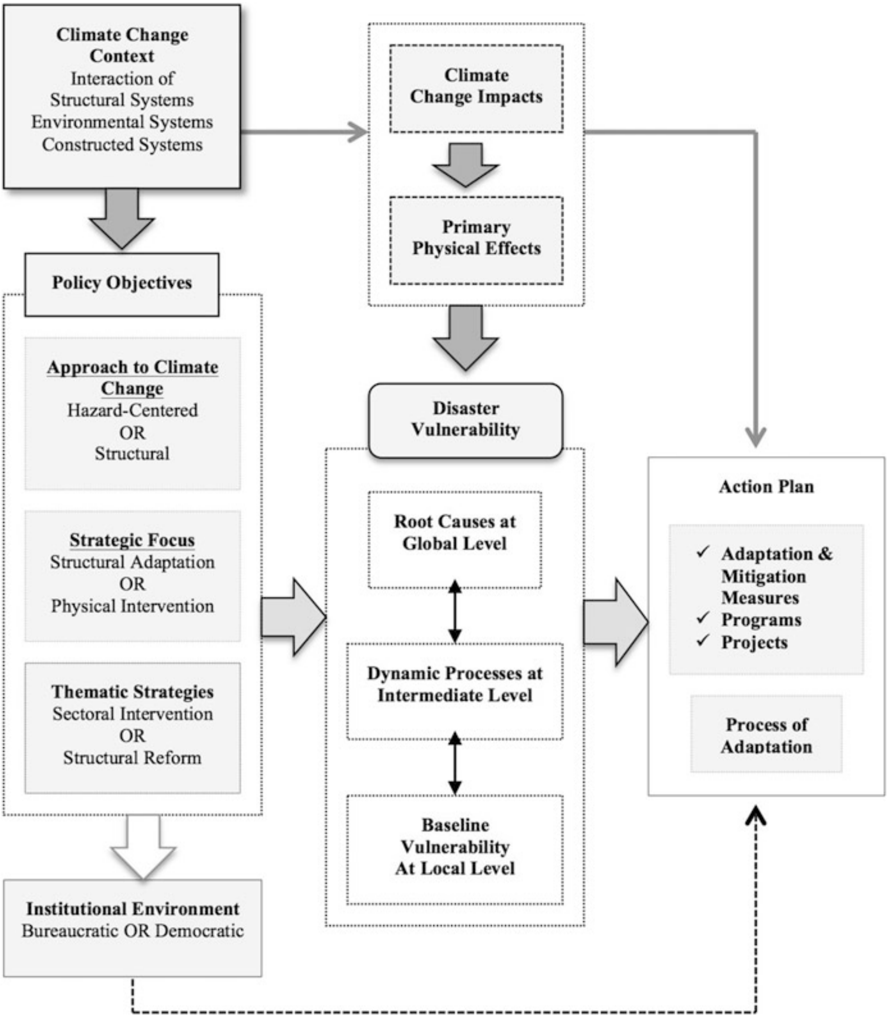

Fig. 1 Analytical framework to examine climate change policy

This includes evaluation of policy objectives, strategic focus, and institutional environment with regard to climate change impacts and vulnerability. Second is the action plan; it examines the thematic areas of action plan, adaptation and mitigation measures, and detailed programs and actions with regard to the strategic focus and objectives.

The Political Economy of Disaster Vulnerability and Climate Change

Since Bangladesh has got its sovereign identity in 1971, the rest of the world has known it mostly as a disaster-prone country with high level of poverty. Despite having very rich sociocultural background, natural resources, and geopolitical opportunities, this image and identity of being a "disaster-prone" and "poor" country have always been singled out and portrayed with much enthusiasm into the international arena by most of the policymakers and power elites of this country. Promulgating this image has been associated with a hazard-centered attitude to disaster vulnerability. This attitude has made profound impacts on the national policy initiatives and actions concerning the climate change issues. Over the last three decades, with the financial support from international donors and development partners, the government of Bangladesh has invested over $10 billion (at constant 2007 prices) to make the country "less vulnerable" to natural disasters. These investments in many cases included large-scale physical adaptation measures such as flood management schemes, coastal polders and embankments, cyclone and flood shelters, and the rising of roads and highways above flood levels (MOEF 2009). Owing to the disaster-prone image and hazard-centered attitude, the investment went mostly for physical intervention, while reducing the root causes of disaster vulnerability has largely been ignored.

Within the key policy documents of Bangladesh, climate change as a strategic focus was absent until 2005. Environment and sustainability, as the concerns for development, were first addressed in the Fourth Five-Year Plan (1990–1995) and received more emphasis in the Fifth Five-Year Plan 1997–2002 (GOB 1998). Chapter 10 of this plan, "Environment and Sustainable Development," recognizes the need for integration of environmental issues into development planning and activities and suggests a policy outline and brief strategies for sustainable environment management. The plan mentions "disaster management" in subsection 10.8 of this chapter and suggested five measures, mostly physical, to reduce "disaster impact" – (1) massive afforestation, (2) construction of appropriate housing and cyclone shelters in the coastal belt and raised earthen platforms in the flood-prone areas, (3) construction of strong embankments in the coasts and islands, (4) implementation of an effective early warning system, and (5) incentives and awareness creation at the grassroots level. The underlying factors other than natural hazards that make a group of people more vulnerable to disaster impacts were completely overlooked in this plan.

Climate change, as a main policy focus, was first incorporated in the National Adaptation Program of Action (NAPA) (MOEF 2005) in 2005. The policy suggested future coping mechanisms to reduce adverse effects of climate change, including variability and extreme events, and to promote sustainable development. It outlined 15 adaptation strategies that included several measures for sectoral intervention. It also outlined some facilitating measures such as capacity building, research, and dissemination of knowledge and information. The policy emphasized physical vulnerability to climate change and accordingly it suggested large-scale physical intervention projects. The conception of social vulnerability is literally absent throughout the document. NAPA had never been implemented; however, building on this document, the then government had prepared and adapted the Bangladesh Climate Change Strategy and Action Plan (BCCSAP) in 2008. BCCSAP was prepared as a response to the decision of the Seventh Session of the Conference of the Parties (COP7) of the United Nations Framework Convention on Climate Change (UNFCCC). The post-NAPA preparation of BCCSAP was one of rapid development in policy context targeting the then Copenhagen Summit. This quick revision of national policy suggests that earlier documents might have been prepared hastily to tap into the growing possibility of international funds in climate change adaptation (Nicola et al. 2011). It is also not unlikely that the possibility of harnessing international finance for adaptation might have been a reason to identifying costly physical interventions.

Building on the BCCSAP 2008, in 2009 the government of Bangladesh prepared the Climate Change Strategy and Action Plan 2009 (BCCSAP 2009) which is at present the most important climate change policy document in place. The BCCSAP 2009 mentions six key mitigation measures. Most of the adaptation and mitigation measures, however, are physical, immediate effects centered, short to medium term, and to be achieved through external intervention. The most recent policy document, Sixth Five-Year Plan (2011–2015) (GOB 2012), includes climate change issues as an integral part of development plan. Chapter 8 of this plan, "Environment, Climate Change, and Disaster Management for Sustained Development," suggests supporting communities and people in rural areas to strengthen their resilience and adaptive capacity as a high priority for the coming decades. However, the document outlined its target based on benchmarks identified against the six-pillar framework of BCCSAP 2009. As a whole, the policy context suggests a hazard-centered attitude to disaster vulnerability, which is reflected explicitly in the adaptation and mitigation strategies that focused more on "physical vulnerability" to hazard than on social vulnerability to disasters.

Alongside the image of a "disaster-prone" country coupled with the "hazard-centered" attitude to disaster vulnerability, a number of political economic factors make the pursuit of root causes of disaster vulnerability less attractive for the power elites and policymakers. Three main obstacles in this regard are characteristic to the institutional environment – (1) top-down development paradigm and technocratic bias to climate change, (2) hidden power struggles and lack of coordination in the institutional environment, and (3) lack of political will and vested interest of the stakeholders.

Top-Down Development Paradigm and Technocratic Bias to Climate Change

Historically the process of development has been dominated by bureaucrats and power elites, who are more concerned about the development work outlined in the national policy and programs at national level than the people-centered initiatives needed by people living in the disaster-prone areas like coastal belts, char island, and urban informal settlements (Taher 2003). The existing top-down development process and technocratic approach to climate change risk management leaves little scope for participation of the disaster-affected communities in the policymaking and implementation process. Even with the recognition of climate change adaptation and mitigation as integral parts of development process, the conventional attitude to development works undermines context-specific and community-based responses to climate change. The responses are therefore more about physical construction, pre-disaster warning system, and post-disaster relief and construction management, leaving little or no room for the active participation in terms of representation and ownership of the grassroots communities. Subsequently, the rigid policy institutional environment allows no mechanisms through which the vulnerable communities and households can influence national policy and development process.

Hidden Power Struggles and Lack of Coordination in the Institutional Environment

The institutional structure dealing with implementation and monitoring of climate change policies at the local level comprises three broad categories of organizations – public sector (e.g., administrative departments, elected local government bodies), private sector (e.g., NGOs, profit-oriented business concerns, donor agencies), and community-based social groups (e.g., *Shalish committee*, *Samiti*, school committee, branches of political parties, religious committee). The government sector has a three-tiered structure of elected local governance – *Zila Parishad*, *Upazila*, and *Union Parishad* (UP), at district, Thana or subdistrict, and village level, respectively. The public administration system generally follows a vertical pattern of authority where local bodies are linked vertically with its respective Ministry in Dhaka with a minimum delegation to the lower levels. Disaster management, adaptation, and mitigation initiatives are coordinated and monitored at district level and subdistrict level. The coordination mechanism at *Upazila* level is useful but only to a limited extent at the post-decision stage (Taher 2003). There is no room for the local level bodies to coordinate at the policymaking or planning stage.

Being without elected representative for a long time, only recently (in 2011) the senior district level leaders of the ruling political party have been appointed as the *Zila Parishad Proshashok* (District Administrator) with very limited power and authority. Among the three tiers of administration, *Upazila* is considered to be pivotal in the decision-making structure of the government having relatively better linkage and contacts with grassroots people through the *Union Parishads*. But in reality, the *Upazila* chairman, with no executive power, seems to exist with no natural upward link, and the UPs can barely relate to similar bodies of administration above. This situation has given rise to a very strange and inconsistent pattern of governance, which promotes a rather contorted system of hierarchy and lack of coordination (Taher 2003). Even though the *Upazila* chairmen are the responsible persons, in effect the Upazila Nirbahi Officer (UNO), if not the Member of Parliament (MP), exercises real power. In many instances, the MP's interference and influences of other political leaders in local level decision-making and resource allocations also contribute to the disparaging governing system (Siddiqui 2000). In the absence of a democratic structure, it is further aggravated by the rivalry of two groups of officers of the civil service cadres at district and subdistrict levels. The *Union Parishad* (UP) is currently the only local administrative tier closest to the grassroots communities. But despite having a legitimate mandate to "govern," the UP chairmen are unable to assert their authority because they have to almost fully rely on resources or block grants under the Annual Development Plan (ADP) sanctioned from the central government, which often comes late and is far too inadequate to address disaster vulnerability of the local communities (Verulam 2002). However, in some UP's where the chairman is in "good power relation," can wield more financial support and sanctions from above (not necessarily from the electorate), for his constituency. But sometimes success through this informal and rather partisan ways of dealings outside the institutionalized procedure often leads to financial corruption and jealousy and rivalry among the local administration (UZ), resulting in tacit noncooperation (Taher 2003).

Lack of Political Will and Vested Interest of the Stakeholders

Disaster-prone Bangladesh and sufferings of the affected communities bring financial gains, job opportunities, fame, and wealth for a large number of people from different strata of society from home and abroad. These people have their own interests gained through a wide variety of involvements in the process of climate change impact and adaptation. Processes of policymaking, program formulation, research, consultancy, preparation of action plan, international collaboration with donors and aid agencies, project implementation, and so on predominantly involve those who are not "disaster vulnerable." Therefore, for those with vested interest in climate change impacts, the question of whether the initiatives truly build resilient community by eliminating the underlying factors shaping disaster vulnerability or not is rather less important than continuing with whatever initiatives are there, at any cost. Given this national and international network of vested interest surrounding climate change issues, it is difficult to make any paradigm shift in the possessive and defensive mind-set of the concerned policymakers, power elites, and other stakeholders about what makes people vulnerable to natural hazards. Rather the existing hazard-centered mind-set gives them indemnity of the denial of their social responsibility to the grassroots people who are the victims of the unequal social system and power relations. Given this lack of political will, it is hard to challenge the structure of interests in favor of reducing vulnerability of the poor. The interests that must be influenced in order to reduce disaster vulnerability are the powerful elites and political parties with wealth and power over issues such as decentralization of power and bottom-up democratic governance. Only those with high levels of commitment – and power themselves – could consider such a risky venture.

The Bangladesh Climate Change Strategy and Action Plan 2009: A Critical Review

Bangladesh Climate Change Strategy and Action Plan 2009 (MOEF 2009) is the most recent and important climate change policy. It is in fact a revised version of the BCCSAP 2008 and has been prepared by the current government as a part of the overall development strategy of the country. Climate change constraints and opportunities are being integrated into the overall plan and programs involving all the sectors and processes for economic and social development. The policy is divided into two parts, comprised of six sections and an annex. In five sections part one includes the context, outlines the implications and likely impacts of climate change, and provides an overview of different adaptation strategies and mitigation measures. It outlines six pillars or broad areas of strategic intervention. Part two is comprised of section six and an annex provides the strategy with a 10-year action plan based on six pillars. A set of 44 programs under the action plan is outlined in the annex.

Conceptual Focus: Disaster Vulnerability in BCCSAP 2009

Understanding the notion of disaster vulnerability as a conceptual basis is crucial for climate change policy formulation. The strategy has a hazard-centered conceptual focus and deals with climate change issues from a centralized technocratic approach. Lack of conceptualization of the meaning and causation of disaster vulnerability is evident in different components of the policy statements. For example, in the introduction, it states – "Given the specific nature, however, of the problem of climate change particularly those related to future bio-physical and natural processes which are yet uncertain and the intimate link of the relevant national actions with international negotiations for emission control as well as their financing and technological support by and from the developed countries, for continuous monitoring of processes and events (natural, scientific, and negotiations) the Action Plan needs to be coordinated by a body such as a Climate Change Unit specifically created for the purpose by the ministry of Environment and Forests" (MOEF 2009, p. 3). The statement reveals that the policy conceives climate change primarily as a biophysical and natural problem, subject to technological solutions.

There is no definition of disaster vulnerability, neither any explanation of the underlying factors, causes, or dynamic processes that shape vulnerability throughout the document. It mentions the term vulnerability at several sections merely as a general word that refers to its literal meanings such as susceptibility, weakness, defenselessness, helplessness, exposure, etc. Table 1 shows specific examples of indiscriminate use of the term vulnerability throughout the document.

Table 1 Use of the term vulnerability in BCCSAP 2009

Sections and page no.	Use of the term vulnerability	Varied terminology
Message, p-xi	We are most *vulnerable* to climate change, and consequently adaptation is our priority	Vulnerable
Preface, p-xv	Poverty eradication and increased well-being of all *vulnerable groups* in the society with special emphasis on gender sensitivity	Vulnerable groups
Summery, p-xvii	Bangladesh is one of the most *climate vulnerable countries* in the world and will become even more so as a result of climate change	Climate vulnerable countries
Summery, p-xvii	Pillar one – food security, social protection, and health: food security, social protection, and health to ensure that the *poorest and the most vulnerable* in society, including women and children, are protected from climate change and that all programs focus on the needs of these groups for food security, safe housing, employment, and access to basic services, including health	The poorest and the most vulnerable in society, including women and children
Summery, p-xviii	Pillar six – capacity building and institutional strengthening: the needs of the *poor and vulnerable*, including women and children, will be prioritized in all activities implemented under the action plan	Poor and vulnerable
Context, p-2	The challenges now facing the country are to scale up its preparedness and resilience and protect the lives and livelihoods of the people, especially the poorest and the most *vulnerable families*, including women and children	Vulnerable families
Climate hazards in Bangladesh, p-8	Flood: during severe floods it is *the poorest and most vulnerable* suffer most because their houses are often in more exposed locations	The poorest and most vulnerable
Adapting to climate change, p-18	High incidence of poverty and heavy reliance of poor people on agriculture and natural resources increase their *vulnerability* to climate change	Vulnerability to climate change

Climate Change Context in BCCSAP 2009

The background discussion on the core socioeconomic reality provided in the document sheds light on the need for accelerated development through poverty eradication. The strategy is underpinned by the conception that accelerated development is the most effective way to eradicate poverty and build resilience to climate change. It conceives the poverty issue from a traditional economic development perspective and considers poverty as a development problem of a particular socioeconomic group of people living in a particular area (disaster prone). Core issues, such as what makes some people poorer while others richer?, is poverty the result of development or lack of development?, what are the causes of poverty?, and are the poverty issues local or global?, are addressed inadequately in the background section of the strategy. Addressing these issues is important to understand how natural hazards turn into disasters for a particular group of people and what makes some people vulnerable to disaster, others not, within the given socioeconomic and political systems.

Thus, the document lacks focus on the structural dynamics and political economy of poverty and development in the context of Bangladesh. The strategy outlines the climatic context in terms of “climate hazards in Bangladesh” and “impacts of climate change.” It summarizes the context as “Likely impacts of global warming on Bangladesh and required investment” in Box 8 (MOEF 2009, p. 26). The policy highlights climate change issues in terms of “global warming,” “immediate impact,” “result,” and “investment needed” (MOEF 2009, p. 26). It suggests adaptation and mitigation measures in terms of “investment needed” and refers to the goal in terms of “social protection for the vulnerable/community-based adaptation” (Table 2). The strategy looks into the climate change impacts and effects from a hazard-centered approach, which emphasizes the geophysical impacts and consequent physical effects, damages, and loss of assets and property caused by natural environmental phenomena and hazards. It does not mention anything about how, when, and why natural hazards turn into disasters for a particular group of people. It does not address the structural factors, i.e., the social, economic, and political aspects of vulnerability. As shown in Table 2, this hazard-centric approach is explicitly reflected in the suggested adaptation and mitigation measures which are mostly top-down and technocratic intervention by nature. However, the strategy mentioned about “social protection for the vulnerable,” but it does not provide any definition or elaboration of attributes of social protection or vulnerability.

Policy Objectives and Strategic Focus

Adaptation to climate change is the major strategic focus of BCCSAP 2009. The thrust of the strategy is on sustainable development, poverty eradication, and increased well-being of all vulnerable groups in society with special emphasis on gender sensitivity. Drawing on the principles of sustainable development, the strategy suggested activities in all four building blocks of the Bali Action Plan – adaptation, mitigation, technology transfer, and adequate and timely flow of

Table 2 Climate change impacts, effects, and suggested interventions in BCCSAP 2009

Climate change context	Resultant impacts	Primary physical effects	Key adaptation and mitigation measures
Cyclones with increased frequency and severity	Higher storm surges	Damage to natural and built environment	Cyclone shelters
Heavier more erratic rainfall in the monsoon seasons	Higher wind speed	Damage to agriculture (crop, livestock, and fisheries)	Forestation
Lower more erratic rainfall in dry seasons	Higher river flow	Scarcity of water and shortage of safe drinking water	Polders
Melting of Himalayan glaciers	Riverbank erosion	Displacement of people	Embankments
Sea level rise	Increased sedimentation in riverbeds	Threat to food security and livelihoods and health	Raised roads and railways
Warmer and more humid weather	Increasing drought and scarcity of drinking water	Over-topping and breaching of embankments	Water management
	Higher river flows in warmer months then reduced flows and increased saline intrusion	Widespread flooding	Flood proofing
	Submergence of low lying coastal areas	Loss of homes and agricultural land into the river	Improved crops and cropping system
	Saline water intrusion into rivers and into groundwater aquifers	Drainage congestion	Possible industrial relocation
	Increased prevalence of disease and disease vectors	Water logging	Early warning system
		Loss of fertility of agricultural land	Health, education, and awareness building
		Displacement of settlements	Communications

Source: Extracted from MOEF (2009, pp. 14, 18, 26)

funds. The main objectives of the strategy are (1) to increase the country's resilience to climate change, (2) to reduce and/or eliminate the risks climate change poses to national development, and (3) to rapidly develop the country following a low-carbon growth path. In general, the strategic focus is broadly pro-poor and responsive to the notion disaster vulnerability. In a consistent manner, the first and second objectives are about resilience and risk reduction with strategic potentially of being a people-centered policy. However, as the strategic focus and objectives are translated into the action plan in terms of mitigation measures and detailed programs, it confirms the hazard-centered and physical intervention-oriented adaptation strategy of the policy as discussed in the next sections.

The Action Plan

The strategy outlines an action plan based on six thematic strategic focus or six pillars: (1) food security and social protection, (2) comprehensive disaster management, (3) infrastructure, (4) research and knowledge management, (5) low-carbon development, and (6) capacity building and institutional strengthening. The action plan provides a 10-year program to build the capacity and resilience of the country to meet the challenge of climate change over the next 20–25 years. The BCCSAP 2009 mentions six key mitigation measures: (a) cyclone shelter, (b) embankments, (c) afforestation, (d) early warning systems, (e) awareness building, and (f) communications. There are 44 programs outlined under six pillars that include the first set of activities which are to be undertaken for adaptation in line with the needs of the communities and the overall development program of Bangladesh.

Owing to the technocratic approach to climate change issues, except the first and the sixth pillars, all the other four pillars reveal top-down macroscale strategies. The thematic strategies hardly outline any bottom-up and people-centered strategic words. The strategies are devoid of significance of the age-old local knowledge and coping strategies and social capacity of the grassroots households or community (Fig. 2).

Most of the adaptation and mitigation measures are physical, immediate effect-centered, short to medium term, and to be achieved through external intervention rather than community-based actions (Table 2). The programs (P) detailed under the six thematic strategies (T) reflect the technocratic nature of the action plan. Except few exceptions, in general, the programs are prescriptive, top-down, and meant more for the government, private, NGOs, and other stakeholders, less for the grassroots community people. The community people are treated as passive actors and left at the receiving end of the program, while other stakeholders are treated as the active players in preparation, implementation, and monitoring of the action plan. Table 3 reveals examples of some programs and actions detailed under the action plan. Comments are included against the programs in support of this argument.

Institutional Environment

It is argued in BCCSAP 2009 that the strategy and action plan were developed through a participatory process involving relevant ministries and agencies, civil society, research organizations, the academia, and business community. However, since the preparation, consultation, and formulation of the strategy, there was no

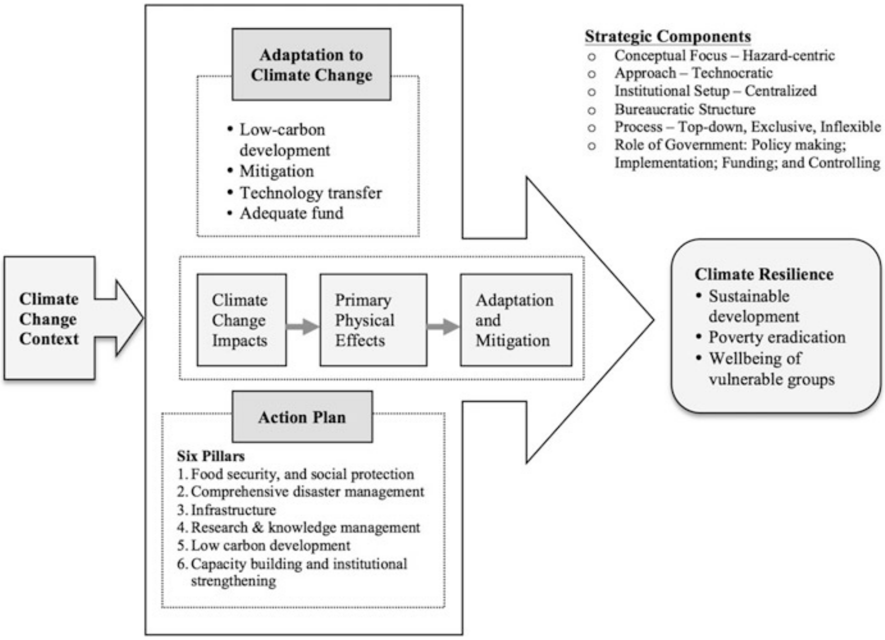

Fig. 2 Strategic framework of BCCSAP 2009 (Source: Diagrammatic interpretation by the authors based on the first five sections of MOEF 2009)

real participation of the grassroots community. The consultations were limited to experts, government officials, selected local government representatives, NGOs, and other stakeholders that hardly allowed for grassroots community participation; reflections of their voice; alternative proposals and strategies for adaptation; or community-based policy preparation.

The institutional setup of the strategy suggests that the action plan will be implemented under the guidance of the National Environment Committee, chaired by the prime minister, and will be coordinated by the Minister of Ministry of Environment and Forests (Fig. 3). The institutional setup reveals a top-down, centralized, rigid environment dominated by the ministers and government officials. It does not elaborate how the high-profile national committees, particularly the "climate change focal point" at different ministries, will delegate administrative power and coordinate with the local government. The policy does not mention any reform for the existing institutional environment, which is not very efficient in dealing with climate change adaptation and mitigation initiatives. Regarding the local level governance, it does not suggest any effective institutional mechanisms for horizontal coordination to deal with inter-sectoral issues across different sectors. This is particularly important for the management of inter-sectoral policy and action plans. There exists an environmental committee at divisional level chaired by the commissioner with representation from different government agencies at division level. However, the committees for the most part are nonfunctional and no

Table 3 Examples of programs designed in a top-down approach

ID	Thematic strategy	Program	Example of action	Authors' comments
T1P7	Food security, social protection, and health	Water and sanitation program for climate vulnerable areas	Investment for additional water supply, adopt deep-set groundwater technology	Community and household-based rainwater harvesting is an important local adaptation strategy already in place which needs to be explored
T3P1	Infrastructure	Repair and maintenance of existing flood embankments	Continuing flood protection by embankments	Should rethink continuing construction of embankments and polders for flood control, as it is detrimental for the natural environmental system. Coastal polders are historic strategic mistake done by the then decision makers in the 1950s, which was a technocratic military solution hostile to the natural environmental system. These types of engineering solutions in coastal belts have already altered the natural deltaic land-water system of coast, resulting in higher riverbed and water logging in lower inland. Should consider alternative land use and spatial planning, and planned resettlement
T3P3	Infrastructure	Repair and maintenance of existing coastal polders	Repair and construct polders based on higher sea level and storm surge	
T3P6	Infrastructure	Adaptation against future cyclones and storm surge	Construct new polders, cyclone shelters	
T4P1	Research and knowledge management	Establishment of center for research, knowledge management, and training on climate change	To increase institutional and human capacity of concerned professionals, government officials	Does not include capacity building of local community, households, and community-based organizations

(*continued*)

Table 3 (continued)

ID	Thematic strategy	Program	Example of action	Authors' comments
T4P4	Research and knowledge management	Monitoring of ecosystem and biodiversity changes and their impacts	Set up monitoring system, report, and recommend adaptation measures	Does not include research and monitoring of cultural and behavioral changes and their impacts on the social systems, which are crucial for building resilient community
T6P3	Capacity building and institutional strengthening	Strengthening human resource capacity	Enhance capacity of key staff of government, private sector organizations, ad NGOs for accessing international and national carbon and climate change funds	Does not include enhancement of local institutions, people, and community-based organization's capacity

Source: Extracted from the Annex of BCCSAP (2009), MOEF (2009, pp. 39–73)

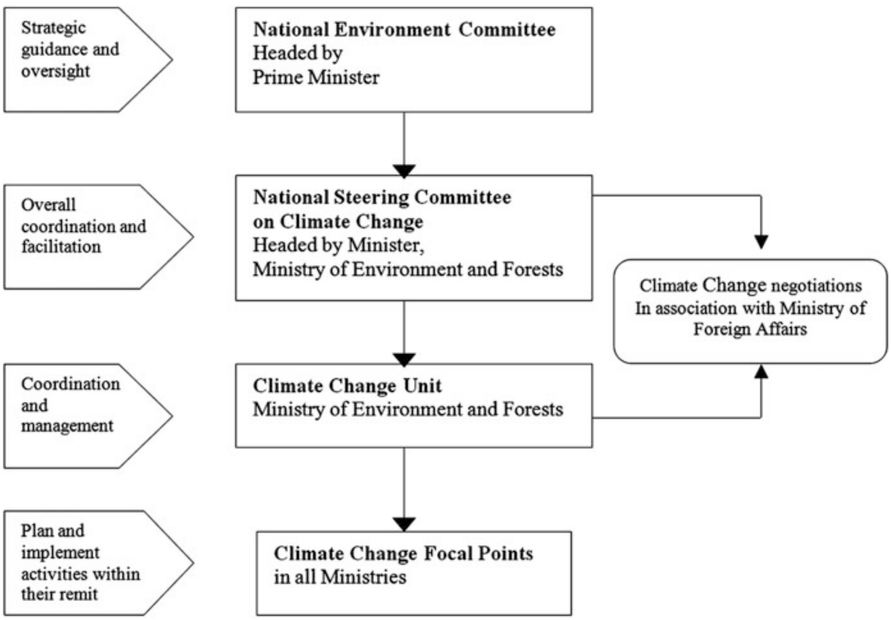

Fig. 3 Institutional setup of climate change action plan (Source: MOEF 2009, p. 30)

such committees exist at lower administrative levels. The suggested institutional setup thus is the reiteration of the existing nondemocratic and bureaucratic governance system. Therefore, risk remains that the same political economy might hinder successful implementation of the policy.

Integrating Disaster Vulnerability in Policy Context: A Conceptual Framework

Climate change is not only an environmental concern but also a development concern for Bangladesh (Parvin and Mostafa 2012). This means that climate change as an issue must come out of the environmental problem to take a center stage as a major development problem created by the unjust structural systems. This requires a paradigm shift in the policy context that would support structural reform with the strategic vision to eradicate social vulnerability of people. However, this type of fundamental shift in policy meets serious resistance from the power elites, policymakers and bureaucrats, and numerous beneficiaries of the prevailing systems. Nonetheless, that resistance is not stronger than the threats of climate change which must have to be addressed not by individual power and wealth but by communal spirit and capacity. With this hypothesis, the study suggests an alternative conceptual framework for the integration of social vulnerability approach in the climate change policy context of Bangladesh (Fig. 4).

Outline of the Conceptual Framework

- *Policy Context*

  The policy should understand the climate change context not merely from a hazard-centered perspective but as a result of dynamic interrelationship among the social, economic, and environmental systems.
- *Policy Objectives*

  The policy objectives should focus more on pro-poor community-driven climate-resilient development targets in place of traditional economic growth-laden development.
- *Approach to Climate Change*

  Climate change issues should be conceived from a people-centered participatory approach instead of technocratic approach.
- *Conceptual Focus*

  The policy environment should be underpinned by the conceptualization of the notion of climate change impacts and adaptation from structural perspective instead of hazard-centered perspective.
- *Strategic Focus*

  The strategic focus should be on “climate change adaptation through eradication of social vulnerability and reduction of structural inequality that results in disaster risks.”

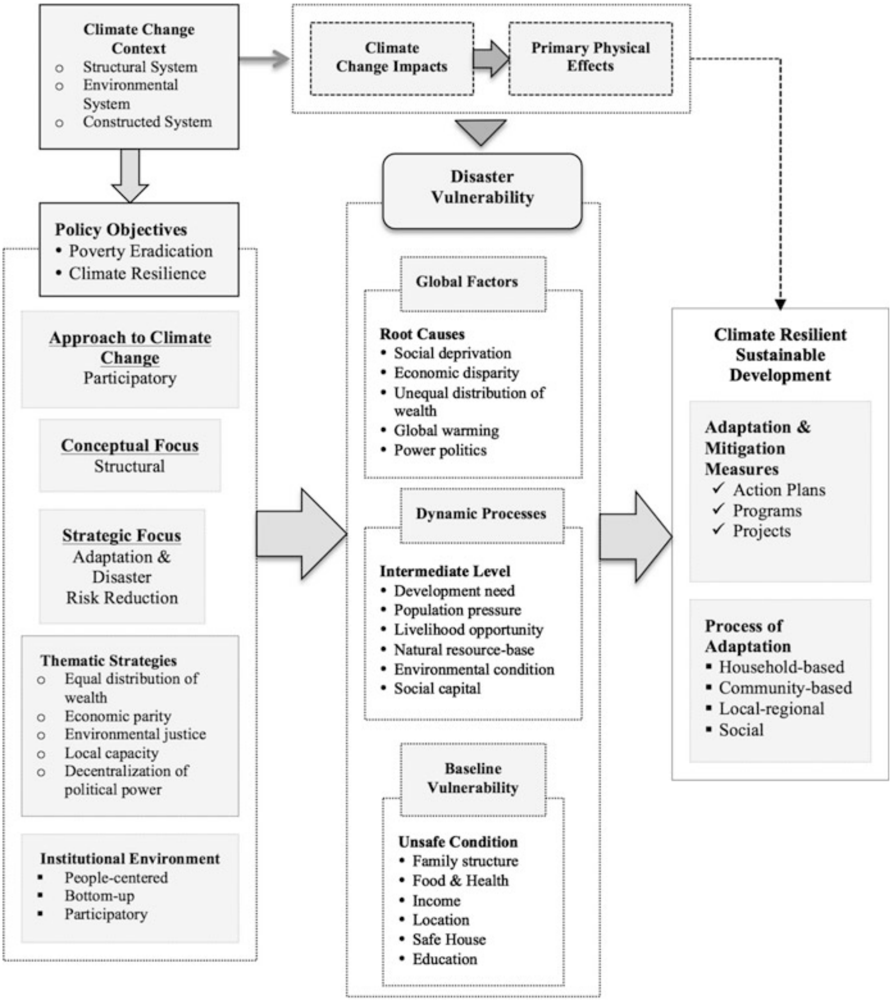

Fig. 4 Conceptual framework for the integration of social vulnerability approach in the climate change policy context of Bangladesh

- *Thematic Strategies*

  The policy should be based on following seven thematic strategies as seven pillars of climate change adaptation plan:

  1. Social-ecological justice – strategies to eradicate the root causes of vulnerability through necessary reform in the social systems such as equal access to assets, infrastructure, and ecological services; re-distribution of safer land; and ensuring food, health, education, and income security
  2. Economic parity – strategies to ensure equal distribution of wealth, diversified livelihood opportunities, and equal access to productive sectoral resources

3. Environmental justice – strategies to ensure environmental protection and biodiversity, prevention of environmental degradation, mitigation of global warming, and environmentally friendly development
4. Local capacity – strategies to research and build on the indigenous knowledge and local adaptation practices and strengthening community capacity learning from their inherent strengths of living with disasters
5. Planned resettlement – strategies to support gradual migration of people living in disaster-prone areas, planned evacuation of settlements from ecologically fragile areas, and long-term guided development of potential destinations (at national, regional, and international level) for the climate-induced migrants
6. Decentralization of political and institutional power – strategies for the development of local government institutions with the objectives of "devolution" and "deconcentration" of decision-making power and creating a community-based enabling institutional environment
7. Comprehensive climate change management – strategies for short-, medium-, and long-term management of climate change impacts; hazard-research, knowledge, and information management; and ensuring sufficient fund raising and management

- *Institutional Environment*

  The institutional structure should be people centered, democratic, and participatory. The governance should be by the people, of the people, and for the people. In place of vertical top-down administration, there should be horizontal, community-based, bottom-up administration where the government's role should be of coordinator, facilitator, and fund provider.

Conclusion

In the backdrop of a social system characterized by a high level of inequality, poverty, and deprivation, climate change is only one aspect of the social vulnerability of grassroots people in Bangladesh. Impacts of climate change therefore adversely affect the capability of the poor and disadvantaged to reduce their vulnerabilities. This implies that any responses to reduce disaster risks should start off with a clear recognition of social vulnerability at every stage of adaptation process. Bangladesh government is fully committed to manage climate change with a vision to eradicate poverty and achieve economic and social well-being for all the people. This will be achieved through a pro-poor climate change strategy, which prioritizes adaptation and disaster risk reduction and also addresses low-carbon development, mitigation, technology transfer, and the mobilization and international provision of adequate finance (MOEF 2009). Notwithstanding the resource constraints, Bangladesh has already developed state-of-the-art warning system and has taken the lead among the LDCs in climate change response in terms of policy initiatives, research, program design, and implementation of adaptation strategies, and this work is continuing. However, Bangladesh is yet to develop context-responsive comprehensive policies that will guide climate change adaptation as an indispensible part of development process in an integrated manner. The critical review of the policy context reveals that existing climate change policies lack in conceptualization of disaster vulnerability as a social phenomenon and, therefore, do not address the structural dynamics of disaster vulnerability adequately. In a country like Bangladesh, where lack-of-development led problems are persistent, there is an urgent need to reform the unequal structural systems through a paradigm shift in the policy context. Climate change impacts in this regard offer an opportunity to formulate policies and adaptation strategies in such a manner that would enable the country to develop resilience not only to climate change but also to poverty and social inequality.

Abstract

Climate change has imposed an extra burden on the social and economic challenges faced by Sri Lanka, due to increasing vulnerability of a majority of its people whose livelihoods are dependent on climate-sensitive natural resources, mainly dealing with agriculture. The National Agriculture Policy (NAP) of 2007, National Livestock Development Policy (NLDP) of 2007, and National Fisheries and Aquatic Resources Policy (NFARP) of 2006 are the key policies that govern Sri Lanka’s crops, livestock (including poultry), and fisheries sectors, respectively, under variable and changing climatic conditions. Sri Lanka has taken measures to adapt to climatic risks in these sectors at various levels. The establishment of Climate Change Secretariat of Sri Lanka is a significant step towards integrating and mainstreaming climate change adaptation activities to the development planning of the country. Sri Lanka, being a party to the United Nations Framework Convention on Climate Change (UNFCCC) since 1994, has made considerable attempts in its policy framework and strategic approaches to address the impacts of climate change in crops, livestock, and fisheries sectors, which are directly related to food production. Adaptation to climate change in these three key sectors of Sri Lankan economy is supported by the National Environmental Policy (NEP) of 2003, National Climate Change Policy (NCCP) of 2012, and National Climate Change Adaptation Strategy (NCCAS) 2011–2016. As discussed in detail in this chapter, Sri Lanka has an enabling policy environment in supporting the adaptive strategies and building resilience to climate change. However, given the inherent complexity in adaptation to climate change, the country is facing a challenging situation especially due to the intricacy brought by the institutional coordinating mechanism in the three sectors. A significant level of capacity constraints exists in the sectoral institutes in meeting their mandates to implement policies and strategies related to climate change in Sri Lanka.

Keywords
National policies • Agriculture • Crops • Livestock • Fisheries • Adaptation • Sri Lanka

Introduction

Sri Lanka is located about 80 km southeast to the Indian subcontinent, lying between 5° 55′ and 9° 50′ north latitudes and between 79° 42′ and 81° 53′ east longitudes. The country comprises of a main island and several small islands off the northern end. The mainland has a maximum length of 435 km in the north–south direction and a maximum width of 240 km in the east–west direction. It covers a total area of 65,625 km^2, including 2,900 km^2 of inland water bodies. The island consists of a mountainous area in the south-central part and a vast surrounding coastal plain. The population is estimated to be 20.3 million (Central Bank 2013), and the highest projected population (23.3 million) would be in the year 2046 (Ministry of Environment and Natural Resources 2011). There are 103 natural river basins in Sri Lanka, with a total length of about 4,500 km. In addition, there are a significant number of reservoirs including ancient irrigation tanks and recently constructed multipurpose reservoirs with a total area of 169,941 ha (Ministry of Environment and Natural Resources 2009). Sri Lanka can be divided into 46 agroecological regions based on the amount of monthly rainfall and its distribution, soil type, altitude, terrain, and land use (Punyawardena 2007).

Climate and Climate Change in Sri Lanka

The climatic pattern of Sri Lanka is determined by the generation of monsoonal wind patterns in the surrounding oceans. Four basic seasons exist based on rainfall, namely, the first inter-monsoon (FIM) period from March to April, the southwest monsoon (SWM) period from May to September, the second inter-monsoon (SIM) period during October to November, and the northeast monsoon (NEM) period from December to February. Out of the major climatic parameters, temperature, rainfall, and humidity are of special significance, which can cause a substantial impact on the agricultural productivity of the country. The relative humidity (RH) generally ranges from 70 % to 90 % during morning and 55 % to 80 % during late afternoon depending on the geographical location. Nevertheless, being a tropical country, solar radiation hardly limits the crop growth under general weather conditions. Analysis of climate data has shown that the country's average temperature is significantly increasing at a rate of 0.01–0.03 °C per year (Fernando and Chandrapala 1995; Premalal and Punyawardena 2013). Recent studies have also shown that cumulative annual or seasonal rainfall of major climatic zones in Sri Lanka during the last few decades has not undergone a significant change (Nissanka et al. 2011; Marambe et al. 2012).

Crops, Livestock, and Fisheries Sectors in Sri Lanka

The agriculture sector includes crops, livestock (including poultry), and fisheries as main subsectors. About 33 % of the employed population is involved in agriculture-related activities. Though the contribution of the agriculture sector to the gross domestic production (GDP) is only 11.1 % with an annual growth rate of 5.8 %, this sector plays a vital role in the rural economy (Central Bank 2013). The composition of the agriculture GDP in Sri Lanka as of 2012 is illustrated in Fig. 1.

Sri Lanka is rich in agro-biodiversity (Pushpakumara and Silva 2008) with different rice (dehusked paddy), other cereals, pulses, vegetables, roots and tubers, spices, and fruit varieties. Among them, paddy is the main agricultural crop cultivated in the country, while tea and coconut have the highest contribution to the GDP of the plantation sector (Central Bank 2013). Paddy cultivation has received a greater attention from the ancient times, especially in the dry zone of the country. The paddy sector contributes about 1.3 % to the GDP. The other food crops consisting of coarse grains, condiments, grain legumes, vegetables, tuber crops, and fruit crops contribute to 3.3 % of the GDP. The majority of the other food crops are mainly cultivated in the dry zone of Sri Lanka under rainfed and irrigated conditions. The livestock sector contributes to about 0.8 % of the GDP of Sri Lanka. In the rural economy, livestock species such as cattle, buffalo, goats and pigs, and poultry are reared as an additional source of income, whereas more attention is directed toward crop cultivation. The fisheries sector contributes around 1.8 % to the GDP of the country. Fish products are an important source of protein, providing around 54 % of the animal protein consumed in Sri Lanka (Census and Statistics 2010).

Out of the four rainfall seasons, two consecutive rainy seasons make up the major growing seasons of Sri Lanka, namely, *Yala* and *Maha* seasons. Generally

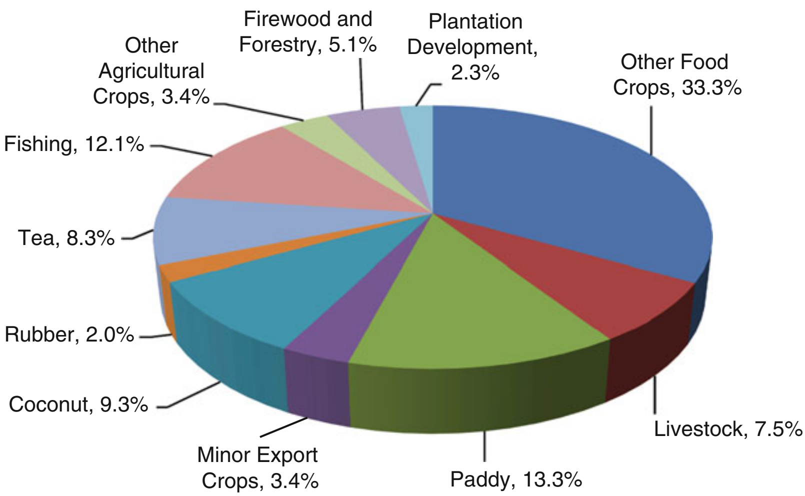

Fig. 1 Composition of the agriculture GDP of Sri Lanka (Source: Central Bank 2013)

Yala season is the combination of FIM and SWM rains. Since SWM rains are effective only over the country's southwestern sector, the length of this season in the rest of the country confines only to 2 months. Hence, the *Yala* season is considered as the minor growing season of the country. The major growing season of the island, *Maha* season, begins with the arrival of SIM rains in October and continues up to late January/February with the NEM rains. In each agroecological region, the traditional and modern farming systems have developed fitting into the local climatic conditions. Thus, the changes in climatic factors such as temperature, rainfall (including rainfall pattern), relative humidity, air temperature, solar radiation, air circulation, and wind are highly linked to the variability observed in the agricultural productivity of the country.

Climate Vulnerabilities and Impacts

Climate change is a crosscutting issue, and it is increasingly recognized as a necessary component of development-oriented decision-making process. In order for development investments to become resilient to anticipated climate change, it is important to understand the nature of vulnerability from a subnational perspective and reflect this variance in development strategies that are formulated at different administrative levels.

The climate vulnerability of Sri Lanka has been assessed considering the major development sectors such as agriculture, water resources, coastal resources, and human health and nutrition, which are the mostly vulnerable sectors in the economy that determine the livelihoods of the people. Apart from these, climate change has already created changes in the dynamics of invasive alien fauna and flora (Marambe et al. 2010), while the national parks situated in the dry zone have already felt the impact of climate changes on the wildlife. Zubair et al. (2005) reported that the seasonal and multiyear climatic anomalies would probably contribute to the human-elephant conflict in Sri Lanka. Climate change has also affected the infrastructure of the country, namely, transport, roadways, and makeshift dwellings.

The two National Communications on Climate Change (Ministry of Forest and Environment 2000; Ministry of Environment and Natural Resources 2011) discuss the effect of climate change on food security with special emphasis on vulnerable groups of Sri Lanka. The Second National Communication (Ministry of Environment and Natural Resources 2011) clearly states that the rural populations in Sri Lanka are exposed to the adverse impacts of climate change as their livelihood is mainly dependent on agriculture, fisheries, and forestry, which are vulnerable to climate change.

Change in the climate temporally and quantitatively would affect the national food supply and livelihoods of the farming community. Seo et al. (2005) identified that the developing countries will be more vulnerable to climatic changes due to being located in hot climatic zones, having a greater fraction of their economies in climate-sensitive sectors (e.g., agriculture), and the economy relies on labor-intensive technologies with fewer adaptation opportunities. However, the climate change impacts on developing countries remain poorly understood as only few studies have successfully measured the effects of climate on the developing economies. Eriyagama et al. (2010) reported that the change in climatic factors has direct impacts on the agricultural production of Sri Lanka. A recent study conducted by Punyawardena et al. (2013) based on 22 physical and socioeconomic parameters that are directly related to the three components of climate change vulnerability, namely, exposure, sensitivity, and adaptive capacity (McCarthy et al. 2001), has revealed that spatial variations of vulnerability of Sri Lanka to climate change vary according to socioeconomic, environmental, and institutional conditions of respective administrative districts. This pattern does not necessarily follow in the most exposed and geographically sensitive districts.

The Climate Change Secretariat of Sri Lanka has mapped the vulnerability of different crops and livestock to drought, flood exposure, and sea-level rise changes with the agroecological zone of the country. The crop and livestock production systems of dry and intermediate zones of Sri Lanka are more vulnerable for the impacts of the climate change. The impacts of climate change and the vulnerability of the agriculture sector are summarized in Tables 1 and 2.

Table 1 Major impacts of climate change on the agriculture sector in Sri Lanka

<table>
<tr><th>Climate change</th><th>Tea</th><th>Rubber</th><th>Coconut</th><th>Paddy</th></tr>
<tr><td>Temperature increase</td><td>Affects quality parameters of high-grown tea</td><td>Not known</td><td>Affects pollen development and viability; number of nuts per bunch</td><td>Affects pollen development causing sterility and empty grains</td></tr>
<tr><td rowspan="2">Erratic rainfall – too high</td><td>Affects harvesting</td><td rowspan="2">Reduce days available for tapping</td><td rowspan="2">Not known</td><td rowspan="2">Affects land preparation and sowing and needs no rains at harvesting</td></tr>
<tr><td>Enhances soil erosion</td></tr>
<tr><td>Erratic rainfall – too low</td><td>Affects yield</td><td>Not known</td><td>More than two consecutive months without rain is detrimental</td><td>Affects land preparation. Insufficient soil moisture affects growth</td></tr>
<tr><td>Sea-level rise</td><td>Not known</td><td>Not known</td><td>Salinization of coastal coconut lands</td><td>Loss of paddy lands in coastal areas; salinization of soil and irrigation water</td></tr>
<tr><td rowspan="2">Climate dependency</td><td>Entirely rainfed</td><td>Entirely rainfed</td><td>Entirely rainfed</td><td rowspan="2">Rainfed with supplementary irrigation</td></tr>
<tr><td>Low temperature at high elevations affects quality</td><td>If less than 500 mm affects yield; non-rainy days for tapping</td><td>Annual rainfall not less than 1,500 mm</td></tr>
</table>

Table 2 Major impacts of climate change on livestock and fisheries sectors in Sri Lanka

Climate change	Livestock	Fisheries
Temperature increase	Affects the fertility, influences the quality of feeds available for ruminants, and changes the disease and parasitic occurrence	Affects breeding habits and levels of production and influences the quantity and quality of feed available
Erratic rainfall – too high	Threat to animal life due to floods	Loss of habitat in inland water bodies
Erratic rainfall – too low	Threat to animal life due to water and food scarcity	Threat to animal life in inland water bodies
Sea-level rise	Loss of habitat	Loss of habitat
Climate dependency	Direct effect on fertility and indirect effect on production	Direct effect on breeding and indirect effect on production

The Global Context of Climate Change, Regional Initiatives, and National Commitments

The Global Context

In response to the warnings issued by scientists in the 1970s on the impact of enhanced natural greenhouse gas effect, causing the Earth to become warmer if the pattern of emission of greenhouse gases (GHGs) continues, the Intergovernmental Panel on Climate Change (IPCC) was established in 1988 by the World Meteorological Organization (WMO) and the United Nations Environment Programme (UNEP) to develop an international policy instrument to address the issue of global warming, leading to the development of the UNFCCC. The UNFCCC was adopted at the Rio Summit of the United Nations (UN) in 1992 with the objective of stabilizing the atmospheric GHG concentration at a level that will prevent dangerous human interferences with the climate system. Since then, the parties have continued to negotiate in order to agree on decisions and conclusions that will reduce global greenhouse gas emissions. Adoption of the Kyoto Protocol in 1997 is a landmark event in such negotiations where the developed countries collectively committed to reduce emissions of six key greenhouse gases at least by 5.2 % from their total GHG emissions recorded in 1990, during the first commitment period 2008–2012 (Ministry of Environment 2006).

Regional Initiatives

The South Asian Association for Regional Cooperation (SAARC; comprises of eight countries, namely, Afghanistan, Bangladesh, India, Maldives, Pakistan, Nepal, Myanmar, and Sri Lanka) has moved along with the global and other regional mandates in tackling issues related to climate change (http://www.saarc-sec.org/). The SAARC has signed a memorandum of understanding with the South Asia Co-operative Environment Programme (SACEP; July 2004), United Nations Environment Programme (UNEP; June 2007), and the United Nations International Strategy for Disaster Reduction (UNISDR; September 2008) and was accredited as an observer to the UNFCCC process at the 16th Conference of the Parties (COP 16) in 2010.

Since 1987, SAARC has reiterated the need to strengthen and intensify regional cooperation to preserve, protect, and manage the diverse and fragile ecosystems of the region including the need to address the challenges posed by climate change and natural disasters. Accordingly, a Technical Committee on Environment (TCE) was established in 1992 to examine the recommendations of the regional studies to identify measures for immediate action and decide on modalities for their implementation. The SAARC countries have adopted common positions at various international negotiations related to environment and climate change. The TCE has been entrusted with the coordination and monitoring of implementation of the 1997 SAARC Environment Action Plan and SAARC Action Plan on Climate Change (July 2008) under Article VI of the SAARC Charter (http://saarc-sec.org/areaofcooperation/cat-detail.php?Cat_id=54). The SAARC also has established the SAARC Coastal Zone Management Centre (SCZMC) in 2004 to promote cooperation in planning, management, and sustainable development of coastal zones, including research, training, and awareness in the region (http://www.sczmc.org/).

The SAARC Environment Action Plan has been adopted by the Third Meeting of SAARC Environment Ministers (Male, 15–16 October 1997), which have identified some of the key concerns of member states and set out the parameters and modalities for regional cooperation. A SAARC Convention on Cooperation on Environment as stipulated under the Item 17 (Legal Framework) of the Action Plan was signed during the 16th SAARC Summit (Thimphu, 28–29 April 2010) and was entered into force after it has been ratified by all member states. The key initiatives and proposals in the Thimphu Summit in 2010 are as follows: (a) establishing an Intergovernmental Expert Group on Climate Change to develop clear policy direction and guidance for regional cooperation; (b) exploring the feasibility of a SAARC mechanism that will provide financial capital for low-carbon technology and renewable energy projects; (c) strengthening the understanding of shared water bodies in the region through a marine initiative; (d) establishing the Intergovernmental Mountain Initiative to study mountain ecosystems and glaciers and their contribution to livelihoods and sustainable development; (e) establishing the Intergovernmental Monsoon Initiative on the evolving pattern of monsoons to assess vulnerability due to climate change; (f) commissioning a SAARC Intergovernmental Climate-Related Disasters Initiative on the integration of climate change adaptation (CCA) with disaster risk reduction (DRR); (g) establishing institutional linkages among national institutions in the region to facilitate sharing of knowledge and capacity building programs in climate change; (h) enhancing cooperation in the energy sector to facilitate energy trade and development of efficient conventional and renewable energy sources including hydropower; (i) preparing an action plan on energy conservation by the SAARC Energy Centre (SEC); and (j) creating a web portal on energy conservation for exchange of information and sharing of best practices among SAARC member states.

The SAARC Action Plan on Climate Change (2009–2011; http://saarc-sdmc.nic.in/pdf/publications/climate/chapter-2.pdf) has identified seven thematic areas of cooperation in relation to climate change, namely, adaptation, mitigation, technology transfer, finance and investment, education and awareness, management of impacts and risks, and capacity building for international negotiations. Though there is no direct identification of agriculture-related sectors in this action plan, the issues have been embedded in areas such as adaptation and management of impact. However, SAARC has now formed a focal group to identify the adaptation measures to minimize the impacts of climate change on agriculture. The action plan lists the areas of capacity building for Clean Development Mechanism (CDM) projects: exchange of information on disaster preparedness and extreme events, exchange of meteorological data, capacity building and exchange of information on climate change impacts (e.g., sea-level rise, glacial melting, biodiversity, and forestry), and mutual consultation in international negotiation process as the priorities.

The SAARC Disaster Management Centre (SDMC; http://saarc-sdmc.nic.in/index.asp) was established in New Delhi, India, in 2006 to provide policy advice and facilitate capacity building including strategic learning, research, training, system development, expertise promotion, and exchange of information for effective DRR and management. The mandate of the center has been expanded to include the development of a Natural Disaster Rapid Response Mechanism. Road maps have been developed to include coastal and marine risk management plan, community-based disaster risk management, application of science and technology in DRR, and urban risk management, drought management, and flood risk management in South Asia.

Apart from the SAARC initiative, there are two regional neighboring corporations in Asia that have strong and committed efforts in adapting and mitigating global climate change. Both Central Asia (CA) and Association of Southeast Asian Nations (ASEAN; http://www.asean.org/) regional corporations have climate change response policies and environmental, legal, and regulatory framework for meeting their commitments under the UNFCCC. The details of these corporations on climate change mitigation policy and activity frameworks are not discussed in this chapter.

National Commitments

Sri Lanka ratified the UNFCCC on 23 November 1993 and entered into force on 21 March 1994 and was among the first 50 countries to have ratified the convention. This was followed by becoming a signatory to the Montreal Protocol (on substances that deplete the ozone layer) and the Kyoto Protocol, which commits countries, i.e., mainly Annex I parties, to reduce their collective emissions of greenhouse gases.

Even though Sri Lanka is a non-Annex I country with a per capita emission of greenhouse gases (GHGs) as low as 0.6 t of CO_2 equivalent per year and the total emissions from all sectors at 20,794 $GgCO_2$ equivalents (Ministry of Environment and Natural Resources 2010), it is the objective of the Government of Sri Lanka to encourage and facilitate investments in climate-friendly development activities while fulfilling the country obligations and contributing to the ultimate objective of the UNFCCC.

Sri Lanka has established a Climate Change Secretariat (CCS) within the Ministry of Environment and Renewable Energy (ME&RE) to facilitate, formulate, and implement projects and programs at the national level with regard to climate change. The GHG inventory for the year 2000 has been prepared (Ministry of Environment and Natural Resources 2011) and an update is currently being done. The Centre for Climate Change Studies (CCCS) was established in 2000 (http://www.meteo.slt.lk/cccs.html) under the Department of Meteorology of Sri Lanka to conduct research, monitor climate change, and provide the general public with current information on climate change and allied issues. The Initial National Communication on Climate Change under the UNFCCC was prepared in 2000 (Ministry of Forest and Environment 2000), which indicated sectors that are most vulnerable to climate change and subsequent impacts, the sectors that mostly contribute to climate change, and the required mitigation options and adaptation responses, while the Second National Communication was completed in 2010 (Ministry of Environment and Natural Resources 2011). The national capacity needs to implement the UNFCCC have also been identified (Ministry of Environment and Natural Resources 2007a).

The Policies and Legislations Related to Climate Change and Relevant Sectors in Sri Lanka

Being a crosscutting phenomenon, the climate change issues have been addressed in different sectoral policies in Sri Lanka. These policies have addressed the adaptive and migratory capacities of the country at different priority levels.

National Environmental Policy (NEP) of 2003

The National Environmental Policy (NEP) of 2003 (http://www.climatechange.lk/ccs_index.html) provides the direction and framework for managing and caring for the environment in Sri Lanka and spells out the directions needed in relation to the basic natural resources such as land, water, atmosphere, and biological diversity and the environmental strategies to be followed by key economic sectors. Under the segment on land resource management, the NEP recognizes the need for providing interventions to increase agricultural productivity and sound agricultural practices in all cultivated land in the island, especially where land degradation is the most serious issue. The NEP also states that the environmental changes that affect land resources will be monitored and the real costs of environmental damage from the misuse of land will continually be assessed, on the basis of recognized priorities. Article 2.2.10 of the NEP on reducing the risk of climate change states that "The risks of climate change will be managed by implementing adaptive strategies that minimize the impact of climate change on both the people, and the economy, of Sri Lanka." The policy directives identified in NEP to accomplish this are as follows: (a) review the effect of climate change on Sri Lanka through the development of impact scenarios and response strategies, (b) develop policy scenarios for the use of CDM and its application for Sri Lanka, (c) evaluate the needs to enter into future potential trading system for carbon reduction including the necessity for clear and secure property rights or entitlements to land and carbon, and (d) develop an information database through the ministry in charge of the environment.

The National Climate Change Policy (NCCP) of 2012

The National Climate Change Policy (NCCP) of 2012 is the overarching policy dedicated to address the issues of climate change in Sri Lanka. Paragraph 14 of Article 27 in Chapter 6 (Directive Principles of State Policy and Fundamental Duties) of the Constitution (1978) of Democratic Socialist Republic of Sri Lanka clearly states that "the state shall protect, preserve and improve the environment for the benefit of the community." This governs the activities of all state, private sector and nongovernmental organizations, and individuals in protecting the environment of the country. Besides that, the NEP of 2003 carries the Policy Statement 4 indicating that "Environmental management systems will be encouraged to be flexible so as to adapt to changing situations (e.g., climate change, invasive species and living genetically-modified organisms) and adopt the precautionary principle as priority areas requiring action." In addition, the National Environmental Outlook (Ministry of Environment and Natural Resources 2009), the Caring for the Environment II 2008–2012 (Marambe and Silva 2008), the Addendum to the Biodiversity Conservation Action Plan (Ministry of Environment and Natural Resources 2007b), the Initial and Second National Communications to UNFCCC (Ministry of Forestry and Environment 2000; Ministry of Environment and Natural Resources 2011), and the National Action Plan for the *Haritha Lanka* (Green Lanka) Programme (National Council for Sustainable Development 2009) highlight the need to address climate change issues as priority interventions.

The Initial (Ministry of Forestry and Environment 2000) and Second (Ministry of Environment and Natural Resources 2011) National Communications to the UNFCCC presented by the Sri Lankan government have identified agriculture, water resources, and public health as the most affected sectors due to climate change. While Sri Lanka is vulnerable to many impacts of climate change, the island nation's contribution to GHG emissions is relatively low when compared even with other developing countries, and hence, adaptation has naturally been a priority in climate change policy in Sri Lanka. The NCCP clearly states that while taking adaptive measures as the priority, Sri Lanka will actively be involved in the global efforts to minimize the greenhouse gas emissions within the framework of sustainable development and principles enshrined in the UNFCCC and the Kyoto Protocol.

The NCCP of Sri Lanka provides guidance and directions for all the stakeholders to address the adverse impacts of climate change efficiently and effectively. Accordingly, the NCCP has included statements related to periodic assessment of vulnerability to adverse impacts of climate change in the socioeconomic and environmental sectors. This information will be highly useful in adaptation to adverse impacts in short as well as long term and mitigation, which are the two main pathways to minimize the adverse impacts of climate change. The NCCP of Sri Lanka has been formulated with the primary goal of "Adaptation to and mitigation of climate change impacts within the framework of sustainable development," with seven objectives, namely, (1) sensitize and make aware the communities periodically on the country's vulnerability to climate change; (2) take adaptive measures to avoid/minimize adverse impacts of climate change to the people, their livelihoods, and ecosystems; (3) mitigate greenhouse gas emissions in the path of sustainable development; (4) promote sustainable consumption and production; (5) enhance knowledge on the multifaceted issues related to climate change in the society and build their capacity to make prudent choices in decision making; (6) develop the country's capacity to address the impacts of climate change effectively and efficiently; and (7) mainstream and integrate climate change issues in the national development process.

The NCCP contains broad policy statements under the thematic areas of vulnerability, adaptation, mitigation, sustainable consumption and production, knowledge management, and general statements. As the NCCP is the key policy directive in relation to climate change, it links to the sectoral policies. The key issues in relation to crops, livestock, and fisheries are directly addressed under the themes of adaptation and mitigation and indirectly addressed in themes on sustainable consumption and production, knowledge management, and general areas. Table 3 provides the summary of those areas addressed in NCCP.

National Climate Change Adaptation Strategy for Sri Lanka (2011–2016)

The National Climate Change Adaptation Strategy (NCCAS) for Sri Lanka (2011–2016; Ministry of Environment and Natural Resources 2010) has been developed while accepting the fact that Sri Lanka is not a significant contributor to global warming. However, being an island nation, it is vulnerable to the impacts of climate change mainly due to the increases in the frequency and intensity of disasters such as droughts, floods and landslides, variability in climate, and sea-level rise.

The adaptation strategies in relation to agriculture are entrusted mainly under the thematic area of "Minimize Climate Impacts on Food Security." In addition, the plantation sector has been addressed under "Improve Climate Resilience of Key Economic Drivers" as the plantation agriculture is more of an economic activity. The adaptation strategy has followed an integrated approach to minimize the

Table 3 Issues related to agriculture (crops), livestock, and fisheries sectors addressed in the NCCP

Thematic area in NCCP	Issues related to agriculture, livestock, and fisheries
Direct approach	
Adaptation (food production and security)	Take timely action to address the adverse impacts on crop and animal production and fisheries sectors due to climate change and to minimize the impacts on food production and to ensure food security
	Encourage climate resilient, environmentally friendly, and appropriate innovative technologies while recognizing and promoting the utilization of appropriate traditional knowledge and practices in food production
Adaptation (conservation of water resources and biodiversity)	Promote integrated watershed and water resource management and efficient water use through technologies and behaviors adaptive to changing weather patterns and trends
Mitigation (agriculture and livestock)	Encourage environmentally sound and socially acceptable agriculture and livestock practices within the framework of sustainable development
	Promote appropriate innovative technologies while encouraging the utilization of appropriate traditional knowledge and practices
Indirect approach	
Sustainable consumption and management	Promote sustainable consumption and production considering the family as the center of focus to ensure wide dissemination of environment-friendly lifestyles and practices in the path of sustainable development
Knowledge management	Adopt multiple approaches to enhance knowledge, skills, and positive attitudes of different stakeholders at all levels to address multifaceted, current, and emerging issues of climate change
	Facilitate and promote the availability, accessibility, and sharing of climate change-related information across all sectors at all levels
General statements (institutional coordination)	Develop and strengthen an interinstitutional coordinating, collaborating, and monitoring mechanism for effective implementation of the activities related to climate change at national, provincial, district, and divisional levels under the National Focal Point to the United Nations Climate Change Multilateral Agreements

Source: http://www.climatechange.lk/policy.html

climate change impacts on food security involving irrigation, crops, livestock, fisheries, nutrition (health), and environment sectors as part of the initiative to ensure Sri Lanka's national interests are adapted to be resilient to potential climate change-induced risks. Table 4 summarizes the adaptive strategies related to the crops and livestock sectors in NCCAS. The adaptation strategies for the fisheries sector have been addressed under the thematic area of "Safeguard Natural

Table 4 The adaptive strategies related to agriculture (crops) and livestock

Adaptation strategy	Priority adaptive measures
1. Ensure ability to meet food production and nutrition demand	(i) Increase awareness on alternative options to meet nutrition requirements
	(ii) Improve weather forecasting and information dissemination
	(iii) Ensure easy access to seed stock alternatives to counter rainfall variability
	(iv) Research climate impacts/adaptive measures for the agriculture, livestock, and fisheries sectors
	(v) Conserve genetic resources for future crop and livestock improvement
2. Ensure adequate water availability for agriculture	(i) Promote water-efficient farming methods and crops to improve water productivity
	(ii) Improve maintenance of existing tanks and reservoirs including their watersheds and catchments
	(iii) Adopt and promote the principles of Integrated Water Resources Management (IWRM)
	(iv) Construct new reservoirs and trans-basin diversions to meet demand
3. Mitigate food security-related socioeconomic impacts	(i) Encourage risk transfer methods such as insurance
	(ii) Research climate impacts on long-term food security and agriculture value chain
	(iii) Identify and help vulnerable fishing communities to adapt or relocate
4. Increase awareness and mobilize communities for climate change adaptation	(i) Increase awareness on climate impacts on food security and on the potential adaptive measures
	(ii) Pilot test and scale up community-level agriculture/livestock/fisheries adaptation models
	(iii) Improve utilization of field-level coordination mechanisms and civil society organizations
	(iv) Promote risk transfer initiatives
5. Minimize impacts of climate change on the plantation sector	(i) Research climate impacts and adaptive measures in plantation subsectors
	(ii) Pilot test and scale up subsector-specific adaptation measures
	(iii) Evaluate and exploit potential productivity benefits due to climate change

Source: Ministry of Environment and Natural Resources (2010)

Resources and Biodiversity from Climate Change Impacts." Since this thematic area is commonly addressing the broad environmental issues, the strategies are mostly crosscutting. However, there are two strategies listed under this theme, which are directly related to the inland fisheries and coastal sector as given in Table 5.

Table 5 The adaptive strategies related to fisheries and wetlands

Adaptation strategy	Priority adaptive measures
1. Enhance the resilience of coastal and marine ecosystems and associated vulnerable species	(i) Promote integrated coastal resource management, particularly at Special Area Management (SAM) sites
	(ii) Restore and rehabilitate degraded coastal ecosystems and depleted coastal species
2. Enhance climate change resilience of natural inland wetlands and associated species	(i) Protect marshes/flood retention areas in urban areas and limit land conversion
	(ii) Prevent discharge of industrial effluents and solid waste into inland wetlands
	(iii) Control and manage saltwater intrusion into coastal freshwater wetlands
	(iv) Strengthen coordination and streamline management of wetlands across relevant agencies

Source: Ministry of Environment and Natural Resources (2010)

Though the NCCAS is supported with comprehensive sectoral analysis under different thrust areas related to food security, agriculture, livestock, and fisheries, it suffers with a serious lapse in two important areas, namely, energy and health. While the energy sector is completely missing in the priority strategic thrust areas, the health sector has not been adequately addressed in NCCAS probably due to the overemphasis on production aspects. The proposed strategic interventions and implementation strategies for the priority thrust areas in the NCCAS (Ministry of Environment and Natural Resources 2010) are summarized in Table 6.

The National Adaptation Plan (NAP)

Sri Lanka is currently in the process of developing the national adaptation plan (NAP) according to the adaptation strategies laid down to tackle variable climatic conditions.

Other Policies and Actions Related to Climate Change

The national overarching policy of Sri Lanka, *Mahinda Chintana*, Vision for the Future (MFP 2010), envisages an agricultural renaissance and spells out activities to develop the agriculture (crops), livestock, and fisheries sectors and to ensure future food security. Likewise, the *Mahinda Chintana* 10-year Horizon Development Framework 2006–2016 (Ministry of Finance and Planning 2006) provides commitment for the rehabilitation of degraded agricultural lands, establishment of a early warning system or drought and strengthening drought relief, strengthening rainwater harvesting systems, promotion of sustainable agriculture, and adoption of an integrated management system for the land resource, among the many aspects of

Table 6 Strategic interventions for climate change adaptation

Identified area of adaptation	Adaptation actions	Responsible agencies
1. Minimize climate change impacts on food security		
Ensure ability to meet food production and nutrition demand	(i) Prioritization of nutritional issues expected to exacerbate with climate change	Department of Agriculture (DOA)
	(ii) Implementation of awareness program to different population categories	Department of Meteorology (DOM)
	(iii) Empowerment of women in poor farming communities in sustaining household-level food security and nutrition	Department of Health (DOH)
	(iv) Adopting new/improved forecasting technology	Disaster Management Centre (DMC)
	(v) Increasing the technical capacity on forecasting	DOA

work to be undertaken to conserve and sustainable use of land in the country. Hence, *Mahinda Chintana* focuses on majority of the issues faced by Sri Lanka related to environment and climate change.

The National Council for Sustainable Development (NCSD) was established in Sri Lanka under the Presidential Secretariat in 2009. The NCSD is chaired by H.E. the President of Sri Lanka with the purpose of seeking a successful blend of the best of modern science and the richness of traditional knowledge for natural resource management and sustainable use, facing the major challenges of climate change and protection of the environment. The NCSD was instrumental in ensuring government policies on environment, and climate change has been translated into action through "Green Lanka for Sustainable Future" (Action Plan for *Haritha Lanka* Programme; National Council for Sustainable Development 2009) and also further entrust stating that "Sri Lanka abides by the global treaties and agreement on environmental and climatic change and will strengthen Sri Lanka's tie with the UN Agencies." Ten missions included in the action plan are (1) clean air; (2) saving the fauna, flora, and ecosystems; (3) meeting the challenge of climate change; (4) wise use of the coastal belt and sea around; (5) responsible use of the land resources; (6) doing away with the dumps; (7) water for all and always; (8) green cities for health and prosperity; (9) greening the industries; and (10) knowledge for the right choice. The Action Plan for *Haritha Lanka* Programme directly addresses climate change through its Mission 3 focusing on establishing food security in the face of climate change threats. The program also indirectly supports measures needed for adaptation in the crops and livestock sectors through Missions 5 (land) and 4 and 7 (water). This Action Plan has short-term, medium-term, and long-term targets spanning 2009–2016 that are relevant for adaptation to climate change.

The National Policy on Air Quality Management of 2000 and the Draft National Policy on Clean Development Mechanism (NPCDM) are two policy and planning instruments, which directly address climate change in Sri Lanka but with no direct reference to the crops, livestock, and fisheries sectors, as they deal especially on the mitigation. However, the NPCDM has indirect implications on those three sectors. The NPCDM is in total compliance with and complementary to the Sri Lanka Strategy on Sustainable Development (Ministry of Environment and Natural Resources 2007c) and the National Action Plan for *Haritha Lanka* Programme of Sri Lanka. The Ministry of Environment, while recognizing the need to embark on CDM activities, has also established two study centers at the University of Peradeniya, Sri Lanka (agriculture and forestry), and at the University of Moratuwa, Sri Lanka (transport and industry), to ensure that there will be continuous interventions and input from the researchers and academia on implementing the CDM projects.

In light of the increasing impact of climate change and the need for future preparedness, the Ministry of Disaster Management and Human Rights (as the leading ministry) and the Disaster Management Centre (DMC) (as the national-level agency) have been mandated to formulate national- and local-level disaster risk management programs and aligning them with the sectoral development programs. In addition, an intragovernmental network has been established with the assistance from Japan International Cooperation Agency (JICA) to connect the Department of Irrigation (DOI), National Building Research Organization (NBRO), Department of Meteorology (DOM), DMC, Police Communications, Media Networks, and seven district offices that are most vulnerable to disasters. This network is expected to facilitate the sharing of GIS maps and other data to better coordinate and manage response activities.

Being cognizant of the irreversible impacts of climate change on the ecosystems and development programs of Sri Lanka, in 2006, the Cabinet of Ministers of the Sri Lankan government directed all government agencies to undergo a Strategic Environmental Assessment (SEA) for all policies, plans, and programs prior to their implementation. The Central Environmental Authority (CEA) of Sri Lanka has carried out SEAs for Trincomalee Development Plan (Eastern Province) and Greater Hambantota Development Plan (Southern Province) and for the Northern

Province Development Program (http://www.isea.lk), while the Sri Lanka Tourism Development Authority (SLTDA) has completed two SEAs for tourism development in the Dedduwa Lake area (Southern Province) and in Kalpitiya area (Northwestern Province). The SEA activities are expected to fine-tune the development programs in Sri Lanka while incorporating environmental concerns to them. The SEAs for Gampaha District (Western Province) and Uva Province are currently being conducted.

The sectoral policies and legislations governing the crops, livestock, and fisheries sectors of Sri Lanka play a crucial role in embedding the climate change concerns in plans and programs implemented under respective sectors. The linkages of these policies in relation to climate change concerns of the country are highlighted below.

Key Development Policies That Govern the Crops, Livestock, and Fisheries Sectors

The National Agriculture Policy (NAP) of 2007

The National Agriculture Policy (NAP) of 2007 deals with food and export agricultural crops and floriculture with the aim of solving problems in these sectors and facilitating their rapid growth. The objectives stipulated in the NAP have been designed to meet the basic needs of the farming community in terms of food security and nutrition and enhanced employment opportunities and income generation by the adoption of technically feasible, socially acceptable, economically viable, and environmentally friendly agricultural production technologies, marketing, and related strategies. The policy includes promoting agricultural production, seeds and planting materials, fertilizers, pesticides, agricultural machinery, postharvest technology, irrigation and water management, land use, soil conservation, traditional agricultural crops, home gardening, and agricultural research. It also deals with providing agricultural credit, agricultural insurance, and agricultural extension and education and promoting marketing, agro-based industries, investments in agriculture, institutional development, sharing of plant genetic resources, and youth involvement in agriculture.

The key issues promoted in relation to climate change in the NAP are (a) production and utilization of organic and bio-fertilizers to gradually reduce the use of chemical fertilizers through Integrated Plant Nutrition Systems (IPNS); (b) minimizing the use of synthetic pesticides through promoting biopesticides and Integrated Pest Management (IPM); (c) conservation of water resources, efficient water management, and soil moisture retention techniques; (d) prevention of water pollution from agriculture; (e) adhering to the National Land Use Policy when allocating land for cultivation purposes; (f) land conservation within watershed areas; (g) enforcing the provisions of the Soil Conservation Act; (h) conservation of traditional agricultural crops and methodologies relating to organic farming, pest control, preservation and processing of food for nutritional and medicinal purposes, and facilitation of the exchange of such knowledge among the farming community; and (i) home gardening and urban agriculture to enhance household nutrition and income.

The National Livestock Development Policy (NLDP) of 2007

The National Livestock Development Policy (NLDP) of 2007 deals with developing the dairy and poultry subsectors and animal feed resources of Sri Lanka. The dairy sector is regarded as the priority for public sector investment in livestock development in the country. There is no direct government involvement or support in the meat subsector, but private sector activities are permitted, and the government takes responsibility for ensuring public health safeguards and quality standards in the meat industry. The goals and targets of NLDP are as follows: (a) the achievement of sustainable and equitable economic and social benefits to livestock farmers; (b) increasing the supplies of domestic livestock produce at competitive prices to the consumers; (c) achieve increased self-reliance of at least 50 % in domestic milk by 2015; (d) double the current domestic production of poultry products by 2015; and (e) domestic livestock products to be competitive with the imported livestock products. Though there is no explicit reference to climate change scenario in the NLDP, the achievement of the objectives of the policy could only be realized by being cognizant of the variable and changing climate in Sri Lanka, which will be facilitated by the NCCP.

The National Fisheries and Aquatic Resources Policy (NFARP) of 2006

The National Fisheries and Aquatic Resources Policy (NFARP) of 2006 promotes increasing the production of marine and inland fisheries and conserving the resource; development of aquaculture; improvement of infrastructure facilities for fisheries, including fishery harbors, product marketing, research, and use of nonliving aquatic resources; extension and training; uplifting of the socioeconomic status of the fisher community and rehabilitation of fisheries affected by the conflict and the tsunami; institutional and legal framework; and international cooperation and conservation of the environment. The objectives of the NFARP are to (a) improve nutritional status and food security of the people by increasing the national fish production, (b) minimize postharvest losses and improve quality and safety of fish products to acceptable standards, (c) increase employment opportunities in fisheries and aquatic resource-related industries and improve the socioeconomic status of the fisher community, (d) increase foreign exchange earnings from fish and aquatic product exports, and (e) conserve the aquatic environment.

Institutional Setup for Managing the Crops, Livestock, and Fisheries Sectors and Implementing Climate Change Policies and Programs

The management of the crops, livestock, and fisheries sectors is carried out by completely different institutions and agencies in Sri Lanka at both national and provincial levels with many commonalities and complexities. The crop production subsector is divided into plantation crops, non-plantation food crops, and export crops. Accordingly, these sectors are coming under the purview of different ministries and line agencies and research centers/institutes. At the national level, the plantation crops sector is under the purview of the Ministry of Plantation Industries (MPI) with the Tea Research Institute (TRI). The Coconut Research Institute (CRI) and Rubber Research Institute (RRI) are mandated to carry out research, development, and extension work related to the respective disciplines. The non-plantation food crops sector is under the purview of the Ministry of Agriculture (MOA) with the Department of Agriculture (DOA) being the responsible entity, while the Ministry of Minor Export Crop Promotion (MMECP) looks after the interests of the export crops sector (except tea, rubber, and coconut) with the Department of Export Agricultural Crops mandated for research, development, and extension activities. The Ministry of Sugar Industry Development (MSID) with the line agency Sugarcane Research Institute (SRI) is responsible for research and development of the sugar sector in the country. The Department of Animal Production and Health (DAPH) and the Veterinary Research Institute (VRI) are mandated with research and development in the livestock subsector as well as with the conservation of indigenous livestock germplasm. The livestock sector is under the purview of the Ministry of Livestock and Rural Community Development (MLRCD). The Ministry of Fisheries and Aquatic Resources (MFAR) is primarily responsible for formulating policies, plans, and programs for the development of fisheries and aquatic resources with the Department of Fisheries (DOF) being the main responsible entity for program implementation.

The provincial-level activities concerning the three sectors are carried out by the relevant provincial ministries and provincial departments of respective sectors. For example, there are eight provincial ministries representing the crops, livestock, and fisheries sectors identified at different levels of importance according to the area of interest within the province. The Department of Agriculture, Department of Animal Production and Health, and Department of Fisheries and Aquatic Resources Development are devolved subjects by the constitution of Sri Lanka having their sister departments at the provincial levels.

Given the diverse and dispersed policy framework and the related institutional setup in place with regard to crops, livestock, and fisheries sectors, the governance and regulations of adapting to and mitigating climate change risks are even more dispersed. Though the coherence of policies could be seen in sectoral policies and a good integration of those in the environmental and climate change policy, the strategic priorities and action plans need a close attention as there is a certain level of non-coherence and non-integration when policies are translated to the work plans, the implementation of which is coming under the purview of different government institutions working independently.

UNFCCC Negotiation and Adaptation-Related Policies of Sri Lanka

Though Sri Lanka was a party for the UNFCCC and the Kyoto Protocol as discussed above, the internal development thrust was not focusing on climate change and its impacts until recent years. This was mainly due to the domestic security issues, which were also aggravated with the devastating Asian tsunami disaster in 2004 that affected Sri Lanka significantly. The national policy focus on climate change was boosted mainly with the intense negotiations on adaptation at the UNFCCC COP13 held in Bali, Indonesia. At the COP7 held in 2001 in Marrakesh, Morocco, the decision was taken to establish a work program to support the least developed countries (LDCs) to include the development of the National Adaptation Programme of Action (NAPA). The NAPA focuses on urgent and immediate needs for which further delay could increase vulnerability or lead to increased costs at a later stage. During the negotiations, it was implied that NAPA would be the base document for provision of immediate adaptation finances for vulnerable countries. Though this was a turning point in adaptation-related actions globally, not being an LDC, Sri Lanka was not included in the program. However, this decision created a momentum within Sri Lankan environment discourse evident with different dialogues and events on adaptation requirements.

The famous Bali Action Plan (BAP) that laid the road map for a global agreement in 2009 (at COP15) recognized the four main pillars of negotiations, viz., mitigation, adaptation, technology, and finance, and had a significant influence in local climate change policies, especially in relation to adaptation. Adaptation was brought up frequently in national policy discussions in post-BAP times. This is evident in the Action Plan for *Haritha Lanka* Programme in Sri Lanka, which included a dedicated mission on climate change with predominant focus on adaptation. In 2009, the Sri Lankan government forwarded an "information and views" submission to UNFCCC as agreed upon in COP 14. This submission proposed to promote "Sustainable Human Development Index (SHDI)" as the main global development index while recognizing ecosystem-based adaptation as the main strategy for adaptation. It also recognized the requirement of "hardware" (such as infrastructure) and "software" (socioeconomic processes) for adaptation. This vision laid the foundation to the development of the NCCP and NCCAS. The similarities between this submission and the NCCAS structure are high so that the national policy development on climate change could be attributed to global policy processes.

Mainstreaming climate change sensitivity into development process has been discussed widely in UNFCCC processes. This was highly emphasized in the Cancun Adaptation Framework agreed by the parties at COP 16 of the UNFCCC. The Sri Lankan government initiated a process of interministerial committees and discussions in 2010 along with the intersessions. The focus of NCCAS of Sri Lanka was placed at mainstreaming adaptation to economic development strategy of Sri Lanka, which shows how the international negotiation outcomes have put into action in national policy level. In addition, Sri Lankan cases have been submitted to UNFCCC in adaptation-related discussions (http://unfccc.int/files/kyoto_protocol/application/pdf/srilanka060209.pdf). For example, Sri Lanka forwarded a submission (http://unfccc.int/resource/docs/2013/sbsta/eng/misc02.pdf) on Nairobi Work Program (NWP) rollout to the Subsidiary Body for Scientific and Technological Advice (SBSTA) to the Bonn session in 2013 highlighting the adaptation requirements of its main economic crop, tea. This was the first time that Sri Lanka highlighted the adaptation requirements to stabilize its economy at SBSTA level and was a result of in-country discussions pertaining to climate policies. As per the Cancun Adaptation Framework (CAP Decision 1/CP17; http://unfccc.int/resource/docs/2010/cop16/eng/07a01.pdf#page=4) of 2010, all developing country parties were requested to develop and implement national adaptation plans (NAPs) building upon the experiences on developing NAPAs (Decision 1/CP.16, UNFCCC). As stated previously, Sri Lanka is currently in the process of developing the NAP bringing in an additional policy framework on climate change adaptation.

Conclusion

Sri Lanka, while being vulnerable to climate change in social, economic, and resource perspectives, has shown promise and strength to build up resilience with effective adaptive action to minimize the adverse effect of the inevitable changes of the climate. Despite the magnitude of the efforts and initiatives taken by the government, demonstrating its commitment and obligations to the global context by ratification of conventions, a serious gap still exists especially in the implementation of policies and strategies. Creating awareness among the general public for constructive actions to address complex climate change issues is still far below the expected levels. Increasing speculations make the much needed mainstreaming difficult to agree upon and implement, further exacerbating climate risks.

Sri Lanka pays more attention on adaptation to climate change, which is a reasonable decision as the country is not a main polluter in the global scenario. However, mitigation also needs to be considered when planning national development programs to support internationally accepted targets to reduce GHG emissions. In the context of managing expectations of the public and decision makers regarding the adaptation process, it is an urgent need to formulate a coherent work plan focusing on a commonly shared vision, involving all principal stakeholders, and reconciling diverse perspectives. One key recommendation is to carefully plan and execute long-term national programs for supporting public participation in climate change adaptation aimed at educating and building capacity of all stakeholders.

Sri Lanka owns a cohesive policy environment, which is conducive for implementation of appropriate climate change adaptation and risk reduction plans. Hence, it is a duty left with the policy implementers to identify the specific needs of the sectors and climate-proof the sectoral development initiatives of the country to ensure sustainability. Participation of all stakeholders, especially the general public, needs to be realized in every single step during this process by building capacity especially at the local level to help communities understand the climate risks and link them to sectoral activities. Thus, the programs should be designed and targeted accordingly to meet the expectations of a diverse group of stakeholders. Effective mainstreaming requires informed consensus on climate change risks, objectives, and policies that are based on a good understanding of the roles and responsibilities of all players, including ministries representing the crops, livestock, and fisheries sectors, other line ministries on environment and planning, and the participation of vulnerable communities. Shared responsibility is fundamental to successful implementation of targets having common goals.

As perceived especially in the Asia-Pacific region, responding or reacting to climate change has become the sole responsibility of environmental agencies. This situation is particularly challenging for a country like Sri Lanka where an accelerated growth rate in the economy is expected during the postwar period and due to the Herculean task of obtaining participation of people in the war-affected areas in the implementation of activities for a common goal. Given that the adaptation strategies are always entangled with livelihood activities, the responses to climate change will no doubt come under increased scrutiny and pressure. Hence, the mainstreaming of climate change adaptation actions needs to be matched by adequate capacity building and awareness attempts, tailor-made for the different role players.

Abstract

This chapter investigated the role of energy efficiency as a means of meeting energy needs in the developing economies of West Africa (a region suffering from energy poverty), as well as adaptation to global warming, Climate change and its related risks. It draws on a literature survey to buttress the fact that energy efficiency remains the surest pathway to curb energy and resource wastage, and also reduction of the impending consequences of man-made carbon emissions to the ecosystem. The chapter compares energy profiles and climate vulnerabilities of three West African states. The metrics used in this study can be used for the easy assessment of climate risks posed by inefficient also energy usage, deforestation, and negative trends in the transportation sector of countries in the West African region.

Keywords

Energy efficiency • Climate Change • Strategic response • Risks • Sub-Saharan Africa • Technology and Innovation

Introduction

Climate change is among the major challenges the African continent faces today. In addition to handling matters related to climate impacts on agriculture as the project CALESA (http://www.calesa-project.net/) did, there is a pressing need to look at other mitigations options. In this context, there have been a number of persistent questions on uncertainties in the level of variability in the climate system and whether factors such as an increase in solar irradiance or a reduction in volcanic activity might account for a substantial amount of the warming seen in the twentieth century (Crowley 2000). A set of studies and detailed comparisons of climate models suggest that anthropogenic changes, particularly increases in greenhouse gases (GHG), are probably responsible for climate change (Crowley 2000).

The United Nations Framework Convention on Climate Change (UNFCCC) defined *climate change*s as a change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere, in addition to natural climate variability observed over comparable time periods (UNFCCC 1994). The convention also described the term "adverse effects of climate change" as changes in the physical environment or biota resulting from climate change, which has significant deleterious effects on the composition, resilience, or productivity of natural and managed ecosystems or on the operation of socioeconomic systems or on human health and welfare (UNFCCC 1994).

The energy sector remains one of the main contributors of greenhouse gas emissions (IEA & UNEP 2007). The current global energy situation is vulnerable and expensive, threatening the climate and eroding energy security, and the growing energy needs of the developing world pose a major challenge for energy decision makers (OECD 2007). The current situation of access to modern energy services in Africa is alarming. It is worse in the rural areas of many sub-Saharan

African (SSA) countries with the exception of South Africa, where they heavily depend on biomass (wood, animal dung, agriculture waste, etc.) for more than 80 % of their cooking energy use (ECA 2007). Electricity use per capita is less than 2 %, and in most African countries electricity consumption has stagnated due to low supply and an inadequate form of energy supply for the end usage (ECA 2007). It is salient to note that the level of energy utilization in an economy, coupled with the efficiency of conversion of energy resources to useful energy, is directly indicative of the level of development of the economy (ECN 2003). It is then obvious that the lack of access to sufficient, quality, and reliable energy critically constrains socio-economic advances and development. This brings to light the unique challenge that Africa and other developing economies face today in reaching their development goals in a sustainable manner. Population growth in these areas of the world increases the number of people without access to modern energy services; this increases, indirectly, the proportion of people using animal dung, fuel wood, and kerosene as cooking fuels which will, in turn, increase carbon emissions.

The rapid and intensive economic and industrial growth in developing countries (especially the fast-growing economies such as China and India) is causing higher energy demand. The rising oil and gas demand, if unchecked, will accentuate consuming countries' vulnerability to supply disruptions and price shocks, causing poorer countries to be at risk of loss of real income and with adverse impacts on the budget deficits and account balances of importing countries (IEA and UNEP 2007). Adverse impacts caused by climate change will be most striking in the developing nations because of their geographical and climate conditions, their high dependence on natural resources, and their limited capacity to adapt to a changing climate (UNFCCC 2007). It is also salient to state here that relative to people living in developed countries, developing economies are more vulnerable to Climate change due to inadequate resources (financial, technologies, human and social capital) to adapt and mitigate the risks of climatic changes (Commonwealth 2008; World Bank 2011). The developing countries in regions of Africa, Asia, Latin America, and Small Island Developing States (UNFCCC 2007; Commonwealth 2008) will be adversely affected. Billions of people living in developing countries face the challenges of food and water shortages and greater risks to their health and life as a result of climate change (UNFCCC 2007). The effects of droughts with reduced agricultural yields are seen in famished areas of Somalia and increased flooding from sea surges or rivers in cities such as Kolkata and Mumbai, India; Dhaka, Khulna, and Chittagong; and large areas of Bangladesh (UNFCCC 2007; Commonwealth 2008).

The energy sector has been identified as the main problem area, but it may also be part of the solution. Energy efficiency will be the fastest way to meet global energy needs (OECD 2007) and will decrease the impact of the energy sector on the climate and the consequent danger posed by Climate change to entire humanity.

The objective of this chapter is to buttress the fact that promoting and implementing energy efficiency are among the most promising approaches to meeting the world's energy needs, especially in the developing economies of West Africa. Secondly, this chapter illustrates the fact that energy efficiency offers a useful contribution to curbing global warming and helps to address the challenges posed by climate change.

This chapter draws on a literature survey as evidence of the fact that energy efficiency remains the surest pathway to curbing energy and resource wastages and averting the impending and dire consequences of mankind's carbon emissions that are distorting the ecosystem. The chapter compares energy profiles and climatic vulnerabilities of three West African states and then continues by proposing strategies that can be used to tackle Climate change in West Africa through efficient energy use.

Energy Usage in West Africa

The West African states comprise fifteen countries with a population of about 262 million, representing 40 % of the total population of SSA (Ouedraogo 2011). In 1975, the member states of West Africa formed the regional body called Economic Community of West African States (ECOWAS). ECOWAS is typical of SSA countries, which is known for having the lowest per capita energy consumption rates compared to other developing economies in Latin America, Europe, Asia, and Middle East (UN-EDESA 2004). It would seem controversial to talk about energy efficiency in SSA when one only looks at the low-energy consumption per capita statistics. The ECOWAS region is rich in commercial energy resources in the form of petroleum, natural gas, and also hydro resources that could be used to generate electric power. However, most of the rural population lacks access to modern energy that forces them to resort to crude energy sources without considering the environmental consequences.

The combined gross domestic product (GDP) for ECOWAS was estimated at \$139 billion as of 2005, and Nigeria's economy is larger than the combined GDP of all other ECOWAS countries, with a GDP of \$78 billion. According to the US Energy Information Administration (EIA) (2011), Nigeria has 37.2 billion barrels and 187 trillion cubic feet of proven oil reserves and natural gas, respectively, with a production capacity that has been close to 2.9 million barrels per day but is, however, producing less than that due to vandalism and sabotage. As of 2003, Nigeria had 96.3 % (5.6 quadrillion Btu) of ECOWAS energy production, consumed 66.7 %, and emitted 76.9 % (33.16 million metric tons) of the community's carbon emissions (Clough 2007). So when one is analyzing the political, socioeconomic, and other related issues about ECOWAS, it is not out of place to see Nigeria taking a center stage.

Table 1 below shows energy usage, electric power consumption, and carbon emissions in three ECOWAS states.

Household Energy Consumption in West Africa

A survey of energy efficiency practices in Nigerian households by Abdul Majid and Hussaini (2011) showed that most people do not fully understand the energy efficiency concept apart from the fact they have to use energy-saving bulbs for

Table 1 Energy usage and vulnerabilities of three ECOWAS states

Mali	80 % of the population is employed in agriculture
	44 % of the country's GDP comes from agriculture, animal husbandry, and fishing
	Over 90 % of energy consumed comes from biomass
	Substantial rise in the informal wood fuel supply sector is accelerating the deterioration of the ecosystem
	Anticipated construction of 20 dams along Niger River, a resource shared between four countries
	Proposed dam impact assessments do not look at the effects of climate change on anticipated water flows
	No coordinated emergency/disaster management system exists
	Lack of information regarding risks and associated economic impacts
Nigeria	Agriculture is rain-fed; only 1 % of the 33 % of arable land is under irrigation
	70 % of the population is employed in agriculture
	30.1 % of energy consumed is from biomass while 43.3 % is from petroleum products
	80 % of the population use biomass for their energy needs
	Modern renewable energy production represents less than 5 % of the country's energy consumption
	Volatility in the Niger Delta generates instability in upstream petroleum supply industry
	50 % of oil production is offshore
	Oil production and gas flaring has damaged surrounding marine ecology and agricultural lands irreversibly
	Country's financing hub – Victoria Island – is vulnerable to impacts of the rise in the sea level
	Lake Chad – an important freshwater source for the four countries that surround it – is only 5 % of its original size
Senegal	Agriculture is rain-fed
	Substantial volumetric reduction from 650 m^3 to250m^3 in the Senegal River, the country's main hydroelectric source 43.5 % of all energy consumed comes from biomass
	90 % of all electricity produced comes from hydrocarbons
	One fifth of electricity generated is wasted due to technical inefficiencies
	Petroleum imports account for more than 43 % of revenue exports, making the country vulnerable to fluctuating oil prices
	Rising sea level is causing the salinization of freshwater table

lighting and switch off appliances when leaving their houses. The survey was carried out in urban and semi-urban areas of the country. Most rural households in SSA rely primarily on traditional biomass energy supply for their cooking fuels, such as firewood, charcoal, and agricultural waste (UN-EDESA 2004). Studies show that the scarcity and higher cost of these biomasses resulted in switches to lower-quality biomass fuels such as cow dung and agricultural residues (Kaale 2002 as cited in UN-EDESA 2004); this was established in Ethiopia in one of these

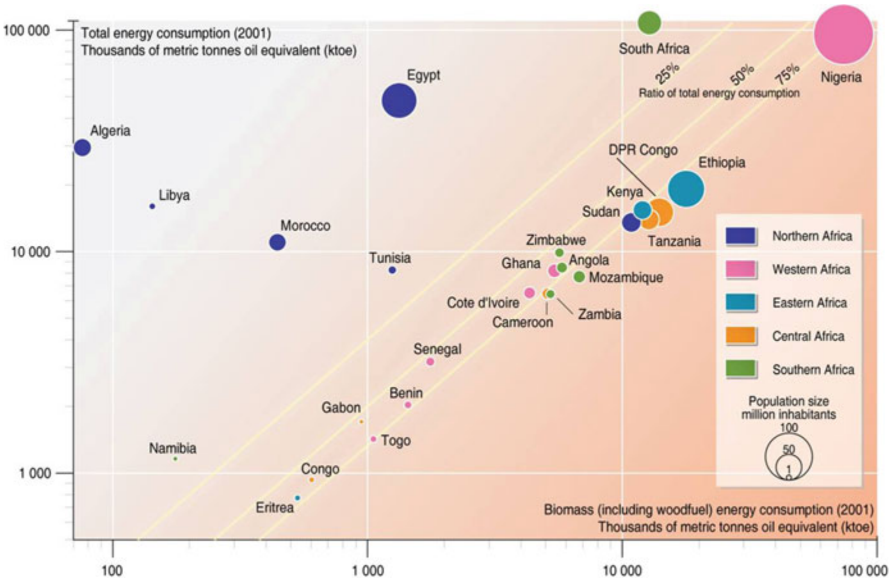

Fig. 1 Biomass fuel usage in Africa

studies but is typical of most SSA countries. The use of biomass fuels causes myriads of problems to humans and the environment. The harvest of wood for fuel leads to deforestation, erosion effects, and ecological degradation, and the incomplete combustion also leads to indoor air pollution. Figure 1 shows that the wood fuel usage in African and West African countries is among the highest in the world.

Most households in the urban areas in sub-Saharan Africa use a mixture of fuels, which may be due to higher income and having better access to modern energy services. Electricity (primarily from coal-based power stations) dominates household energy consumption in South Africa; others use relatively cleaner energy forms such as electricity, LPG, and kerosene.

Another survey carried out in Nigerian cities showed that incandescent bulbs (40–200 W) are principally used for lighting, and this serves as a significant source of energy wastage (CREDC 2009). Most homes, commercial buildings, and government buildings still have such bulbs installed. Kerosene lamps and candles are common lighting used in most rural areas in SSA. Another study found out that kerosene is the main energy source for lighting in the rural areas of the East African country (Ethiopia), while in urban areas electricity was the main source (UN-DESA 2004). However, Mekonnen and Köhlin (2009) noted that households in Ethiopia engage in multiple fuel use (fuel stacking) rather than the idea of a complete switch to other (more expensive) fuels as their incomes rise. Fuel stacking (multiple fuel use) in urban areas in sub-Saharan Africa (with no exceptions in West African states) remains a challenge for the campaign for energy efficiency. The case of a complete fuel switch has been recorded in Senegal where deliberate government policy, giving tax breaks (exemption from customs duties on equipment connected to butane), and later awarding subsidies for this fuel in 1987 caused the amount of LPG being used to increase from less than 3,000 t in 1974 to nearly 100,000 t in 2000. The report as cited in UN-EDESA (2004) stated the constraints and challenges of achieving complete success in the fuel diversification process in Senegal.

This study did not consider the energy consumption of residential buildings for most of the populace in ECOWAS states due to a lack of sufficient data. Moreover, most of the ECOWAS states do not need much energy to warm their buildings because of their location in the tropics; rather, there is a need for air conditioners for hot climates. However, energy-inefficient air conditioners remain a matter for the high-income earners among the urban populace in the region.

Agricultural Energy Consumption

The dearth of data on energy use in the agricultural sector in West Africa remains an issue. This is not unique to the region but seems to be a general problem for Africa with the exception of a few countries. Most economies in Africa depend on agriculture, except for countries that are largely dependent on mining and oil exports such as Botswana, Cameroon, Congo, Nigeria, South Africa, Zambia, and Zimbabwe (FAO 2012). The lack of mechanized agriculture in Africa forces those involved to use human labor (readily available from the teeming human population), serving as an important source of power for agriculture in West Africa and other SSA countries (UN-EDESA 2004). Across West Africa, energy use in agriculture is very low. However, energy use is still involved in agricultural production and processing. The use of fossils in drying agricultural products remains a practice.

A significant proportion of energy used in the transport sector is linked to the distribution and marketing of agricultural products (FAO 2012). According to FAO (2012), it is not easy to separate the biomass used in agriculture from that used in households except in economies with large commercial farming subsectors such as Côte d'Ivoire, Kenya, South Africa, and Zimbabwe.

The Transportation Sector

The United Nations Economic Commission for Africa (UNECA) (2011) states that the industrial and transport sectors are the biggest consumers of fossil fuels in Africa. The transport sector accounts for over 60 % of the crude oil consumption in the region. Sokona (2012) also stated that the transport sector consumes a large proportion of the commercial energy supply and passenger transport by car absorbs the vast majority of the energy used in the transport sector. This is obvious in some West African states where a poor network of road infrastructure and mass transit programs make cars the most predominant form of transport in most African countries. According to Trans-Africa Consortium (2010), the road network suffers from a

Fig. 2 Traffic congestion on a major road in Abuja, Nigeria (Source: nigerianewsline.com)

lack of regular planned expansion and from a lack of long-term maintenance. This affects energy supplies and increased carbon emissions from the engines of numerous passenger cars used for transportation. The transport sectors in Nigeria, for instance, is in a poor condition considering the number of trucks distributing refined petroleum, food crops, other goods, and raw materials from one region to the other. Most of these trucks and cars are imported as secondhand products and emit more carbon emissions as they are near the end of their life cycle. The poor network of roads leads to traffic jams in most urban cities with cars emitting more carbon emissions than they would necessarily do when traveling the same distance.

It is pathetic to behold the traffic jams in most cities in some developing nations with the consequent carbon (CO_2) emissions and working hours wasted on those roads. Figure 2 gives an idea of the amount of energy wasted in traffic jams in major cities in some developing countries. The cars use more energy to get to a particular location due to "Go Slow," a term for a peculiar traffic jam in Nigeria, where cars are forced to move at a snail's pace on the roads to avoid potholes. The Trans-Africa Consortium (2011) cited the case of the Bus Rapid Transit (BRT) in the commercial capital of Nigeria, Lagos. BRT recorded a reduction of 32 % fuel consumption for vehicles used along its dedicated corridors, resulting in the reduction of 25,000 t of CO_2 per year due to the implementation of the BRT services (20 times less CO_2 emitted per passenger transported compared to private car). The BRT case is different when compared to other West African cities such as Dakar and Ibadan in Senegal and Nigeria, respectively, where old minibuses are used to transport passengers. Another study cited by the Trans-Africa Consortium in Ghana stated that fuel consumption for minibuses and taxis is much higher per passenger/km than for larger city buses. *The results of the study suggest that it would require 22.5 times more fuel for a taxi to* *carry the same number of passengers than for a large bus over the same distance, and 6.6 times more for a minibus. In 2008, 107 MMT buses used 1.3 million litres of diesel to carry about 12.5 million people. Therefore, 400 minibuses or 900 taxis would be required to carry the same number of people over the same distance, and they would use about 8.5 million and 28.8 million litres of diesel respectively, more than doubling the fuel required* (Trans-Africa Consortium 2010). The overcrowding of the larger buses also helped to increase the index results for the buses.

Industrial Energy Usage

West Africa is not yet industrialized but the mining and raw materials extraction industries dominate the industrial sectors. There are, however, a few energy-intensive industries, such as VALCO, a transnational aluminum production company in Ghana, petroleum refining companies in many countries, and fertilizer companies and steel and cement plants in Nigeria (Sokona 2012). The cement industry is one of the most energy-intensive sectors. According to the World Bank (2009), energy represents about 20–40 % of total production costs and also a significant source of greenhouse gases, accounting for about 5 % of the annual global anthropogenic carbon dioxide emissions – representing 1,800 million tonnes of CO_2 emissions in 2005 from the use of fossil fuels and chemical reactions during clinker processing. The average CO_2 intensity ranges from 0.65 to 0.92 tCO_2 per tonne of cement across countries with a weighted average 0.83 tCO_2/t1.

The World Bank (2009) also reported that the cement industries recorded 203 out of 4,364 CDM projects submitted for registration to UNFCCC as of January 1, 2009. Africa registered only 28 CDM projects (2.1 %) out of 1,300 projects registered worldwide, with only three new projects submitted for registration from the cement industry in Africa. The three projects registered were the bundled blended cement projects in two plants owned by WAPCO in Nigeria, the Jatropha plantation and biomass residues for partial substitution of coal in the SOCOCIM plant in Senegal, and biomass and biomass residues used as alternative fuels in a CEMEX plant in Egypt.

The registered CDM projects involved the most commonly used methods of cement blending, fossil fuel substitution and switching with alternative fuels/biomass, waste heat recovery processes, and other energy efficiency measures. The knowledge that would have been developed from engaging in the CDM projects would have also been transferred to other sectors of the economy. However, the whole of SSA countries and not just ECOWAS ignored this great opportunity, allowing China and India to register 110 and 49 projects, respectively.

It is not uncommon to see this kind of response in Africa where some countries such as South Africa, Cote d'Ivoire, and Kenya, which do not currently produce oil, have more efficient refineries than oil-producing countries such as Nigeria, Angola, and Gabon. As a result, these countries with more efficient refineries have become regional suppliers of oil products. The energy usage pattern of an average end user in Nigeria, for example, is typical of a government that has not made a serious effort to stop the flaring of associated gas in oil refining in more than 50 years of crude oil exploration.

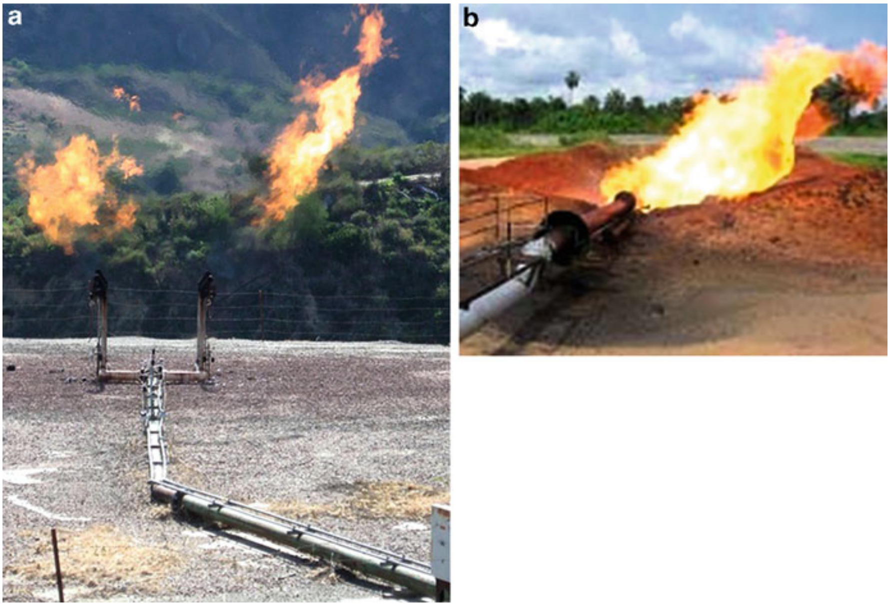

Fig. 3 (**a**) Gas flaring in Nigeria (Source: www.justmeans.com), (**b**) Gas flaring in Nigeria (Source: Friends of the Earth International)

The pictures in Fig. 3a, b depict what is seen in the Niger Delta region in Nigeria where corporate entities without any serious government intervention have wasted enormous gas resources and money that should have accrued from natural gas sales for over 50 years. Beyond that, they have contributed to global warming with all impunity. One has to wonder why these corporate entities – most of them unfortunately multinational – do no tact on the findings of their sustainability reports around the globe.

Nigeria remains a good example of where energy efficiency must be taken more seriously because of its leading role in ECOWAS and Africa, and there cannot be sustainable development in ECOWAS if countries such as Nigeria are not actively helping. The best place to start promoting the concept of energy efficiency and reducing carbon emissions may be with the governments in the main developing economies of ECOWAS. These countries must learn to show leadership and direction.

Energy Consumption and Climate Change

The climate is changing drastically and is a matter of concern to all well-meaning people in the world. The diagram in Fig. 4 shows the change in global temperature, carbon dioxide, and dust concentrations over thousands of years. These are dangerous trends which humanity must consider and make efforts to avert the impending and dire consequences. The satellite images of Lake Chad over a 30-year period (Fig. 5) portray a very dangerous trend for the environment and the ecosystem, which seriously threatens the livelihood of the human population in the neighborhood.

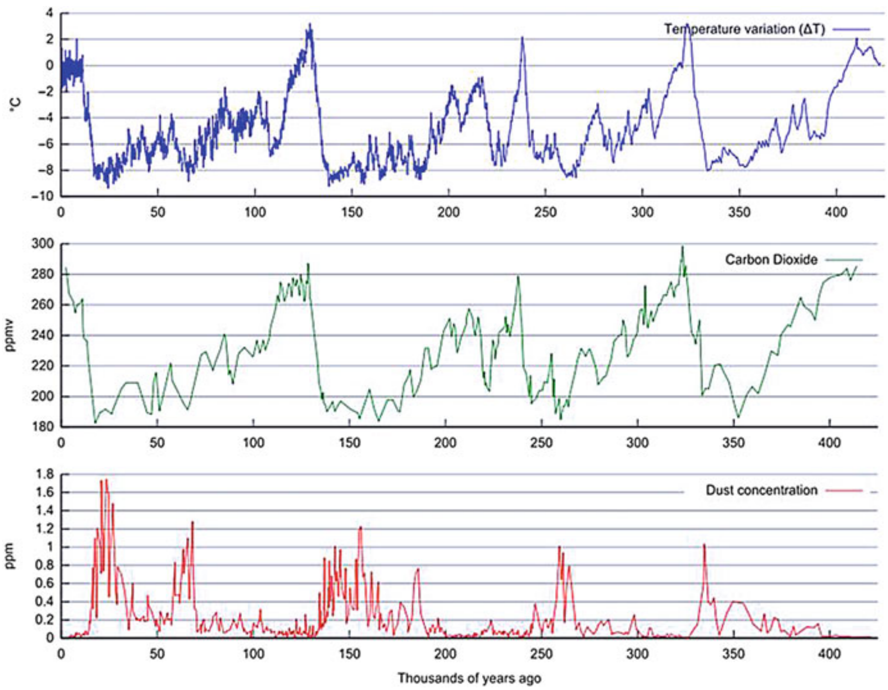

Fig. 4 Change in temperature, CO_2, and dust concentration (Source: http://en.wikipedia.org/wiki/Climate_change)

Both the low-income countries and the developed countries all contribute to Climate changes. Lack of access to modern energy services constrains people living in poor countries to resort to low-quality energy sources with high carbon emissions. Poor countries also lack the infrastructure (national grid, off-grid generation, greenhousing estates, regulatory bodies, energy standards, etc.) that ensures energy efficiency. In cases of developed countries with high energy- intensive sectors, the location of high energy-intensive industries and power generation from fossil fuels all contribute to high carbon emissions and consequently to climate change. It is not surprising to see that the developed countries with high energy intensity have greater carbon emissions than the developing countries.

Comparison of Energy Profile and Risks of Climate Change in Three Selected West African States

This study selected Mali, Nigeria, and Senegal for a comparison based on their energy profiles and risks of Climate change. Table 1 gives a summary of the economic profile, energy usage, and Climate change vulnerabilities of these three states. Table 2 states the energy use (kg of oil equivalent per capita) indicator, electricity consumption (kWh per capita) of the three countries and other ECOWAS

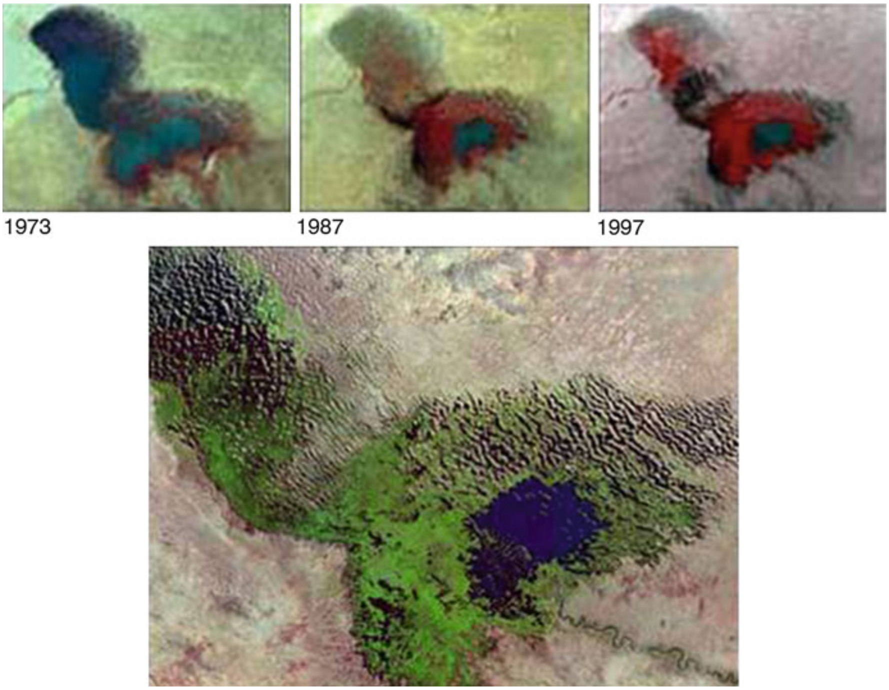

Fig 5 Satellite picture of Chad Lake in 2001 (Source: en.wikipedia.org/wiki/Lake_Chad)

countries in 2009, and then the consequent increase in the level of carbon emissions and degradation of forest reserves.

Mali has 80 % of its population employed in agriculture with 44 % of the GDP coming from the agricultural sector. Nigeria's population also has 70 % of the population employed in the agricultural sector. Biomass constitutes over 90 % of all energy consumed in Mali, a reasonable number of Nigerians use biomass, while Senegal seems to have a much lower consumption of biomass. Senegal forced a certain proportion of its population to switch to LPG from biomass and has a lower percent of biomass consumed compared to Nigeria and Senegal.

Nigeria produces the largest quantity of crude oil in West Africa and also consumes more petroleum products than the other two countries. Senegal generates electricity mostly from hydrocarbon sources compared to Nigeria and also Mali, which has an energy supply mix of natural gas and hydro resources. Based on the data in Table 2, Nigeria uses more energy than Senegal but the latter generated more electricity than Nigeria. Mali has no data on its energy use and electricity generated in the World Bank (2011) report. Moreover, Nigeria has emitted more carbon than Senegal. This is obvious due to the gas flaring activities of the crude oil exploration in Nigeria. Nigeria has lost more forest reserves (sq. km) than the two other countries from 2000 to 2010, followed by Mali. Senegal seems to have had better control of her wood fuel consumption and preservation of her forest resource.

Table 2 Energy use and carbon emission and forest reserves in ECOWAS from 2000 to 2010

Country	Year	Energy use (kg of oil equivalent per capita)	Electric power consumption (kWh per capita)	CO_2 emissions (metric tons per capita)	Forest reserves (sq. km) ('000)
Ghana	2000	404	330	0.3	60.9
	2005	394	247	0.3	55.2

Source: http://ddp-ext.worldbank.org/ext/ddpreports/ViewSharedReport

However, Senegal is still vulnerable to flooding since it has a 1350 km coastline with flat interior terrain and housing, and over 75 % of its population lives less than 60 km from the coastline. Nigeria also has 850 km of low-lying coastline, but Mali's proximity to the north of Africa makes it vulnerable to desertification and other associated climatic risks. The drying up of Lake Chad and the loss of forest reserves are indications of climate change in West Africa. This is shown on Fig. 5, a satellite image of Lake Chad in 2001. The countries near to the north of the Sahara face more desertification, low rainfalls, low agricultural outputs, and migration, while low-lying coastline countries may soon face salinity of fresh water and flooding of low-lying plains. The comparison shows that all three countries face peculiar climatic risks but their energy efficiencies differ. Senegal is more energy efficient than Nigeria and Mali.

Conceptual Approach

Energy efficiency is simply the ratio of energy services output to energy input (Herring 2006). The concept of energy efficiency has to do with getting the most out of every unit of energy produced or consumed. This concept is deeply rooted in eco-efficiency which emphasizes the use of fewer resources to produce more things. Eco-efficiency does not merely focus on material use and waste reduction but is also concerned with resource productivity by maximizing the value added per unit of resource input. Eco-efficiency is achieved by the delivery of competitively priced goods and services that satisfy human needs and bring about a better quality of life while progressively reducing ecological impacts and resource intensity throughout the life cycle, to a level at least in line with the Earth's estimated carrying capacity (Michaelis 2003).

Energy efficiency can be seen as the Cinderella of the global campaign against climate change (KPMG 2010). It seems to lack the glamour of clean and renewable energy technologies and has historically attracted less generous tax benefits and other incentives, but the climate does not care whether CO_2 is reduced by greener and cleaner technology or lower energy consumption, as long as it is reduced (KPMG 2010). After several literature reviews, it is obvious that the concept of energy efficiency remains the short-term and sustainable approach to energy poverty in developing countries. Africa and other developing nations can adapt better to Climate change by adopting energy efficiency as this will serve both as a short- and long-term measure. Case studies cited in literature portray the fact that energy efficiency is yielding the expected results (USAID 2009), and these case studies are cited in this chapter.

Energy efficiency is widely accepted as the most cost-effective way to mitigate climate change and accounts for 50 % of the potential halving of energy-related CO_2 emissions by 2050 (WBCSD 2010). Stabilizing the concentrations of these gases at a level that would avoid human distortion of Earth's climate requires drastic changes in the fuel mix, more efficient production and use of energy, and measures that prevent carbon dioxide from being released to the atmosphere over geological timescales (IEA and UNEP 2007).

Energy Efficiency Is Key to Energy Security

About 1.6 billion people in developing countries, making up one-quarter of the world's population, do not have access to electricity in their homes, while some 2.5 billion people rely on traditional fuels and technologies for cooking and heating (IEA and UNEP 2007). This threatens the realization of the United Nations Millennium Development Goals since the identification and implementation of cost-effective policies to meet these needs are both difficult tasks as they often encounter resistance from industry and consumer interests (IEA and UNEP 2007). Energy security is increasingly seen as a prerequisite for sustainable development and poverty alleviation and a condition for achieving the UN's millennium development goals, including the aim to halve the proportion of people in poverty by 2015 (OECD and IEA 2010). The costs of inactivity outweigh those of implementing the required policies, so there is a need to develop effective policies, since providing access to sustainable clean energy supply is vital not only for curbing global warming but also for reducing poverty and misery in West Africa and around the world.

However, world energy consumption is predicted to increase by 54 % from 2001 to 2025, and much of the growth in worldwide energy use is expected to be in the developing world (IEO 2004). Since the first oil crisis of the 1970s, economic growth and energy consumption have stopped moving in tandem in many industrialized nations, but the world's energy needs have still grown steadily and will continue to grow, especially in the large emerging economies such as China and India. Energy efficiency will ensure that these developing countries do not toe the previous path of the developed ones. Collectively, the world can achieve some level of energy security if the developing economies use energy efficiently in their quest to industrialize.

Energy Efficiency as a National Strategic Response

In every risk lies an opportunity which can be explored. The Climate change is creating a business paradigm shift (Energetics 2009). Regional bodies, countries, organizations, and firms now have the responsibility to ensure that risks and opportunities are identified, assessed, managed, optimized, and effectively managed. The greatest risks and opportunities are likely to be driven by shifts in government policy, investment in technology and innovation, and the impacts of social change (Energetics 2009). The reality is that energy efficiency involves people, systems, software, technology, and organizations, all of which are linked together in new ways.

This chapter will closely look at four strategic approaches that could be used to enhance energy efficiency and curb Climate changes in West Africa. They are government policy and regulation, investment in technology and innovation, socio-cultural change, and then regional integration and cooperation towards energy efficiency and Climate change adaptability.

Government Policy and Regulation

The innovation required for developing energy-efficient technologies and social cultural change, to ensure efficient energy utilization by citizenry, is unlikely to take place without government direction (Praetorius et al. 2009). Some economists have emphasized that taxation could be used to spur innovation technologies as well as abate carbon emissions (Herring 2006). The direct taxation on the quantity of CO_2emissions will be an incentive across all fields of innovation that will help to save energy and/or reduce CO_2 emissions (Praetorius et al. 2009). This school of thought believes that taxation ushers in induced innovation because appropriate tax regimes on fossil fuel usage make its use more expensive for private and industrial consumer, making demand increase for energy-efficient technologies. This will motivate enterprise in the direction of a technology push for energy-efficient technologies (Praetorius et al. 2009). However, taxation as an instrument will only work in economies where people pay taxes and governments utilize taxes entrusted in its hands. This chapter does not hold the view that taxation alone as an economic instrument will be used to cut CO_2 emissions. Those economists that hold contrary views about the concept of energy efficiency should think of a systemic approach to tackling global issues and challenges. It is preferable to use an integrated approach that will involve the use of sustainable policies and scientific, technological, and sociocultural approaches to tackle the issue of climate change. Since the energy sector has been identified as the main contributor of emissions of greenhouse gases (IEA and UNEP 2007), policies that promote the more efficient production and utilization of energy contributing to a reduction of almost 80 % of CO_2 emissions (OECD 2007) should be introduced. Sustainable energy policy in developing countries will have to integrate energy efficiency as a measure to mitigate risks of climate change. Such energy policies will support the establishment of smart and off-grid power generation to avoid energy losses during long transmissions. Sustainable energy policy will support the increase in the energy supply mix of the country, with more emphasis on renewable energy sources than fossil energy sources. Government policies that support oil subsides do not encourage energy productivity, as seen in most oil-producing countries (McKinsey & Company 2007). The oil subsidies are responsible for the lack of energy productivity in the Arab Gulf which stand in contrast to what is obtainable in European countries and Japan (McKinsey & Company 2007; Licklider 1988). Oil and fuel subsidies seem to encourage energy wastage. Deregulation of the energy sector will go a long way in ensuring energy efficiency. Governments must stipulate standards for the major players in energy generation and distribution to ensure efficiency in the energy sector. Governments in developing countries can introduce policies that support energy efficiency, starting with programs aimed at the design and construction of green housing and buildings (with the retrofitting of efficient heating, ventilation, and cooling systems, lighting systems, and solar hot water heaters) for public utilities and commercial and private purposes. There are energy standards, green codes, and labels for products in the market, and it is strongly advised that ECOWAS countries ensure compliance in the importation of green products as this will ensure that energy-consuming appliances and equipment are used in the country. This also applies to legislation that will enforce efficiency in both the production and usage of energy. It is obvious that there will be future legislation for energy efficiency both in developed and developing economies if the issues of global warming and climate change are to be taken seriously. It has been the practice in a number of countries for governments to offer financial incentives for energy efficiency improvement schemes, based on government policy in this regard (UNE/A 2007). Incentives and tax rebates will foster a wider cooperation for efficiency among consumers and actors/players in smart grid networks and other energy enterprises. In developed economies such as in the United States, there are three main incentives which include production tax credits, investment tax credits, and grants for investors in energy efficiency (KPMG 2010); ECOWAS countries can copy this example.

Investment in Technology and Innovation

The challenges of Climate change can be tackled with technological innovations that will enhance energy-efficient technologies (OECD 2007), if not now, then certainly in the long run. There is a need for new institutions, management techniques, and market contracting arrangements that can serve as incentives which will, in turn, serve as the motivations for energy and materials users to seek out evermore efficient technologies that are ecologically friendly (Scarlett 2010). In Nigeria, for instance, there is a common assumption that Nigeria generates more than enough energy for their consumption and that the problem lies with management, distribution, and efficient utilization of the energy generated. Entrepreneurs are needed to exploit the opportunities created by energy wastage whereby there will be a shift in focus from compliance and risk management to market leadership in technological innovations that will drive the low carbon economy in developing countries like those of the ECOWAS states. Technological innovations are essential and required to reduce the amount of energy use and carbon (IV) oxide (CO_2) emissions, to monitor energy use (smart metering), and also smart switches for turning off and on during energy peak and off-peak periods. The use of incandescent bulbs (40–200 W) is a significant source of energy wastage and they are still commonly used (CREDC 2009). Most homes, commercial buildings, and government buildings still have such bulbs installed. Low-energy lighting technologies will serve as better alternatives for street lighting where incandescent bulbs are still in use in cities across most ECOWAS states. A case study on public private partnerships (PPP) initiated by Asian Electronics Limited (AEL) and nine cities using energy service company (ESCO) contracts described how the partnership worked alongside municipal corporations in India to install energy-efficient streetlights and upgrade central monitoring systems (USAID 2009). Lighting technologies are the quickest to retrofit, visible, and easily verifiable in energy-efficient projects, and its energy-saving potentials are instantaneous (USAID 2009). This would be a good starting point for energy entrepreneurs in Africa, like in Asia where some projects had started, such as those in India. The AEL's street lighting projects installed more than 25,000 waterproof energy-efficient tube lights and 100,000 retrofit energy-efficient tube lights, which are controlled by 4,000 automatic load monitoring systems at all of its switching points (USAID 2009). AEL projects were expected to realize energy savings of nearly 13 MW and carbon savings of approximately 40,000 t of CO_2 equivalent per year, thus achieving energy consumption savings of up to 60 % (USAID 2009). Technological innovations that offer energy savings are more helpful in solving energy inefficiency challenges in developing countries considering the size of the human population involved. Technological innovations for monitoring energy usage are already in the market to enhance energy efficiency. Public enterprises, business firms with numerous infrastructural bases, large industrial estates, and housing estate schemes in developing countries can monitor energy usage. It is important to note that most multinational corporations are making their operations more sustainable by investing in software that can help them manage their energy usage in response to large increases in utility costs (Worthington 2010). Software, such as ENXS produced by ENXSUITE, has been developed as a project portfolio management tool for the energy space. ENXS 6.0 works with utility billing systems, providing invoicing and reconciliation, and has introduced a new web services interface for smart grid and energy management integration (Worthington 2010). These developments may not take place in developing countries in the immediate future, but a good starting point will be through the deployment of smart meters and development of smart grids. Smart metering is a system used to measure the energy consumption rate of households and communicate the information to both the user and the local utility provider for monitoring and billing purposes (Bleischwitz et al. 2009). The smart metering system can be coupled with energy efficiency services (energy audit and energy performance contracting, etc.), home technologies, and new smart grid two-way control systems to integrate distributed generators. Smart metering provides the possibility for residential customers to obtain more accurate bills and prepayment options, therefore initiating the consciousness and behavioral change required to monitor their energy use, making it easier for them to switch to better energy suppliers (Bleischwitz et al. 2009). It has been recently observed in Nigeria that most electricity end users who use smart meters turn off their appliances and switch the meters off while they are away to avoid their meters from recording energy use. They now avoid the cost of leaving their appliances on when not in use. The development or transfer of these technological innovations will enhance energy efficiency in developing countries. It will assist homes and business firms to monitor energy consumption and avoid wastage. The innovations seen in the monitoring and managing of energy portfolios has created opportunities for energy entrepreneurship where jobs can be created for managing energy portfolios in developing economies especially for firms that generate their own energy.

The mobile telecommunications industry stands out as a good example of business that needs energy generation for its operation, and they have acquired numerous power generation bases. Optimizing energy efficiency in this sector will not only reduce its environmental impact but also cut operating costs and help to make communication more affordable for everyone. Finding new efficient energy solutions also helps spread access to communications by opening up more options for the installation of radio sites in a sustainable manner with low impact (Ericson 2007).

Sociocultural Change

The cultural capital of somewhere can be described as a cultural background and a basic value system that is shared by the individuals in a community and manifests in their attitudes and habits, including consumption patterns (Bruno et al. 2008).

The consumption pattern and customer responsiveness to new energy-efficient technologies (OECD 2007; Bruno et al. 2008) affect the energy consumption and CO_2 emission of that particular location. The sociocultural approach to energy efficiency is to increase the energy utilization by sharing with others or selling access to them (Bleischwitz et al. 2009) from the excess capacity one has generated for his/her own consumption.

Most developed economies are seriously developing green and sustainable communities who share resources, as seen in smart grid energy generation. There are community energy generation enterprises in several countries which include car- and bike-sharing enterprises. Car-sharing is the concept of renting a car every time one is needed instead of purchasing one outright (Bleischwitz et al. 2009). Car-sharing reduces the number of vehicles on the road. Thus, reducing the energy input and the raw material charge of car manufacturing significantly decreases the CO_2 emissions from the usage of the car (Bleischwitz et al. 2009). Effective transport systems with good mass transit buses and railway systems could be an alternative for developing countries that do not have entrepreneurs who can venture into the car-sharing business. It remains important that ECOWAS and other developing countries should educate their citizens on the need to avoid following the unsustainable path of the Western world with wasteful lifestyles and high energy usage. Developing countries must engage in enlightening their citizens of a social transformation that will embrace efficient resource use and energy efficiency. A case study on the use of incandescent bulbs with energy consumption of 40–200 W as mentioned above suggests a lifestyle of energy wastage across Nigeria (CREDC 2009). It is also evident that most of these incandescent bulbs are left switched on to know when public electricity supply is available. It is salient to say at this point that to introduce a sociocultural change, governments in developing countries must show direction and leadership by displaying efficiency in all resource usage, minimizing energy waste in the generation and distribution of energy, installing energy-efficient technologies in government building, and engaging in other green programs.

Regional Integration and Cooperation Towards Energy Efficiency and Climate Change Adaptability

ECOWAS as a regional body will play a strategic role in the promotion of government policies and regulations on energy standards and its response to climatic challenges. It has to strengthen the already existing institutions such as the ECOWAS Centre for Renewable Energy and Energy Efficiency, which has the mandate to help develop renewable energy and energy efficiency markets in West Africa, formulate policy, and build capacity and quality assurance mechanisms, as well as well-designed financing plans. The center is also supposed to implement demonstration projects with the potential for future regional expansion.

Energy efficiency can be shaped by a social network where the actors in the network learn by sharing knowledge, ideas, and best practices. The industrial, transport, agricultural, energy sectors could have existing tacit knowledge, perceived truths, routines, practices, and methods regarding energy efficiency within these sectors. These established energy efficiency measures in one sector can be transferred to a different sector through regional communities of practice and trade associations which guide and regulate practices in these sectors. Beyond helping to share best practices in energy efficiency among member states, ECOWAS can help to fund pilot projects that promote energy efficiency in member states. It could choose to finance and sponsor these projects with counterpart funding from the nations involved with projects or with international development partners and donors.

Conclusion

The economic crises are deeply rooted in the energy crisis, as once there is low supply of energy, then a looming economic collapse can be expected. Crude oil prices kept increasing until the global meltdown, and then, energy prices had to decrease drastically. Energy crises also precipitate environmental degradation; this is seen more in developing economies where people lack cooking fuels. They tend to cut down forest resources and reserves. The equation above gives a vivid summary.

$$\text{Energy crisis} = \textbf{Economic crisis} + \textbf{Environmental crisis}$$

Energy use is today linked to economic growth and status. It is therefore proper to state here that no economy can grow far above its supporting ecological system; doing so will cause imbalances which we are witnessing in global warming and Climate change. Mankind has impacted heavily on the environment, leaving a large ecological footprint trailing behind our activities. Technological innovations have made us understand that the world is a global village. As civilized nations move towards material and energy efficiency, and then to sustainable development, they must not leave the developing nations behind. The effects of gases flared in the south of the Atlantic surely do not remain there; they reach the atmosphere and will certainly reach other places around the globe through multiplier effects. We must therefore care about what happens all over the globe:

> To each generation comes its allotted task; and no generation is to be excused to perform that task. Theodore Roosevelt.
>
> Some people who live before us paid dearly for us to be where we are today. It took the resilience of Thomas Edison to help us utilise electricity today. We must let the future generation know it must be produced and utilised efficiently.

Figure 6 tries to show us that humanity has changed its material use from resource wastage to efficiency by replacing wood fuel and animal dung as cooking

Fig. 6 historical changes in fuel

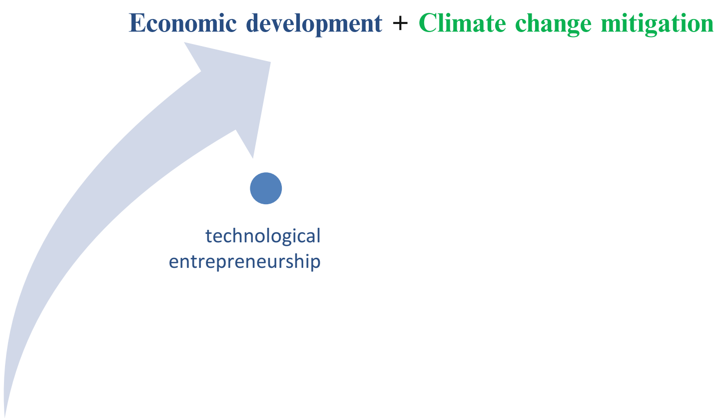

Fig. 7 Technological entrepreneurship as a solution to energy and economic crisis

fuels with coal, crude oil, and then finally with renewable energy sources today. As more developing nations try to industrialize, collective efforts must be made to ensure that they do so sustainably; otherwise, they will create common problems for all in the future. We can help by making sure developing economies have education deeply rooted in science, technology, and innovation studies with entrepreneurial good skills. Figure 7 shows that technological entrepreneurship could alter the equation above. It could change energy crisis, which in turn will after affects economic and environmental crisis. Then, the citizens of such developing countries can contribute to their national indigenous knowledge by providing quality skills and technological innovation that can be adapted into solving their local challenges. In so doing, efficiency will be achieved when technological innovations meet market gaps created by production systems (which leave no room for wastage of materials or energy losses). This will ultimately help to curb the effect of climate change.

ECOWAS as a community of developing countries should build the capacity to change the uncertainties of Climate change into manageable risks. Energy poverty is a challenge that creates opportunities to be exploited. Every risk has a positive side, and the higher the risks, the greater the reward.

Enhancing Biodiversity Co-benefits of Adaptation to Climate Change

Kanako Morita and Ken'ichi Matsumoto

Contents

Abstract

We explore effective management of the interplay between the United Nations Framework Convention on Climate Change (UNFCCC) and the Convention on Biological Diversity (CBD) to enhance the biodiversity co-benefits of adaptation. By using the framework of interplay management in environmental governance, this research analyzes (1) the interactions between the UNFCCC and the CBD via ecosystem-based adaptation discussions, interactions that could reduce negative impacts and enhance positive effects on biodiversity, and (2) the efforts of the relevant actors in these interactions. We show that the CBD is addressing tangible ecosystem-based adaptation issues and that the UNFCCC refers to these efforts. However, there is limited explicit collaboration between the two Conventions because of their different characteristics. The key actors who are especially important in efforts to strengthen linkages between the two

agencies with respect to ecosystem-based adaptation are the UNFCCC and CBD secretariats; the Joint Liaison Group (JLG), which links national adaptation programs of action and national biodiversity strategies and action plans; multilateral aid agencies such as the Global Environment Facility (GEF) that serve as financial mechanisms to UNFCCC and CBD; and national government ministries that address environmental problems in developing countries and can coordinate relevant actors at the national level.

Keywords

Ecosystem-based adaptation • Interplay management • UNFCCC • CBD

Introduction

Climate change and biodiversity issues are interlinked, although they are addressed by distinct governing bodies. Climate change needs to be considered within biodiversity conservation action because climate change affects biodiversity. Similarly, aspects of biodiversity conservation must be part of climate change mitigation and adaptation because if not well planned, these activities could impact biodiversity negatively.

This chapter explores the management of interaction between climate change and biodiversity governance agents, with a focus on adaptation. Adaptation is a response to climate change, and it can influence biodiversity in positive or negative ways. Although the primary institutional frameworks of adaptation currently fall under the United Nations Framework Convention on Climate Change (UNFCCC), reducing the negative impacts and enhancing their positive effects of adaptation on biodiversity are within the purview of the Convention on Biological Diversity (CBD). Successful management of the interaction between climate change and biodiversity governance agents could maximize the positive effects of adaptation in terms of both climate change and biodiversity. This research uses the framework of interplay management in the field of international politics, which focuses on efforts by relevant actors to address and improve institutional interaction and its effects (Stokke 2001; Oberthür 2009; Oberthür and Stokke 2011).

This chapter analyzes the negotiation processes and relationships of the UNFCCC and the CBD, with a focus on ecosystem-based adaptation. Ecosystem-based adaptation applies biodiversity and ecosystem services as part of an overall strategy of response to the adverse effects of climate change (SCBD 2009). It can not only play a role in reducing climate change impacts but could provide social, cultural, economic, and biodiversity co-benefits. The CBD has been developing tangible, ecosystem-based adaptation activities, and the UNFCCC acknowledges these efforts. There is however limited explicit collaboration between them because of their different mandates, negotiation processes, and actors involved. This chapter goes on to analyze the key actors involved in efforts to improve collaboration and implementation of ecosystem-based adaptation. These actors include the UNFCCC and CBD secretariats, parties to the UNFCCC and CBD (national governments of developing countries), aid agencies, and NGOs. Our analysis identifies efforts to improve institutional interactions between the UNFCCC and CBD.

Increase Positive and Minimize Negative Effects of Adaptation on Biodiversity

In most cases, adaptation can increase positive and reduce negative effects on biodiversity through such initiatives as environmental impact assessments, technology impact assessments, or strategic environmental assessments (SCBD 2009, p. 38). In this chapter, we focus on ecosystem approaches to adaption as defined above. Ecosystem-based adaptation may include sustainable management, conservation, and restoration of ecosystems as parts of an overall adaptation strategy that hopes to achieve social, economic, and cultural co-benefits for local communities (CBD Decision X/33).

Table 1 presents examples of ecosystem-based adaptation measures that achieve co-benefits, including biodiversity. An example is mangrove conservation, which not only provides protection from storm surges, a rising sea level, and coastal inundation (thus addressing climate change issues) but also protects biodiversity and conserves the habitats and species that live and breed in mangrove areas.

Ecosystem-based approaches to adaptation have been defined and examined by the CBD. Ecosystem-based adaptation has also been reflected in UNFCCC adaptation discussion although the discussion is less extensive than that of the CBD. Ecosystem-based adaptation has been initiated by various actors in both developed and developing countries (UNFCCC 2013a). Multilateral organizations and aid agencies such as the United Nations Environment Programme (UNEP) launched the Ecosystem-based Adaptation Flagship Programme, whose activities include providing policy support and decision-making tools for policies and programs and piloting activities on the ground. The work is carried out in collaboration with numerous partners, including the United Nations Development Programme (UNDP), the International Union for Conservation of Nature (IUCN), United Nations Habitat, the Global Environment Facility (GEF), and donors, civil society organizations, and academia (UNEP 2013). Ecosystem-based adaptation projects are also implemented by aid agencies, national governments, and international NGOs. The Australian Agency for International Development (AusAID) supports a project to increase taro crop diversity in Samoa, and the World Wildlife Fund (WWF) supports a project for the Mesoamerican reef in Belize (see Table 4).

In this chapter, we analyze ecosystem-based adaptation in developing countries, which are generally more vulnerable to climate change than are developed countries, and where multiple aid agencies and international NGOs are involved. Note: ecosystem-based adaptation is an emerging concept and research is therefore constrained by limited data.

Table 1 Examples of ecosystem-based adaptation

Adaptation measure	Adaptive function	Co-benefits: Social and cultural	Co-benefits: Economic	Co-benefits: Biodiversity	Co-benefits: Mitigation
Mangrove conservation	Protection against storm surges, sea level rise, and coastal inundation	Provision of employment options (fisheries and prawn cultivation)	Generation of income to local communities through marketing of mangrove products (fish, dyes, medicines)	Conservation of species that live or breed in mangroves	Conservation of carbon stocks, both above- and belowground
		Contribution to food security			
Forest conservation and sustainable forest management	Maintenance of nutrient and water	Opportunities for recreation	Potential generation of income through: ecotourism, recreation	Conservation of habitat for forest plant and animal species	Conservation of carbon stocks
	Flow	Culture protection of indigenous peoples and local communities			Reduction of emissions from deforestation and forest degradation
	Prevention of land slides		Sustainable logging		
Restoration of degraded wetlands	Maintenance of nutrient and water flow, quality, storage, and capacity	Sustained provision of: livelihood	Increased livelihood generation	Conservation of wetland flora and fauna through maintenance of breeding grounds and stop over sites for migratory species	Reduced emissions from soil carbon mineralization
	Protection against floods or storm inundation	Recreation	Potential revenue from recreational activities		
		Employment opportunities	Sustainable use		
			Sustainable logging of planted trees		

Establishment of diverse agroforestry systems in agricultural land	Diversification of agricultural production to cope with changed climatic conditions	Contribution to food and fuel wood security	Generation of income from sale of timber, firewood, and other products	Conservation of biodiversity in agricultural landscape	Carbon storage in both above- and belowground biomass and soils
Conservation of agrobiodiversity	Provision of specific gene pools for crop and livestock adaptation to climatic variability	Enhanced food security	Possibility of agricultural income in difficult environments	Conservation of genetic diversity of crop varieties and livestock breeds	
		Diversification of food products			
		Conservation of local and traditional knowledge and practices	Environmental services such as bees for pollination of cultivated crops		
Conservation of medicinal plants used by local and indigenous communities	Local medicines available for health problems resulting from climate change or habitat degradation, e.g., malaria, diarrhea, and cardiovascular problems	Local communities have an independent and sustainable source of medicines	Potential sources of income for local people	Enhanced medicinal plant conservation	Environmental services such as bees for pollination of cultivated crops
		Maintenance of local knowledge and traditions		Local and traditional knowledge recognized and protected	
Sustainable management of grassland	Protection against flood	Recreation and tourism	Generate income for local communities through products from grass (e.g., broom)	Forage for grazing animals	Maintenance of soil carbon storage of soil carbon
	Storage of nutrients			Provide diverse habitats for animals that are predators and prey	
	Maintenance of soil structure

Analytical Framework

The academic literature contains studies of the interactions among environmental institutions, where one institution affects the development or performance of another. Young (2002), Oberthür and Stokke (2011) and others have developed case studies of various international environmental institutions in areas such as climate change, biodiversity, ozone depletion, ocean-related issues, and trade policy. Young (2002) studied the characteristics of interactions among environmental institutions and categorized the interactions as vertical/horizontal or political/functional interplay. In contrast, Stokke (2001) and Gehring and Oberthür (2008) focused on the causal mechanisms of institutional interplay.

The research cited above focuses on institutional relationships, but does not identify factors that enable the creation of effective institutional interactions that can resolve conflicts between institutions. Recent studies of interplay management examine the governance of institutional interactions by focusing on the efforts and effects of relevant actors in addressing and improving institutional interactions (Oberthür 2009; Oberthür and Stokke 2011). This research uses an actor-centered approach and examines how conflicts can be avoided through: (1) analysis of the relationships between the UNFCCC and CBD and the interactions between these two agencies in regard to adaptation and (2) analysis of the roles of the relevant actors, including the secretariats of the UNFCCC and CBD, aid agencies, national governments in developing countries, and NGOs.

Several studies analyze the differences and similarities between climate change and biodiversity regimes for forest issues (Morgera 2011; Savaresi 2011; McDermott et al. 2012; van Asselt 2012). However, there is no research on adaptation that analyzes the contribution of actors in managing climate change and biodiversity governance.

Institutional Interactions and the Role of Actors in Adaptation

Adaptation Negotiation Under the UNFCCC and CBD

Ecosystem-based adaptation has been discussed under both the UNFCCC and CBD. The UNFCCC and CBD are part of the three Rio Conventions (the third is the United Nations Convention to Combat Desertification, UNCCD), which emerged from the 1992 United Nations Conference on Environment and Development (UNCED) in Rio de Janeiro. Although the UNFCCC and CBD are sister Conventions, they have different objectives, administration, secretariats, and party members. Table 2 shows the structure and characteristics of the two Conventions.

The UNFCCC primarily focuses on climate change mitigation, particularly those issues identified in the Kyoto Protocol. However, the necessity of adaptation is also explicitly stated in the text of the UNFCCC and the Kyoto Protocol, acknowledging that climate change impact is unavoidable (Morita 2010). Adaptation has been discussed under the UNFCCC and the Kyoto Protocol in

Table 2 Structures of the UNFCCC and CBD

	UNFCCC	CBD
Establishment	Opened for signature in 1992 at the UNCED	
	Entered into force in 1994	Entered into force in 1993
Objectives	Stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system	Conservation of biological diversity
		Sustainable use of its components
		Fair and equitable sharing of the benefits arising out of the utilization of genetic resources
Administration	Under the UN	Under the UNEP
Secretariat	Headquarters: Bonn	Headquarters: Montreal
Parties	193 parties + European Union	192 parties + European Union (the USA is nonparty)
Related to adaptation	Workstream: Nairobi Work Programme, National Adaptation Programmes of Action, National Adaptation Plans, Loss and Damage	Workstream: Biodiversity and Climate Change including ecosystem approaches to adaptation
	Adaptation-related funds: Special Climate Change Fund	
	Least Developed Countries Fund	
	Adaptation Fund (under the Kyoto Protocol)	

Source: Created based on the information in UNFCCC and CBD websites

relation to: the clean development mechanism, technology transfer, research and systematic observation, capacity building, adaptation to adverse effects of climate change, Least Developed Country (LDC) assistance, national communications, and financial mechanisms. Adaptation began to receive increasing attention following the UNFCCC Conference of the Parties (COP 6) in 2000 (Morita 2010).

Currently, there are four workstreams on adaptation under the UNFCCC: the Nairobi work program on impacts, vulnerability, and adaptation to climate change (NWP), National Adaptation Programmes of Action (NAPA), National Adaptation Plans (NAPs), and the Work Programme on Loss and Damage (UNFCCC 2013b). In 2010, the Cancun Adaptation Framework resulted in negotiations on greater action, grouped into five clusters: implementation, support, institutions, principles, and stakeholder engagement. The Framework includes establishing processes for NAPs and the Work Programme on Loss and Damage. In addition to the workstreams, the Framework includes establishment of an Adaptation Committee to promote timely and coherent action under the Convention:

1. NWP: This work program is established to assist all parties, in particular developing countries, LDCs, and small island developing states, to enhance knowledge about adaptation. The NWP is undertaken under the Subsidiary Body for Scientific and Technological Advice (SBSTA) and is implemented by parties, intergovernmental and nongovernmental organizations, the private sector, communities, and other stakeholders. Currently, ecosystem-based

adaptation has been discussed under the NWP. COP 12 renamed the 5-year program of work "Nairobi work programme on impacts, vulnerability and adaptation to climate change" in 2006.

2. NAPA: This process was established in 2001 to provide LDCs the opportunity to identify priority activities that respond to their urgent and immediate needs to adapt to climate change. The LDC Expert Group provides technical support and advice.
3. NAP: This process was established under the Cancun Adaptation Framework to enable LDCs to formulate and implement national adaptation plans as a means of identifying medium- and long-term adaptation needs and developing and implementing strategies and programs to address those needs. The LDC Expert Group for NAPA also provides technical guidance and support to NAPs.
4. Work Programme on Loss and Damage: This program, also established under the Cancun Adaptation Framework, aims to consider approaches to address loss and damage associated with climate change impacts in especially vulnerable developing countries.

Article two of the UNFCCC mentions the importance of ecosystem-based adaptation, stating that "the ultimate objective of this Convention . . .is to achieve. . . stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time frame sufficient to allow ecosystems to adapt naturally to climate change. . .."

At the UNFCCC COP 14 in 2008, Sri Lanka and Palau proposed an ecosystem approach to adaptation (IISD 2008, p. 13), and at the UNFCCC COP 16 in 2010, the Cancun Agreement was adopted. As the Agreement states, it "Invites all Parties to enhance action on adaptation under the Cancun Adaptation Framework, . . .by undertaking, inter alia, the following: . . . Building resilience of socioeconomic and ecological systems, including through economic diversification and sustainable management of natural resources" (UNFCCC Decision 1/CP.16, II paragraph 14(b)). Ecosystem-based adaptation has also started to receive attention under the NWP. In June 2011 at the UNFCCC SBSTA 34 session, the SBSTA request of the secretariat to undertake interim activities under the NWP included compilation of information on ecosystem-based approaches to adaptation (FCCC/SBSTA/2011/L.13). This information was compiled prior to the UNFCCC COP17 in 2011, and it reflected activities of the CBD. The UNFCCC also created an ecosystem-based adaptation database on its website (UNFCCC 2013a). At the COP 17, the secretariat was asked to organize workshops in collaboration with NWP partner organizations and other relevant organizations. Included was "a technical workshop on ecosystem-based approaches for adaptation to climate change, before the 38th session of the SBSTA, taking into account the role of ecosystems, including forests, in adaptation; vulnerability and impacts in ecosystems; the implementation and benefits of ecosystem-based approaches for adaptation; and lessons learned, including through the three Rio Conventions" (UNFCCC Decision 6/CP.17, paragraph 4 (b)). This workshop, organized under the NWP, was held in Dar es Salaam, United Republic of Tanzania, in March 2013 (FCCC/SBSTA/2013/2). At the subsequent SBSTA 38 meeting in June 2013, ecosystem-based adaptation was mentioned in the NWP draft conclusions (FCCC/SBSTA/2013/L.9).

Specific ecosystem-based adaptation measures have been subject to more discussion by the CBD than by the UNFCCC. At the CBD COP 7 in 2004, recorded decisions cite the potential of an ecosystem-based approach to adaptation (CBD Decision VII/15, paragraph 8), and under the CBD COP 8 and COP 9, decisions established the links between adaptation and biodiversity conservation (CBD Decision VIII/3 and IX/16). The CBD COP 10 in 2010 invited "Parties and other Governments....to consider the guidance below on ways to conserve, sustainably use and restore biodiversity and ecosystem services while contributing to climate-change mitigation and adaptation: Recognizing that ecosystems can be managed to limit climate change impacts on biodiversity and to help people adapt to the adverse effects of climate change; implement where appropriate, ecosystem-based approaches for adaptation, ...as part of an overall adaptation strategy that takes into account the multiple social, economic and cultural co-benefits for local communities;..." (CBD Decision X/33, paragraph 8 (j)). The CBD COP 11 in 2012 addressed ecosystem-based adaptation and the NWP, encouraging parties and other governments to "...support the strengthening of inventorying and monitoring of biodiversity and ecosystem services at appropriate scales in order to evaluate the threats and likely impacts of climate change and both positive and negative impacts of climate-change mitigation and adaptation on biodiversity and ecosystem services" (CBD Decision XI/21, paragraph 6 (e)), "Encourages Parties and other Governments to... consider reviewing land-use planning with a view to enhancing ecosystem-based adaptation to climate change..." (paragraph 6 (f)), and "Requests the Executive Secretary... to... identify relevant workshops and activities within the NWP and countries' NAPs under the UNFCCC, and disseminate such information....with a view to enhancing knowledge-sharing on ecosystem-based approaches" (paragraph 7 (a)).

The first Ad Hoc Technical Expert Group (AHTEG) on Biodiversity and Climate Change, established in 2001, extended the CBD discussions. The AHTEG aimed to add technical and scientific advices for the integration of biodiversity considerations into the measures that might be taken under the UNFCCC and its Kyoto Protocol to implement mitigation and adaptation (SCBD 2003). The second AHTEG on Biodiversity and Climate Change, which convened in 2008, complied and described the characteristics of ecosystem-based adaptation in the CBD Technical Series (SCBD 2009).

The CBD has attempted to add ecosystem-based adaptation to the discussion on the NWP and has attempted to unite the two Conventions in the ways in which they address adaptation. In the UNFCCC SBSTA 31 Plenary (COP15) in 2009, the CBD stated at the conclusion of the work of the second AHTEG on Biodiversity and Climate Change, "ecosystem-based adaptation is not sectorally limited, but addresses potential adaptation needs across many sectors," "ecosystem-based adaptation is highly relevant because it: can be applied at all levels; may be more cost-effective and more accessible to rural or poor communities than measures based on hard infrastructure and engineering; and can integrate and maintain traditional and local knowledge and cultural values," and "ecosystem-based adaptation approaches can also contribute to climate change mitigation by conserving or enhancing carbon stocks and reducing emissions caused by ecosystem degradation and loss" (Statement of the CBD at UNFCCC SBSTA 31 Plenary). Furthermore, the final report of the AHTEG on Biodiversity and Climate Change (SCBD 2009) was transmitted to the UNFCCC COP 15 by the CBD COP 9 with a view to convening a joint meeting of the two bureaus (CBD Statement at the UNFCCC SBSTA 31 Plenary).

At the UNFCCC COP 16, the CBD highlighted the outcomes of its COP 10, stating that the discussions focused on a number of issues related to the NWP, including the development of joint activities at national levels, the promotion of ecosystem-based approaches for adaptation and mitigation especially for protected areas, and improving information on the impact of climate change on biodiversity (CBD Statement at the UNFCCC SBSTA 33 Plenary). The CBD also invited the UNFCCC to collaborate with it (CBD Statement at the UNFCCC SBSTA 33 Plenary).

Thus, although there is limited explicit collaboration between the UNFCCC and the CBD, the CBD has actively discussed ecosystem-based adaptation, and the UNFCCC has acknowledged CBD's work. Table 3 summarizes the adaptation discussions under the UNFCCC and CBD.

Efforts of the Relevant Actors to Support Interaction

We next analyzed the contribution of relevant actors in efforts to encourage discussion and interaction between the UNFCCC and CBD on ecosystem-based adaptation. The actors are the UNFCCC and CBD secretariats, multilateral and bilateral donors, national governments in developing countries, and NGOs.

Table 4 presents examples of ecosystem-based adaptation activities in developing countries. This table illustrates the many actors involved in projects, and their efforts are analyzed in terms of the identified activities.

Secretariat Efforts

Secretariats are important for improving the interactions between the UNFCCC and CBD vis-a-vis ecosystem-based adaptation, but they currently play differing roles. The CBD secretariat has developed significant influence in international negotiations and cooperation (Siebenhüner 2009), while the UNFCCC secretariat has not promoted the political ideas of the committee or proposed specific technical approaches (Busch 2009).

The Joint Liaison Group (JLG) was established in 2001 as an informal forum among the three Rio Conventions for exchanging information, exploring opportunities for synergistic activities, and increasing coordination (CBD 2013). The JLG comprises the members of the secretariats, the executive secretariats, and the officers of scientific subsidiary bodies (CBD 2013). The JLG clearly has the

UNFCCC		CBD	
COP 6–9 (2003)	Adaptation issues were discussed under various agendas. Adaptation begins to receive more attention following COP 6 (2000)		
COP 10 (2004)	Decided the Buenos Aires program of work on adaptation and response measures, which describes ways to respond to the adverse effects of climate change (UNFCCC Decision 1/CP.10)	COP 7 (2004)	Stated that the application of an ecosystem approach could facilitate the formulation of climate change mitigation and adaptation projects that also contribute to biodiversity conservation and sustainable use at the national levels (CBD Decision VII/15)
COP 11 (2005)	Adopted a 5-year work program on the SBSTA on impacts, vulnerability, and adaptation to climate change (Decision 2/CP.11)		
COP 12 (2006)	Renamed the program to NWP (FCCC/CP/2006/5)	COP 8 (2006)	Parties, other governments, and so on are encouraged to development rapid assessment tools for the design and implementation of biodiversity conservation and sustainable use activities that contribute to adaptation (Decision VIII/30)
COP 13 (2007)	Decided to launch "a comprehensive process to enable the full, effective and sustained implementation of the Convention through long-term cooperative action, now, up to and beyond 2012," including addressing "enhanced action on adaptation" (Decision 1/CP.13)		
COP 14 (2008)	*Sri Lanka and Palau, speaking also for Micronesia and the Marshall Islands, proposed an ecosystem approach to adaptation*	COP 9 (2008)	Showed the proposals for the integration of climate change activities within the work programs of the Convention, including conducting in-depth reviews of the work programs by considering such as the contribution of biodiversity to adaptation and measures that enhance the adaptive potential of components of biodiversity (Decision IX/16)

Table 3 (continued)

UNFCCC		CBD	
COP 15 (2009)			
COP 16 (2010)	Decided to establish the Cancun Adaptation Framework including establishing NAPs process, Work Programme on Loss and Damage, and Adaptation Committee (Decision 1/CP.16)	COP 10 (2010)	Mentioned the role of ecosystem-based adaptation and call for the integration of ecosystem-based adaptation into relevant strategies and careful consideration of different ecosystem management options and objectives (Decision X/33)
COP 17 (2011)	Decided the structures and functions of the Adaptation Committee (Decision 2/CP.17). Adopted COP decisions on NWP (6/CP.17), NAPs (5/CP.17), and Work Programme on Loss and Damage (7/CP.17)		
	NWP: *secretariat and NWP partner organizations, etc., are requested to organize a technical workshop on ecosystem-based approaches for adaptation*		
COP 18 (2012)	Adopted COP decisions on approaches to address loss and damage (Decision 3/CP.18), work of the Adaptation Committee (11/CP.18), and NAPs (12/CP.18)	COP 11 (2012)	Decisions touch on ecosystem-based adaptation and NWP such as encourages parties to support strengthening inventorying and monitoring of biodiversity and ecosystem services to evaluate both positive and negative impacts of climate change mitigation and adaptation on biodiversity and ecosystem services. Also requests the Executive Secretariats to identify relevant workshops and activities within the NWP and countries' NAPs under the UNFCCC (CBD Decision XI/21)

potential to strengthen the links between the UNFCCC and CBD secretariats concerning ecosystem-based adaptation.

The COPs of the three Conventions have recognized that adaptation is an area of importance (JLG 2004). The executive secretaries of each Convention identify adaptation, capacity building, and technology transfer as priority areas for their discussion (JLG 2004). The three secretariats have also identified options for

Table 4 Examples of ecosystem-based adaptation in developing countries

Name	Country	Ecosystem	Name of implementing institution
Responding to shoreline change and its human dimensions through integrated coastal area management	Mauritania, Senegal, Gambia, Guinea Bissau, Cape Verde	Marine and coastal	UNDP, GEF, UNESCO
Enhancing adaptive capacity in semiarid mountainous regions, Bolivia	Bolivia	Mountain, forest, and woodland	The Netherlands Climate Assistance Programme (NCAP)
The CEIBA-PILARES project	Ecuador and Peru	Forest and woodland	Nature and Culture International
Coping with drought and climate change in the Chiredzi district	Zimbabwe	Agriculture, rangelands, and grasslands	Government, UN Agency
Integrated National Adaptation Plan – Colombia highland ecosystems	Colombia	Mountain; Inland water	GEF; World Bank; Conservation International
Drought-resistant agriculture in El Salvador	El Salvador	Agriculture	Red Cross, World Food Programme
Community-based coastal habitat restoration (“Green Coast Project”)	Indonesia, Sri Lanka, India, Thailand, and Malaysia	Marine and coastal, forest and woodland	Wetlands International, Both Ends, WWF, IUCN
Integrating agroforestry practices in the farming system in Grenada	Grenada	Agriculture, mountain	Government of Grenada
Integration of climate change risk and resilience into forestry management (ICCRIFS)	Samoa	Forest and woodland	UNDP, GEF, Government of Samoa
Jordan Valley Permaculture Project	Jordan	Agriculture	National Center for Agricultural Research and Transfer of Technology, Jordan; Permaculture Research Institute (PRI) of Australia
Kikuyu Escarpment Forest	Kenya	Forest and woodland	Birdlife, Kenyan Forestry Service
Kimbe Bay: scientific design of a resilient network of marine protected areas	Papua New Guinea	Marine and coastal	The Nature Conservancy
Assessing the Impacts of Climate Change on Madagascar’s Biodiversity and Livelihoods	Madagascar	Forest, marine and coastal	Government of Madagascar, USAID, Conservation International, WWF

Ecosystem-Based Adaptation in Marine, Terrestrial, and Coastal Regions as a Means of Improving Livelihoods and Conserving Biodiversity in the Face of Climate Change	Brazil, Philippines, South Africa	Marine and coastal; forest and woodland; agriculture; inland water	Federal Environment Ministry of Germany, Conservation International Foundation

Source: UNFCCC 2013a

improving cooperation, including: (1) the promotion of complementarity among the national biodiversity strategies and action plans (NBSAPs) under the CBD, national action programs of the UNCCD, and the UNFCCC NAPA for LDCs; (2) the development of joint work programs or plans, joint international workshops, and joint capacity-building activities (including training and local, national, and regional workshops to promote synergy in implementation); and (3) case studies on interlinkages (CBD 2013). In 2007, at the seventh JLG meeting it was agreed that an information note on adaptation activities, plans, and programs adopted within the framework of each Convention should be drafted (JLG 2007).

The degree of willingness to enhance links between the UNFCCC and CBD executing secretariats is different: in general, the CBD more actively connects UNFCCC and CBD processes. For example, at the tenth JLG meeting in 2010 the Executive Secretary of the CBD invited his counterparts at the UNFCCC and UNCCD to convene a high level dialogue between themselves and the Secretary General at the CBD COP 10. He also shared the CBD proposal for a joint work program between the three Rio Conventions and a proposal to have an extraordinary meeting of the Rio Convention COP (JLG 2010).

Although the UNFCCC is generally passive about linking the two processes, it admits the importance of interaction on specific topics like adaptation. In 2010, also at the tenth JLG meeting, the Executive Secretary of the UNFCCC expressed concern about the CBD proposals for a joint work program and an extraordinary meeting of the Rio COPs. The concern was that the proposals would infringe on the mandate of the UNFCCC secretariats and that the topic of adaptation is still under active negotiation. Nevertheless it was acknowledged that focusing on specific topics can move the synergies agenda forward and that the NAPA, NBSAP, and national action programs of the UNCCD may be conducive to the promotion of such synergies (JLG 2010).

Although the JLG does not explicitly address ecosystem-based adaptation, the Group is important in linking the adaptation work of the UNFCCC and CBD secretariats. Further, the JLG links the works of NBSAP and NAPA, which are vital for strengthening ecosystem-based adaptation discussions.

Donor Efforts

Although the number of ecosystem-based adaptation programs and projects remains limited, multilateral aid agencies such as the GEF and the World Bank and bilateral aid agencies such as the United States Agency for International Development (USAID) and AusAID have engaged in research and implementation of ecosystem-based adaptation. In this section, we describe the efforts of both multilateral and bilateral aid agencies.

With regard to multilateral aid agencies, the GEF (see chapter "▶ Financing Adaptation to Climate Change in Developing Countries" in this handbook), serving as the financial mechanism of the UNFCCC and CBD, plays a vital role implementing ecosystem-based adaptation and linking the two Conventions. In 2004, at the fifth JLG meeting, the secretariats of the Rio Conventions discussed adaptation, capacity building, and technology transfer. This discussion was in preparation for an informal meeting with the GEF CEO (JLG 2004). The point was made that "synergy (among the objectives of the three conventions in adaptation activities) can be promoted through meetings between the Executive Secretaries of three conventions, the GEF and the Implementing Agencies, and further supported through cooperation between the Scientific and Technical Advisory Panel (STAP) of the GEF, and the respective scientific and technical subsidiary bodies of the conventions" (JLG 2004). In 2012, the GEF developed *Operational Guidelines on Ecosystem-based Approaches to Adaptation* (GEF/LDCF.SCCF.13/Inf.06) which assists agencies and project proponents that seek aid through the Least Developed Countries Fund or the Special Climate Change Fund. The GEF has supported ecosystem-based projects such as Adaptation to Climate Change Impacts in the Syunik Mountain Forest Ecosystems of Armenia and Integrated National Adaptation Plan: Colombia Highland Ecosystems (see Table 4).

Furthermore, the implementing agencies of the GEF such as the World Bank, the UNEP, and the UNDP are also actively engaged in research and projects on ecosystem-based adaptation. World Bank projects and programs support biodiversity conservation and the protection of natural habitats and ecosystem services, thereby contributing to effective mitigation and adaptation strategies (World Bank 2009). Other organizations including the International Union for Conservation of Nature, United Nations Habitat, as well as donors, civil society organizations, and academia have established ecosystem-based adaptation flagship programs (UNEP 2013).

Bilateral aid agencies and countries such as the Netherlands and Germany support ecosystem-based adaptation activities. The USAID supports the ecosystem-based adaptation project Assessing the Impacts of Climate Change on Madagascar's Biodiversity and Livelihood, and AusAID supports the Increasing

Taro Crop Diversity project. Although the number of projects funded by both multilateral and bilateral donors is limited, the ecosystem-based adaptation activities of bilateral donors are more often confined to specific areas and sectors, than those of multilateral aid agencies like the GEF (UNEP 2013). Bilateral aid agencies also lack the comprehensive guidance and strategy on ecosystem-based adaptation supports and implementation and have less influence in discussions of the UNFCCC and CBD.

National Government Efforts

Several developing countries are beginning to discuss ecosystem-based adaptation activities. Although it is early to evaluate their efforts in promoting ecosystem-based adaptation and linkage between the UNFCCC and CBD, national ministries with environmental mandates in developing countries are likely to play a significant role.

Although a number of industry or sector-specific ministries are involved in adaptation issues (e.g., Ministry of Agriculture of Grenada, Ministry of Agriculture and Fisheries of Samoa, and Kenya Forest Service), many of the ecosystem-based adaptation projects implemented in developing countries are funded by multilateral and bilateral donors and are likely to be endorsed and managed by the national ministries that address environmental problems (e.g., Environmental Management Agency of Zimbabwe, Ministry for the Environment and National Natural Parks of Colombia, and Ministry of Natural Resources and Environment of Samoa).

Cambodia's Ministry of Environment approves and supports projects such as ecosystem-based approach to integrate climate change-resilient livelihoods and floodplain management for the Tonle Sap supported by Conservation International and ecosystem-based adaptation approach to climate change along the Mekong River (Kratie Province in Cambodia) supported by the WWF (Cambodia's Ministry of Environment 2013). Examples in other countries include Integration of Climate Change Risk and Resilience into Forestry Management project in Samoa, executed by Samoa's Ministry of Natural Resources and Environment through supports from UNDP (Samoa's Ministry of Natural Resources and Environment 2013), and Adaptation to Climate Change Impacts in the Syunik Mountain Forest Ecosystems of Armenia, executed by the Ministry of Nature Protection in Armenia. The ministry that addresses environmental problems is likely to be a key to supporting ecosystem-based adaptation in developing countries, because it is usually the focal point of the UNFCCC and the CBD, and has the capacity to both coordinate actors at the national level and to help link the UNFCCC and CBD.

NGO Efforts

Many international NGOs working in nature conservation actively support and implement ecosystem-based adaptation in developing countries, including the World Wildlife Fund, Nature Conservancy, BirdLife International, CARE, and Conservation International. Conservation International is supporting ecosystem-based adaptation projects, such as the Tonle Sap project in Cambodia (see above), the Integrated National Adaptation Plan (Colombia highland ecosystems), and

Ecosystem-Based Adaptation in Marine, Terrestrial, and Coastal Regions as a Means of Improving Livelihoods and Conserving Biodiversity in the Face of Climate Change projects in Brazil, Philippines, and South Africa.

Such international environmental NGOs are actively encouraging ecosystem-based adaptation activities, but their support and activities are limited to specific areas or they play only a subsidiary role of multilateral and bilateral aid agency support. NGOs therefore have limited influence in strengthening links between the UNFCCC and CBD on adaptation.

Conclusion

Ecosystem-based adaptation, which has the potential to improve biodiversity conservation and reduce climate change impacts simultaneously, is addressed by both the UNFCCC and CBD. This chapter explores the management of the interaction between climate change and biodiversity governance, which could enhance ecosystem-based adaptation efforts and maximize the positive effects of adaptation on both climate change and biodiversity. This research used the conceptual framework of interplay management in international politics.

This chapter shows that the CBD has been involved in a greater number of tangible ecosystem-based adaptation activities than the UNFCCC, and coordinated ecosystem-based adaptation dialogue between the UNFCCC and CBD has been attempted. However, they are not fully coordinated because of the different characteristics of the two Conventions.

To promote ecosystem-based adaptation and improve collaboration between the UNFCCC and CBD, this research analyzed how the key actors can develop adaptation discourse and strengthen the links between the two UN Conventions when approaching the topic. The study suggests that to enhance links between the two Conventions, it is important to involve: the secretariats of UNFCCC and CBD, the JLG that links NAPA and NBSAP, multilateral aid agencies like the GEF that serve as financial mechanisms to the UNFCCC and CBD, numerous key actors, and the various national government ministries that address environmental problems in developing countries and who can coordinate relevant actors at the national level.

Environmental Law, Public Policies, and Climate Change: A Social-Legal Analysis in the Brazilian Context

Thiago Lima Klautau de Araújo

Contents

Abstract

This chapter aims to analyze the laws and public policies in relation to climate change in Brazil, its implementation, and concrete results. Through a review of legislation and state of the art, this chapter gives evidence to the positive and negative interventions of the public policies since the 1950s until the present moment, using some examples, such as the bad initiative of construction of roads that promoted the deforestation and the good work made in Paragominas, Pará, to reduce environmental degradation and deforestation. As results, this chapter proposes a new perspective of the environmental law and reveals its importance in order to cope with the challenges of climate change and environmental issues, in an integrative way. In order to do so, it seeks to integrate society and governments' efforts to make possible the changes in the present climate situation, as it has been made in some isolated cases, such as Paragominas.

Keywords
Climate change • Environmental law • Greenhouse gases emission • Public policies • Sustainable development

Introduction

Currently the approach to climate change focuses on technical issues and possible solutions for reducing the emission of greenhouse gases. Rising chances of international agreements and treaties are one of the, or perhaps the only, alternatives to the reformulation of the paradigm of the relationship between man and nature.

Little is said about the importance of environmental legislation and regional public policies as an alternative solution. It happens that, while it awaits a global decision, if nothing is done at national or local areas, the climate change issue is getting worse. International law is essential to resolve the issue, but alone will not take effect.

This is because law is an area full of meanings that makes sense to those related to a particular reality and so is considered a local knowledge (Geertz 1983). This chapter tries to rescue the importance of law and public policies for the solution of climate change problems, understanding that both are essential for achieving a positive or negative response.

Having as context the legal and legislative axe and the one of public policies, as a way to define, understand, and deal with the climate changes, this chapter was organized into three complementary parts. The first part is an overview of environmental issues discussed globally since the 1970s. The second part deals with the Brazilian environmental legislation and brings some challenges and inconsistencies between theory and practice. The third part discusses the need for the implementation of sustainable development as a tool for equalization of climate change problems; points out the good example of Paragominas, Pará; and discusses the importance of an integrated action across the whole society.

At all points, it is evidenced the need of a multidisciplinary and interdisciplinary analysis, where natural and social sciences are considered sources of environmental law, but it can also be an valuable tool for the practical implementation of the acquired knowledge in those areas.

Climate Change and Legislation: Old and New Environmental Problems That Societies Have to Deal with

Nowadays, climate change is recognized as the major environmental problem and has long been a matter of global concern of societies. Climate change public policies express the formal position of governments, somehow synthesizing scientific contributions, the political positions, and economic, social, and cultural constraints, “mainly emphasizing the mitigation and adaptive processes to CC and the possibilities of intervention at the level of ecosystems and human actions” (Alves et al. 2014).

In the public discourse, the debate on the need for change in public policy and on what role business and society has to perform in order to prevent the progression of global warming or to develop the mitigation of impacts caused by climate change is usual, among other phenomena associated with it. In international agreements and conventions, this is a very recurrent theme, in which countries commit themselves to freely accept targets for reducing the emission of greenhouse gases.

This innovation in discussions about environmental issues has resulted, around the 1970s and the 1980s, from the realization of the fact that the planet could, actually, join an unprecedented environmental crisis, caused by human activity, and whose main target would be mankind itself. In the words of Édis Milaré (Milaré 2009, p. 171):

> The sustainability of the planet is, without doubt, in the hands of man, the only being capable of, with his actions, break the dynamic equilibrium produced spontaneously by the interdependence of the forces of nature and modify the regulatory mechanisms that, under normal conditions, maintain or renew natural resources and life on Earth.
>
> It is not to be against progress, but to promote and harmonize the economic and social development with minimum environmental requirements, using and conserving the natural resources and commiserating synchronously (at the present time) and diachronically (through successive times) with all humanity. The fate of future generations is thus in the hands of present generations.

It is true that such international laws have the mission of transformation of the global mentality. But it is also true that the attention given to them is not the most satisfying and does not even make big differences in the situation.

The Kyoto Protocol, for example, was a very positive initiative in theory, but in practice it did not bring great results, since most countries did not comply and will not be able to meet its goals and others do not even come to sign it, as the United States.

The decrease or increase in the emission of greenhouse gases turns out to be much more related to public policies of national of local governments than actually to international agreements or treaties.

To understand the legal systematic of climate change and what is being done to combat them through laws, it is necessary to first understand the environmental legislation.

The specific case addressed in this chapter is that of Brazil, whose federal legislation on environment has many commendable points, but its application in everyday life does not get the expected results. This could end up meaning that a country that has enormous potential to be strategic and decisive in mitigating the effects of the uncontrolled environmental situation, end up turning over a polluter country.

Brazil's Environmental and Legal Contexts

The environmental issue in Brazil presents a slightly different situation from the global context. Despite being one of the first countries to formalize strict laws in the sphere of protection of environment, its territorial extent, the lack of political will and oversight, and insufficient resources for maintenance and expansion of certain state measures preclude effective implementation of law.

Already in 1967 was the creation of the Law n. 5197, which deals with the protection of wildlife (Brasil 1967). Many other laws came before the 1980s, a period in which there was a spread of environmental discourse, however, without actually producing effects in the real world.

What is considered the major mark in the Brazilian environmental legislation, and particularly interesting in this analysis of climate change, is the creation of the Law n. 6938, of August 31, 1981, which established the National Environment Policy (Brasil 1981).

This law provides incentives for environmental protection and defense against pollution, in order to balance the environment and preserve the biota, air, natural resources, etc. Despite not specifically addressing climate change in the conceptualization of the law, one can understand that they fall into the category of environmental degradation (Art. 3, II), as denoting "adverse change in the characteristics of the environment."

There is also needed to emphasize that some principles in the existing Law n. 6938/81 are related directly to the combat against climate change. They are presented in Art. 2 of that law and are listed as items. Let us look at the most important for this issue: I, government actions to maintain the ecological balance, considering the environment as a public asset to necessarily be secured and protected in order to allow its collective use; II, rationalization of land use, water, and air; VI, encouraging study and research oriented to the technologies for the rational use and protection of environmental resources; VII, monitoring the state of environmental quality; and X, environmental education at all levels of instruction, including community education, aiming to enable communities to participate actively in environmental protection.

It happens that this statute, although advanced for the time, only received regulation nearly nine years after its enactment, with the Decree 99.274/90 (Brasil 1990), which brought the form with which the National Environmental Policy could be implemented. For nine years, the law has had its effectiveness limited by the fact that it provided "what to do," but did not provide "how to do."

So it has been the rhythm of environmental policies in Brazil and is no different in relation to climate change. Emission control is regulated by the National Council of the Environment – CONAMA – through resolutions (a kind of normative with legal value reduced, compared to the laws). This greatly hinders the access of citizens to the rules, because it is necessary that it has a very specific legal knowledge to seek regulations conducted by environmental agencies.

However, this is not a prediction of the 1988 Constitution (Brasil 1988). In its Art. 225, the Constitution says: "Everyone has the right to an ecologically balanced environment, property of common use to people and essential to a healthy quality of life, imposing upon the Government and the community the duty to defend and preserve it for present and future generations." This is called the "principle of participation," which talks about the need for civil society to participate in the preservation, discussions, decisions, and surveillance.

This provision is important, but with the way it operates the Brazilian government today, it has not been fulfilled as it should. How to participate if the population has no access to effective legislation and regulation? How to help in the preparation of laws and regulations, if the competent organs are dressed of technicality but are influenced by economic power?

The Brazilian environmental doctrine (Milaré 2009, p. 194) states that there are three forms of popular participation in the protection of the environment:

> The planning and management of the environment are thus shared between the Government and society, since the environment as a resource for the development of mankind, is, of course, one of the highest expressions of the "common good."
>
> There is the need therefore to examine in what extent the Brazilian legislation contemplates public participation in environmental protection.
>
> Álvaro Mirra, in excellent exposition on the subject, points out three basic means by which social group can act:
>
> (i) Participating in the process of creating the Environmental Law;
> (ii) Participating in the formulation and implementation of environmental policies, and
> (iii) Acting through the judiciary.

However, it is almost impossible to have direct participation of the population in environmental issues. Not to be long on a subject that is important to this chapter, but it is not your main theme, we will analyze the situation of acting through the judiciary. There are five types of judicial actions, which are very rare to be used by the population. The main reasons for this are related to technical or specific legal issues (for example, it is difficult to find a lawyer specialized in environmental law or afford to pay one), and the legitimacy to propose a lawsuit in this field.

Not only the citizens do not have money to afford the costs of a lawsuit, as in almost all cases, the population does not know where to turn. The five possible actions are: direct action of unconstitutionality of a law or normative act; public civil action; popular action; collective writ; and writ of injunction. In the large majority of cases, the active role (legitimacy) is carried by the Public Ministry, which overloads the prosecution, and does not solve the situation. One has to make the observation that despite not being legitimized by law, doctrine and jurisprudence can claim to be bringing collective writ by the Public Ministry.

This reflects that although the five judicial means are celebrated by the doctrine (that considers them a meaningful intervention of population), in practice this popular participation through judiciary does not exist. One of the reasons that explain this situation is amount of bureaucracy to sue with a direct action of unconstitutionality, popular action, or writ of injunction. It is very common that people would rather give up before the action. In most cases, citizens don't know who are the authorities that have the legitimacy to propose the lawsuit.

This is one of the types of political influence on the environmental determination, and they exist in all forms of public policies for the environment.

There is much political influence in the decisions of an environmental nature that Brazil has limitations for emissions of harmful gases to human health, such as carbon monoxide, but has not yet established limits to vehicular emission of greenhouse gases such as carbon dioxide. The lack of this regulation is the opposite of all global policies aimed to minimize the degradation of the environment. In addition to this, the lack of emission control does not allow that cars circulating in Brazil are more economical and efficient, which, besides polluting the atmosphere and harming the climate, imposing more costs to Brazilians, both in private cars or public transport.

Regulating vehicle emissions is not as complicated as it sounds, even in the case of the Brazilian automotive industry. The manufacturing facilities in Brazil produce engines for several countries that have already established emission limits. The Brazilian automakers have the technology to build more economical engines, but they do not make them available to the domestic market due to a possible decrease in the profit margin, as the pieces for more efficient cars encumber production. As the cars sold in Brazil are already the most expensive in the world, market hardly would accept higher prices, which would force declining corporate earnings.

Something that is urgent is being stalled by economic interests. Since the 1980s there are discussions about the need to reduce vehicle emissions of carbon dioxide, but governments do not show concern in addressing this demand. Environmental congresses invoke that need for at least 10 years, but there is no practical advance in the regulations. Anfavea (National Association of Automobile Manufacturers) presses the government to postpone the limitations and thus gain time, as Anfavea did to delay turning airbags into required items of security, for example, or to increase the taxes for imported cars. Attitudes like these, as well as highly reprehensible, are extremely harmful to the environment, consumers, and the market.

We must mention that it is very important to change habits and tailor products to the needs of preserving and avoid catastrophic climate changes to come, and for this reason, the limitation of vehicular emissions of pollutants of all kinds is so necessary. More economical and efficient cars pollute less, and if they do not solve completely the problem, they would help to mitigate some aspects of climate change.

Another element that draws attention in Brazil is the kind of pollutant emissions. There are considerable emissions in agricultural activities, in deforestation, fires, transport, power generation (since the policy established by the governments of Lula and Dilma directed to energy sources privileging thermoelectric power plants), etc.

The main source of emissions of greenhouse gases in Brazil is deforestation that is being decreased for five consecutive years, and in 2012 Brazil registered the least amount of these gases in 20 years. The worrying fact is that the high emissions in all other branches mentioned above was alarming, especially in the energy sector with an increase of 126 % between 1990 and 2012 (Miranda 2013).

To get even worse this scenario, after years of decline in deforestation, between 2012 and 2013, there was an increase of 28 % in the deforested area (Miranda and Nublat 2013), which incurs more emissions and worsening climate change.

The Brazilian Federal Government fails to invest in environmental enforcement, not to restrain conduct detrimental to the environment and not to encourage the prevention of environmental damage. It does not stimulate popular participation in environmental protection and also does not promote environmental education in schools. In the long term this is extremely harmful, since mankind races against time and tries to remedy the damage already installed on the grounds of lack of appreciation of the importance of the environment and climate balance.

However, some measures have enabled local governments amazing changes in this pessimistic scenario.

The Effects and Side Effects of Public Policies

In addition to the principles laid down in the Constitution, it is necessary to articulate public policies in all sectors in order to make possible to solve social problems, protect the environment, and develop the economy.

These three points mentioned above are the basis for sustainable development. It is hard to achieve the point of balance between them, but it enables real progress as it combines advances in all relevant areas to society.

Brazilian public policies in general, have failed in recent years, especially considering the catastrophic results of federal government interventions since the end of the 1950s until the present time.

On becoming president of Brazil, Juscelino Kubitschek – loved or hated political figure in Brazil – motivated by interests which are not ours to comment on this chapter, encouraged what would be the biggest mistake of Brazilian history since the proclamation of the republic: the destruction of railroads and their replacement by roads. Began the works starting in Brasilia and trying to interconnect it with other cities, Juscelino did the federal government getting numerous debts – which are still being paid – for the construction of several roads to major Brazilian cities, called BRs.

The intention was to develop the national automobile industry, which until then only produced the "refined" Romi Isetta (version BMW Isetta) and Fusca (VW Beetle), both with 100 % of imported pieces. Indeed, the creation of highways has greatly increased the production, sale, and diversity of national car models; however, the negative effects were extremely negative.

There was degradation of the Amazon forest, with numerous fires, eliminating several green areas and the beginning of landholdings in the region. This degradation affected strongly the environmental biodiversity, delivered over the years, at least hundreds of millions of tons of carbon into the atmosphere.

Some of these roads were created within areas of native vegetation, native forest that is absolutely necessary for the ecological balance. It happens that these roads ultimately attract people who did not have land in other regions of Brazil, to occupy marginal lands to BRs. The state of Pará was one of the most affected and still suffers from the almost uncontrollable deforestation. The majority of municipalities in this federal unit were created as a consequence of this road expansion, because there were no such settlements before installation of roads.

One of these newborn cities is Paragominas, Pará, near the BR-010, called the Belém-Brasília road. Planned from one of the defeated projects for the construction of the Federal Capital, Paragominas was a small town, but because of its diverse forest, mineral resources and its strategic location began growing faster than his frame stand (like Belém after the construction of the highway), and the chaos was settled.

Paragominas was known internationally by the number of homicides, by the increasing violence, environmental degradation, and the high rate of deforestation. As a way of getting this scenario worse, another activity developed in the region was the production of charcoal, highly polluting and greenhouse gas emitter.

This city was the example of chaos and lack of public intervention, both in environmental and climate issues. The emission of gases arising from fires and charcoal production contributed not only to the increase of global temperature but also to the occurrence of respiratory problems in the population, especially in the summer season (in the Amazon there is only summer and winter), when the proliferation of smoke coming from those predatory activities was common.

However, with a well-succeeded articulation between the city government, the state government, farmers, and population, Paragominas radically changed its course. Currently, it is known as a fine example of the performance of the government that can change the reality of a place and positively modify the relationship between man and nature. The deforestation started to be near to zero, and the deforestation area was 0.032 % in 2012 (Instituto Ethos et al. 2013).

Government intervention occurred in several areas, as has been well elucidated by a Brazilian magazine of general circulation (Barbosa 2011):

> Over time, the project that was born of a social pact was expanding partnerships with government institutions and the private sector. Then Paragominas decided to be the first municipality in Pará to monitor and verify deforestation, in a partnership with the Institute of Man and Environment of Amazon (Imazon). In one year they achieve a reduction of almost 90 % in deforestation. In March 2010, the Ministry of Environment announced the exclusion of Paragominas from the list of the largest Amazon loggers.
>
> Currently, the city has 66 % of preserved forests and vast extension of Permanent Protection Areas in agricultural properties. Inspired by the social and environmental transformation of Paragominas, 94 other municipalities of Pará today develop similar initiatives.
>
> "Before, to grow, we were destroying the forest. Now, we are the municipality that restores more green areas in the Amazon," boasts Demachki. The importance of preserving the environment is diffused by a program of environmental education in schools. "It is our mission and converge arms and minds towards social development and environmental preservation," says.

This successful example was adopted as a reference to 11 other cities in Pará (Carvalho 2011), which joined the Green Cities Program of the state government in order to get out of the list of cities that most deforest the Amazon forest.

The most important lesson that can be drawn from the case of Paragominas is that it is possible to recover environmentally highly degraded areas, help the planet, and interfere positively to the reduction of global warming, without losing the ability of economic growth. The ones who visit the city have a good surprise to find that it is a lively, cheerful, well-urbanized, organized city, with a dynamic and growing economy, where the population have excellent quality of life.

However, such results would be much easier to achieve if they would not be dependent on the political will. What occurred in that city is a reflection of a good relationship between all sectors of society, with the collective effort to balance a state of degradation.

The global challenge of public policies related to climate change is exactly the same that was in Paragominas: changing paradigms of using natural resources so that people can live better. Although, in a global scale, local differences between political groups are replaced by very expressive differences between countries and economic forces, which defend at all costs to maintain the environmental problems that currently occur.

Something has to be done urgently. However, one cannot expect that people individually can solve the problem of climate change, because the major causes for greenhouse gas emissions are not only the individuals. Governments need to intervene in an integrated and systematic way. But it seems that countries are waiting to see who will be the first to take steps in this direction. No nation is truly committed to tackling climate change without first checking if other competing countries will.

The restriction of pollutant emissions is often misunderstood because it’s seen as implying a decrease in industrial capacity and production of a country. But this is not true, if we observe that what is needed is to check the other alternatives and doing so to prevent recession or economic downturn.

Paragominas reached a stable social and economic level, even without degrading nature, and keeping their activities into new ecological standards. If it was possible there, it is possible globally. Undoubtedly it was possible using a tool often overlooked and discredited, called “public policy.”

Conclusions

National environmental laws, combined with effective and integrated public policies created by the dialogue between producers, investors, local power, and population, can effectively contribute to an improvement in climate change solutions.

International laws and treaties will only take effect if built on a structural transformation of industrial production and ways to maintain, or improve, economical context of the signatory countries, never forgetting that are indeed less polluting alternatives and viable solutions.

Paragominas managed to continue growing and producing wealth, however, without destroying and degrading the municipal area, preserving the environment and health of all citizens. This is possible globally, if there is the participation of companies and local governments, sharing good examples and building a more positive reality for all.

Financing Adaptation to Climate Change in Developing Countries

Kanako Morita and Ken'ichi Matsumoto

Contents

Abstract

Adaptation assistance is a key element in promoting adaptation measures in developing countries. However, adaptation finance has not fully met the needs of adaptation in developing countries because of its limited amount and ineffective distribution. This chapter provides implications for designing more effective financing for adaptation under the United Nations Framework Convention on Climate Change, by analyzing the characteristics of two types of existing adaptation financing targeting Asia–Pacific developing countries: (1) multilateral adaptation funds related to the Global Environment Facility (GEF) and (2) bilateral

official development assistance. The effects of the two financing schemes are compared, focusing on their financing rules and procedures and their targets and effects. The chapter shows that the adaptation finance schemes have strengths and weaknesses. The GEF-related multilateral adaptation finance has the potential to bring together various donors and organizations in implementing adaptation, while it has complex financing procedures and rules. Bilateral official development assistance is able to provide more adaptation finance, while it is more influenced by donors' interests. To promote adaptation activities effectively in developing countries, there is a need for an international framework for coordinating adaptation financing that enhances the strengths and minimizes the weaknesses of both financing systems.

Keywords
Financing • Adaptation • Global environment facility • Bilateral official development assistance • Asia–Pacific

Introduction

Climate governance involves the provision of financial resources to developing countries which are vulnerable to climate change. Assistance for adaptation to climate change is one of the key elements in promoting adaptation measures in developing countries. Developing countries are expected to be more affected by climate change than developed countries (IPCC 2007) because of geographical reasons and the lack of capabilities, financial resources, and technologies to implement adaptation measures. Further, climate change will ultimately threaten to prevent developing countries from achieving and sustaining their poverty reduction and development goals.

Under the United Nations Framework Convention on Climate Change (UNFCCC), developing countries have called for developed countries, which are primarily responsible for climate change, to assist their implementation of adaptation. The UNFCCC article 4, paragraph 4, calls for developed countries to assist developing countries "that are particularly vulnerable to the adverse effects of climate change in meeting costs of adaptation to those adverse effects," and financing for adaptation has been one of the key agendas in the UNFCCC negotiations on adaptation.

Three adaptation-related funds – the Special Climate Change Fund (SCCF), Least Developed Country Fund (LDCF), and Adaptation Fund – were established under the UNFCCC and the Kyoto Protocol, in the seventh session of the Conference of the Parties (COP) to the UNFCCC in 2007. In the sixteenth session of the COP in 2010, the Cancun Agreements were adopted; the agreements included US$30 billion in fast-start financing from developed countries to support both mitigation and adaptation in developing countries up to 2012, and the intention to raise a further US$100 billion per year by 2020. At the meeting, the parties also decided to establish the

Green Climate Fund, which aims to support developing countries by financing mitigation and adaptation projects, program policies, and activities (launched in the next COP meeting in 2011).

Further, developed countries have started to finance adaptation-related activities through official development assistance (ODA), and multiple aid agencies, international organizations, and nongovernmental organizations (NGOs) have started to assist adaptation in developing countries.

However, current adaptation finance has not fully met the needs of adaptation in developing countries. This is because of not only the lack of adaptation finance but also the lack of effectiveness of the distribution of adaptation finance.

This chapter presents implications for designing more effective financing for adaptation under the UNFCCC, by analyzing existing multilateral adaptation funds under the UNFCCC and the Kyoto Protocol and bilateral ODA for adaptation, targeting developing countries in the Asia–Pacific region.

Multilateral and Bilateral Finance for Adaptation

Although the estimates of costs of adaptation for developing countries are vague because of the complexity and variety of adaptations, all the estimates suggest the adaptation costs in developing countries will be in the ballpark of tens of billions of US dollars per year (UNDP 2007; UNFCCC 2007) or even higher, at US$70–100 billion per year (World Bank 2010).

Compared with the level of discussion on how to mobilize funds to achieve the adaptation needs of developing countries, there has been less discussion on the effective distribution of financing for adaptation. To mobilize finance for adaptation and to increase the willingness of donors to increase funds, it is necessary to show how funds are used. This chapter focuses on multilateral adaptation funds under the UNFCCC and the Kyoto Protocol, and bilateral ODA for adaptation outside the UNFCCC.

Multilateral Finance for Adaptation: Funds Related to the Global Environment Facility (GEF)

In the case of multilateral finance, this chapter focuses on GEF-related multilateral adaptation funds, which are the SCCF, LDCF under the UNFCCC, Adaptation Fund under the Kyoto Protocol, and GEF Trust Fund. The GEF operates the SCCF and LDCF, which are funded by voluntary contributions from individual countries. The GEF provides secretariat services to the Adaptation Fund Board on an interim basis, and the Adaptation Fund Board supervises and manages the Adaptation Fund (Decision 1/CMP.4 [decision adopted by the fourth session of the COP serving as the meeting of the Parties to the Kyoto protocol]).

(1) SCCF: Finances projects relating to adaptation; technology transfer and capacity building; energy, transport, industry, agriculture, forestry, and waste management; and economic diversification (UNFCCC Decision 7/CP.7). The SCCF has received approximately US$189 million as of October 1, 2012 (GEF/LDCF.SCCF.13/Inf.02).
(2) LDCF: Supports a work program to assist LDC Parties to carry out, inter alia, the preparation and implementation of national adaptation programs of actions (UNFCCC Decision 7/CP.7). The LDCF has received approximately US$370 million as of October 1, 2012 (GEF/LDCF.SCCF.13/Inf.02).
(3) Adaptation Fund: Finances concrete adaptation projects and programs in response to the Kyoto Protocol in developing countries that are particularly vulnerable to the adverse effects of climate change. It is financed by a share of proceeds of the Clean Development Mechanism (CDM) project activities and other sources of funding. The CDM allows a country with an emission-reduction or emission-limitation commitment under the Kyoto Protocol to implement an emission-reduction project in developing countries, and such projects can earn saleable Certified Emission Reduction credits, each equivalent to one ton of CO_2, which can be counted toward meeting Kyoto targets (UNFCCC 2013a). The share of proceeds amounts to 2 % of Certified Emission Reductions issued for a CDM project activity. The Adaptation Fund is supervised and managed by the Adaptation Fund Board, which comprises 16 members and 16 alternates and meets at least twice a year (UNFCCC 2013b). There is a strong mandate from the UNFCCC (LDCF and SCCF) and the Kyoto Protocol (Adaptation Fund) to keep these as distinct funds, and the Adaptation Fund is unique in its revenue regime, the composition of its governing body, and the "direct access" modality (the Adaptation Fund provides eligible developing countries direct access to the fund; GEF 2009). The Adaptation Fund has received approximately US$325 million as of March 31, 2013 (AFB/EFC.12/8).

GEF also operates its GEF Trust Fund, which has been the primary financial source of the GEF and also supports adaptation. The GEF, established in 1991, is the largest public funder of projects to improve the global environment (GEF 2013a), and the GEF provides grants in seven different areas: biodiversity; climate change; chemicals; international waters; land degradation; sustainable forest management/reducing emissions from deforestation and forest degradation in developing countries (REDD+), one of the climate change mitigation measures discussed under the UNFCCC; and ozone layer depletion. Additionally, the GEF supports cross-cutting issues and programs: results and learning of the projects, earth funds and public–private partnerships, capacity development, small-grant programs, country support programs, and gender mainstreaming (GEF 2013b). The GEF formally serves as a financial mechanism for the UNFCCC, Convention on Biological Diversity, Stockholm Convention on Persistent Organic Pollutants, and United Nations Convention to Combat Desertification and supports the implementation of the Montreal Protocol on Substances that Deplete the Ozone Layer (although there is no formal link between the GEF and Montreal Protocol). The GEF is managed by 10 implementing agencies, namely, the

United Nations Environment Programme, United Nations Development Programme (UNDP), World Bank, Asian Development Bank, African Development Bank, European Bank for Reconstruction and Development, Food and Agriculture Organization of the United Nations, Inter-American Development Bank, International Fund for Agricultural Development, and United Nations Industrial Development Organization (GEF 2013c).

The GEF Trust Fund is replenished every 4 years. During the period of GEF 4 from 2006 to 2010, adaptation measures were supported by Strategic Priority on Adaptation (SPA) funding (US$50 million), which was provided by the GEF Trust Fund. The SPA was a groundbreaking initiative designed to support pilot and demonstration adaptation projects that provide real benefits and can be integrated into national policies and sustainable development planning (GEF 2013d). In GEF 5, from 2010 to 2015, adaptation-related works are financed through the LDCF and SCCF, and the GEF Trust Fund does not finance adaptation.

Bilateral Finance for Adaptation: Bilateral ODA

With regard to bilateral finance for adaptation, bilateral ODA outside the UNFCCC including European countries, Japan, and Australia has supported adaptation in developing countries. For example, so far, Japan, Germany, and Australia are the three largest bilateral donors financing adaptation in developing countries in the Asia–Pacific region. In 2010 and 2011, Japan financed US$2486 million, Germany US$480 million, and Australia US$318 million.

The Organisation for Economic Co-operation and Development (OECD), of which the developed countries mentioned above are members, has worked mainly on three areas on adaptation: (1) economic aspects of adaptation (providing guidance on a range of different economic policies and tools that countries will need to implement efficient adaptation), (2) adaptation and development (work to integrate effective adaptation into development activities for developing countries), and (3) adaptation in OECD countries (helping developed countries to ensure that key economic sectors and vulnerable groups are prepared for adaptation; OECD 2013a). The second area focuses on providing guidance for bilateral donors, by providing policy guidance to offer concrete information on how to facilitate the integration of adaptation within development processes (OECD 2009), providing an overview and assessment of tools for screening climate risks and integrating adaptation into development planning processes (Hammill and Tanner 2011), and providing the first empirical assessment of monitoring and evaluation frameworks used by development cooperation agencies and sharing lessons learned and common characteristics of monitoring and evaluation for adaptation (Lamhauge et al. 2012).

Unlike the case for GEF-related multilateral adaptation funds, it is difficult to track the process of adaptation finance from bilateral ODA. Atteridge et al. (2009) calculated the amount of annual adaptation finance (as ODA) of Agence Française de Développement, the Japan International Cooperation Agency (JICA), and the German Development Bank in 2008, but there were no comprehensive data on adaptation finance of bilateral ODAs. In December 2009, the OECD Development Assistance Committee (DAC) members approved a new marker to track aid in support of adaptation, which complements the existing climate change mitigation marker and allows the presentation of a more complete picture of aid in support of developing countries' efforts to address climate change (OECD 2013b). Data have been obtained using the adaptation marker since 2010. In 2011, DAC members also agreed to extend the application of the mitigation and adaptation markers to non-concessional development loans (OECD 2012). According to the OECD data, OECD countries provided approximately US$16795 million in the form of bilateral ODA to assist adaptation in developing countries in 2010 and 2011 (OECD Creditor Reporting System database, see p. 5).

Research Approach

In adaptation research, financing for adaptation has begun to receive more attention (Klein et al. 2007; Möhner and Klein 2007; Barr et al. 2010). However, much discussion and research have focused on how to mobilize adequate funds to promote adaptation in developing countries (Müller 2008; Persson 2011; Eisenack 2012), and there has been less discussion regarding effective and efficient ways to distribute these funds (Barr et al. 2010; Fankhauser and Burton 2011). There has not been much progress toward the design of effective and efficient financing for adaptation in developing countries.

This chapter analyzes the characteristics of existing multilateral and bilateral adaptation financing for developing countries in the Asia–Pacific region, by focusing on how the financing is allocated to these countries, which is an important element in examining the effectiveness of the financing. As mentioned above, this study focuses on two types of funding sources: (1) GEF-related multilateral funds for adaptation, namely, the SCCF, LDCF, Adaptation Fund, and GEF Trust Fund and (2) bilateral ODA adaptation finance. The effects of the two financing systems are compared, focusing on their differences and similarities in how finances for adaptation are distributed and the institutional barriers to finance for adaptation. To be more specific, this study analyzes (1) adaptation financing rules and procedures and (2) adaptation financing targets and effects (i.e., characteristics of adaptation distributions by country and sector). With regard to the GEF-related multilateral adaptation funds, this study especially focuses on the SCCF and LDCF as these are the two major adaptation-related funds that the GEF is currently managing.

This research uses not only the qualitative data from related reports published by donors and NGOs and academic papers but also quantitative data from databases mainly constructed by the GEF, OECD, and Climate Funds Update, as described below.

(1) GEF Project Database (GEF 2013e): The GEF provides information on projects that are funded by the GEF Trust Fund, and also the SCCF and LDCF. Also, adaptation project data received from GEF officers are used (GEF 2013f, g).

(2) OECD Creditor Reporting System (CRS) database (OECD 2013c): Unlike the DAC annual aggregates database, which provides comprehensive data on the volume, origin, and types of aid and other resource flows, the CRS provides detailed information on individual aid activities, such as information on sectors, countries, and project descriptions. As stated above, in 2010, an adaptation marker was added to the CRS database, and adaptation data have been collected since 2010 using the marker.

(3) Climate Funds Update (Climate Funds Update 2013): This database is a joint initiative of the Heinrich Böll Stiftung and the Overseas Development Institute. Climate Funds Update tracks all multilaterally governed funds focused on climate change and major bilateral initiatives. The database focuses on the funding of adaptation, mitigation, and REDD+.

This study focuses on developing countries in the Asia–Pacific region, which include Bangladesh, Bhutan, Cambodia, China, Cook Islands, Fiji, India, Indonesia, Kiribati, Lao PDR, Malaysia, Maldives, Marshall Islands, Mongolia, Myanmar, Nepal, North Korea, Pakistan, Palau, Papua New Guinea, the Philippines, Samoa, Singapore, Solomon Islands, Sri Lanka, Thailand, Timor-Leste, Tonga, Tuvalu, Vanuatu, Vietnam, Micronesia (Federated States of), Nauru, Niue, Tokelau, and Wallis and Futuna. The countries include small-island developing states (SIDS) and LDCs that are particularly vulnerable to climate change. SIDS in Asia Pacific include Fiji, Kiribati, Micronesia (Federated States of), Nauru, Palau, Papua New Guinea, Samoa, Singapore, Solomon Islands, Timor-Leste, Tonga, Tuvalu, Vanuatu, Cook Islands, and Niue. LDCs in Asia Pacific include Bangladesh, Bhutan, Cambodia, Kiribati, Lao PDR, Myanmar, Nepal, Samoa, Solomon Islands, Timor-Leste, Tuvalu, and Vanuatu.

Adaptation measures involve multiple sectors. This study uses the following categories of adaptation: water (water supply and sanitation), natural resource management (biosphere and biodiversity protection), agriculture (agriculture, forestry, fishing, and food), infrastructure (social infrastructure and services, transport, communication, energy, industry, mining, construction, tourism, and education), human health (health and population), disaster risk management and coastal zone management (reconstruction relief and rehabilitation, disaster prevention and preparedness, and emergency response), and others (climate information services, etc.).

Characteristics of Multilateral and Bilateral Adaptation Finance

Institutional Strengths and Challenges in Implementing the Rules and Procedures for Adaptation Financing

GEF-Related Multilateral Adaption Finance

As mentioned above, the SCCF, LDCF, and GEF Trust Fund are all managed by the GEF, and the GEF also provides secretariat services to the Adaptation Fund Board on an interim basis. This section mainly focuses on the SCCF and LDCF rules and

Source: GEF 2011a, b

procedures. Table 1 shows the processes and key concepts in preparation for project implementation in the SCCF and LDCF project cycle. The project cycle for the SCCF is similar to that employed by the GEF Trust Fund, while that for the LDCF is more streamlined than that employed by the GEF Trust Fund. Each of the stages of the project cycle is approved by the LDCF/SCCF Council and/or GEF chief executive officer (CEO). The GEF Agency works closely with the country at each successive step and ultimately assists the country in implementing the project (GEF 2011a, b).

Following the CEO endorsement of the project, the SCCF and LDCF funding is ready to be released to the country through the implementing agency, and the project can begin implementation. The implementing agency is responsible for preparing specific reports during certain stages of the project, and the agency is required, for example, to submit project implementation reports on an annual basis and to submit a terminal evaluation to the GEF Evaluation Office within 12 months of the operational completion of a project (GEF 2011a, b). To measure the progress and results of the project, the GEF secretariat and its agencies have developed a Results-Based Management Framework. The work plans of the Results-Based Management in GEF 5 include establishing and implementing an updated Annual Monitoring Review process for GEF 5, upgrading and integrating portfolio monitoring in the Project Management Information System, and developing tools to enhance portfolio monitoring (GEF/C.39/6/Rev.1). Furthermore, to assist the tracking of project-specific outcomes and output indicators, which are reported in the annual Project Identification Form, the LDCF/SCCF Adaptation Monitoring and Assessment Tool has been devised (GEF 2011a, b, 2013h).

The strength of the GEF in financing adaptation is that it operates funds in close connection with the UNFCCC. The UNFCCC requests that the GEF finances adaptation in developing countries. Additionally, since the financial mechanism of the GEF involves several implementing agencies, and co-funding agencies, the GEF is able to bring together various donors and organizations in implementing adaptation. The former CEO and Chairperson of the GEF, Monique Barbut, stated that the GEF is important in financing adaptation. She listed the general strengths of the GEF as follows:

> The GEF is a financial mechanism under the United Nations conventions. Unlike other aid agencies, the GEF receives guidance from the conventions. The GEF has institutional links with the United Nations conventions and United Nations systems. The legitimacy of the GEF is different from any other aid agencies. The GEF is able to fund the projects which produce the global environmental benefits. The GEF is able to support the environmental projects which have technical and institutional risks. GEF funding is based on grants. When an agency agrees to a loan, it has to be sure that the loan will be repaid and it thus has to ensure that only confirmed technologies are being used, so as to avoid large risks in the project. However, the GEF has not been built on this logic. The GEF is supposed to test new technologies in pilot projects and to be innovative, and it is able to do this because most of the GEF's assistance is from grants. (Interview with Monique Barbut, the CEO and Chairperson of the GEF, 23 May 2009). Other aid agencies only take little technical and institutional risks of the environmental projects. (Interview with Monique Barbut, 23 May 2009)

As for the strengths of the GEF in funding adaptation, she stated:

> The GEF is able to play a central role in coordinating a variety of people in different aid agencies and organizations. The GEF is only a funding mechanism and does not have enough money itself. However, the GEF is able to bring together the various donors and organizations to implement climate change adaptation projects, and is able to be a central part of the climate change adaptation financing. (While, for example, if the money is put to other aid agencies like the UNDP, the money will be used only for the UNDP projects.) The UNFCCC asks guidance and strictly review reports on climate change adaptation to the GEF. (Interview with Monique Barbut, 23 May 2009)

In this way, the GEF has general strengths in financing adaptation in terms of having strong links with the UNFCCC, receiving guidance from the UNFCCC COP, and involving multiple donors and organizations in the financing process. Additionally, since the GEF financing is based on grants that recipients do not need to repay, the GEF can take risks in implementing new pilot adaptation projects (Interview with Monique Barbut, 23 May 2009).

However, the general challenges facing GEF-related funds are as follows. First is that the GEF's governance structures are seen by developing countries as complex and weighted in favor of donor countries, and the rules and structures make accessing funding difficult and time-consuming (Mitchell et al. 2008). Second, there is a lack of transparency in decision making that appears to be the prerogative of powerful individuals (Mitchell et al. 2008). Compared with the one-country-one-vote voting procedure of the Adaptation Fund under the Kyoto Protocol, the GEF is subject to the traditional and, according to developing countries, far less democratic GEF voting procedure that requires a majority of both countries and donations to carry a vote (Grasso 2011, p. 364). This has been made evident by the negotiation processes of the Adaptation Fund; developing countries constantly demanded their inclusion in the governance structures of the Adaptation Fund and strenuously rejected the GEF as the financial entity to manage it, owing to their scant participation in the GEF governance system (Grasso 2010, p. 146). Thirdly, there is a fundamental concern about the low level and the lack of predictability of funding provided through the LDCF and SCCF (GEF NGO Network Statement on GEF Programming Strategy paper for Adaptation to Climate Change under the LDCF and SCCF [GEF Meeting on Financing for LDCF and SCCF, 4 April 2013]).

With regard to the complex and time-consuming processes, although funding through the GEF is not formally conditional, requirements attached to funding include burdensome reporting and co-financing criteria (Ayers and Huq 2008). For example, the LDCF and SCCF, addressing the adverse impacts of climate change, impose additional costs on vulnerable countries striving to achieve their development goals. The LDCF and SCCF finance the "additional costs" imposed on vulnerable countries to meet their adaptation needs due to the adverse impacts of climate change, while the costs associated with baseline development activities must be supported by co-financiers (Ayers and Huq 2008; GEF 2009).

Although the GEF Trust Fund is not used for financing adaptation in GEF 5, unlike the SCCF and LDCF, the GEF Trust Fund needs to act according to GEF principles. The two main principles of the GEF, regarding "global environmental benefits" and "incremental costs," particularly limit the implementation of adaptation projects. Concerning global environmental benefits, mitigation activities, which aim at reducing atmospheric greenhouse gas concentrations, clearly have global benefits; however, for adaptation activities, it is difficult to imagine how global benefits can be gained, for adaptation mostly takes place at the local level (Klein 2002). The SCCF and LDCF under the UNFCCC must follow the decision of the COP, and "additional costs," which SCCF and LDCF finance, cover the full cost of adaptation if the developing country already has resources for its basic development program. Conversely, the GEF Trust Fund's "incremental costs" associated with transforming a project with national benefits into one with global environmental benefits are more difficult to identify.

Table 2 shows the major distinctions between the GEF Trust Fund and SCCF/LDCF.

Bilateral ODA Finance for Adaptation

Bilateral ODA mainly supports adaptation in developing countries through mainstreaming adaptation into traditional ODA. Mainstreaming involves the integration of policies and measures that address climate change within development planning and ongoing sectoral decision making so as to ensure the long-term sustainability of investments and to reduce the sensitivity of development activities

Table 2 Distinctions between the GEF Trust Fund and SCCF/LDCF

	Conventional GEF Trust Fund	SCCF	LDCF
Project must have global benefits	Yes	No	No
Projects must have adaptation benefits	No	Yes	Yes
Funding allocated according to the Resource Allocation Framework or STAR[a]	Yes	No	No
Projects financed according to the "incremental costs" principle	Yes	No	No

Created from GEF (2011a, b)
[a]The recently denominated STAR has been developed for climate change mitigation (GEF 2009)

to both the current and future climates (Klein et al. 2007). OECD members agreed on the Declaration on Integrating Climate Change Adaptation into Development Co-operation at the meeting of the OECD DAC and the Environment Policy Committee at the ministerial level in 2006. Additionally, the Statement of Progress on Integrating Climate Change Adaptation into Development Co-operation was adopted at the 2008 DAC High-Level Meeting. As mentioned above, the OECD has worked on adaptation and development (work to integrate effective adaptation into development activities for developing countries) as one of its three main areas. The OECD has, for example, provided policy guidance to bilateral donors to help facilitate the integration of adaptation within development processes (OECD 2009) and provided an overview and assessment of tools for screening climate risks and integrating adaptation into development planning processes (Hammill and Tanner 2011). Further, the application of the adaptation marker to data beginning in 2010 has allowed the tracking of adaptation finance through bilateral ODA.

Although the OECD provides general policy guidance for integrating adaptation in development processes, each bilateral aid agency establishes its adaptation support strategy for developing countries. Japan is the largest bilateral ODA adaptation funder for developing countries in the Asia–Pacific region. Figure 1 shows the general environmental ODA from Japan to developing countries.

The JICA published the report *JICA's Assistance for Adaptation to Climate Change* (JICA 2007) and presented the JICA's possible cooperation for adaptation by sector, and the JICA's approaches to adaptation. Further, the report showed how existing development projects had potential effects on adaptation. Since then, the JICA has supported projects that will enhance adaptation effects. In 2011, the JICA published *JICA Climate Finance Impact Tool for Adaptation* (JICA 2011), which is a reference document that discusses issues in mainstreaming adaptation during the planning stages of country assistance strategies and individual projects by summarizing them as concepts and guidelines. Figure 2 shows the formulation processes for adaptation projects and business-as-usual development with adaptation options.

Each bilateral aid agency has its own strategy and focus. With regard to Germany, the German Technical Cooperation (GTZ), which is now part of the German Society for International Cooperation (GIZ), has worked on mainstreaming adaptation. The GTZ (GIZ) published a manual for practitioners, *Climate Change*

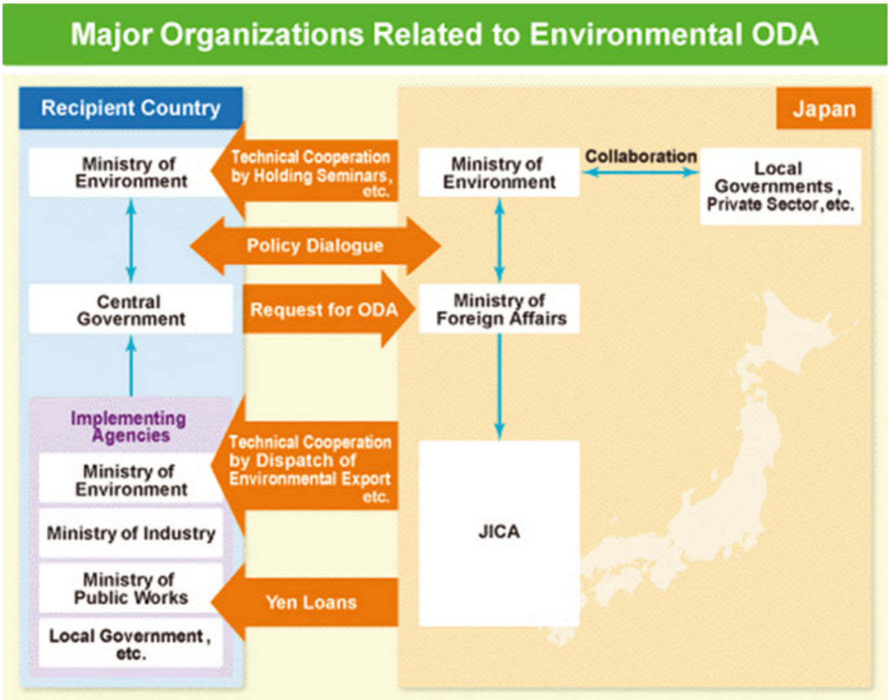

Fig. 1 Japanese environmental ODA (Source: Ministry of the Environment of Japan (2013))

Information for Effective Adaptation, which aims to enhance the capacity of those practitioners and decision makers in developing countries by translating relevant aspects of climate change research into their everyday working contexts, by describing the concrete steps of (1) how to obtain climate change information, (2) how to interpret it adequately, and (3) how to communicate the resulting knowledge in a careful and responsible way (Kropp and Scholze 2009). Further, the GIZ has developed a Climate Proofing for Development method. Applying Climate Proofing for Development at the scale of an entire country is a very efficient means of mainstreaming the issue of adaptation in national agendas and budgetary decisions (Hahn and Fröde 2011).

Bilateral ODA could use financial and human resources effectively and efficiently by mainstreaming adaptation into the development process, rather than by designing, implementing, and managing climate policy separately from ongoing activities (Klein et al. 2007). As mentioned above, several bilateral aid agencies such as the JICA and GIZ have started to integrate adaptation into their ODA activities. In this way, by mainstreaming adaptation into bilateral ODA activities, the recipients are able to make good use of bilateral aid agencies' experience and skills that have been acquired from previous development projects involving adaptation-related activities. Additionally, unlike the case for GEF-related financing, bilateral aid agencies can provide the full costs of projects, as they do not require co-funding from other donors. This makes it easier for developing countries (which have difficulty finding co-funders) to implement projects. Furthermore, bilateral aid agencies finance projects not only through grants but also by loans. Developing countries that have a relatively strong economic basis can thus implement large-scale projects funded by loans. In addition to the abovementioned benefits, when the interests of bilateral aid agencies match the needs of developing countries, the developing countries can more easily receive funds from bilateral aid agencies than from multilateral aid agencies.

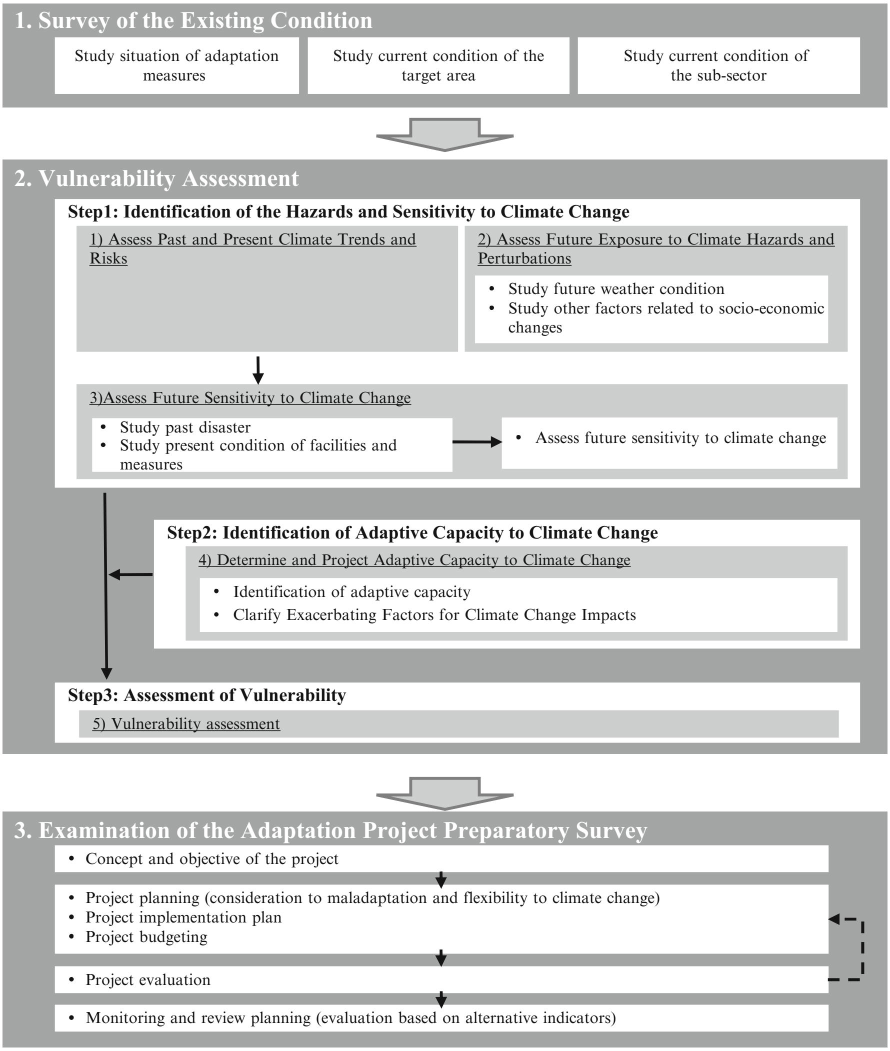

Fig. 2 (continued)

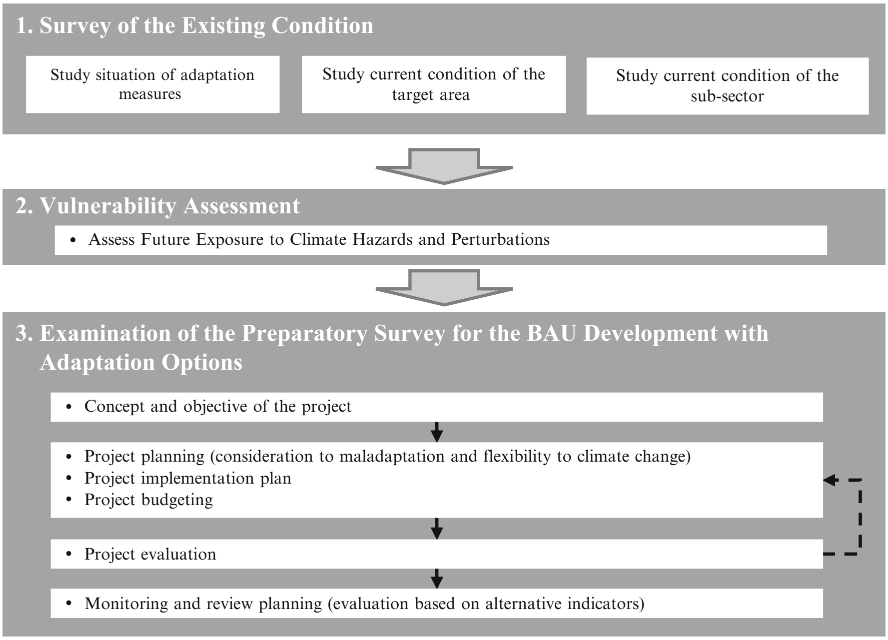

Fig. 2 Formulation processes for an adaptation project and business-as-usual development with adaptation options (Source: JICA (2011))

However, in general, the bilateral development assistance is one of the tools at the disposal of developed country governments as an element of their foreign policies and is usually aligned with their strategic objectives and interests, and the mix of aid motivations varies from one donor country to another and also over time (Sagasti et al. 2005, p. 69). Sagasti et al. (2005) described that there appear to be three main sets of rationales for development assistance: international solidarity and religious motivations, narrow and enlightened self-interest, and the provision of international public goods. For example, in general, Japan allocates more aid to its neighbors in East and Southeast Asia, which are also its main trade partners and the principal destinations of its foreign investments (IBON International 2009).

As described, when the interests of bilateral aid agencies match the adaptation needs of developing countries, it is likely that the developing countries will be more easily able to receive funds for adaptation from bilateral aid agencies than from multilateral aid agencies. However, since bilateral aid is generally more influenced by donor interests as compared with multilateral aid, when the interests of bilateral aid agencies do not match developing countries' adaptation needs, developing countries will have difficulty receiving sufficient funds. Furthermore, another controversial point in funding adaptation through bilateral ODA is the additionality to existing ODA commitments (i.e., ODA contributions at 0.7 % of gross national income). There are concerns that the use of existing funds such as ODA for adaptation could take the pressure off donors to provide additional resources (Yamin 2004) and that ODA-related adaptation activities are diverted from ODA commitments (Oxfam 2007).

Adaptation Financing Targets and Effects

The previous section compared the characteristics of two types of adaptation financing according to their rules and procedures. This section describes how these adaptation finances are actually distributed to adaptation in developing countries in the Asia–Pacific region quantitatively. As mentioned above, this study analyzes the allocation of adaptation finance using the data from the OECD CRS, GEF, and Climate Funds Update databases. Further, to examine the characteristics of distribution of adaptation finance to developing countries in the Asia–Pacific region, this research uses the accumulated amount of finance. This is because aid agencies usually provide finance to adaptation programs and projects that are implemented for several years, and the amount of finance in only a specific year does not present fairly the trends of distribution of adaptation finance. As for GEF-related multilateral adaptation funds, the total accumulated amount of finance is used. With regard to bilateral ODA, since the OECD has introduced an adaptation marker for data from 2010 onwards, the accumulated amount of finance for 2010 and 2011 is used.

Allocation of Adaptation Finance to Developing Countries in the Asia–Pacific Region

Financial support for adaptation contributed to developing countries in the Asia–Pacific region through multilateral funds is so far limited. As described in Table 3, GEF-related multilateral adaptation funds (accumulated) are much less than the accumulated amount of adaptation finance from bilateral ODA to developing countries in the Asia–Pacific region (total for 2010 and 2011). Further, although

Table 3 Adaptation finance for developing countries in the Asia–Pacific region (US$ million)[a]

GEF-related multilateral adaptation funds (accumulated)	Bilateral ODA adaptation finance of five major countries and the total (2010 and 2011)
SCCF: 75	Japan: 2486
LDCF: 181	Germany: 480
Adaptation Fund: 78	Australia: 318
GEF Trust Fund: 20	EU institutions: 243
	Korea: 202
Total: 354	Total: 4771

Data source: Climate Funds Update, OECD CRS, and GEF databases (detailed GEF data received from the GEF on June 5, 2013)

[a]The amount of GEF-related multilateral adaptation funds is approved and distributed dataThe amount of bilateral ODA adaptation finance reflects current prices

bilateral ODA provides more adaptation finance than GEF-related multilateral adaptation funds, the average share of adaptation financing to the total climate change finance in the Asia–Pacific region (total for 2010 and 2011) is only 29.8 %. This shows that the bilateral ODA has more interest in financing mitigation than adaptation.

Allocation of Adaptation Finance to Different Countries in the Asia–Pacific Region

Next, this study focuses on how the adaptation finance is distributed to each developing country in the Asia–Pacific region. Figure 3 shows the amount of finance that developing countries in the Asia–Pacific received from the four GEF-related multilateral adaptation funds. Table 4 shows the finance received from each GEF-related multilateral adaptation fund.

Note that “Regional” in Figure 3 and Table 4 is finance contributed to regional projects. The countries included in Regional 1 are the Cook Islands, Fiji, Marshall Islands, Micronesia (Federated States of), Nauru, Niue, Palau, Papua New Guinea, Samoa, Solomon Islands, Tonga, Tuvalu, and Vanuatu; Regional 2 comprises the Cook Islands, Fiji, Kiribati, Marshall Islands, Micronesia (Federated States of), Nauru, Niue, Palau, Papua New Guinea, Samoa, Solomon Islands, Tonga, Tuvalu, and Vanuatu; Regional 3 comprises Asia and the Pacific; and Regional 4 comprises Cambodia, China, Lao PDR, Myanmar, Thailand, and Vietnam. The same regions are used in Table 4.

Figure 4 shows the amount of adaptation finance that developing countries in the Asia–Pacific region received from all bilateral ODA. Table 5 presents the finance

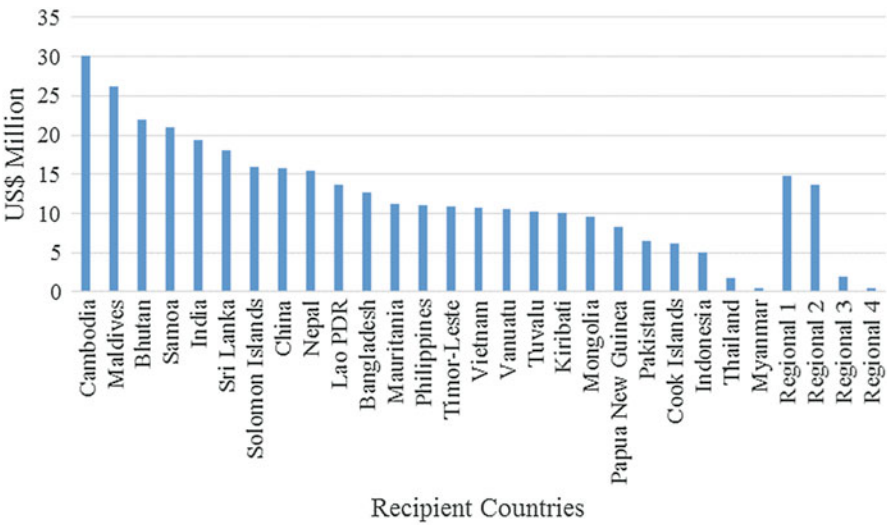

Fig. 3 Allocation of adaptation finance from four GEF-related multilateral adaptation funds to the Asia–Pacific region (Data source: Climate Funds Update database)

Table 4 Allocation of adaptation finance from the SCCF, LDCF, Adaptation Fund, and GEF Trust Fund to the Asia–Pacific region (million US$)

	SCCF		LDCF		Adaptation Fund		GEF Trust Fund (GEF4) – SPA	
1	China	15.8	Cambodia	24.0	Maldives	14.4	India	9.6
2	Regional 1	14.8	Bhutan	22.0	Sri Lanka	10.8	Sri Lanka	4.2
3	Philippines	11.0	Nepal	15.5	Samoa	10.2	Kiribati	4.1
4	Vietnam	10.7	Regional 2	13.7	Solomon Islands	8.6	Regional 3	2
5	India	9.8	Lao PDR	13.6	Papua New Guinea	8.3		
6	Indonesia	5.0	Bangladesh	12.7	Pakistan	6.5		
7	Sri Lanka	3.1	Maldives	11.8	Mongolia	6.5		
8	Mongolia	3.0	Timor-Leste	10.9	Cook Islands	6.2		
9	Thailand	1.7	Samoa	10.8	Cambodia	6.1		
10	Regional 4	0.5	Vanuatu	10.6

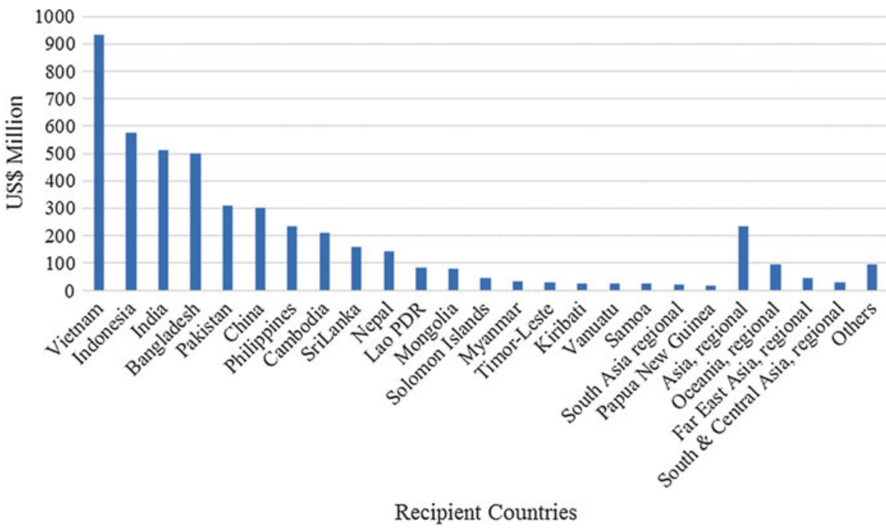

Fig. 4 Allocation of adaptation finance from bilateral ODA to the Asia–Pacific region (Data source: OECD CRS database)

that developing countries in the Asia–Pacific region received from three of the largest bilateral ODA funders (i.e., Japan, Germany, and Australia).

Note that "regional" includes finance to regional projects and initiatives. "Asia regional" comprises Far East Asia, South and Central Asia, and the Middle East.

Table 5 Allocation of adaptation finance from Japan, Germany, and Australia to the Asia–Pacific region (US$ million)

	Japan		Germany		Australia	
1	Vietnam	679.6	China	181.6	Oceania, regional	56.3
2	India	402.4	Vietnam	53.8	Solomon Islands	34.1
3	Indonesia	357.3	India	43.3	Indonesia	27.9
4	Pakistan	257.6	Bangladesh	40.4	Kiribati	21.9
5	Bangladesh	215.3	Lao PDR	32.5	Papua New Guinea	19.5
6	Cambodia	149.4	Asia, regional	22.8	Asia, regional	18.5
7	Sri Lanka	145.7	Philippines	22.7	Philippines	15.8
8	Philippines	144.3	Cambodia	17.2	Timor-Leste	14.8
9	Mongolia	41.6	Nepal	17.1	Vanuatu	14.2
10	Lao PDR	19.4	Far East Asia, regional	13.8	Vietnam	11.1

Data source: OECD CRS database

"Far East Asia regional" comprises Cambodia, China, Indonesia, Lao PDR, Malaysia, Mongolia, North Korea, the Philippines, Thailand, Timor-Leste, and Vietnam; "South and Central Asia regional" comprises Afghanistan, Armenia, Azerbaijan, Bangladesh, Bhutan, Georgia, India, Kazakhstan, the Kyrgyz Republic, Maldives, Myanmar, Nepal, Pakistan, Sri Lanka, Tajikistan, Turkmenistan, and Uzbekistan; "Oceania regional" comprises the Cook Islands, Fiji, Kiribati, Marshall Islands, Micronesia (Federated States of), Nauru, Niue, Palau, Papua New Guinea, Samoa, Solomon Islands, Tokelau, Tonga, Tuvalu, Vanuatu, and Wallis and Futuna. As the countries in the Central Asia and Middle East are outside the scope of this research, the data of finance to each country in these areas is not included.

Comparing GEF-related multilateral adaptation funds with bilateral ODA adaptation finance, GEF-related multilateral adaptation funds in general support adaptation in developing countries of the Asia–Pacific region more broadly in terms of having fewer gaps in financing among developing countries including SIDS and LDCs. However, bilateral ODA adaptation finance focuses on emerging countries such as Vietnam, Indonesia, and India. However, there are differences in the characteristics of adaptation finance among GEF-related multilateral adaptation funds and among bilateral ODA adaptation finance. As for GEF-related multilateral adaptation funds, compared with the SCCF and LDCF, which finance a wide range of developing countries and regional projects, the Adaptation Fund and GEF Trust Fund finance only a limited range of countries. With regard to bilateral ODA adaptation finance, Japan has intensively financed Vietnam (followed by India and Indonesia), while Germany intensively finances China (followed by Vietnam and India) in the Asia–Pacific region. Unlike Japan and Germany, which intensively finance adaptation in emerging countries, Australia intensively finances adaptation in the Oceania region including SIDS and LDCs, because the primary geographic emphasis of its adaptation program is on Australia's neighboring island countries (Australian Agency for International Development 2013).

Allocation of Adaptation Finance to Different Sectors in the Asia–Pacific Region

Figures 5 and 6 show that the financing targets of GEF-related multilateral adaptation funds and bilateral ODA adaptation finance differ. The former focuses on financing adaptation in disaster risk and coastal zone management sectors, while the

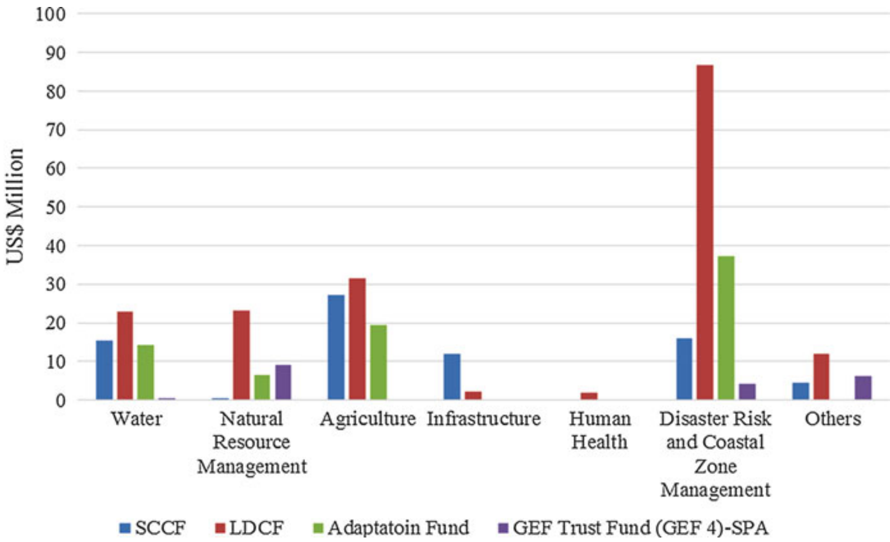

Fig. 5 Allocation of GEF-related multilateral adaptation funds to sectors in the Asia–Pacific region (Data source: Climate Funds Update and GEF databases)

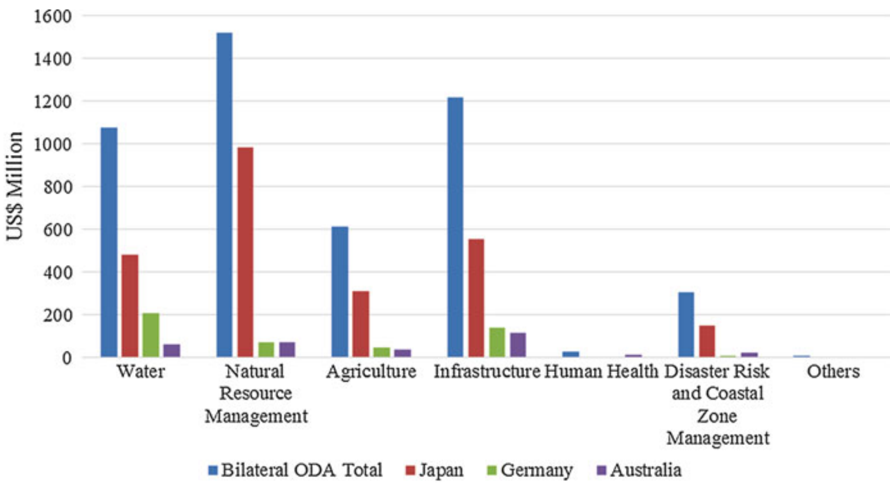

Fig. 6 Allocation of bilateral ODA adaptation finance to sectors in the Asia–Pacific region (Data source: OECD CRS database)

latter focuses on financing natural resource management, water, and infrastructure sectors. The differences in the main targeted sectors of the two types of financing probably arise from the differences in the adaptation needs of the main targeted developing countries in the Asia–Pacific region. Roughly, GEF-related multilateral adaptation funds mainly finance SIDS and LDCs in the Asia–Pacific region, which require adaptation in terms of disaster risk and coastal zone management, while bilateral ODA adaptation finance is mainly used by emerging countries that are likely to require assistance in natural resource management, water, and infrastructure sectors. Neither fund well finances adaptation in the human health sector.

Concluding Remarks: Creating an Effective Institutional Framework for Financing Adaptation

This chapter presented the characteristics of GEF-related multilateral adaptation funds and bilateral ODA adaptation finance, especially focusing on the distribution of adaptation finance to developing countries in the Asia–Pacific region. Finance for adaptation is one of the key elements of climate change governance.

By analyzing the rules and procedures and the financing distributions of the two types of adaptation financing, this study showed that both multilateral and bilateral methods of financing adaptation have various strengths and challenges, and different characteristics, and showed the importance of enhancing their strengths. For example, GEF-related multilateral adaptation funds are controlled in close connection with the UNFCCC. The GEF is able to bring together various donors and organizations in implementing adaptation projects and programs and also to comprehensively finance SIDS and LDCs in the Asia–Pacific region. Additionally, the funds are particular focused toward financing adaptation measures in the sectors of disaster risk management and coastal zone management in the area. However, the complex financing procedures and rules pose challenges to the effective implementation of GEF-related funds; the funds usually go toward additional costs or incremental costs of adaptation programs and projects and are limited compared with bilateral ODA adaptation finance.

Conversely, this analysis showed that bilateral ODA adaptation finance is larger and able to meet the full cost of adaptation projects. However, bilateral ODA is more influenced by donors' interests, and the bilateral aid agencies tend to focus on financing adaptation in emerging countries in the Asia–Pacific region. Additionally, each donor has different strategies in terms of their financing targets: countries and sectors. Bilateral ODA tends to finance more adaptation in the sectors of natural resource management, infrastructure, and water in the Asia–Pacific region, compared with GEF-related multilateral adaptation funds.

To promote adaptation activities effectively in developing countries in the Asia–Pacific region, this research shows that it is important to enhance the strengths of each financing scheme. In doing so, it is necessary to construct an international framework for coordinating adaptation financing. The Green Climate Fund, which was launched at the UNFCCC COP meeting in 2011, will finance both mitigation and adaptation actions in developing countries. To make effective use of the existing funds and new Green Climate Funds for adaptation, it is necessary to establish common rules and criteria to identify the needs of adaptation in developing countries and to monitor and evaluate the adaptation activities.

Acknowledgments This research was supported by grants from the Global Environment Research Fund of the Ministry of the Environment of Japan (S-11, S-10, and E-1201) and JSPS KAKENHI (24710046).

Contents

Abstract

India is among the developing countries that are vulnerable to climate change, while also in need to promote economic growth to alleviate poverty. To promote sustainable, low-carbon, and climate-resilient growth, India will require continuous efforts in mitigation and adaptation through Nationally Appropriate Mitigation Actions and National and State Adaptation Plans. This chapter analyzes the financial requirements for mitigation and adaptation in India and highlights that

Note: All financial estimates of Government of India in Indian Rupee were converted to US$ at the most prevailed rate of 2014, 1US$ = 60 INR

multilateral agencies' support in climate mitigation and adaptation has been higher in the past than the funds received through global funds established through climate change conventions. The chapter recommends that though continuous support of multilateral agencies will be required in the future, efforts to access mitigation and adaptation funds must be made through global climate change negotiations.

Keywords
India • Climate finance • Mitigation • Adaptation

Introduction

Dash et al. (2007), Goswami et al. (2006) showed considerable evidence of a changing climate in India, on increase in sea surface and land temperature and changes in rainfall pattern. The Indian Network for Climate Change Adaptation (INCCA 2010) report based on PRECIS model results (Kumar et al. 2006) predicts an average temperature rise of 2.0° centigrade in India with 1.0–4.0° centigrade at extreme ranges by 2050. The model also predicts increased annual precipitation, lower frequency of rainy days, and increased rainfall intensity. Cyclonic disturbances though in lower frequency are expected to be of increased intensity, and there is increased risk of storm surges and sea-level rise of 1.3 mm/year on average.

In India, climate change is likely to have severe impacts on key sectors like water (Gosain et al. 2006; Mall et al. 2006). Agriculture sector is expected to decline in production though there may be a short rise in production (Kavi Kumar 2007). The likely impacts of climate change on key sectors like agriculture and water combined with large rural population depending on a climate-sensitive sector for livelihood and with a low adaptive capacity due to poor socioeconomic conditions increase the vulnerability to future climate changes (Shukla et al. 2003; Brenkert and Malone 2005). Over 21 % of population are under below poverty line; the poverty level in rural and urban areas was estimated to be 25.7 % and 13.7 % respectively for the year 2011, and over 60 % of India's population are still rural and dependent on agriculture (Planning Commission 2013).

India is a developing country with low records of historic emissions. It is only after the economic reforms in the 1990s that the economy started to grow and the consumption of fossil fuels increased, leading to raising emissions. Despite its growth in emissions in the last two decades, India's per capita emissions are way below the world average of about 4.5 tonnes per capita (Table 1; Fig. 1).

Electricity sector alone contributes to over 38 % of total greenhouse gas (GHG) emissions. By October 2013, fossil fuels still contributed a large share – approximately two-thirds – of electricity production; coal constitutes about 58.75 % of India's primary energy resources followed by natural gas (8.91 %) and oil (0.52 %), while the rest is provided by nuclear (2.11 %), hydro (17.39 %), and other renewable energy sources (12.32 %) (Source: Ministry of Power 2013). With the economic

Table 1 Emission scenario in India

Years	Economic growth/GDP growth	CO_2 emission in billion tonnes	Per capita emission
1990	1.3	0.98	1.2
1994	7.3	1.23	1.3
2000	4.35	1.48	1.5
2007	9.60	1.99	1.6
2011	8.39	2.01	1.7

Source: NATCOM 2012

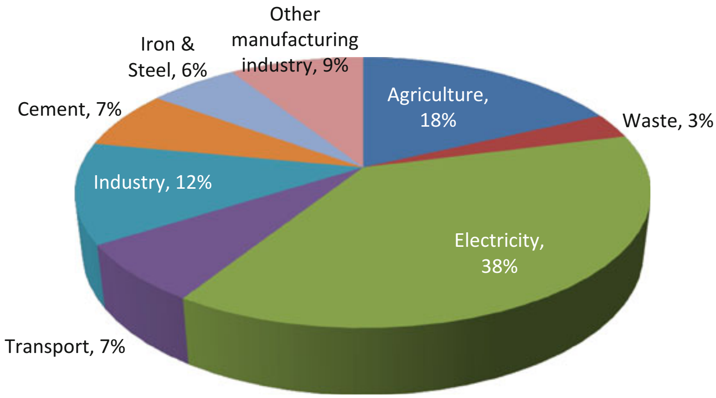

Fig. 1 Emission from various sectors (Source: INCCA 2010)

growth since the 1990s, the emissions have increased from 0.73 billion tonnes in 1994 to 1.02 billion tonnes in 2000 at a compounded annual growth rate (CAGR) of 5.5 % in the electricity sector, meanwhile in 2007, the energy sector emissions grew to 1.3 billion tonnes. A study on projection using different models estimates India's GHG emissions in 2031 to vary from 4.0 billion tonnes to 7.3 billion tonnes of CO_2 (Climate Modelling Forum 2009). The production of coal and power from coal is likely to be the major source of energy production in India in the coming years and shall remain the major cause of GHG emissions (NATCOM 2012).

Given the impacts and vulnerability of climate change in India, adaptation is very necessary and should at least be on a no-regret and co-benefit approach (Sathaye et al. 2006). To alleviate poverty in India, the 12th 5-year plan (2012–2017) aims at a faster economic growth, which shall mean raising GHG emissions as the economic growth is driven by high energy consumption especially produced from fossil fuels. The Government of India is committed to keep its per capita emissions below the world average and in 2009 declared that India's emissions on the intensity of GDP shall be aimed to be reduced by 20–25 % based on the 2005 level by year 2020. The remaining of this chapter will look at financial challenges for mitigation, adaptation, and low-carbon growth in India.

Mitigation and Adaptation Costs

This section looks at financial requirements for successfully implementing Nationally Appropriate Mitigation Actions such as the National and State Action Plans on Climate Change and to take economic growth in a low-carbon path. The financial requirement of scaling of renewable energy is also discussed.

National Action Plan on Climate Change (NAPCC)

In 2007, at the 13th Conference of Parties (COP) to the United Nations Framework Convention on Climate Change (UNFCCC), also known as the Bali conference, developing countries agreed to develop Nationally Appropriate Mitigation Action (NAMA), and subsequently, India released the National Action Plan on Climate Change (NAPCC) in June 2008.

The financial estimates and descriptions of NAPCC's missions are presented in the following table (Table 2).

A sum of about 58 billion US$ shall be required for successful implementation of the National Action Plan on Climate Change through the 12th plan period (2012–2017).

The State Action Plan on Climate Change (SAPCC)

The 16th COP to the UNFCCC held in 2010 at Cancun established the National Adaptation Plan (NAP) process as a way to facilitate effective adaptation planning in least developed and developing countries. NAPs are aimed at reducing vulnerability to the impacts of climate change, by building adaptive capacity and resilience, and to facilitate the integration of climate change adaptation in the countries' plans for economic development. In 2010, the prime minister of India urged the states to develop the State Action Plan on Climate Change (SAPCC) to decentralize NAPCC objectives, while addressing state-specific climate change issues. The SAPCC is a set of regional action plans on climate change prepared by the state government. SAPCCs are to be prepared according to a common and generic framework while providing scope for incorporating state-specific contexts and situations and, at the same time, be integrated into state-level planning process.

The SAPCC aims to mainstream climate change concerns in key sectors, although the states are free to choose their own focus sectors for the SAPCCs. Typical sector mix includes agriculture, forestry and biodiversity, water resources, energy, industries, mining, urban development, health, disaster management, and transport. The SAPCC should give targeted mitigation plans, for example, in energy sector, it should give present GHG emission scenarios, future energy needs, and how SAPCC shall address mitigation through energy efficiency or renewable energy. On the adaptation side, the SAPCC should identify vulnerable sectors and regions and develop adaptation plans.

Table 2 National mission on climate change

	Mission	Brief description	Estimated costs/ benefits for period 2012–2017	Details of financial estimates were derived from
1	National green mission	To reach national target of 33 % land area under forest and tree cover from the current level of 23 %. Mission to be taken up on degraded forest land through direct action by communities, organized through Joint Forest Management (JFM) Committees and guided by Department of Forests	9.42 billion US$	http://moef.nic.in/downloads/public-information/GIM-Report-PMCCC.pdf
2	National mission on energy efficiency	The mission aims to provide binding targets to designated consumers (DCs) to achieve energy efficiency during period 2011–2014. There are about 685 DCs mainly heavy industries and power sector that are required to specific energy consumption reduction targets. The mission works through a market mechanism of Perform, Achieve, and Trade (PAT), wherein the DCs can trade their excess credits to below achievers	The energy efficiency benefits is estimated to be about 12 billion US $ and can reduce about 98 million tonnes of CO_2	http://www.moef.nic.in/downloads/others/Mission-SAPCC-NMEEE.pdf
3	National solar mission	The mission targets include (i) deployment of 20,000 MW of grid-connected solar power by 2022, (ii) 2,000 MW of off-grid solar applications including 20 million solar lights by 2022, (iii) 20 million sq. m. solar thermal collector area, (iv) to create favorable conditions for developing solar	16 billion US$	http://mnre.gov.in/file-manager/UserFiles/draft-jnnsmpd-2.pdf

		manufacturing capability in the country, and (v) support R&D and capacity-building activities to achieve grid parity by 2022. The program also aims to reduce to the cost of solar power along with creating favorable conditions for solar manufacturing industry		
4	National mission on sustainable agriculture	Mission aims to devise strategies to make Indian agriculture more resilient to climate change. Identify and develop new varieties of crops (thermal-resistant crops, alternative cropping patterns, capable of withstanding extreme weather). Orientation of agricultural research systems to monitor and evaluate climate change and recommend changes in agricultural practices. Convergence and integration of traditional knowledge	18 billion US$	http://agricoop.nic.in/imagedefault/whatsnew/nmsagidelines.pdf
5	National water mission	The Overall objective is “Conservation of wter, minimization of wastage, and esuring its equitable distribution both across and within states through integrated water resource management”	4 billion US$.	http://wrmin.nic.in/writereaddata/nwm28756944786.pdf
6	National mission on sustainable habitat	Targets improvements in energy efficiency in buildings, management of solid waste, and accelerating modal shift to mass transport	9 billion US$	http://www.urbanindia.nic.in/programme/uwss/NMSH.pdf

(*continued*)

Table 2 (continued)

	Mission	Brief description	Estimated costs/ benefits for period 2012–2017	Details of financial estimates were derived from
7	National mission on sustaining Himalayan ecosystem	To evolve management measures for sustaining and safeguarding the Himalayan glacier and mountain ecosystem. The mission would seek to address the impacts in Himalayan region and establish community-based management of Himalayan ecosystems	0.2 billion US$	http://dst.gov.in/scientific-programme/NMSHE_June_2010.pdf
8	National mission on strategic knowledge of climate change	Mission to identify the challenges of and the responses to climate change through research. Understand the Socioeconomic impacts of climate change including impact on health, demography, mitigation patterns, and livelihoods of coastal communities. Establishment of network of dedicated climate change-related units in academic and scientific institutions	0.4 billion US$	http://www.dst.gov.in/scientific-programme/nmskcc_july_2010.pdf

Source: National Action Plan on Climate Change, Govt. of India

Many state governments have initiated SAPCCs, thanks to the technical and financial support from multilateral development agencies. The estimation of the costs of implementing SAPCC is cumbersome. A study has observed that existing estimates of costs, for both adaptation and mitigation, in the range of US$3–5 billion over a 5-year period for states of similar size and climate change challenges, are inconsistent mainly because of the variation in the methodologies adopted for vulnerability assessment, development of adaptation plans, and mitigation targets (Mandal et al. 2013). The total financial requirement for implementing the State Action Plans on Climate Change for all 28 Indian states can be about 120 billion US$ for the 5-year period (2012–2017) as estimated from the budgetary provisions provided by the SAPCC of various states.

Low-Carbon and Sustainable Growth

It is necessary for the country to explore all options of energy efficiency and increase renewable energy production (Parikh 2012), which are key efforts in mitigation as well as in low-carbon development. The Government of India established an expert group on low-carbon strategies for inclusive growth. The expert group submitted its final report in 2014, which notes that through appropriate strategies such as increasing share of renewable energy, energy efficiency, sustainable and low-carbon transport, improving carbon sequestration in forestry, and implementing building codes, the projected emission in 2030 can be reduced from 3.6 tonnes per capita to 2.6 tonnes per capita. However, the report estimates that around 834 billion US$ at 2011 prices shall be required over the two decades between 2010 and 2030 (Planning Commission 2014).

Renewable Energy Targets

Starting with the 9th plan period (1997–2002), India accelerated the pace of renewable energy development. India's renewable energy installed capacity has grown at an annual rate of 22 %, rising from about 3.9 gigawatt (GW) in 2002–2003 to about 28 GW in March 2013. Renewable grid power capacity contributes 12.88 % of India's total installed power capacity and is fast becoming an increasingly important part of India's energy mix. The Government of India has ambitious plans for renewable energy production in India. The National Solar Mission alone aims to establish about 22 GW by 2022. The consolidated funds required for grid-connected renewable energy technologies, biomass/agriculture waste, bagasse cogeneration, urban and industrial waste to energy, small hydropower, solar, and wind are about 2.2 billion US$, and off-grid renewable energy programs such as family biogas plants, biomass gasifiers from rural energy supply, decentralized solar photovoltaic system, micro-hydel water mills, and solar thermal systems for water heating and improved cook stoves are also to cost about another 3 billion US$ for a period (2012–2017) (MNRE 2011).

Adaptation and Mitigation Costs Summary

The estimates of mitigation costs vary from available data, and it shall depend on future policies on energy production/consumption and economic growth. The Stern review (2007) estimates that the loss due to climate change could be about 3–5 % of GDP per annum for developing countries, and (Urvashi et al. 2011) estimates for adaptation are in ranges of 70–100 billion US$ per annum for the developing world for the period 2010–2050. Though specific estimates of adaptation costs for India are not available, the estimates provided in State and National Action Plans on Climate Change by the Government of India adds to about 185 billion US$ (2012–2017), which is in range of scientific studies. The expert group on low-carbon growth of the planning commission estimated the costs for pursuing low-carbon growth to be about 834 billion US$ for a two decade period using low-carbon growth model, which is a multi-sectoral, dynamic optimization model that maximizes present discounted value of private consumption subject to commodity supply, natural resource, and technology constraints. Though accurate estimates on adaptation and mitigation are difficult, it can be concluded that India needs billions of dollars over the next two decades to implement its adaptation programs and take in a low-carbon path for economic development. The next section will look at financing options on mitigation and adaptation.

Financing Climate Change Mitigation and Adaptation

Measuring Mitigation and Adaptation Costs

For investment in mitigation and adaptation, India must carefully evaluate the costs and benefits and the possible trade-offs involved in investments. Use of policy instruments like carbon tax must also be understood to know its impacts on the economic growth. About 80 % of India's energy needs are met from fossil fuels; in this context, a number of studies have analyzed the patterns of energy usage and carbon emission and have evaluated the role of pricing and taxation policies in mitigation as well as revenue generation for investment in clean energy (such as Parikh and Gokarn 1993; Das et al. 2007; Murthy et al. 1997). Fisher-Vanden et al. (1997) assessed the option of carbon tax in India and concluded that participating in cap-and-trade (CAT) mechanism would be better for India than carbon taxes. The debate is still on for and against carbon taxes and domestic mitigation efforts that may incur GDP losses. This has led to dilemmas in fixing targeted emission reductions and estimating costs of mitigation.

Measuring the costs and benefits of adaptation at regional level is even cumbersome, which is a challenge in making informed decision or prioritizing domestic investments. Nambi et al. (2010) noted that an assessment of adaptation costs for India, as well as for subregions, is required for effective resource allocation. Adaptation costs estimated by Stern (2007) for India and other developing countries are also argued to be overestimates (Yohe and Tol 2008), which is mainly due to uncertainties in projections and impacts of climate change. This knowledge gap on understanding the mitigation and adaptation costs has led to challenges in estimates on adaptation and mitigation costs in India as noted in section "Adaptation and Mitigation Costs Summary."

Global Climate Finance for India

Based on the principle of equity recognized in global conventions like the UNFCCC, the developed countries are supporting developing and least developed countries in their adaptation and mitigation efforts. The first commitment period of the Kyoto protocol (2005–2012) provided much financial benefits in renewable energy and energy efficiency in India through the Clean Development Mechanism (CDM). India, during the first period of the Kyoto protocol, was a leading CDM beneficiary next only to China with over 470 projects registered with certified emission reduction (CER) close to 17 million tonnes. Almost 85% of CER came from the energy sector on both renewable energy projects and on improving efficiency in nonrenewable energy sector. This not only provided financial benefits close to US$ 300 million at the peak rate of 15 US$ per tonne of emission reduction but also provided scope for energy efficiency and increasing the share of renewable energy. However, CDM projects were not useful in supporting adaptation or sustainable development or helpful in alleviating poverty (Subbarao and Lloyd 2011) (Table 3).

Successful Case of CDM The Bachat Lamp Yojana (BLY) is a public-private partnership program introduced by the Bureau of Energy Efficiency (BEE) to hasten market transformation toward energy-efficient lighting in domestic households by providing compact fluorescent lamp (CFL) at subsidized rate. To reach out to 192 million households and targeted 400 million light points in India by 2011, with an electricity-saving potential of 20,000 MW (by 2011), BLY was the largest CO_2 reduction "program of activity" registered till date with CDM from India (*Source*: Bureau of Energy Efficiency, India. http://www.beeindia.in/schemes/schemes.php?id=1).

Reducing emissions from deforestation and degradation combined with conservation and sustainable management of forests is REDD+, which many developing countries, including India, have been pressing in global UNFCCC negotiations for financial incentives toward carbon mitigation through sustainable management of forests. While the National Green Mission is itself aimed at reducing deforestation

Table 3 Registered CDM project in India

S.I. no.	Sector	No. of projects	No. of CER (annual)	No. of CER (2012)
1	Energy industries (renewable/ nonrenewable sources)	850	69,555,674	19,061,210
2	Manufacturing industries	41	2,074,541	899,459
3	Energy demand	75	2,653,226	1,161,307
4	Waste handling and disposal	22	1,710,094	769,893
5	Metal production	3	877,754	1,257,076
6	Transport	4	964,777	288,670
7	Afforestation and reforestation	5	947,197	114,277
8	Fugitive emissions from fuel (solid, oil, and gas)	1	56,400	56,400
9	Chemical industries	3	320,114	247,946
10	Energy distribution	2	967,681	121,562
Total		1,006	80,127,457	23,977,800

Source: cdmindia.gov.in

and increasing forest cover, the financial requirement to successfully implement the mission can be made available through REDD+ mechanism. Though the REDD + mechanism and the guidelines for financial incentives are not fully developed, India in the future will definitely be looking forward to financial incentives through REDD+.

Financial Support from Multilateral Institutions

The review of funds provided by major multilateral institutions during the period January 2004 to 31 December, 2013, for climate change mitigation and adaptation is evaluated in the table below evaluated in Table 4.

Funding Pattern

In renewable energy projects, much of the funding is on the solar energy sector; the Asian Development Bank (ADB) is supporting the Jawaharlal Nehru National Solar Mission, while the United Nations Development Program (UNDP) supports projects on improving biomass as energy for rural India. In energy efficiency, UNDP is supporting projects on promoting energy efficiency in commercial buildings, Indian railways, and steel rolling mills and in selected small and medium enterprises, which are among the largest consumers of electricity in the industrial sector. On the climate mitigation side, funding is largely on sustainable and low-carbon transport such as metro rails by ADB, which supports through loan for Bangalore and Jaipur metro rail projects, and UNDP is supporting 125 million US$ sustainable transport projects for ten Indian cities through building capacities of government agencies, national/state urban transport departments, and municipal corporations, engaging transport experts in sustainable urban transport planning, and creating awareness on regulations to reduce urban transport emissions.

In climate adaptation, the funding from multilateral agencies includes sustainable coastal areas management by ADB; the World Bank is funding the development of watersheds and irrigated agriculture and water-bodies restoration and management. Further, UNDP and ADB are supporting in the areas of soft adaptation such as institutional building and building capacities of stakeholders on climate change adaptation, as well as supporting the National Action Plan on Climate Change. The multilateral agencies have also been supporting environment improvement programs. The ADB is supporting environment improvement programs in a few cities and World Bank loans are sought for major national environment programs, such as Ganga Action Plans. In recent years, there is also more funding toward disaster risk reduction. UNDP is supporting disaster risk reduction (DRR) in major cities and on DRR and climate change adaptation to extreme events like floods and drought, while the World Bank funding is largely on post-disaster recovery such as tsunami reconstruction and rehabilitation of Uttarakhand state from the flash flood disaster that occurred in June 2013, which caused damages to

Table 4 Financial support from multilateral institutions

Multilateral agency	Renewable energy (million US$)	Energy efficiency (million US$)	Climate change mitigation (million US$)	Climate change adaptation (million US$)	Disaster risk reduction (million US$)	Environment management (million US$)	Total in million US$
Asian Development Bank	3,164	1,234	427	305	381	3,106	8,617
World Bank	672	232	100	1,321	1,431	3,064	6,820
UNDP India	61.33	66.88	131.26	6.51	21	41.49	328.47
Total	3,897.33	1,532.88	658.26	1,632.51	1,833	6,211.49	15,765.47

Source: Compiled by author based on project sheets from respective institutes website the infrastructure like roads and had severe impact on tourism sector and local livelihood and about 250 million US$ was made available for reconstruction.

In addition, major multilateral agencies and technical and financial support from other institutions should be acknowledged. The German Society for International Cooperation (GIZ) supports several climate mitigation and adaptation programs. USAID is supporting a project on low-carbon development; Department for International Development (DFID), International Fund for Agriculture Development (IFAD), Canada AID, Swiss Agency for International Cooperation (SDC), and Japan Bank for International Cooperation (JBIC) are other institutions that are supporting climate mitigation and adaptation and environment management in India.

It can be noted from Table 4 that the total financial support through major multilateral agencies has been about 16 billion US$ for a period 2004–2013, which are partly also as loans that are to be repaid, and given the estimates for adaptation and mitigation efforts such as the National and State Action Plans on Climate Change, which ranges in 100 billion US$, there is a huge challenge to meet these requirements through funding from multilateral agencies.

Conclusion

India has already placed a carbon tax of INR 50 per tonne of coal produced or imported to India, which is used in National Clean Energy Fund (NCEF) since year 2011 and has collected an amount close to six billion US$ by March 2014. The NCEF is using this fund to finance renewable energy projects in India. The expert group on low-carbon strategies for inclusive growth warns that there could be a drop in GDP as a larger share of GDP may need to be diverted for renewable energy, energy efficiency, and investments in low-carbon strategies. Clearly, financing the entire mitigation and adaptation efforts through domestic funds is not feasible given the trade-offs it faces with economic growth and international financial support is required.

The review of financial support in mitigation and adaptation shows that India benefited about 300 million US$ through CDM projects and received about 16 billion US$ as grants and loans from multilateral development agencies. The United Nations Framework Convention on Climate Change (UNFCCC) has established the Green Climate Fund, Adaptation Fund, and Fund for Least Developed Countries (LDCs) to support developing countries (DCs) and LDCs in their effort to adapt to climate change. Accessing such funds by developing countries like India is far from being successful, though India has formally submitted five proposals to the Adaptation Fund Board (ABF). To successfully implement the Nationally Appropriate Mitigation Actions and Adaptation Plans and to steer the economic growth in a low-carbon pathway, India will require continued financial and technical support from multilateral agencies by engaging in global climate change negotiations; India should actively push for continued support of developed countries in adaptation and mitigation finance. India's commitment to low-carbon and climate-resilient economic development needs appreciation from developed world through financial and technical support. Though agencies like World Bank have supporting post-disaster rehabilitation like in Uttarakhand, future burden on domestic financial abilities to meet the loss and damage from such extreme weather may become more difficult. International aid cannot solely be depended in the future for post-disaster reconstruction and rehabilitation, and India and other developing countries will be actively looking forward for global support in the climate change negotiations for loss and damage compensation also that started in COP 19 at Warsaw.

From Risk to Opportunity: Climate Change and Flood Policy in Bangladesh

Muhammad Jahedul Huq and Louise Bracken

Contents

Abstract

This study identifies current gaps and opportunities of existing flood regulatory frameworks and national climate change strategies of Bangladesh. In so doing, the research develops a framework to reconcile the interest of land, water, and people in order to reduce the vulnerability of extreme flooding and develop strategies for future flood management. The study reveals that the existing flood

regulatory framework is only effective for relief and response during times of flooding but has significant gaps and inadequate provisions to increase communities' adaptive capacity and resilience to deal with future flooding vulnerability under climate change. The flood management system also suffers from a lack of coordination, complex institutional frameworks, and budgetary constraints. The findings of the study also reveal that people's/communities' participation is at a very early state in flood-related project formulation and implementation, and they are totally absent at the level of flood management committees. In addition, the study strongly urges introduction of evidence-based flood policy formulation to reconcile the interest of land, water, and people. Working in this way will give people and communities a voice in the decision-making process, ensure the participation of vulnerable people in decision-making around flooding, and take immediate initiatives to fill the existing gaps and weaknesses of flood management system in Bangladesh.

Keywords
Flood • Disaster risk reduction • Climate change adaptation • Resilience • Bangladesh

Introduction

Fluvial flooding is unquestionably the most recurrent and devastating natural disaster in Bangladesh, and further increases are estimated due to climate change projections (GOB 2009a, b; Mirza et al. 2003; Mirza 2002; Agrawala et al. 2003; Ali 2011; Dasgupta 2007). Fluvial flooding occurs when rivers overflow and burst their banks, due to high or intense rainfall which flows into them. Typically, fluvial flooding in Bangladesh occurs when discharges from several major rivers coincide within a short period of time with heavy monsoon rainfall. It is stated that unprecedented population growth, continuous wetland encroachment, and unplanned increases of infrastructure on floodplains in Bangladesh will accelerate this flooding vulnerability under climate change. This increased flooding vulnerability and uncertainty will diminish the flexibility of the country's ability to react to flood events as well as the appropriateness of traditional flood management strategies. Consequently, changes in duration, depth, and timing of fluvial flooding might bring drastic changes in the country's subsistent agriculture (Younus 2010) and livelihood of the poor in particular, with the possible result of pushing more people below the poverty line (Mirza 2002). Hofer and Messerli (2006) contend that in the last two decades, the people of Bangladesh have demonstrated resilience to flooding in the form of autonomous adaptation, but at the present time, their ability is exhausted due to the changing pattern of floods in terms of frequency, intensity, and time of occurrence. Furthermore, historical and contemporary data clearly demonstrate that the impact of floods is a key factor hindering the development process of Bangladesh.

The study presented follows a critical review method in order to investigate and strengthen flood management policies to facilitate adaptation and to increase resilience of those communities most vulnerable under climate change in Bangladesh (Samuels et al. 2006; Mirza 2002). This paper begins presenting a brief overview of key concepts (disaster risk reduction, climate change adaptation, and resilience) and the notion of people-centered policy as a framework of research. Section "Flood Management in Bangladesh" then provides an evaluation of existing flood management strategies in Bangladesh including the regulatory framework around flooding; a critical review of existing flood regulatory frameworks to address flooding under climate change with special regard to the contribution of resilience. Climate change adaption (CCA) and disaster risk reduction (DRR) are found in section "Review of Flood Regulatory Frameworks in the Context of DRR, CCA, and Resilience". Section "Key Issues, Gaps, and Constraints" identifies the opportunities and constraints of existing flood management policies to reduce the vulnerability due to extreme flooding and potential damages and transferring risks in terms of changes in monsoon, temperature, and sea level rise for long-term climate change. Conclusions are reported in section "Conclusion."

Analytical Framework

This section provides an analytical framework for the concepts of disaster risk reduction (DRR), climate change adaptation (CCA), and resilience. These three concepts provide a suitable analytical framework, which focuses on people-centered policy (development) within the context of flood- and climate change-induced vulnerability. In effect, this foundation for analysis highlights the importance of people's participation in decision-making in increasing the effectiveness of flood vulnerability reduction under climate change.

Understanding the Key Concepts

Considering the notion of risk and vulnerability as the key underlying concept of DRR (UNISDR 2004; Concern 2005; White et al. 2004), this paper views DRR as "the systematic development and application of policies, strategies and practices to minimize vulnerabilities and disaster risks throughout a society, to avoid (prevent) or to limit (mitigate and prepare) adverse impacts of hazards, within the broader context of sustainable development" (UNISDR 2002, p. 25). Therefore, DRR adopts a broad range of guidelines including policy/regulatory issues and planning practices to fill the gaps between development and humanitarian works to protect lives and assets by reducing vulnerabilities and enhancing resilience (Concern 2005; Mitchell and van Aalst 2008; Twigg 2004).

Similarly, the conceptualization of CCA includes an open process or ongoing actions to improve the condition, measures, or strategies to reduce vulnerability and to introduce new initiatives to increase resilience in order to cope or to adjust with climate change-associated adverse effects (Andreasen 2011; Schipper 2004).

So, adaptation can be a specific action, for instance, changing cropping pattern, employing water efficient irrigation practices in drought-prone areas, planting saline-tolerant rice varieties, and a system change such as diversifying livelihoods. Additionally, it incorporates policy and institutional reform, which might change particular activities or make available additional services to vulnerable people, which in turn may help them to make better decisions (Raihan et al. 2010). Therefore, in the context of DRR and CCA, this paper characterizes resilience as the long-term ability or capacity of individuals, communities, organizations, or countries to take/make effective strategies and measures to reduce and to cope with and respond to extreme events as well as organize recovery after these shocks (Twigg 2001, 2009; IFRC 2012; UNISDR 2002).

The Framework of Research: People-Centered Policy Development

It has been established that the relationship between nature and society is complex and that their association is nonlinear. Nature and society also interact in a coupled and integrated way. Hence the study uses the concept of socio-ecological resilience to examine the floods in Bangladesh. The socio-ecological resilience approach greatly enhances understanding the nature of processes and socio-ecological system response, which in turn facilitates achieving socioeconomic development as well as maintaining a healthy ecosystem of rivers and floodplains simultaneously. Here, socio-ecological resilience is the capacity or ability of a human and physical environment to respond or absorb or shape each other within their own domain in an informed manner (Adger 2000; Peterson 2000). Moreover, this approach is a tool rather than being a theory that engages different stakeholders, particularly the poor and most vulnerable communities, in the decision-making process to reduce flood risks and floodplain development (Warner et al. 2002). The approach also incorporates new ideas from resilience in order to better analyze and manage transitions to more sustainable development pathways in social-ecological systems.

The concept of people-centered policy integrates DRR and CCA in development policies and programs. Thus DRR polices incorporate the preferences/priorities of communities most at risk. It also follows a bottom-up approach by power sharing and access to justice against discrimination and exclusion. Moreover, this approach not only gives the primary responsibility to vulnerable communities to protect their own land and properties from floods but also creates an opportunity to perform active citizenship through collective action to reduce flood risks (Johnson et al. 2007, 2008). Figure 1 provides an overview of people-centered policy development, which places the poor and vulnerable community at the center of the policy formulation process. This facilitates the participation of flood-afflicted groups from project formulation to its implementation. The diagram represents three different circles, which are denoted as DRR, CCA, and resilience. The characteristics of these three concepts are different from one another, but there is an increasing recognition that DRR, CCA, and resilience share a common focus in reducing vulnerabilities and thus contribute to sustainable

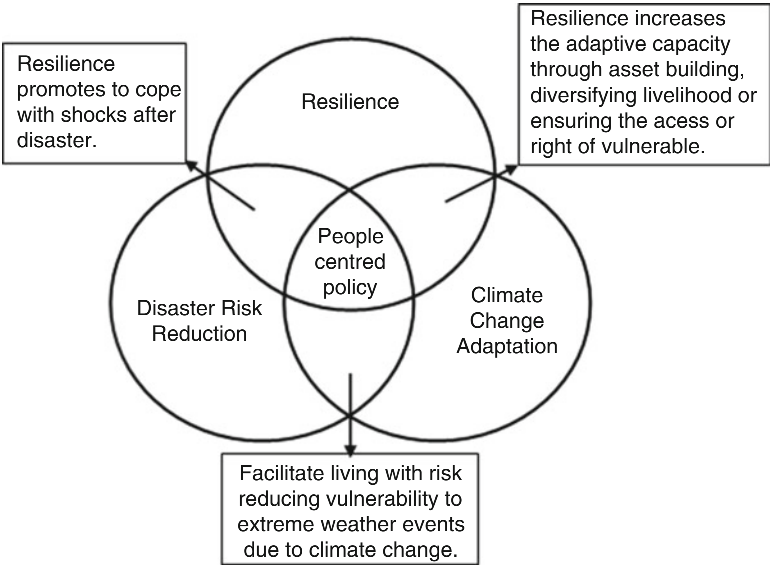

Fig. 1 Conceptual framework for people-centered policy (development)

development (CEPA 2012). In so doing, this study argues that a people-centered flood policy framework provides support to increase and build people's resilience and adaptive capacity through diversifying livelihoods and by ensuring access and rights of poor and socially disadvantaged groups to reduce vulnerabilities to flooding under climate change.

Flood Management in Bangladesh

Flood management in Bangladesh has continuously evolved over the last 60 years from relief rehabilitation, to flood prevention, toward flood preparedness. In early periods, particularly before the political partition of the Indian subcontinent, there were no government-led flood management systems. In the 1960s, after a series of disastrous floods, large-scale engineering structures gained importance to control flood water in order to introduce high-yielding rice varieties to meet the demand of a growing population (Haque and Zaman 1993; Haskoning 2003; Cook 2010). After the independence of the country in 1971, small-scale flood control and drainage projects were implemented by the World Bank, the Asian Development Bank (ADB), and the Dutch government. Similarly, after the floods of 1987 and 1988, the Flood Action Plan (FAP) was formulated with the help of the United Nations Development Programme (UNDP) and the World Bank, focusing on traditional large structure-oriented plans. However, actual actions have not been taken yet due to people's resistance against structural measures. Later in 1995, FAP was accepted by the Government of Bangladesh (GOB), and donor agencies incorporated local people in partnership with experts and professionals in water management (Chadwick and Datta 2003; Sultana et al. 2008).

In 1998 a disastrous flood brought a new dimension to flood management strategy in Bangladesh emphasizing “integrated water management, floodplain morphology and flood forecasting and warning” (UNEP 2002, p. 35). This strategy takes into account livelihood development and reduces the vulnerability of the most disadvantaged in society. However, the big floods of 1987, 1988, and 1998 also brought changes in policies, in particular the formulation of new plans/strategies and incorporation of new institutions for future flood management. As Sultana et al. (2008, p. 7) explain:

> . . .the 1987 and 1988 floods resulted in the FAP process which led to debate over policy directions and delayed any structural works. These floods also catalyzed changes in policy direction and brought forward the involvement of new actors who introduced new concepts to public discourse such as compartmentalization. Similarly, environmentalist and civil society lobbies emphasized land-use planning and flood retention in 1998, indicating a major change from the ‘engineering coalition’ and its policy beliefs that had dominated much of the previous 50 years.

At present, there are different regulatory frameworks and stakeholders (Fig. 2) involved directly and indirectly at different levels of flood management in Bangladesh. The Bangladesh Water Development Board (BWDB) is the principal national institution concerned with flood management and disseminates flood information to all related government departments and organizations. Additionally, the Ministry of Water Resources (MOWR) and recently (2012) established Ministry of Disaster Management and Relief (MDMR) act as national level coordinators of

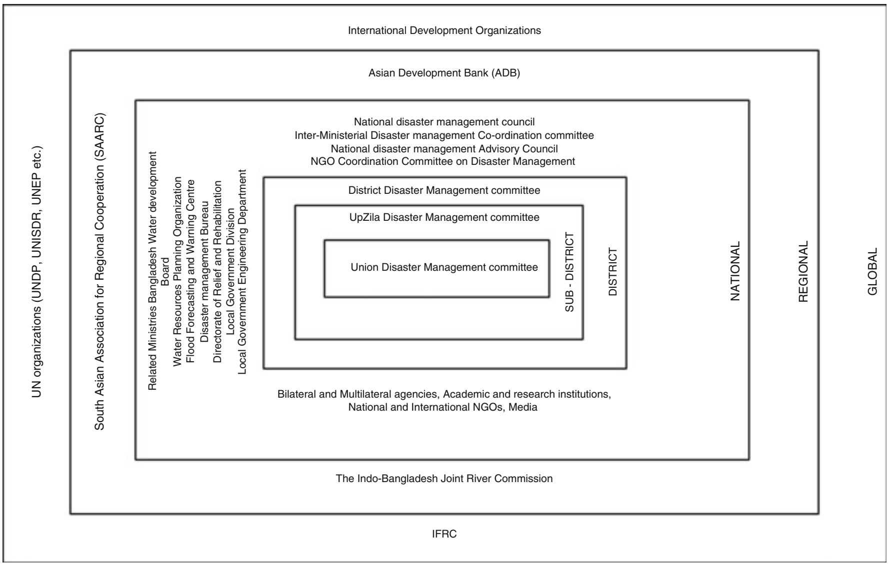

Fig. 2 Different levels of stakeholders’ engagement in flood management in Bangladesh

flood management relating to water and disaster management, respectively. However, during flood events, overall coordination is the responsibility of the latter ministries and the Inter-Ministerial Disaster Management Committee. Although Bangladesh has no specific plans and policies for flood risk management, the National Water Policy and Water Management Plan is especially formulated for effective management of the country's flooding problem. A Comprehensive National Strategy for Disaster Management and Standing Orders on Disaster (GOB 2010a) has also been developed, which defines the roles and responsibilities of different agencies in different stages of disaster management. The following section examines these national flood regulatory frameworks to identify existing efforts and responses in the context of risk reduction, adaptation, and resilience to flooding under climate change.

Review of Flood Regulatory Frameworks in the Context of DRR, CCA, and Resilience

Although flooding is an annual phenomenon in Bangladesh and costs about 0.5–1.5 % of total GDP (World Bank 2010), the country has no specific flood regulatory frameworks. Here, flood regulatory frameworks mean a set of acts, policies, and plans/strategies, which are related to flood management in Bangladesh. There are few regional and international regulations which Bangladesh considers for flood management. However, after the independence of the country in 1971, major changes in flood regulatory frameworks occurred after the devastation caused by floods in 1987 and 1988 and the beginning of the country's new political era in 1990 (Sultana et al. 2008; Chadwick and Datta 2003; Pal et al. 2011). Section "Review of Flood Regulatory Frameworks in the Context of DRR, CCA, and Resilience" consists of three subsections which present a critical analysis of the legal frameworks, sectoral policies, and different planning documents in order to identify the gaps and opportunities of existing flood management in Bangladesh.

Review of National Legal Frameworks

The Standing Order on Disaster (SOD)

The SOD was first prepared in 1997 and later revised in 1999. SOD is formulated to "outline the role and responsibilities of the ministries, divisions, agencies, organizations, committees, public representatives and citizens to cope with any natural disaster" (GOB 2010a, p. i). It also instructs all concerned authorities and responsible persons to follow respective guidelines during the normal time for disaster preparedness, emergency period, precautionary and warning stage, disaster stage, and post-disaster stage. Moreover, the order also provides an institutional mechanism to ensure the coordination of disaster-related activities among and within the different levels of actors. Significant changes to SOD took place in 2010 when the recommendations of the World Conference on Disaster Risk Reduction (2005) on vulnerability to climate change were adopted. The SOD also evolved when Bangladesh became a signatory to the Hyogo Framework Action (HFA) (2005–2015), which mainstreamed DRR and CCA in all natural disasters.

At present, disaster management in Bangladesh is regulated under the SOD and follows reactive approaches of disaster management, particularly centered on traditional relief and responses during and post disaster. SOD adopted DRR in 2008 and highlighted disaster preparedness as the basis for autonomous adaptation, but in reality it is not present at the local level (Haque and Haque 2009), and there is no contingency plan for flood management. Additionally, SOD does not clearly define the roles and participation of affected communities. A study by Rashid (2008) on the implementation of SOD at the local level found that most Union Disaster Management Committee (UDMC) members have no knowledge about SOD nor their roles and responsibilities. Resource constraints to execute disaster management plans are also a challenge. As a result, local-level disaster management committees only function during the disaster period for relief distribution and response operations. Although this regulation clearly defines the roles and responsibilities of each institution, it does not provide any indicative guideline for reducing risks and vulnerabilities, e.g., building code for floods, or specific directions such as spatial planning for infrastructure (road, culvert, and rail).

National Disaster Management Act (DMA)

The DMA (2011) is enacted to enforce the SOD, especially to ensure the accountability of all disaster-related agencies and persons, who are responsible to reduce disaster risks for protecting people's lives, livelihoods, and assets. The key provision of the DMA is to establish a disaster management department to coordinate the activities of all government and development partners. It also gives power to the president to declare a "national disaster" and to form a "national disaster fund" (MODMR 2012b). Most importantly, this act gives preference to the ultra-poor and socially excluded people in DRR and emergency response activities. However, this act inherited its strategy from the country's traditional disaster management approach – relief and rehabilitation – and is therefore reactive. It calls for flood risk assessment before doing any construction but does not give any instruction to real estate developers. It does not even provide any opportunities to perform collective actions for flood risk reduction. Additionally, it proposes punishment for negligence of emergency response, but does not make any legal provision for those who are responsible to increase people's vulnerability by occupying floodplains or flood flow zones for further use.

Draft Water Act

The draft water act (2012) is prepared to adopt and to make effective the National Water Policy (1999). This draft act entrusts the Executive Committee of the National Water Council to ensure integrated, equitable, and sustainable management, development, utilization, and protection of water resources of the country. However, it does not directly deal with climate change and floods in Bangladesh, but makes provisions for catchment-wide river management. It also insists on exchanging regional data and information for transboundary rivers with neighboring countries for long-term water resources as well as flood planning and management. Additionally, the draft act emphasizes not to build any infrastructures that may affect the natural flow of rivers, but allows for embankments along the major rivers to protect people and their assets from future floods. It does not give any clear direction ordering conservation and protection of other wetlands and floodplains as designated flood flow zones, which might indirectly induce unplanned use of floodplains to meet the growing demand of land. Moreover, people's participation in water resource planning and management is not included in the draft act, while the National Water Policy operates to ensure stakeholder engagement at all levels.

Review of National Sectoral Policies

As previously mentioned, Bangladesh has no single flood management policy. But national water policy plays an important role in directing and guiding reduction and management of flood-related problems. Apart from this, there are other policies, which are directly related to causes, impacts and management of flooding in Bangladesh. The following policy matrix (Table 1) provides an overview of those policy objectives and their key thrusts, which are focused on risk reduction, adaptation and resilience to flooding.

Review of National Plans/Strategies

National Adaptation Programme of Action (NAPA)

NAPA-2009 is an updated and revised version of NAPA-2005, which originated under the guidance of the United Nations Framework Convention on Climate Change (UNFCCC) in response to the Seventh Conference of Parties to address the countries' urgent and immediate actions in regard to CC (GOB 2005). The new plan identified 45 adaptation measures classified into six broad thematic areas, which were intended to contribute toward enhancing adaptive capacities and resilience of vulnerable communities. The revised NAPA set its strategic goals to facilitate DRR, on sustainable development and also on institutional capacity building to accelerate adaptation. However, this plan has no special measures. In fact no provisions for making space for water, to reduce flood risk and vulnerability, are made. Although NAPA claims to follow a participatory approach during preparation, it does not incorporate local-level stakeholders, and even the role of community and non-state actors in project implementation is not clearly spelled out. NAPA-2009 does not provide any guidelines to mainstream the identified adaptation measures in other government plans. Moreover, the plan lacks the institutional framework and economic capacity to put all adaptation measures into operation.

Table 1 Matrix of flood-related policies

Sectoral policy and implementing ministry	Objective(s)	Key policy thrusts related with DRR, CCA, and resilience
National Disaster Policy (draft) (2012), Ministry of Disaster Management and Relief	Reducing people's vulnerability and unacceptable risks through effective response and recovery management at all levels	Focuses on people's participation in disaster management (DM), flood-based risk management programs using social vulnerability analysis and participation of co-riparian countries on data exchange for flood forecasting and early warning dissemination
		Section 8 raises the profile of DM in different sectors like agriculture, education, health, water, food security, land use, and planning to enhance the adaptive capacity and resilience of the community
		Calls for humanitarian assistance during and after floods to cope with that adverse effects and put importance on social safety nets to increase the resilience of poor and vulnerability communities
		This draft policy also details out the responsibilities of different state and non-state actors. But it lacks specifics contribution from the annual budget and coordination mechanism among the institutions and actors
National Agriculture Policy (final draft) (2010), Ministry of Agriculture	Increase food production to meet the growing demand and to attain food security at all levels	This revised policy identifies CC and increasing intensity and frequency of floods as key threats for future agriculture and calls for research to develop weather forecasting and early warning for the primary economic sector, to invent new flood tolerant varieties and deep water crop management
		Under section 5 in the policy (agriculture extension), it proposes a bottom-up approach to include the needs of farmers and to provide extension services to "landless, marginal, small, medium, large with special emphasis on women and youth"
		It also highlights promotion of suitable crops considering different agroecological zones and expertise of farmers

(*continued*)

Table 1 (continued)

Sectoral policy and implementing ministry	Objective(s)	Key policy thrusts related with DRR, CCA, and resilience
		To increase resilience, the policy suggests adequate financial support and ensuring the availability of agricultural commodities (fertilizer, seeds, irrigation) to all particularly, small, marginal, and tenant farmers to enhance productivity and also makes provision for special programs for low-lying areas of the country to protect crops from flood
		Recommends special assistance and agricultural rehabilitation during and after disaster, respectively, introduces insurance scheme and generates income activities for affected farmers to cope and adapt with respective disasters
National Wetland Policy (2009), Ministry of Land	Sustainable use of wetland to increase and maintenance of the existing level of biological diversity including fish resources and to promote the value of wetland for economic development	Revenue-driven rural wetland management motivates this legislation
		No specific mention to use and conserve wetlands for flood management
		There are few condition/obligations of leasing wetland like give preference to poor and socially disadvantaged fishing community, ensure the irrigation water during dry season, which might increase the resilience of fishing and farming community
National Urban Sector Policy (2006), Ministry of Local Government, Rural Development and Cooperatives	Ensure sustainable urban development through decentralized development, optimal utilization of land use, functional local government, and participation of community	Focuses on local urban planning including land-use zoning, incorporation of green infrastructures, and restrictions of housing in flood-prone areas and suggests protecting environmentally sensitive areas to reduce the vulnerability of flooding
		It also deals with the improvement and rehabilitation of slums, housing for the poor, and different measures to cut the number of poor. Additionally, it emphasizes community participation for flood preparedness and response capabilities

(*continued*)

Table 1 (continued)

Sectoral policy and implementing ministry	Objective(s)	Key policy thrusts related with DRR, CCA, and resilience
National Land Use Policy (2001), Ministry of Land	Land zoning to control unplanned land use and loss of croplands, sustainable land use comply with natural environment and to ensure better utilization for economic development of the country	Although the policy is very much diverted to ensuring economic development of the country, it also recommends ensuring environment sustainability through protection of the natural environment to reduce disaster vulnerability
		It does not make any direct observation on climate change, flooding, and the role of land-use planning
		It identifies unplanned urbanization, and low land filling might increase the intensity of flooding, but it does not suggest any specific measures to make space for the water or make room for rivers
		It proposes construction of road cum flood embankments in a way that will not affect the natural flow of water and minimize encroachment of wetlands
National Rural Development Policy (2001), Ministry of Local Government, Rural Development and Cooperatives	Rural poverty reduction and socioeconomic improvement through increasing food production, development of physical infrastructure and skill human resources, ensuring participation of women with men, and promoting effective local government system	This policy gives priority in financing and implementing flood control project and encourage environment friendly land use to increase food production. Besides, it also allows use of unutilized low lands for cultivation
		It highlights poor and socially disadvantaged communities for housing, access to credit, insurance for agriculture, health, education, women empowerment, etc. to increase adaptive capacity and resilience to future flooding
National Water Policy (1999), Ministry of Water Resources	Maximum and efficient utilization of all available water resources in order to attain self sufficiency in food production and managing all water-related disasters	This policy does not mention any specific measures on flood and CC but indirectly addresses, which might facilitate DRR and adaptation to climate change
		In section 4.1 of the policy, it emphasis on comanagement of international rivers and exchange of data and information (hydrology, morphology, changing basins characteristics, and flood early warning) to understand and management of existing and future extreme events

(*continued*)

Table 1 (continued)

Sectoral policy and implementing ministry	Objective(s)	Key policy thrusts related with DRR, CCA, and resilience
		Policy also calls for developing flood forecasting, flood-proofing systems, i.e., designating flood risk zones, flood embankments for urban and economic importance areas, raising plinth of infrastructure in rural areas, and cropping patter adjustment to cope with extreme flooding
		Section 4.13 of the policy accounts for the preservation of *haor*, *boar*, and *beels* to gain optimum economic benefits rather than conservation for retaining flood water and a source of livelihood of rural people
		Most importantly, it highlights stakeholder participation as an "integral part of water resource management" and makes a provision to engage target groups in all water-related projects
National Forests Policy (1994), Ministry of Environment and Forests	Afforestation, enriching biological diversity, control forest depletion and social forestry for poverty reduction	This policy starts with the recognition of forestry to reduce the impact of global warming and CC and to maintain an ecological balance
		It demands plantation on flood embankments and river banks and highlights the need to keep 20 % of total country's land as forest – in order to decrease surface runoff and soil erosion to avert disastrous flooding and rising river beds due to sedimentation
National Environmental Policy and Action Plan (1992), Ministry of Environment and Forests	Protecting natural environment, controlling pollutions and sustainable use of natural resources	This policy does not deal with CC but specially recommends for control and management of those factors, which might exacerbate flooding risks and vulnerabilities under climate change

Source: MOWR 1999; WARPO 2001, MOFDM 2012; MOL 2009; 2001; MOEF 1992, 1994; MOA 2010; MOLGRD&C 2006; Haque and Haque 2009; Nishat et al. 2011; IUCN 2008; Pal et al. 2011; MODMR 2012a

Bangladesh Climate Change Strategy and Action Plan (BCCSAP)

BCCSAP, as an extension of NAPA, was prepared in 2008 and later revised in 2009. This 10-year (2009–2018) plan had 44 programs grouped into six broad sectoral pillars in order to "build the capacity and resilience of the country to meet the challenge of climate change" (GOB 2009b, p. 27). Following a sectoral approach, the plan of action emphasized infrastructure-based flood control management including construction of embankments, dikes, and excavation of rivers to increase the water retention capacity. Similarly, it suggested improvement of early warning and community capacity building for flood preparedness and development of insurance schemes for future risk management. As a way to support resilience, it developed nine programs under the theme of food security, social protection, and health and six programs to strengthen institutional adaptive capacity and mainstream CC into regulatory frameworks. In this context, GOB formed the Climate Change Trust Fund (BCCTF) to execute this plan and made a provision of US$100 million per year since 2009 from the annual national budget.

Despite the fact that Bangladesh has suffered and is still suffering due to heavily engineered flood control projects developed in the 1990s, BCCSAP surprisingly endorses similar programs to reduce future flood risks (Alam et al. 2011). For instance, Bangladesh Water Development Board (BWDB) under the Ministry of Water Resources is responsible for constructing highly engineered flood infrastructure (e.g., embankment, dam, etc.) and receives the largest budget, 36 % of the allocation made under BCCTF (Khan 2012). This plan of action is developed without any policy reference and does not give any policy direction to formulate any national climate change policy. Like NAPA, this plan is prepared by experts and consultants to the detriment of the landless and the sharecropper. Poor fishermen's participation is ignored during its formulation process. Moreover, it does not focus on any regional cooperation for flood risk reduction, which is an imperative to address flooding under climate change in Bangladesh (Alam et al. 2011; Raihan et al. 2010).

National Water Management Plan (NWMP)

The NWMP was developed in 2001 and adopted by the GOB in 2004. It provides a framework for development, management, and use of water resources aiming to attain the country's national development goals. This plan adopts light structural measures in the name of river improvement programs such as flood control and drainage schemes to increase food production. It also encourages improvement of flood forecasting and flood preparedness for flood risk management and advocates involvement of local people in water resource planning and management. Moreover, it proposes flood proofing of 3.5 million dwellings in river islands and *haor* areas and raises all national and regional roads and railways for temporary safe haven for flood victims and movement during flood emergencies. It is frustrating that only a very small part of the plan is implemented. Lack of continuous and sufficient funding, and clear authority and coordination of the agencies involved are also major challenges to implementing and managing flood-related interventions.

National Sustainable Development Strategy (NSDS)

NSDS (2008) has been developed with the vision to "ensure sustained economic growth, environmental protection and social justice which implies improvement of livelihood options of the people, reduction of poverty; ensuring wise use of natural resources, good governance and people's participation" (DOE 2008, p. i). It recognizes natural disaster (flood and cyclone) and climate change as the key challenges to sustainable development in Bangladesh. It identifies the impact of floods on the national economy and infrastructure as well as on human security due to future increased vulnerability. But the strategy focuses on future water security to ensure food security of the country rather than a well-defined flood risk management under climate change. The proposed strategies under the theme of agriculture and rural development, and social security and protection might contribute toward increasing resilience and adaptation with climate change-induced flood risks. Although this strategy emphasizes peoples' participation at all levels to attain sustainable development in Bangladesh, its implementation is hampered by a lack of an institutional framework and absence of coordination with other regulatory frameworks.

National Plan for Disaster Management (NPDM)

The NPDM (2010–2015) aims to introduce a comprehensive risk reduction culture and thus bring changes to strengthen institutional capacity for better disaster recovery and response management at all levels. This is why it makes provisions for accountability of institutions, involvement of all stakeholders, and empowerment of at-risk communities. It indicates all relevant sectoral plans to adopt DRR and CCA, where the NPDM will act as a basic guideline. Additionally, this plan makes a requirement to prepare all local-level risk assessments and risk reduction action plans by 2010. But up to October 2009, this had only taken place in 622 Union Councils from 16 districts (of Bangladesh's 4451 Union Councils in 64 districts) under the project of Comprehensive Disaster Management Project (CDMP-I) (CDMP 2010). However, meteorological data and information on climate change at the lowest level are not available in Bangladesh, and the guideline for preparing local-level risk assessment does not adequately address climate change (CDMP 2010). Similarly, this plan is not developed and does not create space for participation of vulnerable communities in its implementation. This plan announced two distinct funds for relief and rehabilitation, and risk reduction, respectively, but these have not yet been formed.

Sixth Five-Year Plan

The fundamental objective of the sixth 5-year (2011–2015) plan is to "develop strategies, policies, and institutions that allow Bangladesh to accelerate growth and reduce poverty" (GOB 2010b, p. 2). This plan identifies seven key priority areas, including environmental sustainability. This broad thematic area includes important initiatives which might reduce flooding vulnerability under climate change. These initiatives consist of increasing forest coverage to 15 % by 2015, restoring and protecting wetlands and natural water flows in line with conservation act, implementing land zoning for sustainable management of land and water, and also integrating DRR and CCA into development project design and budgetary allocations. As a way of increasing resilience, the plan suggests that the government should allocate more resources for social protection and promote pro-poor natural resource management. However, very little has been done in the past due to a limited budget and resource constraints. Since DRR has no specific budget and is not yet mainstreamed in all sectoral plans and institutions, DMB as well as its local committees cannot implement any interventions.

Perspective Plan of Bangladesh

The perspective plan (2010–2021) recognizes the impacts of climate change on development, particularly acknowledging the impact of flooding due to climate change on the national economy, and identifies it as one of the key challenges to becoming a middle-income country by 2012. This plan defines flooding as a problem of "excessive water during wet/monsoon season" and recommends mixed (structural and nonstructural) measures for flood prevention. Further emphasis is put on constructing new embankments and strengthening flood forecasting and warning for future flood risk reduction. Similarly, it points out adaptation to climate change as a prime force for the development of Bangladesh. As the plan (GOB 2010c, p. 110) states: "adaptation to increased flooding would require full flood protection embankments along the major and medium riverbanks. Since the country's population continues to grow resulting in huge pressures for settlements to extend into flood vulnerable zones, embankments are *sine qua non* for flood protection in Bangladesh." In addition, the plan outlines a number of key strategies including mainstreaming climate change issues in sectoral policies, plans, and programs, facilitating adaptation to climate change, and increasing institutional capacity. These strategies have to be carried out in order to enhance resilience to climate risks and impacts mobilizing resources from bilateral, multilateral, and other international donors.

Key Issues, Gaps, and Constraints

This section details the findings of the study and analysis based on the research questions. Analysis and discussion is conducted in light of the theoretical framework and review of flood regulatory frameworks of Bangladesh.

Risk-Based Approach

Considering risk as the probability of occurrence and adverse consequence of flooding, flood regulatory frameworks in Bangladesh adopt a technocratic approach to flood management, which alters the risks by modifying the physical vulnerability of the people and built environment in order to limit the losses from flooding (Warner et al. 2002; Sayers et al. 2002; Samuels et al. 2006). These planning policies emphasize site-specific flood risk assessment to determine the flooding vulnerability of a particular area and suggest engineering solutions as mitigation strategies to eliminate or reduce the level of risk (DMB 2010). Although the planning policies propose flood risk assessment to limit the extent of development in flood-prone areas, it promotes more urbanization to fulfill the short-term demand of housing and carefully avoids the natural flood risk reduction as a long-term objective (MOWR 1999; WARPO 2001). Therefore, the provision of "full protection against floods" for urban areas might encourage others to develop floodplains into new urban areas. This in turn exacerbates the conflict between land and water in the future. In addition, this way of occupying floodplains has a detrimental effect on the natural environment as it hampers biological productivity and reduces the ecosystem services.

To increase the resilience of communities, planning policies offer mostly short-term DRR rather than reduction of vulnerabilities per se. The flood management decision-making process is developed on the basis of the outcome of the risk-based approach, which avoids the root causes of vulnerability. In this instance, risk is therefore seen as a technocratic and scientific view of disaster, which blames nature and its hazards as the causes of people's vulnerability (Collins 2009; Wisner et al. 2004). This is interpreted as the reason why authorities avoid the social, political, and economic aspects of flooding vulnerability and promote flood-proofing infrastructure for flood risk reduction. The root causes of anthropogenic drivers (i.e., high population growth, land-use change) are the pathways to increase the intensity of effects of flooding, which are not taken into account. Research has found that people who live in floodplains and are most vulnerable to flooding are the poor (Walker and Burningham 2011). Thus hazard risk reduction rather than vulnerability will not enhance the people's adaptive capacity and improve their socioeconomic resilience. Furthermore, the key objective of all policy frameworks is to increase or ensure economic growth and economic development of the country. As a result, the market-based policy frameworks do not increase the adaptive capacity and resilience of the poor and socially marginalized groups but rather increase flood risks of the country by deteriorating the natural environment (Alam 2008).

As a nonstructural measure, Flood Forecasting and Early Warning (FFEW) in Bangladesh is not adequate due to limited communication and dissemination facilities (USAID 2008). These include limitation of accuracy and reliability of forecast, limited coverage, insufficient coordination and feedback, and ambiguity of warning messages (ADB 2006). Here, river water level is used for FFEW, which is a concept not well understood by the community. Additionally, the warning message does not carry other relevant information such as the expected flood water travel time in respective areas, potential inundated area, and water depth due to flooding. The inundation map, which is prepared by the flood forecasting and warning center, does not cover subdistrict (*Thana*) level flooding information. Moreover, inadequate access to upstream inflows and rainfall data and information from India is still a key weakness for accurate flood forecasting (MOWR 2006; ADB 2006).

(Social) Justice and Equity

The flood regulatory frameworks of Bangladesh adopt a top-down and heavily engineered approach (Rasul and Chowdhury 2010) as well as the principles of maximum utility, whereas sustainable flood management requires the principles of equality and vulnerability (Johnson et al. 2008; Brown and Damery 2002). The principle of maximum utility uses cost-benefit analysis for decision-making, which places emphasis on only the economic efficiency of risk reduction. As a consequence, it favors the well-being of majority of taxpayers or economic importance areas and ignores the communities at risk in the rural areas (Newborne 2009; Samuels et al. 2006). This principle is very much evident in most flood-related policies of Bangladesh. Additionally, most of the flood management frameworks are prepared by experts and consultants where people's participation or a deliberate process with real flood sufferers is absent. There is no representation from vulnerable or flood-affected communities in local-level disaster management committees. This technocratic approach of flood risk identification and management is a barrier to attain a fair and sustainable flood management policy in practice.

The two key documents (NAPA and BCCSAP) of climate change in Bangladesh have been prepared and revised without any participation of vulnerable communities (GOB 2009a, b; Raihan et al. 2010; Alam et al. 2011). As mentioned previously, NAPA follows an expert-driven and impact-based approach for adaptation formulation. It therefore misses the key features of vulnerability and is likely to lead to ineffective resources use. It might also intensify the vulnerability of the most vulnerable (Ayers 2011). Similarly, the sectoral approach of adaptation to climate change in BCCSAP left behind the poor, landless, and socially disadvantaged communities' involvement and priorities in respective sectoral programs, although it indicates mainstreaming vulnerable communities including women and children (Alam et al. 2011). These observations make it clear that the issue of vulnerability and targeting the vulnerable are inadequately addressed in existing flood management frameworks including policy making. This "multifaceted nature of vulnerability" might be a key challenge for successful execution of flood policies in Bangladesh (Johnson et al. 2008).

Coordination and Management

Flood risk management in Bangladesh is centralized and follows a command and control approach. The two leading ministries (MOWR and MOFDM) are responsible for the implementation of flood control projects as well as relief and response works during and after flooding events. But climate change and its related issues are only dealt with by MOEF. There are other institutions, which are directly and indirectly involved in flood management. This large institutional involvement lacks coordination and creates conflict of interests among the institutions. Zimmermann et al. (2010) argue that there is no coordination between GOB and donors for risk reduction and preparedness. Policy is still focused on emergency response. GOB also states that harmonization among donors and regional coordination is not still institutionalized. Furthermore, international and national development organizations implement their own DRR action plan in many different ways. It is well acknowledged that DRR and adaptation to climate change is location specific. But surprisingly, the local government of Bangladesh has no specific involvement in flood risk reduction except emergency management. Even local governments of flood-prone areas have no budgetary allocations for immediate emergency response. Flood-prone communities also have no role in flood management.

Climate Change and Uncertainties

Climate change is acknowledged as one of the key flood drivers in global policies, and it poses a significant threat to flood-prone counties like Bangladesh. But very few policies, plans, and acts incorporate it to address future development challenges. GOB and other bilateral development agencies (World Bank, Danida, DFID, ADB, etc.) develop special plans where climate-induced flood risks receive special importance. Those plans provide guidance as well as formulate different programs to increase communities' adaptive capacity and resilience to reduce flooding vulnerability. However, the majority of the climate change projection scenarios have been derived from regional climate change models where the study of Agrawala et al. (2003) is widely cited in the literature related to CC in Bangladesh. Recently, the Climate Change Cell (CCC) of Bangladesh has generated new temperature and rainfall scenarios using another regional model – PRECIS (CCC 2009). But the results of this model are not used in BCCSAP, which is the national plan of Bangladesh for climate change adaptation and mitigation.

This first NAPA (2005) of Bangladesh adopted the findings of Agrawala et al. (2003) for changes in temperature but used a modified version for changes in precipitation. This modification was carried out on the judgment of the NAPA core team rather than any GCM modeling exercise (Ahmed 2006). Later, the same scenarios of NAPA 2005 were applied in BCCSAP (GOB 2008, 2009b). NAPA 2009 which uses the partial output of the PRECIS model for changes in temperature and the rest of the data (changes in precipitation and sea level rise) is taken from NAPA-2005. This inconsistency in climate change documents shows a high level of uncertainty, which in turn limits the potential accuracy of future flood projections under climate change. It may also cause difficulties for policy makers and planners when making decisions on risk reduction and adaptation to flooding. Moreover, India is going to implement a river-linking project to redirect the flow of the Brahmaputra and Ganges basin toward the south and eastern parts of India to irrigate drought-prone areas (Bandyopadhyay and Perveen 2003; Shukla and Asthana 2005; Rahman 2005). This might cause a significant impact on the future discharge and flow velocity of transboundary rivers, which is not taken into consideration when estimating future changes in flood regime (GOB 2009a).

Opportunities in Existing Flood Regulatory Frameworks

The existing flood policies in Bangladesh are designed for effective relief and response to flooding but also have provision to increase the capacity to cope with disasters. Existing policies only respond to flood season, whereas floods at other times can also have a serious impact on poor people's lives and livelihoods, contributing to increase future vulnerability. Therefore, apart from the effective and timely response to flooding, it is imperative to help affected communities to enhance their adaptive capacity to cope with flooding and preparing for the future (Mutasa 2010). Additionally, the current draft of the National Disaster Policy (2012), draft of the National Agriculture Policy (2011), and new NPDM (2010) merely emphasize access and availability of resources in order to ensure sustainable livelihoods to create a "buffer" against flooding. Moreover, these policy frameworks still consider flooding along with other disasters as a crisis management rather than long-term planning.

The GOB acknowledges CC as a catalyst for future extreme flooding and has accordingly placed emphasis on flood risk reduction to increase the people's adaptive capacity as well as their resilience (GOB 2009a, b). NAPA and BCCSAP, as a part of medium-term and long-term climate change planning, highlight different flood risk management and reduction strategies including risk sharing such as insurance mechanism for the future. Additionally, these strategies adopt capacity-building programs for vulnerable communities and institutions and also "research and knowledge management" to assess the scale and impact of CC on the national economy for future informed planning. As a part of integrated disaster management, it incorporates the strengthening of community-based programs, a component which is missing in other flood-related policy frameworks. Moreover, it highlights the importance of increasing resilience of the poor and vulnerable "through development of community level adaptation, livelihood diversification, better access to service and social protection" (GOB 2009b, p. 27). Most importantly, BCCSAP has a specific annual allocation from the national budget to implement its programs and projects. There are few opportunities available in existing flood regulatory frameworks in Bangladesh, and now it depends on GOB to initiate and translate these opportunities into programs and projects in order to prepare the vulnerable communities to face future climate change-induced extreme flooding.

Conclusion

The above evaluation of flood regulatory frameworks provides an overview of the effectiveness of existing flood risk reduction, CCA, and resilience-related policies, plans, and strategies of Bangladesh. This study reveals significant gaps in policies/plans/acts to offer an effective mechanism to deal with climate change and future flooding across all sectors and their limited understanding of DRR and its linkages with CCA. It finds that there are policies/plans/acts that have recently incorporated climate change issues, but not all are finalized and no specific budgetary allocation and institutional framework for effective implementation of DRR and CCA activities has been initiated. Policies and regulations also fail to ensure the participation of vulnerable communities in flood risk planning and management. These planning policies are strongly in favor of flood-proofing urban areas and emphasize the significance of housing in the name of broad social and economic development.

As a result, the policy fails to accommodate the approach of social justice, which is the key principle of sustainable development to target the poor and most vulnerable, creating new forms of vulnerability. Moreover, there is no clear direction or guideline to mainstream DRR and CCA into the overall development of planning frameworks to enhance the resilience of vulnerable communities.

Appropriate and efficient implementation of flood regulatory frameworks and responsible institutions is seen as crucial in building the capacity of communities to resist flood risks and effects of CC, which might have the potential to reduce their vulnerabilities and increase their resilience to CC. Considering the gaps in existing regulatory frameworks, evidence-based people-centered policy formulations should be introduced to ensure the effective participation of all stakeholders including the active participation of vulnerable people for better flood management system in Bangladesh. Overall, "the overhauling of class relations" and narrowing the gaps between rich and poor through social transformation can provide a platform to ensure sustainable flood management under climate (Custers 1992). This is the prerequisite of all effective measures to reduce flood risks and vulnerabilities and to enhance people's resilience accordingly.

Gender and Social Equity in Climate Change Adaptation in the Koshi Basin: An Analysis for Action

Manohara Khadka, Golam Rasul, Lynn Bennett, Shahriar M Wahid, and Jean-Yves Gerlitz

Contents

Abstract

The impact of climate change is disproportionately higher on women, the poor, and socially disadvantaged groups. Yet, existing adaptation approaches and perspectives pay little attention to the special needs of these groups. Based on primary and secondary information collected from Nepal's Koshi Basin, this paper looks at differences in levels of multidimensional poverty between different social groups and tries to assess how these differences shape their respective

capacities to adapt to climate change. It examines some of the challenges and constraints these different groups face in the adaptation process and the strategies they use to cope and adapt. Analysis reveals that women and marginalized social groups, especially Dalits and Muslims, experience deeper levels of multidimensional poverty and that, in turn, constrains their ability to adapt to climate change. Rural women are relatively more vulnerable to the adverse effects of climate change than men due to the complex socioeconomic, institutional norms and gender roles/relations that determine their access to and control over the physical, economic, human, and social resources required for adaptation. The results suggest that an interdisciplinary approach to climate change adaptation is needed that recognizes and addresses the special needs, roles, and constraints of women and disadvantaged groups. The organizational and policy processes as well as the capacity of women and disadvantaged groups needs to be enhanced to achieve better results or positive impacts of adaptation planning and implementation. A broader governance framework is suggested that would enhance the capacity of women and disadvantaged groups to respond proactively to climate change while at the same time working to change unequal power relations, institutions, and processes that have made these groups more vulnerable.

Introduction

Climate Change and the Need for Adaptation

Climate change is a global threat to people's well-being, especially to those with limited resources and livelihood options (Dankelman 2002; Denton 2002; Yamin et al. 2005; Mehta 2007; Brody et al. 2008; Lambrou and Nelson 2010; Alston 2013). The Hindu Kush-Himalayan (HKH) region is experiencing higher temperatures and increased variation in rain and snowfall. Although mountain people have always been exposed to droughts, floods, soil erosion, and changes in the crop cycle (Shrestha et al. 1999; Tsering et al. 2010), the intensity and frequency of such stress events has increased over recent decades. Appropriate adaptation is critical, particularly for the poor women and other socially marginalized groups who bear a disproportionately high burden of climate change impacts. These groups require special attention to facilitate inclusive and sustainable adaptation (Dankelman 2002; Mitchell et al. 2007; Mehta 2007; Neumayer and Plümper 2007; Nightingale 2009; WHO 2011). The degree of vulnerability of an individual or group to climate change depends on the capacity of that individual or group to adapt; adaptive capacity is in turn shaped by economic, physical, institutional, and social factors, including gender, that determine the access to and control over economic and social resources (Adger et al. 2009; Jones and Boyd 2011; Lambrou and Nelson 2010;

Nightingale 2009; WHO 2011). Understanding the context specific to gender and social issues that affect the abilities of different groups to respond to climate change is very important for the design and effective implementation of local adaptation plans and strategies in the HKH region. This chapter aims to contribute to this understanding based on findings from the Nepal's Koshi Basin.

While the need for better adaptation to climate variability and change has been recognized at policy level (GOI 2008; MOE 2011), the collection and analysis of data disaggregated by gender and social group has been limited, hence the social implications of climate change, climate policies, and other drivers of change in the Koshi Basin (Khadka 2013) are poorly understood. As climate change and gender studies globally show, vulnerability and adaptation to the adverse effects of climate change are gendered social and economic processes: men and women across different social, economic, and education levels, ages, and caste/ethnic identities experience and respond to the shocks and stresses of climate change in very different ways. Men and women with diverse identities have differential capacity to cope with and adapt to change (Brody et al. 2008; Jones and Boyd 2011; Lahiri-Dutt 2014; Mehta 2007; Mitchell et al. 2007; Plan Nepal 2012). Sound and socially responsive climate change adaptation policies and governance practices are an important means of reducing vulnerabilities and empowering men and women across different social identities.

This chapter focuses on the Nepal Koshi Basin and examines the following three issues: (a) how the intertwined economic, sociocultural institutions and gender roles operating in the Nepal's Koshi Basin condition the ability of different social groups to respond to climate change-related shocks and build their resilience, (b) to what extent has the current climate change policy in Nepal recognized gender and social vulnerability to the negative effects of climate change and developed measures to enhance the adaptive capacity of most disadvantaged groups for more equitable outcomes, and (c) what possible approaches can be used to integrate gender and social issues into climate change programs in the Basin.

This chapter has seven sections. The first three sections introduce the rationale and the conceptual framework for the study. The fourth section discusses methodology used to collect and analyze data on multidimensional poverty and gender inequalities in Nepal's Koshi Basin. The findings on the multidimensional poverty levels of different social groups, their perceptions on climate change, and some of their strategies for coping with and adapting to the change are presented in the fifth section. A review of Nepal's national policy on climate change adaption is presented in the next section, and the final section offers conclusions and a suggested framework for action.

Gender and Social Equity Perspectives in Climate Change Vulnerability and Adaptation Frameworks

Women, men, and members of diverse social groups experience climate vulnerability differently and have different levels of capacity to adapt (Denton 2002; Mehta 2007; Mitchell et al. 2007; Demetriades and Esplen 2008; Brody et al. 2008;

Nightingale 2009; Skinner 2011; Alston 2013). Members of poor and socially marginalized households and women suffer more than other social groups when faced with natural disasters, including climate change (Bern et al. 1993; Oxfam International 2005; Gautam et al. 2007; Neumayer and Plümper 2007; Mehta 2007). Often men have more access to information on climate changes, ideas for adaptation, control over decision-making mechanisms, productive assets, and social capital (Alston 2013; Mburu 2014).

Women can also be at higher risk of losing their life during climate-induced disasters (Bern et al. 1993; Oxfam International 2005; Sharmin and Islam 2013). During the Bangladesh cyclone in 1991, the mortality rate among females over the age of ten was three times higher than that among males (Bern et al. 1993) and three times as many women as men died in Indonesia and India in the 2004 Asian tsunami (Oxfam International 2005). The higher female death rate has been attributed to gender norms on what men or women should look like, do, or have (Oxfam International 2005; Neumayer and Plümper 2007; Sharmin and Islam 2013). For example, in rural Bangladesh, women are not allowed to leave their home without a male relative (Sharmin and Islam 2013) and are expected to wear a sari, which hampers running and swimming; thus they are less able to move rapidly to a safe place during a disaster (Neumayer and Plümper 2007). However, gender norms hindering women's ability to prepare for disasters and benefit from development can be changed through better legislation, policy, institutional practices and decision-making, and investment in gender-sensitive research and capacity-strengthening programs that empower women (Alston 2013; Björnberg and Hansson 2013; World Bank 2014).

The Intergovernmental Panel on Climate Change report (2001) documents the fact that inadequate access to resources such as income, skills, knowledge, and other assets contributes to the increased vulnerability of some groups to climate change. In addition, social perception, interplay of power, and structural biases built into some institutions and processes can result in unequal access of certain groups to decision-making and opportunities for improved livelihoods (Lama and Buchy 2002; World Bank and DFID 2006; Arora-Jonsson 2011; Alston 2013).

Building local people's "resilience," or their ability to adapt to the adverse effects of climate change, is a priority agenda of governments, non-governmental organizations, and development agencies in the HKH region (GOI 2008; MOE 2011; NDRC 2007). Adaptation is increasingly viewed as an essential social process for reducing vulnerability to the negative impacts of climate and other drivers of change (Adger 1999; Yamin et al. 2005; Demetriades and Esplen 2008; Nightingale 2009; Adger et al. 2009). As with vulnerability, the factors that shape and affect people's capacity to adapt are not limited to biophysical and economic dimensions; the gender, caste/ethnic, and class identities of members of a community also play an important role in their respective adaptive capacities (Demetriades and Esplen 2008; Adger et al. 2009; Nightingale 2009; Arora-Jonsson 2011; Onta and Resurreccion 2011; Jones and Boyd 2011). Power relations are particularly important in determining vulnerability and adaptive capacity in the Hindu Kush-Himalayan context, where the majority of rural people derive their livelihoods from agriculture, animal husbandry, seasonal migration, daily wage labor, and the provision of ecosystems service and goods. Especially in the Indian and Nepal regions of the Koshi Basin, the social relations based on gender, caste, and ethnicity are still strong, creating significant differences between and among men and women in terms of economic, political, and educational opportunities and influence in policy and rural development processes. Therefore, gender and social equity perspectives are critical to understanding differential vulnerability to climate change and to designing adaptation plans and programs that not only reduce the overall adverse impact of climate change but ensure that climate change does not deepen existing inequalities in the HKH in general and the Koshi Basin in particular.

The Need for an Interdisciplinary Approach

Dominant approaches to adaptation (Agrawala and Fankhauser 2008; Bala and Hossain 2013; Benioff et al. 1996) tend to be dominated by economic and biophysical perspectives. However, these perspectives do not adequately recognize differential vulnerability based on gender and social identity or the specific practical and strategic needs of women and economically and socially marginalized groups. Nor do these approaches recognize that these diverse groups have different levels of capacity and, thus, need differentiated approaches to adaptation (Nightingale 2009). This situation is reinforced by the prevailing lack of an interdisciplinary perspective that considers the linkages between adaptation to climate change and social and gender equality.

The failure of climate policies and adaptation programs to take social dimensions into account can have significant deleterious effects on women and other economically and socially marginalized groups. They also fail to use the intimate knowledge of local conditions that rural women and indigenous communities can contribute to climate adaptation processes (Nyong et al. 2007; Lambrou and Nelson 2010). Women and other marginalized groups hold indigenous knowledge of low-impact low-cost methods and coping strategies that can support development of resilient farming practices in response to climate change (Meinzen-Dick et al. 2011). For example, rural women in Sikkim, India, and Nepal have conserved ecologically sensitive areas in community-managed forests and private lands, as well as plants that were nearing extinction. They conserve local landraces of crop varieties through maintaining home gardens and the practice of seed exchange between communities (Karki and Gurung 2012; Dhakal 2012). This indicates how local natural resource management and farming practices can contribute to adaptation. Therefore an effective response to climate change requires a holistic and interdisciplinary approach that includes a sociocultural perspective and pays explicit attention to gender and social relations (Brody et al. 2008; Hannan 2009; Nightingale 2009; Lambrou and Nelson 2010; Arora-Jonsson 2011; Jones and Boyd 2011; Alston 2013; Björnberg and Hansson 2013; Lahiri-Dutt 2014). This study adopts this perspective and assesses the vulnerability and adaptive capacity of different social groups by gender, caste/ethnic identity, and poverty. A climate change adaptation framework for action is proposed that emphasizes the gender and social dimensions of the adaptation process and offers suggestions on how existing policy and institutional frameworks can take the social dimension into account in adaptation planning and implementation for achieving equitable social outcomes.

Study Area, Data Collection, and Social Diversity

This research is based on primary data collected from Nepal's Koshi Basin region using a survey for the quantitative data and collecting qualitative information through ten key informant interviews, six focus group discussions with women and men householders, and field observations in two districts. The Koshi Basin region occupies parts of India, Tibet/China, and Nepal and is one of the ten major river basins in the HKH region. Secondary data were obtained from a thorough review of the relevant literature from the HKH region and the Koshi Basin, including recent national statistics from Nepal and a review of Nepal's climate change, and social development policies.

Nepal's Koshi Basin is located between China and India. While the northern part of Nepal's Koshi Basin is inhabited mostly by ethnic groups speaking Tibeto-Burman languages and practicing Buddhism, in the southern part the Hindu influence on sociocultural practices is dominant.

Survey Methods

The survey was carried out in Nepal's Koshi Basin as part of a program to better understand and facilitate climate change adaptation implemented by the International Centre for Integrated Mountain Development (ICIMOD). Quantitative data were collected from a total of 5,383 households (62 % male informants and 38 % female) in 14 of the 26 districts in the Nepal part of the Koshi Basin (Fig. 1) between 2011 and 2012, using the poverty and vulnerability assessment (PVA) survey instrument (Gerlitz et al. 2014). Households were the basis for survey. Since men are generally considered the households heads, they tended to take on the respondent role in the survey. Hence, there were substantially more male respondents than female.

The recommended sample size was 384 households for each district. Household selection within districts was based on a multistage random sample with an equal probability sample of elements at all stages. The primary sampling units (PSUs) were village development committees (VDCs) and the ultimate sampling units (USUs) were households. To guarantee a good geographical coverage as well as the inclusion of the urban population, all VDCs in a district were divided into the categories "urban" (municipalities and district headquarters), "rural, quarter 1" (generally northwest), "rural, quarter 2" (generally northeast), "rural, quarter 3" (generally southwest), and "rural, quarter 4" (generally southeast) and listed. Initially, PSUs were selected randomly from each of the five lists. In all districts, one VDC was selected from the list of urban PSUs. The USUs were selected using random walk procedures (Gerlitz et al. forthcoming). The survey was carried out in

Fig. 1 Map of the Koshi Basin showing the study districts within the Nepal part

two parts, and the second part included more details and some additional questions; thus some of the results are based on responses from the second part of the survey only. The final numbers of respondents used in the analysis of individual questions were lower than the number of surveyed households, as households were excluded when data for a question was missing.

The Study Area Population

The Koshi Basin's inhabitants include men and women from a wide variety of caste/ethnic and religious groups. Women slightly outnumber men (50.5 % vs. 49.5 %); 82.3 % of the people in the region are Hindu, 13.3 % Buddhist, 1.5 % Christian, 1.2 % Muslim, and 1.7 % others (Field survey 2011, 2012). For the purposes of the survey, respondents were divided into broad ethnic/caste groups that reflect overall social advantages and disadvantages. These groups were the Janajatis/ethnic groups, or indigenous peoples, who traditionally have a special cultural association with forests, water, land, and other natural resources from which they earn their livelihoods (Sherpa 2012), the so-called "upper" caste Brahmins and Chhetris, the "lower" caste Dalits, and a diverse "middle" caste group. Among Janajatis, the Newars tend to be more advantaged (Gurung 2006); thus for the purposes of some analysis, Newars have been grouped together with the upper caste Brahmins and Chhetris, referred to as Brahmin/Chhetri/Newar (BCN).

Janajatis represented the single largest group (43.4 %), followed by BCNs (31.1 %), Dalits (15.8 %), "middle caste" groups (8.6 %), and Muslims (1.2 %). Although Muslim is a religious group, it is treated as a caste/ethnicity category in Nepal due to its social distinctiveness (Sharma 2014) and the need for greater attention to mainstream them as one of the important social groups in national development policies and practices (UNDP 2009). The "middle caste" groups in the sample were all from the three Tarai (plains or Madhes) districts and represent a fairly wide range in terms of their social and economic status. The proportion of Dalits in the surveyed areas was higher than in the national population (13.2 % according to the 2011 Census), and the proportion of "middle" caste groups and Muslims was lower.

By geographical region, the survey respondents are categorized into the caste/ethnic groups from tarai/plain areas (e.g., Tarai Brahmin/Chhetri, Tarai "Middle Castes", Tarai Janajati, Muslims, Tarai Dalits) and the caste/ethnic groups from the Hill/Mountain areas (e.g., Hill Brahmins, Chhetri, Newars, Hill/Mountain Janajati, and Hill Dalit).

Data Analysis

Data were analyzed at three levels. First, the multidimensional poverty across different social groups was analyzed using the Multidimensional Poverty Measure for the HKH region (MPM-HKH) (Gerlitz et al. forthcoming). This measure includes six dimensions in which well-being/deprivation can be assessed and a total of 15 indicators used to measure these six dimensions (Table 1). The indicators used to measure poverty or deprivation in each dimension were specific to the Hindu Kush-Himalayan region.

The second level of analysis involved an examination of gender-based social vulnerabilities with a focus on gendered access to resources and economic opportunities, gender roles, responsibilities, social norms, and their implications for women's adaptive capacity. The ways different social groups perceived climate

Table 1 MPM-HKH – poverty dimensions and indicators

Poverty dimensions	Indicators
Education	Literacy and education
Health	Illness, health care, and food consumption
Material well-being	Assets (TV, radio, telephone) and dwellings
Basic facilities	Electricity, drinking water, and sanitation
Social capital	Access to community decision-making and social networks
Physical accessibility	Access to markets, hospitals, a bus stop

change, its adverse effects, and their adaptive capacity were also examined. This, along with a review of Nepal's existing climate change policies, constituted a third level of analysis.

Results and Discussion

Multidimensional Poverty and Vulnerability by Social Group

Figure 2 shows the MPM-HKH and the poverty headcount for each of the nine major caste/ethnic discussed above. In terms of the incidence of multidimensional poverty (shown in red) and the Multidimensional Poverty Index value (shown in blue), the Tarai and Hill Dalits are significantly more deprived than all the other groups.

Nearly half or 48 % of Tarai Dalit households are multidimensionally poor, closely followed by the Hill Dalit with 31 % in poverty. Dalits from the Tarai and Hills also have the highest poverty index values (0.21 and 0.14 respectively), followed by the Muslims and Hill Janajati, both with index values of 0.11 or roughly half those of the Dalits.

The MPM-HKH also allows us to look at differences in the composition of poverty and in the importance of different dimensions of deprivation for different groups. Thus in Fig. 3 we see that for all the Tarai caste/ethnic groups, accessibility (shown in tan) is not a factor contributing to deprivation. Tarai Dalits and Tarai Brahmins benefit equally from the greater connectivity and road networks present in the plains areas. Similarly, all the hill/mountain groups suffer to some degree from the poorer connectivity and access to transportation in the mountainous regions.

Yet among the hill/mountain groups, those who face the greatest challenge in terms of physical accessibility are the Janajati – who often live on the higher slopes and more remote valleys. Although physical accessibility is not a big issue for Tarai Dalits or Muslims, these groups are highly deprived in terms of access to basic facilities such as sanitation, water and electricity, material well-being, education, and health. It is interesting to note that, while Nepal's Human Development Report, 2009, showed Muslims as having the lowest Human Development Index (0.401) measured in terms of life expectancy, education, and income, followed by all Dalits

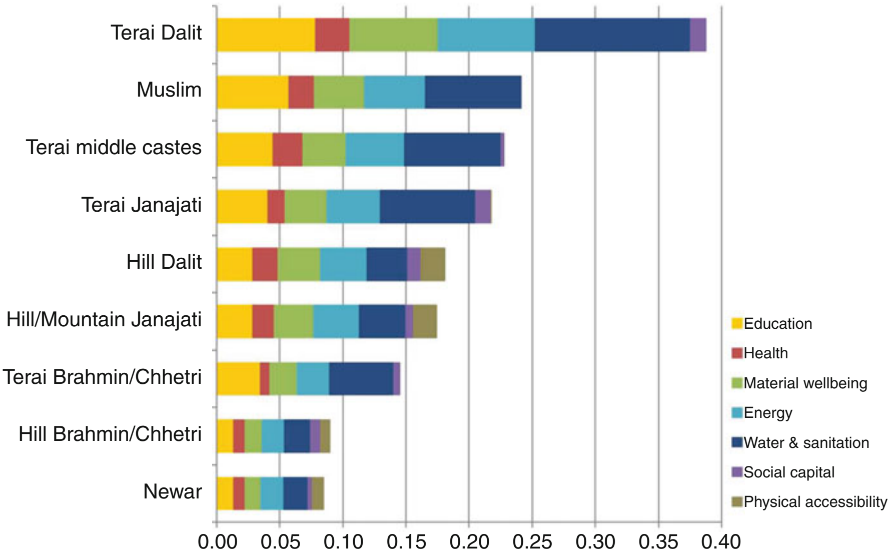

Fig. 2 MPM-HKH index value and headcount by social group

(0.424), the MPM-HKH shows the Muslims doing better than either the Hill or the Tarai Dalits. This is consistent with the most recent National Living Standard Survey in 2010/2011 that shows a significant drop in consumption poverty among the Muslims since the 2003/2004 survey.

The MPM-HKH in the Koshi Basin shown in Fig. 3 indicates that some groups within some communities could be potentially more vulnerable to climate change than others. For example, lack of social capital is a major constraint for Tarai and Hill Dalits and Muslims to cope with and adapt to the negative effects of climate change. Social capital helps people formulate livelihood strategies that enhance their ability to cope with extreme weather conditions as Dulal et al. (2010) point out. Membership in formal and informal institutions and opportunities to have voice and influence in decision-making in the institutions and networking with multiple stakeholders are some indicators of social capital (World Bank and DFID 2006; UNDP 2009). In the Nepal's Koshi Basin, Dalits and Muslims report greater difficulty in influencing the local decision-making processes than members of the Brahmin, Chhetri, Newar, Janajati, or Tarai "Middle Caste" groups (Fig. 4).

As shown in Fig. 4, different social groups differ in their perception of their ability to influence local- and higher-level decisions that affect them. In terms of higher-level decisions, households from all caste/ethnic groups felt they had little influence – though more BCN households felt they could influence such decisions than Dalit households (31 % and 18.1 % respectively). In the area of local-level decision-making, Muslim households showed the lowest levels of self-perceived influence: 34.9 % compared to 46.7 % for Dalits and 70.4 % for Brahmins and Chhetris.

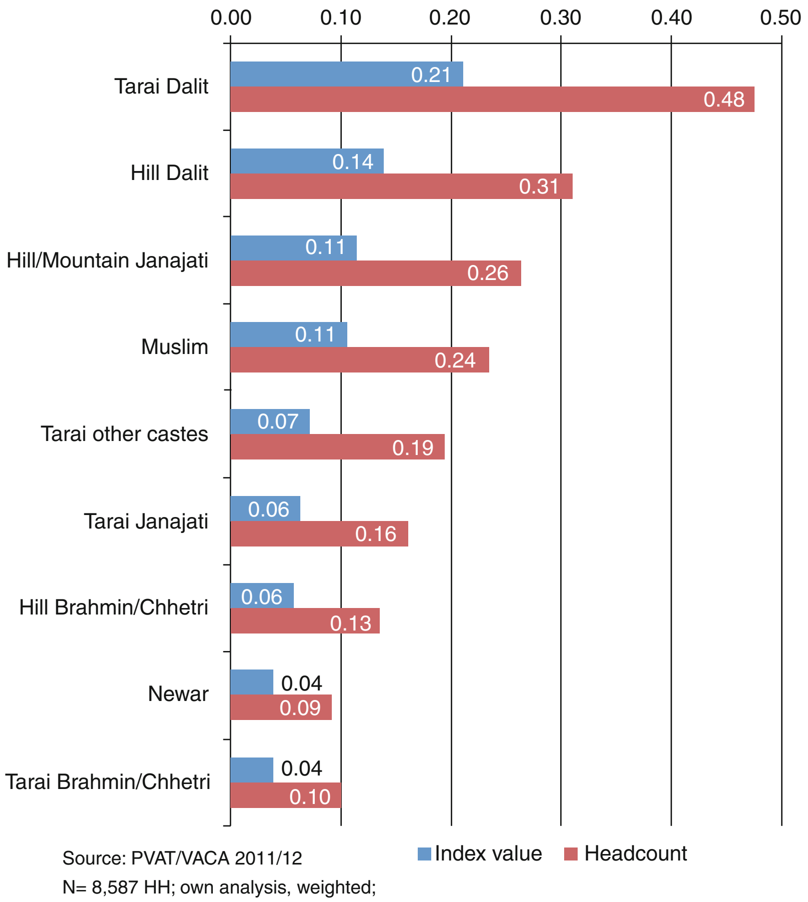

Fig. 3 MPM-HKH index value and absolute contribution of poverty dimensions by social group

One factor that is linked to the low levels of Dalit and Muslim social capital is their low level of education which restricts their access to information about climate change, adaptation ideas, and services that are communicated in texts. Low education levels coupled with low levels of social capital in turn reduce their ability to influence decision-making mechanisms related to climate change adaptation and reduce the likelihood that they will be represented by members of their own community when critical decisions are made. Dalit women are even more likely to be left out of communication and decision-making "loop" regarding climate change adaptation – unless climate change communication approaches make special efforts to respond to the additional barriers to participation they face as women. As McOmber et al. (2013) point out, women farmers' ability to adapt to climate change tends to be weaker in part because they are left out of many communication channels.

The high levels of health deprivation among Dalits and other marginalized households evident in quantitative data were also evident in field observations in

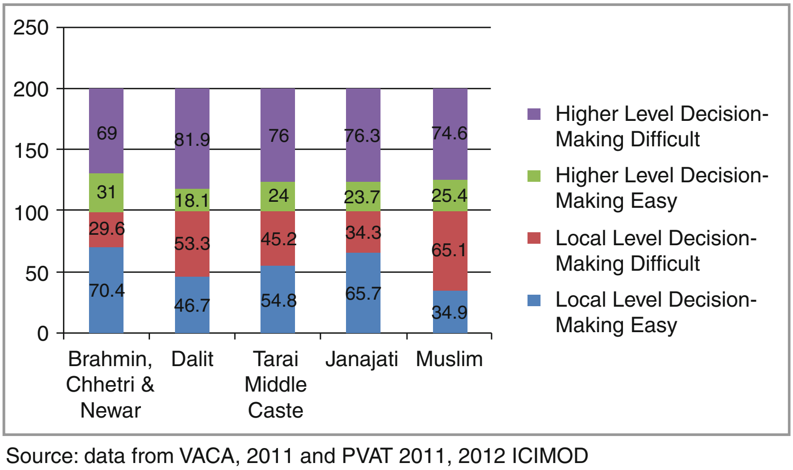

Fig. 4 Influence in decision-making process by social group (% response, $N = 5{,}378$) in the Koshi Basin, Nepal

flood- and drought-prone areas of the Koshi Basin where these groups were found to suffer more from illnesses such as typhoid, body swelling, diarrhea, and jaundice (Field note, July 2012). Although not specific to the Koshi Basin, case studies and reports from Nepal (Rai Paudyal 2008; Khadka 2010a; ANPFa 2011; DNF 2012) indicate that the majority of Dalits are landless or land poor. Many live in temporary houses and are in sharecropping relations that make them dependent on landowners.

Their houses tend to be flimsy and unable to withstand high winds or floods – another source of vulnerability to climate-induced hazards. Dalits are also more likely to live in disaster-prone areas such as sloping areas, riverbanks, and land susceptible to soil erosion or landslide (DNF 2012; Jones and Boyd 2011).

The above discussions indicate that socioeconomically marginalized social groups tend to be most vulnerable to the negative effects of climate change and have inadequate capacity to cope with and adapt to the negative impacts of climate change and climate-related hazards.

Gender-Based Social Vulnerability

Gendered Access to Productive Resources and Economic Opportunities

Resource availability and economic opportunities for women and men were analyzed on the basis of land ownership and involvement in different activities. The results are shown in Table 2. Fourteen percent of the surveyed households reported that women owned some land against 81.5 % for men. Men worked more in agriculture, livestock raising, fishery, and other economic activities, while women contributed more to the "care economy" through spending their time in cooking;

Table 2 Gendered access to resources and economic opportunities

Parameter	Gender	
	Women	Men
Agricultural land and cultivation		
% of households with agricultural land owned	14.0	81.55
Average no. of household members working on farm	1.7	1.5
Involvement in household work including looking after household members (% of women/men engaged in activity[a])		
Cooking	92.9	1.4
Fetching water	57.9	2.7
Collecting fuelwood	42.4	6.3
Seed purchase	16.1	51.1
Caring for children and the elderly	46.5	2.4
Involvement in cash income activities (%) of time		
Selling agriproducts in the market	16	34.7
Average no. of family members per household employed in paid work for 10 or more months	0.13	0.38
Migrants outside country (% of total)	12.0	88.0
Average no. of migrants per household (outside country)	0.02	0.32
Average annual remittances received per household from migrants within country (USD)[b]	14	118
Average annual remittances received per household from migrants outside country (USD)[b]	13	339

[b]1 USD = NRs 95

caring of children, the sick, and elderly; collecting water and fuelwood, food processing, and other chores traditionally classified as "domestic activities" or "housework." Nearly all women (93 %) were engaged in cooking meals compared to only 1 % of men. Men were more active in purchasing seed and selling agriproducts; women's roles focused more on collecting water and fuelwood. This finding is similar to observations by others in Nepal (Acharya and Bennett 1981; Regmi and Fawcett 2001; St. Clair 2003). There were also marked gender differences in income-earning opportunities. On average, more men had access to paid employment for 10 or more months (0.38 per household compared to 0.13 for women). This finding from the Koshi Basin survey is consistent with the 2001 and 2011 census data showing that men are seven times more likely to migrate to urban areas or abroad for work or study than women (Khadka 2013). In the Koshi Basin survey, 88 % of those migrating for employment were men, so women's contribution to remittances was correspondingly low. Households received an average value in cash and kind of USD 14 from women and USD 118 from men who had migrated for employment within the country and USD 13 from women and USD 339 from men who had migrated abroad.

Table 3 Time cost of collecting fuel and water (hours/day)

Social group	Collecting fuelwood		Fetching water	
	Men	Women	Men	Women
Brahmin, Chhetri, Newar	1.03	2.14	0.57	1.16
Dalit	1.04	1.59	0.93	2.29
Tarai middle caste	0.32	2.31	0.65	2.11
Janajati	1.12	2.08	1.02	1.52
Muslim	0.40	1.45	0.45	1.33
Average	0.78	1.91	0.72	2.28

Source: Field survey 2011, 2012

Time Spent Collecting Fuel and Water and Implications for Gender Vulnerability

Table 3 shows the average time spent by men and women from different social groups in collecting fuel and water. Women spent an average of 4.19 h per day collecting water and fuelwood and men 1.5 h. The additional time spent by women on these activities may limit their ability to participate in cash income-generating activities, community leadership, or taking advantage of economic opportunities created as a result of climate change. In the Koshi Basin, as elsewhere in most of South Asia, women have the primary responsibility for fetching water, and this has a number of implications for them in terms of time and work burden. During prolonged drought, women must often travel long distances to alternative water sources when nearby springs dry up. The drying of springs due to climate change has led to increase in women's drudgery (Dixit et al. 2009). Women's workload also increases in post-disaster situations because the usual sources of water, fodder, and fuelwood are disrupted, forcing them to walk longer distances to secure these essential resources for their families (Mehta 2007; Swarup et al. 2011). Moreover, gathering fuel and water from very fragile, harsh (too cold or too hot), sloping, remote, and difficult terrain and socially insecure areas also increases the vulnerability of women and girls when these resources are disrupted by the impacts of climate change.

Social Institutions/Norms: Implications for Adaptive Capacity

A number of social norms or institutions restrict women's access to services, resources, and decision-making. For example, the social institution of *purdah* or veiling (practiced mostly among the Madhesi Brahmin, Chhetri, and "middle" castes and Muslim women) is strong in the Tarai plain districts of the Nepal's Koshi Basin and presents a major obstacle to women's full economic and political participation. In these areas women's mobility, social interactions, and reproductive decisions are largely controlled by male household members. In focus group discussions, women would only speak out when no men were present in the group. In all groups in the Tarai and in higher-status groups throughout the Basin, there is a social stigma attached to women who work for others – especially for wages – and women are expected to have male protection when they move outside the home. Thus Tarai women in households, where men have migrated, rely heavily on the remittances sent by their husbands or sons (field notes, July 2012). Although Dalit women suffer less from restricted mobility, they are generally forced by economic need to carry out low-status wage labor. They also tend to experience more gender-based violence (Ghimire 2008; Gurung et al. 2014). In migrant households in the Hill districts of the Nepal Koshi Basin, women don't control the use of remittances; instead their husbands instruct them from abroad over phone on where and how to spend the funds they have sent (Adhikari and Hobley 2011).

Other social institutions such as early age of marriage, dowry, ideas of women's impurity during menses and after childbirth, and other forms of gender discrimination such as violence against women, son preference, and the tradition of patrilineal land inheritance in the Koshi Basin also reduce women's ability to adapt to climate-related stresses. Early marriage limits girls' ability to complete their education and their chances to gain some degree of economic empowerment.

The prevalence of the patrilineal system of inheritance where landed property transfers from father to sons within a family further disadvantages women who have limited rights to own family land and other properties (Gurung et al. 2014). Land ownership by women is an indicator of their empowerment and ability to influence household food security and well-being (Allendorf 2007). In the Nepalese context, being a landowner confers social prestige and increases a person's ability to influence household and community decisions (Allendorf 2007; Rai Paudyal 2008). Women's limited ownership of land thus has implications for their ability to respond to climate change impacts. For example, since most women do not own the land they work, they tend to lack the authority to decide on changes in land-use practice and cropping system as an adaptation strategy.

Women's membership in local water user associations (WUAs) and other community organizations and their meaningful participation in decision-making about natural resources are very minimal in the Koshi Basin. Interviews with Dalit women and Muslim women indicate that their voice on water access and distribution is rarely heard in water user committee meetings because men, mostly non-Dalits, who are in the major decision-making positions (e.g., chair person, secretary, advisor) are more interested in using the water for irrigation than for drinking and sanitation (Field note, July 2012).

A study from Sarlahi district of the Koshi Basin indicates that more girls than boys under age 5 died from flood-related disaster. This is probably related to the strong son preference throughout the Koshi Basin that leads to favoring boys when hard choices are made in the allocation of resources (Bartlett 2008 in WHO 2011, p. 12).

These findings suggest that social institutions/norms along with gender inequalities in access to and control over productive resources and livelihoods options affect the adaptive capacity of women, especially the socially and economically disadvantaged women in the Koshi Basin.

Climate Change and Socially Differentiated Impacts

People's Perceptions of Climate Change and Livelihood Problems

People living in the Koshi Basin are experiencing the impacts of climate change. Around 84 % of respondents had perceived some type of change in the environment (climate) in the past 10 years (Fig. 5). They reported an increase of events such as drought, flood, erratic rainfall, hailstorms, landslides, fire, high temperatures, poor seed development, livestock disease, insect attacks, and crop pests. More than 80 % of the households interviewed mentioned that the temperature and rainfall patterns had changed over the previous decade; 60 % said that the hot season had become hotter and 35 % that the cold season had become colder. Changes reported in precipitation included more erratic rainfall, fewer rainy days, precipitation coming later in the season, decreased summer precipitation, and decreased annual rainfall. These perceptions are consistent with the findings of other climate change research in the study area (Sharma et al. 2009; Mandal et al. 2013).

People in the study area are also experiencing a variety of interconnected environmental, social, and economic problems and challenges that have negative effects on their livelihoods (Table 4). The kinds of problems perceived differed somewhat between caste/ethnic groups; 52 % of non-Dalit households reported experiencing environmental problems as a significant issue over the past decade, compared to 43 % of Dalit and 33 % of Muslim households. This is probably because non-Dalit households are more likely to farm their own land, and thus, changes in seasonal cycles of rainfall and temperature may have a more direct impact on their livelihoods. For Muslims and Dalits, social problems were more prominent with 58 % of the Muslim and 45 % of the Dalit households reporting social problems compared to 38 % of the non-Dalit households. Economic problems were reported by a roughly the same percentage of households in all groups (9 % of Muslims, 10 % of Dalits, and 7 % of non-Dalits). This may be linked to the higher dependency of Dalit and Muslim household on agricultural wage labor to sustain their livelihoods. Overall economic factors appeared less problematic than environmental or social problems for all respondents, regardless of gender or caste/ethnicity.

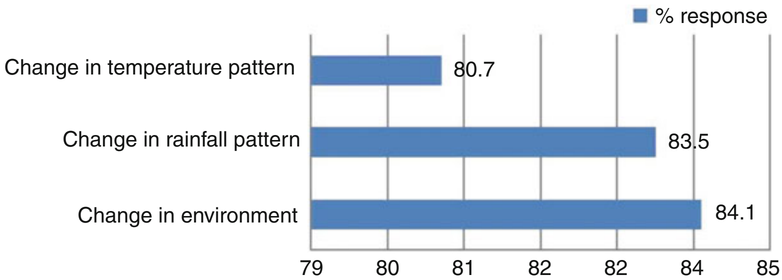

Fig. 5 Perceived change over the past decade

Table 4 Problems noted by respondents during the last decade

Social group	Type of problem

Gender-Specific Impacts of Climate Change

A number of aspects of climate change experienced in the Koshi Basin have gender-specific impacts. One of these is the increased shortage of water. The number of households in the Nepal part of the Koshi Basin who fetch water from rivers or streams and open wells has increased over the past decade, whereas the number with access to a covered well as the main source of water for domestic use went down by 60 % (Khadka 2013). This is because of the disappearance of underground water and lack of water management for recharging the ground water. As noted earlier, women and girls do most of the work to fetch water for cooking, cleaning, washing, bathing, and drinking (for people and animals) in the Koshi Basin. Reduced access to covered wells means that women and girls have to walk farther to fetch water, which increases their workload, and collecting from open sources means they (and their families) are more exposed to unsafe water. In focus group discussions, women mentioned that they have to walk at least 1 hour on average to fetch a bucket of water. A recent study by Plan Nepal (2012, p. 24) suggests that girls are most likely to be affected by climate change in some of the Koshi Basin districts because when local water and forest resources are depleted, they are the ones who have to travel long distances to collect fuelwood, fodder, and water.

The shortage of water has direct implications for overall family health and sanitation. Children with limited access to toilets and sanitation suffer more from diarrhea (Bose 2009). Only 67 % of households surveyed had toilets. Respondents in the Tarai districts reported that they preferred to practice open defecation and didn't want to build or use toilets because of the lack of water. The percentage of households owning a toilet was lower for all Tarai groups (Brahmin/Chhetri 56 %, Janajati 47.9 %, "middle castes" 36 %, Dalits 22.2 %) than for all hill groups (Brahmin/Chhetri 85 %, Janajati 68 %, Dalits 68 %). This finding corroborates other studies (MOHP 2011). Girls skip school when they are menstruating because of poor sanitation facilities at school. Also, the number of days out of school has increased for girls by up to 65 % in both the hills and the Tarai due to climate-induced disasters (Plan Nepal 2012, p. 32).

Floods trigger human disease, social insecurity, and mental stress. It was apparent from focus group discussions with women in flood-affected communities that many infants suffered pneumonia and mothers experienced joint aches and body swelling after giving birth in houses which are not flood resistant and have cold and wet floors (field note July 2012). Women also reported experiencing gender-based violence during water hazard events. Sexual harassment, attempted rape, and sexual abuse against women and girls are common in the temporary shelters where flood-affected people must reside (Acharya and Aryal 2008).

Key informants specifically mentioned the way that the flood in 2008 had affected food security and gender roles. Poor farmers used to rely on farm work from their landowners. When the fields turned into barren land covered with sand, the marginal farmers lost an important livelihood source and even the large landlords suffered losses. Young men who used to migrate for work in India or Nepal in the agricultural off-season have now begun to migrate for longer-term work, especially to the Gulf countries, leaving women, the elderly, and children behind. The women left behind reported encountering abuse and harassment from relatives when they had to take over previously male responsibilities, such as going to district headquarters for extension services (UN RCHCO 2013). Men's outmigration has also increased women's already heavy workloads, as they have to carry out livelihood activities and participate in social activities previously done by men in addition to their household and farm activities (Adhikari and Hobley 2011).

In Sindhuli district winter rains were reported as reduced, absent, or coming at the wrong time; hence most families have given up planting millet, barley, and buckwheat (Plan Nepal 2012), which are sources of iron and other nutrients that help overcome malnutrition and anemia problems that many women and children in Nepal experience (MOHP et al. 2012). Similarly, farmers in Makwanpur district have stopped planting mustard, millet, and pumpkin that used to grow abundantly a few years ago due to the reported decline in productivity of these crops which could be related to lack of water (Plan Nepal 2012). Selling mustard and vegetables in local markets is one of the sources of subsistence income for rural women in the Nepal Koshi Basin. Reduced production of these products has meant a loss of income-generating opportunities for women.

Differential Coping Capacity

Respondents were asked what they had done to cope with the environmental, social, and economic problems they had encountered over the last decade; the results are shown in Table 5. Men and women in all groups reported that they had borrowed money from relatives, friends, local money lenders, and village/cooperative funds. Overall, men were more likely to borrow money than women, but women were more likely to borrow from cooperatives or village funds. Cooperatives or village funds were also more important for BCN and Janajati people than for Dalit, Tarai "middle castes," or Muslim groups. This could be a reflection of higher membership

Table 5 Ways of coping with social, environmental, and economic problems

Common coping strategies	Social group by caste/ethnicity % response ($N = 2{,}299$)					Social group by gender % response ($N = 2{,}299$)		
	BCN[a]	Dalit	TMC[b]	Janajati	Muslim	Women	Men	Overall
Borrowed money from relatives	32.7	41.2	46.2	30.3	20.7	33.8	35.6	34.8
Borrowed money from moneylender	24.4	37.7	30.8	30.3	27.6	26.6	31.8	29.5

[b]Tarai middle castes

in community level financial institutions among these groups, but this needs further research. For most groups except Muslims and Tarai "middle castes," borrowing money from banks was generally less important than borrowing from other sources. Selling livestock or jewelry was an important strategy for BCN and Janajati groups but less or not at all for Dalit, Muslim, and Tarai "middle caste" people. It was also more important for men than for women. Muslim and BCN groups also used their savings to buy food.

The results show that for households in the study area with such assets, using their financial and physical capital is an important strategy for coping with the impacts of climate change. Borrowing money, selling livestock, and spending household savings on food however have the potential to increase the level of vulnerability. Building people's resilience – that is, their ability to adapt positively rather than just cope with or survive the impacts of climate change – is the goal of climate change policies and programs. In the following section, some examples of people's resilience are discussed.

People's Resilience

People in the Nepal part of the Koshi Basin have developed some resilience to adapt to climate change. Villagers in Maunabudhuk, Dhankuta district, have continued to build traditional multipurpose ponds close to their homes to harvest rainwater (ISET 2009). Water can remain in these ponds for more than 4 months and is used for livestock and irrigating fruit trees. Farmers have shifted their production from cereals to cardamom that requires less water but fetches a higher price than cereals (ibid).

The indigenous farming practices of farmers in Nepal are another example of community resilience. Intercropping with several crops is a commonly used strategy in the mid-hills of Nepal, including the Koshi Basin districts. Farmers plant millet and soybean in the same plot and intercrop climbing beans in maize fields to fix nitrogen and act as natural fertilizer (Jansen 2010). Soybean has also been planted along the bunds of paddy fields to prevent erosion and provide additional revenue. In some villages, farmers also have traditionally planted three different crops (lentil, black bean, and sesame) on the same land. The crops are alternated each year to minimize pests and diseases and improve soil fertility and nutrition (ibid). Farmers practice mulching or cover crops to conserve soil moisture. They introduce legumes or nitrogen-fixing crops into the major crops such as maize or wheat. Legumes provide additional income and protein-rich food in case the major crop fails or is lost (Shrestha et al. 2014).

To combat crop diseases, farmers resort to indigenous pest management practices such as bio-pesticides, scattering ash or cow urine, crop rotation, and intercropping (Jansen 2010; Shrestha et al. 2014). In response to erratic precipitation, farmers have adjusted the agricultural calendar by delaying or moving forward the time of sowing and harvesting their crops (Jansen 2010). Farmers also have practiced income generation activities that are low-cost and less labor intensive and cannot be affected by the adverse effects of climate change. For example, they are involved in value chains of high-value products and services, such as non-timber forest products, medicinal and aromatic plants, indigenous honeybees, and ecotourism (Choudhary et al. 2011; Pratap et al. 2012). As case studies reveal (Mitchell et al. 2007; Karki and Gurung 2012; Shrestha et al. 2014), women farmers are actively involved in the promotion of homestead gardens, water ponds and tree conservation in ecologically sensitive areas, agroforestry, off-seasonal vegetables, alternative energy technologies (biogas, improved cooking stoves), and agricultural soil management.

Policy Frameworks and Responses to Climate Change

Mainstream policies on climate change tend to consider women as a vulnerable group rather than recognizing them as an important resource or as agents of change for development. So far such policies have tended to mention the need to consider women's participation rather than specifying measures to achieve it. For example, although Nepal's National Adaptation Programme of Action (MOE 2010) recognizes women's roles in household activities and the possibility that adverse effects of climate change might increase their vulnerability, it does not have any specific strategies for gender inclusion (Kumar 2011; Mainlay and Tan 2012) or for overcoming the social vulnerability that constrains women – as well as the poor and socially marginalized – from improving their adaptive capacities. The NAPA (MOE 2010) framework has six broad strategic elements (agriculture and food security, water resources and energy, forests and biodiversity, public health, urban settlement and infrastructure, and climate-induced disaster), but none mentions gender or social identity as an important issue in the adaptation process. The nine projects prioritized for climate change adaptation lack clear mechanisms for the inclusion of women and other disadvantaged groups and strengthening their adaptive capacity, networking, and decision-making power over the use and management of local natural resources (Mainlay and Tan 2012).

Similarly, although Section 8.4.2 of Nepal's Climate Change Policy (2011) states the importance of "ensuring the participation of poor people, Dalits, marginalized indigenous communities, women, children, and youth in the implementation of climate adaptation and climate change related programmes" (see MOE 2011, p. 7), the policy has no analysis of gender, social exclusion/inclusion, or the indigenous knowledge and skills that many caste/ethnic groups hold in terms of natural resource management and local livelihoods. Hence there is little conviction behind the stated commitments and no empirical evidence upon which to base necessary governance and policy measures to ensure women and disadvantaged people enjoy their right to participate in and benefit from adaptation programs and processes. Many studies of Nepali society have identified the persistent inequalities and the influence of social elites and men in local decision-making and participation processes (Lama and Buchy 2002; Nightingale 2002, 2006). The challenges to making development equitable and sustainable in the natural resource sector are well known. Yet Climate Change Policy and related governance structures are blind to social outcomes in the sense that they lack specific implementable provisions that can be monitored to ensure participation of women, the poor, and socially marginalized in decision-making and their access to climate change funds. There are no clear mechanisms to ensure that members of excluded groups have equitable access to these and other benefits that climate change adaptation and mitigation strategies would generate at all levels. Nor have any measures been put in place to restructure institutional practices and decision-making processes or to build the necessary capacity needed to implement climate change policies and programs in equitable and gender-inclusive ways.

Strengthening the knowledge and capacity of the government and other stakeholders, including the private sector and farmers, on climate change and its impacts on ecosystem services, the hydrological cycle, and people's livelihoods are most critical elements of climate change adaptation strategies (Tsering et al. 2010; Bartlett et al. 2010; Tiwari et al. 2014). Adaptive capacity-strengthening actions can include not only extension and training but also research and assessment, climate-sensitive planning, policy change, implementation, and monitoring (Tsering et al. 2010). Although both the NAPA and the Climate Change Policy mention the importance of capacity building, neither of these policy instruments gives much emphasis to specific capacity-building actions. They pay even less attention to strategies to transform the social, governance, and institutional structures that mediate responses to climate change.

Both the Climate Change Policy 2011 (MoE 2011) and the NAPA 2010 (MoE 2010) call for at least 80 % of financial resources for climate change adaptation to be available at community level to fund local-level adaptation activities. Yet the policies lack the overall governance structure and specific operational measures needed to ensure that the poor, ethnic/caste minorities, women, and other traditionally marginalized social groups have access to these funds. There are also no specific provisions to ensure that the fund would not be used in ways that could actually harm these groups. Tiwari et al. (2014) also note that there is a gap in institutional arrangements and capacity to effectively implement the Climate Change Policy provision requiring that 80 % of the climate change budget be spent on local level adaptation programs benefitting the poor and other marginalized social groups. Critics (Ojha 2011) point out that the governance institutions see communities as passive beneficiaries rather than active partners in development, and this also undermines the capacity of men and women natural resource users to develop adaptation measures appropriate to their needs.

Researchers have noted that communities have adapted to climate variability and other changes for many years, and, accordingly, their indigenous knowledge can be critical for climate change adaptation processes (Yamin et al. 2005; Nyong et al. 2007; Eriksen et al. 2011). From a gender perspective, men and women often have different knowledge about biodiversity resources and their sustainable use (Khadka and Verma 2012). All these sources of local knowledge are relevant for the climate adaptation process and need to be integrated into adaptation strategies. At present, however, this understanding is missing in Nepal's climate change adaptation strategies and climate policy. These policies tend to be guided by a purely biophysical and economic perspective and do not take into account the persistent sociocultural and structural inequalities in Nepali society when defining vulnerability and adaptation measures. Inclusion of social and gender issues and approaches in policy frameworks needs to be part of the policy process (Keeley and Scoones 2003). More effort is needed to develop local gender and social analysis capacity, to include women and other socially excluded groups in higher-level decision-making positions and policy making, and to ensure that social/gender expertise and financial resources are available for assessing vulnerability and adaptation at different scales so that Climate Change Policy processes can be made more gender inclusive and responsive to the needs of women and the most vulnerable social groups (Nightingale 2009; Khadka 2010b; Brown 2011; Nellemann et al. 2011; Lahiri-Dutt 2014).

Conclusion

This chapter shows how different social groups, including women, experience different levels of poverty and vulnerability to climate change impacts, face different challenges and constraints in adaptation, and have different resources with which to respond. Making adaptation more inclusive and sustainable requires an interdisciplinary approach to data collection and analysis that complements natural science research with approaches from social science that are able to bring in the perspectives and priorities of diverse local groups. It also requires more accountable governance systems that not only recognize varied levels of adaptive capacity among citizens but are committed to and capable of responding appropriately to reduce preexisting disparities. Compared to men from the dominant BCN group, Dalit and Muslim men and women – and indeed, women from all groups in the study area – are relatively more vulnerable to climate change. They are in a weak position to prepare for and cope with the negative impacts of climate change. Yet, despite their disadvantaged social and economic positions and greater exposure to the shocks and stresses caused by climate change, these groups have developed creative adaptation strategies that need greater recognition.

Nepal's NAPA (MOE 2010) and the Climate Change Policy (MOE 2010), however, are not sufficiently sensitive to gender and social equity. They lack provisions and institutional measures that could help empower women and other disadvantaged groups to participate in and benefit from climate change adaptation program and policy processes at all levels.

Recommendations for Action

An appropriate analytical and governance framework is required to mainstream social and gender dimensions into adaptation policies and strategies. Development of such a framework is beyond the scope of this paper, but we suggest the following elements to stimulate critical thinking.

- To better understand the complexity of climate change vulnerability and adaptation from the perspective of gender relations and across different castes/ethnicities, ages, classes, and locations, **complement natural science methods and frameworks with gender analysis and social science approaches**.
- **Recognize** the differential impacts of climate change on women and men and socially marginalized groups, the different levels of challenges and barriers that they experience, and their different capacity to adapt; and address their specific needs and priorities.
- **Integrate** gender and social dimensions into climate change policies and strategies including adaptation and mitigation; food security and agriculture; health, water, and sanitation; forestry; disaster-risk reduction; energy and technologies; and infrastructure.
- **Strengthen** the capacity of the government and non-state actors to better understand the social and gender dimensions of vulnerability to climate change. A first step in developing this understanding is to **insist on the collection, analysis, and reporting of gender and socially disaggregated data** and to use the knowledge generated as the basis for policy and program development. It is also important that disaggregated data are used to monitor outcomes

for different groups so that continuing or increasing disparities can be identified and addressed.

- **Change governance systems to enhance the access and entitlement of rural women and socially marginalized groups** to natural, financial, and social resources, including land, water, forest, and biodiversity, as well as health care, technology, training, education, and information, to improve their capacity to adapt to climate change.
- **Recognize that everywhere local people who work on the land and have deep contextual knowledge of the management of local natural resources are an important resource** in developing positive responses to the challenges of climate change. It is especially important not to overlook the knowledge of rural women and indigenous peoples.
- **Facilitate** access to information, knowledge, and gender and culturally appropriate technologies to make adaptation more successful and more equitable. Make sure that this knowledge is communicated using a variety of channels including those that can reach nonliterate groups.
- **Pay attention to governance structures for climate change adaptation**. Make specific provisions to ensure that women and socially marginalized groups can participate meaningfully in local and national adaptation planning, including the process of developing National Adaptation Programmes of Action (NAPAs). The accountability to ensure that funds meant to assist these vulnerable groups actually reach them must be clearly laid out and monitored.

Acknowledgements This research was conducted under the Koshi Basin Programme at the International Centre for Integrated Mountain Development (ICIMOD), which is supported by the Australian Government through the Sustainable Development Investment Portfolio (SDIP) for South Asia. We thank the Himalayan Climate Change Adaptation Programme (HICAP) of ICIMOD, funded by the Norwegian Government, and the Adapt Himal project of ICIMOD funded by IFAD for providing access to the PVAT and VACA datasets. Gender, Governance, and Climate Change Adaptation

Melissa Nursey-Bray

Contents

Abstract

This chapter attempts to highlight the role that gender plays in the context of climate change adaptation. It uses a discourse analysis approach to comparatively present a review of the role gender plays in climate change adaptation. Currently, two discourse storylines dominate the exploration of gender and climate change. One tells a story about women being disproportionately impacted by climate change and constructs them as ongoing victims. The other storyline explores the role women play in building adaptation and simultaneously presents women as both being more resilient and having more agency in these contexts. Applying a gender lens to governance could include enhancing the role of existing communities of practice. This chapter attempts to provide a detailed review of and means by which to understand and present how climate change and climate change adaptation is driven

by gender and the implications of this for ongoing adaptive governance. This chapter adds to gender analyses by considering the role of communities of practice arguing that their deliberate utilization can enable gender to be productively rather than negatively utilized to build robust, socially just, and innovative adaptation regimes.

Keywords
Gender • Climate change • Adaptation • Communities of practice

Introduction

Climate change is an issue that is affecting human societies and ecosystems on a global scale, albeit in variable ways at localized levels (Adger and Kelly 1999). Gender is important in trying to understand climate change impacts and societal responses to it. Gender is often at the heart of power and knowledge interactions but is as yet, understudied: "Whereas the concepts of class, poverty and race make regular appearances in social scientific analyses of global climate change, the same cannot be said for gender" (MacGregor 2010).

Further, it is often difficult to disentangle the role of gender from all the other impacts because as Terry (2009) notes climate change does not occur in a vacuum, but in the context of a multitude of other risks, including globalization conflict, health issues such as HIV/AIDS, and poverty. "Climate change is not gender neutral. Studies reveal that women and men's decisions differ along risk taking lines, use and type of coping strategies, adaptability, and advice taking and information seeking behaviours. Much of this has to do with existing gender roles and inequalities (Dankelman et al. 2008). The effects of climate change, including disaster and emergency situations, can magnify these and create new inequities and vulnerabilities" (Quinn 2009, Cannon 2002).

How societies deal with and adapt to its impacts and, within that, how gender will affect and be affected by impacts and response to climate change is the concern of this chapter. Currently, many studies focus on the negative impacts of climate change on women and specifically women in the developing world who tend to be poorer and likely to be disproportionately affected by climate change (FAO 2011). This chapter builds on this work and presents two key discourse storylines around gender and climate change which are catalyzed around (i) impacts and (ii) adaptation. The chapter argues that a gender lens can be built on in addressing impacts and building adaptation to climate change, via communities of practice which play a role in building local and adaptive governance regimes. The chapter concludes with a presentation of some key communities of practice and their activities in this context.

Method

Using the issue of gender as the focus, this chapter utilizes historical documents and discourse analysis to examine the way in which gender is discussed and then the implications of this for climate and gender policy. In this chapter "gender" refers to the socially constructed norms, roles, and relations that a given society considers appropriate for men and women. Gender determines what is expected, permitted, and valued in a woman or a man in a determined context (Alston 2013; Nelson 2011; WHO 2010).

Discourse analysis is a tool that assists in understanding the variations and constructions in and around gender. This is partly because the use of discourse helps the understanding of different actors' perspectives, in turn stimulating a fuller understanding of how individuals engage within policy processes, an "engagement that is fundamentally communicative and hence discursive" (Rydin 2005, p. 77). Discourse analysis can also assist in linking different actors and power/knowledge regimes to impact on decision making (Feindt and Oels 2005). Understanding the role discourse plays is important because of "its capacity to reveal the role of language in politics, its capacity to reveal the embeddedness of language in practices and its capacity to answer 'how' questions and to illuminate mechanisms" (Hajer and Versteeg 2005, p. 175). It is also a method that offers the capacity to explore power and its correlative concept knowledge and how they play out in practice. To paraphrase Dingler (2005) but replacing nature with the notion of gender: "The discourse of *gender* is a discourse of power where the constellations of power determine the construction of *gender*." Gender and climate change are both innately and intensely imbued with "wicked" power relations that, when together, are worth exploring so as to better understand how to use those dynamics to resolve rather than constrain the key issues facing society today: "The study of discourse also allows one to see how a diversity of actors actively try to influence the definition of the problem" (Hajer and Versteeg 2005, p. 177). Finally, given the global reach of both gender and climate change, using discourse analysis can help us map at various scales the multiple trajectories and distribution of power within the climate change/gender domains (Keil and Debban 2005; Oels 2005).

After Hajer (1993), who typifies the ways in which language about a subject and the on-ground activities join together as a discourse coalition, the chapter reports on two major discourse storylines or coalitions that emerge out of the literature and practice around gender and climate change. A discourse coalition is defined as "the ensemble of a set of story lines, the actors that utters these story lines, and the practices that conform to these story lines, all organized around a discourse" (Hajer 1993, p. 47).

Results

As Okali and Naess (2013, p. 3) argue, "when gender is used by mainstream agencies to talk about women, two contrasting pictures of women emerge: either they lack agency and hence the ability to exploit opportunities (and as a consequence struggle to fulfil their responsibilities in difficult if not near impossible circumstances), or, as is especially the case to-day, they behave as resourceful providers and reliable entrepreneurs." An interrogation of the literature and case studies finds this is indeed the case but it is in fact embedded within a broader delineation of gender in the context of (i) impacts and (ii) adaptation. In the context of climate change, gender discourse around impacts tends to focus on women and on women in the developing worlds, whereas discourse around adaptation is more differentiated, examines the experience of both men and women, and often focuses on the role of women as agents of change and people to depend on.

Storyline One: Women Are Disproportionately Affected by Climate Change

Overall what emerges from a review of studies in this area is a driving discourse that asserts that even in developed countries, women are disproportionately impacted by climate change (FAO 2010). Specifically, gender-differentiated situations such as poverty will exacerbate the increasing impacts of climate change over time. For example, 70 % of the 1.3 billion people living in poverty are women and “Gender-related inequalities are pervasive in the developing world. Although women account for almost 80 % of the agricultural sector in Africa, they remain vulnerable and poor” (Denton 2002). Forty percent of the poorest household in urban areas are headed by women, and while women dominate the world’s food production (up to 80 % in some cases), they still own less than 10 % of the land. Where women’s socioeconomic status is greater, it is clear that they are more resilient to impacts (Neumayer and Plumper 2007).

In the instance of natural disasters, studies highlight that the stronger the disaster, the greater effect on the gender gap, especially as more often than not, natural disasters lower the life expectancy of women. For example, boys are often given preferential treatment in rescue efforts over women and girls, women are often in the home and thus less able to get out of the disaster zone. During cyclone disasters in Bangladesh in 1991, 90 % of rather 140,000 mortalities were women. In South Africa, women, especially poor women, are impacted by climate policies, but do not get the opportunity to be part of the decision-making process (Anneke et al. 2010). Women in Mexico find their livelihoods are affected by changes in climate (Beuchler 2009). In Malawi, exposure, sensitivities, and adaptation all vary between women and men, with men generally having more opportunities than women. This highlights the need for policies to build better access to and involvement in climate programs for women (Kakota et al. 2011).

Women will be more exposed in developing countries to greater health and mortality risks, including water contamination, malaria, heat exhaustion, increase in infectious diseases, scarcity of water, salinization of water, flooding, mortality as a result of extreme weather events, disruption through forced migration, impacts of incomes after extreme events, and issues cased by family- and household-related stress and injury, including suicide (WHO 2010; Kukarenko 2011). For example, nutritional status affects women’s ability to deal with climate change; in South and Southeast Asia 45–60 % of women at reproductive age are underweight and have nutritional deficiencies, which means, for example, that more women than men will tend to die during a sustained heat wave or during drought and food shortages. In Hurricane Katrina, most of the victims trapped in New Orleans were African-American women.

In Sri Lanka during the tsunami, men survival rate was higher due to the fact that boys, not girls, are traditionally taught how to swim and climb trees. In disasters women are also more likely to be at risk of assault and abuse and have to physically depend on others due to pregnancy (WHO 2010; Smyth 2009).

Gender norms will also often dominate how public space is to be used or how women are to appear in public. For example, as Wong (2012, p. 15) notes of floods in Bangladesh, "…warning information was transmitted by men to men in public spaces, but rarely communicated to the rest of the family, and as many women are not allowed to leave the house without a male relative, they perished waiting for their relatives to return home and take them to safe place." Nagel (2012) notes that mores of masculinity, and adherence to notions of war, and men's dominance in science and government also mean that women are disproportionately disadvantaged by the moral and ethical frameworks which guide their lives.

Enarson and Morrow (1998) in their book *The Gendered Terrain of Disaster* state that gender inequalities more than differences explain the disproportionate impact of disaster on women and girls. This gendered terrain of disaster is characterized by a number of features seen in Table 1 below.

Alston (2011) notes there are also many gendered impacts in developed countries, such as Australia, but in this case focuses on people living in rural areas. In summary she outlines impacts including increasing poverty, financial pressures, emotional stress and other impacts, difficulties in accessing employment on and of farms, social isolation, community decline, marital and intergenerational conflict, loss of access to services and resources, the loss of young people from the district, and the demand placed on older people to work past retirement to make ends meet (see Alston 2003, 2006, 2007, 2012; Cole and Mitchell 2011).

Table 1 Gendered terrain of disaster

Live below the poverty line
Rely upon state-supported social services
Lack savings, credit, insurance
Lack inheritance rights, land rights, control
Be unemployed or work in the informal economy
Be self-employed, home-based, contingent workers
Reside alone, be rearing children alone
Depend on functioning caregiving systems
Depend on public transportation, travel with dependents
Reside in public housing, mobile homes, rental housing informal settlements
Live at risk of assault, and abuse, be displaced by domestic violence shelter
Be responsible for others (family, kin, neighbors), as paid and unpaid caregivers
Physically depend on others due to late pregnancy, recent childbirth age chronic illness
Be living with disabilities and chronic illness
Be subject to male authority in the household regarding use of emergency assets and key decisions about evacuation and relocation

Storyline Two: Women Have Resilience and Sometimes Agency in Adaptation Contexts but Are Still Often Disadvantaged Within Adaptation Programs

Discourse around gender and adaptation is more nuanced. However, again, women emerge as the victims and, in this case, negatively impacted by adaptation efforts – even where agency is present. As a discourse storyline, there is a much greater differentiation between examination of men and women, with poverty emerging as an important factor influencing the uptake or not of policy. Wurririmi et al. (2013), and Nelson and Stathers (2009) in examples from Tanzania, show the important role women play in building adaptive capacity. The social capital that women bring to the villages in the Mwanga District meant that despite having limited access to livelihood assets, they were key drivers to creating the networks and labor required to conduct new and adaptive activities to respond to climate change.

Understanding gender sensitivities is revealed as being important to developing successful climate initiatives. For example, a case study from Bangladesh highlights that despite best intentions, the involvement of women in a solar energy committee and subsequent involvement in the project, in fact, created more work and difficulties for the women. Despite their committee membership no one listened to their voice and the extra energy provided by the solar project meant women in fact worked harder and longer hours due to increased availability of light (Wong 2009). This suggests that the underlying gender frameworks also need addressing before understanding how to develop gender effective climate responses. Nagel (2012) notes that where mores of masculinity dominate means that men's ideas of adaptation – which often favor large-scale engineering "fixes" – will take precedence and thus are less likely to be culturally palatable to women.

Conversely, initiatives in the Pacific (Lane and McNaught 2009) highlight the benefits of applying a gender-sensitive lens to climate change adaptation. Comprising efforts from the Red Cross and Red Crescent movement, the UNDP, and the WWF, this program identifies some best practices in gender-responsive programming. For example, the Samoan Red Cross has worked with locals to translate difficult climate change terms into nontechnical language accessible to women as well as men. Women have been invited to participate in early warning programs that harness their local knowledge. Another example is the development of a climate witness toolkit that is designed in response to the gendered needs or women in the region, thus enhancing engagement with and participation in climate adaptation initiatives.

In Uganda, Africa, adaptation for smallholder famers similarly faces challenges given the responses and decisions of male and female farmers differ. However, understanding how both genders make decisions makes it easier to apply adaptation programs that will work over the long term (Nabikolo et al. 2012).

In Australia, men and women also adapt differently to change due to their different positions in society (Altson 2011). In rural areas particularly women will be focusing on farm tasks, working off the farm, and trying to sustain social networks, whereas men will tend to be more involved in the on-ground activities of trying to farm under increasing climate impacts.

There is also a differentiated gender impact in indigenous communities. For example, in both Canada and Australia, men and women have different roles in environmental decision making and land and sea management. Men and women both use and have knowledge about the environment in different ways; hence their experience of how it will change and be impacted by it will be different. Aboriginal women in Tasmania, for example, are concerned about climate impacts on particular shells they use to make jewelry. Aboriginal men in Arnhem land and within the Arabana people of Kati Thanda-Lake Eyre are concerned about how increasing temperature and longer more extended drought will affect species that they hunt (Nursey-Bray et al. 2013). Women in Northern Territory are turning to aquaculture as an adaptation to building their livelihood options in the face of other threats to their society as a result of climate change (Petheram et al. 2013).

There are emerging examples of women acting proactively and asserting agency after disasters to protect themselves from further harm. One case is of Honduran women in La Masica, who initiated gender-sensitive training about early warning systems so that in the event of future disasters, they would know what to do. In Micronesia, women accessed traditional knowledge about hydrology to help them survive drought. In Bangladesh, where women sustained immense loss of life and other impacts in the floods of 2004, women in the district of Gaibana organized a committee that helped women know what to do in the event of future floods (CARE 2010).

Implications

This discourse analysis so far has found that two key discourses dominate the discussion around gender and climate change. One discourse explores the impacts of climate change on gender, while the other reveals the ways in which adaptation both drives and is affected by gender. Out of these dimensions a number of further characteristics emerge. First, gender in both discourses (although better differentiated in the latter) still primarily focuses on and uses the term *gender* to mean *women*. Most considerations of impact and adaptation (with the notable exception of Alston's work) focus on the situation of women in developing countries as against those in developed worlds. Finally, most work focuses on gender in the context of disaster – flood, fire, drought, and wind (hurricanes). This means that understanding of how gender may impact on and flow within the complicated networks of power and knowledge relations, relations that actually characterize day-to-day life, and most importantly the crucial minutiae of decision making within society is not as yet explored in depth.

Second, the two representations of impacts and adaptation tend to focus on the role of women as victims but as Terry (2009) argues, "Highlighting the agency that poor women, as well as men, demonstrate in the face of climate risk counteracts the tendency in the discourse to cast them as powerless victims. In fact, women often have an especially important role to play in adaptation, because of their gendered indigenous knowledge on matters such as agriculture."

There is a temptation in this area then for studies to fall into stereotypical representations of men and women, which makes policy making and decision making easier in one respect, but less effective as it does not address the nuanced nature of gender and responses to climate change. The discourse about gender thus has implications in practice. The question is, why? Clearly there are differences in power, incomes, access to resources, cultural mores, and biology that mediate gender effects in relation to climate change (Bjornberg and Hansson 2013). Climate governance frameworks, in both mitigation and adaptation, need to become more variegated to enable the fundamental reshaping of policy along the gender-sensitive lines that is needed. Is it possible to counteract this primary focus first on women and second on women as victims? How can governance be constructed such that women and men are both equally represented and given equal – if different – responsibility in decision making?

Ways Forward: A Gendered Governance Framework

Studies advance an adaptive governance response that will "contribute to preserving gender-differentiated distributions of power, solidify stereotypical gender roles and reinforce women's vulnerability to climate change" (Bjornberg and Hansson 2013, p. 717). Alternatively, Skinner (2011) suggests that societies must (i) change the way climate change and its responses are framed, (ii) create gender-aware policies and institutions, and (iii) create an enabling environment for gender-aware, people-centered climate change responses that contribute to social and gender transformation. Policy and governance could also proactively incorporate gender dimensions into preexisting planning processes.

Communities of Practice

However, in this chapter it is argued that the linguistic emphasis in research and programs on gender *as women* needs to change. Further research needs to be conducted into understanding how men, as well as women, are affected by and will respond to climate change; they also are both affected by climate change, albeit in different ways. Where clear inequalities exist between men and women, these need to be redressed in meaningful ways and ways that will address the power and other relations that really drive decision making. Given the importance of social networks in decision making, and the often dominant role women play in building, maintaining, reinforcing, and saving networks, the deliberative use of communities of practice as conduits for adaptive management is one way forward. As communities of practice (CoP) tend to emerge naturally rather than by intent and are situated within the social context within which they arise (Klein et al. 2005), they provide a practical forum within which to pursue a gender lens to climate change.

CoP was first defined by Lave and Wenger as "groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly" (Lave and Wenger 1991). Wenger (1998) then extended the concept constructing CoP as the basic building block of social learning systems bound by three elements: joint enterprise, mutuality, and a shared repertoire of communal resources. Shared passions and problems (Wenger et al. 2002) and shared expertise (Ward and Peppard 2002) must be present for a CoP to naturally emerge. Barab et al. (2004) note that the ideal CoP is "a persistent sustained social network of individuals, who... [are] focussed on common practice and/or mutual enterprise." In practice, CoPs can be communities identified by the following traits: (i) the formation of group identity, (ii) the ability to encompass diverse views, (iii) the ability to see their own learning as a way to enhance learning, and (iv) a willingness to assume some responsibility for colleagues' growth (Grossman et al. 2001). Samuelowicz and Bain (2001) argue for the idea of communities of interest (CoI), which are characterized by (i) shared ideological and procedural assumptions and (ii) codes, slogans, and keywords accepted by that community. Finally, Klein et al. (2005) argue for a typology for CoP around the two key elements of structure and knowledge activity and include four models: (i) stratified sharing, (ii) stratified nurturing, (iii) egalitarian sharing, and (iv) egalitarian nurturing.

In the environmental realm, a CoP may manifest as a group working together on revegetation or climate adaptation programs. A CoP around blueberry production has enabled adaptive practice by those in the industry so they remain competitive (Hummel et al. 2012). Eishof (2003) argues the use of CoP can be enabling by creating the conditions for interdisciplinary responses to difficult problems. However, while some work has been undertaken on the utility of CoPs in the context of water management, community-based adaptation, or community engagement (Nursey-Bray 2012), its value as a form of governance is underutilized and as a mode of adaptive management has multiple advantages. In catalyzing around a common practice, the use of CoP as a collaborative governance tool enables the formation of roles for both men and women that will assist in achieving common goals (Baldwin and Austin 1995; Warhurst 2006). It will help ensure that practice moves from the individualized neoliberal norms to a more communal decision-making environment (Barr et al. 2012).

Second, communities of practice can galvanize social and adaptive learning as they provide the fora through which people can work together and learn from their mistakes but in a safe environment. Members of a CoP thus learn through doing, becoming, and belonging (Lawthorm 2011). Critical reflection is an important part of learning, and Ng and Tan (2009) highlight the efficacy of CoP in this context stating that they offer conditions for "critical reflective learning where reflection is implicit and intuitive in nature, and general and contextual in scope and object" – particularly appropriate for the issue of climate change. As the focus of the work is the common practice, it also creates a more democratic working environment, which allows for more gender-sensitive decisions to be made. In providing a buffer for people to work within, and the possibility of ongoing learning, adaptive capacity is built which in turn enhances the ability to deal with uncertainty. McDermott (cited in Bandy et al. 2008, p. 443) notes that "Communities of practice are ideal vehicles for leveraging tacit knowledge because they enable person- to-person interaction and engage a whole group in advancing their field of practice. As a result, they can spread the insight from the collaborative thinking process across the whole organization." While CoPs are perhaps hard to establish by intent, designing the conditions within communities to enhance learning is (Wubbels 2007, p. 232).

The use of CoP as an adaptive governance tool can also enable the incorporation of different forms and kinds of knowledge, and in many cultures where knowledge is mediated by gender, with men and women having different responsibilities for different sets of information, this again makes the governance process more equitable and helps all members within it to assert their own storylines and build diversity of views and perspectives. This is crucial to ensure best practice in knowledge management (Bishop et al. 2008). Importantly, CoPs play a role in ensuring governance processes of "becoming rather than being" which means that the temptation to fall into gender roles and constructions is harder. Dionnet et al. (2013) use an example of a simulated CoP in natural resource management (NRM) to show how CoPs can help communities become better at becoming involved in community management, a process of "becoming rather than being" as it is fluid over time. CoP can also create the conditions for innovation, vital in addressing a complex problem in complex systems like climate change (Barragn-Ocana et al. 2012). This also enhances inclusivity (Angelides et al. 2008).

The fluid nature of CoP also means that they have the capacity to change and adapt as the problem changes or with the introduction or exiting of new and old members. Given the focus is on practice, CoP creates a spatial rather than geographical governance arrangement which allows flexibility in the decision making or, as Gammelgaard (2010) shows, virtual communities of practice. Robinson and Raymond (2013) in an Australian case study of communities of practice of rural landholders found that working with CoPs enabled them to better understand the factors affecting decision making about climate adaptation. As such, CoPs could similarly assist in getting deeper understanding of factors motivating gender in adaptation and thus how to construct decision-making processes within formal institutions. For example, the Women's Environment Network, in Australia, is a CoP that actively promotes and educates women about climate change with a view to building their capacity, across multiple sectors, and enabling them to invest in formal policy making about it via mechanisms such as media, events, or committee work. In a review of global CoPs reflect that they offer flexibility as well as stability as a means of governance. Finally, a CoP will support and legitimize governance at local scales, which will assist women in particular to assert their rights and capacities to be part of local adaptation practice. This will help in building sustainable communities that are in transition (Barr and Devine-Wright 2012).

The overarching advantage of seeking to utilize CoP as conduits for gender appropriate governance in a climate change context is the fact most people are already members of existing networks and CoPs. For example, "GenderCC" is a list serve of over 450 members which "is dedicated to information exchange and networking among those committed to gender justice in climate change, on topics relating to gender and climate change issues, women's rights, gender relations and gender justice in the context of climate change and climate related policy making" (http://www.gendercc.net/about-gendercc/network.html). Not only does this network galvanize around a community of practice focused on gender and social justice but also links multiple network together – GenderCC also hosts or provides links to many other networks working in related areas and at an international scale. Thus, there is no need to “reinvent the wheel” but build on existing frameworks, to streamline their focus, and help reshape power and knowledge relations so they become gender sensitive.

Conclusion

In this chapter, a discourse analysis has provided insight into how gender is treated in the context of climate change. The chapter documented two key discourse storylines, the first being the argument that women will be disproportionately affected by climate change and the second that women although having resilience and some agency will also be disadvantaged in the context of adaptation policy. Analysis of these studies further highlights an emphasis on women over men and a focus on developing over the developed world. While it is clear that the position and role of women in climate change contexts need strengthening, it is important to also find ways of building governance frameworks that incorporate women *and* men, thus providing an appropriate gender lens to decision making. Applying an adaptive governance approach that deliberatively utilizes existing communities of practice is suggested as one way forward. Communities of practice both build on existing networks while providing future opportunities to do things differently and make better decisions. Ultimately, gender matters, thus a system of gender-sensitive governance, one which recognizes the collective responsibility and needs of both women and men, will be the most adaptive and resilient over time.

Abstract

Successfully improving the capacities and communication on climate adaptation in water resources in Paraguay requires enhanced acceptance and understanding of both climate change and variability adaptation (CCA and CVA respectively). This is firstly to realize that the country has some intrinsic vulnerability being already impacted by climate threats on specific geographic and time scales. Climatic trends, cycles, and extremes impact the rich agropastoral basis of the economy, e.g., GDP and exports. The current deficit of CVA implies some lack of CCA to future scenarios. Secondly, we suggest focusing on building capacity on climate science and management through the (i) reinforcement of science-driven knowledge, e.g., future climate projections and scenarios; (ii) enhancing the communication of climate services within the Rio de la Plata basin (RPB) to make them more user-friendly; and (iii) training of climate science managers (CSM) capable of understanding and communicating climate-related issues, as well as to plan management policies. Thirdly, the coproduction of knowledge by natural and social scientists, engineers, managers, and users is necessary in order for them to be better informed and to produce flexible scenarios and plans. Journalists should participate to be acquainted with climatic events and time scales. Some of these activities have already been done or are being developed: (i) the reinforcement of science-driven knowledge, i.e., a dynamic climate downscaling was carried out with PRECIS tool; (ii) a master's degree in global change was created; (iii) regional climate services are improving; and (iv) the understanding of the impacts of CCA and CVA is increasing. A climate forum can provide the required platform to build capacity and communication awareness and the coproduction of knowledge with elected authorities, stakeholders, and journalists, further allowing for a consensual climate adaptation process.

Introduction

Paraguay is vulnerable to the impacts of climate change and variability; however, the country's social, economic, and environmental sectors do not perceive it yet. The main conclusions of the United Nations Economic Commission for Latin America and the Caribbean (ECLAC/CEPAL) named "Regional Study of Economics of

Climate Change South America" (CEPAL 2010) on climate vulnerability, impacts, and adaption on water resources and agriculture in Paraguay can be summarized as follows:

- The country is rich in water resources and does not have to implement adaptation measures yet but for specific cases. However, it could be impacted whether locally or seasonally by 2050.
- Summer crops and livestock (beef and dairy cattle) will suffer the effects of warming and rainfall regime changes, whether by less precipitation during summer or more intense short-term rainfalls; thus water storage could become a usual practice by 2050.
- The impact of droughts in terms of affected people should increase from the baseline (2007) by 23 %, 39 %, and 74 % by 2020, 2030, and 2050, respectively.

Since 2009, the pressure of climate stressors is very likely increasing. Gross domestic product (GDP) average country's increase from 2009 to 2013 was above 5 % (from −4 % to +14 %, BBVA 2013; DGEEC 2013). More than half of these changes are associated with agriculture and livestock production and exports (soybean and beef). The GDP will continue increasing at high rates during 2014 (BBVA 2013) which will push both the inflation and the interest rates (García 2014).

The observed warming and wetting signals over South America (Skanski et al. 2013), the likely expected warming and uncertain precipitation evolution for 2020–2050 (Bidegain et al. 2012; Pasten and Giménez 2012), and the disaggregation of climate impacts on regional and seasonal basis in Paraguay suggest that adaptation to climate change could not be evaded over the next decade.

This article focuses on building capacity and communication on climate threats on water resources adaptation in the Paraguay River basin as follows: (i) regional climatic and water resources information; (ii) the frameworks of climate variability and change adaptation (CVA and CCA); (iii) the perception of climate variability in the media; (iv) the existent regional climate scenarios and services useful to support both current climate variability and future climate change adaptations; (v) the development of a master in global change degree devoted to climate science and management within the Paraguay River basin (PRB); (vi) the regional climate services to cope with climate variability within La Plata basin (LPB); and (vii) the communication of climatic data to stakeholders.

Geographical Setting and Climate Vulnerability of Paraguay

Paraguay is located in the center of South America, having 406,752 km^2 land area with a population of 6.7 million inhabitants (DGEEC 2013). It accounts for 13 % of the Rio de la Plata River basin (3.1×10^6 km^2, La Plata basin from now), almost one third of which within the Paraguay River basin (the Paraguay basin from now on). The country is divided by the Paraguay River into two major regions – Western (Chaco) and Eastern (Fig. 1) – and 17 departments (provinces). The former is part

Fig. 1 The Rio de la Plata basin and Paraguay. The Paraguay River divides the country into a western dry region named El Chaco and an Eastern wet region (es.wikipedia.org/wiki/Cuenca_del_Plata)

of the ecosystem known as "Gran Chaco Americano" shared with Argentina and Bolivia, a large plain in which the main economic activity is beef production. The latter is confined between the Paraguay and Parana rivers, having a more undulating topography, good drainage, and large subtropical forests. Because of the increasing exploitation of agriculture, e.g., soybean and livestock, the Eastern Region, border with Argentina and Brazil, suffered a high rate of deforestation over the last few decades. The Pantanal wetlands shared by Paraguay, Bolivia, and Brazil are placed to the north of the basin.

The agropastoral activities use about 70 % of the available water resources. Threats in their ecological and hydrological functions from climate change and variability are already installed in the region, requiring a proper planning and management of water resources to successfully cope with current variability and to adapt to future changes. Thus, water availability and allocation is central for the prosperity of Paraguay and the other countries of the La Plata basin (Argentina, Brazil, Bolivia, and Uruguay) which are world's leading exporters of soybean and beef, as well as strong producers of other cereals and dairy products.

Riverine populations are the most vulnerable to climate risks due to floods and inundations. The consequences of long-term climate change and variability in the Paraguay basin are not well known yet, but observed changes in extreme events have been associated with loss of life, economy, infrastructure, and biodiversity of ecosystems (Wantzen et al. 2008).

Future climate scenarios (2030–2080) for Southeastern South America (SESA) centered on Paraguay were generated for temperature and precipitation (Alves and Marengo 2010; Bidegain et al. 2011, 2012; Pasten and Giménez 2012) from global climate models (GCMs) outputs with IPCC socioeconomic scenarios SRES A2 and

B2 (Carter et al. 1994). Despite the uncertainties inherent in this type of construction of future scenarios, the greatest warming is expected over the north and northwest (Chaco and the Paraguay basin) and the least over the southeast (Eastern Argentina, Uruguay, and Southern Brazil). Paraguay would experience for the 2020s and 2050s a warming around +1 °C and 2.5 °C, respectively. There is a significant difference in the precipitation estimation; the greatest reductions (−6 %) would be located over the Paraguay basin and the largest increases (+5 %) in the Eastern Region. Most models' outputs show an increase in rainfall over November and December. This trend should already occur in the 2020s but should be more noticeable in the 2050s, when it is expected up to 1 mm/day in October at Asuncion and other sites within the PRB.

Climatic and Hydrologic Setting

Paraguay has a great regional climatic variability. The vegetation in the Chaco Region is semiarid to the northwest and subhumid megathermal savanna to the northeast and the Paraguay River basin. The rest of the Eastern Region is humid wet megathermal with maximum humidity levels in the departments of Alto Paraná, Itapúa, and Canindeyú (Table 1 and Figs. 2 and 3). Rainfall has an annual cycle with a period of high (October to March) and one with low rainfall (April to September). The Western Region has minimum precipitations during the months of austral winter (July and August), when rainfall becomes scarce, and the maximum is observed during summer (December and January). Although in the Eastern Region, especially in the southeastern zone, the same seasonal variation is also observed, it is not as pronounced as in the Western Region.

The behavior of the annual rainfall totals (Table 1) for the period 1961–1990 shows a minimum of 596 mm/year in Boquerón (Chaco region) and a highest of 1,667 mm/year in Itapúa (Eastern Region) where two large hydroelectric power generation dams are located (Itaipú and Yacyretá). The seasonal rainfall is well defined, the summer (DJF) and spring (ND) being the rainiest and the winter (JA) the driest.

Table 1 Yearly means of temperature and accumulated rainfall (1961–1990) for 7 of the 17 departments of Paraguay (Source: Climatic Research Unit-CRU, Hadley Centre, UK; 50 × 50 km)

		Yearly mean temperature and accumulated rainfall	
Department	Region	°C	mm/year
Alto Paraguay	Chaco	**25.2**	839
Alto Paraná	Eastern	**21.3**	1,620
Boquerón	Chaco	24.1	**596**
Canindeyú	Eastern	22.0	1,543
Central	Eastern	22.7	1,401
Itapúa	Itapúa	21.4	**1,668**
Presidente Hayes	Chaco	23.7	1,013

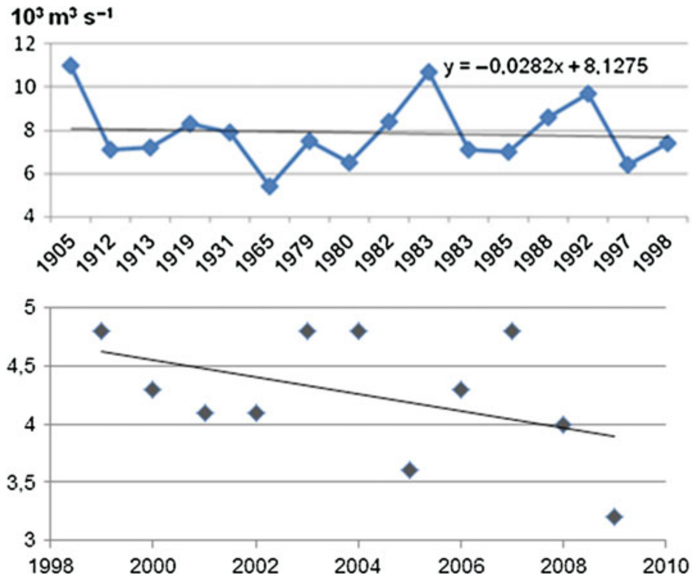

Fig. 2 Paraguay River floods at Asuncion from 1905 to 1998 (*above*, Barros et al. 2006) and from 1999 to 2009 (*below*)

Water Resources and the Paraguay River Basin

The nature and extent of current environmental impacts within the Paraguay River basin are of mixed nature: primary human induced, such as deforestation and land degradation, and increasingly climate induced, mostly climate variability impacts such as drought and flooding.

Some of the environmental impacts on the La Plata basin and particularly the Paraguay basin water resources are the following (modified from Tucci and Clarke 1998):

- Evolution of hydroelectric dam reservoirs in the upper Parana basin in Brazil since 1960
- Deforestation since 1950
- Agricultural intensification since 1970
- Urban developments due to changes of inundation, navigation, and conservation patterns in the upper Paraguay River basin
- River flow increase since 1970 attributable to changes in land cover and climate

The Paraná and Uruguay rivers together with Paraguay River (a tributary of the former) are the main tributaries of the La Plata River. The Paraguay River has a low gradient in its origins giving rise to vast Pantanal wetlands (Fig. 1),

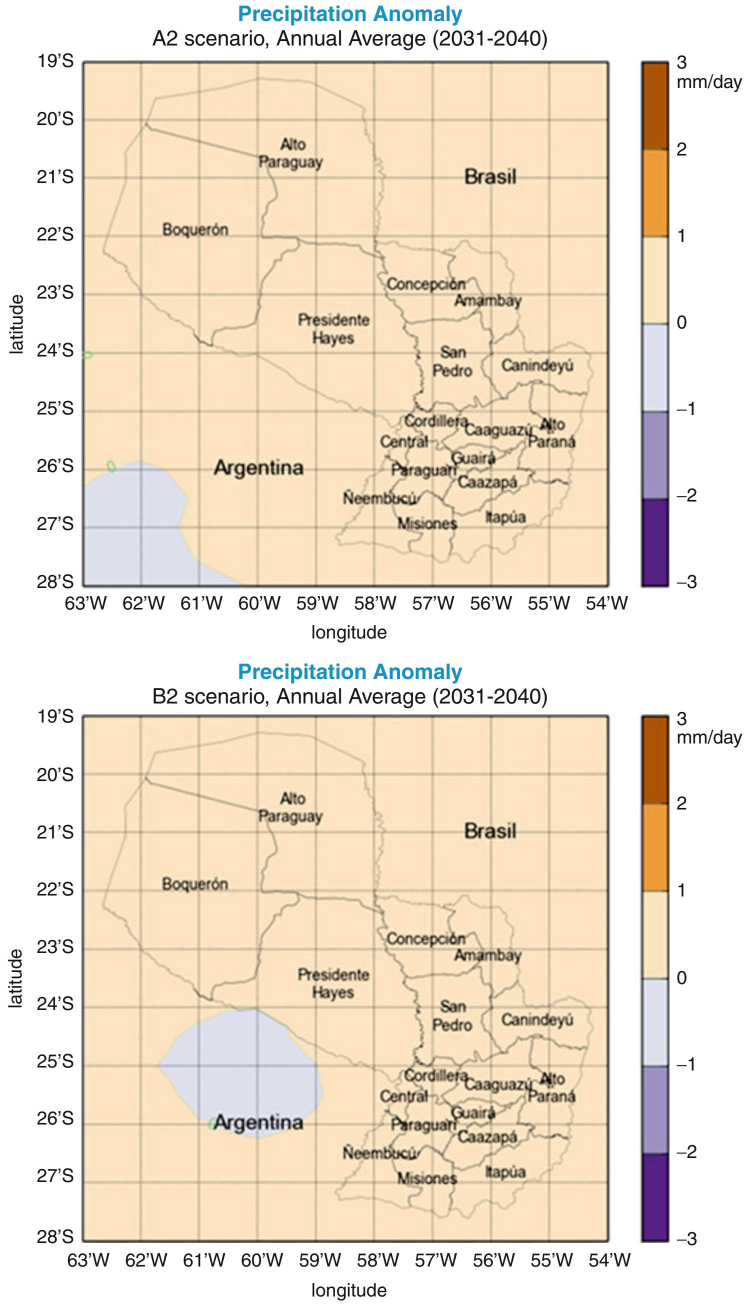

Fig. 3 Expected precipitation (mm/day) anomaly for 2031–2040 from the climatic reference 1961–1990: (*above*) scenario A2. (*below*) scenario B2 (From Pasten and Giménez 2012)

the largest wetlands in the world, with ca. 220,000 km^2. This gradient causes a delay in the flood wave around 4 months between the north and south of the Pantanal region.

The Paraguay River flow is maximum during austral winter and minimum in September and January. Average river flow is 3,000–4,000 m^3/s (varying from 800 to 12,000 m^3/s). These extremes are about 1–9 m water level at Asunción. Most floods in Asuncion take place between May and July in phase with the winter maximum annual flow cycle. They are originated in the upper and middle Paraguay basins, mostly related to El Niño Southern Oscillation (ENSO) warm phase (El Niño) and are independent of the Pantanal output (Barros et al. 2004). The typical occurrence of floods up to 2–3 m is each 3 years covering 80 % or plus of the country's plains reaching 4–5 m or plus during El Niño events, e.g., 1983. Wetlands have a great flood buffer capacity protecting agriculture, infrastructure, and human settlements (Neiff et al. 2000).

Time series of yearly maximum floods during the period 1905–1998 shows a slight decreasing trend with cycles, such as the one from 1999 to 2009 (Fig. 2). To forecast these cycles of ca. 10–15 years is a challenge to manage the basin.

The potential impacts of climate change in the Paraguay basin are the increases in temperature, rainfall intensity, and the frequency and severity of extreme events such as inundations, heat waves, storminess, and prolonged droughts. These events would impact agriculture, livestock, and human populations due to the increased risk of urban flooding and water-borne diseases. The rise in upper basin erosivity as a consequence of summer rainfalls and of the sedimentation in the lower basin should increase the risk of droughts and forest fires because of greater evapotranspiration and less precipitation during the low-water level period. These changes should impact the aquatic ecosystems all over the basin (IPCC 2007; Project Sinergia 2011). The data presented in Table 1 which shows likely temperature increase and uncertain rainfall evolution support changes in evapotranspiration.

Climate Change and Variability Adaptation

> Adaptation is "the adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities". (IPCC 2007)

Because of the extensive uncertainties that exist in the future drivers of and responses to climate change, future scenarios are necessary to explore the potential consequences of different management response options (Moss et al. 2010). The construction of climate scenarios and adaptation strategies (Climate Science Management, CSM) evolved over the last two decades from a science-driven approach led by earth and natural scientists to a citizen-driven one where social scientists have an important role.

However, the concepts and framing of adaptation are not the same worldwide. Here "climate adaptation" is referred to as "The adjustment to any threat or harm from continuous climate change or discrete climatic and meteorological events"

(Nagy et al. submitted). Since the strong El Niño event of 1997–1998, ENSO-related variability has become the Climate Science Management priority in Latin America (IPCC 2001) including Paraguay (Grassi 2001; CEPAL 2010). We take for granted that climate adaptation is a top priority in our region and suggest that the highly distributed extreme hydrometeorological events since 2012 are changing the perception and interpretation of climate threats and vulnerabilities worldwide, as well as the need for both mitigation and adaptation now.

Three framing of adaptation can be distinguished (Dupuis and Knoepfel 2013):

- Climate change adaptation (CCA)
- Climate variability adaptation (CVA)
- Vulnerability-centered adaptation (VCA)

These authors argue that a lack of adaptive capacity is not sufficient for explaining the implementation deficit related to CCA which relies on different limiting factors depending on the context. A lack of adaptation to current climate variability and observed change is a failure to keep pace with development in the "adaptation deficit" (Burton 2004). This concept captures the notion that countries are underprepared for current climate conditions, much less for future climate change. The shortfall is not the result of low levels of development but of less than optimal allocations of limited resources (EACC 2012). "Persistent vulnerability to climate variability is a symptom of an adaptation deficit in socio-ecological systems" (Preston et al. 2013).

Climate Change and Variability in the Media

The media ABC Color is an important disseminator of information in Paraguay based in Asunción. It is the most widely circulated daily newspaper, fostering civic consciousness of citizenship providing sustained support for education at all levels. It summarizes important concepts, which may reflect and even create public opinion on climate change.

When we were finishing this article, a press article about the current climate extremes was published in Paraguay (ABC Color Newspaper, January 16, 2014). We do not agree with all what is written in the article, but have synthesized the most important concepts because it could reflect and/or create public opinion about climate change. As many press articles do all over the world, it mixes climate anomalies, variability, and change and accuses the government of inaction.

> Paraguay is gradually suffering the impacts of climate change. There are extremely hot days and heavy rainfalls, without precedent in the last few decades. Experts from the unit of Risk Management of the Ministry of Agriculture and Livestock highlight the impacts of water stress on crops, fruits, pasture and livestock. The drought and heat excess difficult navigation in the Paraguay River. There is little action on mitigation or adaptation. The Directorate of the Environment (SEAM) generates the ideas for mitigation and adaptation. Notwithstanding, these problems are not having an adequate response yet.

We agree with ABC with regard to the impacts and the need of increasing actions, especially preparedness to climate extremes and adaptation. The increase in climate analysis and modeling, information and public awareness, and education of managers are key steps to facilitate government and NGO's climate adaptation planning.

How to Deal with Adaptation Under Uncertainty in Paraguay?

Here we suggest that in order to cope with variability, emphasis must be put on building capacity to develop a community of experts in Climate Science Management and the coproduction of knowledge with the aim of increasing public awareness and trust, through a participatory and informed process. Climate variability adaptation (CVA) facilitates coping with unexpected extremes and planning climate change adaptation (CCA).

The countries of the La Plata basin have been learning to cope with variability (CVA) to sustain growing local consumption and food exportation. However, "managing variability" seems not to be enough because of the ongoing changes in climatic patterns and the high level of dependence their economies have on climate, water resources, and grasslands.

Under a likely warming scenario of 1 °C or plus and uncertain rainfall in a decade or so, the top priority CVA in the Paraguay basin should evolve together with planned CCA plans based on natural or socioeconomic accepted thresholds to continue a sustainable development. Even if Paraguay is very rich in natural resources and the Chaco region is naturally dry and resilient, it is vulnerable to changes in water availability which could worsen under expected changes (CEPAL 2010). A good strategy could be based on the concept of Butler and Coughlan (2011) "Adapting to variability before change and using preexisting adaptation strategies for climate variability as a proxy for future adaptation planning" Climate variability has been a driver to increase regional capacities to forecast and manage resources and production under uncertainty which is basically risk management (Jones 2010), even if risk probability is often only estimated. There is also a need of better vulnerability assessments and VCA.

The region is suffering an increase in seasonal, interannual, and decadal variability. Thus, to forecast short-term events within the boundaries of synoptic and climatic scales is becoming more difficult in spite of more resources allocated.

There are several ongoing climate vulnerability, impacts, and/or adaptation projects on water resources, agriculture, health, and biodiversity in Paraguay, mostly with neighboring countries Argentina, Brazil, and Bolivia (CEPAL 2010; Project Sinergia 2011, www.portalsinergia.org.br; Báez et al. 2014; REGATTA Project "Gran Chaco y Cono Sur," www.granchaco13.wix.com/comunidad). They are mostly focused on CVA, environmental degradation and preservation, early warning and monitoring, risk analysis, and transboundary water.

From now on, we present some activities we have been developing over the last few years to build capacity to understand global change science and management.

Future Climatic Scenarios

A dynamic climate downscaling centered in Paraguay was carried out with PRECIS tool (UK Met Office Hadley Centre-HADC) based on the runs of the HadRM3P mesoscale Global Circulation Models (Pasten and Giménez 2012).

The comparison between the observed climatology (data from Climatic Research Unit-CRU, University of East Anglia, UK) and the modeled one for the period 1961–1990 shows the model reproduces very well the precipitation in much of Paraguay, except in Alto Paraguay, Boquerón, and Presidente Hayes in the Chaco region. The correlation of expected temperature trends for the time frame 2011–2050 is significant (95 % confidence interval) for temperature in the departments of Alto Parana, Boquerón, Central (Asuncion), Itapúa, and Presidente Hayes with both scenarios A2 and B2, whereas the expected increases in precipitation are not significant. The temporal behavior of rainfall is quite well reproduced but overestimated in the months of high precipitation. In the north, center, and south of the Eastern Region, both climatologies are quite similar. With regard to temperature, the model reproduces very well the seasonal behavior in the Chaco region. However, in most cases, the model underestimates the average temperature in the hottest months, whereas in the Eastern (wet) region, there is a good fit between both climatologies. Modeled future increase in both precipitation and temperature for 2013–2040 is shown as anomalies (Figs. 3 and 4, respectively).

The future A2 and B2 scenarios for 2031–2040 can be summarized as follows: a marked and significant increase of the mean annual temperature, with increases between 1.3 °C and 1.6 °C for the scenario A2 and 1.1–1.4 °C to the B2 scenario from the period 1961–1990. The precipitation shows a slight increase for 2040, but the trend is not significant.

The outputs of the Japanese MRI-CGCM2.3 high-resolution model for SESA (Bidegain et al. 2011) give quite similar results. Yearly mean temperature and precipitation fields for the La Plata basin are very well and well represented, respectively, for the calibration period (1979–2003) which already includes a significance increase in both parameters. Expected warming varies from +1 °C to +2 °C for 2015–2039 and from +3 °C to +4 °C for 2075–2099, which are less to the southeast and greater to the northwest of the La Plata basin. Thus, for the time horizon 2040–2060, a likely range is +1.5–2.5 ºC, which is in close agreement with the previous results from GCM downscaling. Precipitations are expected to increase in Eastern Paraguay, Southern Brazil, and Uruguay by + 5 % (2013–2039) and 10 % (2075–2099) with regard to 1979–2003, which is very similar to the values around 1990.

Regional Climate Services: Technological Resources to Cope with Climate Variability Adaptation

One of the drivers of climate variability in the La Plata basin is El Niño Southern Oscillation (Barros et al. 2004, 2006). However, there are deficits in the knowledge of other climate drivers, and so climate prediction is still limited.

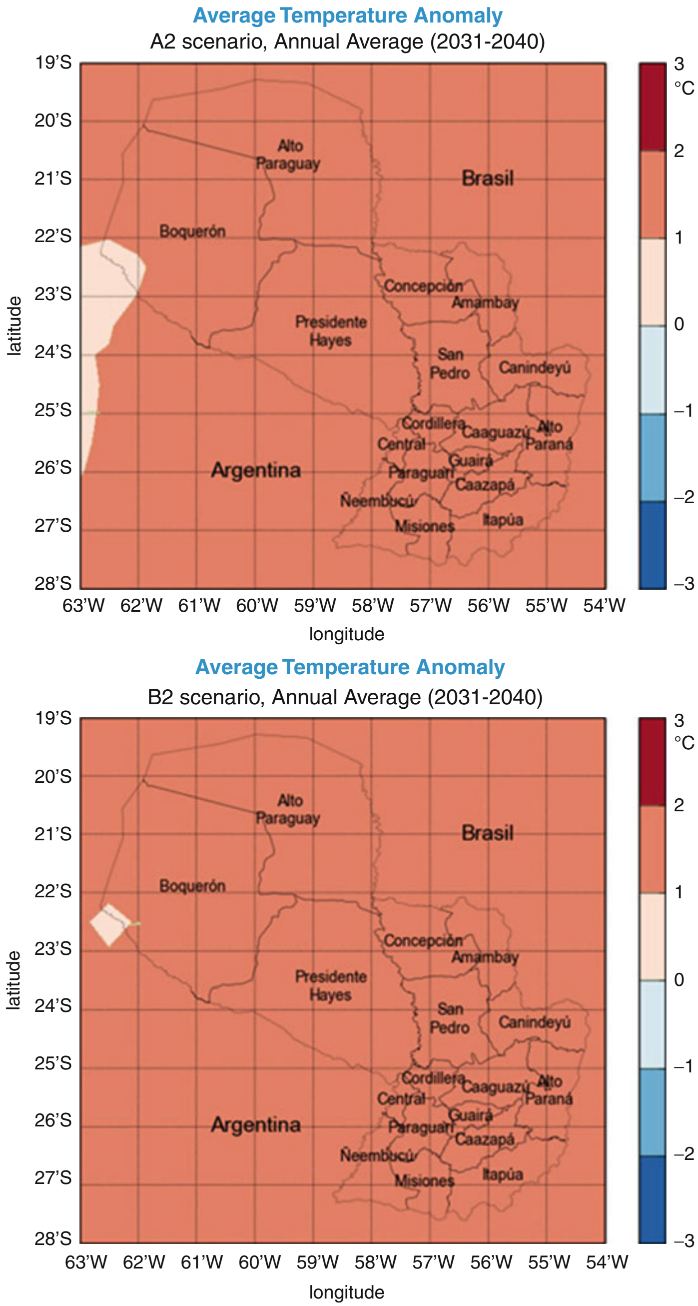

Fig. 4 Expected yearly temperature anomaly for 2031–2040 from the climatic reference 1961–1990: (*above*) scenario A2. (*below*) scenario B2 (From Pasten and Giménez 2012)

Since December 1997, there have been developed regional climate forum for Southeastern South America (SESA) in the form of a climate forecast consensus expressed as tertile probability (less than the normal, normal, and above normal) for the region between the latitudes 19 °S and 35 °S and to the east of the Andes. This prognosis is developed by experts of the Meteorological Services of Argentina, Brazil, Uruguay, and Paraguay; the Center of Weather and Climate Forecasting of Brazil; the University of Buenos Aires with its partners; and the University of the Republic of Uruguay.

While these forecasts are widely used by the various user sectors, an urgent upgrade of both the methodology of development and communication to users is required.

The World Meteorological Organization (WMO) joined the Board of Intergovernmental Climate Services (JISC) within the Global Framework of Climate Services in July 2013. This initiative seeks to develop climate services at global, regional, and local scales as a response to climate variability and change. Four priority areas were defined:

- Food production and agriculture
- Water and energy
- Health
- Risk reduction of natural disasters

The climate services are based on the following pillars:

- Scientific knowledge
- Climate observing networks
- Platform for users
- Training

The overall goal is the production of climate forecasts on monthly, seasonal, yearly, and decadal time scales, oriented to the four sectors of users aforementioned. Two Regional Climate Centers (RCCs) are being implemented in South America:

1. The western center placed in the International Center for Research on the El Niño Phenomenon (CIIFEN), with headquarters in Guayaquil, Ecuador (http://ac.ciifen-int.org/rcc/)
2. The southern center (RCC-SAS), whose concept is a virtual center, managed by the meteorological services of Argentina and Brazil, with the participation of the meteorological services of Paraguay and Uruguay

These centers are staffed with a structure and governance and must comply with the standards of the WMO. The RCC-SAS developed an experimental website, which will be available in the short term. Both centers will monitor the main climatic variables as well as weather forecasts, supported by the regional climate forum.

Capacity Building: The Master Degree in Global Change and Climate Risks

The capacity of communities to adapt to global change and climate threats is determined by their level of development and allocation of resources and its scientific and technical capacity. The direction of climate change is uncertain, so that emphasis should be put in the increase of the capacity for adaptation and risk management in relation to key sectors in the Paraguay basin, such as agriculture, water resources, biodiversity, and health. To decrease the impact of climate threats, adaptation must be integrated into the overall development policies (Watson et al. 1998), and scholars must promote an interdisciplinary knowledge management to face global change and its impacts. It is important to address the threats from climate change and variability issues beyond science, without forgetting that the human dimensions are indispensable so that climate adaptation be effective.

Global change is recognized as the greatest challenge that humanity has to face in the coming decades, being a challenge for science, given that it transcends the traditional boundaries between disciplines. This requires an integration of inputs that overflows the conventional structure of the existing educational programs. There are two important questions that require more qualified staff in global change teaching and research with regard to water resources. Firstly, how does it work for the Paraguay basin, within the regional system, in relation to the biogeochemical cycles? Secondly, how could the land use and climate changes affect the functioning of the Pantanal-Paraguay ecosystems?

The Polytechnic Faculty of the Universidad Nacional de Asuncion (FP-UNA) developed a master's degree (MSc) in global change with emphasis on climate risks (Coronel et al. 2012) offered since 2014. This degree was designed to understand, from the scientific knowledge, factors and sectors in which there is a need to intervene (management). The program will trigger among its participants a search process for innovative alternatives that have to be translated into the design and implementation of research and development projects and implementation of alternative technologies in the productive processes, e.g., agriculture and hydroelectric power generation. It is hoped also to reinforce the generation of novel regulations, education, awareness, and citizen participation. Graduates will be knowledgeable about the use of climate scenarios and the approaches to evaluate climate vulnerability, adaptation, mitigation, and risk management.

The degree emphasizes education and research on global change science and management. To achieve this goal, professors and experts from Paraguay and the region have been integrated within the program. The MSc degree is addressed to graduates in sciences, social sciences, agriculture, and health that are working or have the chance to work as teachers or researchers or are at the forefront of public and private units which are engaged in environmental issues sensitive to climate change and variability.

Communicating Climate Data and Scenarios to Stakeholders in Order to Improve Adaptation

What do stakeholders and decision-makers need to know in order to plan and implement adaptation? When the media analyze climate issues, e.g., the ABC Color Newspaper article of January 16, 2014, focus is on to the current climate, especially extremes. Thus, they may both increase public awareness and confusion about climate threats and perspectives, searching more for government level responsibilities than focusing on climate change and variability. We suggest building capacity and public awareness on climate science and management.

The director of the Risk Management Unit of the MAG had said (ABC Color June 6, 2011) that he is taking into account the regional climate services forecast and that he is aware of the increasing trends in temperature and precipitations. He outlined the need to have a good prognosis and communication to farmers on extreme meteorological events to manage crops and of El Niño events which can cause floods in the upper and middle RPB where agriculture and livestock activities are predominant.

In order to achieve a better communication between scientists and stakeholders, there needs to be a coproduction of knowledge (Roux et al. 2006; Biesbroek et al. 2009; Nagy et al. 2014). We suggest to focus on the enhancement of both top-down and bottom-up approaches which requires not only resources but also the integration of all involved representative citizens (stakeholders at all levels of making decisions). However, we must avoid the illusion of public participation being that crucial as to scientists' information and feedbacks being underestimated. The ways to achieve a better integration of experts from the academia, government, and users are by means of education and training, e.g., the MSc in global change, and the increase of public awareness and participation through workshops and webinars. Stakeholders are included to not only be informed and give their opinions but also participate together with experts on building future scenarios and participatory planning. These meetings should serve to discuss current priorities with expected future threats, harms, and thresholds. The participation of journalists is desired in order for them to be acquainted with climate issues and to communicate them.

A simplified mix of risk management and adaptive management approaches to deal with both climate threats and uncertainty could be summarized as follows:

- What are the main directions of change?
- To focus on "what if" and "what is at risk" statements.
- To integrate scientists and stakeholders the best available "science and monitoring in order to gradually change plans accordingly to how climate changes/varies."
- To better communicate current and expected climate evolution and associated impacts at all climate management time scales.

A good example of participation and communication on what has been done over the last 2 years is the periodic webinars of REGATTA Climate Adaptation Project Gran Chaco y Cono Sur Americano (http://kp.iadb.org/Adaptacion/es/Cono-Sur/Paginas/inicio.aspx).

Conclusion

In order to achieve a better communication of climate information and capacities to address adaptation regarding water resources will require the following steps:

- To assume the threats of current and plausible climate futures
- To increase scientific knowledge and monitoring
- To train climate science managers in order to transcend the boundaries of disciplines and climate threats and impacts
- To increase the quality of climate information from both the climate services and the media, further allowing to have a better informed population
- To produce cooperative knowledge based on both the science and the needs and perceptions of stakeholders

We, as scientists and engineers from the academia and government, strongly believe on scientific knowledge and – as practitioners – the need of integrating local knowledge. We support the promotion of climate forum on water resources, agriculture, hydroelectric power generation, and riverine populations' risks, where the state of the art on climate variability and change and the perception and needs of stakeholders are discussed. We also believe that it is necessary to avoid the illusion of participation as it was the "approach to truth" but the way to generate feedbacks to learning by doing.

International Policy on Climate Change and Its Influence on Russian and Belarusian Legislations and Practice

Siarhei Zenchanka

Contents

Abstract

This chapter attempts to illustrate the influence of international policy and legislation on national ones and their implementation in practice of environmental protection. Comparative analysis norms of Russian and Belarusian legislation in climate change with international policy are used. The practical results of realization of these norms are considered. The comparison of environmental legislations of Russia and Belarus with international ones shows the concurrence and the difference of the laws. Consequently, there is the need to develop new laws and improve the existing ones. This chapter considers possible ways to improve the national legislations in climate change and presents a good practice in Russia and Belarus in environmental protection which shows social responsibility of leading enterprises. Climate change impact on economic development is considered. Russia and Belarus are the countries where the quantity of greenhouse gases is below the limit. Nevertheless, a great work has been done in these

countries to limit emissions. The national policies are not always concurrent with international, which tend to remove these countries from the world process of sustainable development.

Keywords
Environmental policy • Climate change • International legislation • National legislation • Greenhouse gases • Environmental protection

Introduction

The climate changes have always been present in the Earth history. Glacial periods alternated with the periods of warming, i.e., ages of reduction of glaciations (interglacial periods). Now the Earth is in the Quaternary period which ends the Cainozoe. Approximately 12 thousand years ago, the Holocene began which is being continued to present time and is characterized by relatively stable climate. The last climatic period of the Holocene is the Sub-Atlantic period. The average annual temperature in the Sub-Atlantic period was lower than that in the previous Atlantic period (World Climate 1934). During the Sub-Atlantic period, there were fluctuations in temperature that led to ecological effects influencing life and activity of people.

This period can be divided into several ages (Chromov and Petrossiants 2012):

- Period of warming (2500–1600 years ago) when climate conditions moved to modern conditions; Period of dry and warm climate (1600–1200 years ago, fourth–eighth centuries A.D.)
- Period of soft and warm climate, small climatic optimum, (1200–800 years ago, eighth–fourteenth centuries A.D.)
- Fall in temperature, small glacial period (800–150 years ago, fourteenth–nineteenth centuries A.D.)
- Climate warming from the middle/end of the nineteenth century to present time (with a small fall in temperature in the middle of the twentieth century and renewing of warming in the last half century)

These climate changes were due to natural phenomena in general – the sun activity, tectonic process, and change in the parameters of the Earth orbit. The changeability of the climate system is determined by different mechanisms of positive and negative feedback between the components of the system: atmosphere, ocean, cryosphere, land surface, and biosphere, which can have an impact at time period from 10 to 100 years.

The process of the warming acceleration started from the second half of the twentieth century which is linked with anthropogenic activity. It was established that the influence of anthropogenic activity is due to the action of the several main factors:

- The increasing quantity of atmospheric carbon dioxide and some other gases come to atmosphere due economic activity so-called hotbed gases or greenhouse gases (GHG)
- The increasing volume of atmospheric aerosol intensifying the dispersion and absorption of radiation in aerosol particles
- The increase of heat quantity formed due to economic activity that acts on atmosphere heating

The first factor of anthropogenic climate change has the largest influence. Therefore, at the present stage, it is very important to combine the efforts of mankind to reduce the influence on the Earth climate of the economic activity connected with the increase in quantity of GHG in the Earth atmosphere.

It is necessary to consider the third factor, i.e., the growth of the quantity of heat due to economic activity as the Earth is an open system and the input flow of energy must be equal to output flow of energy for its stable operation. When this condition is not fulfilled, the Earth will be heated or cooled. Using of mineral sources of energy of the Earth leads to the increase of the Earth temperature.

The work of heat power stations causes the increase of the mass of atmospheric aerosol which results in strengthening of scattering and absorption of radiation on its particles (the second factor of anthropogenic impact on climate).

The aim of this chapter is to analyze international and national policies of Russia and Belarus in the area of climate change and to consider the implementation of these policies.

Methodology

International legislation has priority over the national one. At the same time many international agreements do not have the status of law, and to put them into effect, the consent of a certain number of parties is required. Documents adopted at national level do not sometimes meet international agreements. The comparative analysis of international agreements and national documents will help in understanding of the national aspects of legislation.

Materials from the official sites of UN, EU, Russia, and Belarus were used for the comparative analysis. The results of different investigations published in the reports of international and national official and nongovernmental organizations were also used.

International Climate Change Policy

The international community started to pay special attention to climate change since the mid-1980s of the twentieth century. Scientists all over the world have come to the conclusion that climate change and human activities are linked

(Forrester 1971; Medous et al. 1972; Meadows et al. 1992, 2004; Budyko and Izrael 1991; Report 2002). It also became clear that the problem is very complex, and therefore it is necessary to bring together scientists from all countries to obtain more precise conclusions and forecasts. In 1988 the World Meteorological Organization (WMO) and the United Nation Environmental Programme (UNEP) created the Intergovernmental Panel on Climate Change (IPCC). The global task of IPCC is preparing the regular reports in environmental fields. The first report was published in 1990 (Houghton et al. 1990). In this report IPCC confirmed the threat of climate change due to anthropogenic activity and called to prepare a special global treaty to solve this problem.

The last IPCC (2007) report pointed that "warming of the climate system is unequivocal, as is now evident from the observations of increases in global average air and ocean temperatures, widespread melting of snow and ice and rising global average sea level." Considering the reasons of such warming, the authors of the report mention that "Most of the observed increase in global average temperatures since the mid-twentieth century is *very likely* due to the observed increase in anthropogenic GHG concentrations. This is an advance previous conclusion that "most of the observed warming over the last 50 years is *likely* to have been due to the increase in GHG concentrations." "It is *likely* that there has been significant anthropogenic warming over the past 50 years averaged over each continent (except Antarctica)."

It is necessary to point that experts are very careful calling the reason of climate change and noting at the same time that "the observed patterns of warming, including greater warming over land than over the ocean, and their changes over time, are simulated only by models that include anthropogenic forcing."

Besides that IPCC publishes special reports, methodic reports, technical papers, and supporting materials accessible at IPCC site (https://www.ipcc.ch/publications_and_data/publications_and_data.shtml).

Modeling and scenario tools form the basis of a number of global and regional assessments that project future environments on the basis of changes in drivers of ecosystem change and biodiversity loss according to various development scenarios (IEEP 2009).

Ministry Declaration adopted at 2nd World Climate Conference in Geneva in October–November of 1990 supported the idea of preparing special global agreement on solution to climate change.

United Nations General Assembly in December of 1990 adopted a resolution 45/212 (UN 1990), on the bases of which a special Intergovernmental Negotiating Committee on this problem was formed. As a result of its work, the framework convention was adopted by governments at the 5th session of the committee (UNFCCC 1992). The convention was open to signing at UN Conference in Rio at 1992 and came into force on the March 21, 1994.

At present more than 190 countries are the parties of the convention including Russia and the Republic of Belarus, all industrial countries, countries with transition economy, and most developing countries.

The object of this convention is "to achieve, in accordance with the relevant provisions of the Convention, stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner."

UNFCCC maintained the total concept for the realization of international activity directed to solving the problem of climate change. The main goal of this concept is stabilization of GHG concentration at the level that prevents their adverse effect on the climate system.

Convention parties adopted some obligations directed on the solution of the problem of climate change. All countries have to develop and present special reports called national communications. These national communications should have the information about the level of GHG emission and fulfilled and planned actions in the country.

It was clear that the positions of the convention could not solve the problem of climate change and the decision on the expansion of the convention was adopted in Kyoto, Japan, December 1997. Kyoto Protocol (1998) defines the goals on limiting of emission for industrial countries, and the innovation mechanisms were suggested to achieve these goals.

The Kyoto Protocol came into force on February 16, 2005, when 55 parties ratified it. Countries with well-developed industries must reach 95 % level of CO_2 in comparison with its level in 1990. Kyoto mechanisms are:

- International emissions trading. Parties with commitments under the Kyoto Protocol (Annex B Parties) have accepted targets for limiting or reducing emissions. These targets are expressed as levels of allowed emissions, or "assigned amounts," over the 2008–2012 commitment periods. The allowed emissions are divided into "assigned amount units (**AAUs**)."

Emissions trading, as set out in Article 17 of the Kyoto Protocol, allows countries that have emission units to spare – emissions permitted to them but not "used" – to sell this excess capacity to countries that are over their targets. Thus, a new commodity was created in the form of emission reductions or removals. Since carbon dioxide is the principal greenhouse gas, people speak simply of trading in carbon. Carbon is now tracked and traded like any other commodity. This is known as the "carbon market."

- Clean development mechanism (CDM). The clean development mechanism (CDM), defined in Article 12 of the Protocol, allows a country with an emission reduction or emission limitation commitment under the Kyoto Protocol (Annex B Party) to implement an emission reduction project in developing countries. Such projects can earn saleable certified emission reduction (CER) credits, each equivalent to one ton of CO_2, which can be counted toward meeting Kyoto targets.

The mechanism is seen by many as a trailblazer. It is the first global environmental investment and credit scheme of its kind, providing a standardized emission offset instrument, CERs. A CDM project activity might involve, for example, a rural electrification project using solar panels or the installation of more energy-efficient boilers.

The mechanism stimulates sustainable development and emission reductions, while giving industrialized countries some flexibility in their emission reduction or limitation targets.

- Joint implementation (JI). The mechanism known as “joint implementation,” defined in Article 6 of the Kyoto Protocol, allows a country with an emission reduction or limitation commitment under the Kyoto Protocol (Annex B Party) to earn emission reduction units (ERUs) from an emission reduction or emission removal project in another Annex B Party, each equivalent to one ton of CO_2, which can be counted toward meeting its Kyoto target.

Joint implementation offers Parties a flexible and cost-efficient means of fulfilling a part of their Kyoto commitments, while the host Party benefits from foreign investment and technology transfer.

United Nation Environmental Program considers climate change as one of the major challenges of our time (Climate Change 2010) and suggested climate change subprogram for strengthening the ability of countries, particularly developing countries, to integrate climate change responses into national development processes. The subprogram has four key goals:

- Adapting to climate change: UNEP helps countries reduce their vulnerability and use ecosystem services to build natural resilience against the impacts of climate change.
- Mitigating climate change: UNEP supports countries in making sound policy, technology, and investment choices that lead to GHG emission reductions, with a focus on scaling up clean and renewable energy sources, energy efficiency, and energy conservation.
- Reducing emissions from deforestation and forest degradation (REDD) is an effort to create a financial value for the carbon stored in forests, offering incentives for developing countries to reduce emissions from forested lands and invest in low-carbon paths to sustainable development. REDD+ goes beyond that to include the role of conservation, sustainable management of forests, and enhancement of forest carbon stocks.
- Enhancing knowledge and communication: UNEP works to improve understanding of climate change science and raise awareness of climate change impacts among decision-makers and other target audiences.

The detailed rules for the implementation of the Kyoto Protocol for developing countries were adopted at the Conference of the Party in Marrakesh, Morocco, in 2001, and are referred to as the “Marrakesh Accords.” Without waiting for the end of the Kyoto Protocol, the Parties to the Kyoto Protocol took part at conferences of the Parties (COP) and discussed problems connected with its realization and extension.

The COP16 took place at Cancun and was hosted by the Government of Mexico. The meeting produced the basis for the most comprehensive and far-reaching international response to climate change the world had ever seen to reduce the carbon emissions and build a system which made all countries accountable to each other for those reductions.

The COP17 took place from November 28 to December 9, 2011, in Durban, South Africa, as a part of the United Nations Climate Change Conference which delivered a breakthrough on the international community response to climate change. Progress was made toward establishing a new international framework in which all states participate.

In Doha, Qatar, on December 8, 2012, the "Doha Amendment to the Kyoto Protocol" was adopted. The amendment includes (Doha 2012):

- New commitments for Annex I Parties to the Kyoto Protocol which agreed to take on commitments in a second commitment period from January 1, 2013, to December 31, 2020
- A revised list of greenhouse gases (GHG) to be reported on by Parties in the second commitment period
- Amendments to several articles of the Kyoto Protocol which specifically referenced issues pertaining to the first commitment period and which needed to be updated for the second commitment period

On December 21, 2012, the amendment was circulated by the Secretary-General of the United Nations, acting in his capacity as Depositary, to all Parties to the Kyoto Protocol in accordance with Articles 20 and 21 of the Protocol.

The 19th session of the Conference of the Parties to the UNFCCC and the 9th session of the Conference of the Parties serving as the Meeting of the Parties to the Kyoto Protocol will take place from November 11 to 22, 2013. The conference will be held in Warsaw, Poland.

During the first commitment period 37 industrialized countries and the European Community committed to reduce the GHG emissions to an average of five percent against 1990 levels. During the second commitment period, Parties committed to reduce GHG emissions by at least 18 percent below 1990 levels in the eight-year period from 2013 to 2020; however, the composition of Parties in the second commitment period is different from the first (Doha 2012).

Russia and Climate Change

Russia ratified UNFCCC in 1994 and Kyoto Protocol in 2004 году. As a result Kyoto Protocol entered into force for all its parties. The main goal of Russia in accordance with Kyoto Protocol was not to overcome the average level of emission of GHG in the period 2008–2012 years against 1990. In spite of the intensive economy growth, the common level of anthropogenic emissions of GHG in Russia at present time is less than in 1990.

Commitment period of the Kyoto Protocol was established within the period of 2008–2012. In the Federal Law (2004), Russia declared that its participation in the second period of commitments would be decided separately and depend on the progress of the international negotiations, on international agreements, and on its understanding what measures should be taken to prevent global environmental challenge. In the communication dated December 8, 2010, and sent to the secretariat of the UNFCCC on December 9, 2010, the Russian Federation indicated that it did not intend to assume a quantitative emission limitation for the second commitment period.

In accordance with UNFCCC and Kyoto Protocol, Russia develops its national policy on preventing the climate changes and their negative consequences, on limitation and reduction of anthropogenic emissions, and on increase of GHG.

Kyoto Protocol and UNFCCC provided the following conditions necessary for participation at Kyoto mechanisms:

- Fulfillment of quantitative obligations on emission reduction
- Adoption of National Action Plan and measures for reduction of GHG emissions in accordance with the quantitative commitments
- Creation of National system of accounting of GHG emissions and discharges
- Organizing the National register of the accounting units of GHG emissions
- Establishment of a quantitative value carbon credits on the basis of the inventory data in 1990
- Reporting to the UNFCCC secretariat in the form of national communications
- Examination of reports by international team of experts, etc.
- Development of National Climate Change Policy
- Creation of national system of monitoring of GHG emission

Action plan (2005) for the realization of the Kyoto Protocol in Russia was adopted on July 15, 2005. Plan involved four sections. The first section included measures for reduction of GHG emission in different sectors of economy. The second was dedicated to the creation of national system of inventory of GHG emissions and their removal by forests. Economic mechanisms of the Kyoto Protocol were considered in the third section. International activity and negotiation process on the following international convention were discussed in the fourth section.

Starting from 2007 different legislation acts aimed at the further realization of the measures for mitigation of climate change and adaptation to climate change have been adopted:

- Decree of the President of Russia of June 4, 2008, № 889 “On some measures to improve the energy and environmental efficiency of the Russian economy”
- The concept of long-term socioeconomic development of the Russian Federation until 2020
- Russian Government Resolution № 1-r of January 8, 2009, “On the main directions of the state policy in the sphere of electrical energy efficiency from renewable energy sources till 2020”

- The program of anti-crisis measures of the Government of the Russian Federation in 2009
- Federal Law of November, 2009, “On energy saving and energy efficiency”
- “Climate Doctrine of the Russian Federation” of December 17, 2009
- “The Energy strategy of Russia until 2020”
- “Action plan for realization of Climate Doctrine” of April 25, 2011

All these documents contain regulations concerning the conditions of realization of the Kyoto Protocol. Climate Doctrine (2009) is based on fundamental and applied scientific knowledge about climate and related areas:

- Assessment of the past and the current state of climate system
- Assessment of the factors of the influence of anthropogenic activity on climate
- The forecast of the possible climate changes and their influence on the quality of life of people in Russia and other regions
- Assessment of the security and vulnerability of ecosystems, economy, population, governmental institutions, and infrastructure of the state in relation to climate change and adaptation of the existing facilities to climate change
- Assessment of the possibilities to mitigate human impacts on climate

Action plan (2011) for the realization of Climate Doctrine considers all measures and organizations to achieve the goals.

Fundamental principles of the Russian climate change policy are (Communication 2010) as follows:

- Global feature of Russian interest in climate change and its consequences
- National interest priority in the development and realization of climate policy
- Clarity and availability of the information on climate policy
- Recognition of the need for actions, both within the country and as a part of the full international partnership of the Russian Federation in international research programs and projects relating to climate change
- A comprehensive account of the possible losses and gains due to climate change
- Precaution in the planning and implementation of measures to ensure the security of the person, the economy, and the state from the adverse effects of climate change

From 1990 to 1998 there was a decline in emissions, affecting all sectors, it related with the dynamics of the economic situation in the country in the Russian Federation. Later, during the period of economic growth, there was a steady increase in emissions. In 2011, total GHG emission was by 16.3 % higher against 1998, but remained 30.8 % against 1990 emissions (Report 2013).

Decline in GHG emission in Russia directly depends on the energy strategy. At present the energy consumption of Russian economy 2.3 times greater than the average world index on the average and 3.2 times greater than EU indexes (Climate Change 2012).

Climate doctrine (2009) considers the increase of energy efficiency in all sectors of economy and the development of renewable and alternative energy sources ad priority direction of the development.

In accordance with Kyoto Protocol, Russia could take part in all mechanisms of protocol. But actually Russia did not realize this opportunity.

Analyzing the use of flexible mechanism under the Kyoto Protocol, Gromova (2011) demonstrated inefficiency of the existing system of implementation of the emissions trading, clean development mechanism (CDM), and joint implementation (JI) in Russia. The procedure of taking decision on the presented projects is very complicated and need to be improved. At the end of July 2010, the first 15 JI projects were with CO_2 equivalent reduction about 30 million tons. In November 2010 the expertise of 58 projects with 75.6 million tons of CO_2 equivalent was fulfilled.

The program "Climate and Energy" of WWF is aimed at the decrease of global emission of CO_2 and other GHG and at the timely assistance to adaptation of ecosystems to climate change. From 2011 WWF started the "green" development of energy directed at technological modernization of Russia.

Some large Russian companies adopted their own program of energy saving and resource economy:

- Corporation "Gazprom" estimated GHG emission at their enterprises and created an emission register.
- Oil company "Lukoil" adopted the corporative conception and activity plan on the bases of the Kyoto Protocol.
- Company "Norilski Nikel" estimated GHG emission in its Polar division and developed "Information analytical system making inventory and monitoring GHG," the forecast of emissions till 2015 was fulfilled.

Belarus and Climate Change

Climate change is a complex problem, which, although environmental in nature, has the consequences in all spheres of existence on our planet. Belarus shares global concerns on the impact of climate change and supports international efforts on reducing carbon emissions. The norms of international agreements in the field of climate change act in Belarus are the following:

- United Nation Framework Convention on climate change was signed on June 12, 1992, at the UN conference in Rio de Janeiro and was approved on April 10, 2000, by the President of the Republic of Belarus.
- Kyoto Protocol to UNFCCC. The Republic of Belarus joined it in 2005 in accordance with the Decree of the President of the Republic of Belarus.

At present the Republic of Belarus has well-developed legal system with a remarkable number of the subordinate laws which may be found at site (www.minpriroda.by).

The law “On environmental protection” is the basic environmental law. This law defines principles and goals of environmental protection, objects and parties involved in environmental protection.

The law “On atmospheric air protection” is directed at the conservation and improvement of the quality of atmospheric air.

Joining the Republic of Belarus to UNFCCC and Kyoto Protocol involves the adoption of legal acts regulating the relations in the field of GHG emissions and the rights on GHG emissions. Some of such acts are as follows:

- The Resolution of the Council of Ministers of the Republic of Belarus of December 30, 2005, No 1582 “On realization of norms of the Kyoto Protocol to UNFCCC.” This Resolution adopted the action plan on realization of norms of the Kyoto Protocol to UNFCCC for 2005–2012.
- The Resolution of the Council of Ministers of the Republic of Belarus of April 10, 2006, “On State cadastre of anthropogenic emissions of GHG from sources and their removal by sinks.”
- The Resolution of the Council of Ministers of the Republic of Belarus of August 25, 2006, No 1077 “On National register of carbon units of the Republic of Belarus.”
- The Resolution of the Council of Ministers of the Republic of Belarus of September 7, 2006, No 1155 “On the Strategy of decreasing of emissions of GHG and their removal by sinks in the Republic of Belarus in 2007–2012.”
- The resolution of the Council of Ministers of the Republic of Belarus of August 4, 2008, No 1117 “On the National programme of measures on mitigation of climate change in 2008–2012.”

It is seen that the Republic of Belarus has fulfilled its obligations on UNFCCC and Kyoto Protocol. Institutional and legal bases were created to take part in the flexible mechanism of the Kyoto Protocol. “Strategy of decreasing of emissions of GHG and their removal by sinks in the Republic of Belarus in 2007–2012” and “The National programme of measures on mitigation of climate change in 2008–2012” were adopted. National system of GHG inventory was also developed. The Republic of Belarus regularly presents National Communications under the United Nations Framework Convention on Climate Change.

The Fifth National Communication (2009) contains the results of implementation of the UNFCCC and Kyoto Protocol from 2006 up to 2009 and includes the information on national circumstances, generalized data on inventory of the GHG emissions and their removals in sectors of energy, industry, agriculture, land use change and forestry, waste, policies and measures on decrease in GHG emissions and their forecast indicators, the assessment of vulnerability and adaptation of the national economy to climate change; data on newly adopted normative and legal documents in the country; data on the National Registry of Carbon Units; and information on current R&D facilitating to reduce GHG emissions and prevent their impact on climate change.

The analysis of various projection scenarios of GHG emission reduction shows that Belarus has exhausted the potential of relatively low-cost actions for the reduction of these emissions. Any other emission reduction measures as well as the mechanisms to support environmentally sensitive actions require substantial investment of funds which are not available in the country, specifically in the crisis situation. It was expected that the resources the country needs could be partially raised by selling available emission quotas in 2008–2012.

There is a national procedure defined by legislation act to approve the project directed at decreasing of GHG emission. Some projects were approved, but their realization will be possible when Belarus gets access to flexible mechanism under the Kyoto Protocol.

Nevertheless there is an activity on preparing and realization of the volunteer projects directed at the reduction of the GHG emission. One of such projects is "Restoration of peat lands."

The fact that the amendment of the Republic of Belarus to the Annex B to the Kyoto Protocol stipulating quantitative obligations and providing the opportunities for using flexible mechanisms has not been ratified by the required number of the Parties to the Kyoto Protocol (only 26 Parties from 141 needed) poses an obstruction to this.

It is expected that Belarus will be a party of the second commitment period of the Protocol. It can help Belarus to fix its obligations and present the possibility to use the flexibility mechanisms of the Kyoto Protocol. But at the consultations held in Minsk on January 21–22, 2013, with the participation of the representatives of public authorities and experts from Belarus, Russia, Ukraine, and Kazakhstan, the sides postponed the ratification of the Doha amendment to Kyoto Protocol, regulating the second commitment period of the Kyoto Protocol, at least until the end of 2013.

Belarus continues its work on the reduction of climate change. New "State programme of measures directed at mitigation of climate change consequences in 2013–2020" was adopted by the government decree on June 21, 2013, № 510. As the previous program, it is aimed at:

- Realization of measures on fuel and energy economy in energy sector
- Stabilization of the level of GHG emissions due the use of resource saving technologies in energy-consuming sectors of economics
- Optimization of waste management
- Improving of the quality and increase of the volume of GHG absorbers

The Climate Change Performance Index

The analysis of the results presented in the Climate Change Performance Index (CCPI 2013) shows that the climate policies of Russia as well as Belarus are estimated negatively. Russia dropped to 56th position of 61 participants and Belarus dropped to 35th position (it lost 8 positions). This data was calculated on the statistics of 2010 and the use of the performance indices – the level of emissions, the development of emissions, renewable energy, and climate policy. All these performance indices for Russia were found as very poor, whereas the performance indices for Belarus were at moderate and poor levels.

Conclusion

Up to the present, the Kyoto Protocol is the only international legal document that at least to some extent regulates the global climate change and the reduction of GHG emissions. The new agreement will start working only in 10 years; it is unknown if it is going to be efficient.

Note that the withdrawal of Canada from the Kyoto Protocol and refusal of Japan and Russia to take any obligations on the second commitment period lead to the loss of status of the protocol. The USA and China are not the parties of the protocol. These countries produce the greatest amount of emissions.

At the same time the developed countries make considerable efforts to decrease the level of emissions. The data in *The Wall Street Journal* presented on the site (http://bin.ua/news/economics/faec/140951-ssha-otkazavshiesya-podpisat-kiotskij-protokol.html) indicated that in 2011 against 2005 China, India, and Russia showed the increase of emissions, but Japan, Canada, Germany, Great Britain, and EU as a whole showed the decrease of emissions; the most significant progress in decreasing of emissions was being demonstrated by the USA.

If Russia and Belarus do not join the second commitment period, their companies will no longer be able to benefit from carbon market. They will not get investments for modernization and reconstruction of enterprises, for creation of new high technological enterprises. As a consequence the competition of Russian and Belarusian producers will fall.

Linkage of Agricultural Productivity Improvement and Climate Mitigation Action in Africa

Labintan Adeniyi Constant and Harald Winkler

Contents

Abstract

This study explores the relations between agricultural productivity improvement and mitigation potentiality in Africa mainly in Ghana, Kenya, Rwanda, and Zambia characterized by different agricultural production system and agroecological zones.

Firstly it used Decomposition of Productivity Number Index approach to evaluate the country's agricultural productivity during their pre- and post-economic market openness. Secondly, the country's agriculture, forestry, and other land use (AFOLU) emission is assessed, while the last part uses robust regression to determine their impact on country's agricultural productivity.

It is found that agricultural productivity is improved relatively during the country's post-economy liberalization. Annual agriculture emission is higher in Kenya with relative annual changes, while changes in forest land emission are considerably in Rwanda. The regression analysis showed that an increase in agricultural emission contributes to a relative decrease in, respectively, Ghana, Rwanda, and Zambia agricultural performance. This means a decrease in their

DOI 10.1007/978-3-642-38670-1_37

agricultural productivity. However, agricultural emission is contributing to improvement of Kenya agricultural performance. This means an increase in Kenya's agricultural productivity. Furthermore, forest land sink has positive implication of agricultural productivity in Rwanda. Forest land therefore is contributing to an improvement of Rwanda agriculture production performance. In addition, there is no significant impact of land use change emission on the selected countries' agricultural performance.

Finally, this chapter found that under the selected country's production system, their goal of improving their agricultural sector performance by 6 % toward 2015 will reduce Ghana agriculture emission intensity, transform Zambia in agriculture carbon neutral country, increase Rwanda forestry sink potentiality, and increase Kenya agriculture net emission intensity.

This chapter highlights on the need to investigate the linkage on case-by-case basis due to the difference in the country's agricultural system and agroecological zones, while the cost of mitigation will constitute an important indicator in decision making.

Keywords

Agricultural productivity • GHG emission • Mitigation • Africa

Introduction

Agricultural sector in Africa is a key source of economic growth and a large source of foreign exchange, saving, and tax revenue. It contributes to over 40 % of currency earning, feeds and generates income for low-income household, and alleviates poverty. Despite several agricultural reforms undertaken in African countries, the gap between the sector supply and the demand is still very high. The sector is characterized by low productivity, high production cost, low mechanization, intensive labor use, limitation in credit accessibility, and market accessibility difficulties. Furthermore, it is estimated that the region population will rise from 770 million to 2 billion by 2050 (FAO 2009) which will significantly increase the agricultural demand.

Moreover, increase in climate change extreme events frequency such as drought and flood increased more pressure on agricultural inputs accessibilities such as water and arable land. This is likely to result in a decrease of the sector production yield. A recent study in assessing the impact of climate change on agricultural productivity reveals that average cereal yield in sub-Saharan Africa will decrease at 3.2 % in 2050 (Nelson et al. 2009; Ringler et al. 2010) with an aggregate decrease in yield, respectively, of 17 %, 5 %, 15 %, and 10 % of wheat, maize, sorghum, and millet (Knox et al. 2012). This will affect the region's food availability and increase the vulnerability of low-income households.

The agricultural sector including crop and livestock production, forestry, and associated land use changes are also identified to be major sources of greenhouse gas (GHG) in Africa and in addition has great sink potentiality (IPCC 2006). It has been estimated that in sub-Saharan Africa, over 43 % of the total CO_2 emissions originate from land clearing from agricultural use and a further 316 billion tons of CO_2 eq is stored in top soils at risk from degradation (Gledhill et al. 2011). According to IPCC (2006) the sector's major emission sources are enteric fermentation (natural digestive process in ruminant animal), manure (manure management, manure applied to soil, and manure left on pasture), synthetic fertilizers, rice cultivation, crop residues, cultivated organic soil, and CO_2 emission from burning crop residues, forest, and land use.

Indeed, the trade-offs between agricultural growth and GHG emission intensity in Africa have been recognized by scholars and policy makers; however, more efforts were allocated to adaption strategies instead of mitigation actions. The mitigation matter started after COP15 in Copenhagen in 2009 where non-Annex 1 parties were invited to submit their "Nationally Appropriate Mitigations Actions" in order to ensure "sustainable development." Therefore, the concern about mitigation of climate change in the agricultural sector grew in Africa.

Climate change mitigation action in the agricultural sector will have co-benefit effects for the sector. On one hand, they will improve the sector inputs efficiency. Sustainable land management (SLM) practices will contribute to mitigating climate change in sub-Saharan Africa, by sequestering carbon in soils and vegetation (sink potentiality), reducing emissions of greenhouse gases (carbon dioxide, methane, and nitrous oxide), and reducing the use of fossil fuel and agrochemicals (Woodfine 2010). This will improve land resource resilience and productivity by maintaining long-term productivity and ecosystem functions (land, water, biodiversity) and increase productivity (quality, quantity, and diversity) of goods and services (including safe and healthy food). On the other hand, SLM practices will offer smallholder's opportunities to reduce the need for labor, capital- and fuel-intensive land preparation, and tillage. This can constitute a very good agricultural financing opportunity in Africa through carbon trade system and improve rural household development (Shames et al. 2012; Winston et al. 2012; Byamukama et al. 2012; Masiga et al. 2012).

Although the African agricultural sector present an important potential of mitigation, very limited research does quantify the mitigation level, the cost of possible mitigation actions in the region agricultural sector, and how mitigation action will influence the country's agricultural development policy goals and vice versa. The region's key agricultural development policies include the Comprehensive Africa Agriculture Development Programme (CAADP) launched in 2003. The policy aims to boost African country's agricultural annual productivity performance by 6 %, enhancing economic growth, eliminate hunger, and reduce poverty through sustainable agricultural production practices and intensive investment (NEPAD-CAADP 2010). This includes sustainable and efficient agricultural input such as land and water resources management. The policy may have some implication on the region climate change mitigation policy option. This chapter then explores the contribution of country's agricultural productivity improvement policies in mitigating climate change in African countries. This means assessing the contribution of agricultural productivity improvement to carbon dioxide equivalent GHG emission abatement and the associated cost. It highlights policy maker on appropriate actions to yield the sector sustainable development policy goal.

Theoretical Approach of Agricultural Productivity Assessment

Chambers (1988) defined the concept of productivity measurement as an approach to assess the production rate of technical change. He emphasized that firm productivity is conceptualized by two main components. The first component is partial factor of productivity (PFP) which is the ratio of firm total output Q_i and any m_i input used to produce that output. The second component is the total factor of productivity (TFP) which is the firm total output Q_i ratio with summation of all input $x_{i.}$

Indeed, Farrell (1957) following Debreu (1951) and Koopmans (1951) analyzed difference in performance of firms which yield each a given quantity of output (oriented output) using a certain amount of inputs. They found that difference in the firm's productivity is explained by their ability to produce the given amount of output using minimal input (technical efficiency) and economics scale. The last term is the firm's allocation efficiency of producing a maximum quantity of output using an optimum input. Taken into account technological progress, the technical efficiency change will also contribute to their productivity component (to their performance). This is illustrated in Fig. 1 where x_{ns} is the quantity of input use to

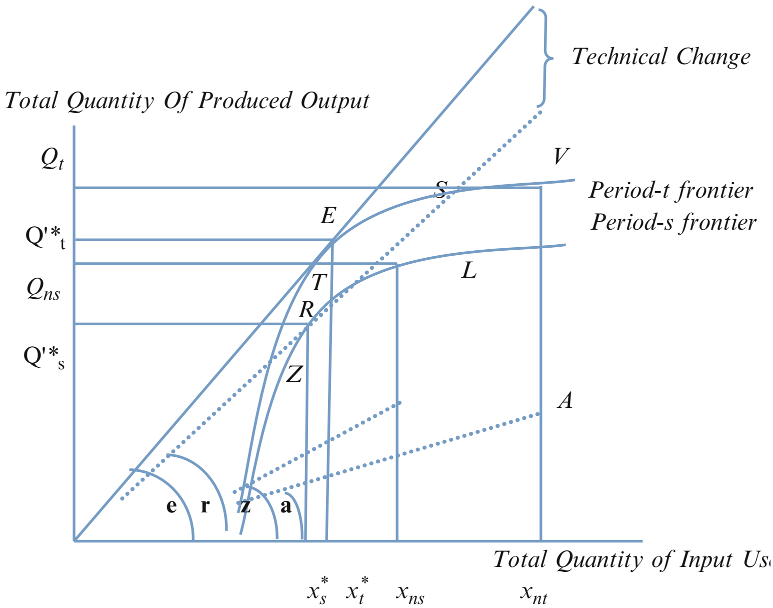

Fig. 1 Decomposition of firm production performance using respectively technology s and t (Source: author own composition)

produce and Q_{ns} quantity of output during the first period using technology s. Using the same technology s, x_s^* is the minimum input required to produce an optimal quantity of output Q_s^*. When the firm production technology changed to new technology t during the second period, x_{nt} is the quantity of input used to produce a given quantity of output Q_t. Notwithstanding, under the new technology, x_t^* is the minimum quantity of input required to produce an optimal level of output Q_t^*.

However, Balk (2001) argues that firm productivity is not only explained by technical change and economics scale. He concludes that output mix effect could also influence firm productivity. This means the combination of firm's given producing total output. Similar conclusion has been made by Coelli et al. (2005) and O'Donnell (2010). This is illustrated in Fig. 2.

Nonetheless, it is common to assess firm's production performance for a given time period using these approach and investigate explanatory exogenous driving factors of difference in yield performance. This is essential to investigate why a firm performs differently within one period or across period. However, nowadays, the concern of climate change and introduction of climate change mitigation policy could also considerably influence the firm's performance in agriculture sector; the concern on the sector contribution to GHG emission and goal of improving agricultural productivity raise interest to explore how mitigation policies could influence this goal in Africa. But how could this be investigated?

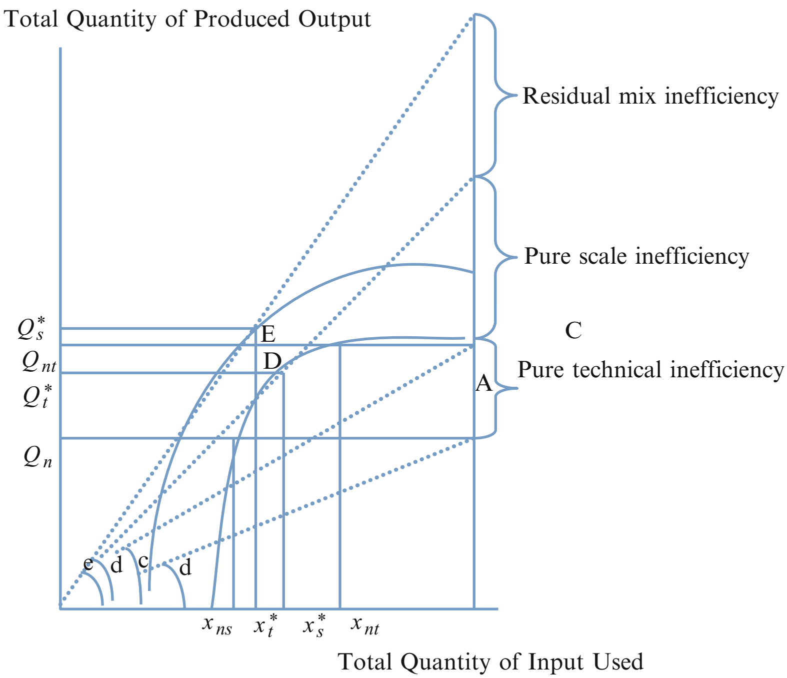

Fig. 2 Robust decomposition of firm production performance under respectively technology s and t (Sources: author own composition)

Agricultural Productivity Driving Factor and Mitigation Potential

Most studies which evaluate agricultural productivity improvement conclude that agricultural research (Ruttan 1996; Chang and Zepeda 2001), agricultural extension, agricultural infrastructure (Evenson and Pray 1991; Antonio and Robert 2001; Evenson 2000), resources allocation (Jorgenson 1988), climate change, and government effectiveness are major driving factors of agricultural productivity (Sharmistha and Richard 2006; Mandemaker et al. 2011).

However, unlike climate change, a change indicator which can contribute to an increase or a decrease in productivity, most studies emphasize extreme events such as drought or flow. Usually, rainfall is the proxy used for drought or flow. This leads more to adaptation strategy to control drought and flood in order to reduce their effect on agricultural crop productivity (You and Ringler 2010). Moreover, uncertainties in rainfall used as drought or flood proxy reveal the difficulty of using this approach (Jemma et al. 2010).

Perhaps, a recent study emphasizes that emission reduction from agricultural sector present great potential for agricultural productivity improvement (Pete Smit et al. 2008; Capper 2011; Baker et al. 2012; Gerber et al 2013).

Capper (2011) in analyzing mitigation in livestock sector argues that improving productivity has considerably reduced the carbon footprint of dairy and beef production and its share by consumers is extensive, when traditional systems have a lower carbon footprint.

Pete Smit et al (2008), by exploring GHG mitigation potential in agriculture sector, conclude that agricultural practices can potentially mitigate greenhouse gas (GHG) emissions which will contribute to improving land productivity. This includes improving cropland and grazing land management and restoration of degraded lands and cultivated organic soils with high potential, while water and rice management, set aside, land use change and agroforestry, livestock management, and manure management have low potential.

Baker et al. (2012), by assessing US agricultural productivity growth contribution to mitigation potential with focus on land management, found that lower crop and livestock productivity growth leads to higher emissions from land use change and management, while lower emissions from livestock operations has a minimal net impact on aggregate emissions.

Indeed, Bryan et al. (2011) evaluated the linkage between agricultural productivity and mitigation potential in Kenya at a small-scale level and found that small-scale mitigation action thought integrated soil fertility management and soil water conservation has contributed to the improvement of crop productivity in Kenya.

Recent developments show that an adoption of climate smart practices will contribute to achieve emission target in the agriculture sector (World Bank 2011) and could also affect the sector productivity. This will be achieved through sustainable farming practices contribution to land fertility and water. However, very limited research does investigate how AFOLU emission intensity can also affect the agricultural sector through their direct impact. This constitutes another exogenous factor which may be a robust proxy than annual rainfall accounting.

Methodology and Data Sources

*S*ample: The study considers four African countries, namely, Ghana, Kenya, Rwanda, and Zambia where agricultural sector account for, respectively, 26 %, 28 %, 32 %, and 20 % of their GDP (WRI 2013). Among different economic reforms undertaken in those countries as in most African countries, the agricultural sector has been fundamental. Indeed, in 1990 their agricultural sector was liberalized in order to stimulate the sector competitiveness and create good private investment climate. This also has included improvement of their land policies. This contributes to increase in their agricultural production and their exportation. However, the intensification of their agricultural production contributes differently to each country's agriculture, forestry, and other land use emission typology.

The first part then assesses their agricultural productivity, profitability, and changes in their production abilities. It applied the decomposition of Productivity Index Number proposed by O'Donnell (2010) to assess selected countries' total productivity factor (TFP), profitability (PROF), and term of trade (TT). The TFP is the appropriate indicator which quantifies their agricultural production performance or frontier, while the PROF measures their agricultural sector profitability which depends on their production cost and their production output cost. However, the TT indicate the ratio between country exported output price and imported output price.

Simulation is done using DPIN software. Inputs and outputs agricultural data have been collected from FAO database, Ghana Ministry of Food and Agriculture (MOFA), Kenya Ministry of Agriculture, Rwanda Ministry of Agriculture and Animal Resources, Zambia Ministry of Agricultural and Livestock Agricultural Science and Technology (ASTI).

Land: Arable land and permanent crop area (ha)
Labor: Economically active population in agricultural sector (man/ha)
Fertilizer: Amount of fertilizer and herbicide used (kg/ha)
Seed: Planted material (kg/ha)
Agricultural machine: Total agricultural machine and tractor used per 100 m^2
Crop: Aggregated major crop production (kg/ha)
Vegetable: Aggregated vegetable and fruit production (kg/ha)
Cash crop: Aggregated major cash crop production (kg/ha)

Due to limitation in prices data availability, input and output prices on 2008 have been used. Statistical descriptions of the input and output data used are presented in Tables 1, 2, 3, and 4 below.

The second part access their figure of AFOLU emission intensity per ha. Emission data is collected from FAO statistical database.

The third part evaluates the effect of AFOLU emission on selected countries' agricultural productivity using two-stage Data Envelopment Analysis (DEA) approach. However, the two-stage results can suffer from correlation error between input variables used in the first stage when assessing firm performance and

Table 1 Summary of agricultural inputs-outputs in Ghana

explanatory variables used in the second stage when assessing firm performance driving factors (Wilson 2003; Simar and Wilson 2007). An alternative approach was proposed by Simar and Wilson (2007), who developed single and double bootstrap procedures to reduce the drawbacks. Their approach also allows the second-stage regression to be estimated and inferences to be made using robust logit regression method. This is done using Stata11.

The regression formula is explicit as follows:

$$Ln(TFP) = c + \alpha \ln(Agriex) + \beta \ln(R\&D) + \varphi \ln(Goveff) + \delta_o \ln(Land)$$
$$+\delta_1 (Labor) + \phi \ln(A) + \gamma \ln(Fo) + \lambda \ln(Lu) + \varepsilon$$

Where c is constant coefficient and α, β, φ, δ_0, δ_1, ϕ, γ, λ are elasticity of explanatory variables driving factors of the agricultural productivity. ε is the term of random error.

Agriex is the number of agricultural research staff; R&D means the expenditure for agricultural R&D. These data have been collected from Agricultural Science and Technology Indicator database.

GOVEFF quantifies government effectiveness. This data is collected from the United Nation Conference on Trade and Development (UNCTAD) statistical database.

Land, labor, and AFOLU emission data are collected from FAO statistical database.

The last part concludes and gives some recommendations.

Result and Discussion

Analysis of crop land use emissions across those four countries reveals that between 1990 and 2010 land use, net emission has been relatively much higher with relative change over a year in Zambia and in Rwanda with an average of 0.065 Gg CO_2 eq. which is lower in Ghana and Kenya. This is illustrated in Fig. 3 below.

Analysis of forest land net emission reveals that forest land emission is much important in Kenya, Ghana, and Zambia over the period 1990–2010. However, after 2010 forest land net emission/removal has been negative in Rwanda. This is illustrated in Fig. 4 below.

However, emission from agriculture is much important in Kenya with an average of 0.056 Gg CO_2 eq./Ha and much lower in Ghana, Rwanda, and Zambia. This is illustrated in Fig. 5 below.

From AFOLU emission perspective, it can be concluded that emission level varied considerably between sources and within countries. Land use emission did not change significantly after the agricultural sector market openness, while high land use emission is observed in Zambia. Similar for forest land net emission, while forest land sink potential increased in Rwanda. Furthermore, agriculture emissions varied considerably in Kenya which is the higher agriculture emitter among these countries.

Analysis of agricultural productivity, profitability, and term of trade reveal that:

In Ghana, before the agricultural market liberalization, there is a decrease in the country's agricultural productivity by 46 %. This follows an increase by 46 % after the sector liberalization. While within the same period, there is a net increase by 197 % in the sector profitability. Similarly, there is a net increase in the sector term of trade by 196 %. This is illustrated in Fig. 6a below. However, this performance has been achieved with relatively low change in input technical change efficiency and significant change in input mix efficiency while input scale efficiency does not change. This is illustrated by the Fig. 6b below.

In Kenya, during the reference period, there is a net increase in agricultural productivity by 23.4 %. The net increase in country agriculture profitability is 100 %. Similarly the net increase in the sector term of trade is 39 %. This is illustrated in Fig. 7a. However, a change in inputs scale efficiency is not significant while there is relative change in input scale mix efficiency and input technical change efficiency. This is illustrated in Fig. 7b below.

In Rwanda, during the considered period, the net increase in agricultural productivity is 13.4 %, while there is net decrease in the sector profitability by 95 %. Similarly the net decrease in the sector term of trade is 148 %. This is illustrated in Fig. 8a. However, analysis of inputs efficiency reveals that there are no significant changes in inputs scale efficiency while input mix efficiency does change considerably with relatively lower changes in the country's inputs technical change. This is illustrated in Fig. 8b.

Finally in Zambia, agricultural productivity increased by 69.9 % before 1990 and increased by 16.4 % after, while the profitability has increased by 2.1 before 1990 and decreased by 0.6 after the liberalization. The term of trade decreased over the period with 1.18 decreases before 1990 and 1.13 decreases after. This is illustrated in Fig. 9a. However, analysis of oriented input efficiency reveal relative change in input technical changes over the period and significant change in inputs mix efficiency before the agricultural sector market openness while this

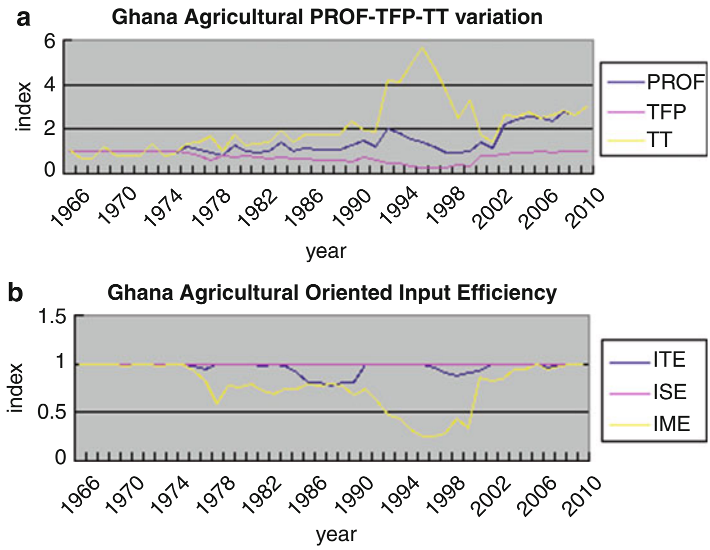

Fig. 6 (**a**) Ghana agricultural productivity profitability and term-of-trade variation between 1965 and 2010. (**b**) Ghana agricultural oriented inputs efficiency variation between 1965 and 2010 (Sources: author own composition based on FAO emission database)

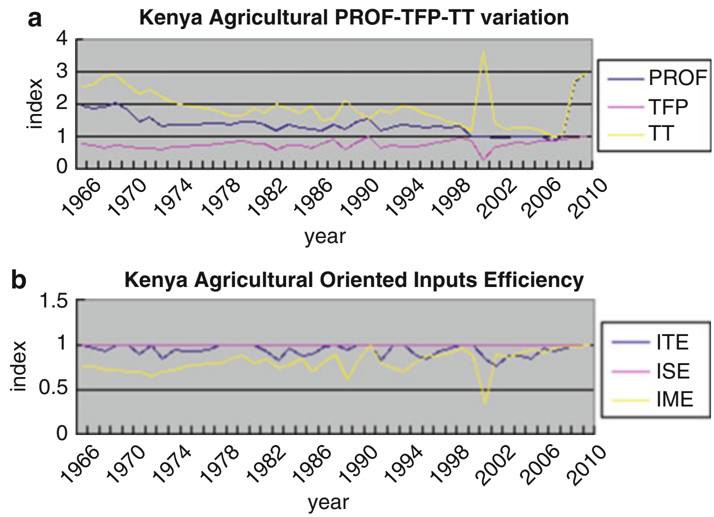

Fig. 7 (**a**, **b**) Kenya agricultural oriented inputs efficiency variation between 1965 and 2010 (Sources: author own composition based on FAO emission database)

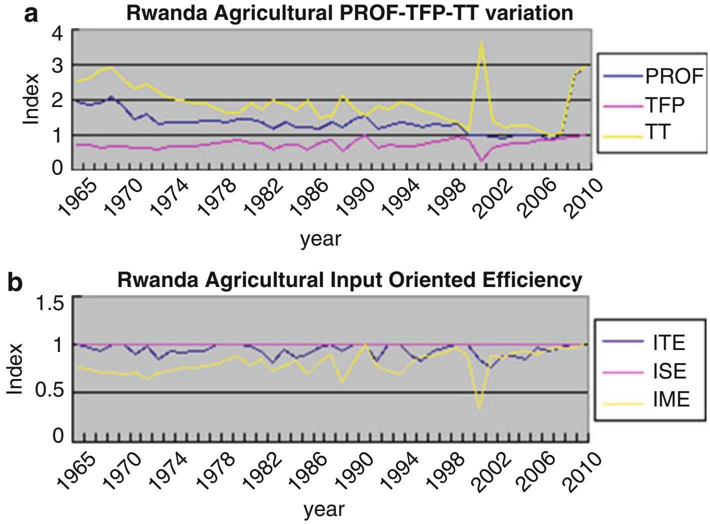

Fig. 8 (**a**) Rwanda agricultural productivity, profitability, and term-of-trade variation between 1965 and 2010. (**b**) Rwanda agricultural oriented inputs efficiency variations between 1965 and 2010 (Sources: author own composition based on FAO emission database)

change is much lower after. There is no significant change in scale efficiency. This is illustrated in Fig. 9b.

In summary, over the considered, period agricultural productivity is low across countries with relative improvement after the liberalization. However, in term of inputs used efficiency, there is no observed changed at scale level over the whole period. This explains that producer resource allocation does not change significantly, while production technical change has relatively changed over the years. This highlights on inefficiency of agricultural inputs such as labor fertilizer, water used in these countries, and their intensive agricultural production system. Therefore, inefficient fertilizer applied may contribute to increase in the sector emission, while climate change impact on water may increase water availability which in return will affect the sector productivity.

However, analysis of the result of the regression between country agricultural productivity and number of agricultural research staff, expenditure in agricultural R&D, government effectiveness, land, labor, and AFOLU emission reveals that agricultural emission and forest land net emission have similar significant impact on agricultural productivity as R&D, agricultural extension, government effectiveness, land, and labor, while the impact of land use on agricultural productivity is not significant. This is illustrated by list of Tables 5, 6, 7, and 8. Therefore, mitigation action in land use could be a possible option but will not have any gain or loss in this study's selected countries performance improvement.

It shows that total agricultural emission has considerably reduced country agricultural productivity respectively by 1.67 at 70 % in Ghana, by 0.04 at

35 % in Zambia, and by 0.66 at 19 % in Rwanda. This means that emission from agriculture sector does contribute to decrease in Ghana, Zambia, and Rwanda agricultural production performance. However, in Kenya, it is found that the emission from agricultural sector contributes to improvement of the country agricultural productivity. This confirms the need of exploring the linkage

between agricultural productivity improvement and emission impact according to each country's statement. The main reason is the complexity of country's agricultural production system and their agroecological zones. The result of this study of course does not support emission increase in Kenya but highlights that emission reduction could improve the country's agricultural production performance, as can constitute constraints for a country like Kenya that will need to achieve national goals in this sector. The cost of any emission reduction strategies then needs to be evaluated.

Notwithstanding, forest land net emission/sink impact on agricultural productivity has been significant only in Rwanda. It has contributed to the improvement of the country's agricultural performance by 2.1 at 19 %. This supports the fact that forest land in Rwanda has high carbon sink potential and deforestation will obviously reduce that sink. This is also consistent with the result of Rose et al. (2012) on analysis of agricultural productivity and deforestation. He found that improvements in Latin America or Southeast Asian crop TFP (ceteris paribus) led to an increase in inaccessible and accessible forest loss and pasture land conversion to cropland.

Therefore, considering 2010 as baseline, any 1 % increase in agriculture emission will decrease agricultural productivity in Zambia by 0.04 %, in Rwanda by 0.66 %, and in Ghana by 1.67 %. This will contribute to a decrease in their respective performance and will require then more investments in order to mitigate emission from agriculture. This will cost respectively 46.40Cedis/t/ha (US$ 23.2) in Ghana, 49.25 ZMK (US$ 0.09) in Zambia, and 346 FR/t/ha(US $0.53) in Rwanda. While in Kenya any 1 % decrease in agriculture emission will cost 2062.5 Ksh/t/ha(US$23.5). Therefore, the opposite scenario means a gain in each country.

Similarly, any 1 % decrease in forest emission through afforestation/reforestation in Rwanda will contribute to improve the country's agricultural productivity by 2.15 %. This will contribute to save 152 Rwanda Franc/tone/ha(US$ 0.23).

In a related development, the CAADP goal of achieving 6 % of agricultural productivity toward 2015 will increase the country's annual mitigation potential in agricultural sector by respectively 3.75 % in Ghana, 100 % in Zambia, and 150 % in Rwanda. While in Kenya it will contribute to an increase of the country emission by 9 %. Moreover, in Rwanda it will create an additional 2.85 % increase for the country forestry land emission. This means that the policy will help to reduce the total agriculture emission in Ghana and yield 0.00019 Gg CO_2 eq., while in Zambia the agriculture will become carbon neutral.

Nonetheless, the policies will transform Rwanda from net total agricultural emission to yield agricultural sink country at −0.0000319 Gg CO_2 eq., while the country forestry sink potentiality will increase and yield −1.31 Gg CO_2 eq.

In contrast, the policies will increase the total agriculture emission in Kenya and will yield 0.0068 CO_2 eq.

Conclusion

Agricultural productivity is relatively low in sub-Saharan Africa. Despite several reforms, it is even below the world average. Indeed, most countries did integrate the sector economics liberalization into their economics market liberalization in 1990.

The agricultural productivity did increase relatively during the period of post-economic openness. The relatively low agricultural productivity during the post-market liberalization is also observed in this study's selected countries. Indeed, the goal of improving the sector productivity rises during this decade and becomes a priority in most government policies' agenda. This includes the Comprehensive Africa Agriculture Development Programme. The policy is expected to bring annual growth of 6 % of TFP. This leads to expansion and intensive agriculture practices in some countries. However, the debate created by recent study which identifies agricultural sector as main emission sources in Africa raises more interrogation between scholars and government on the trade-off between productivity improvement and mitigation action in agriculture sector. This study finds that mitigation action in agriculture sector could help to reduce emissions and improve the sector productivity. However, not all mitigation action will contribute to improvement of the agricultural sector performance improvement. Therefore, some mitigation will also contribute to deterioration or decline in country agricultural production performance. This is the finding in this study's sampling countries.

Mitigation action will increase agricultural productivity in Ghana, Zambia, and Rwanda, while it will decrease productivity in Kenya. The need of implementing appropriated mitigation action is therefore essential. Appropriated sustainable land management (SLM) practices taking into account the country's agroecological zone, appropriate technology, and farmer ability to adopt the technology coupled with available resources will be more suitable for improving the country's agricultural production performance. Moreover, SLM could be developed toward climate smart agriculture (CSA) concept.

Indeed, the effects of land use changes are not significant and do not contribute to any changes in the selected country's agricultural production performance. This emphasizes that mitigation action can be assessed only by analysis of the response of each country's agricultural production system.

Therefore, the debate on how African countries will respond to mitigation action commitment in agricultural sector will depend on the impact of emission in agriculture sector and how emission reduction could benefit the sector. This includes the cost of the implemented mitigation action.

Abstract

Purpose – This chapter discusses and compares the climate change policies of Argentina and Canada at the international, national, and local level. Starting with a discussion of both Argentina and Canada's positions in the UNFCCC, the chapter then explains the positions and policies that have been implemented in the national and then local level of each country.

Methodology/approach – This chapter is an analysis and comparison of laws, policies, and practices through not only a discursive analysis of their official positive legal meaning but also through an analysis of their actual applied impact. A multilevel institutional analysis is utilized such that the climate change policies of Argentina and Canada are analyzed at the international, national, and local level.

Findings – At the international level, a discourse surrounds Argentina and Canada in terms of developing and developed country and global justice. At the national level, each country has different official laws and discourses surrounding climate change; however, at the regional level in both countries, many similarities exist in respect of climate change mitigation and adaptation in both positivistic legal meaning and actual applied reality. This chapter hypothesizes that a problematic gap exists between the climate change institutional framework and the "real" climate change being experienced by local people.

Practical implications – The similarities in the actual applied experience of climate change mitigation and adaptation in Argentina (a developing country) and Canada (a developed country) at the regional level, contrasted with the different characteristics at the national and international level, offer insights into the challenge of effective implementation of climate change mitigation and adaptation.

Originality/value – The multilevel institutional analysis and comparison of Argentina and Canada in respect of climate change mitigation and adaptation reveal significant structural governance challenges for the effective implementation of climate change mitigation and adaptation goals of the UNFCCC. Overcoming these challenges may facilitate implementation of climate change mitigation and adaptation goals.

Keywords

UNFCCC • Climate change mitigation • Climate change adaptation • Multilevel institutional analysis

Introduction

This chapter discusses and compares the climate change policies of Argentina and Canada using a multilevel institutional approach focusing on the international, national, and local level. The local level selected in Argentina is Mendoza; in Canada, the Prairie Provinces of Alberta and Saskatchewan have been selected. Argentina and Canada's positions in the UNFCCC are strikingly different, but many similarities exist at the local level. Both are water-scarce areas with significant irrigation and some similarities in institutional context at the local level surrounding climate change, although at the international level they are very different, one being a developed and the other a developing country. This chapter explains the positions and policies that have been implemented in the national and then local level of each country, assessing the policies' actual impact hypothesizing that there is a problematic gap between the climate change institutional framework and the "real" climate change local problem.

In the Canadian case, it is anticipated that climate change will result in increased water scarcity, more frequent extreme events (e.g., droughts, floods, storms), and changes or disturbances in climate regimes which will impact ecosystems with such events as forest fires; insect outbreaks (e.g., mountain pine beetle); vector-borne disease, such as West Nile virus; and the introduction of nonnative plants and animals. All of these impacts will place significant pressure on the environment as well as on human activities, such as farming, agriculture, forestry, development, and industry in the Prairie Provinces (Sauchyn and Kulshreshtha 2008).

Mendoza's regional productive model, based on Andean irrigated oasis agriculture, is seriously threatened in the context of most climate change scenarios. Global climate change projections indicate a probable decrease of snow in the mountains with a consequent decrease in the yearly streamflow (Boninsegna and Villalba 2006a, b). These climate factors could seriously increase the water deficit and compromise the oasis survival (Boninsegna and Montaña 2013). The Prairie Provinces are in central Canada. Mendoza Province is in the Central West region of Argentine, by Andean cordillera. The yearly precipitation is scarce (200 mm) and occurs during hot summers, frequently with hail. Additionally, the high levels of sun radiation have a direct impact on evapotranspiration and therefore on crops' water stress.

This chapter will demonstrate that the institutions that best address the "real" climate-related local problem of water scarcity are very far from the mitigation and adaptive practices that the climate change paradigm promotes. The practices of institutions with climate and agriculture mandates focus on an agricultural production model, not the climate change problem. These institutions are good information producers, but are not grasping the "real" climate change local problem of water scarcity.

Position of Argentina and Canada at the UNFCCC

The United Nations Framework Convention on Climate Change, the international treaty whereby parties cooperatively consider actions to limit average global temperature increases and resulting climate change, was ratified by Canada in 1992 and Argentina in 1994 (UNFCCC 2013). Kyoto was the significant legally binding agreement on emission reductions. Kyoto, however, did not provide for legal remedies and was therefore a rather toothless agreement (Pardy 2004). In Doha, Qatar, in 2012 the Kyoto Protocol was amended such that Annex I parties agreed to a second commitment period from January 1, 2013, to December 31, 2020 (UNFCCC 2013). Canada, an Annex I country, withdrew from the Kyoto Protocol providing notice in December 2012 and terminating its commitment in 2013 (United Nations 2012).

The communication filed by Canada in 2010 with the UNFCCC Secretariat stated that Canada expected to be 802 Mt above its Kyoto Protocol target of 2,792 Mt during the 2008–2012 period (Government of Canada 2010). The latest communication filed by Canada states that Canada emitted 702 Mt of GHGs that year, about 19 % above its 1990 total of 591 Mt, excluding the land-use change and forestry (LULUCF) sector. Currently the energy sector is responsible for the majority of emission (81 % consisting of stationary combustion, transport and fugitive emission sources) and the agricultural sector responsible for only 8 % of emission. Some reduction has occurred since 2008 (Government of Canada 2013). These reductions are touted to be as a result of regulation within the transportation and energy sector, as well as reduced manufacturing sector emission. Unstated is the fact these reductions could be as a result of the global recession that has occurred since 2008.

When in December of 2011, Canada withdrew from the Kyoto Protocol, the conservatives blamed the liberal government for having made an error committing to the protocol. Prime Minister Stephen Harper has set a target of reducing annual emissions to 17 % below 2005 levels by 2020. This is a much lower threshold to meet than the initial Kyoto Protocol target of cutting below 1990 emissions levels (CBC 2011; De Souza 2012). Publicly the Prime Minister had rejected carbon pricing or a carbon tax (supporting regulating each sector instead) and closed the National Round Table on the Environment and the Economy because the research group promoted carbon taxing (Scoffield and Ditchburn 2012). However, in Privy Council documents obtained under access to information legislation, Canada stated it supported the development of new market-based mechanisms expanding the scale and scope of carbon markets (De Souza 2013). It would appear that currently the Canadian government's position on climate mitigation is somewhat confusing. At this time, no legislated carbon reduction measures are in place in Canada.

Argentina ratified the UNFCCC in 1994 and the Kyoto Protocol in 2001. Argentina, a non-Annex 1 country, has submitted two national communications: the first one in 1997 – revisited in 1999 – and the second one in 2006. The third communication is in the process of being prepared. During this period, Argentina has adopted several mitigation norms and regulations, specifically to reduce emissions. Argentina's position in the context of climate change commitments has changed since the signature of the agreement, moving from a proactive innovative position to a low-profile one. In 1999, at COP 15, Argentina announced an emission reduction target linked to its GDP (SAyDS 1999). At that moment, this was an innovative event because it was the first time that a developing country had agreed to meet a voluntary quantified GHG limitation target. The proposal meant that Argentina was not locked into a fixed emission level as had been the case of the commitments adopted by developed countries under the Kyoto Protocol. Rather, Argentina would be allowed emission increases according to economic development (Conte Grand

and D'Elía 2011, p. 2). But this active role and innovative goal lasted a short while. Actually, by the time this target was presented, a new government had already been elected in Argentina, and its new authorities had announced that they would not agree with this commitment. Following governments have maintained the same position (Conte Grand and D'Elia 2011).

Argentina's current position is the "common but different responsibilities" principle (Chojo 2011). (This principle indicates that developed countries with greater resources (the *historically responsible countries*) must fund projects outside its borders in developing countries.) As was defined by the now ex-president Kirchner, Argentina is an environmental creditor, and it will charge developed countries in sustainable growth. Nowadays Argentina generates 6 % of the global emissions (WRI 2011). Overall emissions increased by 4.1 % from 1997 to 2000. As has been evidenced in the 1990–2000 inventories, GHG emissions originate mainly in the energy sector (including transportation) and 44 % in the agriculture and livestock production sector (Di Paola and Rivera 2012, p. 14) The weight of agriculture emissions (half of total national emissions) is very important. This is why taking only into account the energy sector emissions may lead to erroneous interpretations of the local contribution to climate change (Honty 2011, p. 55). Actually, some reports (not authored by the government) assessing scenarios emissions by sectors claim that the agricultural sector is not the second but the first source (CEADS 2012). In addition, agriculture emissions are also alarming in another sense. Argentina's profile as a highly agriculture country, where grain and agricultural products export are the main national revenue, makes it very vulnerable to climate variability. Extreme events could seriously affect the prices of commodities. Emission scenarios emphasize the importance of making changes, if Argentina wants to improve its resilience.

The national positions of Argentina and Canada are very different. Canada appears committed in principle to the reduction of GHG emissions and its pledges at Copenhagen; however, it has pulled out of any legally binding pledges of emission reductions. From a legal positivist stance, it is not required to take any future action. Argentina on the other hand has claimed entitlement to increasing its GHG emissions through the principle of common but differentiated responsibility. Each country has situated itself within the discourse that exists at the international level surrounding developing and developed country and global justice. The situation at the national and regional levels of each country is, in contrast to this, quite similar.

Climate Change Institutions at the National, Regional, and Local Level in Argentina and Canada

The institutions involved in climate change at the national level, and then the regional/local level, will be discussed starting with Canada and then Argentina. Thereafter, the climate change policies at the national, regional, and local level in Argentina and Canada will be outlined. An analysis and comparison of Canada and Argentina, their institutions, mandates, and practices will follow.

Climate Change at the National Level in Canada

Canada is a federal country, and accordingly different functions are assigned at the federal and provincial level. In Canada, at the federal level of government, two departments have been tasked with key lead climate change responsibilities: Environment Canada has a specific role in relation to mitigation of greenhouse gases, while Natural Resources Canada has specific responsibilities in relation to adaptation to a changing climate. These are the two most important departments, although other federal government agencies and departments also have roles in relation to climate change such as Health Canada with its role in safe drinking water and Parks Canada with its mandate for water resource management and protection within national parks.

Environment Canada has a mandate to preserve and enhance the quality of the natural environment, conserve and protect Canada's water resources, forecast weather and environmental change, enforce regulations relating to trans-boundary waters (international and interprovincial), and coordinate environmental policies and programs for the federal government. Because of Environment Canada's mandate, changing weather and, hence, climate change itself are central to aspects of its mandate. In addition to its long-standing environmental protection mandate, Environment Canada is responsible for overseeing the federal government's plan on the reduction of greenhouse gas emissions and the regulatory framework supporting this plan. The central regulatory tool in the reduction of greenhouse gas emissions established by the federal government is the *Clean Air Act* (Bill C-30 tabled in 2006 as "An Act to amend the Canadian Environmental Protection Act, 1999" in the First Session of the 39th Parliament) which will be the responsibility of Environment Canada. However, this act still has not been proclaimed and become Canadian law.

Canada's latest communication to the UNFCC states that Canada takes a sector-by-sector approach to mitigation and cites regulatory changes in the transport and energy sector (Government of Canada 2013). One group, the Large Final Emitters Group, was established in 2002 as part of Natural Resources Canada, but with the release of *Project Green: Moving Forward on Climate Change* in 2005 (Environment Canada 2009), the group was transferred to Environment Canada given the government's intent to regulate Large Final Emitters under the *Canadian Environmental Protection Act, 1999*, S.C. 1999, c. 33. This group, made up of staff of Environment Canada, is responsible for working with key industry sectors to reduce annual greenhouse gas emissions. Through its discussions with industry, provinces and territories, and other stakeholders, the Large Final Emitters Group was tasked with designing policies and measures that are effective in encouraging reductions and are administratively efficient and clear while still maintaining the competitiveness of Canadian industry. In 2004 Environment Canada mandated that large facilities report greenhouse gas emissions through the Facility Greenhouse Gas Emissions Reporting Program (Canada 2012a). The 2001 report shows that while large electrical utilities in Canada have reduced greenhouse gas emissions in Canada by 32,278 kt, non-conventional oil extraction have increased this number by 20,706 kt from 2005 to 2011 (Environment Canada 2013).

Natural Resources Canada promotes the responsible use of natural resources (mining/materials, energy, forests, hazards, explosives, the north, earth sciences, and the environment) for the protection of human health, the environment and the landmass, and other research related to forestry, mining, and energy sectors. Natural Resources Canada leads the development of the Northern Gateway Pipeline Project, a contentious development to transport energy across Canada's north for export. At the same time, Natural Resources Canada's Environment section leads impacts and adaptation to climate change and conducts climate change research.

Although other departments may have minor roles in climate change, the next most significant federal department involved in climate change, Agriculture and Agri-Food Canada (AAFC), has undergone significant cuts in the recent past reducing its climate change mandate. The Prairie Farm Rehabilitation Administration (PFRA) was created as a special agency in 1935 in response to severe climate impacts on the Prairies caused by the multiyear droughts of the 1920s and 1930s. Its mandate related to improving the security of prairie land and water resources to achieve greater economic security of agriculture in the semiarid prairie region; its role recently evolved to include national agri-environmental activities related to promoting farm practices that afford a competitive profitable agricultural sector with improved protection of the environment from potential agricultural contamination risks. PFRA was incorporated into Agri-Food Canada in 2009, and then its staff mostly phased out through retirement in 2012 onwards (Hurlbert et al. 2010).

The Provincial Level in the Prairie Provinces

The provincial governments of the three Prairie Provinces have similar challenges within the bureaucratic structure in responding to climate change because of the breadth and depth of the challenge and the preexisting government structure of institutions created prior to today's focus on climate change and water. Each province's response to climate change has been somewhat different in both form and substance. Generally, one particular provincial department is tasked with climate change, and a few others have supporting mandates or programs. One similarity between the provinces is that municipalities have a very localized role in relation to providing drinking water to residents, responding to floods and emergencies, and land-use planning decisions within their borders.

In Alberta, Alberta Environment is tasked with addressing climate change. After establishing its 2002 climate change plan and after a series of public meetings, Alberta renewed its climate change plan early in 2008 (Alberta Environment 2008). Alberta Environment is also tasked with both the protection and wise use of the environment and natural resources. Most activities affecting the environment must be reviewed through environmental assessment by Alberta Environment. Alberta Environment also carries the bulk of the responsibilities relating to both water and the environment, which includes surface and groundwater allocation, flow regulation, water supply and flood forecasting, pollution control, regulation of municipal potable water systems, and developing watershed management plans in conjunction with local groups. Alberta Environment also establishes and enforces drinking water and wastewater objectives and legislation.

In Saskatchewan, the ministry of the environment has been central in developing a climate change strategy. This ministry protects and manages Saskatchewan's natural resources, leads environmental water quality monitoring and enforces environmental protection guidelines, sets water quality regulations and objectives (including those for drinking water and waste water), and retains legislative responsibility for enforcing municipal drinking water regulations. Unlike Alberta, which manages both climate and water resources under the environment department, Saskatchewan manages its water resources by a separate Crown corporation, the Saskatchewan Water Security Agency. The Saskatchewan Watershed Authority (the Saskatchewan Water Security Agency's predecessor) was created to manage water in a holistic fashion aimed at protecting water source; the agency was established in 2002 as a direct response to the North Battleford drinking water disease outbreak in 2001. Saskatchewan Watershed Authority is responsible for protecting source water by promoting stewardship, water management, and water allocations and diversions and developing watershed and source water protection plans in partnership with watershed groups. Other departments also play a key role in responding to climate change, including the Ministry of Agriculture in respect of farming, improving farming practice, enforcing the Agricultural Operations Act, promoting environmental farm planning, and encouraging the adoption of agricultural beneficial management practices (BMPs) to protect water resources and the environment.

Climate Change at the National Level in Argentina

Argentina, as Canada, is a federal country and its national constitution (1994) confers provincial states primary ownership (*dominio originario*) of natural resources (including water and land). In relation to **adaptive practices**, the federal government's ability is limited as it does not have any jurisdiction in relation to natural resources. Argentina does not have a specific national **law or legislation on climate change** (in fact, the minimum environmental protection Presupposition law does not contemplate climate change or adaptation practices). General Environment Law N. 25.675 is the most general related law and stresses the necessity of interjurisdictional coordination in terms of environment ordering. It is a thoroughly promising law as it establishes interesting guidelines that help decrease national state development which would be at the expense of that of provincial states (thereby retarding their development) (Salerno 2009, p. 310). However, its resource limitations restrain an adequate enforcement of the law (Cetrángolo et al. 2004).

Also at the federal level is the Secretary of Environment and Sustainable Development (SAyDS). This entity is the authority for the enforcement of the law 24295 by which Argentina ratified the UNFCCC (Presidential Decree 2213 of year 2002). Within this Secretary, the Unit of Climate Change (UCC) was created to advise SAyDS Director on Law 24295 application and UNFCCC implementation. Many other governmental areas have responsibilities on climate change issues. One of these is the Environmental Federal Council (COFEMA) which brings together all provincial environment departments with national government representatives. Within this council, there is a special group on climate change. The expectations on this council were many because it was supposed to be an organ exclusively created to integrate provincial and national visions. However, so far it has shown major limitations of resources (technical and financial) and an unbalanced political weight. So as yet, it has not achieved a genuine incorporation of provincial visions within the national environmental strategy.

The last institution is the Climate Change Government Committee where government organisms, important public institutions, and COFEMA representatives meet. All these institutions lead by CCO develop the Climate Change National Strategy (CCNS), the major national climate change policy instrument.

The Provincial Level in Mendoza

At the provincial level, in Mendoza two institutions are supposed to be related to climate concerns – at least they have the "climate" word in their name. The Climate Change Agency was created in 2007 as a coordination arena between public and production sectors, science institutions, and NGOs. According to its official site, its goal is "to promote programs and environmental, social and economic projects including provincial, national and international public and private sectors...; to prevent actions that may cause ecological damage or affect province natural resources quality and preservation... and to recommend mitigation practices and adaptation strategies to minimize climate change consequences in Mendoza" (Agencia Mendocina de Cambio Climático (n.d.)). An intention so wide, intangible, and nonspecific has left this institution achieving little. But the real weakness of this institution is that it does not handle its own funds. Instead, it must rely on the meager amounts derived from federal programs which in turn are received from international organizations. This situation leaves this agency as *just as a lot of good intentions*. The second climate provincial institution is the Agriculture and Climate Contingency Directorate. This is the provincial *agri-climate* referent. Its goal is to assess extreme climate events, but it is mainly concerned with supporting farmers avoiding agricultural damages, specifically hail and frost. The Climate Change Agency depends on the Land, Environment, and Natural Resources Ministry and is oriented toward sustainability and resource conservation; the Agriculture and Climate Contingency Directorate depends on the agri-industry and technology ministry with a completely different orientation toward agricultural development.

One last institution in Mendoza is definitely dominant in dealing with climate and water resources: the General Irrigation Department (DGI). Although formally it does not have a climate mandate, it does in practice given that the main local global change problem is drought. As DGI is the most important water government institution – in a land where irrigated agriculture is the only possible – it turns into the most significant institution for coping with "real" global change problems, even more than the other two mentioned. DGI is a strong institution that since 1884 has been modeling the wine regional agriculture production model. This strength comes from a development model established in 1884 (the year in which the current water law in the province was enacted): water coming down the Andes is stored, distributed, and systematized in agricultural irrigation systems and finishes as crops or virtual water for export. Water management is a key support for this model which is still valid today. In 1884 it was designed by a planning elite with enough political, social, and economic power to influence the productive destinations of the region. This has not changed: today DGI meets the interest of the most wealthy and powerful regional producers and remains far from adaptive also avoiding mitigation practices that climate problems demand. Currently Mendoza's provincial constitution states guidelines for water, but environmental policy is lacking here.

Finally, at the bottom level, municipalities also have specific domains related directly to environment, but these are mainly rhetorical offices. Instead, these are the municipalities' production offices which are, "in the real world," the closest government institutions to small farmers. But at the same time they are the least economically empowered institutions. They can hardly provide material support but advice small farmers how they should proceed claiming other levels.

Climate Change Policies at the National, Regional, and Local Level in Argentina and Canada

In Canada, provincial and federal ministries appear to overlap or duplicate climate and water mandates and services. Because climate was not contemplated when Canada mapped out jurisdictional matters between the federal and provincial governments in its constitution of 1867, it spans both levels of government. Similarly, the jurisdictions of natural resource management are shared by mutual agreement and often by joint programming and funding between the national and provincial governments in Canada. The potential duplication is resolved in practice in two ways. Firstly, matters which are within federal jurisdiction such as First Nation lands, international and interprovincial waters, and interprovincial undertakings are governed by the federal government departments and legislation; matters within provincial control, such as provincial lands and natural resources (including water management), are governed by the provincial legislation and policy of the provincial government departments. Secondly, in the event that it is not clear whether a particular issue or activity falls under provincial or federal government jurisdiction, there are many federal and provincial agreements resolving these issues, which generally provide that the strictest legislation shall apply. For example, under administrative or equivalency agreements with many provinces, federal environment legislation is held in abeyance providing provincial legislation is equivalent to, or more stringent than, that expressed in federal acts. Agriculture, water, and environmental issues are commonly shared jurisdictional matters between the federal and provincial governments. The Prairie Provinces have had specific policies surrounding climate change and adaptation for the past several years.

The Canadian government, led by Prime Minister Stephen Harper, has been accused of "muzzling" its scientists by not allowing them to speak to journalists without preapproval, which is often denied (Ghosh 2012; Burgmann 2012). Having pulled out of the Kyoto Protocol and having officially rejected a carbon tax, the federal government led by Prime Minister Stephen Harper introduced the *Clean Air Act* (Bill C-30 tabled in 2006 as "An Act to amend the Canadian Environmental Protection Act, 1999" in the First Session of the 39th Parliament). This draft bill was amended in 2007, but has not yet been passed into law. Instead, $345 million of funding was allocated to promoting the use of biodiesel and ethanol and $300 million to helping homeowners become more energy efficient (CTV News 2006, 2007). In addition to other grants to cities and provinces for various initiatives including transit initiatives and climate impact research in the Arctic, in 2009 billions of dollars were allocated to clean energy research and development and demonstration projects such as carbon capture and storage and energy retrofit programs, aimed at improving the environment as well as employment opportunities (Canada 2009). Canada has invested $236 million since 2006 in climate adaptation initiatives (Government of Canada 2013).

Saskatchewan's previous New Democratic Party Government issued an Energy and Climate Change Plan in 2007 which was a cross-governmental vision in response to climate change and the development of a province-wide climate change adaptation strategy which included working with research organizations and supporting critical local research on climate change and adaptation (Government of Saskatchewan 2007). These goals have been reiterated in the 25-Year Saskatchewan Water Security Plan (2012). Several watershed groups have developed drought plans as outlined above. Currently, climate legislation relating to mitigation remains on the legislative agenda but is yet to be proclaimed.

In Alberta legislation has been in existence since the Climate Change and Emissions Management Act (2003), a precursor for Alberta's Climate Change Strategy (Alberta Environment 2008). In addition to establishing a carbon offset market and providing consumer rebates in relation to energy efficient products, two programs were also introduced, a greenhouse gas reporting program and a greenhouse gas reduction program. These relate to the establishment of a greenhouse gas limit. In 2003 Alberta also created a "Water for Life Strategy" focusing on issues of quantity, quality, and conservation of water, all important issues in preparation for and during drought. The strategy initiated three important activities: (1) planning for future management of water via the provincial climate Change Adaptation Strategy, (2) development of land-use frameworks, and (3) watershed planning through local watershed groups. Alberta has policies in place to mitigate climate change. Alberta has passed legislation requiring large emitters to reduce their emissions by 12 % using an average of 2003 as a baseline. These requirements apply to emitters making up 70 % of Alberta's emissions.

In Argentina the Climate Change National Strategy (CCNS) is the most important climate policy instrument. Although it is not finished yet, since its origin in

2009, the strategy set up under two axes (mitigation and adaptation) which include a considerable number of action guidelines that include commitment and participation of different sectors, institutions and important actors, programs, projects, and also specific indicators to assess or measure the changes (Nazareno 2013). According to what has been reported in its Second National Communication, Argentina has implemented some measures to comply with the UNFCCC, especially mitigation practices to cope with GHG reduction. These include a carbon fund to encourage projects under the UNFCCC's Clean Development Mechanism (SAyDS 2008), a National Program for Rational Use of Energy and Energy Efficiency (United Nations 2011), a national program encouraging the use of bioethanol and biodiesel (ibid.), a law for the sustainable management of forests, and an urban solid waste management plan supported by a loan from the World Bank for constructing sanitary landfills and landfill gas capture (ibid.). The SAyDS, in agreement with the provinces and with the funding of the World Bank, has developed since the year 2005 an Urban Solid Wastes National Strategy. Given that around 60 % of the disposal of urban solid wastes is still in open air dumps, the central objective of this strategy is the protection of the health of the population by the replacement of these dumps with controlled landfills. Likewise, the subsequent capture and elimination of the methane are also contemplated in this strategy (second communication).

Lastly, the *glaciers preservation,* Law N. 32.016, which has been recently created dictates minimum budgets for core presuppositions to protect nationally glacial water sources. Adaptation measures at the national level are much more limited than mitigation practices and include actions to reduce risk disasters in the land-use planning process and the agricultural sector.

At the provincial level, the Climate Change Agency defines as a priority energy and water efficiency, but their practices are limited to audits, diagnosis, and awareness of the population. Occasionally these activities articulate with activities in the municipalities but always limited within the framework of education campaigns. The Agriculture and Climate Contingency Directorate, as stated above, orients its policy toward damage prevention and mitigation, managing support and providing advice to farmers affected by frost and hail. DGI water policy is the most related to extreme drought events associated with GC in the region. Among the most important measures, Mendoza's DGI stated in 2014, for fourth consecutive year, water emergency. This statement is put into effect by decree of the governor, and it is a portfolio of measures to be implemented after the finding of a severe decline in river flows. While it is a big scope policy which it is supposed to reduce water availability for all uses, it affects mainly irrigation. The effect on livelihoods of farmers using irrigation water is different, as not all producers depend in the same way from water coming "down the river and channels." This large number of institutions formally designed to address the global change problem and their policies overlapped each other in their functions, which creates confusion among producers. More importantly, this situation creates few opportunities to be sensitive to the needs of producers affected by the effects global change.

Analysis and Discussion

The comparison of Canada and Argentina has been organized into three themes: the dominance of a model of production, institutional fragmentation, and institutional silos. In respect of institutional silos, the most problematic features of this are climate, water, and territory. Each feature will be discussed in turn.

The Dominance of a Model of Production

Argentina is an agricultural exporter and here lies its main income source. Therefore, it is highly vulnerable to climate variability and extreme events, as these can severely affect domestic production and the price of commodities worldwide. However, the long-term goals proposed in the CCNS are framed in the same production, reproduction, and consumption model that makes Argentina vulnerable (Llanos 2014). The national strategy planned to address global change focuses on how to adapt the current model of production to new climate conditions. The CCNS does not set specific rules to limit the expansion of the agricultural frontier and thereby to limit deforestation and soil degradation. This will result in the displacement of small farmers and original people living on the existing agricultural lands. Further, the strategy does not promote agri-ecological practices or introduce regulations to native seed conservation. Neither the global change nor climate change plans offer a strategy for the improvement of small and medium producers (Llanos 2014). By this, the government does not define clear measures that improve Argentina or reduce its vulnerable condition. Although a radical change of the agricultural model isn't anticipated, there is no clue of any robust mechanisms or alternative agricultural model that could take Argentina into a sustainable long-term adaptation process. Also considering that half of the total national emissions comes from agriculture sector, the current agriculture model reproduction included in the CCNS does not show a very promising picture for the country.

The continuity of the dominant agricultural model underlying Argentina's national position is also reflected at the provincial level. Although the wine production of Mendoza is not within the main exporting commodities of Argentina, the agency that administers the water (for irrigation) reproduces the poorly sustainable extractive production model through an unequal water allocation and discount system. Intuitively, opportunity to increase the export of this product is being foregone.

Canada too has a dominant model of production, albeit slightly different than the Argentinean agricultural model. In Canada, in the study region of the Prairie Provinces and post 2008 recession, the dominant model is that of energy exporter. Canada is the sixth largest energy producer in the world, after Russia, China, Iran, the United States, and Saudi Arabia (International Energy Agency 2013). This energy production predominantly occurs in the study region. The current national Canadian government and governments of Alberta and Saskatchewan are expending considerable effort in maintaining the energy industry attempting to build several pipelines to take the crude oil and tar sand oil out of the northern area of the province to refineries and customers around the world. This production model also exists within the agricultural sector in Canada where focus is on exports and increasing food production. Any adaptation measures focus on the adaptation of farming practices to meet a changing climate with very little, but occasional, consideration for or focus on an alternative model of agricultural production (See Magnon and Sommerville 2012).

This dominant production model especially that of energy production could be a cause for the skepticism to climate change among local producers, albeit change of this attitude was noted (as reported in Hurlbert 2011). A struggle is ongoing in the Canadian media in relation to climate change between deniers and science (Arnott 2013). The government agenda appears to support climate change deniers. Funding cuts to scientific research (CAUT 2013) and massive cuts to federally employed scientists have occurred and will impact the northern Prairie Provinces and its oil sands in a unique way. One specific example is the loss of 11 regional libraries of aquatic research and the disposal of a environmental study in relation to building an oil pipeline in the 1960s and 1970s (Galloway 2014). This research would have acted as a baseline for current proposed pipelines in the same area.

Institutional Fragmentation

The global change institutional framework in Argentina shows a multilevel network of global change – related institutions. But this complexity does not translate into better support to local actors who are affected by the events of global environmental change in different sites of the country. The continuity from national to provincial levels is a fragmented framework that becomes evident at the regional level (the province and municipal levels) and has a greater consequence on everyday life of regional production and its actors. DGI is the local institution that should best address the "real" global change local problem, although as it was already mentioned it is very far from mitigation and adaptive practice. DGI focus on an *agricultural production model* that does not consider the global change problem. At the same time, provincial climate institutions' practices do not grasp the "real" climate change local problem (drought and water scarcity). Due mostly to lack of funds, they are just good information producers. A problematic gap exists between the global change institutional framework and the "real" global change Mendoza regional problem: drought and water scarcity. Each institution meets or deals with different actors. One (province institutions governing water) oriented toward large (powerful) actors and the other (climate institutions governing *emergencies and municip*alities) to small (disempowered) producers.

Argentina's institutional features have an impact on local farmers and in their capacity to overcome climate problems. A study of local producer's perceptions on state institutions confirms the hypothesis about the gap and the lack of capacity to cope with and reduce the impacts of climate change events on local actors (Mussetta and Ivars, Interviews, Mendoza, September 2012).

This fragmentation creates a situation of uncertainty within actors and gives them a negative opinion of state institutions. This perception is general, but it changes within different actor profiles. Small producers have the firm conviction that they obtain "nothing" from the state. They evaluate it as a single homogeneous entity, and they do not distinguish between local, provincial, or national authorities or type of institution (if they are talking about tax collection agencies, research organizations, or others). The exception to this generality is the municipality. This is the closest state arm to small farmers, and accordingly, these are the institutions approached by farmers for immediate assistance, especially in extreme climate event situations. However, producers do not receive as much as they claim because municipalities do not have very limited resources or competences to solve the problems. Instead, local municipalities work as mediators between small farmers and other government levels.

From a different standpoint, larger producers understand and clearly differentiate the various state levels, and they have a much more complete knowledge of the complexity of the state bureaucracy in its various offices and functions. This knowledge allows them to access privileged information provided by the state and therefore be in a better position to access economic benefits (tax breaks, direct subsidies, state grants). Further, these actors distinguish "political" from "technical" agencies which allows them to make informed decisions on issues such as water supply, efficiency, and financing (ibid.).

In Canada, a multitude of water organizations and climate institutions exist at the federal, provincial, and municipal level which make interagency coordination an issue. Government officials are often confused themselves about mandates and roles let alone the public and agricultural producers. This has resulted in often frustration by agricultural producers in having to deal with a large number of agencies in relation to a specific problem (Hurlbert and Diaz 2013; Bakker and Cook 2011). There is not a national water strategy, therefore no effective Canadian water vision with clear priorities and a comprehensive policy approach and no comprehensive climate change and adaptation plan (Hurlbert et al. 2010). In Alberta, this has constrained the development of more agri-industry and further irrigation systems.

Clear inequity also exists in Canada in respect of adaptive capacity. First Nation communities are the most vulnerable, partly because of a history of colonialism that characterizes the integration of indigenous people in Canada (Magzul and Rojas 2006). The Canadian government agencies and their incentives and adaptation mechanisms have aimed at improving the competitiveness of the sector in global markets and thus fostered larger-scale production, larger farms, and larger equipment. Fewer producers are producing more crops. A relatively small group of large farmers has replaced many small producers (Hurlbert and Diaz 2013).

Institutional Silos

Another significant feature of the framework fragmentation is that climate and water (as well as territory, since local governments are responsible for land use) are separated and managed by different institutions as if they were three separate dimensions. **Climate** is institutionally managed by provincial agencies that are almost exclusively rhetorical and whose policies do not have any specific scope for adaptation to global change. **Water**, the main natural resource to address the climate change in dry lands such as Mendoza, is administered by an institution with a long-standing history which has all the resources to decide what, who, and how to target, not only the management of the natural resource, but the entire provincial production system. Finally **territory** is formally the responsibility of municipalities. If the attention of climate change problems **requires** a comprehensive approach, the design and institutional practice of what should be understood as the same interconnected problem is empirically separated and fragmented.

A similar situation exists in Canada. Climate is the jurisdictional responsibility of both the national government and the provincial governments. Only paltry amounts have been spent on addressing adaptation to global change. Water is a matter of provincial jurisdiction and managed in very different and disparate ways by the provinces. However, in reality a patchwork exists as pockets of federal jurisdiction are situated in interprovincial and international water, federal lands, and First Nation lands. Territory is situated at the municipal and provincial level with an interesting separation between land-use planning and water planning making integrated watershed management a stretch goal. The most problematic feature of this situation in both Argentina and Canada is the consequences on actors' adaptive capacities. The following pages, reflecting local producer perceptions, will set out this idea.

Climate: In the Argentinean case, climate effects assistance mechanisms (that the Provincial Climate Contingency manages) are designed for the larger producers, not for small ones. This is because this office sets so many restrictions (such as regulations, guarantees, or financial solvency) that small farmers are unlikely able to access benefits. Therefore, not only must producers cope with the significant problems associated with lack of water, but they also have to manage to overcome hail and frost damage. Supportive mechanisms are mostly only affordable by wealthier farmers. The Climate Contingency office in the end becomes barely helpful because it appears far from the small actors and has little influence on their likelihoods. On those occasions when small producers get some kind of aid, it is never enough to recover from damages. In addition to this situation, these groups of producers are also affected by other non-climate processes such the low crops prices in the general price structure. For small producers, it represents more a state-constraints source than a supportive office for contingency.

Similarly in Canada, large producers are the biggest recipients of national and provincial assistance. As an example, small farmers often find crop insurance unaffordable, and complaints have historically been more common in Saskatchewan than in Alberta (RCAD 2012; Warren and Diaz 2012). Alberta has more consistently provided financial resources to maintain attractive premium rates in the wake of major drought events. Frustration in Saskatchewan stemmed from the effects of severe drought in the late 1980s and 2001–2002 on the finances of the program when payouts overtook the value of farmer premiums and government contribution levels; the Saskatchewan program fell into deficit. In response, premiums were raised to levels that farmers found exorbitant, and payout levels were reduced during the 1990s and early 2000s. A new government elected in 2007 addressed farmer concerns by injecting the cash required to make premiums and payouts more attractive. Since 2007 farmer participation in crop insurance in Saskatchewan has increased significantly.

Paradoxically, in both Argentina and Canada, the state discourses, small producers emerge as the main object of protection. Among the major producers, and to a lesser extent among medium-sized producers, who are able to access those benefits, negative perceptions of state are not associated with lack of help for climate contingencies events but about the constraints of economic policies at the national level. In short, crop insurance in Canada and Argentina is not the same for all: not because climate contingency is not a general event, but because some are better prepared to avoid or overcome these effects (because in turn they can reach state-offered climate protection). Others are not, and this makes them more vulnerable.

Water: Water scarcity is a general problem, and all actors recognize it. In Argentina, the unequal treatment is seen both in superficial and underground water distribution. In the former, only those with water rights take part in the decision making processes. In the second, underground water pumping is not an actual option for everyone because of its high pumping cost. On the other hand, pumping permissions are not always within the legal framework. They are managed by DGI in a centralized and discretionary manner, in favor of powerful actors. Underground water is really significant as it is what makes the difference during scarcity and restricted irrigation. Fragmentation and differentiated traits depicted previously are confirmed by actors, especially the disadvantaged (small producers located in middle and low areas of the basin) far from the big water storage at the top of the basin (Montana and Boninsegna (forthcoming)). Producers recognize that it is the provincial irrigation institution (DGI) which would have the power and ability to solve this problem. But they also recognize that they cannot reach this institution, just the same as with the climate agency, although with some differences. Here, the restrictions identified by the producers are not exclusively objective (regulations, taxes impositions). Rather, the problem with DGI is associated with a nontransparent policy making style that for many years has been supporting wealthier wine producers. Small producers explain that in the middle part of the basin, the DGI allows large water splurges and nonlegal water appropriations, while in distal areas there are serious water shortages. Both situations are attributed to the poor organization of the DGI (*ibid.*).

Perceptions are different from the large producers' standpoint, especially situated at the beginning of the basin. This group suffers from water shortage problems, but when water coming down the channels is not enough – a regular occurrence – they use groundwater. So, their complaints are about restrictions on obtaining groundwater licenses during strong water crisis periods. However, they recognize DGI's effort in organizing a water supply system. This difference can be explained because large producers are located upstream and small producers instead are located at the most distal part of the basin. As big water reservoirs are at the origin of the basin, the impacts of a water crisis are notably different in each place. DGI emergency policies during water crisis periods do not ensure an equalitarian water distribution.

In the study area in Canada, only in Alberta is water fully allocated such that no further water allocations can be made. As a result, Alberta has pioneered a water system which operates both on water license allocation from the province as well as allows these interests to be traded separately from the land. Albeit this process has only occurred a handful of times, it is believed by some Albertans in the study area to have been facilitative in meeting challenges in the last significant drought event of 2001 and 2002. The ability to transfer water interests separate from land was cited as a reason why irrigators in the South Saskatchewan River Basin were able to trade water interests in exchange for compensation allowing some producers with adequate capital to grow a crop, while others received compensation. A very robust system of water monitoring and enforcement in this region exists which would have enforced a first in time first in right system allocating the scarce water to a handful of the oldest water licensees. Instead, government officials, irrigators, and others quickly negotiated a compromise allowing municipal water use and the arrangement previously referred to. In accordance with an interprovincial water sharing arrangement, water was delivered downstream to Saskatchewan at this time where water is not yet fully allocated and problems such as these are only starting to arise.

Territory: According to a provincial Territory Ordering Law (8051, year 2009) of Mendoza which establishes policy and guidelines for municipalities and provincial coordinated territory planning, the DGI is supposed to dictate where it would be possible or desirable to expand agricultural area. However, this expansion does not occur, rather the opposite, an encroachment on agricultural land. It is the municipality which grants land-use permissions, and as a result, urban encroachment regularly occurs. Some protection does occur for medium and small producers in the middle and lower areas of the basin in relation to industries such as that of small brick manufacturing expansion. As long as the industry is not too powerful, some protection is attained. An opposite situation is the case of businesses whose powerful real estate interests progress over the best land in the foothills, in the upland areas of the basin. Powerful groups lobby on urban land use and usually determine or influence water allocation and land-use changes to the detriment of those in the middle and lower areas of the basin.

In the Canadian province of Alberta where water is fully allocated, several plans have been drafted. Alberta's Water Act integrates water planning with a consultative policy first created in 2003, Alberta's Water for Life Strategy through s. 7 (Alberta Government 2013). A Water Management Plan for the South Saskatchewan River Basin has been established for the study area which addresses the issue of full allocations and includes the water resources of the Bow, Oldman, and South Saskatchewan River sub-basins; however, no real mention of climate change is made (Alberta Environment 2006). Further complicating this management instrument is the creation of land-use frameworks through the Alberta Land Stewardship Act administered by a Land-Use Secretariat. A Draft South Saskatchewan Regional Plan relates to the case study area and does mention climate **change** and refer to other pieces of legislation (Alberta Government 2013); this area does not align with the watersheds and the regions of the Watershed Planning Advisory Councils. Further, the land-use framework plan is advisory and not binding, so it is unclear how influential at the end of the day this document will be. However, the municipalities participate in the drafting of the water and integrated land-use plans such that jurisdiction is truly on a regional basis. In Saskatchewan as well, land-use planning has been conducted through the Ministry of Environment of the Government of Saskatchewan, while source water protection more recently facilitated by the Saskatchewan Water Security Agency through local watershed groups. As a result, the issue of "territory" and source water is not integrated.

Conclusion

Although the international positions of Argentina and Canada are very different, many similarities in climate change laws and policies exist at the regional levels. Internationally Canada officially is not legally bound to emission reductions but appears committed to a target. Argentina on the other hand has claimed entitlement to increasing its GHG emissions through the principle of common but differentiated responsibility. The positions of each country are situated within the discourse that exists at the international level surrounding global justice and developing and developed countries. The situation at the national and regional levels of each country is in contrast to this and quite similar.

Although Canada has reported reductions in emissions through regulatory efforts, very little legislation has been enacted and no commitment made to carbon taxes. The province of Alberta has legislation in place but Saskatchewan, like Canada, is without a solid legislative framework. In Argentina, several financial tools exist to assist with emission reductions as well as a glacier preservation law but only at the national level. Far from reducing emission targets, at the provincial level of Mendoza, two agencies operate with financial constraints attempting to meet the challenge of climate change. One institution operates within a resource conservation framework; the other embraces an agriculture development orientation. Institutional adaptation in both countries is oriented to "maintaining the same" in respect of development and resulting emissions, both of which are increasing.

The relatively sparse progress in passing and implementing laws and policies in relation to climate change may be as a result of a fragmentation that exists in relation to institutions within the governments at the national, provincial, and regional level in responding to climate change. This fragmentation also means that the real problems of climate change and global change, drought, and water scarcity are not dealt with. Further, a clear inequity between small and large producers is continuing to increase in both Argentina and Canada.

Institutional silos have also been created within government organization. Firstly, climate occupies a very shallow position with institutions appearing more on paper in form than substance. Water agencies and agricultural departments operate within a model of production together with a goal to increase agricultural export instead of adaptation to climate change and mitigation of GHGs. In a similar manner, this model of production results in small producers being further marginalized as the impacts of a changing climate are experienced. Lastly, the territory, or land-use planning, is once again separated from concerns of climate and water and also contains a dominant theme of increasing production. This situation questions the utility of many tools such as Integrated Water Management or Integrated Natural Resources Management that works very well in a conceptual level but experiences serious inconsistencies when put into practice.

Although both Canada and Argentina have been developing many global change policies since the UNFCC C commitments and have demonstrated progress, especially in mitigation strategies, only small gains in legislative implementation have been made. However, regarding adaptation policies, the national political strategy in both Canada and Argentina is oriented to how to fit the extractive agriculture model with new and future climate conditions. This current development strategy followed by both countries appears to be worsening the problem of climate change. Obviously this strategy is problematic, and it is questionable that maintaining the same strategy in the context of harsher climate conditions is feasible. A serious increase of an already existent vulnerability is the most certain scenario. Global change institutions move as if they weren't aware of this situation; they move by parallel paths that hardly meet. The close link between global change policy and development policy in Argentina and Canada generates unsustainable effects on the climate and natural resources and emphasizes economic inequalities between actors whose livelihoods depend on them.

National Adaptation Planning: Lessons from OECD Countries

Michael Mullan, Nicolas Kingsmill, Shardul Agrawala, and Arnoldo Matus Kramer

Contents

Abstract

National governments have a crucial role to play in facilitating preparations for the effects of climate change. This chapter provides an overview of adaptation planning and implementation at the national level in member countries of the Organisation for Economic Co-operation and Development (OECD). It compares different approaches and discusses emerging lessons learnt and challenges

Disclaimer: The views expressed in this chapter are the sole responsibility of the authors and do not necessarily reflect those of the OECD or the governments of its member countries. This chapter has been adapted from OECD Environment Working Paper "National Adaptation Planning: Lessons from OECD Countries" (http://www.oecd-ilibrary.org/environment/national-adaptation-planning_5k483jpfpsq1-en). This report was drafted by Michael Mullan, Nicholas Kingsmill, Shardul Agrawala, and Arnoldo Matus Kramer.

faced based on a survey of OECD countries' National Communications to the United Nations Framework Convention on Climate Change and discussions at a workshop with adaptation policy-makers from 25 developed countries, held by the OECD in 2012.

Finland was the first OECD country to publish its strategy in 2005 and, since then, a further 17 OECD countries have published national strategies to coordinate and communicate their approach to climate change adaptation. Of the remaining OECD countries, eight have plans or strategies under development. The OECD workshop revealed three emerging challenges faced by countries as they move from planning to implementation: addressing capacity constraints, securing adequate financing, and measuring the success of adaptation interventions. Addressing these challenges will be essential to ensure that progress in planning translates into being better prepared for the effects of climate change.

Keywords
Adaptation • Climate change • National planning • Risk management

Introduction

National governments have a vital role to play in determining their countries' success at preparing for the effects of a changing climate. This can be through action, such as raising awareness of the likely effects of climate change, or inaction in the face of policies that provide the wrong incentives to individuals or businesses. Examples of the latter include insurance schemes that encourage excessive development in high-risk areas or underpricing of resources that will become scarcer in the future. Increasingly, governments are using national adaptation planning to provide an evidence-based, coordinated, and systematic approach to their preparations for climate change.

Much of the policy and academic literature on adaptation to date has focused on developing countries, because of their high socioeconomic vulnerability to climate change. However, a growing body of activity and experience of adaptation planning in OECD countries has shed new light on existing challenges. Finland was the first of the 34 member countries of the Organisation for Economic Co-operation and Development (OECD) to publish a national adaptation strategy. Since then, a further 17 OECD countries have developed national adaptation strategies or plans. These have focused on mainstreaming climate risks into local and national policies but with variation in the policy instruments being used, the role of the state, and the assignment of responsibilities between national, state, and local governments.

This chapter provides an overview of the current status of national planning activities and remaining challenges in OECD countries. These countries have made different choices about the degree of central direction, the balance of public and private provisions, and the arrangements for financing adaptation. National governments in federal countries and those with strong local autonomy face different opportunities and constraints than those with more centralized systems. Given this variety, this chapter draws upon the experiences of OECD countries to identify emerging lessons. It is intended to help inform the development and refinement of adaptation policies within OECD countries but also to be informative for developing countries as they develop and implement national adaptation plans (NAPs).

This chapter is organized as follows: "Status of National Adaptation Policies in OECD Countries" examines the record so far in implementing adaptation strategies within OECD countries, drawing on discussions at the *Policy Forum on Adaptation to Climate Change in OECD Countries* in May 2012 and a review of countries' National Communications to the United Nations Framework Convention on Climate Change (UNFCCC) and complementary sources. "Emerging Lessons Learnt" builds on the review of OECD-wide progress to identify some of the lessons learnt from the design and implementation of adaptation programs and their implications for the future.

Status of National Adaptation Policies in OECD Countries

At the international level, adaptation has taken its own prominent place alongside mitigation within climate negotiation processes and is likely to be a critical component of the post-2015 international climate regime. Similar signs of progress can be seen at the national level within OECD countries. This section surveys the current levels of activity across the 34 OECD countries, updating and expanding an earlier analysis by Gagnon-Lebrun and Agrawala (2006).

Overview of Relevant Literature

A major element of the adaptation literature has aimed to provide recommendations on what planning ought to consist of and how governments ought to enact adaptation plans. OECD (2009) provides guidance on integrating climate change adaptation into development cooperation at the national, sectoral, and project levels (OECD 2009). Although targeted at developing countries, the underlying approach of applying an integrated approach to adaptation is consistent with that adopted in OECD countries. The World Resources Institute developed a framework for national adaptive capacity that can be used to evaluate countries' progress and to identify priorities for improvement (World Resources Institute 2009). This framework evaluates institutional arrangements based on their performance in providing five functions: vulnerability assessment, prioritization of measures, coordination, information management, and climate risk management.

These frameworks and guidance have been complemented with analyses of progress to date with respect to national-level planning and implementation of adaptation policies. Gagnon-Lebrun and Agrawala (2006) assessed activity in Annex 1 (developed) countries, largely based on an analysis of National Communications to the UNFCCC. Their review found that adaptation received limited attention relative to mitigation and that countries were at the stage of identifying generic options for responding to climate change rather than formulating comprehensive, mainstreamed adaptation strategies.

More recent studies have looked in greater depth at subsets of OECD countries. These have primarily focused on European countries but some have also included non-European OECD countries, for example, Australia and the United States (Bauer et al. 2011; Preston et al. 2011). Swart et al. (2009) provide an in-depth review of development processes for European countries' national adaptation programs, focusing on six areas: motivating factors for strategy development, research and scientific assessment, communication and awareness raising, multilevel governance, integrating climate change adaptation into sectoral policies, and monitoring and review of adaptation policies. The review identifies several typical strengths and weaknesses in adaptation strategies. The strengths include targeted research and good planning for implementation, review, and funding; weaknesses include a lack of coordination between sectors and unclear allocations of responsibilities between different administrative levels. Preston et al. (2011) further highlight institutional and capacity challenges to implementation.

Other reviews have focused on particular aspects of implementing adaptation policies. Bauer et al. (2011) examines coordination and integration in ten OECD countries, both horizontally across policy sectors and vertically across jurisdictional levels. They find that vertical coordination is usually addressed earlier in federal political systems than in unitary systems but that this difference fades as national adaptation strategies are developed. Westerhoff et al. (2011) analyze the relationships between national-level policies and local-level actions in four European countries. The authors note that national political support and leadership are key factors in the development of national adaptation activities but highlight some regional- and city-level activities that developed in the absence of specific national initiatives. They attribute some of these subnational activities to facilitation through climate change networks.

A common feature of the comparative literature is the emphasis on description rather than evaluation, reflecting both the newness of the field as well as a lack of consensus about the most appropriate approaches for implementation and criteria for judging success. While there is agreement over many of the broad principles for efficient adaptation (such as the need to account for uncertainties), there are still a range of views about how those principles should be put into practice. Swart et al. (2009) stated that it was not possible to provide policy recommendations at the time of their analysis because of the variation between countries' adaptation priorities, climate impacts, and political systems. It cautions that measures that have been successful in one context may not be directly transferable to other countries.

Overview of Progress to Date

This section provides an overview of the status of activities across the OECD as of March 2013, updating the analysis originally undertaken by Gagnon-Lebrun and Agrawala (2006). It uses a survey of National Communications (NCs) to the UNFCCC as the initial source of information on the extent of activity that is underway within OECD member countries.

NCs have three characteristics that make them a useful starting point for this analysis (Gagnon-Lebrun and Agrawala 2006). The first is that they have comprehensive coverage. All OECD member countries have submitted at least one report, and 29 countries published their fifth NCs in 2009 or 2010. For the remaining OECD members – Chile, Israel, Korea, Mexico, and Turkey – the analysis is based on their most recent NCs. Chile, Israel, Korea, and Mexico are the only OECD member countries that are classified as "non-Annex 1" countries under the UNFCCC. This means that they are considered as developing countries and that their NCs are not subject to in-depth expert reviews. Turkey is an Annex 1 country but has only published one NC. The second reason for using NCs is that their format is standardized, which facilitates comparison between countries. The third is that they are official statements and, as such, should reflect the government's perspectives and priorities.

The approach adopted for this section has been adjusted to address the limitations with using NCs as a sole data source. NCs may not fully reflect the progress to date within their respective countries (Gagnon-Lebrun and Agrawala 2006). Some elements may be missed because the NCs are intended to provide an overview of the main activities underway, rather than an exhaustive account of all the adaptation activities taking place within a country. Additionally, the majority of NCs included in the analysis were published in 2009 or 2010, which means that they may precede some important recent developments. Complementary sources of information were used to identify completed and ongoing activities relating to the establishment of institutional mechanisms for adaptation responses and the formulation of adaptation policies that were not identified in the NCs. These sources of information included: documents available on the Climate-Adapt website for EU member states (http://climate-adapt.eea.europa.eu/) and follow-up by email with government officials.

The review, presented in Table 1, is based on a qualitative analysis of every OECD country's NC, assessing eight components of national adaptation planning with regard to both the *scope* and the *depth* of coverage. The assessment of the scope of discussion is based on the level of attention paid to the topic, classified as: (i) extensive, (ii) limited, or (iii) not included. The assessment of the depth of coverage is based on the quality of the discussion: (i) detailed, (ii) generic, (iii) limited, or (iv) not included.

Where there was no coverage of activities for a specific component within a country's NC, but complementary sources indicated that actions had been taken or are currently underway, these additional activities have been identified in the table using cross-hatching.

The analysis distinguishes between two different levels of planning: adaptation *strategies* and adaptation *plans*. In this study, adaptation strategies refer to countries' initial planning or framework documents, which commonly set out governmental approaches to adaptation and communicate general priorities. Adaptation plans refer to more substantive planning documents that identify specific policies and measures to be taken. This division is reflected in Table 1, which groups countries into four subcategories: (i) those that have not published an adaptation strategy, (ii) those that have not published a strategy but have taken significant national action, (iii) those that have published a strategy but not a full adaptation plan, and (iv) those that have published both a strategy and a plan. The distinction

Table 1 (continued)

Legend

Coverage in NCs:

(dark grey)	Extensive discussion
(light grey)	Some mention / limited discussion
(blank)	No mention of discussion

Coverage in complementary sources:

(red horizontal lines)	Activities discussed in other sources
(blue vertical lines)	Activities currently underway
*	Developing a national adaptation strategy
**	Developing a national adaptation plan

Quality of discussion in NCs:

●	Discussed in detail, i.e. for more than one sector or ecosystem, and/or providing examples of policies implemented, and/or based on sectoral/national scenarios.
○	Discussed in generic terms, i.e. based on IPCC or regional assessments, and/or providing limited details/no examples/only examples of planned measures as opposed to measures implemented.

Source: Based on National Communications, supporting publications and complementary information, as of March 2013

between strategies and plans is necessarily imprecise; countries' adaptation planning documents vary widely in their coverage and concreteness. Also, the table only includes national-level documents that target the main climate change impacts (the composition of sectors will depend on specific country contexts). Some countries have published subnational adaptation strategies or plans concerning specific sectors or geographic regions, which can contribute to preparations for climate change but are not included in this analysis.

There has been progress since the review undertaken in 2006 by Gagnon-Lebrun and Agrawala. Table 1 shows that all countries provide information on climate change impacts and future scenarios in their NCs, which was not the case in 2006. According to the current review, 31 countries cover adaptation options in their NCs, compared to 16 OECD countries in 2006 (Gagnon-Lebrun and Agrawala 2006). There has also been significant activity in developing adaptation policies – 27 OECD countries mention policies that are synergistic with adaptation (compared with 13 in 2006), and 27 countries discuss specific adaptation policies or the modification of existing policies to include adaptation (compared with five in 2006). The scale of activity in this area becomes even more apparent when additional sources of information are considered. According to this, 8 of the 16 countries without strategies are currently developing them. All but one of the countries with strategies have either developed or are developing plans.

Emerging Lessons Learnt

The previous section provides an overview of the reported level of activity across countries, but countries with similar levels of activity may adopt substantively different approaches. These differences reflect varying political, social, and geographical contexts, needs, and priorities. Countries with federal systems or strong localized decision-making processes, such as Australia and Norway, have produced overarching strategies for adaptation that establish frameworks within which local adaptation efforts can be implemented. In contrast, unitary states have tended to produce national plans that outline specific adaptation policies and measures for different sectors or geographic areas. Overall, there is a growing volume and a growing diversity of experience to draw upon from OECD countries.

Based on OECD countries' experiences at varying levels of adaptation planning, this section outlines some of the key areas identified by participants at the 2012 workshop.

Evidence Provision

OECD countries have demonstrated significant advances in evidence gathering and in providing tools to assist end users in making use of increasingly sophisticated climate information. Nonetheless, the policy-makers at the 2012 workshop identified two main unresolved issues: developing capacity for adaptation among key decision-makers and reconciling the needs of users with the evidence that can feasibly be supplied.

Capacity for Adaptation

Providing information on climate change and improving decision-makers' capacity to use that information is a central focus of adaptation strategies in OECD countries. Mainstreamed approaches depend upon the relevant decision-makers being aware of the need to consider climate change but also having access to the data and tools required to do so. Investments in climate projections and impact assessments are necessary, but not sufficient, for achieving this (Pfenninger et al. 2010; Swart et al. 2009; Westerhoff et al. 2011).

There is a continuing mismatch between the types of climate information and data available and those required to meet policy-makers' needs (OECD 2012). For example, it is currently very difficult to model the variations in microclimates across mountainous regions, but understanding these variations is essential for disaster risk management. Part of the challenge lies in the tension between the requirements of decision-makers for greater technical sophistication while also ensuring that the outputs are accessible to end users. Progress on the former has been more rapid than on the latter, sometimes reflecting a lack of communication between researchers and end users. In some countries, "boundary organizations," such as the United Kingdom Climate Impacts Programme, have been created to bridge the gap between producers and consumers of knowledge.

OECD countries have adopted a number of approaches to increase capacity for climate change adaptation. For example, Mexico has established a distance learning program to enhance the capacity of subnational-level municipal staff. The United States White House Council on Environmental Quality has issued guidance to United States federal departments to support their development of adaptation policy statements and departmental plans, while supportive working groups and a practitioner-level community of practice facilitate information sharing and capacity development. The United Kingdom's adaptation program has supported the development of multiple tools to assist private actors in making adaptation decisions. This includes the *Adaptation Wizard* and *Business Areas Climate Assessment Tool* developed under the UKCIP. However, despite these clear examples of measures to build capacity, workshop participants felt that there was a continuing need for OECD countries to apply a systematic approach to capacity development.

Strategic Planning

OECD governments have taken a variety of approaches to the processes of achieving national coordination, mechanisms for soliciting stakeholder input, institutional structures adopted, and approaches to prioritizing measures. A clear lesson from this experience is that a strategy document alone is not enough to direct national adaptation. The structure and components of the document are important, but there also need to be effective mechanisms in place to implement the strategy (OECD 2012).

National-Level Coordination

Improving the coordination of adaptation actions is a central aim of adaptation planning, but adaptation *plans* and *strategies* differ in how this is achieved. Adaptation plans typically contain greater detail on adaptation needs and measures, including responsibilities for different actions. This makes it more comparatively clear to assign roles and identify coordination needs for those specific actions. In contrast, adaptation strategies have a different set of needs for coordination. As strategies tend to describe activities and objectives in broader terms, there is a stronger need for general coordination mechanisms to achieve progress. A common approach taken in OECD countries, both for adaptation strategies and plans, has been to establish a central coordinating mechanism to oversee and direct adaptation. Coordinating units vary across countries in terms of the parties involved, their remits and their powers; they include interministerial committees, working groups, and task forces. Of the 24 OECD countries that have established coordinating units, 21 have been led by environment or climate change departments; the exceptions are Hungary, Norway, and the United States.

In the context of developing countries, OECD (2009) recommended that coordination be led by an executive office, in order to provide adaptation efforts with sufficient convening and leadership powers to effectively coordinate actions across departments or sectors. This recommendation was also made by the Independent Evaluation Group's assessment of the World Bank's interventions to support adaptation (IEG 2012). The rationale being that in many countries the environment or climate change departments may be in a weaker position relative to other departments, such as planning or finance. These imbalances – both in terms of political power and funding – can create barriers to sustaining political support for adaptation across government. This can make it more difficult to maintain adaptation objectives in the long term and to negotiate sustainable financial support over time within budget allocations.

However, an advantage of coordination by environment or climate change ministries is that they are likely to be the most aware of the technical requirements of national adaptation plans. For example, French government officials reported that relocating the body responsible for adaptation planning from the prime minister's office to the environment ministry in 2007 helped it to address operational issues and to increase collaboration. Additionally, locating responsibility within a central ministry does not in itself guarantee long-term political or financial support. It may well be a lower priority for central ministries themselves than it would be in a dedicated environment department, which can offset some of the benefits of being in a politically stronger ministry. The experience of OECD countries has not demonstrated a consistent relationship between the location of the coordination unit and the effectiveness of adaptation policy.

The existence of high-level formal structures, such as ministerial coordination groups, can be a weak proxy for the degree of on-the-ground coordination. Given the recent implementation of many countries' national adaptation programs, it may be too early to evaluate coordination groups' effectiveness beyond their initial success in convening representatives from different departments. However, the challenges that these mechanisms are intended to overcome – addressing crosscutting issues and managing cross-departmental actions – require a firm grounding in adaptation policy. This issue is especially pertinent for countries with technical adaptation plans that specify required outcomes and measures for different departments and/or sectors. Some OECD member countries have found it valuable to complement high-level coordinating with working-level groups to provide technical direction. For example, the United States adaptation working group and practitioner-level community of practice support the higher-level coordinating efforts of the Interagency Climate Change Adaptation Task Force.

Stakeholder Engagement

There is inevitably a strong technical element to national adaptation planning, but it is not a purely technocratic process. Policy-makers viewed it as essential to involve a broad set of stakeholders at strategic planning and policy design stages to assist the development of national programs (OECD 2012). As well as improving the quality of policy-making, the process of stakeholder engagement can be useful for raising awareness and interest among key groups. A common feature of national adaptation planning has been the establishment of comprehensive consultation processes to solicit input from key stakeholders and the general public. For example, Austria sought additional stakeholder input for its national planning through expert consultation, an extensive round of workshops with relevant organizations and internet-based engagement. Several countries have relied upon umbrella or intermediary organizations to facilitate the consultation process, given the large number of potential stakeholders. The benefits of this approach are particularly marked when interacting with large, dispersed groups of stakeholders such as the general public or small businesses. The use of intermediary organizations has also been driven by pragmatism, as smaller stakeholders tend to have less capacity to engage with the process (Bauer et al. 2011). In the United Kingdom, the adaptation program partnered with the Confederation of British Industry and the Trades Union Congress to solicit input from employers and employees, while also raising awareness and disseminating guidance.

Identifying and addressing the needs of indigenous groups is a particular concern in some OECD countries. Indigenous groups, who often face significant social and economic challenges, are likely to be at particular risk due to climate change (International Union for Conservation of Nature 2008; Galloway McLean et al. 2009). Indigenous groups may also be less well represented in traditional stakeholder engagement processes (Gardner et al. 2010). In the United States, the Environmental Protection Agency developed a policy statement and plan to ensure consultation and coordination with Indian tribes (Environmental Protection Agency 2011). Although there has been progress made through initiatives such as this, ensuring appropriate engagement and input from indigenous groups remains a challenge for some countries.

Program Structure

In designing their national adaptation programs, OECD countries have had to choose how to organize the delivery of adaptation actions: either mainstreamed within existing departmental portfolios or addressed thematically (e.g., “infrastructure” or “water”). Aligning adaptation to existing departmental responsibilities may help to ensure clear accountability for results but may come at the risk of making cross-departmental interactions less frequent – for example, those between land-use planning and flood risk management. In principle, these interactions should already be addressed by existing policy structures, but in practice this is often not the case. Encouraging integration is particularly important during the development of plans or strategies, as adaptation needs can fall between traditional departmental operations or face overlapping or contradictory approaches from different departments (Bauer et al. 2011). Crosscutting thematic approaches may better enable policy-makers to deal with these critical interactions. This choice is important for setting the direction of both adaptation strategies and adaptation plans. However, the greater level of detail on actions and policies in adaptation plans requires a more thorough examination of organizational responsibilities and greater specificity on responsibilities for implementing actions.

The most common approach in OECD countries has been to combine elements of the two approaches in “sectoral” national programs (though definitions of sectors are flexible and vary across countries). For example, the federal approach in the United States has developed along departmental, regional, and thematic lines. In 2012, federal agencies were required to develop agency-level adaptation plans. In addition to these plans, three national-level strategies that address crosscutting issues (such as the management of freshwater resources) have been developed or are in the process of being developed, and there are a number of other regional initiatives and partnerships. England’s approach initially closely aligned adaptation roles to traditional ministerial responsibilities, with each individual government ministry responsible for developing Departmental Adaptation Plans. However, the forthcoming national adaptation plan will move towards a more thematic approach (UK Department for Environment, Food and Rural Affairs 2012). Mexico's Special Program of Climate Change is based on a combination of departmental and thematic sectors, including a mix of economic sectors (e.g., "agriculture, cattle, forestry, and fisheries"), social concerns (e.g., "health sector"), and crosscutting issues (e.g., "land-use management and urban development" and "disaster risk management"). A number of other OECD countries are also pursuing mixed sectoral approaches, including Chile, Korea, Poland, and Turkey.

Regardless of whether governments take a departmental, thematic, or sectoral approach, coordinating activities within adaptation programs poses a key challenge. Under a thematic approach, governments have to coordinate measures across departments to ensure that thematic goals are met, generally using central coordination groups or mechanisms. Lessons can be learnt from other fields of public policy that face similar coordination challenges. For example, there is a growing body of work in the water policy domain to address issues such as overlapping and unclear allocations of responsibilities, lack of institutional incentives for cooperation, mismatches between impact areas and administrative boundaries, and competition between different departments (OECD 2011).

Prioritization

The selection and prioritization of adaptation options are an essential part of adaptation planning. Governments need to identify the impacts likely to be most socially and economically significant. They also need to prioritize specific issues or actions to ensure an efficient use of public resources. The specific challenges faced by governments depend upon the planning approach taken. In theory, adaptation strategies do not need to include prioritization of vulnerabilities or responses. The key activities proposed in strategies (such as improving the evidence base, capacity building, and mainstreaming adaptation within government activities) do not depend upon the precise details of the climate change impacts faced by the country. In practice, however, adaptation strategies often include some prioritization, in part to communicate important risks or vulnerable sectors. As adaptation plans include greater detail on specific activities and measures, they require a better understanding of key risks and of the options for addressing them. Prioritization is therefore a critical component of adaptation plans and needs to be more comprehensive and based on firmer technical foundations than in adaptation strategies.

Several promising approaches for prioritization have been developed within OECD countries. The approach used by Switzerland identifies key adaptation challenges within individual sectors. This approach uses three criteria to produce an overall "importance" ranking: (i) whether an issue is sensitive to climate change impacts, (ii) whether the impact is important relative to other impacts within the sector, and (iii) whether there is a need for action to address the issue. This ranking feeds into the identification of action areas and key priorities in their strategy (Office Fédéral de l'Environnement 2012). The United Kingdom government's prioritization system draws on their Climate Change Risk Assessment study, which enables the government to identify key climate change risks and to prioritize adaptation policy development both geographically and by sector. This information feeds into the high-level adaptation planning process. Thus, policy development, both for the current program and for the national adaptation plan, is geared towards addressing the critical issues identified. Some governments have also established criteria for choosing between individual adaptation policy options. For example, the Netherlands' national adaptation program used a multi-criteria analysis approach to rank a wide range of adaptation policies according to five criteria: (i) the importance of the policy, (ii) the urgency of the policy in terms of timing, (iii) whether it is a "no-regret" policy, (iv) whether the policy has ancillary benefits for non-climate change policies, and (v) the policy's impact on mitigation policies. Each criterion is weighted according to perceived importance to produce a weighted sum value for ranking policy options (Ministry of Housing, Spatial Planning and the Environment et al. 2007; van Ierland et al. 2007).

Countries' prioritization systems vary in their choice of criteria, the level of importance attributed to each criterion, and the extent to which prioritization is based on quantitative or qualitative inputs. Some of this variation is accounted for by different prioritization needs for adaptation strategies versus those for adaptation plans. For instance, the issue of quantitative versus qualitative decision making is particularly salient for adaptation plans. The lack of sufficient or suitable projections of climate impacts is a key challenge for developing adaptation plans (OECD 2012). This poses less of an issue for adaptation strategies, as they tend to be less specific than plans about the measures to be implemented. It was, however, noted that the lack of climate impacts data does not need to delay the development of national adaptation plans. The evidence base will never be perfect and the benefits of waiting for improved information must be balanced against the costs of delay. As with other areas of public policy, the challenge for policy-makers is to make the best decisions given the available evidence.

Implementation

The overview of national adaptation planning in OECD countries in the section "Status of National Adaptation Policies in OECD Countries" shows that there has been progress in the planning of adaptation but that implementation remains at an early stage. This section examines countries' implementation experiences in two specific areas: financing of adaptation and monitoring of implementation.

Financing the Implementation of Adaptation Measures

There is a choice about how to fund adaptation measures, either through mainstreaming or the use of "ring-fenced" funding. Dedicated funds provide an impetus for action on adaptation but can distort spending decisions and work against coordination with wider government objectives. Conversely, mainstreamed approaches should allow for a more flexible and efficient use of resources but are much less transparent about where resources are being allocated.

Although estimates vary widely, the global costs of adaptation are likely to be in the order of tens to hundreds of billions of United States dollars per year (Parry et al. 2009). Even at the lower end of this spectrum, funding is likely to be a significant hurdle to implementing effective adaptation policies and measures. Securing financing for adaptation programs is therefore a key concern for policy-makers and a key challenge to be addressed in adaptation programs. As in other policy areas, challenges will differ at different stages of adaptation planning. Given their broad focus on improving the evidence base, building capacity and creating an enabling environment for adaptation, strategies have required relatively modest funding for initial climate information and capacity building activities. Adaptation plans, which set out specific actions and establish responsibilities for implementation, ought to be based on an understanding of the likely costs of measures and their benefits. This ensures that funding is sufficient and that the chosen adaptation options represent good value for money.

Few OECD countries specify how their adaptation programs will be funded or the scale of resources required for implementation. Of those that explicitly mention funding, they predominantly focus on preliminary activities such as vulnerability assessments and climate research, rather than the implementation of measures. England's adaptation program has allocated some core funding for adaptation research but has been designed on the basis that the funding of adaptation measures will be achieved by reallocating existing resources. France has estimated the costs of adaptation measures at €171 million per year, but these are expected to be delivered through the usual budgeting process. Mexico's Special Program on Climate Change identifies investment priority areas, but does not specify how such investments would be funded. The United States' program also does not specify how adaptation should be funded, but leaves the financing to individual departments.

The lack of clarity on financing can, in part, be explained by the short time adaptation has been on the policy agenda. Additionally, the focus on mainstreaming in most strategies and plans reduces the need to discuss specific funding mechanisms, as actions are expected to be funded through existing departmental budgetary processes (OECD 2012). Limited details on the actual costs of many adaptation options can also complicate discussions around financing needs and value for money (Biesbroek et al. 2010). Lastly, given current fiscal pressures, the limited discussion of funding in adaptation plans may be a reflection of the limited scale of public resources that are likely to be made available.

Countries' experiences in implementing adaptation also suggest actions that can increase resource availability and maximize the impact of those resources that are available. These include building government support for adaptation by ensuring that adaptation aims are linked to current government priorities (notably economic growth) and by proposing adaptation options that serve multiple purposes and have multiple benefits (OECD 2012). Additionally, participants recommended adapting policy instruments or regulations that are already in place, rather than starting from scratch. Financial constraints have also encouraged governments to engage the private sector in adaptation. As a starting point, governments have started to encourage the private sector to secure its own resilience to climate change (Agrawala et al. 2011), which ought to reduce the need for public investments in adaptation.

Monitoring and Evaluation of National Adaptation Strategies

As countries implement adaptation programs, they will also need to track the effectiveness of actions and the outcomes of adaptation interventions. Sophisticated approaches to monitoring and evaluation (M&E) are currently being developed in Finland, France, Germany, and the United Kingdom. A common characteristic of these frameworks is their initial focus on monitoring progress in creating the right enabling environment for adaptation (Swart et al. 2009). In essence, this entails a focus on monitoring processes (e.g., the number of government departments that have assessed their exposure to climate risks) rather than outcomes (e.g., reductions in vulnerability to climate change). However, regular monitoring must be complemented by longer-term evaluations that examine if set objectives have been achieved, whether these objectives are still valid in the light of new evidence, and if the identified results can be attributed to the adaptation actions taken.

Participants at the policy-makers workshop noted the challenges involved in conducting M&E assessments, including generating baselines for use in assessing progress, attributing causality of outcomes to actions, the high costs of data gathering, and the long time horizons of climate change. Given these challenges, most countries are not yet in a position to evaluate the effectiveness of adaptation efforts using outcomes-based approaches. However, certain M&E approaches can help governments to address these issues. Notably, the United Kingdom's approach combined progress and outcome indicators and should help in making the connection between adaptation policies and observed outcomes. The frequent snapshots of vulnerability provided by the United Kingdom's five yearly Climate Change Risk Assessments (CCRA) are expected to help policy-makers assess progress and provide updated baselines against which adaptation interventions can be assessed. Vulnerability assessments such as these may give countries a means of assessing the broad effectiveness of adaptation programs, as a complement to or in support of tracking the effectiveness of specific adaptation measures.

France's M&E strategy provides an alternative approach intended to help overcome technical and financial challenges to evaluation. France's approach uses existing tools and procedures to review progress. It combines comprehensive monitoring of the implementation of measures (using both process and outcome indicators) with targeted evaluation of key sectors using a range of evaluation techniques, such as impact assessment, cost-effectiveness, and cost-benefit analysis. It also includes a qualitative review of climate change preparedness before and after adaptation interventions. This approach should reduce the need to develop new technical evaluation techniques and the associated costs and challenges with gathering data.

While addressing political and technical challenges in the design and implementation of M&E approaches is critical, policy-makers emphasized the importance of ensuring that the results from M&E assessments feed into the development and evolution of national adaptation programs. This requires both continuous learning (such as regular assessments or periodic reviews) and feedback mechanisms that outline how M&E results, and new information will contribute to ongoing planning and implementation processes (Pringle 2011). To facilitate this, some OECD countries have provided a statutory basis for periodic reviews. For example, in the United Kingdom the 2008 Climate Change Act requires a review of the national adaptation program every 5 years. In Finland, the national adaptation strategy underwent a midterm review in 2009, with a more comprehensive review scheduled for the 2011–2013 time frame. Similarly, there will be a midterm review of the French national adaptation plan in 2013, which will feed into the development of the next plan for 2015, and the Danish strategy will be revised before the completion of its implementation phase at the end of 2018, drawing on annual reports produced by a national coordination body (Swart et al. 2009).

Conclusion

Overall, there has been considerable activity since the 2006 stock take of activity in OECD countries. In 2006, the National Communications focused on discussing projected climatic changes and the resulting impacts. There were some examples of stand-alone adaptation projects but limited evidence of coordinated approaches being adopted (Gagnon-Lebrun and Agrawala 2006). As of May 2013, the majority of OECD countries have started the process of national planning for adaptation: 18 countries have implemented strategies or plans, and a further eight are in the process of producing them. Some of the remaining countries have put in place systems for national coordination, as in the United States, or focused on enabling local and regional action, as in Canada, without articulating their strategies in a single document.

OECD countries have made significant investments in providing evidence and tools to inform the national planning process, for example, developing an increasingly sophisticated understanding of the potential risks of climate change and a growing volume of work on possible adaptation options. Several countries are now planning to go further than this and assess the costs and benefits of adaptation options. These investments, and the prior decades of work they build upon, have already proved a useful input into the policy-making process.

The approaches taken have reflected national circumstances, but some common themes have emerged. The first is that the financing of adaptation actions remains an area with limited evidence on the scale of resource requirements and the sources of funding. In part, this is because there is still a gap between high-level global estimates and localized studies. The costs of adaptation at the national level remain largely speculative at this stage.

The second theme is that the development of evidence on adaptation should go hand in hand with efforts to increase the capacity of end users to understand and apply those resources. Efforts to increase the technical sophistication of climate projections (and related tools) are needed to provide data that are tailored to the decisions being made. But this needs to be complemented with efforts to increase the usability of the evidence that is made available.

Finally, an area that has received limited attention to date is assessing the results of the actions that have been implemented. Economic theory provides some indication of the types of approaches that are likely to be efficient or effective, for example, adopting a flexible approach and aiming for "win-win" and "no- or low-regret options." However, there are different ways of achieving these objectives, and they will not be equally effective. Monitoring and evaluation (M&E) is important for political accountability but also for learning lessons that can be used to inform revisions to the design of programs. Even countries with plans specifying actions, responsibilities, and timescales are at an early stage in their development of M&E strategies. This limited attention to M&E partly reflects the high-level, strategic nature of many adaptation policies, where there is still more work to be done to specify the objectives and trade-offs in ways that are sufficiently detailed to enable assessments of progress.

Abstract

This chapter supports the argument that social science research should focus on adaptation to climate change as a social and political process, by analyzing the politics and interests of actors in climate change adaptation arenas and by acknowledging the active role of those people who are expected to adapt. Most conventional climate research depoliticizes vulnerability and adaptation by removing dominant global economic and policy conditions from the discussion. Social science disciplines, if given appropriate weight in multidisciplinary projects, contribute important analyses by relying on established concepts from

political science, human geography, and social anthropology. This chapter explains relevant disciplinary concepts (climate change adaptation arena, governance, politics, perception, mental models, culture, weather discourses, risk, blame, traveling ideas) and relates them to each other to facilitate the use of a common terminology and conceptual framework for research in a developmental context.

Keywords
Climate change adaptation arena • Governance • Politics • Perception • Mental models • Culture • Weather discourse • Risk • Blame • Traveling ideas • Discourse • Development • Africa

Introduction

While the issue of climate change mitigation has received a significant amount of political and scholarly attention over the past two decades, engagement with climate change adaptation is a younger phenomenon. Although the concept was taken into consideration from the outset of the UNFCCC process in the early 1990s, adaptation gained official political momentum in international climate change negotiations only after the finalization of the *Marrakech Accords* in 2001. The reluctance to embrace adaptation as a viable policy option was partly grounded in the fear that a shift to adaptation would weaken the political will to undertake greenhouse gas reductions (Pielke 1998; Kates 2000; Burton 2009; Schipper 2006; Thornton and Manasfi 2010). The main argument that finally paved the way for adaptation was the scientific observation reported by the IPCC that climate change is already happening worldwide and that in Africa "adaptation is not an option but a necessity" because populations are already facing negative impacts (Boko et al. 2007, p. 452).

The thinking about adaptation in the context of development has also changed considerably since the beginning of the new millennium. Public discourse is now dominated by planned adaptation as a policy response to climatic risks. Adaptation to climate variability/change as a research topic has gained popularity in the natural as well as in the social science disciplines. A large and diverse variety of actors are assembling around the looming "climate catastrophe" (Hulme 2008, p. 11), both in the Global North and South. Development agencies and multilateral institutions, as well as the private sector and civil society organizations, have found their stakes in fighting global warming. And in Africa, we observe the increasing engagement of national and local governments, media, NGOs, churches, and religious and traditional leaders, who shape the politics of climate change.

Climate change has become an "unchallenged consensus" with a respective "apocalyptic rhetoric" (Swyngedouw 2010, pp. 216–218). Critics warn that climate change has become the big "environmental orthodoxy" at the turn of the millennium (Forsyth 2003, p. 36), and threatens to depoliticize the attempt to govern global warming (Swyngedouw 2010). Most climate adaptation research tends to be apolitical, without paying attention to social and political framework conditions within countries, the interests and power of the actors (Lockwood 2013), or the perceptions, priorities, vulnerabilities, and bargaining powers of the potentially affected populations. This leads to a situation where social science perspectives are underrepresented in multidisciplinary research projects on adaptation that are mostly driven by the natural sciences.

Within the social science climate and development studies community, we observe methodological rapprochements with, for example, mixed methods, ethnography, and economic survey techniques being applied by geographers and political scientists. The exchange of different theoretical and conceptual understandings to find a common or interdisciplinary language, however, is also a challenge among social scientists. This is often overlooked in multidisciplinary debates. There are, however, various ways to conceptualize multidisciplinary social sciences in climate change research (see, e.g., Baer and Singer 2014 for their critical "integrated eco-social perspective" approach, which assembles ideas from world systems theory, political ecology, and critical medical anthropology). Over the past few years, however, multidisciplinary studies on climate change have tended to demarcate fields of expertise by employing distinct terminology and publishing in *climate change* journals that seem increasingly disconnected from debates between disciplinary scholars in the social sciences.

Thus, the objective of this chapter is to *denaturalize adaptation* and to bring back "the political" (in the sense of Swyngedouw 2010) in the discussion about climate change. The chapter suggests a number of established concepts from social geography, social anthropology, and political science that are sensitive to discussing empirical findings in a multidisciplinary and developmental context. These concepts highlight the inherent political dimensions of adaptation as well as local/cultural perspectives (*emic perspectives*) on change, risk, and adaptation.

The following section on political agendas will outline the central concepts used in the adaptation debates in political science and geography. In the next section, environmental perception, blame, and risk will be discussed, along with their links to power and politics from an anthropological and geographic point of view. The concluding outlook summarizes the argument for why adaptation needs to be analyzed more often as a socio-cultural, with a focus on emic perspectives as well as on local social and political dynamics.

Political Agendas

Approaches that look at functional applications from administrative and technical perspectives seem to be on the rise. Governance, a former domain of political science, has been appropriated by other disciplines as well as the international development community. When this concept is adjusted to a climate change adaptation context, it tends to take a rather technocratic turn (Fröhlich and Knieling 2013). There are, however, notable disciplinary exceptions (e.g., Adger and Kelly 1999; Tschakert 2007; McMichael 2009; Agrawal 2010; Pelling et al. 2012;

Sheridan 2012; Bassett and Fogelman 2013) as well as multidisciplinary works that provide room for political, historical, and cultural analyses (e.g., Crane 2010; Djoudi et al. 2011; Brockhaus et al. 2012; Wisner et al. 2012).

Multidisciplinary studies show how social, political, cultural, economic, and technological circumstances shape vulnerabilities across scales and how they determine local perceptions and adaptation outcomes. Studies with a political focus also explore how socio-spatial aspects of risk and adaptation are strategically emphasized or de-emphasized by actors to legitimize their political narratives and interventions; often to serve their own interests.

Adaptation to climate change is understood as a politicized *social arena* which has been opened up by the IPCC assessment reports, the political attention these reports received globally, as well as by international funding opportunities under the UNFCCC for adaptation/mitigation planning and implementation in Africa. This has been the starting point for the evolution of *Climate Change Adaptation arenas* (*CCA arenas*) in African countries, which clearly display partial overlap and continuity with older political arenas, such as natural resources management, infrastructure delivery, or development cooperation. The *cross-scalar* and *multi-scalar CCA arenas* are very dynamic, assembling actors with diverse interests who channel flows of information and resources among each other and beyond the arena. The developmental context is characterized by uncertainty with regard to climate change, by the links between poverty and vulnerability in the potentially affected population, as well as by the hegemonic distribution of power and resources among the actors, including governments, local authorities, the public media, civil society organizations, international donors, and the climate research community. Access to information and resources is structured by the socio-cultural, political, and economic status of these actors as well as by their networks.

How adaptation is defined and implemented across multiple scales is strongly influenced by the changing interests of actors in the CCA arenas who exercise *discursive power* and are capable of dominating political negotiations, and therefore, their outcomes. Political agenda-setting is not always as transparent and straightforward as many scholars and practitioners would like it to be (Brooks et al. 2009), and *selective depoliticization* of the adaptation discourse can often be observed. Conceptualizing adaptation as an exclusively environmental problem, with some social challenges on the side of the affected populations that must be solved by applying quick technological and managerial fixes, turns a blind eye to the normative underpinnings of international adaptation and developmental discourse. For example, capitalist modes of production and consumption, the economic growth paradigm, corruption (as well as elite capture), and systemic governance failures are usually not addressed by the actors who benefit from the status quo (Bailey and Compston 2012; Brunnengräber 2013).

From a multidisciplinary social science perspective, it is useful to adopt an analytical approach that frames adaptation beyond an environmental problem with social challenges. This also means to accept that vulnerability to environmental change is directly related to “unsustainable patterns of development combined with socioeconomic inequity” (Pielke et al. 2007, p. 597). Consequently, adaptation research needs to take into account that neoliberalism operates as a form of *meta-governance* and dominates the *discursive arena* of climate change policy (Brunnengräber 2013).

Against the backdrop of the global financial crisis, the thematic focus of national and international adaptation policies has gradually moved away from ideas about environmental regulation to an emphasis on a *Green New Deal*, anchored in market-based instruments and private business solutions. Mainstreaming adaptation and *climate proofing* development projects has ultimately become a "new profit frontier" (McMichael 2009, p. 252). Payments for ecosystem services, carbon trading, crop insurance schemes, and monopoly patents on *climate-ready genes* are symptoms of the neoliberal assumption that the market is indeed the solution to environmental problems caused by a *fossilistic economy*. This idea goes hand in hand with the claim that markets should be the primary means for resource allocation. We need to ask whether it is prudent to expect market-based instruments to facilitate the adaptation of the poor and marginalized who are severely and negatively affected by climate change, when we realize that the same globalized market system is, in many parts of the world and across societies, responsible for creating poverty and local vulnerability in the first place.

This example demonstrates that multidisciplinary research on climate change adaptation needs to critically engage with emerging policy concepts that seem to offer ideological guidance and claim to countervail classical top-down policy approaches.

To extend this argument, we briefly discuss different concepts of *governance* and their normative underpinnings. The term *governance* is highly contested in academia, but has been applied in a variety of contexts, including global governance, earth system governance, public and local governance, organizational governance, corporate governance, good governance, and knowledge governance. The arbitrary use of the term has prompted many scholars of political theory to arrive at a similar conclusion. Finkelstein, especially, argues that *global governance* "appears to be virtually anything," implying that it is not a very useful concept because it lacks preciseness (Finkelstein 1995, p. 368).

Generally, there are three ways in which the governance concept is used in the literature and in public discourses. First, governance can be understood as a *scientific concept* that is employed to conceptualize and empirically trace transformations and institutionalized interventions in societies. Second, governance can be understood as a *normative program* based on the ambition to realize and manage political change. Third, governance also refers to a *critical societal discourse*, which is linked to the wider globalization debate.

These three dimensions of governance are symptomatic for the rapid changes and interactions in a globalized world. We need to make sense of the integrative and disintegrative events which occur simultaneously across space and time, which intertwine the public and the private, the global and the local, and which lead to the continuous emergence of new actor networks and regulative mechanisms that transcend the sphere of the classical nation-state. Climate change is characterized by complex and interrelated socio-economic issues that cut across jurisdictions, administrative scales, the boundaries of ecosystems, as well as fields of disciplinary expertise, and thus it requires new political approaches (Schulz 2011). Finkelstein (1995, p. 367) concludes that it is indeed "reasonable to be uncomfortable with traditional frameworks and terminologies associated with the idea of international relations in an interstate system."

However, while the conventional notion of governance identifies the nation-state as the center of political power, *multilevel governance* focuses on "the threefold displacement of state power and control: (1) upwards to international actors and organizations, (2) downwards to regions, cities and communities, and (3) outwards to civil society and non-state actors" (Termeer et al. 2010, p. 5). The idea of multilevel governance emphasizes the process character as well as the multi-scalar nature of contemporary politics. The normative bedrock of multilevel governance is the belief that the distribution of political power and responsibility across multiple jurisdictions is more efficient than classical monocentric state governance (Termeer et al. 2010).

The *fragmentation* of institutional systems and actor constellations has therefore become an important issue of governance research. Fragmentation on multiple scales is further aggravated by *multiple knowledges*, *conflicting norms*, and *scale mismatches* (e.g., between biophysical systems and governance systems), as well as by conflicting or ill-defined political mandates. Anthropologists working in Africa contribute additional observations to this picture. New decision-making bodies and rules introduced by development cooperation do not usually lead to the disappearance of existing authorities and regulations. Instead, these tend to coexist side by side (Bierschenk and Olivier de Sardan 2003). *Polycephaly* leads to a growing complexity in actors, interests, and legitimate options. It opens up the ground for strategic *forum shopping*, where people can select from available options and decide for themselves which body or authority to consult or which regulation to use as a frame of reference.

As a response to the fragmentation and *polycentrism* of governance processes, the concept of *adaptive governance* has gained increased popularity. Adaptive governance draws on systems and resilience thinking, as well as on ecosystem management approaches (Termeer et al. 2010; Plummer et al. 2013). These approaches have, commonly, an emphasis on the importance of institutional flexibility and learning for the management of complex socio-ecological systems. Adaptive governance considers temporal, knowledge, and network scales, while the concept of multilevel governance is mainly related to spatial, administrative, and jurisdictional scales. The normative goal of adaptive governance is to enhance the capacity of governance systems "to create the right cross-scale and cross-level links at the right time, around the right issues" (Termeer et al. 2010, p. 8). Adaptive governance also stresses the importance of "bridging, boundary or brokering organizations" as intermediaries in cross-scalar governance processes to enhance cross-scale interactions and networking processes, such as knowledge coproduction and conflict resolution (Plummer et al. 2013). Yet, adaptive governance may be prone to nepotism and corruption, unless there are checks and balances for the coproduction of knowledge, networking, and representation by the public media.

In other words, there needs to be a focus on political accountability as well as transparency about who gets invited to join in the political arenas and who is excluded from them.

In academia, climate change adaptation is mostly conceptualized as a subfield of *environmental governance*. Plummer et al. (2013, p. 2) describe environmental governance as a normative approach to achieve ecological sustainability and to exercise "authority over the environment through processes and institutions by which decisions are made." This theorization leads back to our earlier critique of framing adaptation as an environmental problem and de-emphasizing the social, political, cultural, and economic aspects of adaptation. Neither environmental governance nor adaptation is, in practical terms, primarily about the exercise of authority over the environment. In practice, climate change adaptation is rather a question of exercising authority over people and therefore strongly related to questions of power and politics.

Any attempt to research power and authority, however, is directly linked to the basic sociological question of *agency and structure*. Are actors, as individuals and groups, ultimately shaped and governed by structures? Or are actors able to develop their own potential for volitional and creative action? With respect to climate change adaptation, we need to answer whether political and economic structures that have caused the climate crisis in the first place can be overcome and how creative space for societal and economic transformation can be created (Driessen 2013). This is especially true in Africa, where the negative impacts of climate change already demand practical solutions, legitimate political decisions, and adaptation programs. These, as well as the degree of political inclusiveness and priorities of the affected populations, should, therefore, be of great relevance to our research. But how can we learn more about these priorities?

Perception, Blame, and Power

An increasing number of publications addresses the climate change perceptions of local communities in Africa. These *perception studies* stem largely from agricultural and economic research projects, with some multidisciplinary aspirations (e.g., Kemausuor et al. 2011; Cuni Sanchez et al. 2012). Most studies are based on data from household surveys and focus group discussions, which are compared to regional climate and weather data, such as precipitation and temperature changes. They often aim to investigate, to put it in simple terms, whether farmers perceive what scientists have measured. Many of these studies, however, are very loosely connected to the previous work done in social science disciplines and, therefore, do not contribute to a more comprehensive understanding of the mental models through which people give meaning to climate change. A number of studies conclude that farmers have a fatalistic view on climate change.

> A comparative perception study among ethnic groups in Benin revealed that "No participant mentioned the term climate change (or any similar phenomenon even described in

> other words) as a possible cause of the observed changes in climate, and no participant suggested that the trend [. . .] was sub-regional, regional or global [. . .] most farmers were found to have a rather fatalistic approach to climate concerns, with statements like 'climate is a divine phenomenon that we are not in charge of'" (Cuni Sanchez et al. 2012, pp. 122, 124).

Following Roncoli et al., who argue that instead of answering the question of whether farmers' or herder's perceptions match the "reality" of scientific findings, the more interesting questions are how knowledge and experience shape meanings of climate change and how they are integrated into their mental models (Roncoli et al. 2009).

Anthropological work on environmental perceptions in different societies worldwide has pointed out that the ways humans view their natural and social surroundings and order them into categories is culturally specific, with a lot of variation across time and space (Leach and Fairhead 2003; Casimir 2009). This is a testimony to the fact that knowing and perceiving nature are context-bound and socially constructed. The term *reception* has been used synonymously in this context (Rudiak-Gould 2012). *Perception*, however, is more adequate for the description of the process, which is not only about receiving information by seeing, hearing, smelling, or sensing. The notion of perception includes the cognitive process of constructing social meaning about the received information.

Perceptions can be analytically categorized into different elements. Strauss and Orlove distinguish between *description* and *comprehension*. The authors underscore that "the cognitive and symbolic aspects of the weather and climate deserve as much attention as the responses to specific weather events or conditions, since these two are ultimately inseparable" (Strauss and Orlove 2003, p. 6). A more detailed anthropological approach differentiates between *perception, knowledge, valuation, and response* (Roncoli et al. 2009). For the purpose of this text, we will not go into further details of psychological and cognitive studies (for a review on the mental models concept, see Jones et al. 2011).

In as much as knowledge is context specific, so are valuations and responses. Individuals valuate threats and respond in a personal way, which may differ from one person to another; however, there is usually something similar to a cultural consensus about what is commonly considered normal and good, or exceptional and worrisome. Such consensus defines what constitutes a dangerous situation, how it can be prevented, and what is required to adjust to it. In local parlance, dangerous situations are often described as a nontechnical pollution or impurity caused by *moral transgression* and can therefore be perfectly remodeled into a political argument. "Pollution beliefs trace causal chains from actions to disaster" (Douglas and Wildavsky 1983, p. 36).

> Farmers in Northern Ghana explained lack of rain with various social causes, including illegal/immoral land sales, lack of obedience for the older generation, extramarital sex, lack of united action in the community, lack of respect for ancestral spirits, laziness of some farmers, and alcoholism of a rainmaker – all examples of moral transgression. They also mentioned other causes. Moral transgression arguments, however, were prominent in the discussions (Eguavoen 2013).

Some common tendencies are found in many societies: the feeling of worry for an unknown future, the need to feel secure, and a drive to reduce uncertainty. Forecasting based on past experience is a common human process. Climate change literature discusses different models of various scales, and a distinction can be made between *climate models* in their conventional understanding and so-called mental models. "Mental models of local climate change, then, are a summative conception of all a community's climate knowledge based on their observations and experiences of past and ongoing climate variability" (Shaffer and Naiene 2011, p. 224). In addition to their contributions to ground-truth regional climate models, mental models "offer insight into changes and connections that global and regional [statistical] models cannot capture" (Shaffer and Naiene 2011, p. 235). They open up the debate for research on socio-economic transformation, stratification, and power relationships.

On a more general level, people construct culture-specific mental "model[s] of the world whose purpose it is to make predictions" to reduce uncertainty (Casimir 2009, p. 27). "[I]n most societies even before disaster strikes or while in the midst of deciding how to deal with it, people cogitate about their possible causes" (Casimir 2009, p. 29). They do so by relying on scientific models, cultural models, or, even more often, a mixture of both to explain unwanted events. These explanations assign blame to something or somebody, allowing humans to mentally survive in uncertain environments. They also form a precondition for the application of pragmatic counterstrategies.

For causal chains inherently bearing the notion of cause, responsibility, and blame, one can speak of different *models of blame*, which become relevant when the result of the causal chain is categorized as exceptional and dangerous (Eguavoen 2013). Empirically local models of blame, which we observe in rural Africa today, are often a mixed form of *cultural and scientific models* of explaining the world and its basic causal principles. Local beliefs and scientific smattering merge and usually intermingle without being in conflict with each other. By identifying the sources of nontechnical pollution, by assigning blame to culprits, or by relying on scientific explanations, people feel that they are regaining control over lives and environments that are full of danger. "To understand principles of liability, we have to uncover [. . .] social goals [. . .] and the strategies used for reaching them. For this we need cultural analysis that puts every concept of normality under scrutiny" (Douglas and Wildavsky 1983, p. 35).

> Small farmers [in Ghana] attribute social and religious/moral reasons for changing climate [. . .they] do not seem to engage in a blame game as much as the commercial farmers who find Western nations, mining companies, deforestation, charcoal burners, and poor government policies as major culprits. [Commercial farmers] assume the role of victims even though they use more land, deforest more virgin forest and appropriate a large volume of water resources for their farming purposes (Yaro 2013, p. 1265).

These findings show the cumulative effects of economic stratification, bargaining power, political inclusiveness, education, access to information, and the capability to demand governmental support. More generally, "[b]lameworthiness takes over at the point where the line of normality is drawn. Each culture rests upon its own ideas of what ought to be normal or natural [. . .] But of course the idea of normality changes with new knowledge" (Douglas and Wildavsky 1983, p. 35). Conditions that seem to suspend normality, such as during or after a hazard, may lead to exceptional and worrisome situations, which may create risky situations for people and require nonroutine behavior.

According to Casimir (2009, p. 31), it is useful to follow the approach of Lupton (1999), navigating between two established definitions of risk. The first definition follows the scientific line of probability of a loss argument, while the second definition is socially constructed, with risk being a "product of historically, socially and politically contingent 'ways of seeing'" (Ibid. 2009, p. 31). Casimir also suggests acknowledging that there are objective risks which are "often mediated differentially through individual, cultural and historical processes" (Ibid. 2009, p. 31, quoting Lupton 1999, p. 35). Different than in mainstream climate change adaptation literature, risk is not a universal thing in time and space, but a concept that is influenced by individual social status (e.g., age, gender, class, occupation) as well as by natural and cultural surroundings. There are societies that do not use a risk-like concept (Casimir 2009); for example, studies indicate that drought has been defined as a disaster by external actors, while local communities have categorized the same dry conditions as rather normal, and not dangerous, because they rely on other indicators and modes of valuation (e.g., Meze-Hausken 2004; Müller-Mahn and Everts 2013).

Typical climate-related risks (e.g., losing one's home through flooding, losing a harvest through drought, or suffering from a higher probability of getting infected with malaria) are just one side of the story. These losses harm basic human needs, such as food, shelter, health, and security, which are relevant to all human beings. Disaster reduction programs are planned in a way to reduce these official risks. Though the distinction between *official* and *unofficial risk* is not established in the climate change adaptation literature, it is helpful in understanding people's ways of prioritizing risk, assigning blame, and responding to threats (Eguavoen 2013). Official risk, to our understanding, is the consideration of general threats to human well-being. Official risk is formally recognized by governments and aid agencies and is a legitimate object of policy documents.

Unofficial risk, on the other hand, depends highly on the social and cultural context. Unofficial risk means awareness and fear from causal relations that are not scientific, or at least not easy to grasp empirically, such as a fear of the supernatural. It can manifest itself in a fear of sorcery, of the power of ancestral spirits, or of punishment from the Almighty. Belief and superstition are at the heart of unofficial risk and may manifest in different domains of the same society, such as in (re) production, health, kinship, politics, or religion. They are often connected to the immediate social environment: the danger of being betrayed or disregarded or the fear from greed, jealousy, malevolence, and even sorcery from somebody within the family or community. Unofficial risk is usually neglected by scientists, governments, and aid agencies. It is, however, of great relevance to many people in Africa (and beyond), driving their decisions and activities, because it contributes to the cognitive process of constructing meaning around observations of social and environmental change. Moral transgression as a causal variable in cause-and-effect relationships is often reported under conditions of social and economic transformation which bear an uncertainty about the near future.

The analysis of *cultural weather discourses* worldwide has shown that "[a]ccounts of cultural or moral change are often associated with narratives of changing climate and vice versa [...] Weather can be called or diverted by human action, and atmospheric conditions have frequently been explained with reference to a religious context" (Strauss and Orlove 2003, p. 4, for a systematic review of the studies, see Peterson and Broad 2009). There are numerous manifestations of the idea of weather manipulation, rituals for rainmaking and rain-breaking with specialized utensils and offices, oral traditions (proverbs, songs, mythology) that reveal how power is structured within society, as well as scientific technologies for weather manipulations, such as cloud-seeding. The basic idea of this exploration is to understand the linkages between human perception, behavior, and weather phenomena. For example, anthropologist van Beek explores whether environmental problems have repercussions on storytelling and visions of the future. According to him, the relevance of analyzing tales and myths lies in the fact that any presumed past implies a projected future, both hinging on a perceived present. He states that, "whatever the strange forms and curious tales of myths and legends, the topics always address the worries, concerns and crucial dilemmas of the people, including ecological headaches. Often, these are social in kind and political in consequence" (van Beek 2000, p. 30).

Based on evidence from the South African Lovedu society in the 1940s, Douglas and Wildavsky argue that "for a total disaster, responsibility is located at the top. The geographic and social range of the natural disaster indicates the place in the political hierarchy where the likely transgression has taken place" (1983, p. 39). One could simplify this argument by saying that *different scales of blame* exist and that people tend to ascribe responsibility to the scale where the unwanted condition occurs or to the scale where they believe it occurs. Thus, if a harvest fails and farmers do not receive information about similar failures of harvests in other countries, they receive only a knowledge fragment and, thus, tend to perceive failure as a local problem. As a consequence, farmers assign responsibility and blame to the local and sub-local scales (individuals, their community, and their local authorities) instead of ranking it on a larger scale (e.g., a West African region which is affected by climate variability) with other frames of responsibility. Scientific smattering about global environmental change and uncertainty leads to a fallback on familiar models of blame as a local problem (at the local scale). At times, themes of international politics merge in mental models depending on the exposure of farmers to research, global news, and national political interest. Again, these examples can be understood as outcomes of sensemaking:

> Senegalese farmers identified two main causes for climatic changes; resource (mis)management and meteorology, though "a few participants – those who had taken part in our [...] field research on carbon sequestration – cited CO2 and other greenhouse gases as drivers of climate change. The most [...] controversial factor discussed was [...] a cloud seeding device [...] Although none of the discussants had seen the device, the 'machine' was (wrongly) believed to be responsible for the 2005 rains throughout the entire country" (Tschakert 2007, p. 390).

While weather discourses during the 1990s in Tanzania elucidated moral transgression in the community, the loss of the traditional institutions, and the El Nino for the negative changes in rainfall, the discourse in 2004 was that George W. Bush was personally responsible for the hot and dry weather: "it's all because of that Bush and his [Iraq] war. We don't know why God is bringing *us* these problems for *his* mistakes" (farmer quoted by Sheridan 2012, p. 233).

Late Ethiopian Prime Minister Meles Zenawie explained on several occasions that the industrial pollution and CO2 emissions were responsible for the devastating droughts in Ethiopia during the 1980s. The debate on climate change adds another facet to the older debate on the origins of poverty in Africa. The old call for fairness and compensation gets rephrased during international climate negotiations: "we are prepared to walk out of any negotiations that that threaten to be another rape of our continent" (Meles quoted in Eguavoen and zur Heide 2012, p. 107f).

The vulnerability to climate change discourse is wholeheartedly embraced by the government of Tanzania as a welcoming scapegoat to explain the marginalized situation of the Maasai population. The same government recently evicted thousands of pastoralists of their land, and excluded them from their most vital natural resources, to sell the land to a royal Arab family for game hunting purposes (field research by Sara de Wit).

One debate that materializes into the studies on climate change in Africa, if done by social anthropologists or historians, is the well-documented *connection between rain and politics*. "Rain is a political process across much of sub-Saharan Africa [. . .] the authority of leaders in colonial Africa rested, in part, on the performance of rituals to bring rain and ensure the fertility of both people and land [. . .] secular notions of power, legitimacy, and authority now co-exist and hybridize with discourses about rain, morality, and metaphysics [. . .] the politics of rain are deeply interwoven with the politics of kinship, class, ethnicity and gender [. . .implying] the notion that political order brings ecological order in the form of reliable rain – but that conflict brings drought – functions as the rhythm of political improvisation" (Sheridan 2012, p. 231). There are a number of historical examples for the rain-politics link (for a brief review, see Sanders 2003), as well as numerous empirical examples of our times:

Climate change in Mozambique is understood as the result of "lack of rain ceremonies or improper rain ceremonies" (Shaffer and Naiene 2011, p. 233). The background of this lack is political. During the civil war, the government banned traditional rituals, some of the local authorities and many cattle died during the conflict, herds could not be replaced easily after the civil war – both preventing the conduct of the rituals that use animal sacrifices. In the discourse and thus the mental models, post-war disorder was correlated to negative changes in the weather (Shaffer and Naiene 2011).

The Maasai pastoralists in Northern Tanzania perceive changing patterns of rain to have coincided with the introduction of Christianity. With an explicit ban on visiting the traditional spiritual leader, the church contributed to the degrading power of the so-called oloiboni. Instead of praying under the tree, the collective rain ritual nowadays largely takes place in churches, where the power of establishing the connection between God and His people – through mediating rain – lies in the hands of the pastor (field research by Sara de Wit).

Other trajectories of blame can be revealed when investigating *translation practices of climate change discourses* from the global to the local scale and what happens at the intersection of their discursive encounters. Often, climate change is not perceived as a global phenomenon with remote causes and diverse manifestations worldwide, but as a phenomenon localized in cause and effect. However, these perceptions might be altered when *the idea of climate change travels* and fuses in the encounters between this externally imposed idea and local explanatory regimes about a changing climate. In order to explore this "multilevel connection between global and local phenomena," enticed by global environmental discourses, Adger et al. fruitfully employ a *political ecology* approach (Adger et al. 2001). They demonstrate how political ecology forms a fertile analytical lens to trace the *genealogy of environmental narratives*, which identify the power relationships that are supported by such narratives, and the policy prescriptions that emanate from them.

Outlook

In a recent critique of the adaptation concept in the climate change literature, Bassett and Fogelman come to conclude that there is a "strong sense of déjà vu in reading the IPCC reports and climate change journal articles" (Bassett and Fogelman 2013, p. 51). Their content analysis shows that 70 % of the literature under review deems climate impacts as the major source of peoples' vulnerability (Bassett and Fogelman 2013, p. 42). This conceptualization of adaptation bears many resemblances with earlier arguments of the hazard school of thought, which sees vulnerability as the outcome of exposure, sensitivity, and mitigating responses (Bassett and Fogelman 2013, p. 51). With this chapter, we intended to underline why the inherent *climate determinism* (Hulme 2011) in the climate change adaptation literature is highly problematic and why the political needs to be brought back into the discussion of climate change.

First, academic explanations based on political perspectives are still marginalized in the major adaptation discourses (as the social science disciplines are in climate change research), with the effect that structural causes that make people vulnerable in the first place (and that we have discussed under the political agendas) are overlooked. Donor and government interventions, therefore, often remain technocratic, as they do not challenge and address the social and economic factors that lead to peoples' vulnerability. These politically conservative approaches do not challenge the status quo, but tend to fix the deficiencies at the surface (Bassett and Fogelman 2013, pp. 44–46).

Second, in a similar vein, with the emergence of the *adaptation imperative* (a normative imperative invoking the plight of the most vulnerable), there is a strong need for analyses of the discursive framings of adaptation and what they reveal about power relationships (Wisner et al. 2012). Through increased funding possibilities, adaptation programs could share the same characteristics as James Ferguson's *anti-politics machine of development* (Ferguson 1994). Studies need to include an analytical separation of *knowledge about climate change* (mental models of local climate change) on one hand and *knowledge about adaptation resources* (funding, programs, and career opportunities) on the other to get a clearer picture of the dynamics within the CCA arenas.

Third, and closely linked to what has been written above, actors respond to climate change impacts, as well as to the *idea of adaption*, as articulated by science, politicians, the media, and the donor community (Head 2010). Answers to the "adaptation to what and why" question (Pittock and Jones 2000) will have to take into account the fact that actors act upon the scripts provided by potential supporters (Watts 2001; Rottenburg 2009). Adaptation to climate change is more than what the IPCC envisions, and therefore, "adaptation cannot be adequately explained as a response to climatic stimuli, but [. . .] it also involves reactions to prevalent ideas and the incentives of new funds" (Weisser et al. 2013, p. 117). The authors also point out that "Focusing on various translations of the travelling adaptation idea helps to reveal the politics involved in North-South cooperation and thus open up a public space for negotiation" (Ibid. 2013, p. 117).

Fourth, due to the fact that climate funds channeled to the Global South might surpass official development assistance (ODA) in the future, Ireland and McKinnon argue that not only should adaptation research focus on vulnerable communities but also on those "places where policies are made, funding decisions taken, or new themes and approaches circulated amongst development professionals" (Ireland and McKinnon 2013, p. 2). Thus, our research also needs some new agenda-setting including perceptions, priorities, and social dynamics in African research centers, in environmental ministries and agencies, in civil society movements, and in the business context, as well as research about African COP delegations.

Fifth, while the previous argument proposes a new ontology for adaptation, we stipulate that *epistemological reflections about adaptation* similarly deserve attention, as they reveal how different actors may assemble around the adaptation paradigm in the CCA arenas. Adaptation means different things to different people (Head 2010; Bassett and Fogelman 2013), for adaptation activities are embedded in particular socio-cultural contexts (O'Riordan and Jordan 1999; Nelson et al. 2009; O'Brien 2009). As Rottenburg has shown for North–South cooperation, in general, project parties are united under a *common meta-code* (Rottenburg 2005), and in this way, donors and recipients act upon the common objective of adaptation to climate change. While in their interactions they refer to adaptation as a common meta-code, the distinct cultural codes of each of the partners differ profoundly. Program and project activities might be labeled as adaptation to climate change; however, the rational to do so might differ starkly. As Weisser et al. (2013, p. 117) put it: "Adaptations observed in places different from those where the idea of adaptation is produced are modifications of the latter, and can be considered as results of *translation processes*. Ontological and epistemological reflections [. . .] are opening up new perspectives for future research".

Finally, to better highlight the inherent political dimensions and social dynamics of adaptation, as well as the *emic perspectives* on change, risk, and adaptation, we believe that it is very helpful to look beyond the climate change adaptation context. Multidisciplinary research could, more often, build on social environmental sciences and their theoretical contributions. We hope that the suggested concepts and terminology help to support future research in Africa and elsewhere in this regard.

Pricing Innovation in Climate Change Adaptation (CCA): Hedonic Valuation of R&D That Can Favor CCA

Johann Jacob, Jessica Bouchard, Moktar Lamari, and Éva Anstett

Contents

Abstract

Ever since climate change became a collective concern, governments have diversified incentives encouraging firms to mitigate climate change by investing in new technology development. However, many decision makers still question their value and wonder what determines climate change adaptation (CCA) at the firm level. This chapter deals with two questions: What makes some firms more committed to CCA than others? To what extent do R&D-active firms invest in new technologies required by CCA? Data were gathered using a 2012–2013 online survey conducted among 255 R&D-active firms in Canada (Quebec). Our dependent variable measures firm investment in technology acquisition, and independent variables are related to firms' CCA effort and to their context. Our results suggest that CCA-active firms are (i) highly innovative, (ii) intensive in R&D, (iii) investors in physical capital, and (iv) open to external knowledge.

The model developed suggests that firms invest, on average, $5,358 a year to acquire new technologies related to climate change adaptation for each level of impact on CCA (10 levels used in our research). Our results are groundbreaking in terms of pricing the specific R&D impacts on CCA at the firm level. They indicate that the activities of research centers like technology transfer organizations make a difference in terms of CCA, especially to enable actions in the private sector. Our findings also help the public sector to improve its actions targeting CCA (e.g., tax credit or grants for firms acting in CCA).

Keywords
Climate change adaptation • Public-private R&D collaborations • Technology transfer organizations • Cost-benefit analysis

Introduction

Existing productive processes used by industries and firms have major and increasing impacts on climate change. On this subject, the works of Stern (2006) are eloquent, if not alarming. In their pursuit of productivity and optimization of profits, firms generate negative externalities on several fronts (i.e., some results affecting not only the firm but some other parts of the society): air pollution, fumes from harmful waste, overexploitation of fossil fuel resources, greenhouse gas emissions, etc. and the ensuing consequences for climate change (Zarka 2010). At the same time, to assist firms in innovating and adopting technologies that pollute less and are more adapted to the risks of climate change, several government policies and measures have been implemented, particularly in the last decade, to assist and encourage firms in reconciling the seemingly irreconcilable, namely, the requirements of profitability versus the requirements of climate change adaptation (Gupta et al. 2007; Braüninger et al. 2011). In Canada, these efforts have notably expanded in the last 6 years through, for instance, public subsidies that were given to some research centers: technology transfer organizations (TTOs). These organizations (which are research centers specially created to help transfer knowledge from universities and scientific literature to firms) aim to help firms which are seeking to innovate to reconcile their performance objectives with those of adapting to climate change. More generally, these organizations create, acquire, adapt, and transfer new technologies for firms wanting to innovate and improve their competitiveness, not only in local markets but also internationally. All evidence suggests that an apparent evolution is taking place, pressuring firms to consider the effects of global warming and invest in "green" technologies that are more adapted to the specificities of their local environment. Everything seems to indicate that these firms are part of a movement favoring the global environment, like an ecosystem transcending time, space, and the wealth of nations (Gupta 2005).

The complexity of climate change phenomena requires expertise and technologies that firms cannot always acquire alone without any public assistance (Osberghaus et al. 2010). The issues raised by climate change require resilience and a proactive approach that take into account intra- and intergenerational interests, in keeping with the aspirations of the Brundtland Report on sustainable development of the World Commission on Environment and Development in 1987, taken up again by the United Nations at the Rio Conference 5 years later (Zarka 2010).

Public funding of research and development aims at correcting certain market failures related to innovation by encouraging private-sector actors to produce technological innovations enabling the reduction of greenhouse gas emissions or by providing adaptation options. At the same time, recent years have witnessed the appearance of many writings on the relationships linking the necessity of climate change mitigation and the progressive commitments of firms to invest in the acquisition of new technologies that can help them do better in their markets but with productive procedures and processes that are less prejudicial to climate change (Howarth 2003). However, these writings do not help to understand why only some firms invest in the acquisition of new technologies that are compatible with concern for climate change mitigation and CCA. They remain dominated by descriptive and reflective analyses (Paehlke 2014). Not much is yet known about these attributes and, quantitatively, even less about the net economic value attributed by firms to the beneficial spin-offs of climate change adaptation within firms. To our knowledge, no study has valuated the use of grants as a mechanism for stimulating technology transfer in CCA specifically (Intergovernmental Panel on Climate Change 2014a).

The investigations presented in this text advance knowledge by offering empirical evidence concerning the behavior of firms receiving support from TTOs in the area of CCA. In concrete terms, this chapter highlights the determinants that influence certain firms to be more committed than others to climate change adaptation thanks to their effort to acquire new technologies required in CCA. This chapter provides answers to two key questions within the Canadian context. The first question deals with the principal attributes characterizing firms that collaborate with TTOs with regard to climate change adaptation. The second question deals with the economic value of the demands of climate change adaptation according to these R&D-intensive firms.

The remainder of the text has been divided into four parts. The first part puts into perspective the conceptual and theoretical issues linked to the challenges of climate change within the context of industrial activities, in general, and of firms, in particular. The second part presents the empirical approach and data used to respond to the questions asked. The third part deals with the results and interprets their scope and implication for public policies targeting climate change adaptation in the context of firms and industrial activities. The conclusion takes stock of the results and introduces perspectives for action, not only for the public decision makers concerned but also for future empirical research dealing with the same subject.

Theoretical Background

The issue of climate change encompasses several aspects that have raised controversy and differences of opinion in scientific writings. These differences can be explained in large part because the evidences produced cannot be compared regarding the validity of the estimates and hypothesis presented. The estimated costs associated with respect to reducing greenhouse gases are an example, and the economic forecasts concerning the possible expected damages also differ, if the present emission rates are maintained. The recognition of climate change as a significant global challenge originated in the adoption of the United Nations Framework Convention on Climate Change (UNFCCC) in 1992. Since then, global negotiations on this issue have tended to emphasize minimizing the costs related to reducing greenhouse gas emissions. The preservation of ecosystems and the population's adaptation to these changes have been dealt with less (Gupta 2005).

Obviously, all societies are affected by climate change and must face the issue of mitigating its effects and adapting to it. In recent years, the World Bank and the Intergovernmental Panel on Climate Change (IPCC) have published reports exposing the urgency for all states to establish strategies to control climate change. Whereas climate change mitigation programs have tended to have a global focus, adaptation programs have had a regional or local dimension. The IPCC defines adaptation to climate change as an "adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities. Various types of adaptation can be distinguished, including anticipatory, autonomous and planned adaptation" (Intergovernmental Panel on Climate Change 2014a). Climate change mitigation is stated as "an anthropogenic intervention to reduce pressure on the climate system." It includes strategies to reduce the sources and emissions of greenhouse gases and enhance the sinks of greenhouse gases (Intergovernmental Panel on Climate Change 2014a).

Unquestionably, the strategies implemented to respond to the requirements of climate change involve costs and benefits that are distributed asymmetrically through time and generations. The extent of future greenhouse gas emissions depends on the paths of economic, demographic, technological, and energy development of each nation (Pielke 2007; Hallegate et al. 2011). These parameters are therefore complex and linked to the uniqueness of states and regions. In addition, significant uncertainties surround the estimated long-term impacts of climate instability (Intergovernmental Panel on Climate Change 2013) that are, in turn, subject to uncertainty regarding the future paths of socioeconomic development, climate policies to be implemented in the future (Intergovernmental Panel on Climate Change 2013), and the response and adaptation of ecosystems (Intergovernmental Panel on Climate Change 2014b). For example, based on a literature review, the IPCC estimated that the present level of greenhouse gas emissions could cost about 1.5–2 % of the global economic output, with greater impact on developing countries. However, a consensus about these estimates does not exist in the literature, and they differ according to the disciplines and researchers (Howarth 2003). Stern (2006) estimates that these costs would be in the order of 5–20 % in terms of GDP per state. The most recent estimates from the World Bank place climate change adaptation costs at between $70 billion and more than $100 billion annually by 2050 (World Bank 2010).

Climate change has undeniable economic impacts. From an economic standpoint, political entities and socioeconomic organizations combine their climate change efforts by introducing programs that are in the interests of their population. Climate change is indivisible and cannot be measured with precision. This leads firms to adjust their efforts between adaptation and mitigation measures (Maybee et al. 2012).

Nevertheless, there is a consensus surrounding the adaptation measures taken during the last century that turned out to be insufficient. Autonomous actions can be undertaken by the civil society, in particular, but also by private enterprise. In this sense, private actors are expected to take autonomous adaptation measures based on their interests and whose anticipated benefits will be greater than the costs (Maybee et al. 2012). Nonetheless, several experts highlight the fact that autonomous adaptation initiatives can fail for several reasons, in particular, because the agents affected by climate change do not always have the capacities, resources, and other factors necessary to undertake such measures. Moreover, many of these actions cost more than the estimated benefits (Eisenack 2013; Hughes and Chaudhry 2011). Finally, in certain cases, the adoption of a socially desirable behavior (specifically an adaptation action) does not appear to be profitable to a private agent, constituting market weakness situations. For example, negative externalities may result from the adaptation actions taken by certain agents leading to even more harm to third parties (Goulden et al. 2009). As well, a moral hazard situation occurs when a climatic risk is transferred to the population, in particular, through an insurance mechanism or through post-disaster aid offered by the state (Laffont 1995).

Within this framework, some states and international government organizations have recognized the necessity to manage this question and to develop public policies of adaptation and reduction of the effects of climate change. Governments are mainly concerned with formulating adaptation policies and strategies for climate change, as well as developing a governance structure to ensure their implementation. As this policy development process is relatively recent, studies have looked into climate change adaptation measures by setting out their limitations. They have dealt with government failures, in particular, the lack of political and conscientious leadership with regard to needs, as well as the weak financial resources available for these initiatives. In addition, there is the presence of a lack of political commitment, inadequate interstate cooperation, an insufficient level of government expertise (Clar et al. 2013), and limited adaptation capacities, especially in developing countries or in countries with limited access to capital (Brooks et al. 2005). Also, decision makers can occasionally set barriers through their cognitive and behavioral biases (Podsakoff et al. 1990).

The literature includes a large number of studies analyzing policies and interstate cooperation with regard to climate change, but only a minority take an interest in non-state actors and their climate change adaptation and mitigation initiatives. Even so, recent research in this area has permitted to illustrate the importance of accompanying national and supranational CCA measures with additional policies, enabling the mobilization of other actors, such as firms, business associations, and local organizations (Hamit-Haggar 2012; Craft et al. 2013).

Burch et al. (2013) examined this question and brought to light the importance of governments resorting to innovative approaches to encourage industry and private enterprise to take action in this area. By studying Canadian firms involved in R&D having a positive impact on climate change adaptation, they advanced the idea that firms assume an innovative, creative, and dynamic character (Burch et al. 2013, p. 822). They also emphasize that the issue of climate change must be handled by different governance levels; measures must be implemented at the local, regional, national, and international levels.

Several governance experts acknowledge that the rigid, centralized state method cannot respond to all public-policy issues, and the climate change question requires a multi-sectoral, multilevel governance model (Burch et al. 2013, p. 822). This allows actors involved in R&D and CCA to increase their ability to act and make their initiatives more effective while, at the same time, fostering the horizontal and vertical transfer of technologies, knowledge, and information among them (De Coninck et al. 2008).

There is also a consensus that initiatives in the fight against global and national climate change must be accompanied by local action (Craft et al. 2013). As stated above, this issue has major economic impacts that are already being felt. To limit the negative externalities of climate change adaptation and mitigation, measures must be taken to limit the damage and ensure longer-term economic growth. So, it is essential that governments take into account that effective parallel mitigation factors must also be implemented in order to enable climate change adaptation (Paehlke 2014).

In the Canadian context, climate change adaptation and mitigation have followed a tortuous path. A clear example is the Canadian ratification of the Kyoto Protocol and the subsequent withdrawal of approval. In 2007, the Canadian federal government acknowledged that meeting the objectives set by Kyoto would be unachievable and introduced new greenhouse gas reduction targets in a document entitled Turning the Corner. This new policy involves reducing GHG emissions by 20 % by the year 2020, based on 2006 levels (Hughes and Chaudhry 2011). Industry also has a role to play in this issue. In 2007, the industrial sector was responsible for 32 % of GHG emissions in Canada (Hamit-Haggar 2012). Overall, GHG emissions increased by 16.9 % in Canada between 1990 and 2009, representing 22.9 % over its commitments made within the framework of the Kyoto Protocol. In 2011 and 2012, Canada formally withdrew from Kyoto and drastically reduced the size of its environment ministry. The significance of these developments is that they increase the importance of developing innovative local actions and the development of networks devoted to the strategic sharing of information permitting state and private actors working for climate change mitigation and adaptation to work together (Burch et al. 2013).

Thus, Canadian federal and provincial governments resort to a system of governance that is more and more widespread in industrialized countries with regard to climate change. It involves a partnership between the public and private sectors, including the participation of several actors: government agencies and organizations and large, small, and medium-sized businesses. In this chapter, we are targeting this type of partnership between firms and technology transfer organizations (TTOs) that are funded in part by the federal and Quebec governments. Technology transfer organizations are defined as entities acting as catalysts between government and academic research teams, on one hand, and industries, on the other (Grosse 1996, p. 782). Technology transfer is defined as “the process of transferring skills, knowledge, technologies, methods of manufacturing, samples of manufacturing and facilities among governments or universities and other institutions to ensure that scientific and technological developments are accessible to a wider range of users who can then further develop and exploit the technology into new products, processes, applications, materials, or services. It is closely related to knowledge transfer. Horizontal Transfer is the movement of technologies from one area to another. Vertical Transfer is when technologies are moved from applied research centers to research and development departments” (Grosse 1996, p. 782).

The TTOs have the characteristic of assisting firms in R&D and in adopting technologies that are more adapted to the risks of climate change. Their large network is made up of public administrations but, even more so, of small- and medium-sized private-sector firms. There is evidence in the literature suggesting that, despite their size and limited resources, small and medium-sized businesses are able to have significant positive impact on climate change adaptation and mitigation. This can be explained by the fact that, compared to large firms, smaller firms have a closer relationship with their community and their workers and are less subject to pressure from shareholders to maximize profits (Burch et al. 2013, p. 826). In addition, by taking into account the fact that a multi-sectoral, multilevel governance favors the development of climate change adaptation measures, TTOs can play a key role in capitalizing the strengths of the actors in their climate change adaptation efforts, while maximizing their innovation potential and establishing channels of communication among these firms.

Furthermore, to respond to the uncertainty surrounding the question of climate change, several economists and economic actors tackle the problem in terms of cost-benefit analysis (Maddison 1995; Tebaldi et al. 2005). Such an approach evokes the rationality of the economic optimization of dividends anticipated by the actors. This approach consists in taking into account the costs and benefits that would result from a project, in discounting them, then in calculating the real net value. The cost-benefit analysis thus permits to demonstrate the practical implications of a decision from a welfare standpoint (Townley 1998). The cost-benefit method is also thoroughly documented in the literature on R&D. It has been retained for this analysis.

In cost-benefit analysis, the choice of the discount rate has a significant impact on the net present value and is the subject of debate in the literature. The cost-benefit analysis applied to climate change is linked to this debate since it is spread over a long time horizon (Baum 2009; Heal 2009). As a result, choosing a higher discount rate will tend to dissuade taking mitigation measures because the related costs will be higher than the expected benefits to be reaped further along in the future. Conversely, choosing a lower discount rate will permit attributing a higher value on anticipated future benefits and thus gives more importance to decision making to control climate change (Hof et al. 2010). In addition, as this type of analysis focuses on impacts affecting several generations, ethical and moral questions come into play in choosing the discount rate (Stern 2006). It emerges that there is no consensus among experts with respect to this question. In the latest report of the IPCC, it is stated that the rates used vary between 0.1 % and 2.5 % for CCA projects (Intergovernmental Panel on Climate Change (2014a). The Stern Report (2006) exposed the seriousness of the harm to the global economy as a result of climate change, a negative externality whose extent should increase in the future. Nonetheless, this report was the subject of criticism since the discount rate used by the author was 0.1 % which, according to some, resulted in an overestimation of the future impacts linked to climate change and an underestimation of the extent of the costs to be assumed to contain their effects (Dietz et al. 2007). And so, the principal reason why climate change damage estimates in the Stern Report are high is the low discount rate.

Furthermore, to include all impacts in the cost-benefit analysis, economists have developed methods to assign a monetary value to intangible impacts. In fact, certain impacts to be considered in public projects are not exchanged on the market and do not have an assigned monetary value. To assign a value to this type of impact, innovative methods have been developed for this purpose. The most widespread are contingent valuation and hedonic prices.

Method

This analysis was conducted by the *Centre de recherche et d'expertise en évaluation* (CREXE) within the framework of a mandate for the *Ministère de l'Économie*, *des Innovations et des Exportations du Québec*, Canada. This mandate consisted in carrying out a cost-benefit analysis involving the study of 41 technology transfer organizations (TTOs), three of which are independent and 38 of which are members of a vast regional network. These organizations offer innovation services for local firms, specifically small- and medium-sized businesses, in the province. Their research activities are focused on applied and adapted research for direct use by their partners of the private sector; consequently, TTOs are closely in touch with firms' needs, whereas other research centers undertake more fundamental or basic research which is not directly applicable for the private sector. This policy is an example of public-sector intervention created to encourage innovation in the private sector in order for the state's grants to create leverage to increase private investment in R&D.

The data presented are from several sources and databases which can be explained because the costs and benefits studied are felt by different actors, including government agencies, firms, and TTOs. The data relating to impacts concerning governments and public organizations are from internal documents, official reports, and directed and semi-directed interviews carried out with representatives of these organizations. The internal data concerning the three Quebec TTOs were gathered from financial documents, annual reports, and strategic plans supplied by the three firms.

Two types of surveys were conducted between October 2012 and March 2013 among 1,500 firms and public organizations involved in R&D in Canada (Quebec) and working in collaboration with the TTOs studied. First, a telephone survey was carried out by an external firm, with a response rate of 65 %. Then, an electronic survey was carried out. The data were collected using the Survey Gizmo platform; the average response rate for this survey was 25 %.

These two surveys enabled the estimation of costs and benefits, as well as the impacts taken into account in the analysis. The questions were formulated in order to obtain continuous numerical data. For the variables that were more difficult to measure, the questions provided possible responses from 0 to 10 in order to allow respondents to estimate the extent of the impacts studied.

The collaboration with the TTO of the firms included in the sample was therefore analyzed to assess whether their collaboration had an impact on investments targeting CCA. The questions asked to respondents within the framework of the surveys focused mainly on assessing the impact of their firm's collaboration with the TTO: on climate change adaptation, reducing greenhouse gas emissions, the environment, and sustainable development. The sample included 255 firms that completed the survey and offered valid responses to the questions. A descriptive statistical analysis was then carried out using all these data with the help of SPSS software. These results are presented in the following section.

Moreover, to determine the estimated monetary value of the public expenditures leading to the innovations linked to CCA, the hedonic price method was used, which will be described in the next section. This economic method helps to estimate the value of intangible elements, in our case the value of firms' actions in CCA. For the purposes of assigning a value to these intangible attributes, correlation and regression analyses were produced with SPSS. The dependent variable of the multivariate regression that is presented in the following section is the total amount of the firm's contracts with the TTO for 1 year (continuous variable), and the independent variable that interests us is the impact of the firm's collaboration with the TTO on climate change adaptation (the values vary from 0, if the firm perceives no impact, to 10, if the firm perceives a major impact). Two control variables were then introduced into the model. First, as stated in the literature, R&D-intensive firms are characterized by a large workforce devoted to R&D (Grosse 1996). To cover this aspect, we added the variable of the number of staff members allocated to R&D in the firm (continuous variable). We then added the variable of innovation in terms of organizational processes and marketing activities (the values vary from 0, if the firm perceives no impact, to 1, if the firm perceives a major impact). We also introduced other control variables measuring the duration of collaboration with TTOs (number of years) and technological services (training, technological counseling, testing products, etc.), specified as a binomial variable (1 = yes, 0 = no).

Results

The findings of this study will be presented in four steps. We first present the sample characteristics and the descriptive analysis, then the statistical analysis, the hedonic evaluation, and, finally, an ordinary linear regression (OLR) explaining the determinant of investment in collaboration with TTOs.

Descriptive Analysis

To understand further the main attributes of Quebec firms collaborating with TTOs on R&D related to CCA, a characterization of Quebec firms producing impacts on CCA has been produced.

As presented in Table 1, the sample is composed of 255 Quebec firms collaborating with TTOs on R&D. The respondents are divided into two categories: those who perceived an impact of their collaboration with the TTO on CCA and those who did not. 31 respondents perceived impacts of their collaboration on CCA, which represents 12.5 % of this sample. These 31 firms and organizations are involved in the following sectors: public administration (10 %), primary sector (10 %), secondary sector (45 %), and tertiary sector (45 %).

In contrast, 224 respondents did not see impacts of their collaboration with the TTO on CCA. This subsample is composed of similar proportions of public administration (11 %) and firms working in the primary (12 %), secondary (42 %), and tertiary sectors (46 %).

Table 2 presents other attributes of firms investing in R&D impacting on CCA. These firms employ an average of 1,028 employees, and their mean annual earnings total $173 million. The mean impact of the collaboration with the TTO is estimated at $183,662 by the respondents, and the contract amount with the TTO totals an average of $29,358 annually. In contrast, the respondents who do not see impacts of the collaboration with the TTO on CCA present a lower mean number of employees (596) but higher mean annual earnings ($81.3 M). However, these firms have a mean annual contract amount of $16,676 with the TTO, which is lower compared to the firms perceiving impacts on CCA.

Chi-Squared Test and T-Test

As presented in Table 3, the collaboration between the firms investing in R&D impacting on CCA (n = 31) and the TTO led to investments in internal R&D (71 %), external R&D (70 %), access to tax credit for R&D (70 %), and acquisition of machines, equipment, and software (57 %). Furthermore, this collaboration leads

Table 1 Characterization of Quebec firms producing impacts on CCA

Question : Please estimate the impact of your collaboration with the TTO on CCA (on a scale from 0 to 10, 0 representing no impact and 10, a maximal impact)	Impact on CCA >1 ($n = 31$)	Impact on CCA = 0 ($n = 224$)
	n (%)	n (%)
Sector		
Public services	3/29 (10 %)	23/204 (11 %)
Primary sector	3/29 (10 %)	25/204 (12 %)
Secondary sector	13/29 (45 %)	86/204 (42 %)
Tertiary sector	13/29 (45 %)	93/204 (46 %)

Table 2 Characterization of firms investing in R&D impacting on CCA

	Respondents seeing impacts of the collaboration with the TTO on CCA			Respondents not seeing impacts of the collaboration with the TTO on CCA		
	Mean (SD)	Median	n	Mean (SD)	Median	n
Number of employees of the firm	1,028 (3,390)	40	23	596 (1,814)	55	191
Earnings ($) (*annual*)	$17.3 M ($26.8 M)	$7.9 M	26	$81.3 M ($332.5 M)	$8 M	195
Profits ($) (*annual*)	$906,577 ($2.03 M)	$191,326	18	$3.9 M ($22 M)	$391, 000	143
Estimate of the impact ($) *of the collaboration with the TTO*	$183,662 ($312,643)	$50,000	19	$215,740 ($652,189)	$10,000	127
Spin-off benefits ($) *due to collaboration*	$100,834 ($248,510)	$22,843	22	$355,835 ($2.6 M)	–	177
Contract amount with the TTO (*for 1 year*)	$29,358 ($70,157)	$17,500	27	$16,676 ($31,283)	$6,644	184

to the acquisition of exterior knowledge (39 %), the hiring of specialized human resources (37 %), and other innovation-related activities. These results are statistically significant at the 5 % level (chi-square lower than 0.05).

These statistics show that firms that adopt CCA are highly innovative and more R&D-intensive, both internally and externally. Moreover, these companies make investments in capital and are more open to external skills and knowledge. This evidence suggests that TTOs can play an important role in innovation related to CCA.

However, there is no statistically significant difference regarding other parameters, such as the number of employees, the annual earnings, and profits. However, the companies that adopt CCA do not necessarily have large earnings but employ a large workforce.

Overall, it emerges that these firms present the common characteristics of employing large workforces, particularly in R&D, and of being highly innovative in their sector of activity.

Pricing CCA from Implicit Behavior

Hedonic Evaluation

To assess the value attributed by the actors doing R&D on CCA innovation, we used the hedonic pricing method. This method aims to give a monetary value to impacts, which can be broken down into price and measurable quantities. This involves deducting intangible individual preferences and behavior on the markets from other goods and services (Townley 1998). Formulating the argument

Table 3 Characterization of the sample (firms and CCA)

	Firms seeing impacts of their collaboration with the TTO on CCA ($n = 31$)	Firms not seeing impacts of their collaboration with the TTO on CCA ($n = 224$)	
	n (%)	n (%)	Chi sq
Collaboration with the TTO led to investments in			
Internal R&D in the firm or organization	20/28 (71 %)	95/209 (45 %)	0.01**

that the goods themselves are not useful to consumers but the attributes that compose them, Lancaster (1966) established the theoretical basis of this method. A good's overall price results from an implicit valuation of each of its attributes, and it is possible to determine a demand function for each attribute (Travers et al. 2008). This explicit identification of characteristics aims to compare goods despite their heterogeneity (Townley 1998).

Regressions

To understand further how the collaboration with a TTO leads to tangible impacts on CCA felt by companies, a regression model has been developed. The dependent variable is each firm's contract amount for one year (CA) with the TTOs. The independent variable is the impact perceived by the respondents of the collaboration on CCA; the values range from 0, if the firm sees no impact to 10, if the firm sees a major impact (Likert scale). We added several control variables to the model: the number of employees working in the R&D department of the firms, the implementation of innovative products following collaboration with the TTO, the duration of the collaboration with the TTO, and the technological services received from the TTO.

Table 4 Ordinary linear regression (OLR) explaining the determinant of investment in collaboration with TTOs

	Nonstandardized coefficients		Standardized coefficients		
	B	SE	Beta	t	Sig.
Constant	−76,979.219***	19,688.503		−3.910	0.000
Innovation	10,573.764	13,199.239	0.065	0.801	0.425
Climate change adaptation (CCA)	5,358.041**	3,637.278	0.120	2.173	0.044
Duration of the collaboration with the TTOs	5,319.612***	1,210.648	0.366	4.394	0.000
Services received from the TTOs	55,294.401***	13,135.475	0.346	4.210	0.000
Number of R&D employees (Ln)	8,368.429***	3,138.098	0.224	2.667	0.009
Number of observations	143				
R2	0.294				
P-value	0.000				
F	9.036				

Dependent variable: Total amount of contract with the TTOs
**p < .05
***p < .01

Table 4 presents an ordinary linear regression explaining the determinant of investment in collaboration with TTOs. The regression exhibits an R2 of 0.294, significant at the 1 % level (P-value = 0.000; F = 9.306) and comprises 143 observations. The results suggest that our model explains 29 % of the variation of the dependent variable (total amount of the contract with the TTOs). These feet indicators are acceptable, indicating the quality of our model specification. Of these five control variables, four regression coefficients are statistically significant, besides the constant. The CCA variable is significant at the 5 % level, and the other three control variables are significant at the 1 % level.

(1) The relationship between the total amount of the contract with the TTOs and the CCA is positive. Other things being equal, firms allocate, on average, $5,358 for each level of impacts on CCA. (2) The duration of the relationship with the TTOs is also positively associated with the dependent variable and, other things being equal, the amount of the contract increases each year, on average, by $5,320. (3) The services received from the TTOs in terms of training, technological counseling, and testing products increase, all else being equal, the value of the dependent variable by $55,294, which is very high. (4) The number of R&D employees (Ln) is also highly and positively associated with the dependent variable.

Our findings are very inspiring in terms of the amount of money firms are investing in order to acquire useful new technologies devoted to CCA. These results enhance the importance of R&D employees for innovating firms and in this case in the CCA.

Conclusion

The results of this research suggest, first of all, that Canadian TTOs can play a crucial incentive role regarding innovations related to climate change adaptation. Our study's respondents have perceived that their collaboration with a TTO generated both internal and external R&D investments while, at the same time, promoting other innovation activities.

Thus, our conclusions from the analyzed descriptive statistics are that innovative firms in the area of climate change adaptation are more R&D-active and make large investments in physical capital and specialized human resources. They are also more open to acquire external knowledge. On the other hand, contrary to our expectations, there are no significant differences with regard to the other parameters taken into account (see Table 3), such as the number of employees, the marketing activities, and annual profits.

At the same time, this research extends knowledge about the ways of assigning a monetary value to firms' R&D activities impacting on climate change adaptation. The regression model developed suggests that firms invest, on average, $5,358 a year to acquire new technologies related to climate change adaptation, for each level of impact on CCA.

In the light of the content of this chapter, climate change mitigation and adaptation are major economic issues whose costs and benefits are spread throughout a broad time horizon. Even if autonomous private-sector initiatives have been observed, the risks and uncertainties surrounding climate change can curb investments in this area since private firms protect themselves against large potential losses and make sure they obtain a return on their spending (Howarth 2003). Therefore, what emerges from the literature relating to climate issues is that states and public administrations must encourage climate change adaptation efforts by industry and firms and establish conditions guaranteeing their success (Paehlke 2014). To this end, the Canadian government provides financial assistance to technology transfer centers directly targeting R&D-active firms in order to reconcile their performance objectives with those of adapting to issues related to climate change.

The results of this research show that TTOs can play a key role in climate change adaptation within the framework of their collaboration with the member firms of their network. Our work demonstrates how this type of public-private partnership can lead firms to invest in CCA while still developing profitable innovations for the whole society. Our conclusions are also the same as those of writings dealing with the importance of local and regional initiatives concerning climate change. Hence, the development of policies targeting intersectoral exchanges between R&D firms committed to climate change adaptation is an option to be considered by public decision makers. This research therefore suggests the implementation of measures to strengthen private CCA initiatives in order to make them more effective, on one hand, and to make entrepreneurs aware of the crucial role they can play in reducing the risks associated with this issue, on the other. Public authorities should also consider additional incentives, perhaps in the form of tax credits or grants that would then likely stimulate private investment in CCM and CCA. In addition, public funds could also introduce services and activities fostering networking among firms involved in CCA to permit the exchange of good practices, as well as to feed and accelerate the innovation process.

Our analysis opens several possibilities for future research. First of all, the model developed in this study could be improved through the use of a greater number of variables and a larger sample. The addition of new data would thus increase the model's statistical strength and permit a deeper interpretation of the results. This exercise would also make it possible to identify other characteristics attributable to R&D-active firms committed to climate change adaptation. Moreover, other research could be conducted with regard to the intangible attributes surrounding CCA innovations. For example, access to Statistics Canada's chronological data would enable the study of the impacts of public knowledge transfer programs on R&D activities concerning climate change adaptation.

Principles of Emissions Trading

Julien Chevallier

Contents

Abstract

International emissions trading schemes include the Kyoto Protocol and the European Union Emissions Trading Scheme. This chapter documents the main principles behind the functioning of such permits markets, which represent popular environmental regulation tools. Among other design issues, this chapter discusses the various allocation mechanisms available to the regulator. Besides, this chapter underlines the role played by intertemporal flexibility mechanisms (e.g., banking and borrowing) which allow reducing overall compliance costs. Overall, the goal of this chapter is to present in standard textbook reference terms the construction of an emissions trading program, be it at the regional,

Introduction

Emissions trading, or cap-and-trade program, consists in setting a quantitative limit for the emission of a given pollutant and to let the market decide on its price. How do emissions trading schemes work in practice? This chapter aims at answering this question, by casting light on the functioning mechanisms of tradable permits markets. Such markets have been created in order to be able to trade polluted assets, as if they were standard production goods. By diminishing the circulation of pollutants, environmental benefits can be awaited from such schemes. The first issue raised by the creation of a tradable permits market is linked to the distortions which can occur as a consequence of the initial allocation. Initial allocation is the amount of pollutant that is distributed to preexisting agents to start with. Whereas Hahn (1984) contributed first to this debate by demonstrating the non-neutrality of permits allocation for an agent able to exert market power[1] in a static context and concerning the spatial exchange of permits only, this chapter explicitly addresses the critical aspect of initial permits allocation in a dynamic context and concerning intertemporal emissions trading. It is important to bear in mind indeed that a permit can be exchanged across various geographical locations (e.g., from one country to another) but also through time (e.g., one firm transfers permits to the future or from the future). These different kinds of uses of permits are called, respectively, spatial exchange and intertemporal trading.

On tradable permits markets, banking refers to the possibility for agents to save unused permits for future use, while borrowing represents the possibility to borrow permits from future allocations for use in current period. Agents are a very generic term in economics which can represent individuals (e.g., consumers), firms, or governments. In our context, agents are mostly understood here as polluting firms. By allowing agents to arbitrate between actual and expected abatement costs over specific periods, banking and borrowing permits form another dimension of flexibility where agents can trade permits not only spatially but also through time. Abatement cost represents the cost to diminish the quantity of pollution by one unit. In a continuous time model under certainty, Rubin (1996) shows that an intertemporal equilibrium exists on a permits market from the viewpoint of the

[1]For an exhaustive literature review on permits trading and market power, see Petrakis et al. (1999).

regulator and the firm and that banking and borrowing allow firms to smooth emissions. Indeed, it is the role of the government (or the environmental agency) to manage the tradable permits market, which is an artificial construction coming from environmental policy. Regulator can therefore refer to the State or the environmental agency. Under uncertainty, Schennach (2000) shows the permits price may rise at a rate less than the discount rate and new public information may cause jumps in the price and emissions paths.

Such provisions enabled agents to smooth their emissions stream and played a key role in the success[2] of the US SO_2 or Acid Rain Program. Surprisingly, the inclusion of banking and borrowing does not appear as a cornerstone of new "grand policy experiments"[3] dealing with climate change.

We bridge this gap by analyzing the various effects of banking and borrowing that need to be accounted for when designing tradable permits markets. This instrument is described indeed as a double-edged sword in the literature. On the one hand, banking provides incentives to over-comply and leads to an intertemporal reallocation of emissions so as to reach lower social damages. On the other hand, borrowing may give agents with high abatement costs an incentive to delay costly investments in clean technologies by borrowing allowances from future periods and to concentrate emissions in early periods. For example, if it is costly to diminish pollution when extracting coal, firms will pollute on a business-as-usual basis at the beginning of the scheme (by borrowing future permits), and they will wait for technological innovations to diminish their quantity of pollution in the future (and the associated use of pollutants). However, more pollution has occurred in the present time, which is not the objective of the tradable permits market. That is why the provisions on banking and borrowing need to be carefully designed. While the total allocation of permits sets the present value of discounted permits prices, we will see that other effects on the permits price may arise when introducing an intertemporal trading ratio for banked and borrowed allowances. Discounted permits prices can be defined as the total value of a permit discounted through time (by applying discounting as it would apply to any savings account for individual banks).

We therefore address the following two key questions: What are the effects of the initial allocation mechanisms in emissions trading systems? What insights can we get from the existing literature concerning the use of banking and borrowing in tradable permits markets? To detail the impacts of banking and borrowing on environmental damages will also be a priority throughout our analysis.

The remainder of the chapter is structured as follows. Section "Initial Allocation Mechanics" provides a background discussion on the initial allocation mechanics.

[2]The notion of success may be approximated by various effects (preexisting regulatory environment, technology innovation and diffusion, reduction of regulatory uncertainty, aggregate cost savings, etc.), but we will focus on the efficiency of the permits price, i.e., its ability to reflect current information on spot and future prices.

[3]This expression was coined by Stavins (1998).

Section "Banking and Borrowing Provisions" deals with banking and borrowing provisions. Section "Additional Flexibility Mechanisms" introduces additional flexibility mechanisms. Section "Conclusion" concludes.

Initial Allocation Mechanics

This section addresses allocation design issues of existing international emissions trading schemes, namely, the Kyoto Protocol and the EU ETS.

The Kyoto Protocol

The Kyoto protocol is the first of its kind at the international level to introduce carbon trading, i.e., the exchange of carbon dioxide units worldwide. The question of the Kyoto Protocol as an "unfinished business" is often evoked. Very heterogenous sectors were included under the same regulation, which could be detrimental to find the right method to allocate permits depending on price elasticities between sectors.

Since there exists no historical data for carbon emission reduction cost, it may prove particularly difficult to induce a cost-effective allocation of the initial quotas to participating countries. In the context of the Kyoto Protocol, the case of countries supplied with allocations in excess of their actual needs has been coined as *hot air* in the literature.[4] The distribution of a large number of permits to Former Soviet Union (FSU) and Eastern Europe countries (Russia, the Ukraine forming two thirds) may be seen indeed as an imperfection of the Kyoto Protocol, as those countries were given generous allocations to foster agreement during the first phase (2008–2012). Market power concerns arise as industrial firms may benefit from the gap between their initial permits allocation (based on 1990 production levels) and their real emission needs in 2008 (after a period of recession), and the use of these permits surpluses remains unclear.

This situation emerged as a conflict between the internal and the external consistency of the permits market:

- The *internal* consistency refers to the situation where agents freely receive or bid for permits according to their real needs. The regulator may be interested however in distributing more permits to a country than strictly needed (according to business-as-usual emissions or a benchmark for instance) in order to ensure participation to the permits market.[5] As a consequence, one agent may achieve a dominant position which in turns threatens the efficiency of the permits market itself.

[4]See Baron (1999), Burniaux (1999), Bernard et al. (2003), Bohringer et al. (2006), Holtsmark (2003).

[5]Such negotiation with Russia was determinant for the Kyoto Protocol to enter into force on February 16, 2005.

- The *external* consistency of the permits market is linked to the broader debate of climate change as the purchase of a "global public good."[6] This altruistic view embodies the notions of "burden sharing" or "common but differentiated responsibilities"[7] attached to the Kyoto Protocol, whereby developed countries agree to spend a higher income share on fighting climate change than developing countries.[8]

Those conflicting views undermine the negotiation of the cap, which is fixed at a suboptimal level compared to what would be needed to minimize the total damage to the environment. The cap can be defined as the overall quantitative limit of pollutants that can be emitted. The regulator sets the cap, and the market defines the price of the permit. Greenhouse gas (GHG) emission targets under the Kyoto Protocol represent a mere 5 % reduction below 1990 levels. Now if early movers like EU countries are willing to ratchet down the cap, little progress can be achieved without luring in major players like the USA, India, and China. Thus, many difficulties arise to pierce the "veil of uncertainty" around international negotiation.[9]

The fact that the creation of a permits market gives some countries the opportunity to draw a financial advantage without a direct environmental gain (i.e., in the absence of effective emissions abatement) may be puzzling. Yet as stated by Maeda (2003),[10] "[this debate] seems misguided because it focuses on the political importance of the issue, rather than addressing it from an economic perspective."

Overall, the hypothesis that generous allocations that broaden the scope of a cap-and-trade program might also give birth to dominant positions shall not be neglected. Recall that in a cap-and-trade program, the regulator sets the cap, and agents freely exchange permits to define their price.

The European Union Emissions Trading Scheme

This section deals with possible design flaws in the allocation of permits on the European carbon market.

The EU ETS Design: An Overview

The European Union Emissions Trading Scheme (EU ETS) has been established by the European directive 2003–7: this regional trading system for CO_2 emissions

---

[6]See Guesnerie (2006).

[7]See Muller (2002).

[8]Note that the implicit assumptions of the existence of such an environmental Kuznets curve (the environment is a superior good and environmental regulation becomes stricter through time at higher levels of GDP per capita) are left out of the debate.

[9]See Kolstad (2005).

[10]p. 295

covers, across the EU-27 member states, around 11,000 installations[11] representing close to 46 % of Europe's CO_2 emissions. In order to help EU member states to achieve their Kyoto target of reducing emissions by 8 % from those of 1990 level in 2008–2012, the European Union began this commitment in a pilot period from 2005 to 2008. The third European commitment period has started in 2013. Since 2005, the ETS operates independently of the Kyoto Protocol but has been linked to International Emissions Trading (IET) and other flexibility mechanisms in 2007. In this framework, the "Linking Directive" provides the recognition of Kyoto projects credits, Clean Development Mechanism and Joint Implementation credits from the second period in 2008, known as Certified Emission Reductions (CERs) and Emission Reduction Units (ERUs), respectively, for compliance use within the EU ETS.[12] CERs are traded worldwide and not only in Europe as for the EU ETS. Therefore, they can be understood as world proxy for the carbon price.

The EU ETS draws on the US sulfur dioxide (SO_2)[13] trading system for much of its inspiration but relies much more heavily on decentralized decision-making for the allocation of emissions allowances and for the monitoring and management of sources (Kruger et al. 2007). Within the EU-wide Kyoto target, each member state has its own national emissions target as determined under the EU Burden-Sharing Agreement that defines each member state's emissions reduction obligation. Each country is required to develop a National Allocation Plan (NAP), which, among other design features, addresses the national emissions target. A NAP contains the amount of permits allocated to each firm for each country. Each member state has its own registry where changes in the portfolio of its companies are recorded. Furthermore, there is a European Central Administrator, the Community Independent Transaction Log, to oversee the registry systems that will be standardized under European legislation. In that registry, allocations are reflected along with the purchases and sales for each company of the country (Mansanet-Bataller et al. 2007).

The EU ETS is expected to allow for cheaper compliance with the targets under the Kyoto Protocol by letting participating companies buy/sell their emission allowances. In this institutional framework, an amount of two billion allowances has been created each year during phases I and II (before the shift to auctioning in phase III). The EU ETS has started during 2005–2007 with the phase I, followed by phase II during 2008–2012, and phase III during 2013–2020. The price of the allowance is established by the supply and demand of market participants and the level of the scarcity created by the initial allocation.

[11]The definition of an installation effected in the EU ETS is the same as for Integrated Pollution Prevention and Control (IPPC) that is a principal environmental regulatory directive in the EU. Installations are defined as a stationary technical unit where one or more activities covered by the EU ETS are carried out and any other directly associated activities, which have a technical connection with the activities carried out on that site and which could have an effect on emissions and pollution.

[12]See Table 2 for a quick review of Kyoto units.

[13]The EU CO_2 emissions trading scheme was inspired by successful cap-and-trade programs for SO_2 and NOx in the USA (Ellerman and Montero 2007).

Over-allocation or Relative Success?

The EU ETS gently constrains emissions (8 % reduction for EU-27) so as to enforce a low carbon price. Yet the debate has shifted toward a possible over-allocation of permits. The production decisions of private actors are under scrutiny: do permits surpluses constitute a relative success (i.e., firms have reduced their emissions above projected levels) or an imperfection in the design of the system?

As long as governments continue to allocate allowances to existing facilities based on historic emissions, the scheme is flawed by a perverse "updating" incentive. Firms have indeed an incentive to delay early action in abatement technologies since higher emissions today will be rewarded with bigger allocations in future periods.

Buchner and Ellerman (2008) provide a first empirical assessment of the EU ETS allocation process based on 2005 emissions data. They estimate a slight over-allocation of 4 % during the first period of allocation, while there are strong signs that some emissions abatement measures have occurred. But the analysis is not straightforward since "*a long position is not per se evidence of over-allocation*."[14] The difference between 2005 allocation and verified emissions suggests too many allowances were allocated, but the benchmark against which this conclusion is reached may be biased by insufficient data reporting on emissions before 2005 and by a lack of comparability at the EU-wide level. Firms may also be long because of differences in marginal abatement costs or in expectations (regarding economic activity, energy prices, etc.) under uncertainty.

This section has provided an overview of two major tradable permits market along with their allocation methodology. It revealed a wide range of opportunities for strategic behavior in the design of international permit trading regimes. The presence of countries with large permits holdings increases the probability of price manipulation and the risk of efficiency loss in the allocation of abatement efforts between countries.

Banking and Borrowing Provisions

This section develops three kinds of issues surrounding banking and borrowing: *(i)* the environmental and economic effects, *(ii)* the distribution of the emissions stream through time, and *(iii)* the focus on the EU ETS experience (see also the paper by Chevallier (2012)).

Environmental and Economic Effects of Banking and Borrowing

We review the main effects of banking and borrowing provisions from the theoretical literature and empirical experiences on the environmental performance and

[14] p. 2

economic efficiency. When abatement together with endowment of emission allowances is above emissions levels, then regulated industrials bank surplus allowances for potential later use. Thus, an allowance issued for one compliance period may be used by an affected unit for a later compliance period. In the same way, if regulated industrials do not abate enough to cover their emissions level with their allowances endowment, they may borrow allowances from the future allocation. We already know as Haites (2006) noted,[15] "*allowance banking provisions affect basically environmental performance, economic efficiency and market participants' behaviour*." Hence, the regulator's decision of allowing banking creates the significant effects listed below:

Environmental effects:

- Allowance banking and borrowing change the temporal pattern of emissions and may change aggregate emissions and can have environmental, including public health, effects. Allowance banking and borrowing should facilitate adjustment to changes in the emissions cap.
- Banking provisions could also affect the rate of noncompliance and the resulting excess emissions. Evidence suggesting that allowance banking increases the rate of noncompliance is limited. In their experiments, (Cason and Gangadharan 2006) found that allowance banking increases noncompliance and total emissions in a hypothetical scheme with weak enforcement.

Economic effects:

- Allowance banking links future allowance prices to the current ("spot") market price as stated by Maeda (2004).
- Allowance banking and borrowing should improve liquidity[16] in the allowance market. Allowance banking tends to increase the quantity of allowances available to the market and increase the volume of allowances traded. In their experiments, Godby et al. (2000) and Cason and Gangadharan (2006) find that allowance banking increases trading activity.
- Allowance banking and borrowing should improve price stability. If banking is not allowed, allowance prices are likely to be unstable at the end of each compliance period. With no banking, if actual emissions are lower than the cap for the compliance period, the price of allowances should fall to zero at the end of the period since any remaining allowances have no value. With no banking, if actual emissions are higher than the cap for the compliance period, the price of allowances should rise sharply at the end of the period. Allowance banking should dampen such end-of-period price fluctuations and improve price stability.

[15]p. 7

[16]The liquidity market is defined as a market where a large volume of trades can be immediately executed with minimum effect on price (Kyle 1985).

These theoretical considerations on the banking provisions are also supported by Ellerman et al. (2000) on the US Acid Rain Program and by the results of a business simulation game and controlled experiments (Schleich et al. 2006) on the EU ETS. The US Acid Rain Program has been one of the most successful attempts to introduce tradable permits markets in environmental policy. That is why the EU ETS draws mostly on it.

The US Acid Rain Program provided empirical support to the view that market-based instruments may be more environmentally efficient than command and control regulation. SO_2 emissions fell, and the program was characterized by a quick implementation, a positive role of banking (twice as much as required), a good compliance, and no hot spots.[17] These optimistic results may be limited to flow pollutants since for stock pollutants like CO_2, the incentive to abate is less temporally and spatially constraining.

As documented by Ellerman and Montero (2007)[18] for the US SO_2 Program, "*banking of allowances remains the predominant form of emissions trading in Phase I (...) nearly three-quarters of the 9.5 million allowances freed up for emissions trading in the first three years of Phase I were banked for later use in Phase II*." This citation confirms the view of banking and borrowing as a key determinant for the success of a program.

In fact, the salient example is the US Acid Rain Program, where banking has been a major form of emissions trading (Ellerman and Montero 2007; Ellerman et al. 2000). During the first 5 years of the program constituting phase I, 1995–1999, only 26.4 million of the 38.1 million permits distributed were used to cover emissions. The remaining 11.65 million allowances (30 % of all the distributed allowances) were banked and have been gradually consumed during phase II (2000 and beyond). As a result, the phase II cap was expected to be reached sometime between 2008 and 2010. Ellerman et al. (2000) analyze in depth the efficiency of this banking behavior in the Acid Rain SO_2 program. The economically optimal level of banking depends first on the SO_2 emissions in the absence of the trading scheme, second on the SO_2 emission reduction cost function, and third on the discount rate. Using ranges of reasonable values for the discount rate and the rate of growth of SO_2 emissions in the absence of the trading scheme, Ellerman et al. (2008) find that banking behavior has been reasonably efficient during phase I and the first few years of phase II. We report in Table 1 the main features of banking provisions in existing trading schemes.

In a game simulation of the EU ETS, Ehrhart et al. (2005) find that a ban on banking pre-2008 allowances into 2008–2012 leads to an inefficient adjustment to the more stringent cap assumed for the latter period. In their simulation of the EU Emissions Trading Scheme, the ban on banking leads to a low price for allowances during 2005–2007 and underinvestment in emission reduction measures. The more stringent cap triggers a price spike during 2008 and 2009. The higher allowance

[17] Typically, the *cheapest* abatement source is found where the *larger* sources are located.

[18] p. 161

Table 1 Summary of banking provisions and liquidity data for different emissions trading schemes

Scheme	Gas	Banking and related provisions	Bank amount	Allowances traded as % of annual emissions
Current emissions trading schemes				
Acid Rain Program for electric utilities	SO_2	No limit on allowance banking	11.62 million	75–180 %
RECLAIM (Greater Los Angeles Area)	NOx	No allowance banking; can sell surplus allowances to a buyer with a later compliance deadline and buy allowances with a later vintage	0	20–125 %
	SOx	idem	0	10–105 %
Future emissions trading scheme				
Kyoto mechanisms	GHGs	Banking of different units from 2008–2012 period to the subsequent commitment period is restricted as follows:		
		RMUs may not be carried over		
		ERUs, which have not been converted from RMUs, may be carried over up to a maximum of 2.5 % of the party's assigned amount		
		CERs may be carried over up to a maximum of 2.5 % of the party's assigned amount		
		CERs and lCERs may not be carried over		
		AAUs may be carried over without restriction		
		The quantities of RMUs, ERUs, CERs, tCERs, and lCERs are likely to be small relative to the quantity of AAUs, so the banking restrictions can effectively be avoided by using units other than AAUs first for compliance and then banking surplus AAUs		

prices induce overinvestment in emission reduction measures, which causes the price to fall back to the optimal level by 2012.

The comparison of the banking case with the banning banking case is based on the assumption that prices will develop differently in the two cases (Ehrhart et al. 2005):

- If banking is allowed, it is reasonable (under some assumptions like participants having complete information and emission targets being known) to expect that the price development does not exceed Hotelling's rule (i.e., prices develop according to the interest rate or more slowly). Otherwise, arbitrage between periods is possible (Kling and Rubin 1997). In practice, excess emissions permits can be saved for future use or present emissions can be extended for future abatement. As a result, the permit price becomes arbitraged over time.
- In the banning banking case, a lower price is assumed in the first period than in the free banking period case because first period allowances cover only one period instead of two. Analogously, the price in the second period is assumed to be higher due to increasing scarcity of allowances in comparison to the banking case.

Distribution of the Emissions Stream Through Time

Another question needs to be addressed when assessing the relative merits of allowing banking and borrowing in tradable permits systems: how do firms adjust their emissions stream when they benefit from the possibility to freely bank and borrow permits?

A key issue lies in the discount rate picked by firms. Higher or lower discount rates imply respectively more or less borrowing, while a zero discount rate leads to the same level of pollution at each period.

Our analysis therefore highlights potential *negative* consequences of the use of unrestricted borrowing: the concentration of emissions on early periods by delaying abatement decisions and borrowing may aggravate environmental harm. The positive effects of banking on total present environmental damages are reversed, and the level of global pollution is higher than in a situation without borrowing.

Concerning banking, firms invest in abatement technologies and bank allowances when they anticipate an increase in abatement costs superior to the discount rate; otherwise they would not bear additional abatement costs in the current period. This mechanism corresponds to a situation where standards are stricter through time, which is often the case. In the presence of a convex damage function coming from emissions and stricter future standards, the decision to allow banking *reduces* social damages.

This *positive* effect of banking counterbalances the negative aspects of borrowing detailed above and gives us a more precise picture of the task of the regulator when tailoring regulation for permit trading systems. When social damages are an increasing function of the pollution level at time *t*, our policy recommendation consists in authorizing banking and enforcing stricter pollution standards through time. When the cap is constant or becomes less constraining, the decision to allow borrowing leads to either increasing social damages or decreasing costs for firms.

We have seen how permits alter the *timing* and the *magnitude* of marginal damages. We address in the next paragraph the question of introducing a non-unitary Intertemporal Trading Ratio (ITR) including interests on banking and discouraging borrowing to correct these unwanted permits path.

On the Use of the Intertemporal Trading Ratio

In this section, we evaluate the merits of a modified model of banking and borrowing that explicitly takes into account the distribution of the emissions stream through time. Using the interest rate on allowance balances, the regulator may change the time profile and cumulative quantity to approximate more nearly the social optimum.

There are two sources of inefficiencies that might affect the social optimum:

1. The discount rate used by firms
2. The fact that total damages depend on the distribution of the emissions stream through time

A modified banking system may correct the first type of inefficiency highlighted above, but not necessarily the second type.

Due to the effect of discounting future abatement costs, we need to penalize borrowing by an ITR exogenously chosen by the regulator[19] so that if firms borrow a lot of allowances in early periods, they will reimburse more allowances than actually used in the next period.

This "banking and restricted borrowing" according to Kling and Rubin's (1997) contribution yields the following comments:

- Setting $ITR < 1$ provides an efficient incentive to banking, since firms need to reimburse **more** allowances in second period than were borrowed in first period.
- The weight of debt is greater under a modified banking system than under the original system.
- Such a modified banking and borrowing system allows the private and social solutions to converge, assuming constant and linear social damages.

Assuming both banking and borrowing are allowed and there is a positive private discount rate, the introduction of an ITR yields:

- Concerning banking, the opportunity cost of not using the permit is compensated by the ITR payment.
- Concerning borrowing, for each ton of CO_2 non-abated, the gain from agents' private interest rate is reduced by the ITR.
- The primary effect of a nonzero ITR is on time profile, not quantities: there is a change in marginal stock damages over time (more banking and less borrowing relative to a permit system without ITR) and a small effect on quantities intertemporally exchanged.

For greenhouse gases, the optimal rate of intertemporal substitution has been suggested by Leiby and Rubin (2001) as being "*the ratio of current marginal stock damages to the discounted future value of marginal stock damages less the decay rate of emissions in the atmosphere*[20]," increased by the difference between the firm's discount rate and the social planner's discount rate. This result is obtained in a different setting since they distinguish between *flow* (emissions flow) and *stock* (accumulated) pollutants. Typically, CO_2 emissions are characterized by stock damages that do not stop at the end of the program.

We have seen in this section that the correct determination of the intertemporal discount rate may yield greater efficiency gains. With reference to the discussion on the intertemporal trading ratio above, we may cite several time devices used in

[19] Kling and Rubin (1997) suggest the implementation of a discount rate equal to the industry average rate of interest used to finance medium-term capital expenditures (p. 112).

[20] p. 251

tradable permits programs: the Progressive Flow Control in the US Northeastern NOx Budget Program, changed redemption ratios in US Clean Air Interstate Rule (2:1 from 2010; 3:1 from 2015), and growth indexed caps.

To sum up, characteristic features of intertemporal emissions trading include the fact that at the equilibrium abatement costs are equalized among sources and that the distribution of emissions through time need not yield to a concentration in early periods. The decision to allow or not borrowing depends on the arbitrage between the firm's cost efficiency and a higher pressure on the environment. Firms tend to use borrowing if the environmental constraint is constant or does not become a lot stricter over time. That is why it is recommended to introduce a discount rate specific to borrowed allowances.

Prospective Use of Banking and Borrowing in the Kyoto Protocol

This section offers a description of the possible use of banking and borrowing in the Kyoto Protocol. On the one hand, provisions on banking are cited by Klepper and Peterson (2005)[21]: "*Assigned Amount Units (AAUs) resulting from the Kyoto commitment can be banked without a time constraint. Credits from Joint Implementation (JI) or Clean Development Mechanism (CDM) can be banked up to a limit of, respectively, 2.5 % and 5 % of a Party's initial assigned amount. Sink credits can not be banked.*"

On the other hand, implicit provisions on borrowing may be found in the United Nations Framework Convention on Climate Change or UNFCCC (2000) report.[22] As explained by Newell et al. (2005)[23]: "*International climate policy discussions have implicitly included borrowing within possible consequences for noncompliance under the Kyoto Protocol, through the payback of excess tons with a penalty (*i.e.*, interest).*" This penalty could be fixed to 40 % of additional emissions reduction for the next period of the Kyoto Protocol despite uncertainties regarding the enforcement of this particular provision. This question is addressed in depth by Alberola and Chevallier (2009).

In the next section, we discuss the efficiency of the EU ETS intertemporal market. We also question the presence of institutional learning in the EU ETS.

A Focus on the EU ETS Experience

The EUA price path reflected the evolution of market participants' expectations about the scarcity of allowances. Beginning at 8€ on January 1, 2005, EUA prices increased to around 30€ in July 2005, fluctuated during the six following months in the range from 20€ to 25€, then to 30€ until the end of April. This price development surprised most experts and market participants. According to

[21]p. 295

[22]Paragraph II.XV

[23]p. 149

Sijm et al. (2005), the increase was largely due to political decisions on unpredictably strict national allocation plans, but the market reaction was to some extent exaggerated. Behind the price increase there were also high fuel prices, cold weather, the absence of suppliers in the market, and uncertainty about the political environment (Lecocq and Kapoor 2005). The price fell suddenly at the end of June because of weaker UK gas price and the entrance of Czech Republic into the market. The price fluctuated around 21–23€ for the rest of the year. At the beginning of 2006, the price increased to way above 25€ in consequence of cold weather and high fuel prices. For a couple of months the price stabilized, and then it reached a maximum of over 30€ in April driven by fuel prices.

Around April 25, 2006, first rumors occurred about contents of the national emissions reports for the first year of compliance by the EU member states. The official publication of these emissions reports on May 15 verified the rumors. It became apparent that the market was not as short as expected; especially the power producer needed less EUAs than anticipated (Seifert et al. 2008). The release of the emissions data had a market effect on EUA prices, causing a sharp break in the price of all maturities of EUAs. There were further less severe price fluctuations until the complete data were released on May 15; however, the essential adjustment was made in these 4 days, and after May 15, the spot price remained close to 15€ until late September when a further less-pronounced adjustment occurred.

As noted by Buchner and Ellerman (2008), "*this price "collapse" demonstrated a readily observable characteristic of markets of reacting quickly (and from the standpoint of some, brutally) to relevant information*." This is a significant sign of the informational efficiency of the EU ETS. The EUA market can be considered as efficient if prices fully reflect all available relevant information divulged. And there should be no doubt that the release of reliable information concerning emissions covered by a cap-and-trade program is highly relevant. According always to Buchner and Ellerman (2008),[24] "*one plausible explanation is that market observers had over-estimated the level of CO_2 emissions and the demand for allowances caused by rising real output, the adverse weather in 2005, and the higher prices for natural gas relative to coal. But, another more intriguing possibility is that market observers under-estimated the amount of abatement that would occur in the first year of the EU ETS (. . .)*." The cap is always known, but until the release of aggregate emission data, no one has a really good idea of either the level of aggregate emissions or how much emission reduction/abatement is required to comply with the cap. The same phenomenon was observed in the US SO_2 emissions trading program when the first auction revealed emissions and the implied demand for allowances to be much less than expected (Ellerman et al. 2000). Each year, the European Commission will disclose the verified emissions, playing the role of a "banker." After a new increase to 20€ in June, EUA prices stabilized in a range from 15€ to 17€ and then, in consequence of a less cold winter, they have been

[24] p. 33

declining these last 3 months. Recall that European Union Allowances are the carbon trading unit that is exchanged under the EU carbon permit scheme for each ton of carbon dioxide emitted in the atmosphere.

With two trading periods, EU ETS futures markets are divided in two segments which respond to two distinct fundamentals. As it approached the end of 2007, the EU ETS was characterized by two price signals responding to different dynamics, because of the very limited opportunity to carry over unused EUAs from phase I to phase II. While the prices of spot and futures contracts for the first period were down sharply, the prices of futures contracts for the second period surpassed 18€/t. This increase of the second period allowance price is primarily due to institutional factors: the European Commission issued its opinion on ten National Allowances Plans for the second period since the end of November 2006. In doing so, it established the basis for the institutional framework for 2008–2012 and gave indications regarding three factors that will have a decisive effect on the allowance price:

- The Commission has requested that the allowances awarded to installations be reduced. The Commission also reaffirmed its rejection of ex post allowances based on adjusted projections of growth and emissions. Brussels has therefore sent a clear signal of the scarcity of the allowances that will be available in 2008–2012.
- The possible carryover of unused allowances from the first to the second period ("banking") is now subject to conditions that are so restrictive as to make it practically impossible. Nevertheless, banking between the second and subsequent periods is still permitted, which could further increase the scarcity of allowances in 2008–2012.
- The use of credits originating from project mechanisms created by the Kyoto Protocol (JI and CDM) has been significantly restricted. Ireland has thus been forced to reduce its ceiling from 50 % to 21 %, which corresponds to 35 MtCO_2 less over the period; Sweden will have to reduce its own ceiling from 20 % to 10 %, i.e., 11 Mt CO_2 less than planned.

As Ellerman and Parsons (2006) noted,[25] "*it is virtually certain that the EU ETS will then be either long or short; the likelihood of a perfect match between 1st period EUAs and emissions are extremely small. This binary outcome places a limit on 1st period prices that, when coupled with the constraint on inter-period banking, allows a probability of shortage to be calculated taking into account all the uncertainties weather, economic growth, energy prices, and the abatement response to carbon prices.*" Without banking between the two trading periods, they measure the probability of shortage at any point in time by the ratio of the first period price to the second period price plus 40€, which represents the penalty. The penalty will be 100€ thereafter and companies will also have to surrender a compensating amount of allowances.

[25]p. 1

To wrap up, during the first 3 years, banking and borrowing of allowances are allowed. Therefore, we can expect that first period CO_2 prices follow Hotelling's rule which in its simplest model predicts that, under perfect information, the price of an exhaustible resource will rise at the rate of interest r. However, in the case of the ban of banking between the two periods 2005–2007 and 2008–2012, we highlighted a total disconnection between each exchange market and a decline of the first period prices.

Evidence of Institutional Learning Within the EU ETS

The previous discussion suggests that EUA prices are affected by institutional events such as the simultaneous release in April 2006 of 2005 verified emissions by the Walloon Region of Belgium, France, and Spain. Trading based on information before this price adjustment may be characterized as hazardous or speculative, and only these 2005 verified emissions could give a hint about the long and short positions at the installation level. Most of the verified emissions were reported by mid-May. The fact that the EUA price responded quickly to such relevant information may be interpreted as a strong sign of the efficiency of the intertemporal market in the EU ETS. The EU Commission has greatly learned from the 2005–2007 warm-up period. Namely, most of the issues regarding banking and borrowing have been fixed between 2007 and 2008. The transition from phase II to phase III has mostly been characterized by a change in the allocation methodology, going from free allocation (i.e., grandfathering) to actually having to bid for permits (i.e., auctioning).

Additional Flexibility Mechanisms

In this section, we highlight the possibility for firms to achieve their abatement targets not only by intertemporal emissions trading but also by getting credits from projects (Clean Development Mechanism, Joint Implementation, Domestic Offset). Firms may also take advantage of other tradable permits markets options designed to stabilize prices, such as a safety valve or minimum-price auctioning. Table 2 provides a useful glossary of Kyoto units.

Clean Development Mechanism and Joint Implementation

Projects provide more flexibility to operators to fulfill their obligations and increase market liquidity. The use of credits generated by projects, additionally to the number of allowances distributed, may reduce EUA prices even in the presence of high transaction costs for early projects. It also enlarges the range of abatement opportunities for firms and may lower the compliance costs if it is cheaper to invest in JI or CDM projects than trading.

But this hypothesis crucially depends on the relative price of credits, the possibility to access project credits at a lower cost than through trading on the

Table 2 Glossary of Kyoto units

Assigned Amount Unit	AAU means a unit derived from an Annex 1 Party's assigned amount. They are tradable units that Annex 1 Parties may count toward compliance with their emissions target. Each AAU is equal to one ton of carbon dioxide equivalent gases
Certified Emission Reduction	CER means a unit issued pursuant to Article 12 of the Kyoto Protocol. These are tradable units generated by projects in non-Annex 1 Parties under the Clean Development Mechanism. They may be counted by Annex 1 Parties toward compliance with their UN and EU emissions target and are equal to one ton of carbon dioxide equivalent gases
Emission Reduction Unit	ERU is a unit issued pursuant to Article 6 of the Kyoto Protocol. These are tradable units generated by projects in Annex 1 Parties under Joint Implementation. Annex 1 Parties may count them toward compliance with their emissions target. Each ERU is equal to one ton of carbon dioxide equivalent gases
Removal Unit	RMU is a tradable unit issued on the basis of removals of greenhouse gases from the atmosphere through LULUCF activities under Articles 3.3 and 3.4 of the Kyoto Protocol. Annex 1 Parties may count them toward compliance with their emissions target. Each RMU is equal to one ton of carbon dioxide equivalent gases.

Note: These are units derived from Annex 1 Party's emissions target under the Kyoto Protocol. They may be counted by Annex 1 Parties toward compliance with their emissions target and are equal to one ton of carbon dioxide equivalent gases. AAUs, RMUs, ERUs, and CERs are Kyoto units.

market, and the size of the firm (due to informational and administrative requirements). If banking allows to reduce uncertainty on the delivery of CDM or JI projects, those two instruments may be complementary.

From the viewpoint of economic rationality, carbon assets delivered by projects (be it AAUs, EUAs, CERs, or ERUs) should be fungible. This question implies creating gateways between different frameworks. As the second period of the EU ETS coincides with the first commitment period of the Kyoto Protocol, every transaction of EUA is simultaneously backed by a transfer of AAU between the registries of the different countries concerned. The Linking Directive recognizes JI/CDM credits as equivalent to EU ETS allowances. To maintain a single currency within the EU ETS, the participant delivers project credit to the national authority and gets issued an allowance in exchange for it.

Since credits from the CDM projects can be used for compliance during both phases of the EU ETS,[26] they should cap the price of 2008 allowances and provide a better long-term price signal than the price of 2005–2007 allowances to guide decisions as to which emission reduction measures are cost-effective during 2005–2007. No JI credits are available before 2008.

In this context of interlinked schemes at the regional and international levels, the price stabilization properties of banking and borrowing may prove to be useful to convey a unique carbon price. Next, let us discuss innovative schemes at the domestic level.

[26]As soon as they are connected by the International Transaction Log

Domestic Offset Projects

According to Egenhofer and Fujiwara (2007), "*domestic offset projects (DOPs) mirror the concept of project mechanisms articulated in the Kyoto Protocol, but are used within the home country to reduce emissions in the non trading sectors*."

Those voluntary agreements may incentivize low cost reductions in non-ETS sectors that were not identified previously due to the diffuse nature of polluters, provided the reductions are additional. In return, installations get credits in their respective carbon market.

To overcome the potential complexities of administrative requirements for small units and to keep transaction costs at low levels, there is a need for pilot schemes with simplified rules for additionality, baselines, and discounting and that allow pooling.

Some examples may already be found in New Zealand, New South Wales (NSW 2006), and proposals have emerged in Canada (Bramley 2003) and in the USA at the regional level.[27]

An experimental scheme is currently being implemented in France by the CDC Climat. Eligible projects have a concentration on waste, renewable energies, agriculture, and forestry but also concern the sectors of transport and energy efficiency. Within the JI framework, the CDC Climat selects for each project a foreign partner and will buy at a predetermined price ERUs that will be granted by the French government. The upper limit is set to five million ton equivalent CO_2 between 2008 and 2012. Those emission reduction projects will impact the Kyoto target by an equivalent reduction in the national inventory.

Such an innovative scheme is designed to foster the discovery of new low-cost emission reduction sources at the national level. However, its development may be hampered by the EUA price volatility that we commented above. That is why we recommend the adoption of a clear EU-wide institutional framework where a careful use of banking and borrowing may contribute to dampen allowance price fluctuations.

Next, we discuss another flexibility mechanism to limit price volatility called a safety valve.

Safety Valve

Some propositions to cope with the EUA price volatility deal with the inclusion of a "safety valve" in the EU ETS.

A safety valve is a hybrid instrument to limit the cost of capping emissions at some target level whereby the regulator offers to sell permits in whatever quantity at a predetermined price. If prices are greater than expected, the marginal cost of

[27]See for instance the Regional Greenhouse Gas Initiative at *http://www.rggi.org/* and a review of regional initiatives by Roy (2007).

abatement would be limited to the safety valve price. The regulator tries to set the emissions cap at a level where the expected marginal cost of meeting the constraint will match the beliefs about marginal benefits. To avoid being too far away on the high-cost side, the regulator includes a provision to sell emissions permits at some price near that expected cost level.

Jacoby and Ellerman (2004) report this idea emerged out of discussions in the USA around the costs related to the Kyoto Protocol as a way of raising the likelihood of Protocol's ratification by blunting criticism that the cost of meeting the Kyoto targets would be too high. The best example to date of a system that would have required a safety valve is the RECLAIM Program in California.[28]

The inclusion of a safety valve to a tradable permits market is not new, despite strong criticisms about this instrument:

- If the safety valve price is too high, it will have no effect.
- If the safety valve is too low, the quantity constraint is not binding anymore and may be associated with a permanent tax.
- There is a potential loss of "environmental integrity," i.e., a fear of relaxing toward target reduction instead of supporting economically efficient implementation.

These negative effects lead us to be skeptical about the inclusion of a safety valve as a policy recommendation for the EU ETS.

Finally, we discuss another flexibility mechanism linked to the allocation process.

Minimum-Price Auctioning

To improve the stability of EUA pricing during 2005–2012 (before the shift to auctioning), the National Allocation Plans may have included a provision to allocate permits not only by grandfathering, whose "updating" effects based on past emissions may be detrimental to the efficiency of the scheme, but also by auctioning. While it is beyond the scope of this paper to deal with auctioning mechanisms in detail, it is worth emphasizing the benefits of a specific technique called "minimum-price auction" whereby governments could fix a minimum bid level that would serve as a price floor.

[28]According to Harrison (2003), this multisource program regulating SO_2 and NO_x emissions had overlapping control cycles and trading between control groups, so de facto 6-month banking and borrowing. But the temporal flexibility was not enough for such a limited geographic scope, and as unusual weather conditions and lack of new capacity placed high demand on existing units, the permit price rose from $5,000 to $90,000 per ton, i.e., multiplied by 18. The disconnection of electricity and environmental markets associated with other program design failures led the State to eventually take over and provide adequate electricity supply. At the same time, prices of future vintages (borrowing) revealed the short-term nature of the crisis and recognized that it was an unusual case. This experience raises the question of adding several sectors in the same permit market like the EU ETS: wouldn't it be preferable to have different prices for different markets?

Such an allocation process requires a certain degree of coordination between member states on basic auction rules, while the Commission supervises its enforcement as for each NAP. This device guarantees that prices will not drop below a predetermined level and helps restoring confidence in the efficiency of the EU ETS for market participants. But it needs to be configured in accordance to the quantitative limit on projects that might enter the EU ETS for instance.

In this section, we stressed that the banking and borrowing mechanisms should not be seen in isolation of other flexibility mechanisms that firms could use to achieve compliance at a lower cost. Those include mainly projects (JI, CDM, DOP), whose efficiency may be increased by a careful use of banking and borrowing. We discard the use of a safety valve as a useful flexibility mechanism, but we recommend political savvy in auctioning permits using a minimum price.

Conclusion

This chapter summarizes the main functioning principles of tradable permits markets for use in environmental regulation along two dimensions: initial allocation and intertemporal trading.

Among the international emissions trading schemes, we may cite the Kyoto Protocol and the EU ETS. From a political economy perspective, this chapter highlights the difficulties encountered by the European Commission during the validation of the EU ETS Second National Allocation Plans where each national regulator needs to arbitrate between various interests at stakes and reveals the necessary compromise that needs to be found between various conceptions on the role of environmental regulation.

The negotiation process of each NAP at the member state level is typically an example of a manipulable rule whereby industries may conduct lobbying activities to extract more permits as a monopoly rent. With reference to the debate “rules versus discretion” in monetary economics, this unhealthy lobbying by major industries calls for further research to ascertain the conditions under which it would be optimal to delegate the determination of the cap and the distribution of permits to an independent agency (Helm et al. 2003).

Regarding intertemporal flexibility, the theoretical studies agreed on the fact that when it is effective, banking and borrowing allow a reduction of climate policies costs. The incentive to bank emerges more especially with more stringent future environmental targets. Our review of the main theoretical results on the use of banking and borrowing for tradable permits markets provides a balanced picture of the pros and the cons of this instrument: while banking provides incentives for early compliance, unrestricted borrowing may aggravate the environmental harm by a concentration of the emissions stream over specific periods.

Combined with generous and free permits endowments, this situation confirms the view that the EU ETS is only “warming up” in its first phase at the expense of suboptimal abatement choices. The regulator could adopt an intertemporal trading ratio specific to borrowing as discussed by Kling and Rubin (1997), allowing for a better grasp of the possibilities offered by intertemporal emissions trading.

Indeed, a greater reliance on banking and limited borrowing (i.e., with a specific discounting factor) should be promoted to allow firms to smooth their emissions and take investment decisions in abatement technologies with a better capacity to react to the evolution of the carbon constraint over time.

Strategic Environmental Assessment as a Tool to Integrate Climate Change Adaptation: A Perspective for Nigeria

Chika Ubaldus Ogbonna and Eike Albrecht

Contents

Abstract

Nigeria is one of the countries in sub-Saharan Africa vulnerable to current and future climate variability and change. The effects of climatic changes in Nigeria would vary significantly and set to occur in several regions of the country and all sectors of the economy. Climate change is a great challenge to the sustainable development and the Millennium Development Goals (MDGs) in Nigeria. The main purpose of this chapter is to highlight the challenges associated with the current and projected impacts of climate change on the human environment

in Nigeria, to review and explore the potentials of Strategic Environmental Assessment (SEA), and to propose its use in making informed decisions relevant to the implementation of the newly established adaptation programs in the country. Current measures on how Nigeria is responding to recent impacts of climate change are presented. It is imperative that an appropriate environmental assessment tool such as SEA be employed in making rational decisions regarding adaptation options. SEA offers a structured and proactive environmental tool for integration of climate change adaptation into formulating policies, plans, and programs (PPPs) across relevant sectors.

Keywords
Nigeria • Climate Change • Adaptation • Strategic Environmental Assessment (SEA) • Decision-making

Introduction

Climate change is occurring and may have more consequences on the human environment in the future. The fourth assessment report of the Intergovernmental Panel on Climate Change (IPCC), published in 2007, fully confirmed the occurrence of global climate change particularly in developing countries. This report also categorically emphasized that human activities are the main cause of observed changes in climate today (IPCC 2007a). This fact was also restated by the recent published 5th assessment report of the IPCC in 2014 (IPCC, 2014, p. 5). Such anthropogenic influences that contribute to climate change include the burning of fossil fuels, the combustion of biomass, agriculture, and deforestation. According to a German Watch Report, more than 710,000 people have lost their lives as a result of direct effects of over 14,000 recorded extreme weather and climate events which resulted in some damages worth above USD 2.3 trillion (in Purchasing Power Parity) observed globally between 1991 and 2010 (Harmelling 2011, p. 4).

The UNFCCC has already identified adaptation as an option to address climate change. Adaptation in the context of climate change refers to any adjustments that take place in natural or human systems in response to actual or expected climatic stimuli or their effects or impacts, aimed at moderating harm or exploiting beneficial opportunities (Klein 2004; IPCC 2007b; IPCC 2014). "Adaptation, therefore, includes several types of actions (direct protection of people and assets, actions to support this protection, reactions with respect to impacts, etc.), which can be implemented in several sectors such as (agriculture, water, energy, transportation, infrastructural development etc.), associated with different climatic challenges depending on geographic scales and zones (coastal, mountains, urban areas, etc.) and using widely diversified instruments (standards, information, tax measures, transfers, investment choices in infrastructure, etc.)" (IPCC 2007b cited in Hallegatte et al. 2011, p. 3).

To deal with the impacts of climate variability and change in Nigeria, there is a need for robust adaptation measures to be implemented. The United Nations

Framework Convention on Climate Change (UNFCCC) which entered into force on 21 March 1994 provides the basis to adapt to climate change impacts. Nigeria signed the convention on 13 June 1992; its ratification took place on 29 August 1994 which entered into force from 27 November 1994. Article 4(1)(f) of the UNFCCC urges all members to "take climate change considerations into account, to the extent feasible, in the relevant social, environmental, economic and environmental policies and actions, and employ appropriate methods, for example, impact assessments [such as Environmental Impact Assessment (EIA) and Strategic Environmental Assessment (SEA)], formulated and determined nationally, with a view to minimizing adverse effects on the economy, on public health and on the quality of the environment, of projects, programs or measures undertaken by them to mitigate or adapt to climate change" (See full text of the Convention).

The Effects of Climate Variability and Change in Nigeria

Climate change is the latest challenge to achieving sustainable human development targets such as the Millennium Development Goals and objectives set out in the Nigerian development agenda termed "Vision 2020" (NASPA-CCN 2011, p. 1). "Nigeria has a long history of changing weather and environmental conditions this is due to its many climatic zones, ranging from the long coastal zone in the South and the large arid area in the North" (NEST and Woodley 2012). Such changes in climate and weather patterns are now on the increase in several parts of the country. Such trends are validated by recent research, for instance, Nwajiuba and Onyeneke (2010) applied regression model and trend analysis of climate data for a period of 30 years (1978–2007) in the Southeast Rainforest Zone of Nigeria. The outcome of this research shows that decreasing trends for rainfall and relative humidity and increasing trends in temperature and sunshine hours pose severe effects on major crop yields such as maize, cassava, and yam which serve as major food crops in the region. The impact of climate change can already be seen across the country starting from the Sahel in the North to the rainforest and coastal zone in the South (BNRCC 2011). A study carried out by Odjugo (2010) shows that air temperature is constantly on the increase, especially since the 1970s. Despite the relative increase in temperature across Nigeria, observational trends in temperature indicate higher temperature anomalies in the semiarid region of the country than the coastal regions (Odjugo 2010, p. 1). In fact, urban areas and cities are facing new challenges of the so-called urban heat islands. The changing climatic conditions are apparent and have become a big challenge in Nigeria today, posing severe effects on social infrastructure and people's livelihoods. Some of the potential effects of climate change and variability in the country include extreme weather events, temperature increase, increase in flooding, coastal erosion, sea-level rise, and long periods of droughts in the North and variability of rainfall in the South. The expected climate impacts in urban areas in the country are likely to include extreme flooding due to heavy storms, heat waves, freshwater scarcity, and extreme weather events. Furthermore, such climate impacts may add more stress to public infrastructures and on urban sectors such as tourism, transportation, energy generation, and agricultural production. For example, flooding is one of the most pressing environmental challenges in Nigeria today. There are three major ways in which flooding occurs in Nigeria, namely, river flooding, urban flooding, and coastal flooding (Gwary 2008; Adeoti et al. 2010; Bashir et al. 2012). The impacts of flooding have been observed in Nigeria for decades. However, increase in flooding as a result of storm surge and variation in sea levels may become more frequent in the country in the future considering global and regional predictions.

There are several projections, which point to increase in sea-level rise in the Nigerian coastal waters. For instance, a rise in sea level of 0.462 m (above sea level) was recorded in the coastal areas between the year 1960 and 1970 (Udofa and Fajemirokun 1978, Boateng (2010, p.13). It is projected by Awosika et al. (1992) that the Niger Delta area of the country could lose more than 15,000 km^2 of land by 2100 with only a one meter rise in sea level. Lagos and the low-lying coastal areas of the Niger-Delta region of Nigeria are predicted to be equally affected by such events (Awosika et al. 1992). Nwajiuba (2008) foresees that important coastal cities in Nigeria such as Lagos, Port Harcourt, Calabar, and Warri are potential areas for inundation exposure as a result of the projected sea-level rise and storm surge events. Moreover, urban flooding has become one of the greatest environmental challenges in most of the Nigerian cities nowadays (Etuonovbe 2011). Settlements

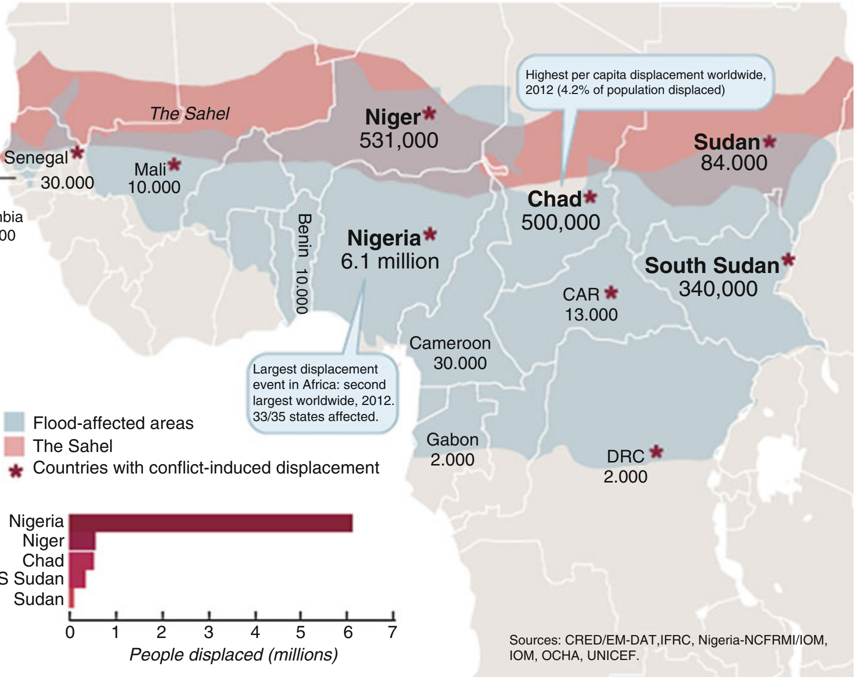

Fig. 1 Map of West and Central Africa flood displacement, June to October 2012 (Source: IDMC/NRC (2013, p. 20))

in the coastal region of Nigeria are being seriously affected due to severe flooding (Uyigue and Agho 2007). Similarly, the International Displacement Monitoring Centre Report (2013) mapped and documented the severe heavy rainfall that affected about 18 countries in Africa from June to November 2012 as can be seen in Fig. 1. The map shows that heavy rainfall event caused flash flooding, inundation, and displacement of vulnerable communities in the region including about 6.1 million people in Nigeria alone.

Factors Increasing Nigeria's Vulnerability to Climate Change

There are several factors that exacerbate the vulnerability of Nigeria to climate change. For example, the rapid shift in Nigeria's demography poses own challenges in the face of climate change. Nigeria's current population is estimated to be about 160 million people and a population density of 138 people per km^2 is growing tremendously (BNRCC 2011, p. 1; Ndujihe 2013). According to a report from the "Building Nigeria's Response to Climate Change project" (BNRCC 2011), increasing population density in the country is an additional pressure on scarce natural resources and food security (BNRCC 2011, p. 1; Nest and Woodley 2011, p. 5). This further increases the vulnerability of the most particularly exposed communities. The rate of population growth and urbanization may also increase vulnerability through inappropriate land-use and land fragmentation. Furthermore, rapid population growth (2.9 % per year) and urbanization with nearly 50 % of the population now living in the urban area has added demand for public infrastructural services (NASPA-CCN 2011, p. 3). This present situation reduces the resilience to a range of climate risks in the country (NASPA-CCN 2011, p. 3). Furthermore, some fast-growing cities and urban areas in Nigeria are mostly situated along the coast and therefore highly vulnerable to the impact of sea-level rise. For instance, the urban and suburban areas of Lagos and the Niger Delta could be adversely affected considering the predictions. The ever-growing coastal slum population living in floating slums and flood-prone wetlands in and around Lagos suburban area is a challenge to urban planning and development. In addition to slum development, the city of Lagos faces a problem of coastal erosion and flooding (Mehrotra et al. 2011, p. 30). Such areas may be drastically affected by climate hazards if the projected climate events would occur (Awosika et al. 1992; Mehrotra et al. 2011, p. 32).

Another factor is land degradation as a result of deforestation and overgrazing in Nigeria (Abiodun et al. 2011, p. 1). This accumulates to large environmental challenges, which have been seen in various parts of the country, in recent times. Climate change would intensify such environmental problems. The incessant oil spillage and gas flaring in the Niger Delta had contributed immensely to the environmental degradation of the region (Ugochukwu and Ertel 2011). Climate change will add to such challenges, as a result will increase the region's vulnerability.

Indeed, both physical and socioeconomic factors dispose Nigeria to the adverse effects of climate change (BNRCC 2010). According to the Nigerian Environmental Study Action Team Report (NEST) (2010), some of these factors include

(1) Nigeria's long coastline (800 km), prone to impacts from the rise in sea level; (2) Nigeria's North prone to drought and desertification; (3) threatened water and energy resources; (4) more than 60 % of the population depends on threatened agricultural and fishing resources; (5) increasing population; and (6) inadequate policies and programs, especially among vulnerable communities and in vulnerable regions. Nigeria is vulnerable to the impacts of climate change largely because approximately 70 % of Nigerians are engaged in smallholder rain-fed agricultural production (NEST and Woodley 2011, p. 10).

In this respect, however, the current and potential impacts of climate change are likely to be different in several parts of the country. For instance, Nigeria's long coastline to the South situated in the coastal/rainforest region implies that a huge number of people living close to the coast are vulnerable to sea-level rise and storm surges, while several communities residing in the Northern part of the country particularly in the Sahel region could experience increased effects of cyclical drought (BNRCC 2011). Current observations in the Sahel region show that the area is susceptible to aridity as a result of increasing high temperatures and reduced frequency of rainfall (BNRCC 2011). Furthermore, biodiversity, coastal settlements, water, agriculture, and land use are expected to be affected by the fast-increasing trend of climate variability in the country.

Policy Response to Climate Change Adaptation

There are several new challenging issues associated with changes in weather and climate deserving adaptation considerations in Nigeria today, perhaps more than the several impacts highlighted as the increase in extreme climatic events pose an enormous challenge to the Nigerian economic growth (DFID/ERM 2009; Sayne 2011). As such, many parts of the country have recorded different kinds of climatic changes, which have led to increase in flooding, heat waves, erosion, and droughts. Erratic increase in rainfall, flooding, and drought, for instance, can reduce efforts being made to achieve sustainable development and the Millennium Development Goal (MDGs) in Nigeria, especially as future vulnerability may not only depend on climate change but also on several other factors such as development pathways (UNFCCC 2010). In this regard, adaptation is essential to reduce the present and future impacts of climate change in Nigeria in order to rescue vulnerable communities, agricultural sectors, ecosystems, and at the same time increase the adaptive capacity of the population.

Globally, awareness on climate change in recent times has been on the increase as well as vulnerability research. As a result, there are several actions from many stakeholders in the public and private sectors especially at the national and local levels that focus on understanding the challenges that besiege climate change issues and what they can do to reduce the associated effects (Hallegatte et al. 2011, p. 3). Such trend is peculiar to Nigeria today although more effort is needed from individuals, nongovernmental organizations, institutions, and particularly from the government, for increasing awareness and public education with respect to climate change adaptation and even on Clean Development Mechanism that targets climate change mitigation in the country. As climate policy objectives are partly formulated at the international level, policies need to be implemented on a national, subnational, or even on the local scale (NEAA 2009, p. 81). The UNFCCC obliges all parties to prepare for adaptation to the impacts of climate change. In recent times adaptation policy has become a focus of researchers and stakeholders as an option to tackle climate change in addition to mitigation. Adaptation in contrast to mitigation is more feasible on a local scale as it addresses specific local impacts of climate change. Moreover, there is not yet an international guideline or perhaps a fit for all approach to adaptation on global scale. This is due to the different levels of vulnerability of social, economic, and ecological systems to myriad consequences of the impact of climate variability and change, and even the cross-sectoral challenges arising from different institutional systems (UNFCCC 2012, p. 4). Recognizing these challenges, increasing number of developing countries has initiated independent adaptation plans and strategies. The coherent approach being taken by these countries aimed to "contribute to efforts towards climate-resilient development, suggesting a long-term continuous process and most importantly periodic revisions" (UNFCCC 2012, p. 4).

Climate Change Adaptation Policy Response in Nigeria

In addition to the drafting of the National Climate Change Policy in Nigeria, the country has also developed adaptation plans that will enable the country to address the emerging challenging issues associated with climate change. The Nigerian national adaptation plan was initiated after accessing the risk and vulnerability of the entire country on current and potential impacts of climate change (UNFCCC 2012, p. 5; Abiodun et al. 2011; NASPA-CCN 2011). The national adaptation plan also considered lessons and knowledge generated from the several project components, such as a research pilot project (e.g., future climate scenario studies, policy development, communication, and outreach as well as youth and gender initiatives (Abiodun et al. 2011). The National Adaptation Plan and Strategy of Action on Climate Change for Nigeria was developed in partnership with the Special Climate Change Unit (SCCU) of the Federal Ministry of Environment of Nigeria and other relevant stakeholders such as the Nigerian Environmental Study/Action Team (NEST) with a financial support from the Canadian International Development Agency (CIDA). The Nigerian National Adaptation Plan has, therefore, been developed in a coherent manner, thereby serving as an exemplary document and a case study on the national adaptation plan for other developing countries that aim to initiate adaptation plans or strategies (UNFCCC 2012). Laudable as the Nigerian adaptation plan could be, there is a need for adequate decision-making during the implementation.

Reminiscence that climate change may lead to loss of between 2 % and 11 % of Nigeria's Gross Domestic Products (GDP) by 2020 and between 6 % and 30 % by the year 2050 as pointed out in the National Adaptation Strategy and Plan of Action on Climate Change for Nigeria. To reduce such potential loss the Nigerian National Adaptation Strategy shows that adaptation planning will take a strategic approach in addressing climate change impacts in the country. Adaptation measures shall focus on all the affected sectors including agriculture (crops and livestock), livelihoods, education, freshwater resources, coastal water resources, fisheries, forest, biodiversity, energy, transportation, communication, industry and commerce, emergency and disaster response, vulnerable groups, migration and security, human settlement and housing, health, and sanitation.

Initiatives for Climate Change Adaptation

Nigeria as a member of the Economic Community of West African States (ECOWAS) plays a key role in developing Climate Change Adaptation Strategies that can help reduce the impacts and consequences of climate change in the region. ECOWAS is making strong efforts to integrate climate issues into economic planning and management at the regional and national scales. The West African Climate Change Adaptation Program initiative is a milestone towards the formulation of the "Regional Plan of Action for reducing vulnerability as climate change impact increases in the West African States" (OECD 2009). Another important step, is a recent establishment of Graduate Programs in two Nigerian Universities under the German initiative on the "West African Science Service Centre on Climate Change and Adaptive Land Use (WASCAL)" which aims to enhance the capacity building in Nigeria and across the West African States.

Furthermore, in order to address the impacts of climate change and global warming in Nigeria and to respond to international obligations, the former president of Nigeria, Olusegun Obasanjo, endorsed the creation of a new unit – "Special Climate Change Unit (SCCU)" – under the Federal Ministry of Environment, Housing, and Urban Development. The unit is established to ensure that the UN conventions and the Kyoto Protocol activities such as the implementation of Clean Development Mechanism and other related issues are effectively addressed. The department has the mandate, to oversee initiatives geared towards reducing climate change impacts on the Nigerian environment and coordinate sectoral measures that can help achieve its goals. The Special Climate Change Unit was commissioned in 2006. Recently it has been established as a full department within the Ministry of Environment. The department is exclusively responsible for coordination of matters relating to mainstreaming climate change adaptation into the national policies. Also, efforts are being made by the Nigerian government, to create a National Climate Change Trust Fund that could help finance strategic actions so as to curb the impacts of climate change (Müller 2013, p. 5).

The Need for Integrated Assessment of Adaptation Options

In order to minimize the impacts of climate change on the most vulnerable communities, integrated assessment of adaptation options is imperative. In this regard, implementation of adaptation measures should be supported by adequate environmental assessment procedures. This is very essential in order to make robust decisions regarding adaptation to the impact of climate change hence such decisions remain complex. However, to reach this target, Environmental Impact Assessment (EIA) and Strategic Environmental Assessment (SEA) are the two unique environmental assessment tools that are used internationally for wide-ranging environmental assessment such as prediction and evaluation of social, economic, health, and environmental impacts of a proposed plan (UNEP et al. 2004, p. 6). According to Sadler et al. (2011) "the introduction of SEA has an integral part of the development of EIA." SEA was developed together with EIA in 1969 with the United States National Environmental Policy Act (João 2005, p. 5).

Nigeria does not yet have a legal requirement and a framework for SEA, but EIA is well established. For instance, Adebanji (2010) pointed out that neither policies, plans, nor programs (PPPs) have been regulated under SEA at the national, regional, or sectoral/industrial level in the Niger Delta region of Nigeria considering several social and environmental challenges that need to be addressed in the area (Adebanji 2010, p. 5).

Now, the question is how can the environmental impact of adaptation programs be reduced and positive effects enhanced in order to avoid decisions that may lead to maladaptation. To address this issue, it is important to first identify the kind of adaptation programs that could help reduce the risks posed by a particular climate hazard and at the same time being environmentally conscious. This challenging task could be possibly addressed through the application of appropriate environmental assessment and decision aiding tool such as SEA. Such assessment procedures can also help phase out programs that may pose a risk to the environment while pursuing the win-win option characterized by overarching benefits of climate change mitigation and adaptation. Therefore, SEA is an important tool to be considered in making informed and robust decisions at the early stage before such policies, plans, or programs can be implemented (OECD 2008a, p. 21). EIA can then be used at a later phase with the aim of improving a particular proposed project. The Implementation of the Nigerian Adaptation Strategy and Plan of Action should be considered in this context. EIA is very relevant in assessing the possible impact that proposed projects particularly infrastructural related adaptation may pose on the environment (Agrawala et al. 2010). On the other hand, "the integration of climate change into strategic planning through the application of SEA should lead to better informed, evidence-based PPPs that are more sustainable in the context of changing climate and more capable of delivering progress on human development" (OECD 2010, p. 4). The authors will not go into details on EIA process in Nigeria, and the overall basic principles of SEA; however; it is assumed that the reader is familiar with EIA. In addition, appropriate citations and links will be provided.

Evolution of EIA

There are many driving forces for the use of EIA worldwide. Firstly, EIA serves as an instrument for sustainable development in developed and developing countries though it has its limits, which are sometimes covered through early assessment of

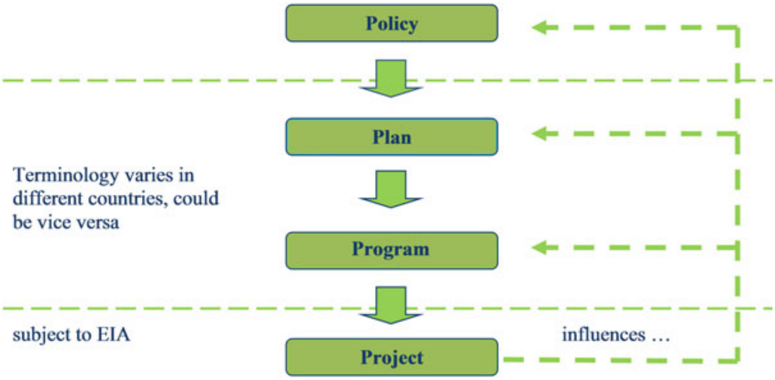

Fig. 2 Links between EIA and SEA (Source: Adapted from Albrecht (2011, p. 156))

three levels of SEA linked to EIA (see Fig. 2). According to Albrecht (2011) one of the reasons for assimilation of EIA by several developing countries is due to the World Bank policy in 1988 which adopted EIA for major development projects. This World Bank operational directive entails that any country seeking development assistance carries out an EIA especially under the World Bank supervision. Henceforth, "EIA of World Bank became mandatory for all projects that may potentially have a significant influence on the environment" (Albrecht 2011, p. 152). The target of the World Bank EIA recommendation is to make sure that projects on funding considerations by the institution are environmentally friendly and sustainable.

A Brief Overview of EIA Administration in Nigeria

Nigeria recognizes the achievement of environmental protection as an integrated policy issue rather than standalone policy targets. The country also seeks to achieve sustainable development through enforcement of adequate environmental policies, laws, and regulations. The EIA Decree No. 86 of 1992 was established under the defunct Federal Environmental Protection Agency (FEPA). The FEPA Act and Regulations were replaced in 2007 by the National Environmental Standards and Regulations Enforcement Agency (NESREA) Act which established the NESREA, giving it the mandate to oversee the protection of the Nigeria's environment through enforcement of these environmental laws in collaboration with the Federal and State Ministry of Environment. Nigeria runs a federal system of government – today the Federal Ministry of Environment is the central environmental authority as it contains the legal requirements to carry out EIA and evaluate the consequences of proposed projects on the environment. The Nigerian Federal Ministry of Environment is therefore bestowed with the mandate of EIA administration in Nigeria. On the other hand, the NESREA is responsible for the enforcement of environmental regulations, rules, laws, policies, and guidelines. NESREA has the entire competence for enforcement of environmental control measures through registration, licensing, and permitting system other than in the oil and gas sector. However, the EIA law and the Urban and Regional Planning Decree No. 88 of 1992 provided principles guiding development of major projects that may likely affect the environment significantly (Federal Republic of Nigeria 1992a, b; Agwu et al. 2000; Ladan 2012b; Ugochukwu and Ertel 2011; Olokesusi 1998).

The Nigerian EIA decree contains the procedure to be followed. In addition, it provides a checklist, for the categorization of projects subject to EIA (Echefu and Akpofure 2003; Ugochukwu and Ertel 2011, p. 18). EIA is mandatory for all major projects that may likely pose significant impacts on the Nigerian environment considering location or size of the project. An example of such projects may include major road construction, industrial and infrastructural development, mining, housing development and projects located in environmental sensitive areas. It is worthy to note that EIA in Nigeria is a licensing tool for proponents, especially those in the oil industry and other mining development to carry out before going ahead with their operations. EIA must be carried out with the input of all the stakeholders and the Ministry of Environment and all other competent authorities. An Environmental Impact Statement (EIS) is usually produced at the end of this process.

Institutional and Legal Challenges of EIA in Nigeria

The Nigerian EIA practices and legal and institutional frameworks have for several years been attributed to several problems and challenges. These include low public access to final EIA reports, insufficient interagency coordination (overlapping of competencies; federal system's challenges), and inadequate stakeholder consultations and public participation. Even though access to environmental information is given by the Decrees No. 86/1992, information dissemination is difficult in practice. Furthermore, full public participation is given but only for 21 days (Federal Republic of Nigeria 1992a; Ugochukwu and Ertel 2011, p. 169; Nwoko 2013, p. 26), and Environmental Impact Statements are not published online. However, it is expected that the Federal Ministry of Environment and the young NESREA will through their good practices and monitoring responsibilities enhance the EIA practice and address such pitfalls recorded in enforcing the provision therein in the past years. More especially as NESREA allows for the collaboration of local and international agencies and nongovernmental organizations including international regulatory bodies such as the UN Agencies, World Bank, Partners for Water and Sanitation (PAWS-UK), United Kingdom Environment Agency (Ladan 2012a), and other interested corporate bodies around the world. Such local and international cooperation could reduce these shortcomings; such cooperation is in the right direction as environmental challenges become more global. However, climate change was not considered during establishment and formal requirement of EIA decree No. 86/1992 procedures; yet, the integration of climate change into the stages of SEA/EIA could be an important step to be realized under the new NESREA enforcement responsibilities and the good practices of the Federal Ministry of Environment in collaboration with relevant environmental departments in the country. Having in mind that climate change is a crosscutting issue, the Federal and State Ministry of Environment, the National and State Urban and Regional Planning Authorities, and other relevant Environmental Agencies can play a key role that could help enhance adaptation decision-making and reduce climate-induced risks.

Aims of SEA

The National Environmental Policy Act (NEPA) established in the United States in 1969 promulgated the first Strategic Environmental Assessment (SEA) regime. SEA is a tool designed to achieve the overarching target of sustainable development, for example, the national targets for the implementation of Agenda 21 and the Plan of Implementation of the World Summit on Sustainable Development known as the Johannesburg Plan of Implementation. The tool being flexible also applies to new environmental challenges such as climate change. The major aim of SEA is to incorporate environmental concerns into strategic decisions which may include policies, plans, programs, regulatory frameworks, and legislations depending on the respective area of application in the SEA provisions. For example, policies and legislations are not included in the area of application of the EU SEA Directive. SEA helps to protect the environment by improving decisions that lead to sustainability targets. The uniqueness of SEA lies in the consideration of environmental concerns from the onset of decision-making in relation to development of proposed plans and subsequent projects such as public infrastructures. Considering the characteristics, "it can be argued that EIA procedure is at times analogous to that of SEA" (João 2005, p. 5). It is worthy to note that countries or nations having an effective EIA procedure as an environmental assessment tool can easily apply SEA using existing EIA institutional structures. This way SEA framework can easily be incorporated within the planning and institutional decision-making procedures. This is possible in the case of Nigeria EIA institutional framework and planning system.

There are two key principles of SEA (João 2005, p. 7). According to João (2005) one of the major principles of SEA is to explicitly identify potential PPPs (or alternatives) and evaluate these alternatives in an assessment context. She emphasized that SEA likewise EIA should not be employed to mitigate environmental impacts of actions that have already been decided upon. Rather the environmental assessment process should be used to inform the decision of what action should take place, i.e., what alternative should be chosen (João 2005, p. 7). The second principle of SEA relates to the improvement of proposals. João (2005) posits that SEA must improve, instead of just analyze policy or programs, meaning that SEA should be effectively used in the formulation of strategic actions: "looking at evolving strategic action afresh and being willing to change and improve such strategies in the light of the SEA findings." Furthermore, the SEA should explicitly contribute to the decision-making process (João 2005). SEA procedure should, therefore, fit more elegantly in the strategic decision-making process (Therivel 2004, p. 61).

There is no common definition of SEA; however, Sadler and Verheem (1996) provides a very well-cited definition; thus SEA is "a systematic process for

Table 1 Some Comparisons between EIA and SEA

EIA of projects*	SEA of policy, plans, and programs**
Takes place at end of decision-making cycle	Takes place at earliest stages of decision-making cycle
Reactive approach to development proposal	Proactive approach to development proposals and programs
Identifies specific impacts on the environment	Identifies environmental implications, issues of sustainable development
Considers a limited number of feasible alternatives	Considers a broad range of potential alternatives
A limited review of cumulative effects	Early warning of cumulative effects and synergistic impacts
Emphasis on mitigating and minimizing impacts	Emphasis on meeting, environmental objectives, maintaining natural systems
Narrow perspective, high level of details	Broad perspective, lower level of details to provide a vision and overall framework
Well-defined process, clear beginning and end	Multistage process overlapping components, policy level is continuing iterative
Focus on standard agenda, treats symptoms of environmental deterioration	Focuses on sustainability targets, get at source of environmental deterioration

Source: CSIR (1996) cited in UNEP (2002, p. 495)
*EIA usually assesses only negative effects on the environment
**SEA (for example the SEA-Directive of the EU) assesses positive and negative effects of plans and programs

evaluating the environmental consequences of proposed policy, plan or program initiatives in order to ensure they are fully included and appropriately addressed at the earliest appropriate stage of decision making on par with economic and social considerations." Similarly, João (2005) provides a brief definition thus SEA is "the process of evaluating the environmental impacts of proposed PPPs, in order to inform decision making." One of the main differences between EIA and SEA is that the scope and processes of the latter are characterized by greater diversity (UNEP 2002 p. 493). Furthermore, the SEA "process extends the aim and principles of EIA upstream in the decision-making process, beyond the project level and when major alternatives are still open" (UNEP 2002, p. 493). SEA represents a proactive approach to integrate environmental considerations into the highest level of decision-making, consistent with the principles outlined in Agenda 21 (UNEP 2002, p. 493). Both SEA and EIA have common elements, although increasing modifications to the procedure and methodology are necessary when moving from the project to the policy level (UNEP 2002, p. 493). While EIA is widely practiced, SEA is increasingly being recognized in several developed and developing countries and international and local organizations as a better tool to make informed decisions and improve developmental programs. Table 1 shows a comparison of the key characteristics of both processes as is given by UNEP (2002, p. 493).

The link between SEA and EIA is established in a tiered manner. According to João (2005) SEA deals with a hierarchy of strategic actions, which ultimately affects what projects are built on the ground (Oxford Brooks University 2004 cited in João 2005). “This hierarchy might differ in detail from country to country but it is usually there, and it is a key aspect of what SEA is all about” (João 2005, p. 5). According to Albrecht (2011) the hierarchical order is ideal as plans and programs usually set a framework for the subsequent project realization (Albrecht 2011, p. 155). The tiered concept helps in sustainable decision-making regarding the implementation of PPPs and any project under such developmental process. SEA is, therefore, largely linked to EIA (Albrecht 2011, p. 155). Figure 2 shows the linkage between policy, plan, and program of SEA and project-specific EIA. It is to be noted that the words policies, plans, and programs are used differently in countries considering the best-suited terminology (Sadler et al. 2011, p. 2; Albrecht 2011, p. 156). However, it is important to define the meaning of policy, plan, and program (PPP) as used in this context. A policy is an inspiration and guidance for action; a plan is a set of linked proposed action with a specific time frame that will implement the policy, while a program can be regarded as a set of proposed projects in a particular area that will implement the plan (João 2005 p. 4; Schmidt et al. 2010).

The Need to Integrate Climate Change Adaptation into SEA in Nigeria

Nigeria has no legal or formal requirement for SEA; however, several developing countries and international organizations are rapidly adopting SEA as a decision-making support tool (Schmidt et al. 2005; OECD 2010; Sadler et al. 2011, p. 2). To better address the numerous environmental challenges such as climate change and environmental degradation in Nigeria, there is a need to supplement EIA with SEA. As climate change becomes a new challenge in planning, incorporating appropriate environmental assessment tool that can aid decision-making has become urgent. SEA is a very relevant tool in this context. “SEA provides a methodology not only for evaluating the impact of policies, plans and programs on the environment, but also for addressing the impact of environmental change on PPPs” (OECD 2009, p. 80). Practical examples documented by the OECD suggest that SEA is an appropriate and more rational environmental assessment tool for climate change adaptation. In order to fulfill the adaptation initiatives effectively, it is imperative to follow good practices. For example, the OECD has produced guidance for practitioners on how to apply and incorporate climate change adaptation within the SEA process (OECD 2006).

Furthermore, SEA being a flexible tool can be tailored to the local context or the specific strategic decision-making or planning process that it seeks to support. SEA can, therefore, serve as an assessment tool for both adaptation and mitigation purposes. In terms of mitigation SEA assesses the environmental effects of the plan in terms of potential emissions of greenhouse gases (GHG) that could be released from the plan and how to reduce them (Larsen and Kørnøv 2009; Larsen et al. 2012, p. 33). For example, any SEA of a development plan for a new urban area can include assessments of GHG emissions generated from traffic (Larsen et al. 2012, p. 33). On the other hand, Larsen and Kørnøv (2009) cited in

Larsen et al. (2012) envisage that adaptation considers climate change as an environmental problem of relevance to plan and if and how it is expedient to adapt the plan for future climate change. For example, the SEA of an overall spatial plan can include assessment of appropriate building sites in the light of future sea-level rise (Larsen et al. 2012, p. 33).

As stated earlier, countries and organizations are increasingly undertaking SEA, using formal or informal procedures (Sadler et al. 2011, p. 2). To the present authors' perspective, there are several reasons why SEA is increasingly adopted. Perhaps, the first reason is that SEA is widely recognized as being effective in integrating environmental protection measures in strategic decision-making. Secondly, several countries are creating activities geared towards sustainable development. SEA is an effective instrument for sustainable development (Albrecht 2011, p. 152). As pointed out earlier in the chapter, the purpose of SEA is to ensure that environmental considerations are taken into account and in order to inform high levels of decision-making, which facilitates assessments of policies, plans, and programs. Furthermore, SEA has the potential of improving PPPs, making sure that they take climate change issues into consideration, especially in countries with the legal provision for SEA (OECD 2009, p. 94). Another reason pointed out by Sadler et al. (2011) is that SEA serves as a lending and aid instrument used by donor agencies.

SEA is a multistage process that encompasses a spectrum of approaches and diverse arrangements, procedures, and methods (UNEP 2002, p. 493). Considering the diverse nature of climate-related impacts and adaptation issues in Nigeria, SEA is a structured planning tool to grind such hydra-headed challenges. An ideal SEA focuses on potential interrelations between concrete plans and programs and environmental changes by looking at the projected future of key socioeconomic variables, like trade patterns, commodity prices, population growth, migration flows while considering climate factors (OECD 2009, p. 80). The Nigerian national adaptation plan is geared towards strategic objectives comprising several sectors and ministries. SEA is better positioned to help improve relevant decisions towards achieving such integrated adaptation targets. According to the OECD (2009), an institution centered SEA approach may be best suited for mainstreaming climate change adaptation into national-level policy-making.

Moreover, in order to enhance national adaptive capacity, important environmental assessment tools should be in place as this will enable mainstreaming of climate change adaptation into sectoral policies. According to the IPCC "one way of increasing adaptive capacity is by introducing the consideration of climate change impacts in development planning, for example, by including adaptation measures in land-use planning, and infrastructure design or by including measures to reduce vulnerability in existing disaster risk reduction strategies" (IPCC 2007, p. 20; IPCC 2014, p.27). Furthermore, considering SEA in a regional land use development plan can enhance potentials for adaptation and make adaptation constraining decisions transparent (Helbron et al. 2011). In this light, quality of the regional plan-making weighting process is potentially improved (Helbron 2008). Climate change adaptation through SEA in Nigeria can be realized by following the existing relevant institutional arrangement and decision-making structures; however, therefore, the tiered approach is pertinent in order to avoid overlap with the existing EIA process. The definition of policy, plan, and program is given nevertheless. To be precise in relation to climate change adaptation in Nigeria, an example of a policy is the proposed National Policy on Climate Change while a plan is the National Adaptation Strategy and Plan of Action on Climate Change for Nigeria (NASPA-CCN). On the other hand, a program could be, for example, Climate Change Migration and Security Initiatives for Nigeria introduced within the Nigerian National Adaptation Plan.

New Strategic Programs That Need to be Integrated into SEA

Hence adaptation to climate change has become very necessary. Nigeria has established new strategic actions to be considered when implementing the national adaptation plan. This gesture is a milestone towards addressing the impacts of climate change ravaging several communities in the country. However, the national adaptation plan must be implemented in a sustainable manner. Adopting a guidance framework relevant for assessing environmental risk that may occur through adaptation actions is imperative. Such a framework would help in improving the integration of climate change consideration into PPPs relevant to carrying out robust adaptation strategies (OECD 2008a). Even though the proposed strategic programs are designed to reduce the impact of climate change on vulnerable communities in Nigeria and enhance adaptive capacity of the affected communities, SEA can be employed as an environmental assessment tool. In this context, SEA could help to make informed decisions so as to ensure that communities are not adversely affected after implementation of such strategic actions, at the same time, improving such adaptation strategies. It is worthwhile to keep in mind that "any adaptation action can create unintended impacts on other natural and social systems" (Adger et al. 2005, p. 81).

Some of these new strategic programs for adaptation to climate change provided in the National Adaptation Strategy and Plan of Action for climate change in Nigeria (NASPA-CCN 2011) include:

- Agricultural Extension Programs Services
- Integrated Water Resource Management Program (watershed and coastal)
- Community-based Natural Resources Management Program (forest sectors)
- Comprehensive Emergency Management Program
- Climate Change, Migration, and Security Initiative (e.g. Economic Development and Poverty Reduction Strategy).

Furthermore, implementation of the National Biodiversity Strategy and Action Plan (NBSAP) is a relevant aspect that needs to be considered in SEA. Hence, the need for action on climate change and biodiversity loss is firmly acknowledged as one of the new environmental challenges in Nigeria (NASPA-CCN 2011, p. 49; NEST 2011, p. 127). SEA is also required by Article 14, paragraph 2 of the Biodiversity Convention.

Benefits and Potential of SEA Within the Context of Climate Change Adaptation

Integration of climate change adaptation into SEA is relatively new particularly in those developing countries without formal requirement for SEA. However, in developing countries where SEA has become part of environmental assessment tool, it provides a ready entry point for climate change consideration in strategic decision-making at the sector level (OECD 2009, p. 101). "SEA as a decision-aiding instrument can contribute to the prevention of conflicts with a policy for adapting to climate change" (Helbron et al. 2011). According to OECD (2009) building climate change consideration into an SEA can help:

- To identify whether sectoral strategies are viable and sustainable under different climate scenarios. For example, in areas facing increasing water stress, SEA can help to assess different strategies for the reform of the agricultural sector with different water requirements to identify which strategy is most sustainable under different climate scenarios.
- To analyze whether a sectoral strategy might lead to increased vulnerability of the sector where natural and human systems are affected by climate change and thus prevent maladaptation.
- To identify which adaptation intervention can enhance the resilience of the sector in the face of climate change (OECD 2009, p. 101).

Potentials of SEA for Climate Change Adaptation in Nigeria

There are several benefits that could be associated with considering climate change adaptation in SEA. Most importantly, SEA application is imperative in meeting relevant policy commitments related to climate change in Nigeria. For example, SEA can help improve decision-making related to proposed adaptation programs of the Nigerian Ministry of Environment to achieve the objectives of NASPA-CCN by:

- Identifying policy, plans, and programs that are sensitive to climate change
- Incorporating stakeholders and public views at an early stage of planning
- Providing environmental-based evidence to support informed decisions
- Improving strategic actions (e.g., national and sectoral adaptation programs) and avoiding the risk of maladaptation
- Determining communities and socioeconomic groups that are increasingly vulnerable to climate change impacts
- Integrating environmental aspects that are often disregarded in sectoral plans, e.g., vulnerability to climate variability and change
- Evaluating the environmental impacts of adaptation strategies as well as possible conflicts with other existing regional or national plans and programs
- Addressing cumulative and synergistic effects which may lead to decisions that could prevent adverse consequences on urban and rural communities.

Conclusion

The present and future climatic changes in Nigeria could be very detrimental to ecosystems and vulnerable communities. Hence, the impacts of such climatic events have become inevitable. Climate change considerations should become part of policy-making and planning process in Nigeria. Adaptation is widely recognized by decision-makers as one of the effective measures to reduce the unavoidable impacts of the changing climate on the human environment. Given that Nigeria has initiated and designed a national adaptation plan with the aim of addressing the emerging climate change impacts across the country, it is also indispensable for a robust implementation of the national adaptation plan. While some progress has been made especially through establishing a National Adaptation Plan for Nigeria, a lot more remains to be done. It is, therefore, imperative to adopt a guidance framework for assessing several environmental risks which may improve the integration of climate change consideration into PPPs in order to make informed decisions and carry out robust adaptation strategies (OECD 2008b). SEA provides a structural approach to incorporating environmental considerations into PPPs at different levels, including sector level (OECD 2009, p. 185).

SEA can help to improve the adaptation programs laid in the national adaptation plan by bringing transparency in their implementation from the early stage of decision-making. SEA can help in improving adaptation programs as it allows for the participation of the public and relevant stakeholders, particularly at the early stage of the overall decision-making putting their suggestions into consideration and even strengthening the subsequent project-specific EIA. Flexibility is one of the characteristics of SEA. This assessment tool is not only a useful tool for climate change adaptation decision-making but also for making decisions related to climate change mitigation and poverty reduction strategies (PRS). However, following good practice climate change adaptation could be considered in the SEA/EIA framework. Adaptation to climate change is a crosscutting issue that needs to be addressed through integrated decision-making. SEA allows for a better cooperation between crosscutting environmental sectors. In this respect, regional environmental authorities have a key role to play in carrying out robust adaptation strategies. There is, therefore, a need for capacity building and training of relevant staff in SEA, EIA, and climate forecast. Training is very essential and crucial to take full advantage and to promote new skills. This would enable stakeholders and policy-makers to envisage the alternatives of future development and to apply the precautionary principle when necessary, so as to reduce climate risks. Therefore, an appropriate environmental assessment tool such as SEA can help spur robust decision-making regarding adaptation options in Nigeria.

The author has contracted many debts in writing this chapter. First of all, the author should like to thank Professor Robert O. Keohane and Professor Lawrence E. Susskind for their perceptive criticism and kind encouragement. Also, the author has indebted to Geena Kim, former teacher of Ewha Womans University High School, for her invaluable advice on elaborating this chapter. Lastly, the author sincerely thanks the editors for giving the author special opportunity to participate in this work.

Abstract

For decades, the leverage of transnational actors has skyrocketed, while still an international regime is crucial in managing climate change. Acknowledging this point, this chapter aims to find how to analyze the structure of climate change regimes, why international cooperation is hardly maintained in the regimes, and how to sustain it. To narrow the gap between theory and reality, this chapter integrates the game theory and the network theory. Game theory is used to analyze the negotiations in the regime, and network theory is widely applied to discuss the structure and interactions among diverse actors. The author verifies that the system inside the regime is still international, whereas outside the regime is similar to the network shape. Furthermore, the structure of the regime analyzed proves to be disadvantageous for sustaining cooperation. Thus, the author proposes practicable solution to sustaining cooperation by finding the actor who could fill the structural holes created in the regime. This chapter is one of the first to implement an interdisciplinary study merging game theory and network theory to deal with climate change regimes. This chapter might be helpful to the policy makers and scholars devising methods to improve the efficacy of regimes on managing climate change.

Keywords

Climate change • International regime • Metaphor of castle • Prisoner's dilemma • Tit-for-tat strategy • Stag hunt • Network • Structural hole • Post-developing country • Power division

Introduction

Since the 1970s, international regime has drawn attention from states as an effective tool for counteracting the effects of environmental problems (Young 1989). Regime is defined as "a set of explicit or implicit principles, norms, rules, and decision making procedures around which actor expectations converge in a given issue-area" (Krasner 1982, p. 186). As the demand for climate change regimes had also been proliferated, Rio Earth Summit declared to establish United Nations Framework Convention on Climate Change (UNFCCC), the first formal and legal international regime specialized in climate change, in 1992. From then on, international regimes have encouraged nations' responsible actions toward climate change.

To the contrary, still a great crux exists. In 2010 and 2011, the quantity of greenhouse gas (GHG) emission has rather swelled twice faster than the worst-case projections leading to 6 °C warming (Voorhar and Myllyvirta 2013). This insinuates that nations have made airy promises, which have barely been kept. To improve the efficacy of climate change regimes, this international practice of negligence ought to be ameliorated. With this perspective, two questions could be raised. First, why does the cooperation achieved in the period of resolution-making hardly sustain to the period of each state's practicing policies? Second, how could the international cooperation achieved by international regime sustain for a long period, without any state's defection?

Before answering to the questions, this chapter casts a cardinal question for the first: Why are international regimes still the crucial tool to manage climate change, in the more dynamically changed world system?

International Climate Change Regimes

Two mainstream international relations theories that have contributed to the discussion on the international regimes are realism and institutionalism. They have antithetic perspectives on the most roles of international regimes. However, there are some hypotheses about international regimes, on which both realists and institutionalists agree (Little 2011, p. 375).

1. States interact with each other in the anarchic international system.
2. States are rational and monolithic players.
3. States are the unit which is responsible for the formation of regimes.
4. Regimes are established based on mutual cooperation in the international system.
5. Regimes promote international orders.

These major hypotheses of regime theory were established in the twentieth century. However, from then on, many other transnational actors, such as international non-governmental organizations (INGOs), transnational corporations (TNCs), and epistemic community (which refers to the group of scholars), have grown as pivotal players in the world politics along with the globalization (Duffield 2001; Edwards and Gaventa 2001; Kahler 2009). Even some studies (Latour 1987; Kim 2011a) applied Actor–Network Theory (ANT) and suggested that the technologies also operate as a key actor in the world politics. That is to say, states are not the only actors in the world politics, and the international system has evolved into a more sophisticated system, which is unwieldy to be dealt with the only *international* political approaches. Given the rise of the transnational actors, the "states" in the hypotheses (1) and (2) would rather be understood as signifying *state governments*. This would facilitate explaining the presence of transnational actors, for it does not reckon the state per se as a unified actor (Willetts 2011, p. 413).

On the contrast, the international regimes still *thrive*. Then how could this be explained? First, path dependence could be one of the conceivable answers (Keohane 1984). When the international regimes were established, states legalized themselves to be the sole formal actors in those regimes. Even if the whole international system has transformed into more complicated ways, the dominant status of states inside the regime is still maintained by the inertia. Other transnational actors could merely have indirect clout on the decisions of regimes by lobbying or acting as facilitators. Thus, the states are the only de facto actors inside the international regimes.

Second, the regimes now simultaneously operate as a contrivance for states to preserve their vested rights against transnational actors. By monopolizing the role of decision-making, they conserve the status as the most authoritative actors in the regimes. Especially, given the fact that environment is a common-pool resource managed perfectly by states and that states retain the best capability to protect the environment (Barry and Eckersley 2005), the leverage of states in the international climate change regime is inapproachable. Due to this vantage of states, other transnational actors would hardly dominate the state (Shaw 2000).

This disjunction between the systems in and out of the regime could be easily explained by *the metaphor of castle* in Fig. 1. States have built a *castle* called international regime and maintain their ascendancy by disrupting other transnational actors' foray to directly participate in decision-making, with the *wall* of international regime. Understandably, states not only act inside the regime but also actively interact with other actors outside the regime.

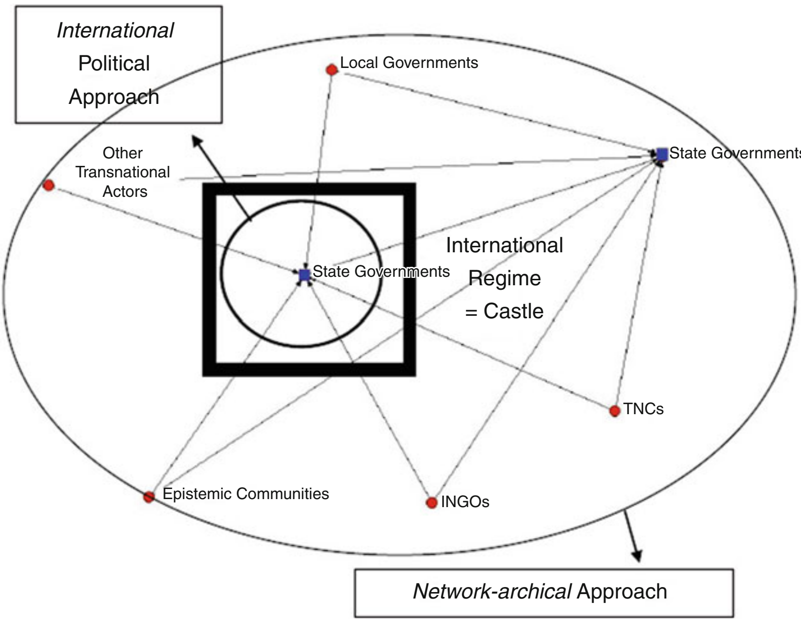

Fig. 1 The metaphor of castle

Thus, inside the regimes do states retain the clout, and the anarchic system persists. This implies that employing game theoretical approaches, which has been applied by the institutionalism, is still valid in analyzing the international regimes. This chapter employs a few elementary game theories: prisoner's dilemma and stag hunt.

First of all, the author would briefly explain what game theory is. Game theory could be defined as "the study of mathematical models of conflict and cooperation between intelligent rational decision-makers" (Myerson 1991, p. 1). The components of game theory often considered to be essential are players, actions, information, iteration, and payoffs. *Players* are literally the actors of the game, the people, or parties participating in it. *Actions* are options that players could choose during the game, which is often divided into two, cooperation (C) and defection (D). *Information* provided for players before the game decides whether the game is *perfect*, which means the player knows what the other would choose if they choose a given action, and *complete*, which implies one knows the characteristics or strategies of the other. *Iteration* is about whether the game is repeated or merely one off. *Payoffs* are the results, which could be either benefits or damages, one receives from the game, depending on what himself/herself and the other chose (Kim 2013).

Prisoner's dilemma has been thoroughly particularized in the field of environmental economics to account for climate change negotiations (Barrett 2003; Decanio and Fremstad 2013; Finus 2001; Wood 2010). On the contrary, few have attempted to exploit the payoff structure of stag hunt (Endres and Ohl 2002). Game theories are expected to analyze what the real model of international regimes is and find out why current regime is insufficient for sustaining cooperation although some criticisms against adopting the model of Stag Hunt and Prisoner's Dilemma exist (Harrison 1983). Also, to elucidate the structure of the regimes more realistically and contain the oversimplification induced by the game theory (Haggard and Simmons 1987), this chapter employs a network theory in discussing some complex aspects of international regimes. Network theory, more precisely social network theory (SNT), is the theory essentially developed in the field of sociology, which is to systematically analyze relationships between individuals.

In dealing with the interactions between transnational actors outside the regimes, this chapter fully adopts network-archical approaches. Current world system is continuously transforming and restructuring through the polymorphous activities of transnational actors. Network theory is congenial to discuss this dynamic system, for it focuses on the interactions between actors and the structure itself and makes it possible to analyze relationships in various levels (Maoz 2010). Also a few studies have successfully employed the network theory to methodically apprehend the international environmental issues (Betsill and Bulkeley 2004). In specific, this chapter employs the perspective of SNT. Through social network analysis (SNA), which has recently been used in the field of sociology to analyze the social network between people by using software such as Ucinet 6.504 and NetDraw 2.137, this chapter tries to analyze the dynamic world politics related to climate change, finding some solutions to make effective resolutions in climate change regimes. This chapter also analyzes the relationship between actors with Ucinet 6.504 and NetDraw 2.137, acknowledging its efficacy verified in some studies (Kim 2011b). Still the author recognizes that the results from SNA could not be absolute, since the analysis of network through SNA is essentially rooted in the researcher's observation (Hanneman and Riddle 2005).

This chapter opts for UNFCCC as a subject matter, as "the UNFCCC continues to play an umbrella role and provides the framework for a number of essential functions, including serving as a legal setting, providing information, and constituting a forum for negotiations" (Keohane and Victor 2010, p. 21).

The Payoff Structure of Current UNFCCC: Prisoner's Dilemma

Ostensibly, UNFCCC seems to be an effective international regime, as it provides and contrives many methods to manage climate change. However, the total amount of emitted GHG has rather increased. This obvious growth of GHG emission negatives the efficiency of UNFCCC. Then, to figure out why current UNFCCC is of little efficacy, the structure of UNFCCC should be analyzed thoroughly. Thus, this chapter systematically analyzes it mainly harnessing the game theory, with supplementing some points through network theoretical approach.

Players

The total number of states currently (2013. 12.) participating in COP is 194. It seems at a glance that analyzing with N-person ($N > 2$) game theory is congruent, as the number of states is more than 2. However, every single state has diverse interests and objectives, due to the significant variances in the international relationship, impact of climate change that states confront, and energy reserve, etc. Due to this divergence of each state's goal, analyzing the game of UNFCCC with N-person game would not be appropriate. N-person game might exceedingly simplify the intricate relationship of parties' interests. Rather, it is desirable to grasp the game of UNFCCC as a *complex of 2-person games*, which is associated with various interests of states. Given states forge linkages with others through the games, the complex could be represented as a complicated network in Fig. 2.

After establishing this network with each other, states discerned that there are some kindred states whose opinions are similar to themselves. As a result, through many times of UNFCCC meetings, states have gradually established coalitions (Shin 2011) as shown in Fig. 3.

The classification of the coalitions is majorly based on the standard stated in the UNFCCC homepage (UNFCCC n.d.). Those coalitions have been the de facto players in the COP. Brief recitation for key stances of each group is stated below.

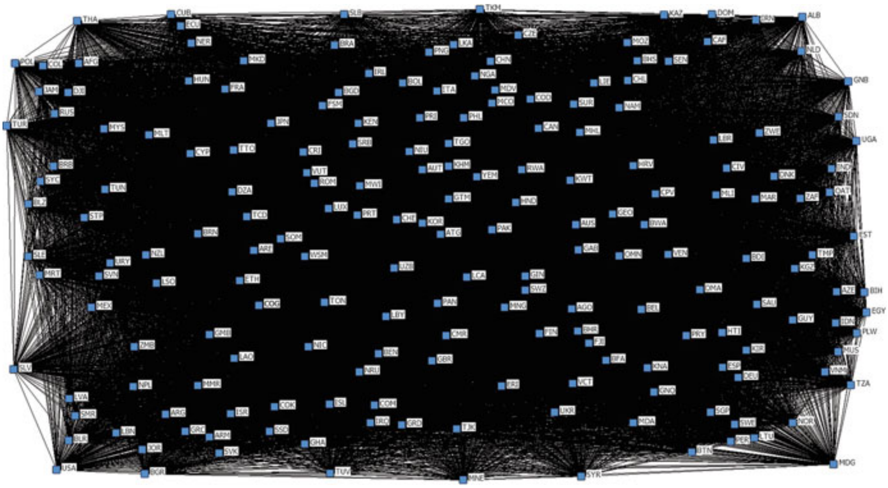

Fig. 2 Two-person game network of parties in UNFCCC

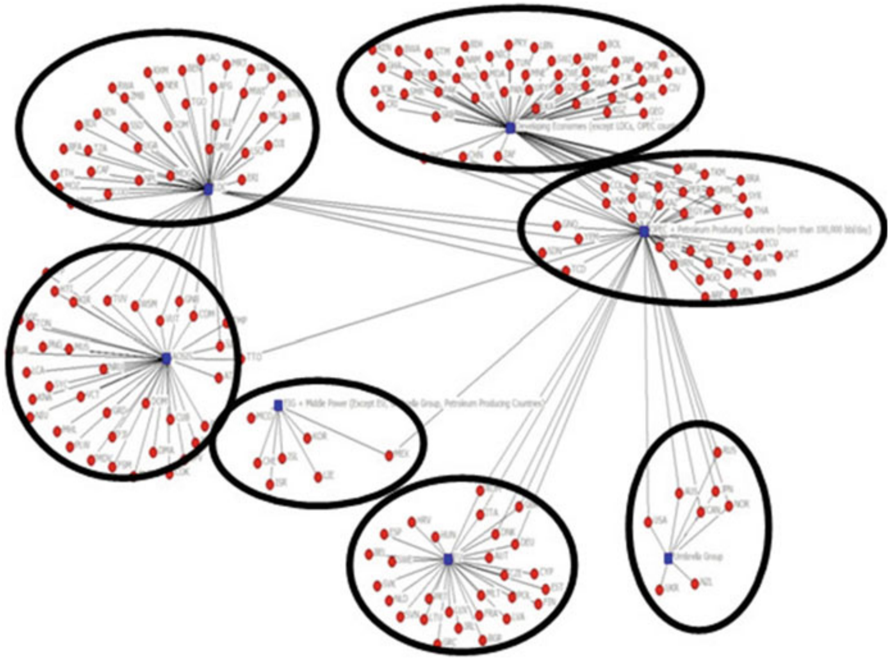

Fig. 3 Coalition building in UNFCCC

LDC (Least Developed Countries)

LDC is a group of nations designated by the United Nations as the most impoverished countries. They are indebted to many developed nations, and those debts are unaffordable. Due to their chronic poverty, they are susceptible to the climate change impacts. Especially, as most of them are located near the equator or deserts, where natural disasters frequently strike, their capacity of climate change adaptation is significantly weak.

OPEC + Petroleum-Exporting Countries (More Than 100,000 bbl/day)

OPEC member countries mainly assert that if states are to regulate the quantity of oil usage to dwindle GHG emission, their economy would be severely damaged. They also have pressed for compensation for the reduction in using petroleum and intentionally disturbed the passage of effective resolutions. Rather, they are more interested in developing clean technologies and carbon capture and storage technologies. Since their major exporting items are crude oil and associated by-products, the chance of their converting stance is scarce (Fig. 4).

Huge petroleum exporting countries are also prudent in agreeing on GHG emission reduction, since exporting an oil has been a major source of their incomes. However, as they retain other industries to substitute it or they exert themselves to expand other industries, their opposition to GHG emission reduction is not so serious as that of OPEC member nations.

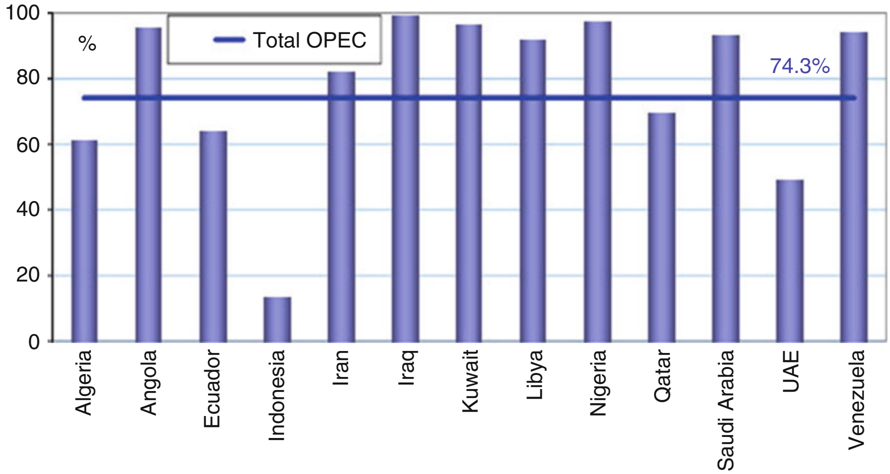

Fig. 4 OPEC member countries' dependence on fossil fuel export in 2008 (Korean Ministry of Foreign Affairs 2010). *Vertical axis: fossil fuel export-to-total export ratio (%)

Developing Economies

Developing economies are represented by China and India. These two mogul states recently give an eye to environmentally friendly industries, including alternative energies. They traditionally stressed the principle of Common But Differentiated Responsibility (CBDR), which is to induce more active supports of developed nations for their sustainable development.

AOSIS (Alliance of Small Island States)

Small island states are in the peril of losing territory and even their whole countries, due to the global warming and consequent rise of sea level. They desperately need the international cooperation to protect their living foundation. Unless the situation hectoring their right to live is completely ameliorated, their stance would be immutable. They clamor for the responsible and effective actions from the whole states to restrain GHG emissions.

EIG (Environmental Integrity Group)

EIG is a group of middle power countries, which are not incorporated in other groups, such as Mexico, Korea (Rep. of), and Switzerland. They aim to mediate between developed nations and developing nations, partially to make constructive plans to manage climate change and partially to hold a leadership in the climate change regime. One of their most remarkable achievements was the establishment of NAMA (Nationally Appropriate Mitigation Actions) Registry, suggested by Korea. It was to encourage the GHG emission reduction and sustainable development of developing economies, by letting them voluntarily construct the mitigation projects and providing the support of developed nations depending on their efforts.

EU (Europe Union)

EU has long been the leading group in the climate change regime. They have acknowledged their own responsibility for climate change and tried to make effective results to mitigate climate change. However, although EU has achieved notable strides in the negotiation, some express concerns on the future of EU's leadership (Obertür and Kelly 2008). Also, lately, the emission trade market of EU has significantly declined both in its size and influence.

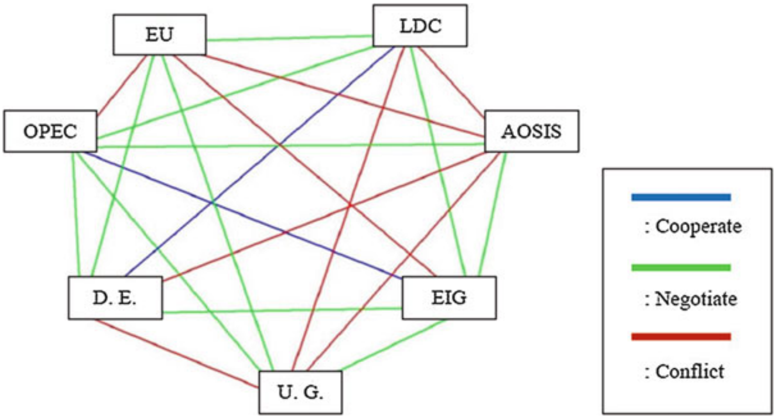

Fig. 5 Network of GHG emission reduction game

Umbrella Group

The Umbrella Group is not a cohesive coalition built with strong fellowship or common interests. Component states, such as the USA, Japan, and Russian Federation, separately try to take the hegemony in the climate change regime. Also, some states constituting this group, such as the Russian Federation, Canada, and New Zealand, are expected to favor with the climate change later (Globalagriculture 2012). This is part of the reason they are not proactive in GHG reduction emission and climate change mitigation.

Synthesis

As UNFCCC majorly pursues climate change mitigation through restricting GHG emissions, players have bickered mostly about whom and how to reduce GHG emissions. It could be called a *GHG Emission Reduction Game*. From now on, this chapter concentrates on this game of UNFCCC. It is the only game that the entire players participate in and could be measured as twenty-one dissimilar 2-person games between coalition groups. The comprehensive frame concerning these twenty-one games is a North–South problem. Thus, the discussion on GHG Emission Reduction Game in this chapter would essentially focus on the altercations related to the North–South problem. This provokes the serious opposition between Developing Economies, LDC, and EU, Umbrella Group. In most conflicts in UNFCCC until now, EU has mediated through its own concession, following the principle of CBDR. This has been the staunch ground for the legitimacy of EU holding the leadership.

Considering the current status of UNFCCC, Fig. 5 shows the game network between coalitions. The relationship between coalitions this chapter discusses is restricted to the climate change issues. For instance, although OPEC and EU are in conflict on climate change issues, they could cooperate in other fields such as economy or security.

Information

UNFCCC is fundamentally an international regime, and thus it curtails the transaction cost and asymmetry of information among nations (Keohane 1984). In doing so, information about one state's climate change policies or favored strategies would have been apprehended by other states. As the nations have communicated with each other at the UNFCCC for 19 times until now, they definitely have understood and accumulated empirical information about other countries' policy preference. In this case, the game could be categorized into *perfect and complete* information game.

Iteration

An international climate change problem accompanies *irreversible* damage, which could not be perfectly restored. Although its major agenda could be changed as time moves on, UNFCCC would not be easily disbanded. This implies that the game of UNFCCC would be iterated *infinitely*, unless the other apparatus is seriously needed.

In specific, considering the role of UNFCCC and COP, two phases are infinitely repeated during the process of the GHG Emission Reduction Game: phase (1) planning (setting GHG emission reduction goals such as predicted amount of reduction, deadline for achieving the reduction goals, etc.) and phase (2) practicing (implementing actual policies for fulfilling the planned goals such as emission trading or carbon tax, etc.). If the players fail to build an effective and realistic plan, players would renegotiate about the plan and redeem it. In this case, the game could not proceed to the next phase, and keeps abiding on the phase 1. During the procrastination in making effective plans, states often take quite extemporaneous or perfunctory measures. If the players successfully devise an effective and realistic plan, they proceed to the next phase, fulfilling the promise stipulated in the resolutions. This cycle of phase 1 and 2 would indefinitely ingeminate as climate change problem could not be perfectly resolved. Figure 6 shows the iteration of two phases and what exactly *sustaining the cooperation* means. Sustaining the cooperation means the situation where players keep choosing C and endeavoring to cope with the climate change. The mutual cooperation should sequentially occur in phase 1 and 2 to consummate the whole process with efficacy.

Actions

Actions that players could choose in the game theory are comprehensively classified into cooperate (C) and defect (D). In the GHG Emission Reduction Game of UNFCCC, C is to cooperate for managing the climate change problem and D is to neglect the indispensability of managing the climate change, implementing makeshift policies. In specific, international cooperation connotes that every player in the

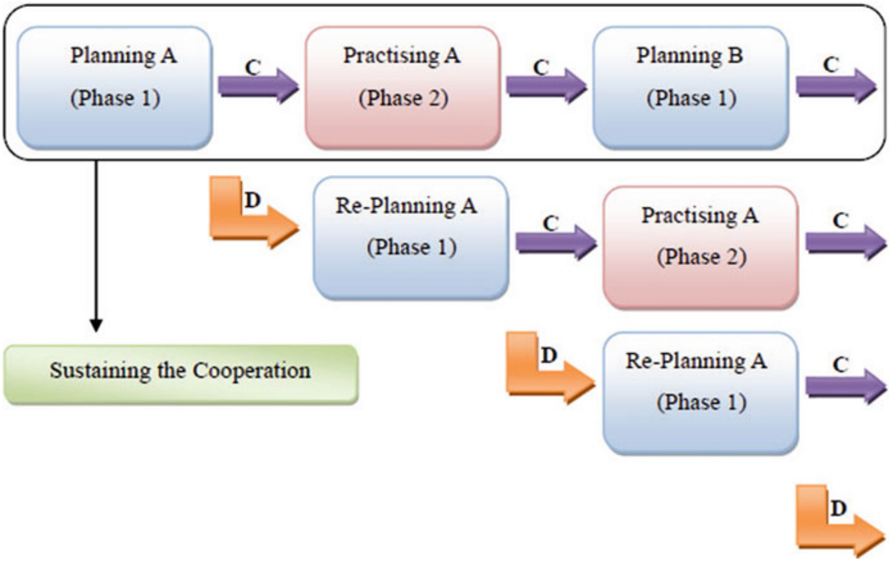

Fig. 6 Iteration model of UNFCCC game

Table 1 Results of choosing C and D in each phase of GHG emission reduction game

C	Phase 1	Producing an effective and realistic mitigation/adaptation plan
	Phase 2	Making an effective and realistic efforts to fulfill the plan
D	Phase 1	Exercising a veto on an effective and realistic plan or producing an abstract and perfunctory plan
	Phase 2	Neglecting the duty stipulated in the plan or implementing perfunctory countermeasures for the plan

game yields their self-interest to some extent, which is usually economic interests. States which choose to cooperate should bear the burden of managing the global common-pool resource. Therefore, strictly speaking, agreements made by one player's unilateral concession could not be called as a result of international cooperation. Table 1 shows the results of choosing C and D in each phase.

Outcome and Payoff

Given the characteristic of climate as a common-pool resource, theoretically players could secure the biggest interest when they unilaterally defect (DC) in the GHG Emission Reduction Game. In this case, the player who defected could obtain profit from economically developing and receiving *boons* from another player's effort of protecting the environment. This is called a free riding, which could generate social dilemma of inequity (Olson 1971). And these egoistic behaviors result in the tragedy of commons, which is consequently prejudicial to everyone (Hardin 1968).

Table 2 Payoff structure of prisoner's dilemma

	C	D
C	3,3	0,5
D	5,0	1,1

When putting climate into the category of national interest, it could fall under the purview of *long-term* interest. The profit states could acquire from mitigating the climate change is not quantitatively measurable in a short period of time. This characteristic of the climate as an economic good would be referential to the concept of *the shadow of the future* (Oye 1986) in the game theory. For nations to value the climate change issues more than now they do, the shadow of the future for managing climate change problems has to be lengthened.

Next-best payoff could be achieved by mutual cooperation (CC). To cooperate with each other, players have to abandon some of their short-term interests by investing in the long-term interest. In doing so, players could effectively cope with climate change and guarantee a secure future.

Third-best choice is mutual defection (DD). By defecting each other, players could strive to economy or national security issues. However, the time keeps moving on and the quantity of irreversible damage would be swelled apace. This possibly would provide short-term benefits of economic development or advanced security which players value the most, but the natural environment would cause grave problems in the near future.

The worst payoff for players is the case of CD, achieved by unilateral cooperation. In this case, the player who chose C turns out to have beaten the air. However much effort the player made to manage climate change, the other player would keep emitting GHG, resulting in the efforts of the player who chose C become profitless.

Therefore, the preference ordering of the game is DC > CC > DD > CD. This implies that the payoff structure could be best explained by *prisoner's dilemma*. Table 2 is the generic payoff structure of prisoner's dilemma. The numbers in Table 2 are not used to signify specific features, but to simply represent the relative size of payoffs.

Synthesizing Aspects of the Game

When aggregating all the aspects mentioned above, the payoff structure of the GHG Emission Reduction Game is *infinitely iterated 2-person prisoner's dilemma*.

In the most cases of prisoner's dilemma (PD), the payoff results in DD. This is because a rational player chooses D, for D is a strictly dominant strategy, which could provide the highest payoff to the player. Also, it is a common knowledge that the other player is also rational and would choose D. Considering this, DD becomes the dominance solvable, as it is the only rationalizable strategy. Here the Nash equilibrium, the payoff with no incentive for both players to change their actions (C or D) and reached by the best response to the other player's choice (Nash 1951), is established in DD. Thus, repeated PD itself has a characteristic of terminating in infinite DD (Kim 2013).

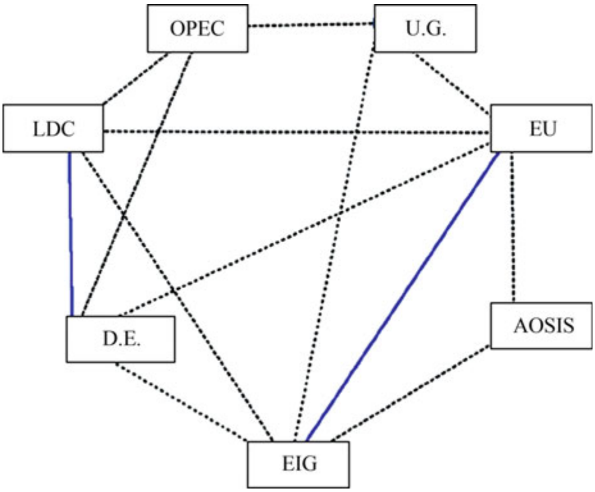

Fig. 7 The dissolution of network between coalitions in GHG emission reduction game

If the situation of DD is iterated in aeternum, what would happen to the game network? To answer this question, this chapter applies the concept of *closeness*, which is one of the most representatively exploited concepts when examining the centrality of nodes in the social network theory (Freeman 1979). Closeness is about the distance between the nodes. The concept of closeness is often restricted to the physical distance when analyzing the structure of societies. However, the distance between actors could also represent the *psychological distance* in the game network of UNFCCC, for players decide to choose C or D by anticipating what the other player would choose in the iterated game, and that process of determining is a mental work, where reputation becomes of importance (Mailath and Samuelson 2006). If players keep choosing D, the distance between them might be elongated. The GHG Emission Reduction Game would end in the dissolution of linkages between players in conflict and debilitation of linkages between players once negotiated as represented in Fig. 7 (conflict: blank, negotiate: dotted, cooperate: solid).

As shown in the Fig. 7, the cohesive game network would become a loose network with many *structural holes*. Through 19 regular meetings of COP, the network between coalition groups has been metamorphosing into the type in Fig. 7. Although states periodically congregate to take measures against climate change, they are mostly disappointed with each other and merely pursue their own interests. If the entire game network were to be imploded in the end, the climate change regime per se would also become obsolete.

Thus, in order to make effective and realistic measures, it is crucial to end the iteration of DD (in the game theoretical approach), which means to bridge the structural holes (in the network theoretical approach). In the next section, this chapter examines the possibility of ending an iterated DD by using tit-for-tat strategy in the PD of the GHG Emission Reduction Game.

Sustaining International Cooperation with Tit-For-Tat Strategy: Is It Possible?

Tit-For-Tat Strategy

Tit-for-tat (TFT) first received a widespread attention after having been introduced in *The Evolution of Cooperation* (Axelrod 2006). TFT program constructed by Anatol Rapoport won the first place in the computer tournament Axelrod held. TFT first chose C and then follows what the other player chose at the previous period. TFT never scored better than others in the specific period of game, as it allows them to defect. However, TFT induced other players to pursue mutual cooperation by letting them perceive the game to be nonzero sum, and as a result, it became a winner in the end.

From the success of TFT, Axelrod (2006) suggests players practice "reciprocity" (pp 136–139). By maintaining the equipoise between the cooperation and retaliation phase, and never defecting first, the simplest strategy of TFT could promote the possibility of mutual cooperation (CC). Acknowledging that TFT is the best to promote cooperation in PD, this chapter examines what the result would be when (1) one player (unilateral) and (2) both players use (bilateral) TFT strategy in the game of climate change.

Limitations of Using TFT Strategy

It is undoubtedly explicit that TFT generates CC better than any other strategy in PD. However, when a player unilaterally uses TFT strategy, it also has a limitation. Axelrod (2006) also states, "The trouble with TIT FOR TAT is that once a feud gets started, it can continue indefinitely" (p. 138). This is a significant disadvantage of TFT in dealing with climate change, now that it would be laborious to sustain international cooperation by using TFT strategy.

First, this chapter takes cases where player 1 uses TFT and player 2 uses (1) nasty and (2) alternation strategy to illustrate the possible quandary induced by the unilateral TFT strategy. Nasty strategy is to choose D for every period of the iterated game. In this case, feud might be perpetuated, since TFT would follow D which nasty always chooses. By doing so, coalition groups could not achieve any further cooperation. Rather, the situation ends with the unremitting DD, which means that the players immerse themselves in managing their short-term benefits, especially the economic development (Fig. 8).

Next, alternation strategy is to choose C at the odd number period and choose D at the even number period. In this case, using TFT would result in the endless iteration of CD and DC. The revealing point is that player 1 always cooperates in an even number phase (except for CC at the first period) and player 2 always cooperates in an odd number phase. As players both choose C in the first period, they could draw a specific resolution. However, in the next period, which is phase 2 (practicing), player 2 chose D, neglecting the duties stipulated in the agreed resolution.

Player 1: C → D → D → D → D → D → D → D ...

Player 2: D → D → D → D → D → D → D → D ...

Fig. 8 TFT versus nasty strategy – perpetuated defection

Player 1: C → C → D → C → D → C → D → C ... → D → D → D ...

Player 2: C → D → C → D → C → D → C → D ... → D → D → D ...

Fig. 9 TFT versus alternation – iteration of CD and DC

To punish this negligence, player 1 chose D in the third period, which is again phase 1 (planning). By doing so, players could not set specific goals of effectively responding to climate change. Then again player 2 and player 1 alternately defect each other. This would not induce effective and realistic measures against climate change (incurring infinitely iterated phase 1) and the mutual cooperation would never be achieved. Eventually, this would end in the perpetuated DD. Rational players would realize it is not of assistance to choose C in case where the other player would certainly choose D. In other words, there is no incentive for players to choose C in the iterated CD and DC. Thus, a rational player would forsake choosing C and adopt the nasty strategy (Fig. 9).

During the successive vicious cycle of defection, the quantity of irreversible damage would uprise as time goes by. If players do not cooperate until the quantity of irreversible damage reaches the point where climate change catastrophe would inevitably occur, there would be no alternative to manage the problem. Understandably, by adopting some strategies such as nice strategy (always choose C), CC could be achieved in the case of unilateral TFT. However, it is a handful of exceptions, which is almost infeasible in the international world. In most cases, where players try to choose D to get more outcome, CC would not be achieved whatsoever. Adopting a unilateral TFT could not completely solve the problem of sustaining international cooperation.

Second, although both players use TFT strategy, sustaining cooperation is not always practicable. To sustain CC, Nash equilibrium has to be formed in CC. In the infinitely iterated game, how much the players value the shadow of the future is to be analyzed. To measure the shadow of the future, the value of future payoff should be converted into the value of current payoff. The average of converted future payoff's value in each period is called discounted average payoff (Kim 2013). Figure 10 shows how to find the discounted average payoff.

First, the discounted average payoff of choosing C (v_c) when both players are using TFT strategy could be evaluated, based on the structure of PD in Table 2, as below:

$$v_c = (1-\delta)\left(3 + 3\delta + 3\delta^2 + \cdots\right) = (1-\delta)\cdot\left(\frac{3}{1-\delta}\right) = 3$$

Discounted Average Payoff v

$$= (1-\delta)(u_1 + \delta u_2 + \delta^2 u_3 + \cdots + \delta^{t-1} u_t + \cdots)$$

$$= (1-\delta)\sum_{t=1}^{\infty} \delta^{t-1} u_t$$

$$(u_t = \text{payoff acquired at the period t},$$

$$\delta = \text{discount factor},\ 0 < \delta < 1,\ \delta \equiv \frac{1}{1+r},\ r = \text{discount rate})$$

Fig. 10 Evaluation of discounted average payoff

From the period t,

Player 1: D → C → D → C → D → C → D → C ...

Player 2: C → D → C → D → C → D → C → D ...

Fig. 11 TFT versus TFT after player 1 first chose D

Next, to find the discounted average payoff of choosing D (v_d), this chapter hypothesizes that player 1 chose D at the period t. Then player 2 would punish it by choosing D at the period (t + 1). This cycle of DC and CD will be infinitely iterated (Fig. 11).

In the indefinite iteration of DC and CD, a player receives 5 in the period of DC and 0 in the period of CD. Thus, the discounted average payoff of choosing D (v_d) is

$$v_d = (1-\delta)\left(5 + 0\cdot\delta + 5\delta^2 + 0\cdot\delta^3 + \cdots\right) = (1-\delta)\cdot\left(\frac{5}{1-\delta^2}\right) = \frac{5}{1+\delta}$$

Last, to establish a Nash equilibrium in CC, v_c should be bigger than v_d ($v_c > v_d$):

$$(v_c > v_d) = \left(3 > \frac{5}{1+\delta}\right) = (\delta > 0.66)$$

This implies that bilateral TFT not always maintain a mutual cooperation. Also, sustaining a CC with bilateral TFT requires players to rate the future payoff monumentally high ($\delta > 0.66$). However, realistically, long-term behoof of managing climate change problem could not be more valued than economy or national security, directly pertaining to the everyday survival of nations. Also, as the payoff from DC is bigger than that from CC, it is exacting to concern to managing long-term interests. This difficulty in recognizing the value of long-term interests makes it almost impossible to take care of the climate change problem.

It is an unquestionable truth that TFT could promote the possibility of cooperation. However, the game of UNFCCC is constituted of two different phases. If one of them results in DD, DC, or CD, the other phases where CC was achieved also become profitless, as phase 1 and 2 compose a uniform process of effective response to climate change.

Radical Change Is Needed

The key reason TFT could not readily sustain the cooperation is that the payoff from DC (5) is bigger than from CC (3). In other words, although CC is achieved at one period, still an incentive to choose D remains mighty. Technically speaking, this is not the problem of TFT. Instead, it is an essential problem that PD has. With TFT, the payoff structure of PD could not be hypostatically ameliorated. TFT could only promote the possibility of cooperation in the iterated game. Thus, the game structure of UNFCCC needs a *radical* change.

The radical change means the transformation between the first and second preference order as CC > DC. The most well-known structure that satisfies this condition is a *stag hunt*. In the next chapter, this chapter explores the structure of stag hunt (SH) as a substitute for PD and ultimately how it could sustain the international cooperation. The analysis of SH not only takes theoretical approaches but also proposes some realistic methods to change the payoff structure from PD to SH.

Stag Hunt as an Alternative to Prisoner's Dilemma

Stag Hunt

The stag hunt game structure was derived from a fable stated in *A Discourse Upon the Origin and the Foundation of the Inequality Among Mankind* (Rousseau 1755). Hunters are gathered to hunt a deer. Then, suddenly the hare appears near the hunters. Here, Rousseau set some conditions. A hunter could not capture a deer by oneself, for it is very fast. The possibility of successfully hunting a stag scales as the number of hunters hunting a stag increases. A hunter could readily catch a hare, regardless of what the other hunters do. However if one catches a hare, the other hunters indispensably could not catch a stag. Also, the value of a hare is less than that of a stag divided into N (the number of hunters).

In this game structure two problems occur in achieving cooperation. First, the problem of *uncertainty*. Although all hunters cooperate to catch a deer, it is not of certainty whether the hunters could hunt it. Only the possibility of successful stag-hunting increases. This could make hunters encounter a dilemma about which to hunt. Second, the problem of *mutual distrust*. Hunters do not know what the others would choose to hunt. Each hunter distresses oneself about the possibility of other hunters' catching a hare, while oneself chooses a stag.

These problems become the main obstacles that make choosing to catch a stag quite risky. If at least one hunter among the hunters chooses a hare, the other players who choose a stag would gain absolutely nothing.

Table 3 Payoff structure of stag hunt

	C	D
C	v,v	0,1
D	1,0	1,1

$v > 1$

Nevertheless, this chapter suggests to transform into *infinitely iterated 2-person stag hunt*. Every other factor of the payoff structure is unchanged, except for the payoffs. In this structure, the preference order of payoffs could be CC > DC > DD > CD, as a stag divided into N is more invaluable than a hare. As a result, mutual cooperation (CC) is more worthy than unilateral defection (DC). This makes a plethora of changes in the choice of players (Table 3).

As the game is constantly repeated, the players (or the hunters) would to some degree discern what each other would choose at the next period. This could help resolve the problem of mutual distrust. In the iterated games, rational players choose the best response to the other player's choice. If the other player is expected to choose a stag, oneself would rather choose a stag and vice versa. There is no incentive for players to choose a stag, when the other player is choosing a hare. It would lead to the outcome of 0. In this case, the Nash equilibrium is formed in CC and DD (Skyrms 2003). This means the iterated SH could beget the sustenance of cooperation or the sustenance of defection.

In addition, the iteration of game could solve the problem of uncertainty. If the mutual cooperation (CC) is eternally iterated, players could share the information and contrive improved methods to catch a stag. This could naturally diminish the uncertainty in catching a stag. However, this could be only resulted from an iteration of CC. Then among the two possible Nash equilibriums (CC and DD), which payoff would be realized?

The answer could be found by employing the concept of payoff dominance and risk dominance (Harsanyi and Selten 1988). Payoff-dominant Nash equilibrium refers to the Nash equilibrium which is Pareto optimal (Pareto efficient) among two or more Nash equilibriums in one payoff structure. In other words, if players choose to deviate from the payoff-dominant Nash equilibrium, one or more players would suffer a loss. In the SH structure, the outcome of catching a stag is always absolutely bigger than that of catching a hare ($v > 1$). Thus, CC is the payoff-dominant Nash equilibrium, and choosing C is a strictly dominant strategy, which could lead to the maximum outcome.

Still, the payoff dominance does not guarantee the realization and sustenance of CC. Risk dominance should also be considered. Risk-dominant payoff is the payoff which is more worthy to take a risk for choosing than the other one. Although $v > 1$, if the value of v is too small (e.g., 1.0001), selecting C becomes a risky choice. It is because hunting a stag when the other player is choosing a hare could result in receiving 0, while hunting a hare always guarantees a payoff of 1 (Kim 2013). Then when could hunting a stag risk dominates hunting a hare? To answer to this question, this chapter compares the risk factor of choosing a stag and a hare. To calculate the risk factor, suppose p is the probability of the player 2 to choose a stag. Then the outcome player 1 could earn from choosing a stag (C) is $p \cdot v + (1 - p) \cdot 0 = pv$ and from choosing a hare (D) is $p \cdot 1 + (1 - p) \cdot 1 = 1$. The risk factor for choosing a stag is the value of p which makes two outcomes of catching a stag and a hare equal. It is $1/v$. Also, the risk factor for D is the value of $(1 - p)$ which makes two outcomes equal. It is $(v - 1)/v$. Last, the risk-dominant payoff is the payoff with the less risk factor. Hence, for CC to be less risky than DD, v should be

$$\frac{1}{v} < \frac{v-1}{v} \Rightarrow 1 < v - 1\ (\because v > 1) \Rightarrow\ v > 2$$

However, in fact, risk dominance problem is not a big obstacle in sustaining cooperation in the iterated game. In the repeated game, the best response is to choose what the other player frequently selects. In this case, the dilemma of risk dominance is naturally diminished, since what the other player would choose becomes obvious as time goes by. Also, due to the payoff dominance of choosing a stag, the possibility of rational players' choosing a stag is far higher than choosing a hare. Hence, if players rationally seek for a bigger payoff and choose C, the situation of CC would be achieved. Then, players would keep choosing C through the iteration process, for they could predict that the other player would also choose C. At this point, due to the iteration, the problem of mutual distrust and the risk dominance becomes nothing to consider.

As the payoff of CC is bigger than DC, there is no incentive for rational players to choose D when cooperation is on the way. This is the supremacy of the SH structure per se against the PD. In the PD structure, although a mutual cooperation is achieved, an incentive to defect always presents. If the payoff earned from the mutual cooperation is the biggest, rational players would not try to defect. Therefore, the solution to sustaining international cooperation is a transformation of the payoff structure from PD to SH.

How to Change Into SH

Changing a payoff structure means to change the value of payoffs which comprise the structure. A transformation from PD to SH requires a change in the ordering between CC and DC. In other words, (1) the benefit received from choosing C should be increased or (2) the disadvantage received from choosing D should be strengthened.

However, strengthening the disadvantage of defection is treacherous. International climate change regimes, including UNFCCC, have a *binding* power, while they do not hold a *coercive* power. Even if UNFCCC could warn the parties which neglect their duties, it is mostly restricted *to psychological burdens* and a little amount of *taint on their escutcheons*. Especially, as most states themselves do not zealously endeavor to manage climate change, they seldom castigate other nations' negligence. In this circumstance, reinforcing an economic sanction against states which choose defection could even make states resign from the UNFCCC.

Realistically, it is also difficult to increase the absolute payoff of cooperation in the game. The cooperation in this case means to put national interests little aside and concern about global public interests. However, in the real world, the absolute value of protecting the environment could not be higher than that of the daily livelihood. The absolute benefit associated with daily living is more material to state governments than that of global public interests. States would hardly value the environment higher than the economy and national security, unless the quantity of irreversible damage crosses the Rubicon.

At this point, game theoretical approach could not give us a clear solution. As an alternative, this chapter employs the network theory. The iteration of DD in PD means the formation of structural holes in the network theory. Likewise, the change into SH, which encourages CC, could be interpreted as filling in the structural holes in the network theory.

However, all coalition players of the UNFCCC game pursue their own interests, and those rational players do not have any incentive to bridge the structural holes to sustain the cooperation. Therefore, an adequate actor could not be found in the level of coalition groups, and instead it would be discovered from the level of discrete state governments constituting the coalitions. Still, some incentive should be provided for each state to take mediating roles.

The incentive for the states could be the *leadership*. Currently, it is of certainty that some states in coalition groups, such as EU, Umbrella Group, EIG, and Developing Economies, vie for the initiative in UNFCCC so as to improve their soft power (Shin 2011). However, as they already belong to one coalition group, they inevitably reflect the major stances of the groups they belong to. The exceptions are the states of Umbrella Group, which is somewhat loose. However, it is doubtful that they could truly arbitrate between different opinions from, generally, developed nations and developing nations, for they have not experienced the circumstances of developing countries.

This implies that regrouping is necessary so as to forge a new group of countries that could mediate between the existing groups. Some middle power countries scattered in each group would be suitable for building a new coalition group and interceding between other groups. Some studies maintain that middle powers are "more responsive to humanitarian values than most, particularly larger states" (Black and Smith 1993, p. 763) and they have played a role as a mediator for a long time in other fields (Holmes 1965). In specific, the new group should consist of middle power, which underwent the experience of being a developing country. Middle power countries which are still classified as developing nations by IMF would not be appropriate, since they could not comprehend the stance of developed nations. Additionally, to ensure the active intercession with unwavering objective, the states' economy should not resort heavily to producing or exporting fossil fuels.

Some representative states that satisfy these all conditions are Singapore and Korea (Rep. of) from the Four Asian Tigers, and Czech Republic from countries recently joined EU. The appellation of the group that binds them into one could be

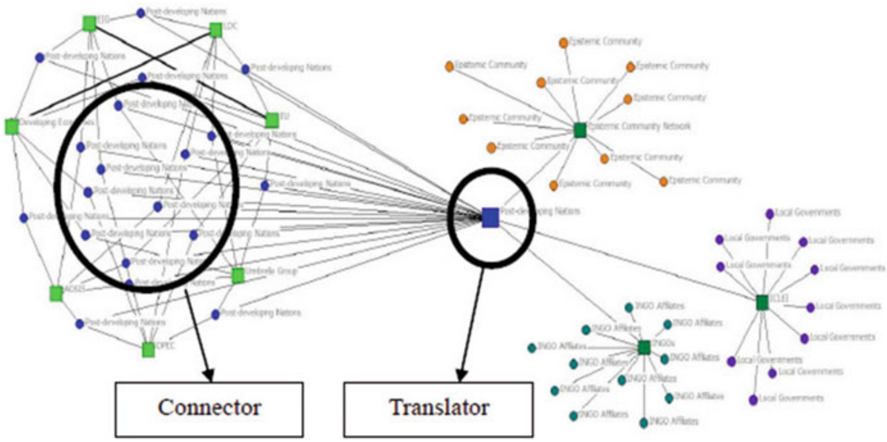

Fig. 12 Post-developing countries as a connector and translator

called *post-developing countries*. This is to emphasize the distinct characteristic these countries have, the transition from developing nation to developed nation.

The only problem left is that the post-developing countries do not have enough political leverage to play a role as a *connector*, who reconstructs the broken linkages in the same level of network. Some studies suggest that middle powers have to obtain support from other international actors to take international leadership (Yamasaki 2009). Thus, given that post-developing countries are originally categorized as middle powers, it would be helpful for them to tighten solidarity with transnational actors, such as INGOs, local governments, and epistemic communities, by working as a *translator*. Especially as INGOs per se have a form of transnational advocacy network (Keck and Sikkink 1998) and local governments have established their own network called ICLEI, post-developing countries could create a cohesive synergy effect when forming a network with those networked actors. Moreover, INGOs or epistemic communities could provide eclectic policy options that could embrace the opinions of multiple coalitions (Raustiala 1997) for the post-developing countries.

Translator links the nodes in the different levels, conveys the flow of meaning, and makes the meaning compatible so that the nodes could assimilate it (Kim 2011a). By operating as a translator connecting the transnational actors outside the regime to the state governments inside the regime, the post-developing countries could hold a high *degree centrality and betweenness centrality* (Freeman 1979), as shown in the Fig. 12.

Through this process, the post-developing countries group is expected to consolidate the leverage in the UNFCCC and ultimately act as a catalyst for sustaining the cooperation among states. Then the regime would operate more effectively and the transnational actors would more dynamically and actively participate in the regime.

Conclusion

This chapter started with raising three major questions and endeavored to find the answers. By applying the game theory and network theory, and sectionalizing the international system into *in* and *out* of the regime, this chapter was able to find to some extent realistic answers.

1. *Why international regimes are still the crucial tool to manage climate change, in the more dynamically changed world system?*

   States have path dependence on the regimes, and they effectively harness regimes to maintain their ascendancy in the international world. This results in the rearing up of transnational actors outside the regime, and the state's insistent dominance inside the regime.
2. *Why does the cooperation achieved in the period of resolution-making hardly sustain to the period of each state's practicing policies?*

   According to the game theoretical analysis, the payoff structure of games constituting the 2-person game network of UNFCCC is PD. Due to the *intrinsic-inferiority* of the PD in sustaining the cooperation, the game of UNFCCC has gotten bogged in a quagmire of ethereal DD, which means creation of structural holes in the network theory.
3. *How could the international cooperation achieved by international regime sustain for a long period, without any state's defection?*

   As the best strategy of TFT could not essentially solve the problem of PD, the radical change into *intrinsically superior* SH is needed, by filling in the structural holes. The role of doing so could be performed by the post-developing countries, through operating as a connector in the regime and translator out of the regime and establishing a staunch network.

   Some studies (Kim 2010; Ha and Kim 2010) argue that the rise of transnational actors would lead to the power shift or power transformation in the international system. However, the analysis on the international regime verifies that the states still own a *castle* that could protect their dominance. Thus, power shift would hardly occur until at least the near future, and rather the expected change could be called a *power division* among international actors.

   Furthermore, as regimes are expected to continuously operate as a critical instrument in managing climate change, sustaining cooperation with the method suggested by this chapter might be of importance. Some states or coalition groups trying to take the initiative might hamper the process of strengthening the position of post-developing countries. Thus, the ultimate success of this network depends on how astute the post-developing countries perform the task as a connector and translator. This chapter would leave it as a subject for future studies.

The Effect of New Public Management Reforms on Climate Change Adaptive Capacity: A Comparison of Urban Planning and the Electricity Sector

Tor Håkon Inderberg, Knut Bjørn Stokke, and Marte Winsvold

Contents

Abstract

From the mid-1980s and onwards, a number of public institutions in Western democracies were subject to New Public Management (NPM) reforms, applying management tools from the private sector, oriented towards outcomes and efficiency. The chapter identifies organizational factors that influence adaptive capacity to climate change and finds that the NPM reforms have changed the sectors, significantly reducing adaptive capacity to climate change. In urban planning project planning has been moved to private actors, undermining formal

responsibility for adaptation. In addition, an increased focus on efficiency and short-term market orientation has reduced adaptive capacity. For the electricity sector, the revolutionary change with the reform in 1991 led to an abrupt undermining of adaptive capacity. The radical change in incentive structures, from encouraging security of supply to an extreme focus on economic efficiency, downplayed robustness and adaptation. The change in formal structure is followed by a corresponding professional demographic change which further undermines adaptive capacity. Whereas both sectors were previously dominated by engineers focusing on robustness of constructions and maintenance, many economists focusing on cost reduction and economic efficiency were employed as a result of NPM reforms.

The chapter shows that adaptive capacity to climate change is influenced by a wide set of organizational factors beyond the traditional discussions, which have important practical implications for public administration.

Keywords

Organizations • Adaptive capacity • Formal structure • Culture • Electricity sector • Urban planning • NPM • Institutional logics • NPM

Introduction

From the late 1980s and onwards, a number of public institutions in Western democracies were subject to the so-called New Public Management (NPM) reforms, which applied management tools from the private sector, oriented towards outcomes and efficiency. These reforms have arguably transformed public organizations in the Western world from unitary and hierarchically managed organizations to more loosely organized clusters of interrelated organizations, with specified tasks. At the same time, climate change poses new challenges within key sectors (O'Brien and Leichenko 2008). With expected higher general levels of precipitation, floods, landslides, and possibly extreme winds, the necessity of implementing climate change adaptation measures is clear. However, the capacity to do so is not necessarily equally present across sectors. This chapter asks how NPM reforms have influenced the capacity to adapt to climate change in two policy areas that stand out as especially affected by changing climate patterns: urban planning and the electricity sector. Comparisons of the organization of public administration and adaptive capacity have been made diachronically within the same sector(s) both between and within countries and between sectors in different countries (see, e.g., Eakin et al. 2011; Huntjens et al. 2012; Eriksen and Selboe 2011; Inderberg 2011). Comparisons between sectors within the same national context are pertinent, however, since it allows us to study how sector-specific effects of organizational reforms affect adaptation capacity differently. This chapter compares the influence of NPM reforms in two different areas within the same national context, using urban planning and the electricity sector in Norway as cases.

The electricity sector and the urban planning sector both represent systems that society is dependent upon, and they both administer critical infrastructure which is geographically widespread, exposed to weather and change in climate. In other respects, the sectors are quite different. While the electricity sector takes responsibility for a limited set of goals, providing a reliable electricity supply to feed end users in an efficient manner, urban planning takes care of a multitude of considerations.

Adaptive capacity has been argued to be resource dependent (Smit and Pilifosova 2003). Norway is known to be rich in natural, financial, and knowledge resources and is therefore generally expected to yield a high adaptive capacity, and in order to shed light on a wider set of barriers to adaptation, Norway is therefore a good choice of case (O'Brien et al. 2006).

In Norway NPM reforms initially fell on barren grounds (Christensen et al. 2007). Eventually, however, NPM reforms were implemented in most sectors, although at different speeds and with sector-specific adjustments. While NPM as a reform wave has been claimed to be in decline, it still yields a prevailing legacy in the public sector (Christensen et al. 2007). Both the urban planning and the electricity sector have in Norway undergone reorganization according to NPM principles, although the specific design of the reforms and the way in which the reforms came about differ greatly. While the electricity sector saw a politically decided total and sudden restructuring, the planning sector gradually developed into a more market-oriented organization form. However, slow changes by no means mean less radical changes over time.

NPM reforms have been shown to alter not only the formal organizational structure but also organizations' cultures and ways of thinking (Inderberg 2011). These dimensions can again influence each other. To come to grips with the effect of NPM reforms on adaptive capacity, both an instrumental and a cultural perspective are applied.

The chapter starts with a presentation of two perspectives on NPM and adaptive capacity. Next, the empirical basis of the study is described and the research elaborated. Third, the two sectors and the changes introduced by NPM reforms are briefly described. In section four, the influence of NPM on adaptive capacity in the two sectors is analyzed and compared, both between the two sectors and also implicitly diachronically between pre- and post-NPM reforms in the two sectors.

Comparisons between the two sectors are set up along the dimensions of formal structure and organizational culture. Data has been gathered through formal documents, research articles, and in particular for the institutional-cultural perspective through extensive interviewing. Representatives of various types of actors from the energy sector and the planning sector have been through semi-structured interviews. For the electricity sector the interviews have been conducted with representatives from public officials in the Norwegian Water Resources and Energy Directorate (NVE), with company representatives and interest organizations, along with public officials. In the urban planning sector, interviews have been conducted in ten municipalities with representatives involved in urban planning, including municipal planners, politicians, architects, and private developers. Altogether, 57 interviews with 97 different persons in urban development were conducted in the period between September 2008 and December 2010. In both sectors, informants have been asked specific questions about formal structures, laws, and regulations and also about change in culture, appropriate courses of action, and modes of behavior over time.

Two Perspectives on NMP and Adaptive Capacity

The chapter assumes that the adaptive capacity of an entity, understood as its "ability or potential to respond successfully to climate variability and change" (IPCC 2007, p. 727), will be affected by the way the sector is organized as well as by specific sector characteristics. With the change caused by the NPM reforms in mind, it is natural to ask how this will influence the capacity to adapt to climate change (Eakin et al. 2011).

On the one hand, NPM reforms have been shown to empower and make leeway for managers to act, to clarify responsibilities, and to create important flexibility for the organizational units. On the other hand, NPM has been criticized for being too one-dimensional in emphasizing efficiency (Christensen et al. 2007). Taking its objectives not from democratic ideals but from market economics (Stoker 1998), it can undermine important considerations within public administration. Various traits associated with NPM, such as managerialism, lack of coordination between organizational units, and narrowing down scope for inherently complex issues, can lead to a reduced policy capacity to handle complex challenges (Painter 2001). Moreover, NPM can be said to lead to change, for example, in public sector legitimacy (Gregory 2001), and the use of individual auditing procedures for goal achievements changes civil servants' feeling of responsibility and narrows the scope of possible action (Shore 2008).

NPM reforms' influence on adaptive capacity can be studied from an instrumental and an institutional perspective. The instrumental perspective assumes that formal structures influence and channel attitudes and actions (Christensen et al. 2007, p. 144). Formal structure describes the explicitly regulated relations between actors at different levels and influence who can do what and how. Formal structures are seen as tools or instruments for organizational goal achievement, and adaptive capacity will in this perspective be contingent on organizational coordination and on the clarity of the distribution of responsibility embedded within the formal structure in the form of directives, incentives, and sanctions (Christensen et al. 2007). The formal structure can be changed in short time to fit the various goals set, and since actions are assumed to be influenced by the formal structure, such changes in formal structure will lead to a change in organizational outcome. The capacity to adapt, therefore, is in this perspective a function of the extent to which adaptive capacity is a prioritized goal and the effectiveness with which the organizational structure is oriented to goal achievement.

A high adaptive capacity will mean a clear distribution of responsibility; efficient coordination of the actions of involved actors in combination with clear expectations and incentives (resources and/or coercion), in the form of directives and legally binding regulations on issues of long-term perspective; robust construction; and location of physical structures. Where relevant, a formal structure that supports mapping of vulnerabilities as well as vulnerability-reducing investments and maintenance will also increase adaptive capacity.

In urban planning, the formal structure in particular regulates the relationship between national, county, and municipal government and private developers. In the electricity sector, the formal structure includes the whole sector from grid companies or entrepreneurs, via the administrative level and the regulators, to the ministry level.

The *institutional-cultural* perspective claims that actors within an organizational field can be seen as constrained by *institutional factors*: "more-or-less taken-for-granted repetitive social behaviour that is underpinned by normative systems and cognitive understandings that [...] enable self-reproducing social order" (Greenwood et al. 2008, pp. 4–5). Institutional factors are understood as relatively stable norms, values, and routines both constraining and empowering action.

Individuals and organizations fulfil or enact identities by following informal rules and procedures that they imagine as appropriate to the situation they are facing (March 1994). Actors thus act out what they believe is expected of them, and action is decided by norms and values. Action, then, is what is deemed appropriate by an actor in a process whereby situation and roles are matched (Christensen and Røvik 1999; March and Olsen 1989). Also, different appropriate behaviors can manifest in *institutional logics* within the same institutional setting, where contradictory practices and beliefs exist (Thornton and Ocasio 2008). Institutional logics can be coupled to professional background (Reay and Hinings 2009) and may compete, coexist, or get defined out, sometimes through change in organizational demography or location (Lounsbury 2007; Reay and Hinings 2009). Institutional logics can often be identified by looking at how organizational actors argue for or against, for example, specific solutions to problems, how specific situations are defined, and through perceptions about what is expected from them in particular situations.

Change in and the relative balance between institutional logics is important for adaptive capacity. Barriers to adaptation will exist where the institutionalized values do not provide a legitimate basis for the implementation of adaptive measures. Therefore, if the NPM has led to a change in institutional logics, this is likely to also influence adaptive capacity.

By this perspective a high adaptive capacity in urban planning and in the electricity sector would be when prevailing institutional logics legitimize climate vulnerability awareness and vulnerability reduction. This can, for example, be the use of climate change scenarios as a basis for decisions, emphasis on robustness, security, and maintenance of physical structures.

The Introduction of NPM into the Spatial Planning and Electricity Sectors

The Urban Planning Sector

Norway has introduced NPM reforms and market forms in urban planning to a greater extent than its neighboring countries (Hanssen and Saglie 2010). According to most of the interviews and as the Norwegian urban planning system is largely decentralized, the practical implications of the reforms have taken place at the local level. Planning authority pursuant to the Planning and Building Act (PBA) is delegated to the municipalities, with the local council as the primary decision maker. Since the mid-1980s, the authority of the national government has been restricted to issuing national guidelines for local planning and to giving final decisions on conflicting planning issues between the municipality and regional authorities (Kleven 2011). The most important NPM-inspired reform in the planning sector took place in 1985, when the PBA opened up for planning initiatives from private actors, thereby terminating the municipal plan monopoly for zoning plans. The formal structure was hence altered in 1985, and a cultural change followed suit: Gradually a new division of labor has emerged in which private developers are plan owners and plan formulators until the plan proposal is submitted, whereas the municipality has gradually taken the role of a more passive, responding approval authority (Høegh et al. 2004). Today, nearly 90 % of zoning plans are formulated by private actors (Falleth et al. 2010). These zoning plans are core documents for the regulation rights and core instruments in the control of urban development. In general, urban planning now tends to center on projects in the form of single zoning plans rather than proactive and comprehensive plans for the urban areas. The operation mode of spatial planning is consequently altered. Detailed formal planning (zoning plans) for urban development is no longer the prerogative of the municipalities. The plans still have to be approved by the local councils, but the plan initiative and plan formulation have in practice been delegated to private actors, and investors and private developers have gained an increasingly prominent position in urban planning and development (Mäntysalo et al. 2011; Nordahl 2006).

This development reflects a politically driven neoliberal trend with great impact on urban planning practice internationally, and the underlying idea corresponds with that of NPM, assuming increased efficiency through management by objectives (Hanssen and Saglie 2010). The ambitions of the municipalities are limited to manage the spatial development through their master plan according to the Planning and Building Act, and their role has increasingly become reactive instead of proactive. The situation is often characterized by negotiations between market actors and public authorities (Falleth et al. 2010; Klausen et al. Forthcoming 2015)). Market actors provide funding for much wanted development, which in turn gives these actors a strong bargain position vis-à-vis public authorities in defining "what to build where" (Falleth et al. 2010).

The workforce in urban planning has remained relatively stable in absolute numbers, although the staffs employed in the private sector have increased relative to the public sector. Urban planners, architects, and engineers dominate both in municipal planning departments and with private developers. Consultants, partly with background in economics, however, are gradually gaining a more prominent position, and they often function as intermediary between the public and the private part of the planning sector (Moen et al. 2004). At the same time, one can, according to the informants in the ten case municipalities, observe a gradual introduction of a new institutional logic related to some of the NPM tools, such as management by objectives. Whereas each project previously had a general responsibility for common public values such as the value of sustainable urban development, the projects are now more narrowly addressing the specific demands articulated in municipal directives and regulations or in the national Planning and Building Act. Goals that are not explicitly mentioned in core documents tend to be ignored.

The Energy Sector

Until 1991 the price of electricity in Norway was regulated through long-term contracts (Midttun and Summerton 1998). The sector was hierarchically regulated through direct public ownership and politically set prices, and largely vertically integrated, meaning that generation and transportation of electricity was usually performed by the same companies. In fact, most of the central grid was owned by state-owned Statkraft while still generating around one third of the nation's electricity (Bye and Hope 2006).

The companies often sold power at self-cost, because of considerations other than economic ones or simply because of lack of economic expertise. Combined with the fact that trade and consumption of electricity were largely domestically confined because of weak connections abroad, this contributed to a steady rise in consumption. Less attention was paid to the cost of projects, something that led to varying outcomes. All investments in production and capacity in this period were subject to cost reimbursement, either through direct market prices, cross-subsidization, or direct subsidies (Bye and Hope 2006).

In the period up to the point of the reform in 1991, emphasis was put on security of supply, as well as general industrial development in Norway. The engineer's values and logic of thinking largely represented the appropriate code of conduct. Other values current at the time were the industrial modernization of Norway, in which cheap electricity played an important part (Olsen 2000, p. 123). The interviewees that have experienced the time before 1991 confirm that the engineers were the dominant group within the sector, and they traditionally emphasized the structure of the grid – secure supply of energy – often over-dimensioning the structures to guard against exposure to climate loads. By the 1980s, however, most of Norway's major dam projects had been completed, and the leakage of expertise began. In addition, there was in the sector a rising awareness of the lack of efficiency and also a changing legitimacy basis due to increased awareness in the general population about the impacts made by hydropower projects on nature. The general view in the late 1980s was that something would have to be done to make the sector more cost-efficient (Thue 1996).

The Energy Act of 1990 was a radical reform resonating with many of the NPM characteristics (Olsen 2000, p. 123). Power suppliers were now to compete for customers through electricity prices set by the market. The act represented a new formal structure in which the power sector was to work. It disintegrated the earlier vertically integrated companies through unbundling production from transmission of electricity into a competitive market and monopolistic functions, respectively, the latter to be subject to government incentive regulation. Efficiency was the main goal of the reform; other public considerations downplayed. Among these was robustness in severe weather conditions, even though awareness to climate change rose on the agenda internationally. Seen in a longer perspective, division and specialization of the NVE in 1986 and devolution of responsibility were clearly inspired by NPM tendencies (Christensen and Lægreid 2001). The responsibility for security of supply was clear as seen by the Energy Law; the individual grid company was to be responsible for any blackout. However, would the regulatory framework provide room for investments for securing supply?

The changes went even further, making it justifiable to see the reform as a clear example of a New Public Management (NPM) reform, inspired by private corporative management (Olsen 2000, p. 180ff). The NVE gradually developed a model for incentive regulation of the grid companies, which was implemented in the later part of the period (Langset et al. 2001). With the model revenue caps could be estimated to use for economic incentive-based regulation of the grid companies. The more efficient the company, the more revenues they were to be allowed.

Investments in grid structures came to a halt, reflecting market-based risks and falling prices due to the massive surplus capacity that had been revealed. But investments made earlier provided some slack for maintenance without increasing vulnerability.

Less formal changes were also evident, although not always highly visible. The most prominent change is perhaps that the economic paradigm changed from a macro-oriented planned economy model to a more micro-based self-regulatory regime (Thue 1996). Along with this reorientation came the entry of the electricity economists. Until just before the reform, the economists as a group did not have any particular foothold within the sector. The market reform implied a change of professional boundaries. The sector was redefined from a primarily technical to a primarily economic issue, skewing the weight of professions towards economic expertise (Midttun 1996). This led to a change of appropriate values which undermined adaptive capacity, from the engineering logic to social economic values of efficiency.

The Effects of NPM Reforms on Adaptive Capacity

As shown above, in both urban planning and in the electricity sector, NPM reforms have carried with them new organizational structures and new institutional logics. Both sectors have become more decentralized and fragmented, and the responsibility for specific tasks has in some cases become unclear. Moreover, both sectors have experienced an increased focus on profit and an increased need to adapt the sectors to the market. In the following sections, how these changes affect the sectors' capacity to adapt to climate change is discussed.

Influence from Formal Organizational Structure

The distribution of responsibility for urban planning and development has been gradually altered along with the introduction of NPM reforms, starting in the mid-1980s. Whereas the municipality used to have the superior responsibility for the whole planning process, the responsibility is now decomposed into specified elements for which different actors, different sectors, and different governmental levels are responsible. The distribution of responsibility has become increasingly complex, and new issues, such as climate change adaptation, can easily be left untended. Document studies and interview data from the ten case municipalities suggest that this ambiguity and complexity in responsibility distribution has indeed been unfortunate for the sector's capacity of climate change adaptation. In this new and decentralized structure, it is increasingly difficult to formally include new considerations in the formal guidelines. Being a relatively new policy issue, the responsibility for climate change adaptation in urban planning has not been given to any actor or sector in particular, neither at the local nor at the national level. Nor has anyone taken the responsibility on a voluntary basis. When asked who is responsible, the developers point to the municipality, whereas the municipality points to the national government, which points back at the municipalities. As long as the municipalities do not receive legally binding directives from the national or regional level, they do not address the issue of climate change adaptation in any systematic way. When unmentioned in the legal framework, the issue is only accidentally addressed by actors who are interested on a private basis. To compensate for the reduced opportunity for direct intervention into planning, the Planning and Building Act contains detailed regulations which private developers must comply with. According to informants, the detailed law specifications at times result in what is perceived as a "regulation overload," exhausting both municipalities and developers and leaving little energy and few resources to consider nonmandatory issues, such as climate change adaptation. Based on the above, it is therefore reasonable to conclude that the gradual changes in the formal structure of spatial planning area have contributed to a reduction in adaptive capacity to climate change. The previous structure, with a clearer responsibility distribution, encouraged adaptations to a higher degree.

The electricity sector has also experienced changes in formal structure, although more abruptly and in a different manner. While the Energy Act divided the grid from the production segments in the organizational field, the grid part, being a natural monopoly, was put under governmental incentive regulation. The responsibility distribution may seem clear on the surface, since the grid company is formally responsible for any failures no matter the cause of them (OED 1990). However, implicit in the structure is also an inherent issue of regulation, in relation with resource availability. Since the grid companies are formally responsible for any failures, it is also their responsibility to invest in maintenance and mapping potential problems. However, this is undermined if the companies through the regulatory scheme are driven one-sidedly on economic efficiency, leading to a potential responsibility gap (Palm 2008). Who is responsible if the companies do not have the framework conditions to make the necessary investments in a robust grid. This unclear responsibility structure did not exist prior to the 1990 Energy Act and clearly brings out ambiguities about responsibility within the formal structure which reduces adaptive capacity.

The multi-sector nature of planning further clouds the question of responsibility. Spatial planning includes economic actors (developers), the municipal planning section, as well as other technical sections, and the plans are sent on hearing to several institutions on different administrative levels and to civil society organizations. The planning process is designed to take care of the varying institutional goals of all these different sectors and actors, and this makes the decision situation complex. The interview data indicate that the large number of different actors that are responsible undermines adaptive capacity, through two different mechanisms. First, as mentioned above, the responsibility not being formally placed combined with a large number of potentially responsible actors leads to collective inaction. Everyone waits for each other to act. Second, when a decision shall be made, multiple goals must be weighted. In this weighting process, climate change adaptation tends to losing against other competing goals such as private developers more short-term and more concrete interests. The field of electricity grid contains fewer different actor types to regulate and is more transparent. The structure of the field is much simpler than that of the urban planning and largely contains three types of actors: privately and publicly owned grid companies; the Transmission Grid Operator (TSO), which owns and operates the main transmission grid; interest associations; the regulator of the Norwegian Directorate for Watercourses and Energy (NVE); and the Ministry of Petroleum and Energy (OED).

When responsibility is spread on many actors, the mechanism for coordinating these actors becomes important. In the land-use planning sector, the main coordination mechanism is the Planning and Building Act, through which the roles and responsibilities of the actors are coordinated. The planning process has several stages, starting with the municipal governments developing overarching master plans for larger areas. Within the frame of the master plans, private developers initiate specific zoning plans that are to be realized. These are sent on hearing to all relevant stakeholders and eventually recommended by the planning authorities and sanctioned by the politicians. Throughout this process there is a lot of both formal and informal contact between the involved actors, and a lot of coordination efforts happen through dialogue and negotiations between the municipality, the private developer, and different regional agencies. These negotiations provide ample space for climate change adaptation to be launched as a subject, but as long as adaptation is not required in the Planning and Building Act, this requires a certain amount of awareness and motivation either with the developers or with the municipal staff.

The planning process mirrors the fundamental principles of NPM organization: The municipality sets the overarching goals in their master plan, outsources the more detailed planning to private actors, and finally controls that these private plans comply with the specifications and goals in the overarching plan. A consequence of this way of organizing the planning process is that measures necessary for climate change adaptation must be articulated as regulations in the overarching municipal master plan, prior to the development of detailed plans. In the more hierarchical pre-NPM system, where authorities were responsible for plans at a more detailed level, issues such as adaptation could be planned and implemented as integrated elements of comprehensive projects. Regarding the possibilities for good climate change adaptation solutions, the fact that private developers are responsible for developing the plans is, according to the informants, believed to reduce the action space for the planning authorities. They can regulate in advance and respond afterward but have less chance to be actively involved in the actual development of specific areas. This illustrates a general problem with NPM organization and management by objectives. The possibility of focusing on new policy areas, such as climate change adaptation, depends on these policy areas being articulated in the formal overarching goals at an early stage. Contrary to the theoretical assumptions, the NPM-oriented system as applied in urban planning seems to be surprisingly inflexible and unable to include new goals and priorities along the way. The power that the planning authorities had before the introduction of NPM, to rapidly adjust to new policy areas and to intervene in ongoing projects, is lost when they do not longer possess the skills or mandate to do the detailed planning. Moreover, their capability for controlling the detailed plans is weakened as they no longer carry out the task of detailed planning and only have desk experience. This competency now rests with the developers and their hired consultants. It must be noted, however, that a hierarchical system can also be slow and inflexible, as decisions must be taken on top and passed down to the implementing level. In the current system, although the different actors in urban planning do not systematically address the issue of climate change adaptation, they are free to do so should they wish, as long as they also fulfil the overarching goals.

Influence from Organizational Culture

Contrary to the instrumental perspective, the institutional-cultural perspective claims that institutional logics and organizational culture strongly shape the range of possible actions for organizational field actors. This happens through mechanisms of *legitimacy* or *appropriate actions*, as accepted within the organizational field. Evident in the electricity sector is a change in institutional logic. This usually happens over time (March and Olsen 1989), although interviews with representatives from the companies and the regulator point to the fact that the strong and rapid restructuring of the sector, along with the delegitimization of the economic inefficiencies leading up to the reform in 1991, led to an incursion of economists in the sector.

The institutional logic in the sector up to the reform legitimized decisions that increased system reliability, security of supply, and system robustness – all while disregarding the economic cost related to these decisions. This engineer's logic encouraged many grid companies, including TSO Statnett, to construct an over-robust grid, something that led to a high adaptive capacity while downplaying the economic costs. Leading up to the Energy Act of 1990, the economist entered the field as an increasingly dominant professional group. Even though there does not exist precise data about the changes in professional demography around this period, the interviews broadly confirm the changes in demography and more importantly the changes that followed in institutional culture.

The process itself was a response to the delegitimization of the engineer's logic in the Norwegian electricity sector. When the alternative norm set presented itself and was emphasized also in the formal structure, it was quickly accepted as legitimate. The new economist institutional logic was as much a product of the reform as the reform was a product of the logic, since both found their legitimacy in the economic efficiency paradigm which easily took the place of the delegitimized engineer's logic.

This new economist's logic has increased legitimacy over time, at least up until the mid-2000s. It is common for actors with noneconomic background to receive courses in economy, as several of the interviewees exemplify. Decisions have to be legitimized by economic arguments whereas earlier it was a system performance focus. This change is more than mere rhetoric; it represents a transformation of cultural basis in the sector that largely influences the real room of decisional maneuverability – and therefore adaptive capacity to climate change.

The economist's logic legitimates decisions which are economically "efficient," reducing the appropriateness in the sector of decisions that are not grounded in economic arguments. In fact the main grid operator Statnett, according to company interviewees, officially operates under instruction of "social economic feasibility." In practice this means that no grid should be constructed unless grounded in the principle of marginal pricing. Since adaptations are often difficult to calculate on grid level, grid adaptations are often left out, something that has been shown to lead to less adaptation in Norwegian grid companies when compared to countries such as Sweden (Inderberg and Arntzen Løchen 2012). Robustness is regarded as a less legitimate goal than economic efficiency in the new institutional logic, and maintenance and security of supply are sometimes regarded as necessary evils that influence efficiency rather than legitimate goals in themselves.

The consequences of the cultural transformation in the electricity grid sector for adaptive capacity can be summed up to that the earlier logic of the engineer encouraged robustness and maintenance to meet challenges to system reliability – possibly disregarding important efficiency considerations. However, the economic paradigm from the early 1990s has overcompensated, with one of the consequences being an undermining of adaptive capacity to climate change within the electricity sector.

The restructuring of the urban planning sector has also seemingly entailed a change in its institutional logic, which can be inferred from how the actors perceive the goals and norms of the sector. With transfer of planning power from the public to the private part of the sector, many of the interviewees in the case municipalities report of a shift in focus from comprehensive urban development encompassing various societal goals to economic gain and market considerations. This corresponds with the goals and values in the two sectors, respectively, and should therefore come as no surprise. The focus on economic gain and market mechanisms as guiding principle in urban planning has its normative basis in the belief that the prize mechanism will merge demand and offer so that the needs of the population are met. Currently, however, the population does not display a need of climate-adapted urban development, and relying on market mechanisms in this regard therefore leads to little or no adaptation. Interestingly, also representatives from the municipal planning departments use this kind of market argumentation, largely accepting the developers' market considerations and objections to adapting to climate change, as valid. The norm that the market knows best has trickled into the public administration as well, and this fact allocates much power to the private developers.

While doing what is good for society is the municipalities' *raison d'être*, for the developers, social responsibility is a more voluntary consideration to make. Whether the private developers as they gain power and their role becomes more important will take responsibility for nonprofitable common interests in urban development such as the need for climate change adaptation remains a question. There are examples in the data indicating that especially some of the big developers do, although there is no systematic trend. About half of the developers interviewed had on their own initiative made some considerations regarding climate change adaptation, and three of them had also taken some adaptation measures, such as increasing building height near the sea shore. But still, such a transfer of power to the market actors does appear to reduce adaptive capacity.

The guiding norms of the planning departments can to some extent be read off the planning department's self-image or identity, something that the interview data indicates varies across the ten case cities. Whereas planning departments in some cities define their role mainly as that of controlling whether plans comply with the formal regulations, other cities have ambitions of being in front in climate change adaptation, both in supplying the terms for urban development and in ensuring that private zoning plans are adapted to future climate change by integrating requirements in their master plan. Causes for differences in municipal self-image have not been looked into, but the presence of dedicated individuals in central positions is a factor that has been found to contribute (Klausen et al. Forthcoming 2015). This means that there are different reasons for adaptation to rise on the agenda, but from an organizational perspective, there is a need to manage adaptation within the organizational structure, in order to not be dependent on "random" dedicated individuals.

Furthermore, the responsibility taken by private developers is likely to change over time. Contrary to the energy sector, NPM reforms have been introduced in the planning sector at a slow rate. The actors in urban planning have therefore, cognitively, to some extent remained inside the hierarchical system. They do not fully comprehend their new role, with an increased responsibility for urban planning as such, and still wait for authoritative signals before they act.

In the institutional-cultural perspective, a sector holds high adaptive capacity if climate change knowledge such as downscaled scenarios was perceived as a valid basis for decision making, along with valuing robustness and adaptations as a basis for decisions. This is to some extent the case in the case municipalities, but when lacking specific regulations and laws, the municipal employees largely underline the need of complying with the norms of society. If the general attitude is that climate change adaptation is not worth spending money on, and if this attitude also prevails with the private developers, municipal planning departments find it hard to use climate change scenarios as arguments for demanding that measures be taken. In such cases where their demands do not comply with the general norms, they feel they need more proof of the coming changes. This is perceived as a lack of relevant information but is often indeed more a lack of information that is perceived as sufficiently valid by the involved actors in urban development and planning.

When planning initiative was delegated to private developers, the culture in the planning sector also seems to have been more law oriented, following standard deregulation theory (Vogel 1996). As the municipalities have been relegated to a role as regulators, the law remains their most important steering tool. When the municipalities were more actively involved in planning, there was, according to informants, more room for discretion. The hands-off steering hence leads to increased focus on rules and regulations, and has further increased the threshold for involved actors to take up nonregulated issues such as climate change adaptation, and this has contributed to a reduction in adaptive capacity.

Although the institutional logic may have changed towards an increased focus on efficiency and market profit, with the introduction of NPM in the planning sector, some professional norms seem to have remained important throughout these changes, according to the informants. The relative strength between municipal bureaucrats and private developers have changed with the NPM reforms, but engineers and architects still play a pivotal role in providing terms for building projects, and they are still occupied by things such as safety and robustness. The professional norms of engineers and architects are in the municipalities observed to be the primary drivers for climate change adaptation.

Conclusions

The chapter has analyzed the climate change adaptive capacity in Norway's urban planning sector and electricity grid sector and the changes in such capacity over the implementation of New Public Management (NPM) reforms. The chapter shows that with the introduction of NPM in the energy sector, the focus changed from system reliability and societal security to economic efficiency. This change in focus happened surprisingly rapidly because professions advocating economic efficiency were extensively recruited and because of the introduction of piecemeal incentive structures and soon outweighed the professions advocating security and the need for robust solutions. In urban planning, a slower process occurred. The introduction of NPM reforms in this sector did change the structure in the area. Where the municipalities were previously behind the planning initiatives taken in the sector, today the entrepreneurs commonly provide the planning proposals. This has changed the dynamic and the central focus from sustainable urban development to the favor of economic considerations. This change has taken place more slowly than in the energy sector, as market-based stakeholder groups gradually have gained more definition power as well as implementation power in the planning process. In both sectors, however, these different changes have resulted in a decrease of adaptive capacity, indicating some equifinality.

Two perspectives have been applied to analyze the changes in adaptive capacity: an instrumental and an institutional perspective. From an instrumental perspective, the NPM reforms have decreased adaptive capacity in both sectors, although the picture is somewhat ambiguous. Particularly two elements of the NPM reforms have affected the structural adaptive capacity of the institutions: management by objectives and delegation of responsibility to independent units not subsumed under the hierarchical structure. In the planning sector, management by objectives, in particular, implies that the objectives for urban planning are defined on the top level, with the politicians. In many of the studied municipalities, the need for adaptation was detected at lower levels in the municipality, for example, with the planning department, but was not addressed until objectives were redefined at the top level, which had not yet happened in the bulk of the case municipalities nor in most Norwegian municipalities (Harvold and Risan 2010). The NPM logic requires that all new policy issues must first be addressed at the top level (often in the form of law), and this makes the system slow in incorporating new goals such as climate change adaptation. When not articulated as a goal at the top level, responsibility for climate change adaptation is not delegated, and when not delegated, not addressed. It must be noted, however, that unlike in the more hierarchical system that prevailed 30 years ago, actors at all levels and in all sectors are free to address the issue of adaptation if they like, and although this rarely happens, there are examples of planning departments and private developers taking action also on their own initiative.

Since adaptation often has wide, abstract, and few short-term benefits when compared to other goals, it risks being prioritized down. Being perceived as a mere expense, climate change adaptation is even more in need of being articulated and delegated and included as a separate goal, within a NPM system, in order to be addressed. Adaptation is therefore vulnerable to unclear responsibility structures. NPM has been criticized for dividing organization into silos (Painter 2001). With cross-sectoral issues such as climate change adaptation that do not easily fit into clear manageable categories, the capacity to manage adaptation and vulnerability reduction is reduced in both the systems analyzed here.

Being a sector mainly responsible for one task, the responsibility structure is clearer in the electricity sector than in the urban planning system. The multi-sector nature of urban planning and the sector's ensuing need to take various interests into account in all decision making further complicate the status of climate change adaptation as a policy issue. Adaptation must compete with the interests of many powerful stakeholder groups, and as long as it is not explicitly delegated to a given organizational entity, it risks being downplayed, and the material shows that in such situations, adaptation can turn into a question of dedicated individuals.

Cultural changes have taken place at a fast rate in the energy sector while in the planning sector the changes have been more gradual. This indicates that professions are strong drivers for changing norms than actor groups or sectors. In both sectors, at least partial prevalence of professional norms guaranteeing a certain level of climate change adaptation was observed, even if the formal organizational structures do not incentivize it (Inderberg 2011).

In sum a reduction in adaptive capacity for both the electricity grid sector and for urban spatial planning after the introduction of the NPM reforms is found. This reduction takes place both because of the changes in formal organizational structures and changes in organizational culture. With increasing challenges to public authorities that require holistic responses instead of piecemeal solutions, there is a need for public administration to emphasize coordination of policy and long-term considerations. Building adaptive capacity means not only access to information and financial resources, but is dependent on adaptation being appropriate considerations, that responsibility in the institutional structure is clear, and that incentive structures are aligned with adaptation as a valued goal.

Contents

Abstract

Significant investments are needed to support the global transition to a low-carbon, climate-resilient future. Unlocking private capital at scale is

This chapter is a shorter and adapted version of Smallridge et al. (2013), which was prepared based on the results of a survey, and a series of interviews undertaken between April and July 2012 to 9 (nine) national development banks from the Latin American and the Caribbean region, and a series of workshops and dialogues organized by the IDB over the course of 2011–2012. Several professionals contributed their expertise for the development and review of the research study.

essential to fill the current financing gap and achieve *transformational* impacts, but there are several barriers to overcome for this to happen.

This study sought to analyze the role that national development banks (NDBs) could play to bridge the financing gap by scaling up private investment. Their knowledge and long-standing relationship with the local private sector places them in a privileged position to understand local barriers to investment as well as risks and opportunities.

Drawing empirical evidence from NDBs' experiences within the Latin American and the Caribbean (LAC) region, the study finds that while many NDBs are already piloting an array of financial and nonfinancial instruments to promote and leverage private low-carbon investments, these institutions are at diverse stages of "readiness" to fully promote climate-related programs. Several NDBs still need to build and/or strengthen capacity and acquire experience in the structuring, risk assessment, and monitoring of climate-relevant projects in order to take a more central role in the international climate finance landscape.

National Development Banks • Low carbon • Climate finance • Private finance • Latin America and the Caribbean

Introduction

Climate finance has become a key topic in international climate negotiations over the past years, as it is a critical element to address the global climate change challenge. Large-scale investments are required to support countries' transition toward a low-carbon and climate-resilient development path (Buchner et al. 2012 based on IEA 2012; World Bank 2010). This has resulted in a developed countries' commitment to mobilize US$100 billion per year by 2020, to collectively support developing countries' mitigation and adaptation needs to respond more effectively to the climate change challenge (UNFCCC 1/CP.16).

Annual global support to low-emission, climate-resilient development activities is estimated in the range of US$ 343–385 billion for 2011, about 47 % of which invested in projects in developing countries (Buchner et al. 2012). While this is a start, this level of investment is far from what is required. The IEA (2012), for instance, suggests that over the 2012–2050 approximately US$ 1 trillion each year will be needed to finance incremental investment in the energy sector alone to promote a low-emission growth. Financial resources have therefore to be scaled up significantly to foster a sustainable development pathway and to address mitigation activities and adaptation needs of a world on a path to 4 °C temperature increase (World Bank 2012; UNFCCC 2008).

Unlocking private sector capital will be essential to ensure large, *transformational*, and long-term impacts across all economies given that public resources are far too scarce to finance the transition alone, particularly in times of fiscal austerity (e.g., OECD 2012). Increased private sector engagement in these activities will also help to reduce the reliance on international and national public finance in the long run and to seeking out and implementing least cost options for climate mitigation and adaptation.

However, efforts to date have not yet been able to mobilize private financing for climate change projects at the scale and speed required (e.g., AGF 2010; The World Bank 2010; Brown and Jacob 2011; UNEP-FI 2009).

In practice, it is challenging to align private sector incentives with public goals. Significant questions remain about how to best mobilize private climate investments and how to design risk-return arrangements that are attractive to private, but also public actors' investments. International climate finance can play a catalytic role in this regard, and national development banks (NDBs) can help to overcome some of the difficulties.

While, until recently, little attention has been paid to NDBs' role in raising and delivering climate finance, the international climate finance community is increasingly aware of NDBs' potential to promote and catalyze private climate finance in developing and emerging countries. This growing awareness is also confirmed by, for instance, the establishment of the International Development Finance Club (IDFC), a network of renowned national and subregional development banks with total assets of more than USD 2.1 trillion (see IDFC.org).

NDBs can play a potentially crucial role in facilitating climate investments and delivering climate finance directly to investors or by leveraging private capital. Their focus is unique, particularly compared to other national public institutions and international financial institutions intermediating climate finance. NDBs are mandated by their respective governments to support the fulfillment of national low-carbon resilient development goals and plans and have the backing of their governments to do so.

Furthermore, NDBs' knowledge and long-standing relationship with their local markets and institutions places them in a privileged position to understand local barriers to investment and opportunities, thereby favoring the financing of private sector activities. NDBs seem to understand better than many other players the conditions necessary on the ground for long-term investment and can better assemble the financing packages tailored to the needs of domestic investors (authors' elaboration based on ALIDE et al. 2012).

NDBs are already playing a significant role in the climate change finance landscape. In 2011 alone, a selected number of NDBs provided around US$ 42.7 billion in financing to programs addressing climate change, around 55.6 % of the total climate finance distributed by public intermediaries (Buchner et al. 2012).

The question is: How could they do more and fully harness their potential? More evidence is needed to understand the conditions and the institutional capacities required for NDBs to become more proactive and effective intermediaries in climate finance.

This research aims to build knowledge and evidence about the key role of NDBs in the climate finance landscape, and the conditions that would enable them to channeling and leveraging climate finance in the most effective way. Specifically, this research analyzes the leverage potential of NDBs, by looking at their unique characteristics and role in scaling up private sector financing for climate change mitigation projects and programs through the leveraging of international and national climate finance in their respective markets. The study does not specifically assess the role NDBs could play to scale up financing of climate change adaptation due to the complexities associated to what is and what counts as adaptation finance and tracking issues (see, e.g., Terpstra 2013 and Jones et al. 2012).

To this end, the study draws empirical evidence from NDBs in the Latin American and the Caribbean region (LAC) – where NDBs have a long tradition and experience in financing private sector investments – by assessing and presenting:

- The key features of NDBs (section "Key Features of NDBs to Scale Up Climate Finance")
- The type of financial and nonfinancial instruments at their disposal to promote private investment in low-carbon, climate-resilient activities and scale up climate finance efforts (section "NDBs' Financial Instruments to Promote Private Finance and Scale Up Investments")
- NDBs' current involvement in the climate finance landscape – i.e., volume of financial resources committed, dedicated financing programs, and participation in international initiatives – and their level of "readiness," i.e., of institutional and technical development (section "Overview of NDBs in the Latin American and the Caribbean Region")
- NDBs' leverage potential (section "How NDBs Can Leverage Private Finance")

A better understanding of these aspects could help NDBs to develop a proactive and efficient strategy for playing a greater role in the international climate finance architecture, in terms of both accessing and leveraging finance from a broader range of sources, and influencing the operational design of future delivery climate mechanisms and channels such as the Green Climate Fund (GCF). The study concludes offering recommendations on how to fully enable these players to scale up investments to the scale needed.

The study adopts a multi-method approach comprising of: (i) a financial survey, (ii) interviews to NDBs, (iii) desk-based analysis, and (iv) a case study approach. It also incorporates insights from a series of workshops and dialogues organized by the Inter-American Development Bank (IADB) in 2011–2012 (see, e.g., ALIDE et al. 2012).

The financial survey was undertaken to elicit the main features of NDBs operating in the LAC region. It contained a series of questions aimed to understand NDBs financial and business activities, the instruments used, and their level of involvement in climate financing and tracking of private finance mobilized. The survey was conducted between April and July 2012 to the NDBs' members of the Latin American Association of Financial Institutions for Development (ALIDE), and targeted nine (9) NDBs involved in climate financing to different extents, and at different stages of institutional development. This sample included the largest NDBs in the region, representing over one-third of the region's NDBs' assets and capital. Concerned NDBs are Agencia Financiera de Desarrollo (AFD) (Paraguay), Banco del Estado del Ecuador (BEDE) (Ecuador), Banco de Comercio Exterior de Colombia (BANCOLDEX) (Colombia), Banco de Desarrollo de El Salvador

(BANDESAL) (El Salvador), Banco Nacional de Desenvolvimento Econômico e Social (BNDES) (Brazil), Corporación Financiera de Desarrollo (COFIDE) (Peru), Fideicomisos Instituidos en Relación con la Agricultura (FIRA) (Mexico), Financiera de Desarrollo Territorial (FINDETER) (Colombia), and Financiera Rural (FINRURAL) (Mexico).

While there is not yet an internationally acknowledged definition of climate finance, the term refers to both public and private.

Following Buchner et al. (2011, 2012, 2013) and given the lack of an internationally acknowledged definition, in this study, climate finance refers to both public and private resources targeting low-carbon and climate-resilient development, with direct and indirect greenhouse gas mitigation or adaptation objectives/outcomes. To determine whether an activity qualifies as mitigation and/or adaptation, the study follows the criteria of the OECD-Development Assistance Committee Creditor Reporting System (see OECD 2011).

Key Features of NDBs to Scale Up Climate Finance

NDBs are well suited to play a critical role in climate finance by delivering financial resources directly to support climate-relevant projects and programs and/or by leveraging private capital toward this end. This is thanks to a number of characteristics (see Fig. 1 which, based on ALIDE et al. (2012), Smallridge et al. (2012) and UN (2006), presents NDBs' key features at a glance), which are also confirmed in concrete examples drawn from NDBs' experiences within the LAC region

I. *Development Mandate*: NDBs are mandated and supported by their respective governments to provide long-term financing to sectors promoting economic and sustainable development, particularly to projects, activities, or sectors of the economy that are underserved by private sources of finance (UN 2006) such as climate-relevant sectors (i.e., energy efficiency and renewable energy). By providing capital at terms and conditions generally more favorable than those prevailing on the market, they help to improve the risk-return profiles of climate mitigation projects, thereby enhancing their attractiveness to investors and encouraging low-carbon technologies to scale up.

> The Brazilian Development Bank (BNDES) places sustainable development at the core of its operations, which is proven by its significant support to the rollout of the country's renewable energy, energy efficiency, and deforestation programs (BNDES.gov.br, BNDES 2012). In 2011, BNDES' disbursements to renewable energy and energy efficiency reached about US\$ 7.2 billion (R\$ 12.3 billion), 31 % higher than in 2008, making it the largest provider of credit to the country's clean energy sector (Buchner et al. 2012, IRENA 2012).

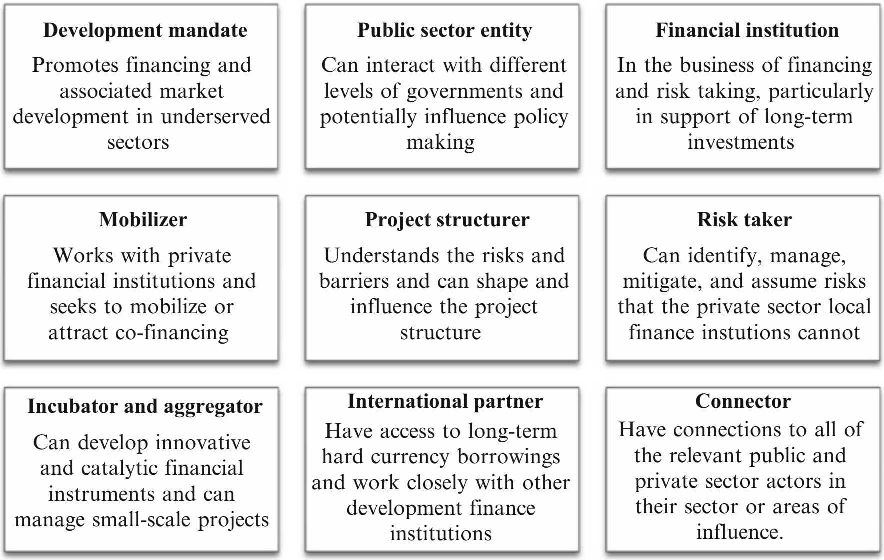

Fig. 1 The key features of National Development Banks (source: Authors' elaborations based on, e.g., Smallridge et al. (2012), ALIDE et al. (2012), UN (2006))

II. *Public Sector Entity*: NDBs have strong relationships with national government and hence can interact with different government agencies and administer nonreimbursable budgetary resources to support national or subnational priority programs, including climate-relevant projects promoted by private sector actors. Because of their involvement and interaction with the financial and nonfinancial private sectors, NDBs can also contribute to policymaking, sharing information about impacts and implementation of various policy options. This is particularly important to create the conditions necessary to scale up climate finance to mitigate climate change and adapt to its impacts.

III. *Financial Institution*: NDBs are in the business of financing and risk taking, particularly in support of long-term investments. Indeed, NDBs are first and foremost financial institutions, often under the same bank supervision rules as commercial banks. They can be mandated to support improvement of financial conditions in local financial markets by "crowding-in" private financial intermediaries into new and innovative areas of investment.

IV. *Mobilizer*: It is typically not in the nature of NDBs to compete. They are expected to complement and "crowd-in" private financial intermediaries by providing appropriate financial and nonfinancial instruments. This role is particularly relevant for leveraging private capital for climate financing. In the fulfillment of their mandate, however, NDBs may also have a reverse effect, "crowding-out" private sector investment or lending.

V. *Project Structurer*: NDBs can promote market development through the provision of additional resources, such as technical assistance, capacity building, and training to project developers, and small- and medium-sized enterprises, to create the demand for financing by helping to develop and structure projects and programs. They also can put together financing packages with terms and conditions in line with local project developers' needs, taking into account local market specificities. It should be noted, however, that many NDBs still have to develop the capabilities necessary to evaluate, analyze, and structure low-carbon projects (Buchner et al. 2012; ALIDE et al. 2012).

In 2006, BANDESAL, the Development Bank of El Salvador established "Empresa Renovable," a financing program aimed to promote micro-, small-, and medium-sized enterprise investments in industrial energy conversion, energy efficiency, and renewable energy (mainly solar PV and small hydro). To incentivize investments, it structured a program entailing:

- A technical assistance grant covering a portion of the costs of feasibility studies and consultancy services to overcome knowledge and capacity barriers
- A credit line at preferred terms and conditions to overcome the lack of long-term finance at competitive rates for investment in these sectors (Bandesal 2012)

VI. *Risk Taker*: NDBs have long-standing relationships with local private sector financial institutions and hence understand the risks and barriers that these institutions confront when financing underserved sectors. Moreover, NDBs – which generally benefit from governments' guarantees – can assume certain project risks that private sector entities cannot or will not take, and therefore can draw incremental private capital into projects.

This is particularly relevant for renewable energy investors whose central challenge is getting an attractive return for the risks taken.

FIRA, a Mexican second-tier development bank, has historically acted as a risk taker, offering guarantee products to tier 1 banks and other financial intermediaries to share the risk of lending, hence facilitating access to credit to local private investors.

To overcome private banks' reluctance in financing renewable energy projects, FIRA' and the Mexican Ministry of Agriculture's guarantee fund, FONAGA Verde, covers first-loss credit defaults in renewable energy and biofuel generation projects.

Another Mexican development bank, NAFIN, has a guarantee program intended to support credit granting through a capital recovery guarantee for financial intermediaries. In the context of energy conservation, renewable energy, and the environment, the program offers up to 50 % selective guarantee, if certain eligibility criteria are fulfilled (Olade and UNIDO 2011; Rangel 2010).

VII. *Innovator and Aggregator*: NDBs can aggregate small-scale projects by adopting a portfolio approach when assessing the credit risk and streamlining the application process to minimize transaction costs, to encourage participation of local financial institutions (LFIs). NDBs can develop and incubate innovative and catalytic financial instruments and demonstrate to the private financial sector the potential profitability within these areas.

VIII. *International Partner*: NDBs have access to long-term sources of local and international financing as well as to nonreimbursable resources for development purposes. Multilateral and bilateral development banks, foreign export credit agencies, and also dedicated climate funds use NDBs as financial intermediaries for long-term hard currency loans as well as for the allocation and disbursement of development grants. NDBs can also blend resources at market and concessional terms from different sources.

Financiera Rural (FINRURAL), a Mexican Development Bank aimed at promoting the development of economic activities linked to the rural sector, was chosen to channel US$15 million from the Forest Investment Program (FIP), a specialized program under the Climate Investment Funds (CIF) aimed at supporting governments in their efforts to reduce emissions from deforestation and forest degradation. Through a dedicated financing line, Financiera Rural will help improve communities' access to finance for low-carbon activities in forest landscapes (IADB 2012).

IX. *Connector*: NDBs' linkages with national and international institutions and between public and private actors enable them to easily establish the connection with all of the relevant players involved in financing climate change mitigation activities and programs. NDBs also have close interactions with social and environmental organizations, as well as with civil society, and are thus often more easily accepted as partners than other lending institutions.

NDBs' Financial Instruments to Promote Private Finance and Scale Up Investments

NDBs' activities and instruments can address both demand and supply needs for finance to overcome constraints associated to the pre-investment and investment phases, thereby fostering private investments in climate-relevant projects (Smallridge et al. 2009, 2012). In particular, NDBs can apply the tools they have to:

- *Increase the demand for investments in climate-relevant projects* (pre-investment stage) by helping to address sector- and country-specific constraints, promote appropriate and stable enabling environments for investment, build awareness and capacity to analyze and structure climate-related interventions, and bring projects and companies to a state of investment readiness. The focus is to encourage, prepare, and educate project proponents to undertake the investments.

- *Provide the necessary incentives to mobilize the supply of climate-relevant investments from the private sector* (investment stage) by offering financial instruments at adequate terms and conditions for such projects and by supporting private investors and local finance institutions to understand and tackle the specific investment and financial risks and barriers. The goal is to attract capital, both debt and equity.

Typical NDBs' financial instruments to leverage climate finance (UN 2009, Smallridge et al. 2012 and NDBs' websites) include:

i. *Grants*: Grants can be used for a variety of activities in both the pre-investment and the investment stages. In the pre-investment stage, grants can finance technical assistance activities to help the project or company become investment ready. Assistance may include training or capacity building at the company level, or financing for the preparation of feasibility studies. Grants can also be more widely used for building awareness and national dialogue to strengthen and/or create environments conducive to climate-relevant investments. In the investment phase, grants can lower the interest rate of loans, extend repayment terms/grace periods, or serve as a guarantee fund for losses. These grants can be blended with NDB loans to support projects directly or to channel them via LFIs.

The Chilean CORFO (Corporación de Fomento de la Producción) has established a program supporting small and medium enterprises to optimize energy consumption. It subsidizes studies for energy efficiency audits, the implementation of energy efficiency measures, and the preparation of investment plans for submission to a funding source. CORFO covers up to 70 % of the total cost of the consultancy, with a limit of about US$10,000. It also supports renewable energy generation projects by subsidizing preliminary pre-investment studies or specialized assessments for up to 50 % of their total costs, up to a maximum of US$60,000 (CORFO.cl, Duffey 2010).

ii. *Tier 1 Loans*: Tier 1 loans are direct loans with some or all of the obligor's credit risk assumed by the NDB. The NDB thus acts like a commercial bank, extending credit directly to a project or a company. The long-term financing can be senior debt, that is, pari passu with other lenders, or subordinated debt, putting the NDB in a role of secondary creditor. In these cases, NDB financing can be blended with concessional funding (grant or low-interest loans) from international partners.

In the case of Brazil, BNDES has participated on a pari passu basis with commercial banks on a number of large wind projects to attract local and international financing. BNDES and the concerned local commercial bank participated in the transaction based on the same terms and conditions. Because such transactions are too large to be funded by a single finance institution, BNDES provides additional capacity through direct tier 1 loans (BNDES.gov.br).

iii. *Tier 2 Loans*: Tier 2 loans are loans by NDBs to a local financial institution – typically commercial banks or other financial intermediaries – for on-lending. NDBs take the credit risk of this financial institution directly, which in turn assumes the credit risk of the project.

As in the case of tier 1 loans, NDBs can blend their own resources with highly concessional resources obtained from their own government, international sources of public financing, and multilateral and bilateral institutions to improve the terms and conditions of their funding to tier 1 banks. As such, they can offer better loan terms and conditions to project developers.

COFIDE the Development Bank of Peru, uses an innovative and unusual channel for financial intermediation for taxis and buses owners that convert their vehicles into natural gas in Lima, namely, local gas stations. The loan repayments are collected via the gas station every time the vehicles are refilled. COFIDE provides tier 2 loans at concessional rates to participating banks. The usage of an existing and secure platform for loans repayment helps to improve the credit risk of individual loans, buying down transaction costs, and allowing wide-scale deployment (COFIDE.com.pe, ALIDE 2011).

iv. *Equity*: Some NDBs have a mandate to provide equity. They invest in companies and projects directly or via private equity, venture capital, or seed funds. NDBs can be in a first-loss position vis-à-vis other investors, or they can invest alongside other investors.

BANCOLDEX Capital, a subsidiary of BANCOLDEX in Colombia, addresses the market gap for venture capital resources by providing equity capital via venture funds managed by a private fund manager (e.g., Progresa Capital, a small venture capital fund focused, inter alia, in alternative energies), rather than investing directly in companies or projects (Bancoldex.com). Often, the NDB investment is seen as an anchor in a fund, drawing additional local and international capital.

v. *Guarantees*: Guarantees and related contingent liability instruments typically involve a NDB providing credit enhancement to a local finance institution, or another third-party financial intermediary providing direct funding or other investments. The NDB assumes some or all of the credit risk associated with a project that might otherwise prevent investors and/or lenders from providing funding.

   There are different types of guarantees. Those related to credit risk are most straightforward and generally better understood by market players. Traditional credit guarantees provide unconditional, irrevocable assurance to a third-party lender that principal and interest will be paid when due in the event the borrower is unable or unwilling to pay. Such guarantees normally cover less than 100 % of the borrower's payment obligations.

Many of the larger finance institutions in Peru have significant exposure and experience in financing hydropower projects and, for internal risk reasons or existing regulations, may have reached their limits in this sector. COFIDE provision of loan guarantee would allow local financial institutions to transfer the risk of financing, thereby promoting investment in the hydropower sector.

Another example is CORFO's capital guarantee and risk capital fund in support of clean energy and energy efficiency projects. This instrument was introduced in 2009 within the bank's Non-Conventional Renewable Energy program to address the specific investment risks of wind, solar, geothermal, and other renewables. In the case of capital guarantee funds, the instrument applies to both CORFO-funded projects and self-funded projects, up to a total of US$7.5 million.

vi. *Management of Funds*: In some instances, NDBs are asked to manage funds on behalf of other entities. In these cases, the NDB is not using its own resources, but rather capital provided by a third party – such as the national government or a foreign donor – managing it for a fee. As a public sector entity which acts within the financial sector, a NDB is an attractive player to take on this role, given its skills, expertise, and reliable systems.

BNDES is the manager of the Amazon Fund, created in 2008 to raise donations for nonreimbursable investments aimed to prevent, combat, and monitor deforestation in the Amazon. In addition to managing the fund, the Bank also raises funds, selects projects, and monitors their progress after they have been contracted.

The Bank is also the trustee of the Brazil National Fund on Climate Change, which was created to finance mitigation and adaptation projects and to support studies on climate change and its effects. The Fund is funded via a special tax on the profits made in the oil production chain; other contributions are collected from public, private, national, and international donors (UNDP 2011).

Table 1 NDBs' instruments to address needs to enhance effectiveness of climate finance

Phase	Climate finance needs	Climate finance activities	NDBs' financial instruments
Pre-investment phase	Technical assistance	Policy development and capacity building	Grants
	Technical assistance	Demand creation	Grants
	Financial contribution	Feasibility study/ project preparation	Partial grant or reimbursable contribution
Investment phase	LFI needs funding	Debt	Tier 2 loan market terms
	LFI needs funding/projects needs subsidized interest rates		Tier 2 loan subsidized interest
	Project needs additional capital		Tier 1 loan market terms
	Project needs additional subsidized capital		Tier 1 loan subsidized interest
	Project needs early stage cash flow room		Tier 1 longer tenor/ grace period
	LFI needs risk sharing		Guarantee
	Projects needs capital		Mezzanine debt
	Project needs equity	Equity	Equity market terms
	Project needs additional equity to draw in additional investments		Equity first-loss position

Source: Authors' elaborations based on, e.g., UN (2006), Smallridge et al. (2012), NDBs' web sites

Table 1 summarizes how NDBs' instruments can be deployed to meet the needs described both in the pre-investment and the investment stage.

During the pre-investment phase, grants or financial contributions can meet technical assistance needs, e.g., capacity building, developing expertise in the preparation and assessment of climate projects, undertaking feasibility and environmental impact studies, and designing and implementing systems for monitoring and reporting results.

During the investment phase, there are two elements in the capital structure to advance investment meeting private actors' needs: debt and equity. On the debt side, the NDB can provide a tier 2 loan if local financial institutions struggle to offer long-term debt for climate projects. Depending on the expected cash flow from the project, the loan can be at market or concessional rates. The latter are, generally, preferable for climate projects to increase the competitiveness of "clean" fuels in comparison to fossil fuels in energy generation. In other cases, the project or company might require the NDB to offer a tier 1 loan, possibly alongside commercial banks on a pari passu basis or on more generous terms, such as longer tenors or lower interest rates to improve the repayment profile of commercial bank debt.

The NDB could also provide a guarantee to bear the risks that the private sector is not willing or able to bear. Similarly, the NDB can help the equity structure by providing additional equity on equal or more favorable terms.

Overview of NDBs in the Latin American and the Caribbean Region

To bring evidence on NDBs' current level of involvement in the climate finance landscape, this section presents insights gathered from the nine (9) NDBs of the Latin American and the Caribbean region ad hoc surveyed.

The survey and dedicated discussions held (see ALIDE et al. 2012) highlighted that NDBs have been increasingly integrating climate change considerations into their core operations and become more active in financing climate change interventions. This goes hand in hand with the growing realization that NDBs have a critical role to play in channeling funds toward low-emission projects and programs.

Buchner et al. (2012) estimate that NDBs in the LAC region contributed at least USD 15.2 billion in 2011, which is about 20 % of the 2011 total commitments of the Development Finance Institutions captured by Buchner et al. (2012).

The contributions of NDBs in the LAC region are likely to grow as governments increasingly involve Development Banks to promote the structuring and financing of mitigation and adaptation projects in an effort to cover the incremental costs of these projects with funds at more favorable terms and conditions. This entails funding their participation in financing and technical assistance programs with multilateral development banks (MDBs) in order to acquire the technical and financial support needed to fulfill this new mandate (ALIDE 2011).

This is, for instance, highlighted by NAFIN's role as the trustee of the Climate Change Fund recently established by the General Climate Change Law in Mexico, as well as the initiatives under development in two Caribbean islands, Saint Lucia and Jamaica, within the adaptation-focused window of the Climate Investment Funds (CIF 2011, 2012). The engagement of these NDBs helps create the institutional framework necessary to channel the Funds' resources to local private entities (e.g., small and medium enterprises and farmers), thereby enabling them to undertake climate-resilience-building measures.

Table 2 provides an overview of the products offered by the nine NDBs surveyed. According to survey responses, some banks are tier 2 only (AFD, BANCOLDEX, COFIDE, FINDETER, and FIRA), while others (BEDE, BANDESAL, BNDES, and FINRURAL) can lend directly to projects (tier 1) or indirectly via LFIs (tier 2). Nearly half of them offer guarantees and other contingent facilities. Technical assistance is an important product for six of the nine NDBs, but only three approved financing in the past three years. Investment of equity, either directly into projects and companies or via funds, is provided by four of the nine banks.

All nine NDBs are involved in climate financing, albeit to different extents, using various instruments, and at diverse stages of "readiness" for actively promoting climate-related programs and activities. For example, AFD Paraguay has only recently become involved in this area, contributing US$220,000 in 2011 for a small reforestation project.

Table 2 Instruments offered by the surveyed Latin American NDBs

			Tier 1 loans (direct)					Equity			
NDBs	Grants/ TA	Tier 2 loans (via LFIs)	Direct equity	Equity into funds	LT investments loans	Guarantees	Other contingent facilities	ST working capital loans	Other	Management of funds	Cofinance with other funds

Source: direct reporting from the NDBs, as of April 2, 2012
Note: *TA*, technical assistance; *LT*, long term; *ST*, short term
Note: (*) since 2012, with the introduction of the Ley del sistema financiero Para el desarrollo, BANDESAL, can provide tier 1 loans. Through May of 2012, no tier 1 loans had been granted. The bank has also recently established a credit line for tier 1 renewable energy generation projects

Considering Paraguay's commitment to addressing the drivers of deforestation and forest degradation, and the recent kickoff of a dedicated UN program (UNREDD + National Program), AFD Paraguay has an increasing role to play in the forestry sector.

Other NDBs have already accessed, or are about to access, international climate funds from bilateral and multilateral entities. BANCOLDEX and FINRURAL, for example, will receive – through the IADB – international public climate funds, including US$50 million and US$15 million from the Climate Investment Funds, respectively. BANCOLDEX will receive funds from the CIF's Clean Technology Fund (CTF) to finance two programs, one to convert the public transport system in Bogotá (US$40 million) and another to promote energy efficiency measures in hotels and hospitals (US$10 million). FINRURAL, which has financing instruments in place tailored to support the rural sector, will also channel resources from the Forest Investment Program (FIP) in 2013 to local communities, through credit lines dedicated to low-carbon projects in forest landscapes.

BANDESAL and FIRA accessed bilateral funds from KfW, Germany's leading Development Bank. With this bilateral funding, BANDESAL supports "Empresa Renovable," while FIRA – under the framework of the Clean Development Mechanism (CDM) – has financed on a zero-return basis the early stages of implementation of a Programme of Activities (PoA) aimed at facilitating the capture and utilization of methane emitted from the anaerobic digestion of wastewater and/or sludge in relevant agro-industries in México. KfW also provided its expertise to develop FIRA's capacity in structuring such programs.

In addition to KfW, FIRA has established strategic alliances with several national and international specialized partners to capitalize on their expertise in the development of long-term sustainable projects while improving its knowledge about environmental issues. Among these alliances are the United Nations Environment Program, its Finance Initiative, and the Sustainable Energy Finance Alliance (UNEP-FI 2012; ALIDE 2011).

To incentivize green investments and address their specific financing needs, all nine NDBs have dedicated programs and instruments in place to finance climate-related projects. With the exception of AFD Paraguay, all offer climate finance on more favorable terms and conditions compared to their conventional credit activities. BNDES, for example, has supported renewable energy projects at interest rates 1.4 % below those practiced for coal or oil thermal plants, and with longer repayment terms (16–20 years versus 14 years for conventional plants). Moreover, BNDES maximum financing participation for renewable sources varies between 70 % and 90 %, while for coal or oil thermoelectric plants is capped at 50 % (IDFC 2012).

How NDBs Can Leverage Private Finance

By channeling national and international sources of funding into country-driven climate change mitigation activities through various financial instruments, and their comparative advantage to other intermediaries more distant from the market, the potential of NDBs to leverage public and private sector resources appears significant.

To our best knowledge, no published work exists so far on the leverage potential of NDBs. It is in fact complex to aggregate the true volume of financial flows from these institutions to private investment in climate-relevant activities, as also noted in IMF (2011). Also, while there is broad agreement on the need to leverage private sector involvement (see, e.g., IMF 2011; AGF 2010), there is no single, universally applicable definition of this term, or methodology to calculate leverage ratios. There is uncertainty about how best to quantify its extent, as this term has different meanings in different contexts and to different people (Buchner et al. 2011; Brown and Jacobs 2011). Furthermore, the leverage factor is not only dependent on the instruments being used, but can vary considerably according to the barriers being addressed, the country/region where the investment takes place, and the specific project characteristics (see Brown and Jacobs 2011). The nature of the intermediary delivering climate finance also impacts the level of leverage potentially achieved.

In financial terms, leverage refers to the ratio of equity to a blend of debt. Financial institutions such as MDBs measure it as the ratio of public to private cofinancing, as they aim to understand and demonstrate the multiplier effect generated by their contributions.

Given that private finance represents the lion's share of the climate finance landscape (Buchner et al. 2011, 2012) and that it is the source that needs to be incentivized and scaled up to achieve the required funding to finance climate change mitigation and adaptation interventions, this study defines leverage as "the process by which private sector capital is 'crowded-in' as a result of the use of public sector finance, and of the financial instruments deployed by public financial intermediaries." This definition builds on Brown and Jacobs (2011).

It is difficult to estimate a specific and sound leverage ratio for NDBs. Few of them consistently track and measure the amount of private sector capital mobilized as a consequence of their activities. This is even more complex in the context of climate finance. However, a look at their advantages and disadvantages compared to those of MDBs indicates the scale of the catalytic effect generated by NDBs. Case studies analysis can also help to shed light into this.

NDBs have a variety of financial instruments at their disposal to facilitate low-emission, climate-resilient investments, many of which are the same as those available to MDBs, but the conditions under which they are provided are different. Building on the methodology developed by the United Nations' High-Level Advisory Group on Climate Change Financing (AGF 2010) to calculate the potential leverage effect exerted by public financing instruments used by MDBs, the study derives the leverage effect that could potentially be exerted by NDBs in LAC.

Table 3 compares the MDBs and NDBs leverage factors of various financing instruments, some of which are generally available to NDBs, but for which no analysis on the use of them by MDBs has been conducted (and therefore N/A is listed in the MDBs column). The leverage factor assumes that the only private capital directly mobilized comes from other financiers, such as local financial institutions. The leveraging potential triggered by a combined set of instruments has not been considered.

Table 3 Comparison of MDBs and NDBs leverage factor

Category of instrument		MDBs theoretical leverage factor	NDBs theoretical leverage factor
Tier 1	Non-concessional debt	2–5 x	2–5 x
	Debt financed via grants	8–10 x	8–10 x
Tier 2	Non-concessional debt	N/A	1 x
	Debt financed via grants	N/A	4–8 x
Tier 1	Direct equity	8–10 x	12–15 x
	Equity financed via grants	20 x	20 x
Tier 2	Direct equity	N/A	12–15 x
	Equity financed via grants	N/A	N/A
	Guarantees at non-concessional rates	N/A	4–8 x
	Guarantees financed via grants	20 x	25 x

Source: Adapted from AGF 2010; Brown and Jacobs 2011
N/A, no data available

Tier 1 loans (both concessional and non-concessional) apply the same leverage factor that has been proposed for MDBs, as there is no reason to believe that the ability of a NDB to draw private capital to projects is any better or worse than that of a MDB. MDBs will have a better credit rating for foreign currency loans, which may entice foreign banks to lend alongside of them. However, for local finance institutions working in local currency, NDBs could have a similar level of leverage.

In terms of equity, leverage is assumed to be higher for NDBs than MDBs. NDBs typically focus on local funds and often act as anchor investors. These funds will then invest in a number of smaller projects in early stages of development. NDBs can draw other institutional investors into the funds, and these, in turn, can draw coinvestors into projects and companies. MDBs tend to work alongside offshore equity providers and can opt for direct investments in larger and relatively more established projects. Sometimes, MDBs will also invest in funds, but the rationale is that local investors will rely more on NDBs to provide a signal or a demonstration effect.

As for guarantees, the leverage factor depends on the type of guarantee offered, but in all cases it is reasonable to expect that a NDB's leverage factor exceeds that of a MDB (i.e., NDB guarantees will be less likely to be called; thus, less capital needs to be allocated) for two main reasons: (a) the NDB can more readily anticipate – and possibly even influence – host country factors, which could impact, directly or indirectly, the likelihood of a guarantee being called, and (b) by operating directly and solely in the host country, the NDB intimately understands local market conditions and the potential impact such conditions may have on the credit quality or commercial performance of a climate-related project.

NDBs' proximity to local finance institutions and local private actors thus suggests that their ability to leverage is equal to or potentially better than that of MDBs for the same instruments.

Leverage Effect by LAC NDBs

At the end of 2011, NDBs in the LAC region had outstanding assets of nearly US$1 trillion and a capital base of US$100 billion, which combined with their capacity to leverage resources makes them unique players in scaling up private investments for climate change mitigation. Table 4 shows the nine NDBs sampled and the size of their capital, assets, and annual business volume for 2009–2011.

The banks analyzed in Table 4 represent over one-third of the LAC region's NDB assets and capital. Five out of the nine banks sampled have systems in place to track how much private finance is being leveraged by their operations, BNDES, COFIDE, FINRURAL, FINDETER, and FIRA, but the majority lack system for specifically monitoring, reporting, and verifying climate investments.

The information provided suggests that these institutions look at leverage in terms of cofinancing. For instance, BNDES reports an average multiplier of about 1.4 times its own contributions for its general operations (based on data from 2009 to 2011). Following the same approach, COFIDE estimates that its tier 2 loans mobilize an additional 20–30 % more from private sources. Commercial banks generally finance up to 60 % of project costs, while the remainder has to come from other private capital. FIRA estimates the relative share of their lending to individual borrowers to be, on average, 54 % of their entire portfolio (over 2009–2011). An average of 31 % has to come from commercial banks, while the remaining from other sources, including other development banks and external sources.

Table 4 Capital, assets, and annual business volume of the sampled NDBs, 2009–2011 (in US$ millions)

NDBs US$ million	Capital base 2011	Total assets 2011	Annual business volumes (approvals) 2009	 2010	 2011

Case Study: NAFIN's Role in Leveraging International and National Public Climate Finance

To shed light on the leverage potential possibly exerted by NDBs, this case study presents how international public climate finance channeled through NDBs can be deployed to mobilize private finance toward public objectives.

Nacional Financiera (NAFIN) has become a key partner in the implementation of the Mexican government's low-carbon development strategies and for accelerating private investments in low-carbon technologies in the country.

Engaging the private sector in low-carbon financing has been a particular challenge in Mexico where, in addition to sector-specific issues (e.g., high investment needs, technology-specific risks, banks' lack of relevant expertise, and high risk aversion), access to credit and the relatively underdeveloped size of the financial sector are major structural barriers in the local economy (IADB 2011a, b). These factors result in a lack of adequate financial instruments to support the renewable energy sector, which results in high interest rates, high transaction costs, a need for large amounts of collateral, and an unexploited renewable energy potential.

Within Mexico's Country Investment Plan, endorsed by the Clean Technology Fund Trust Fund Committee in 2011, these barriers were tackled through international financial and nonfinancial support to structure financing solutions such as the Renewable Energy Financing Facility (REFF) (IADB 2011a, b). This facility was established within NAFIN to fill the financing gap through the provision of: (a) direct loans to project developers, with maturities in the 10–15-year range, and fixed interest rates, to finance the construction of new renewable energy projects (final terms and conditions for borrowers will depend on the characteristics of the project, its internal rate of return, and its risk profile), and (b) contingent credit lines to cover transitory cash flow shortages during the project life cycle (e.g., due to lower than expected energy generation, energy demand, or prices) up to the volume needed to service senior debt (IADB 2011b).

NAFIN was chosen because of its privileged position for channeling – directly or indirectly – international resources, along with its own resources, to local players (i.e., other financial intermediaries or project developers), ultimately enhancing the overall leverage impact of the international funds. The program aimed to leverage the US$70 million of the Clean Technology Fund concessional resources, with at least US$70 million that would come from IADB cofinancing from an existing credit line and a similar amount from NAFIN's own resources (see Fig. 2).

NAFIN would then leverage the overall total (minimum) amount of the US$210 million facility at the project level by catalyzing private capital. Since a single project is not entitled to receive more than US$10 million of the resources of the Clean Technology Fund, and no more than 50 % of its total investment needs from the facility, these conditions aim to maximize the leverage effect as well as the number of projects financed. The IADB estimates that at least US$1.19 billion–US $1.54 billion will have to be mobilized to cover the investment costs of the projects

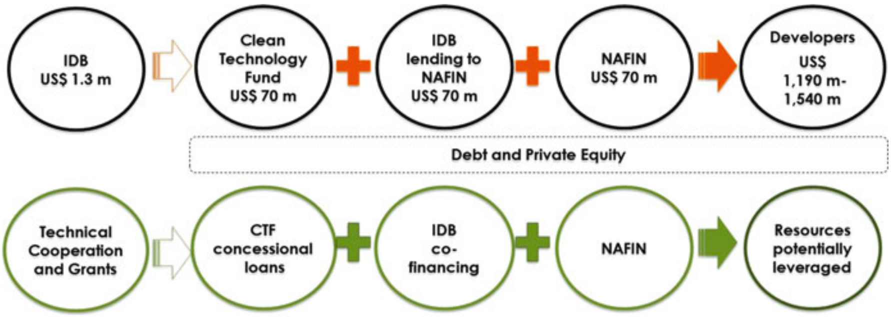

Fig. 2 The estimated leveraging effect of CTF-REFF and NAFIN (source: Authors' elaboration based on IADB (2011a, b))

financed by the facility (IADB 2011a, b). This amount is estimated considering a total 1,000 MW of installed generation capacity and investment costs of US$2–2.5 million per MW, assuming an equity to debt ratio of 30/70 (IADB 2011b).

NAFIN is key to make this happen, as it is in charge of project selection, demand stimulation, and the structuring of financial packages appealing to local project developers and tailored to their needs. The risk-sharing arrangements put in place between NAFIN and borrowers will be critical for unlocking financing, as developers depend on the off-takers' credit qualifications.

NAFIN was a natural partner for the IADB for the execution of this program, given the long relationship between the two and the fact that NAFIN supports private sponsors in the financing of projects with climate change mitigation objectives. NAFIN has proven to be a solvent institution with adequate risk management systems and practices in place. NAFIN has established a sustainable Project Directorate, a unit dedicated to supporting climate-related projects, which received technical assistance from the World Bank. NAFIN has already experience in structuring the financing of wind energy projects, which will likely constitute the majority of the projects supported under the REFF. In fact, it has already supported the financing of the EURUS and the Piedra Larga wind farms in the region of Oaxaca, which are also part of the overall CTF investment plan.

By executing the REFF program, NAFIN's capacity in the preparation, assessment, evaluation, and monitoring of risks in this type of project is expected to be further strengthened. In turn, this capacity and know-how can also then be extended to the local banking system. Local finance institutions that take part in projects will develop their own capacity, familiarize themselves with the risk management and financing requirements of these projects, and develop the institutional capacity required to handle them. This can help to unlock their financing potential ultimately boosting renewable energy investments in the country by exploiting their ability to reach a wide group of interested recipients.

Conclusions

To support the global transition toward a low-carbon, climate-resilient future, there is a pressing need to scale up investments in climate change mitigation. As public financial resources cannot finance this transition alone, unlocking private capital is essential. International and national public funds are critical to mobilize private climate finance by taking on the classes of risks and costs that the private market will not bear.

A number of key features unique to NDBs make them well placed to play a significant role in supporting the transition by acting as intermediaries or sources of climate finance. Their proximity, knowledge, and long-standing relationship with the private sector put them in a privileged position for accessing local financial markets and understanding local barriers to investment. NDBs' services and range of instruments can help to tackle the specific investment and financial obstacles that prevent private actors from engaging in low-carbon projects, thereby promoting private investments. The study shows that their ability to leverage is equal to or potentially better than that of MDBs for the same instruments.

Nevertheless, many NDBs are at different stages of the learning curve for supporting climate finance efforts. Many require technical assistance to develop the capacity needed to assess, analyze, and structure green investment projects.

This was also highlighted by the result of the survey conducted with nine NDBs operating in the LAC region and the discussions had in dedicated forum (see ALIDE et al. 2012). The survey, in particular, highlighted that NDBs in this region are already piloting the use of dedicated instruments in support of climate change mitigation investment, both at the investment and pre-investment stage, and have significant potential for leveraging national and international public and private resources. At the end of 2011, surveyed NDBs in the region had outstanding assets of nearly US$1 trillion and a capital base of US$100 billion that, combined with their capacity to leverage resources, makes them unique players in scaling up private investments for climate change mitigation.

However, the following actions are deemed necessary to enable these players to more effectively scale up private investments:

I. *Enhance the dialogue between national policymakers and NDBs to promote an active role of NDBs in delivering international climate finance*. While in several countries such as Brazil NDBs have a clear government mandate to promote national climate change mitigation programs, most lack such mandate and are rarely involved in the design of such programs. Their advice is also rarely considered for the design and functioning of new climate finance mechanisms such as the Green Climate Fund. To fully harness the potential of NDBs in climate finance, there is the need for considering NDBs' experience and advice for the design and functioning of new climate finance mechanisms, and further use NDBs as vehicles to manage and channel climate finance resources.

II. *Encourage NDBs to develop readiness strategies for international climate finance mobilization and intermediation*. NDBs are at distinct stages of institutional development to operate in new areas of financial practice, such as climate finance. While some like BNDES already have the capacity to be active in climate finance, others still need to develop and strengthen their capabilities in this area. To strengthen NDBs' participation in climate finance, a clear mandate and support from their respective governments, as well as by increasing interactions with relatively more developed regional, national, and international financial institutions such as MDBs. To become credible and reliable intermediaries and access international climate funds, they must also develop the capacity for monitoring, reporting, and verifying climate investments and their environmental benefits. This requires NDBs to develop considerable capacity.

III. *Build knowledge about best practices of NDBs in climate finance.* A better understanding of effective funding sources and channels and the catalytic potential of different instruments can provide lessons to the international climate finance community on what works and what does not, informing the design of existing and emerging financing mechanisms, and helping governments to spend their limited financial resources more effectively. Given the ongoing efforts in the design of the Green Climate Fund, there is a window of opportunity for NDBs to feed lessons from their own financing practices on the ground and experiences with the private sector, thus influencing the future of climate finance.

Assigning NDBs a key role in mobilizing and intermediating international climate finance increases the potential to achieve climate and development goals. Targeted efforts to address a number of issues and themes could substantially improve the capacity of NDBs to make game-changing contributions to the international climate finance landscape.

Water, Food, and Energy Nexus in South Asia: Implications for Adaption to Climate Change

Golam Rasul and Bikash Sharma

Contents

Abstract

Adaptation to climate change has received increased attention in recent years in the academic and development discourse. Effective adaptation to climate change requires the efficient use of land, water, energy, and other vital resources, together with coordinated efforts to minimize trade-offs and maximize synergies. The concept of water, energy, and food nexus is considered to be an effective mechanism for enhancing resource use efficiency, minimizing trade-offs, and maximizing synergies in resource use. However, as in many developing countries, the policy process in the countries of South Asia generally follows a

sectoral approach that does not take into account the interconnections and interdependence among the three sectors. In designing effective adaptation strategies, it is critical to understand the linkages between the nexus perspective and adaptation to climate change. This paper seeks to increase understanding of the interlinkages in the water, energy, and food nexus, explains why it is important to consider this nexus in the context of adaptation responses, and argues that focusing on trade-offs and synergies using a nexus approach could facilitate greater climate change adaptation and help ensure food, water, and energy security by enhancing resource use efficiency and encouraging greater policy coherence. The paper provides a conceptual framework for considering the nexus approach in relation to climate change adaptation, discusses the potential synergies, and finally offers a broader framework and reform measures for making adaptation responses more effective and sustainable.

Keywords
Water-food-energy nexus • Adaptation to climate change • South Asia • Policy coherence • Trade-offs • Synergies

Why is Nexus-Based Adaptation Important?

Climate change is already threatening both the development process and the basic elements of life, such as access to water, energy, food production, and the environment, around the world and especially in developing countries. With 70 % of the expected global population of 9.2 billion people living in cities by 2050, demands for water, energy, and food will increase exponentially. The demand for food is expected to rise by 35 % by 2030 and for water and energy by 40 % each (Hoff 2011). Currently, some 1.2 billion people live in regions with insufficient water to meet human needs, and at least 1.5 billion are without access to modern forms of energy. By 2040, one-third of the world's population will live in areas of water stress (Hajkowicz et al. 2012). Competition for land for food and energy is expected to increase. In 2008, about 100 million tons of cereals (4.7 % of global cereal production) were used in the production of biofuels. Global energy use has approximately doubled over the last 30 years, and by 2040 the demand is likely to grow by more than half again. Thus, competition for land for biofuels is likely to increase further. There is growing evidence that the atmosphere will continue to warm throughout the twenty-first century, which will affect water availability, food production, and energy use and require effective adaptation.

The global community is looking for new approaches and solutions to adaptation to climate change, as well as to meeting development challenges, such as ensuring water, energy, and food security that are critical for human survival and sustainable well-being. Water, energy, and food are all subject to rapidly growing global demand and all face resource constraints, while billions of people lack sufficient access to them (Bazilian et al. 2011). The ongoing depletion of these strategic resources as a result of unsustainable consumption and production patterns is constraining future economic growth and social progress and threatening the very basis of human survival, and the situation is likely to worsen in the face of increased demands. The Rio + 20 Declaration “The Future We Want” stresses the need for balanced integration of economic, social, and environmental concerns in economic development and also highlights the urgent need to address food, water, and energy security in such a manner as to reduce the adverse impacts on human and natural systems as one of the greatest challenges facing humanity.

Meeting this challenge has emerged as a top priority on the national and international development agenda. Mitigation and adaptation are complementary components of a response strategy to climate change, aimed at reducing the extent as well as increasing the resilience to change. Adaptation is critically important in developing countries, where large numbers of people depend on climate-sensitive sectors such as agriculture, forestry, and fisheries; have limited resources and capacity; and live in climate-vulnerable settings such as mountains and coastal areas (WRI 2011, Shrestha and Aryal 2011). The goal of adaptation is to reduce vulnerability to both climatic and non-climatic changes; thus, it is closely linked with the sustainable use and management of water, energy, and food, all of which are vital for sustainable development.

The production and consumption of water, energy, and food are closely interlinked, forming a nexus, with changes in any one component likely to have a marked impact on the others. However, they still tend to be treated as separate issues, both in regular development planning and in planning for adaptation. The failure to recognize the close linkages can result in counterproductive actions that threaten the success and sustainability of planned interventions, which is particularly problematic in adaptation, where changes are being made to enable survival in a future changed situation for which there is no guiding experience. At the same time, recognition of the nexus offers possibilities for planning to be made more effective. There are several compelling reasons for pursuing nexus-based adaptation as an effective strategy to meet future challenges.

Promoting Synergy and Co-benefits: Although interest in adaptation to climate change impacts has surged in recent years, the focus has remained sectoral. The role of the water-food-energy nexus in addressing the competing demands of, and facilitating, adaptation and development has not yet been fully recognized. Historically, most adaptation plans, including the National Adaptation Programmes of Action (NAPAs), have been prepared to meet sectoral goals. They generally focus on sectoral and project-based activities, without adequate consideration, or coordination, of cross-sectoral interactions among key climate-sensitive sectors, such as water, energy, and food, which can be used to minimize trade-offs and promote synergy and co-benefits.

Overcoming Maladaptation Practices: Sectoral adaptation strategies can increase vulnerability or undermine net resilience by decreasing capacity or increasing risks in another place or sector, resulting in maladaptation practices (Walker et al. 2006; Urwin and Jordan 2008; Barnett and O’Neill 2010). For example, in China, excessive use of pesticides in food production has had a negative impact on health costing an estimated USD 1.4 billion per year and has adversely affected farm and off-farm biodiversity (Norse et al. 2001), which in turn has negatively affected food production. Similarly, subsidies for groundwater extraction, provided by many South Asian countries to cope with surface-water shortages and uncertainty in water availability, have led to overexploitation of groundwater, wastage of scarce water resources, and increased demand for energy for pumping, ultimately undermining food and energy security. Baluchistan, an arid region of Pakistan, is now growing apples and other fruit through groundwater irrigation which requires huge amounts of energy, while the country faces crippling shortages of energy for other activities (Mustafa and Qazi 2007; Khair 2013). Overcoming these problems is not possible without taking a nexus perspective to develop integrated solutions.

Ensuring Policy Coherence and Coordination: The prevailing approaches see adaptation largely as a local issue with a community or ecosystem focus (Huq and Reid 2004) and ignore the role of the national, regional, and global policies and institutions which shape adaptation options and choices. Local adaptation approaches often prove unsustainable owing to inadequate institutional support (Agrawal 2010). Climate change brings multiple stresses, and adaptation requires comprehensive and integrated approaches with coordination between different sectors and at different scales: local, national, and regional. As water, energy, and food are critical for human survival and sustainable well-being, managing these vital resources sustainably requires a nexus perspective.

Addressing Planetary Boundary and Resource Scarcity: Ongoing global climate change, the rapidly increasing population, urbanization, globalization, and aspirations for better living standards are already posing a challenge to planetary sustainability, pushing the planet beyond its carrying capacity. Climate change and anthropogenic pressures have exacerbated the pressure on water, energy, and food (Rockstrom et al. 2009). All three sectors are both highly vulnerable to climate change and contribute heavily to that change through their greenhouse gas emissions (Howells et al. 2013; Calow et al. 2011). Adaptation is therefore intrinsically linked to water, energy, and food security. The nexus approach provides a framework for addressing competition for resources through enhancing resource use efficiency. Although the likely impacts of climate change on water, energy, and food production have raised serious concerns and been emphasized in the pursuit of appropriate adaptation measures, the links among water, energy, and food, and the role of this nexus in sustainable adaptation, have not yet been well researched. Failure to consider the nexus of water, energy, and food in resource assessments and policy making has led to contradictory strategies and inefficient use of resources (Howells et al. 2013).

The Need for Urgent Action

With large populations, limited land resources, and growing water stress, South Asian countries face the common challenge of how to grow more food with the same or less land, less water, and increased energy prices. Rice and wheat, the staple foods in the subregion, require huge amounts of water and energy. Efficient and coordinated management of water, energy, and food is critical for adaptation and mitigation to climate change in the region (Rasul 2014).

Organization of the Chapter

Understanding the role of the water, energy, and food nexus in adaptation is an essential basis for designing effective adaptation policies and strategies. This chapter, using South Asia as an example, argues that in the developing world, focusing on the trade-offs and synergies of the water, energy, and food nexus is a potential strategy for integrated and efficient resource management and for adaptation to address future challenges in a systematic way. Following this introductory section, section "Conceptualizing Climate Change Adaptation and the Water, Energy, and Food Nexus" provides an overview of the concepts of climate change adaptation and the water, energy, and food nexus; section "Challenges of Food, Water, and Energy Security and Adaptation to Climate Change in South Asia" discusses the interrelated challenges of water, energy, and food security in the South Asian region and the implications for adaptation to climate change; section "Synergies in the Water, Energy, and Food Nexus and Adaptation Strategies" provides a more detailed discussion of the synergies between water, energy, and food and the way in which the nexus perspective can help in adaptation to climate change; and finally, section "Towards a Nexus-Based Framework for Sustainable Adaptation" offers a broader framework and reform measures for making adaptation responses more effective and sustainable. The study relies predominantly on information drawn from secondary sources, including books, reports, and journal articles. Some information has been drawn from the research experience of the International Centre for Integrated Mountain Development (ICIMOD) in the Hindu Kush Himalayan (HKH) region over the past 30 years, as well as the authors' own research experience in the region.

Conceptualizing Climate Change Adaptation and the Water, Energy, and Food Nexus

Although a growing body of literature is emerging on both adaptation to climate change and the water, energy, and food nexus, the linkage between the two is rarely explored or articulated in the policy-program-action continuum. This section briefly examines these concepts and their linkages.

Evolving Approaches to Adaptation to Climate Change

Adaptation has received increased attention in recent years in the academic and development discourse. Different scholars define adaptation in different ways based on their professional interests (e.g., Adger et al. 2005; Doria et al. 2009; Smit and Wandel 2006; OECD 2009). In terms of climate change, adaptation has been defined as the process or adjustments through which people reduce the adverse effects of climate on their health and well-being and take advantage of the opportunities that their climatic environment provides (IPCC 2007). Adaptive capacity

Table 1 Evolving approaches to adaptation

Feature	1990s	2000s	2010s
Overall objective	Reducing climate risks and impacts	Reducing climate risks and uncertainties	Reducing climate risks and impacts with socioeconomic improvements Mainstreaming climate change adaptation into development
Scope	Sector-based approach, location specific	Sector-based approach, but adaptation mainstreamed into sectoral planning	Trans-sector and transboundary approaches started
Focus of activities	Protective: coping strategies, protection of those most vulnerable to climate risks and with low levels of adaptive capacity	Preventive: coping strategies, prevention of damaging strategies arising from risks to climate-sensitive livelihoods	Transformative: building adaptive capacity, transforming social relations to combat discrimination and underlying social and political vulnerability
Activities	Activities seek to address impacts exclusively associated with climate change: provision of social services; social transfers (food/cash), including safety nets	Managing climate risks: activities seek to incorporate climate-related information into decision-making	Building response capacities: activities seek to build robust systems for problem solving Addressing the drivers of vulnerability: activities seek to reduce poverty and other non-climatic stressors that make people vulnerable

Sources: Adapted from Davies et al. (2013), Calow et al. (2011)

and vulnerability are thus important concepts for understanding adaptation. While vulnerability can be seen as the context in which adaptation takes place, adaptive capacity is the ability or potential of a system to respond successfully to climate variability and change, in order to reduce adverse impacts and take advantage of new opportunities (World Bank 2010).

The concept of adaptation continues to evolve, however, and its focus is gradually changing from simply responding to the impacts of climate change to addressing the underlying factors that cause vulnerability. More specifically, approaches to adaptation have evolved from the initial infrastructure-based interventions to a more development-oriented approach based on building broader resilience to climate hazards by addressing the underlying causes of vulnerability rather than simply responding to the symptoms (Calow et al. 2011; Davies et al. 2013). Trans-sector and transboundary considerations, however, are only just emerging. Table 1 shows how adaptation approaches have evolved over the past two decades in terms of assessment of risks, mainstreaming, focus, and scope. In the 1990s, the focus was on assessment of the climate risks and aimed at reducing climate impacts using a locally specific sectoral approach. In the 2000s, the theory of adaptation, including the notion of mainstreaming, gained momentum faster than policy and practice, although the sector-based approach still dominated in mainstreaming. In the current decade, the emphasis has shifted, with adaptation linked more to sustainable development. There has been a shift away from sectoral approaches and an emerging emphasis on cross-sectoral and transboundary approaches, for example, focusing on river basins.

Broadly, there are two distinct perspectives on how to approach adaptation in developing country contexts. The first focuses on reducing climate change impacts. The second focuses on reducing vulnerability by addressing not only climate change but also other drivers of vulnerability and poverty such as gender and social equity, as well as other structural factors hindering long-term sustainable development.

In practice, most interventions fall somewhere between these two extremes. The development-oriented approach emerged based on the underlying premise that people are vulnerable not only to climate change but also to a range of other stresses, depending on access to resources and other socio-environmental circumstances shaped by political and economic processes (Kelly and Adger 2000; O'Brien et al. 2004). Technological measures designed to adapt to specific changes in climate may fail to address the issues local people consider most urgent, such as access to water, food, and energy and livelihood security.

It is increasingly recognized that successful adaptation will require interventions that address the full spectrum of challenges, including underlying causes of vulnerability, in the context of other theories of risk and development. As pointed out by Schipper (2007), "mainstreaming will not be effective if existing development trajectories are inconsistent with the objectives of adaptation. It is vulnerability reduction that should be integrated into development policy, rather than the creation of explicit adaptation strategies. In this sense, focusing on adaptation before aligning development processes through the creation of enabling conditions for adaptation is like putting the cart before the horse."

Concept of Sustainable Adaptation

Debates on climate change adaptation have taken place largely outside the broader discourse on sustainable development (Bizikova et al. 2013). Sustainable development has only been included as a theme by the Intergovernmental Panel on Climate Change (IPCC) since the third assessment (Munasinghe and Swart 2000), and little attention has been paid to the identifying principles that create synergies between adaptation and sustainable development. Climate change adaptation can be made more relevant to policy by contextualizing it within a sustainable development framework (Robinson and Herbert 2001). Eriksen et al. (2011) define sustainable adaptation as "a set of actions that contribute to socially and environmentally sustainable development pathways, including social justice and environmental integrity. It considers the wider effects of adaptive responses on other groups, places, and socio-ecological systems, both in the present and in the future." According to Doria et al. (2009, p. 815), "Successful adaptation is that adaptation that generates net benefits for the adapting party, in both the short- and long-term, without causing net loss of welfare for the wider society." A sustainable adaptation process requires adjustments in policies, institutions, and attitudes to establish enabling conditions for sustainable development through reduction of vulnerability, while at the same time overcoming factors that cause vulnerability to climate change. Considering that not every adaptation intervention reduces poverty and inequality (and some poverty reduction measures may aggravate vulnerability), sustainable adaptation measures need to specifically target the nexus between vulnerability and poverty (Eriksen and O'Brien 2007; Eriksen et al. 2011) while emphasizing transitions to low-carbon economies (Winkler and Marquand 2009).

Principles of Sustainable Adaptation

Although as yet there is no framework or set of principles for sustainable adaptation agreed by all stakeholders, certain key principles can be discerned:

- Adaptation is an integral part of sustainable development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs, grow, and adapt.
- Adaptation must be addressed in a comprehensive and intersectoral manner, as part of overall development.
- Adaptation of one sector or one community should not lead to a net loss of welfare for the wider society.
- Adaptation responses and mechanisms should be sensitive to the needs of local communities and their resources, knowledge, and culture.

The Concept of the Food, Water, and Energy Nexus

The discourse on food, water, and energy security is driven by the growing pressure on natural resources. The demand for food, water, and energy is growing steadily, but the resources required to generate them are limited and in many cases dwindling (Rockström et al. 2009; State of the Planet Declaration 2012). The interdependencies among water, energy, and food are numerous and multidimensional; this relationship is often called the food, water, and energy nexus (although the order of the components may vary). Although the discourse on this nexus has been gaining currency (Marsh and Sharma 2007; Hoff 2011; Hussey and Pittock 2012), how the concept can be applied to ensure food, water, and energy security is not yet clearly understood. Understanding the different interfaces in the food, water, and energy nexus is critical for taking sustainable adaptation action to address food, water, and energy security.

Complex Interrelationships

- *Water for food and energy*: Water plays a vital role in food and energy production and in sustaining the ecosystems which support agriculture and other economic activities that are critical for achieving food security (Molden 2007; Hellegers et al. 2008).

- *Energy for food and water:* Energy is required for food production (especially irrigation) and for water supply, including extraction, purification, and distribution of water (Nonhebel 2005; Bazilian et al. 2011). About 7 % of the world's commercial energy production is used for managing the freshwater supply (Khan and Hanjra 2009). Agriculture accounted for almost 21 % of the total power consumption in India (Kumar et al. 2012).
- *Agriculture and land for energy and water:* Agriculture has a dual role as an energy user and as an energy supplier in the form of bioenergy. Sustainable agricultural practices such as actions to avoid land loss or degradation save water by increasing soil water storage and groundwater recharge. They also save energy, for example, by reducing the use of energy-intensive fertilizers. Agriculture and food production have a further impact on the water sector through their effects on land condition, runoff, groundwater discharge, water quality, and availability of water and land for other purposes such as natural habitat (Alauddin and Quiggin 2008).

The relationships among food, energy, and water are dynamic. Actions in one area usually have impacts on one or both of the others, with profound economic, environmental, and social implications. Indeed, the security of one sector often cannot be achieved without undermining security in another sector (Newell et al. 2011). The environmental footprints associated with increased water and energy use for food production impose external costs to water and ecosystems, thus threatening the sustainability and resilience of global water and food systems (Khan and Hanjra 2009).

The nexus approach aims to systematize the interconnections and provide tools to assess the use of all resources (Hermann et al. 2012). It is a system-wise approach; it recognizes the inherent interdependencies of the food, water, and energy sectors for resource use, seeks to optimize the trade-offs and synergies, and recognizes the social and environmental consequences (Bazilian et al. 2011; Prasad et al. 2012). Understanding the linkages within the food, energy, and water nexus can provide opportunities to increase resource use efficiency and enhance cooperation and policy coherence among the three sectors. For example, sustainable agricultural practices, such as those designed to prevent land degradation, save water and energy by increasing water storage in the soil and groundwater recharge and by reducing the use of energy-intensive fertilizers. The nexus perspective should help to promote interdisciplinary and mutually beneficial actions (Scott et al. 2011). It can contribute to meeting the future needs of the global population, particularly those who do not have access to safe drinking water and modern energy (Marsh 2008). From this perspective, identification of crucial interactions, conflicting demands, and potential synergies in the water, energy, and food nexus can be a powerful entry point for achieving sustainable adaptation.

Key Principles of the Nexus Approach

The nexus approach is centered around core principles of efficiency, equity, and sustainability; the fundamentals of the approach can be summarized as follows:

- Understand the interdependence of subsystems within a system across space and time, and focus on system efficiency (using a systems-based approach to natural resource policies and regulations) rather than the productivity of individual sectors to provide integrated solutions that contribute to water, energy, and food security and sustainable development.
- Recognize the interdependence between water, energy, and food, and promote the wise development and efficient use of these resources in an environmentally responsible manner.
- Identify crucial interactions, conflicting demands, and potential synergies to minimize trade-offs and maximize synergies across sectors, and encourage mutually beneficial responses that enhance the potential for cooperation between and among all sectors.
- Ensure policy coherence and coordination across sectors to build synergies and generate co-benefits to produce more with less, while reducing loss and waste in the spirit of the 3Rs principle – recharge, retain, and reuse – and contributing to long-term sustainability with limited environmental impact.
- Value the natural capital of land, water, energy, and ecosystems to support the transition to sustainability.

Interfaces Between the Water, Energy, and Food Nexus and Adaptation Strategies

The water, energy, and food nexus and adaptation responses are interlinked in numerous ways. Understanding the interlinkages is critically important for policy makers in devising sustainable adaptation strategies. Table 2 shows the links between the adaptation response and nexus approaches, which share many common features, while indicating complementarities and co-benefits from nexus-based adaptation.

Challenges of Food, Water, and Energy Security and Adaptation to Climate Change in South Asia

South Asia is one of the most dynamic regions of the world in terms of population growth, economic progress, urbanization, and industrialization. The demographic, economic, and environmental changes in South Asia have increased the demand for resources, including food, water, and energy, and intensified their use, which has serious implications for adaptation strategies to ensure food, water, and energy security in the region.

The population of South Asia almost tripled from 588 million to 1.6 billion in the half century from the late 1950s to 2010 and is expected to reach 2.2 billion by 2025. With high population growth and industrial development, cereal demand is projected to rise to 476 million tons by 2025, compared to 241 million tons in 2000 (FAO 2011). But this higher agricultural production has to come from the same

Table 2 Complementarities and co-benefits from nexus-based adaptation

Key characteristic	Nexus approach	Climate change adaptation	Complementarities and co-benefits from nexus-based adaptation
Goal	Ensure efficient use of available resources to support transition to sustainability	Build resilience and enhance adaptive capacities against climate and other risks	Understanding adaptation to climate change is critical for addressing nexus challenges and efficient use of resources is critical for effective adaptation
Core principles	Minimize resource waste and maximize economic efficiency, while accelerating the sustainable supply	Reduce vulnerability by managing climate risks and building response capacity	Since resource scarcity often increases people's vulnerability, the nexus approach may contribute to facilitating adaptation and vice versa
Main focus	Provide integrated solutions that contribute to sustainable development	Minimize shock, risks, and vulnerability and address impacts and risks associated with climate change	Understanding vulnerability to climate change is crucial for assessing nexus challenges; equally integrated nexus solutions can contribute to reducing vulnerability and poverty
Broad strategies	Policy integration, harmonization, and governance to build synergies and generate co-benefits across sectors in a sustainable way	Addressing the drivers of vulnerability to climate change in specific sectors through building adaptive capacity and resilience	Cross-sectoral nexus analysis identifies trade-offs and synergies and integrates policy implementation; diversification increases resilience; the nexus strategy is critical for integration of climate adaptation and mitigation, while broadening the scope to address poverty-vulnerability linkages

amount of land and may be even from less land, because of competing uses arising from population growth, urbanization, and industrialization. Per capita food consumption has remained stagnant in many parts of South Asia in recent years, despite impressive growth in per capita income (Alagh 2010). Low levels of consumption have contributed to persistent hunger and malnutrition (Dev and Sharma 2010) in South Asia.

Increasingly Water- and Energy-Intensive Food Production in the Face of Water and Energy Scarcity

Agriculture consumes about 90 % of the water and 20 % of the total energy used in the region. Water, once considered abundant, has become increasingly scarce with declining per capita water availability in Pakistan, India (Gupta and Deshpande 2004), and China (Liu et al. 2007). With about 60 % of the population in India and 65 % in Pakistan relying on groundwater for irrigation (Qureshi et al. 2010), they are already extracting groundwater 56 % and 25 % faster than it can be replenished, respectively. The increased extraction of groundwater has increased demand for energy and lowered the groundwater table in many parts of the HKH region, especially the northwestern Himalayas. This has created a serious concern for the entire region, as the shortage of water and energy severely constrains not only agriculture but also the overall economic growth and human well-being. For example, the energy shortage in Pakistan is causing a loss of about USD 1 billion and 400,000 jobs per annum (GoP 2013). The situation is similar in Bangladesh, India, and Nepal and is challenging overall macroeconomic stability.

Despite the complex interdependency of food, water, and energy among competing uses, each country in the HKH region has put forward a NAPA to address the issues/impacts of climate change using a sectoral adaptation approach, with little or no attention being paid to a nexus-based system-wise adaptation approach to deal with the vulnerability to climatic and non-climate changes. Considering that water, energy, and food are the vital resources for poverty and vulnerability reduction, it is critically important to prioritize and devise an integrated adaptation option based on a nexus assessment that reduces vulnerability to both climate and non-climate changes.

The key features and challenges of food, water, and energy security and their interlinkages are summarized in Table 3.

Synergies in the Water, Energy, and Food Nexus and Adaptation Strategies

Sustainable adaptation options reduce vulnerability to both climate and non-climate changes and address poverty-vulnerability linkage. As water, energy, and food are vital resources for poverty and vulnerability reduction, understanding the linkages among them is critical for adaptation planning. This section attempts to explore potential areas of trade-offs and synergies or complementarities in the water, energy, and food nexus as a new tool to support development of integrated adaptation strategies. Given the complex interplay of water, energy, and food demand and supply, numerous challenges and opportunities exist to minimize trade-offs and promote synergies to formulate sustainable adaptation options.

While some adaptation measures such as water use efficiency, renewable energy, and growing biofuels on wasteland might have positive implications for water, energy, and food resources, other measures for adaptation and mitigation such as

Table 3 Key features and challenges of food, water, and energy security in South Asia

Key characteristics	Adaptation challenges	Food, water, and energy resources and adaptation to climate change
Food security		
Huge chronically undernourished population About half of the world's poor (46 %) and 35 % of the world's undernourished live in South Asia	Provision of food, water, and energy to a large malnourished population without degrading the natural resource base and environment	To meet the nutritional needs of all, food production needs to double in the next 25 years
Burgeoning human population About 25 % of the world's population (projected to reach 2.3 billion by 2050) live in just 3 % of the world's land area	To feed the growing population, agricultural production will have to increase by 70 %, energy by 40 %, and water by 57 %	Increased pressure on land, water, and energy to meet the increased demand
Declining cropland Per capita arable land continually declining due to population growth, urbanization, and increasing biofuel cultivation to meet the energy demand	Limited options for growing more food grain by expanding crop area	Competing demand for land for food, bioenergy production, and ecosystem services
Intensive food production Food production becoming increasingly water and energy intensive	Adapting to the declining groundwater table	Agricultural growth is constrained due to shortage of energy and water
Changing food preferences toward meat The meat production process requires more energy and water	About 7 kg of grain equivalent energy is required to produce 1 kg of meat	Increased pressure on water to meet the food requirement
Sensitivity to climate change Food production is highly vulnerable to climate change due to rising temperatures, accelerated glacial melting, increased evapotranspiration, and erratic rainfall	Uncertainty in water availability due to rapid glacier melt and changes in monsoon pattern in the Himalayas	Climate change is likely to be a critical factor in increasing water and energy demand for food production and land demand for biofuel production
Water security		
Growing water stress Growing water demand for agriculture, energy, industry, and human and livestock use; annual water demand is predicted to increase by 55 % by 2030 compared to 2005	Providing access to safe drinking water in the face of an increasing variability in the water supply	Water-intensive adaptation practices leading to increased water pollution and waterborne diseases, high child mortality, and poor human health

(*continued*)

Table 3 (continued)

Key characteristics	Adaptation challenges	Food, water, and energy resources and adaptation to climate change
Upstream-downstream dependence on water High dependence of downstream communities on the upstream for water to grow food and generate hydropower	Need for enhanced upstream-downstream coordination and cooperation for sustainable development of HKH water resources	Rivers originating in the mountains are a lifeline for dry-season water for irrigation, hydropower, and major economic activities
Increased dependence on groundwater for food production About 70–80 % of agricultural production depends on groundwater irrigation	Adapting to declining water tables	Groundwater pumping for irrigation requires excessive energy which further increases electricity demand
Energy security		
High energy poverty About 63 % of the population without access to electricity; 65 % use biomass for cooking	Providing adequate and reliable energy to a large population without increasing pollution	Growing demand for water and land for energy production
Underutilized potential for hydropower and clean energy	Adaptation options are restricted	Energy diversification to meet the growing demands of food, water, and economic growth

extensive groundwater pumping, desalination plants, and interbasin transfers of water to deal with water scarcity, and growing biofuels to deal with fuel scarcity, may increase nexus challenges (Bazilian et al. 2011). Clearly, any policy designed to reduce vulnerability to climate impacts in one sector will affect and be affected by water, energy, and food linkages.

Promises of a Nexus-Oriented Approach for Sustainable Adaptation: Potential for Synergy

Some sector-specific adaptation measures have the potential to provide synergistic "win-win" opportunities to enhance climate mitigation or adaptation objectives across one or more of the other sectors in the nexus, while other measures may have negative impacts on mitigation or adaptation potential in other sectors (Table 4). For example, increasing the efficiency of freshwater use as an adaptation measure has the potential for synergy across sectors, as it increases the availability of water for energy and agriculture, while reducing emissions per capita. But at the same time, it has potentially negative implications because resiliency gains from water use reductions may be lost if conserved water is used to expand planted

Table 4 Synergies between climate change adaptation and nexus approaches

Sector-specific adaptation measures		Positive implications for the sector	Potential for synergies across the nexus
Water	Increasing water use efficiency	Reduces water use per capita	Increased availability of water for energy and agriculture
	Switching from use of freshwater to wastewater	Reduces freshwater use per capita	Increased availability of freshwater for food, energy, and other uses
	Switching from wet to dry cooling at thermoelectric power plants	Reduces water use and associated thermal pollution	Increased availability of water for energy and agriculture
	Desalinization	Increase in brackish and freshwater supplies	Increased availability of freshwater and overall water supply for energy, agriculture, and other uses
	New storage and conveyance of water to serve new demands	Increased water supplies to meet demand	Increased availability of freshwater and overall water supply for energy, agriculture, and other uses
	Watershed management	Increased water supplies to meet demand	Increased water supply for energy and other uses, improved water quality, reduction in flood potential
Land	Switching to drought-tolerant crops	Increased/ maintained crop yield in drought areas	Reduced water demand
	Using waste or marginal land for biofuels	Increase in renewable energy	Reduced pressure on nonrenewable energy as some fossil fuels are replaced with biofuels
Energy	Increasing transmission capacity	Reduced economic and social impacts	Potential for reduced emissions if new transmission and wind/solar power supplied to the grid
	Increasing renewable energy e.g., solar, wind, biogas	Increased clean energy and reduced pressure on energy	Reduced greenhouse gas emissions, reduced water demand for cooling, thermal power

Adapted from Skaggs et al. (2012)

acreage. Similarly, mere provision of irrigation water does not guarantee productivity because salinization induced by irrigation reduces productivity. Electricity production in China and India also has water use and carbon emission impacts, 78 % and 52 % of total electricity in China and India respectively is generated using fossil fuel (coal). Electricity generation from wind or photovoltaics is typically much less water intensive than generation from fossil fuels. Water smart technologies can save both water and energy while improving food security. For example, micro-irrigation technologies, such as drip and sprinkler irrigation methods, have been proven to be highly efficient in increasing crop productivity while using less water, thereby saving both water and electricity, which is widely use for pumping groundwater (Narayanamoorthy 2007). Experience has shown how increasing water use efficiency could be a win-win option for nexus-based adaptation (UNESCO 2009). In planning and policy, full consideration of such cross-sectoral interactions is critical to devising adaptation options for enhancing synergies and reducing risks.

There are also strong links between energy, food security, and adaptation. Universal access to adequate, affordable, and reliable renewable energy is both an adaptation and a mitigation response to climate change and also enhances other options and choices for adaptation. Growing biofuels on wasteland can enhance the energy supply and thus reduce dependence on fossil fuels. However, diverting cultivable land for biofuels can threaten food security. Holistic adaptation to climate change can also support achieving nexus security by reducing vulnerability and minimizing the risk of disasters. Understanding the potential synergies in the water, energy, food, and adaptation nexus is critical for effective adaptation and sustainable development.

Nexus-based adaptation offers a pathway to a nexus-smart green economy. For such a transition, efforts to attain food security need to be water, land, and energy smart; efforts to achieve energy and climate protection goals need to be water and land smart; and efforts to reach water goals need to be energy and climate smart. As an example, the so-called Jyotigram scheme for improved access to energy for both households and irrigation (water pumping) in Gujarat, India, is a promising integrated approach which has significantly reduced groundwater overexploitation and increased energy and food security, while raising Gujarat's GDP growth above that of the rest of India (Shah et al. 2009). Another example of a nexus-smart green economy is the Mongolia capital, Ulan Bator, the world's second most polluted city, where a 50-MW wind farm was built that will save 18,000 tons of carbon dioxide and 1.6 million tons of water each year. It has led to an abundant potential for a green environment that can help poverty eradication and provide jobs and sustainable development (Slezak 2013).

There are a number of ongoing approaches that can contribute to development of a nexus-smart green economy that supports adaptation. For example, REDD+ intervention (reducing emissions from deforestation and forest degradation) is a promising adaptation measure to conserve or enhance biodiversity and forest ecosystem services (Danielsen et al. 2011). REDD+ contributes to mitigation, by increasing carbon sequestration, and can also be used as an entry point to support more efficient fuel use. At the same time, measures to improve water use and energy efficiency can also support the sustainability of REDD+ interventions and ensure the permanence of carbon stocks by preventing activity displacement and induced deforestation and by limiting or avoiding damage to the ecosystem from extreme weather events. Similarly, payment for ecosystem service (PES) approaches have a potential to contribute to adaptation by enhancing the provision of ecosystem services, enhancing adaptive capacity, and providing incentive mechanisms to encourage communities to adopt specific measures for adaptation to climate change (van de Sand 2012). Costa Rica's PES program demonstrates ways to conserve and regenerate ecosystems and thus improve long-term adaptive capacity (Sánchez-Azofeifa et al. 2007).

Toward a Nexus-Based Framework for Sustainable Adaptation

South Asia faces a difficult challenge in meeting the growing demands of the burgeoning population for food, water, and energy, and the problem of ensuring food, water, and energy security is further compounded by climate change. The goal of adaptation to climate change is to reduce vulnerabilities to both climatic and non-climate changes; thus, it is closely linked with the sustainable use and management of water, energy, and food, which are also vital for sustainable development.

Understanding the role of the water, energy, and food nexus in adaptation is key to designing effective adaptation policies and strategies. The nexus approach is a system-wise approach that recognizes the inherent interdependencies of the food, water, and energy sectors for resource use and seeks to optimize the trade-offs and synergies, thus enabling adaptation responses to be made more effective and sustainable. The nexus outlook can also help to stimulate critical thinking on aligning the sustainable development goals (SDGs) with planetary boundaries in the post-2015 development agenda.

The nexus perspective is critical to finding a common solution for all three sectors, by determining and resolving trade-offs and exploiting potentials for synergy to meet the increasing demand without compromising sustainability. Strategies to facilitate adaptation to climate change need to incorporate the dynamics among water, energy, and food and develop mechanisms for progressive and transformational change that moves from sectoral to trans-sectoral adaptation. The complex interplay of food, energy, and water demand and supply requires a holistic approach to address the twin challenges of poverty and vulnerability for sustainable adaptation. A framework is required in order to move from a sectoral to a holistic approach. Development of a detailed framework is beyond the scope of this paper; however, a broad approach is outlined, which can be seen as explorative.

Figure 1 suggests an outline for a broad framework for a nexus-based approach to sustainable adaptation. This outline is intended to stimulate critical thinking rather than provide definitive answers. First and foremost is the need to take a nexus-based adaptation perspective in determining the trade-offs and synergies associated with the complex interplay of food, energy, and water demand and supply. The Area A in the Venn diagram represents the situation of an integrated nexus-based response strategy for sustainable adaptation to ensure the security of all three sectors. The second component represents the core policy action fields and associated outcomes that underpin the three sustainability dimensions: economic (increasing resource efficiency), social (accelerating access for all), and environmental (investing to sustain ecosystem services). Finally the third component stresses the need to target the poverty-vulnerability linkages (overlap between poverty eradication and vulnerability reduction) to reduce poverty and vulnerability concurrently, rather than treating them separately, in order to ensure that adaptation solutions are sustainable.

The framework illustrates the need to understand how the context of vulnerability to both climate and non-climate change influences the development of poverty and how people adjust their adaptation strategies, before devising a

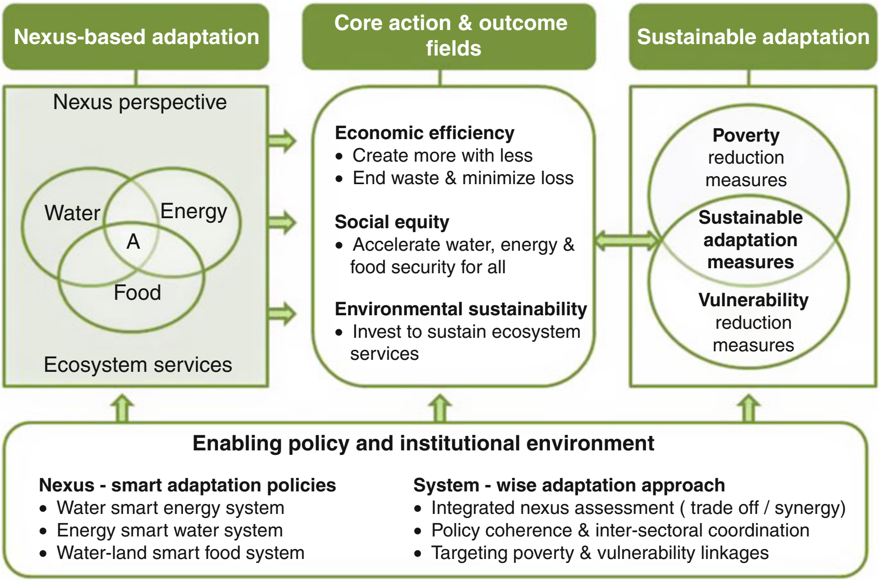

Fig. 1 Outline for a nexus-based adaptation framework to ensure sustainable solutions

nexus-based response strategy. It also shows why adaptation should be an integral part of sustainable development, with climate change implications factored into all development planning, decision-making, and implementation (Leal 2011). In this sense, the framework underscores the importance of identifying the potential synergies and trade-offs between adaptation and mitigation measures and of integrating them in a two-pronged approach to managing the short- and long-term disturbances to the climate in the pursuit of sustainable development. The following are some broad recommendations:

- **Tap new water and energy sources to alleviate competition across sectors:** New sources of water and energy should be exploited through investment in renewable energy, rain and storm water harvesting, widely distributed water storage activities, and reuse of water to alleviate competition across sectors for water and energy.
- **Deepen the nexus knowledge base:** Develop analytical frameworks to better understand challenges and find opportunities for potential synergies in the water, energy, and food nexus and sustainable adaptation. There is a dearth of knowledge about interconnections between water, food, and energy in terms of resource use intensity and the possible areas of trade-offs and synergies, including benefit and cost dynamics and their distributive implications.
- **Promote a system-wise adaptation approach for win-win solutions:** Move from a sectoral to a trans-sectoral approach so that different adaptation responses and measures support each other, synergy is enhanced, and trade-offs are minimized and efficiencies are enhanced.

- **Strengthen policy integration and policy coherence**: Strengthen policy integration and policy coherence, while strengthening institutional capacity for coordinating/managing the water, energy, and food nexus and adaptation together in a holistic way, through stronger integration and governance mechanisms across sectors and among the major actors (public-private-civil society partnerships).
- **Protect essential natural and environmental resources:** Protect essential natural and environmental resources and design mechanisms to include externalities into decision-making by introducing appropriate incentives and regulations.
- **Place nexus-smart policy for adaptation at the center of national development strategies**: Operationalizing the nexus perspective as a tool for adaptation requires appropriate policies and institutional capacities to manage coordination across sectors.

Climate Change Adaptation, Agriculture, and Water Security

Adaptation According to Mode of Climate Variability: A Case Study from Canada's Western Interior

David Sauchyn, Barrie Bonsal, Stefan W. Kienzle, Jeannine-Marie St. Jacques, Jessica Vanstone, and Elaine Wheaton

Contents

Abstract

Successful economies, and sustainable communities, are adapted to the historical mean state of the climate of the region and, to a large extent, to the historical interannual and seasonal variability, with which there is much experience. This adaptation involves familiar strategies, for example, irrigation, and the

corresponding policies, programs, and best practices. There is less experience, however, and therefore fewer adaptation options, in dealing with decadal to multi-decadal modes of climate variability and with unprecedented climate extremes. This scale of variability and extreme events requires a different suite of adaptations that generally are not supported by existing policy and programming. This asymmetry in historical and planned adaptation is illustrated with a case study from Canada's western interior, which has a climate characterized by differences in temperature and precipitation between seasons and years that are among the largest on earth. This chapter examines the interannual to multi-decadal variability of the past millennium, extremes of the past 100 years, and projections of climate change. Municipalities and industry must recognize these multiple modes of variability as they pursue adaptation planning to minimize the impacts of climate change, including unprecedented drought and excess moisture.

Introduction

Communities and economies are vulnerable to the adverse effects of climate change. This vulnerability is a function of (1) exposure to climate hazards and their impacts and (2) social conditions that determine (a) sensitivity, the degree to which a system is affected by climate-related stimuli, and (b) adaptive capacity, the ability of a system to adjust to climate risks and opportunities by increasing its resilience or coping range (Smit and Johanna 2006). Adaptive capacity depends on access to financial, social, and natural resources and institutions, the management of current and past stresses, and the ability of institutions and individuals to learn from experience and to anticipate and plan for future change (Armitage 2005). When exposed to the impacts of climate change, the adaptive response will depend largely on the capacity of a community to deal with the impacts and risks. Thus, vulnerability is determined mostly by social factors, and exposure to climate change is often treated as given in the assessment of social vulnerability. These determinants of vulnerability to climate change are illustrated in Fig. 1. According to this common conceptual framework, the assessment of vulnerability to future climate conditions begins with an understanding of sensitivity and adaptation to past and current climate events and variability.

The box labeled "Future Climate Conditions" in Fig. 1 is a climate change scenario, "a plausible future climate that has been constructed for explicit use in investigating the potential consequences of anthropogenic climate change" (IPCC-TGCIA 2007). Climate change scenarios can be simple arbitrary adjustments to climate variables, or they can consist of climate data derived from other locations or times in the past (analogues), where/when the climate is/was similar to the future conditions anticipated at the current location. However, the most robust and precise

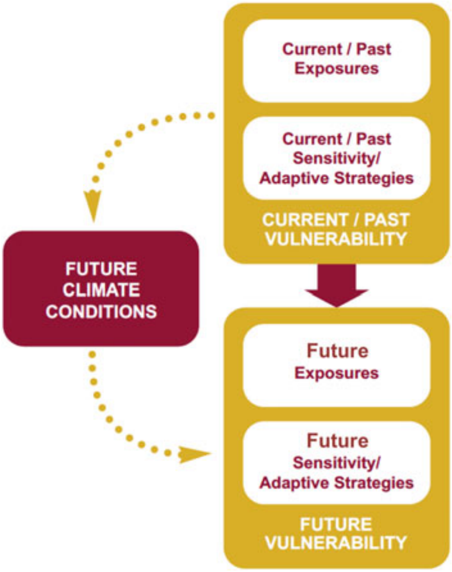

Fig. 1 The standard conceptual framework or vulnerability assessment model (After: Smit and Johanna, 2006)

climate scenarios are derived from global climate models (GCM), "the only credible tools currently available for simulating the response of the global climate system to increasing greenhouse gas concentrations" (IPCC 2007). The conventional approach to deriving climate change scenarios from GCMs, recommended by the IPCC Task Group on Scenarios for Climate Impact Assessment (IPCC-TGCIA 1999, 2007), is illustrated in Fig. 2 using a time series of modeled mean annual temperatures from the Canadian Prairies. According to this standard method, a climate change scenario is the difference in average climate between past and future 30-year periods. This approach reflects a historical lack of confidence in the reliability of short-term (annual to decadal) climate projections. A 30-year mean is the equivalent of a climate normal; it masks the short-term variability and represents the most reliable output from climate models.

GCM projections are less reliable over shorter time frames and smaller spatial domains and for precipitation and other variables related to atmospheric circulation and dynamics. Regional aspects of climate change are controlled by atmospheric circulation patterns, such as the location of the jet stream, but unfortunately the model simulation of the dynamical response of the climate system to anthropogenic forcing is highly uncertain. Climate models simulate the thermodynamics of the climate system and thus temperature, snowmelt, sea ice extent, sea level rise, etc., with greater confidence and consistency. In many regions, however, the most challenging impacts of climate change are not trends in temperature-related variables but rather shifts in the distribution of water supplies and changes in the frequency and severity of extreme weather events (e.g., flooding and drought).

Researchers and practitioners have long recognized the more immediate and challenging impacts are climate extremes and variability, departures from mean

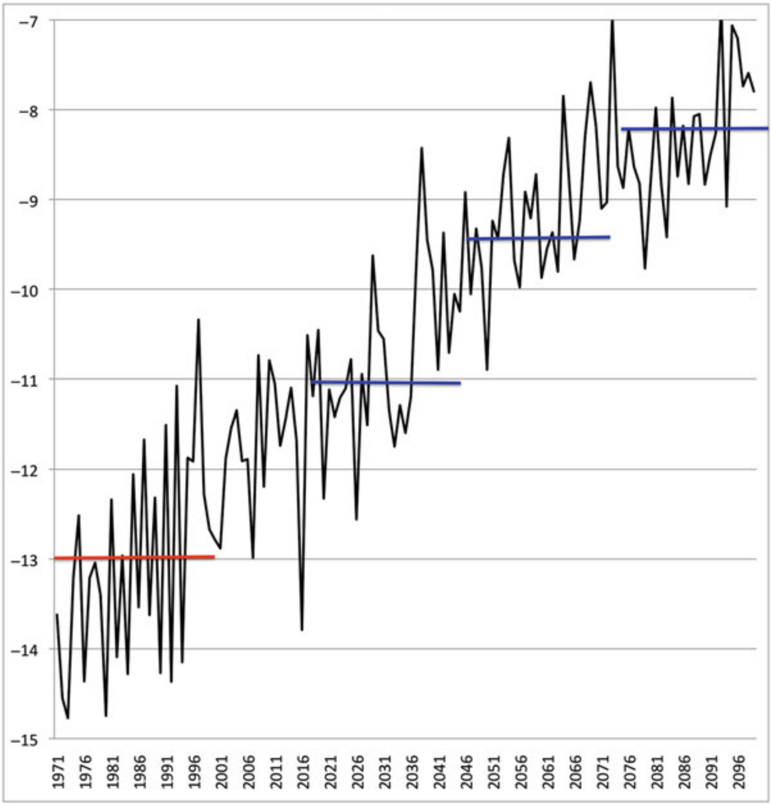

Fig. 2 Mean winter surface air temperature (° C) for the Canadian Prairies from the model CGCM3 (T47) using the SRES A1B greenhouse gas emission scenario. A climate change scenario is the difference (or ratio in the case of precipitation) between the mean value for the baseline period 1971–2000 (*red line*) and the 30-year mean values (*blue lines*) for 2010–2039 (the 2020s), 2040–2069 (the 2050s), and 2070–2099 (the 2080s)

conditions, whether natural (internal) variability or the consequences of global warming. This was clearly pointed out in the 1990s in papers such as "Extreme events in a changing climate: Variability is more important than averages" by Katz and Brown (1992) and "Relative impacts of human-induced climate change and natural climate variability" by Hulme et al. (1999). Much more recently, Deser et al. (2012) pointed out that future climate will be dominated by natural variability for the foreseeable future, and this limits the capacity of climate models to provide predictions of the response of climate regimes to anthropogenic forcing. They demonstrated for North America that natural climate variability "poses inherent limits to climate predictability and the related goal of adaptation guidance" although "other locations with low natural variability show a more predictable future in which anthropogenic forcing can be more readily identified."

Figure 3 is another, more detailed, illustration of the use of climate and social scenarios for impact and adaption assessment and specifically for informing the formulation of policy. The distinction between "top-down" and "bottom-up" approaches has implications for relative roles of researchers from different disciplines and the stage at which local information is introduced. The top-down approach begins with scenarios of global climate and environmental response to anthropogenic forcing and global trends in socioeconomic variables that dictate emissions of greenhouse gases. These global scenarios are then downscaled and applied to the assessment of regional impacts and adaptation options. This approach is typical of multinational climate change assessment that informs international policy, notably the Intergovernmental Panel on Climate Change (IPCC) and the Kyoto Protocol, respectively. Typically, as shown in Fig. 3, stakeholders are engaged to frame regional or national socioeconomic scenarios and adaptation strategies. The strength, and weakness, of the top-down approach is that it relies on the expertise of natural and social scientists to frame the problems and thus chose the appropriate variables and sources of data.

As climate change scientists, the authors of this chapter are familiar and comfortable with a top-down approach, where information about past and future climate variations is generated and delivered largely outside the context of specific vulnerabilities of local communities. The climate change scenarios are projections of trends in those climate variables that are most readily analyzed with the most confidence and precision and that the scientists consider most relevant in terms of the regional climate regime. We have also been engaged, however, in multidisciplinary impacts and adaptation research projects that have taken a "bottom-up" approach to integrating climate science, structural institutional conditions and agency, and the perspectives of stakeholders and decision makers. For example, Diaz et al. (2009) applied the vulnerability framework in Fig. 1 to a multicollaborative study of institutional adaptation to climate change in northern Chile and western Canada. This work highlighted the central role of public institutions in developing adaptive capacity to climate change, but it also demonstrated significant gaps in knowledge and governance practices that lead to a deficit in adaptive capacity.

The bottom-up approach is well suited to the local and regional scales at which the impacts occur and adaptations are identified and implemented. The initial step in Fig. 3 of collecting baseline climate and environmental and socioeconomic data produces a profile of communities that include problems (vulnerabilities) and variables informed by knowledge of local conditions. The bottom-up approach thus combines the observation of local climate change and impacts, and adaptive capacity, with data on projected impacts derived from downscaled outputs from climate and environmental models and adaptation/socioeconomic scenarios. From the perspective of climate science, there is one major implication of the bottom-up approach. Because the relevance of climate variables depends on local conditions, including the perspectives and observations of local people, the most relevant climate risks and variables often are not those that can be analyzed and modeled with confidence and precision. The most serious and relevant climate risks often are understood with the least certainty.

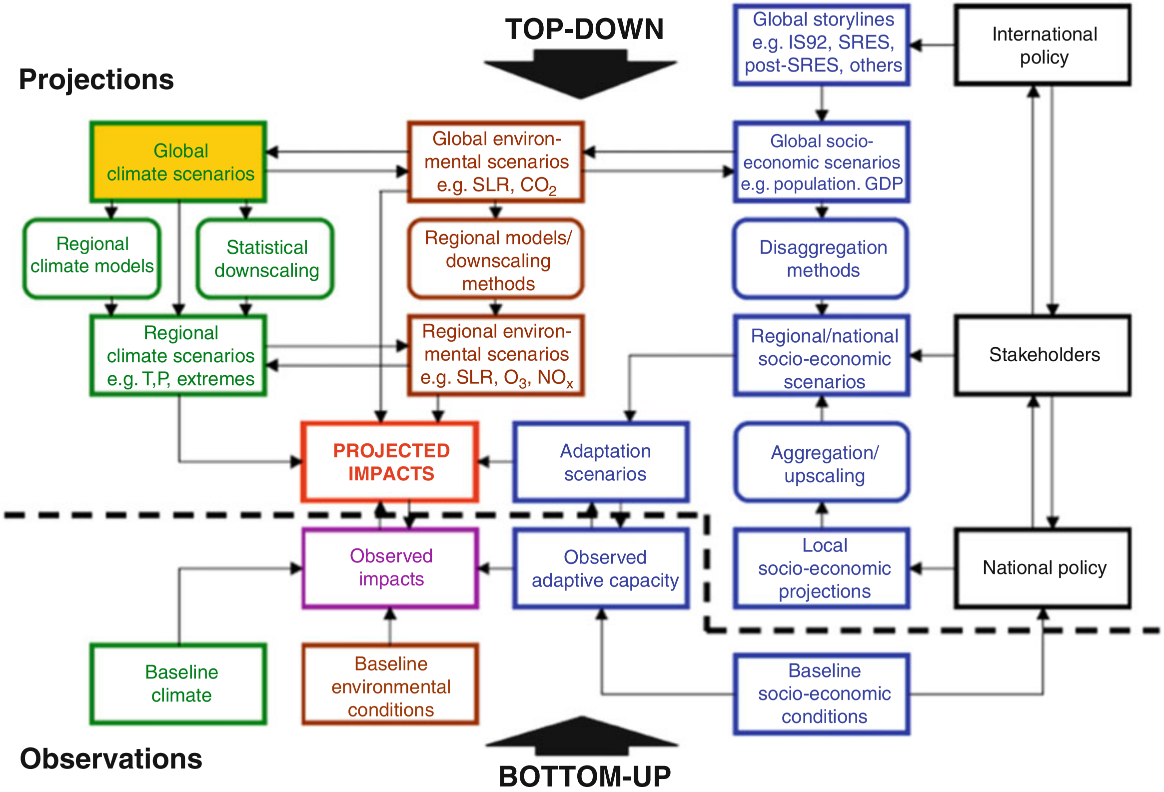

Fig. 3 The *top-down* and *bottom-up* approaches to informing climate change policy with climate and socioeconomic scenarios and related source of data. Information above the dashed is projections and output from models; below the line are observations and the results of data collection in the field (Source: IPCC-TGCIA (2007))

This brief overview of the use of climate change scenarios for the assessment of climate change vulnerability, impacts, and adaptation is an important context for this chapter that explores the disparity between these standard practices in research and application and our experience with the study and scientific support of planned adaptation to climate fluctuations over a range of frequencies or modes of variability. This chapter examines the adaptation strategies adopted by rural agricultural communities in the context of the climate variability of the past millennium, climate extremes of the past 100 years, and anticipated shifts in variability and extremes in a warming climate. We discuss the extent to which rural agricultural communities recognize multiple modes of climate variability and are engaged in adaptation planning to minimize the impacts of drought and excess moisture.

The Case Study: The Canadian Prairies

This chapter argues that the best adaptive adjustments to practices and policies are conditional on the mode of variability to which a community is exposed. Canada's western interior makes an ideal case study to present and demonstrate this argument. It is exposed to an extremely variable climate and some significant projected climate change impacts. Furthermore, the resource-based economy is sensitive to the impacts of climate change on ecological goods and services and particularly water. Among the regional resource industries, this chapter is focused on agriculture. More than 80 % of Canada's agricultural land is in the Prairie Provinces of Alberta, Saskatchewan, and Manitoba. The agriculture sector has an adaptive capacity that has been described as high, which is attributable in large part to a history of adaptation to climate risks.

While the frost-free growing season is relatively short and precipitation is low, ranging on average from 300 to 500 mm per year, the greater challenge for commercial agriculture is the climate variability from year to year. A good indication of the degree of this climate variability is the interannual variation (coefficient of variation) in the climate moisture index (CMI), a measure of the ratio of precipitation to atmospheric water demand (evapotranspiration). An analysis of a global dataset by the Water Systems Analysis Group at University of New Hampshire (wwdrii.sr.unh.edu) showed that the highest year-to-year fluctuations in CMI occur along the humid and dry transition between forest and grassland ecosystems. These areas are characterized by periodic, severe droughts and thus are vulnerable to water stress and/or scarcity. The most extensive regions of extremely variable hydroclimate are in north-central Asia and the northern Great Plains of North American and specifically the Canadian Prairies.

Despite these almost marginal climate conditions for commercial agriculture, a viable export industry has developed over the past 100 years. Annual crop yields in the Canadian Prairies are medium to high, relative to the global range (Foley et al. 2011), despite the northerly latitudes and dry and variable climate. This level of crop productivity extends to a latitude of almost 60°N in northern Alberta. The Canadian Prairies are anomalous; in no place else does commercial agriculture

Fig. 4 The landscape of southwestern Alberta in the vicinity of the village of Enchant. This entire landscape is an expression of adaptation to a dry climate. Center pivot irrigation is the dominant feature. An irrigation canal transects the image from the *upper left corner* to the *middle* of the *right edge*. Rain-fed "dryland" crop production is practiced in strips mostly perpendicular to the prevailing winds to prevent wind erosion and preserve moisture (melting snow) (Source: Google Earth)

succeed at a large scale in a continental climate at high latitudes. This agricultural productivity reflects adaptation to make most efficient use of these marginal climate resources. Adaptation of agricultural practices, policies, and structures to a dry cold continental climate is embedded in the history and landscape of the Canadian Prairies. A complete transformation of the native prairie ecosystems was achieved with the adaptation of farming practices imported originally from the more humid climates of Europe and eastern Canada. Figure 4 is satellite image of southwestern Alberta in the vicinity of the village of Enchant. The structures and land use patterns, mostly related to irrigation, reflect the use and management of water. Beyond the area in this image and throughout the Prairie Ecozone, thousands of reservoirs and "dugouts" and thousands of kilometers of shelterbelts (rows of trees and shrubs) are other adaptations to conserve water and soil.

The Euro-Canadian history of the Canadian Prairies is punctuated by the impacts of drought and the adaptations in response. Sensitivity to drought varies according to type, reliability, and accessibility to water supplies and their management. Snow and glacier melt in the Rocky Mountains is the source of water for irrigation in southern Alberta and parts of Saskatchewan and the water supply for most of the population in these two provinces. In terms of land area, however, most prairie agriculture is dryland farming dependent on precipitation and local runoff. These climatic and hydrographic circumstances dictate the exposure of rural communities and economies to climate risk and the relevance of hydroclimatic factors and variables for an assessment of impacts and adaptation. Because climate fluctuates at various scales from seasonal to decadal to longer-term trends, adaptation to mitigate the impacts of climate variability and change requires an understanding of the risks posed by different modes of climate variability in terms of their likelihood and consequences. These scales or modes of variability are not arbitrary or statistically convenient intervals; there are distinct periodicities corresponding to certain external and internal causes of climate variability. At high frequencies, climate varies between seasons and years. Lower-frequency variability is not as well defined, or understood, but there are dominant modes at decadal and multi-decadal scales. Interannual to multi-decadal cycles have been linked to internal behavior of the climate system and specifically to organized interaction between the oceans and atmosphere (e.g., El Niño Southern Oscillation, ENSO, and the Pacific Decadal Oscillation, PDO) and associated teleconnections to regional climate regimes (Bonsal et al. 2001; Lapp et al. 2013). Longer-term climate trends are related to slow changes in the external controls on climate (i.e., radiative forcing) and centennial-scale shifts in climate that are detectable only in paleoclimate records. This entire range of climate variability has been observed in our study area, Canada’s western interior.

The Historical Record of Seasonal to Interannual Variability and Trends

Climate Variables

Annual and seasonal means of temperature and precipitation, derived from instrumental weather data, define the “normals” for a regional climate regime. In terms of climate risks, however, the most relevant variables are those that impose constraints and threaten productivity and livelihoods. Table 1 is a list of these most relevant agroclimatic variables and indices of climate extremes for the rural communities and agricultural economy of the Canadian Prairies. In a recent analysis of trends in some of these variables, Qian et al. (2012) found that the growing season has lengthened, frost-free days have increased, cold stress has decreased, and heat units are greater than in earlier decades. For example, growing season length has increased about 16–20 days across the southern prairies from 1911–1940 to 1971–2000. Changes in water deficit in the growing season were not statistically significant, and only a few stations had a significant difference in the variances of agroclimatic variables. They concluded that adaptation should include the use of new crop varieties that can benefit from longer and warmer growing season, while withstanding increased risks of heat damage.

Data for the analysis of the climate indices in Table 1 are available from the National Land and Water Information Services (NLWIS) in the form of a daily 10 km gridded climate dataset (1950–2010) for the Canadian landmass south of 60°N. These data were interpolated from the 7,514 climate stations in the Canadian Climate Data Archives (Hutchinson et al. 2009). We used the rank-based

Table 1 The most relevant climate indices for rural communities and the agricultural economy of the Canadian Prairies

Variable	Description	Units
Tmax >= threshold temperature	Annual count when the daily maximum temperature >= chosen threshold temperature, e.g., 25 °C	Days
Tmax <= threshold temperature	Annual count when the daily maximum temperature <= chosen threshold temperature, e.g., 2 °C	Days
Tmin >= threshold temperature	Annual count when the daily minimum temperature >= chosen threshold temperature, e.g., 5 °C	Days
Tmin <= threshold temperature	Annual count when the daily minimum temperature <= chosen threshold temperature, e.g., 0 °C	Days
Frost days	Annual count when daily minimum temperature < 0 °C	Days
Growing season length	Annual count between first span of at least 6 days with Tmean >5 °C and first span after July of 6 days with Tmean < 5 °C	Days
Heat wave days	Count of days in a year that are 5 °C higher than during the 1961–1990 period	Days
Ice days	Annual count when daily maximum temperature <0 °C	Days
Max Tmax	Monthly maximum value of daily maximum temp	°C
Max Tmin	Monthly maximum value of daily minimum temp	°C
Min Tmax	Monthly minimum value of daily maximum temp	°C
Min Tmin	Monthly minimum value of daily minimum temp	°C
Cool nights	Percentage of days when TN < 10th percentile	%
Cool days	Percentage of days when TX < 10th percentile	%
Warm nights	Percentage of days when TN > 90th percentile	%
Warm days	Percentage of days when TX > 90th percentile	%
Consecutive dry days	Maximum number of consecutive days with RR < 1 mm	Days
Accumulated precipitation over 5 days	Annual maximum sum of 5-day precipitation	Mm
Simple precipitation intensity index	Annual fraction of annual precipitation sum divided by the number of precipitation days > 1 mm	Mm
Very wet years	Annual total precipitation when above the 1961–1990 period 95th percentile	Years
Annual precipitation	Annual sums of daily precipitation	mm
Warm spell duration indicator	Annual count of days with at least six consecutive days when TX > 90th percentile	Days
Cold spell duration indicator	Annual count of days with at least six consecutive days when TN < 10th percentile	Days
Diurnal temperature range	Monthly mean difference between TX and TN	°C
Max 1-day precipitation amount	Monthly maximum 1-day precipitation	mm
Max 5-day precipitation amount	Monthly maximum consecutive 5-day precipitation	mm
Simple daily intensity index	Annual total precipitation divided by the number of wet days (defined as precipitation >= 1.0 mm) in the year	mm/day

(*continued*)

Table 1 (continued)

Variable	Description	Units
Number of heavy precipitation days	Annual count of days when daily precipitation >= 10 mm	Days
Number of very heavy precipitation days	Annual count of days when daily precipitation >= 20 mm	Days
Number of days above nn mm	Annual count of days when daily precipitation >= nn mm, nn is user defined threshold	Days
Consecutive wet days	Maximum number of consecutive days with precipitation >= 1 mm	mm
Very wet days	Annual total PRCP when RR > 95th percentile	mm
Extremely wet days	Annual total PRCP when RR > 99th percentile	mm
Annual total wet-day precipitation	Annual total PRCP in wet days (RR >= 1 mm)	mm
Growing degree days >= 0 °C	Annual sum of daily temperatures >= 0 °C	°C
Growing degree days >= 5 °C	Annual sum of daily temperatures >= 5 °C	°C
Growing degree days >=10 °C	Annual sum of daily temperatures >=10 °C	°C
Beginning day of growing season	First day of span of at least 6 days with Tmean >5 °C	°C
End day of growing season	Last day of span of at least 6 days with Tmean <5 °C	°C

Table 2 Trends of selected climate indices for some selected locations in the Canadian prairies (confidence level in brackets)

Location	Annual frost days (days)	Growing season (days)	Heat wave duration index (days)	Annual precipitation (mm)	Growing degree days over 5 °C (°C)
Pincher Creek	−24 (99 %)	+17 (80 %)	+13 (90 %)	−58 (<80 %)	+126 (90 %)
Lethbridge	−9 (90 %)	+21 (95 %)	+19 (99 %)	−76 (90 %)	+132 (95 %)
Taber	−12 (95 %)	+33 (99 %)	+19 (95 %)	−10 (<80 %)	+183 (99 %)
Swift Current Creek	−17 (99 %)	+9 (<80 %)	+12 (90 %)	+2 (<80 %)	+136 (90 %)

nonparametric Mann–Kendall statistical test to analyze the significance of trends in these hydrometeorological time series. Table 2 lists trends in selected climate indices for some selected locations in the Canadian Prairies.

It is evident from this trend analysis that climate change has already impacted prairie agro-hydrological conditions in terms of fewer frost days, a longer growing season, more heat waves, a decline in precipitation in Alberta, and an increase in growing degree days over 5 °C. Figure 5 shows the interannual variation around a

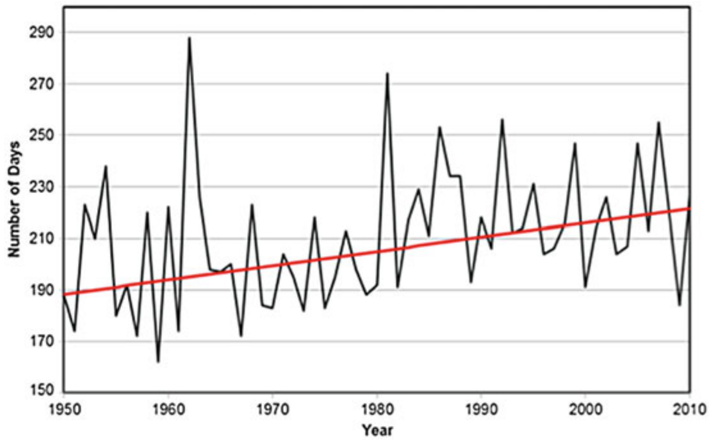

Fig. 5 Time series of the length of the annual growing season and nonparametric trend line for Taber, Alberta. There is considerable interannual variation

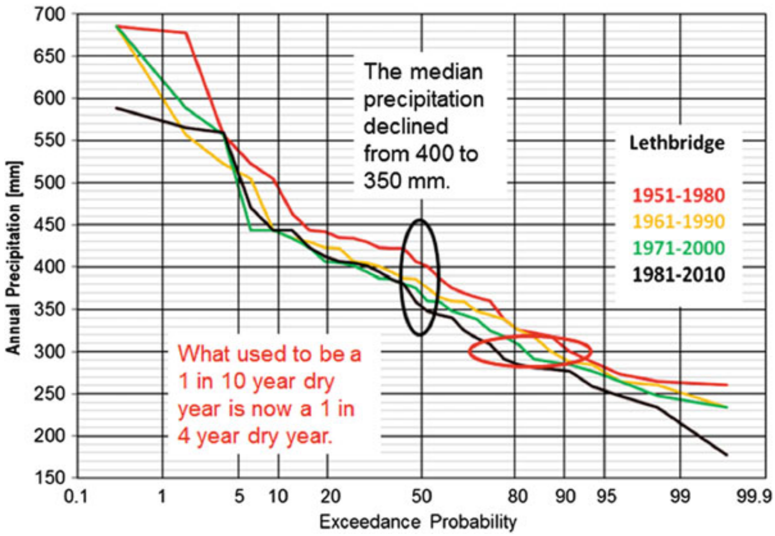

Fig. 6 The exceedence probabilities of four climate normal periods reveal a trend in median annual precipitation at Lethbridge, Alberta. It has declined from 400 mm per year in the period 1951–1980 to a median of 350 mm per year in the period 1981–2010. There is also an increased risk of having a low precipitation year. The probability of 300 mm or less of annual precipitation has increased from once every 10 years in the period 1951–1980 to more than once in 4 years in the 1981–2010 period. This has effects on the sustainability of rain-fed agriculture

trend of increasing growing season length for the town of Taber, Alberta. Figure 6 shows how precipitation normals have changed at Lethbridge, Alberta.

Several indices (usually specific to certain types of drought) have been devised to quantify moisture variability and, subsequently, assess the occurrence of drought

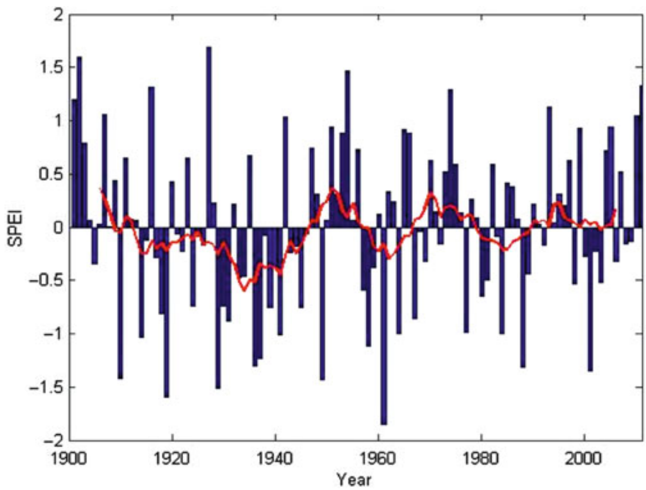

Fig. 7 Areally averaged, agricultural year (September to August) SPEI values over the southern Canadian Prairies (49°N–54°N, 115°W–100°W) for the period 1900–2011. The *red line* denotes the 11-year running mean

and excessive moisture patterns over various regions of the globe including the Canadian Prairies (see Bonsal et al. (2011) for a comprehensive review). A recently developed index, namely, the Standardized Precipitation Evapotranspiration Index (SPEI) (Vicente-Serrano et al. 2010), has been gaining popularity in the literature since it incorporates both precipitation and temperature in its calculation and can be computed for any region of the world at multiple time scales. Figure 7 shows areally averaged, agricultural year (September to August) SPEI values over the southern Canadian Prairie Provinces for the period 1900–2011. Note that negative values represent drier conditions, while positive SPEI correspond to wetter than normal periods. The time series reveals considerable interannual and inter-decadal fluctuations with no discernible long-term trend. Major large-scale droughts occurred during the late 1910s, most of the 1930s and early 1940s, 1958–1961 (with 1961 being the driest year on record), most of the 1980s, and the early 2000s. Conversely, excessive moisture conditions were observed during the early 1900s, much of the 1950s, the 1970s, the late 1990s, and most recently in 2010–2011. Figure 7 reemphasizes the high degree of natural variability in prairie moisture conditions during the instrumental period of record.

Hydrologic Variables

For a region of high natural hydroclimatic variability, such as the Canadian Prairies, it is reasonable to ask if global warming trends can be detected in relatively short instrumental records. Given the economic, environmental, and historical significance of water and the impacts of periodic drought, water levels gauges were

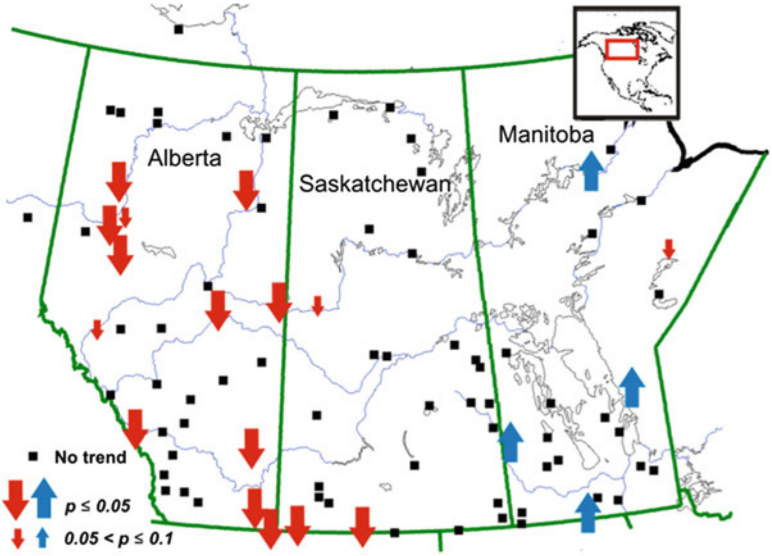

Fig. 8 Geographic pattern of trends in 86 naturally flowing mean-daily streamflow records from the Canadian Prairie Provinces as assessed by a modified Mann–Kendall test. A *red down* (*blue up*) *arrow* denotes a decreasing (increasing) trend; a *black square* denotes no trend

installed at many locations beginning in the early twentieth century. St. Jacques et al. (in press) performed a modified Mann–Kendal trend analysis on 86 naturally flowing streams with active gauges drawn from across the three Prairie Provinces (Fig. 8). The results show a distinct geographic pattern with streamflow generally decreasing in Alberta, some gauges recording increasing flow in Manitoba and few trends in Saskatchewan. The eastern Prairies are responding differently to climate change than the west, with increasing streamflows in Manitoba. These increasing flows have also been detected in neighboring North Dakota.

Further analysis of mean annual streamflow in Alberta for 102 watersheds reveals that 60 time series have negative trends; 14 watersheds had a negative streamflow of over 1 % per year, which means that after 10 years, over 10 % less streamflow would be available if these trends were to continue. The detection of a statistically significant trend does not necessarily imply a trend of practical significance and vice versa. For example, a statistically significant negative trend of 0.1 % per year may be negligible for the water users, while a negative trend of 2 % per year may be of low statistical significance (e.g., 80 % confidence level), given the length of the record and variability around the trend, but have large practical implications within 10 or 20 years. Therefore, the magnitudes of possible streamflow trends need to be reported.

Figure 9 is an example of declining mountain streamflow. The annual hydrograph of the Bow River at Banff, Alberta, has a declining trend (red line). It also exhibits high interannual variability, related to ENSO, and decadal shifts between periods of higher and lower flow, related to the PDO. Runoff from the

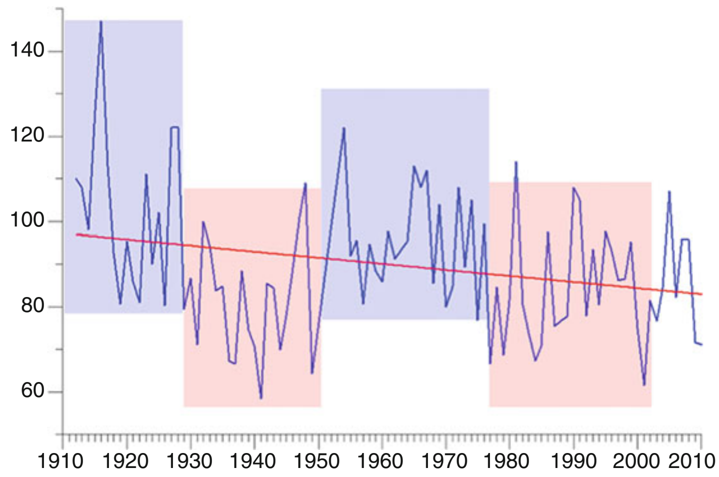

Fig. 9 Mean annual flow (m^3/s) of the Bow River at Banff, Alberta, 1911–2010. The *red line* represents a trend of decreasing annual flow. The *shaded rectangles* represent periods of higher (*blue*) and lower (*red*) flow related to the phase of the PDO

Rocky Mountains is mostly from melting snow. Winter precipitation in western Canada is higher when the PDO is in a negative phase (1890–1924, 1947–1976) and lower when the PDO is in a positive phase (1925–1946, 1977–2008) (Mantua et al. 1997). Streamflow records that span 1½–2 cycles of the PDO, such as the annual time series for the Bow River in Fig. 9, are likely to have declining trends that are the effect of climate change rather than an artifact of multi-decadal periodicity in flow (St. Jacques et al. 2010).

Paleo-Record of Interannual to Multi-decadal Variability

The trends and variability in recorded climate and hydrology documented above (Table 2, Figs. 5, 6, 7, 8, and 9) have important implications for agricultural production and the supply and management of water. This analysis revealed, however, that the detection and interpretation of trends are complicated by the large degree of interannual and decadal variability, including the ~60 year PDO cycle. Paleoclimatic time series provide a longer-term historical context for the interpretation of instrumental data and climate model projections. Tree rings from the subhumid margins of semiarid environments, such as the Canadian Prairies, are especially good proxies of the water budget and measured variables such as precipitation and streamflow (Sauchyn et al., 2011). Using standardized tree-ring width data, the water year (Oct–Sep) flow of the Bow River at Banff was reconstructed from 1107 to 2007 (Fig. 10). The tree-ring data explain about 40–50 % of the variance in the gauge record back to about1650, and then the R^2 declines to about 30 %. Most of the unexplained variance is the underestimation of

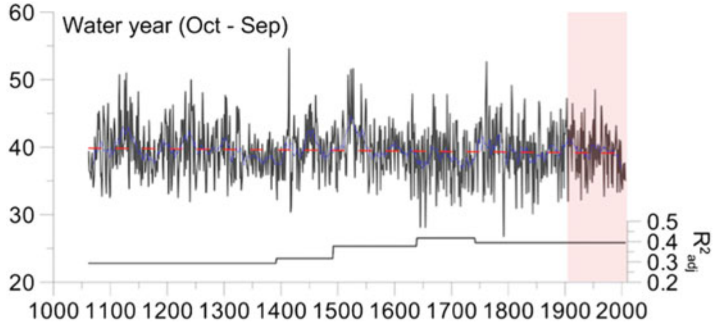

Fig. 10 Water year (Oct–Sep) flow of the Bow River at Banff from 1107–2007 as reconstructed from tree rings. The *pink* portion is the period of instrumental observation used for the calibration of the tree-ring width data. The *dashed red line* is at the level of the mean flow (m^3/sec) for the full reconstruction

high flows, while, on the other hand, tree rings are a good proxy of low flow and drought. The proxy streamflow time series in Fig. 10 indicates that the period of instrumental observation (1911–2007, highlighted with pink shading) is not fully representative of the long-term hydrologic regime. Although 1929–1941, the 1980s and early 2000s stand out as periods of frequent low annual flows, there is a larger range of annual flow prior to the onset of Euro-Canadian settlement and the direct observation of weather and climate. These pre-instrumental low flow periods include the prolonged drought of the mid-nineteenth century when John Palliser declared a large part of the Canadian Prairies "forever comparatively useless" and the extreme low flow of 1796 when to the north at Fort Edmonton furs could not be moved by canoe, "there being no water in the [North Saskatchewan] river" (2003).

The Bow River streamflow reconstruction displays considerable variability around the mean flow depicted with the red dashed line. A spectral (wavelet) analysis reveals that there are two dominant scales of variability in the long-term proxy records of calendar year (Fig. 11a) and water year (Fig. 11b) flow. There is intermittent strong spectral power in the range of 4–12 years, very likely in response to the El Niño Southern Oscillation (ENSO) and also possibly the influence of the 11-year solar cycles of the regional hydroclimate. There also is strong intermittent variability around 60 years, that is, the low frequency of the PDO.

Future Exposure

Ensemble Streamflow Projections

With concern about future flows of the large rivers arising from the Rocky Mountains, there have been various attempts to apply climate model output to projecting future flows. One approach is statistical downscaling: for example,

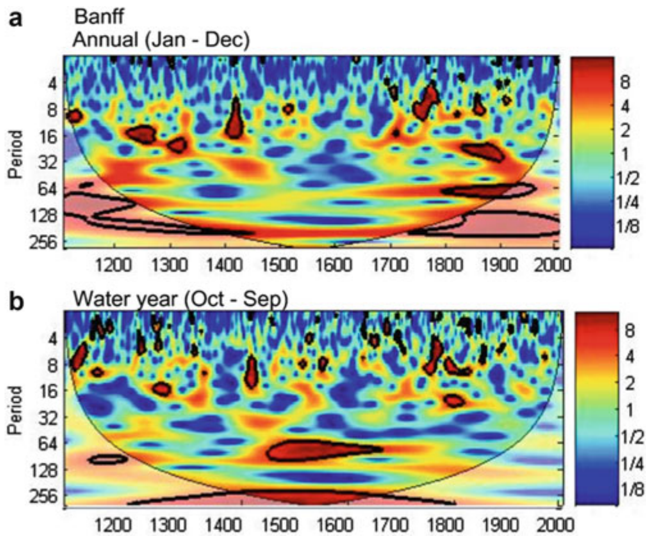

Fig. 11 Wavelet plots derived from the spectral analysis of the Bow River reconstruction: (a) calendar year (Jan–Dec); (b) water year (Oct–Sep). Strong modes of variability are depicted in *red*

streamflow in the South Saskatchewan River Basin can be modeled as a function of the ocean–atmosphere oscillations (St. Jacques et al. 2010) that drive the natural variability of the regional hydroclimatic regime. St. Jacques et al. (2013) drove generalized least squares (GLS) regression models of annual streamflow, using output from an ensemble of 50 runs of ten GCMs from the Phase 3 of the Coupled Model Intercomparison Project (CMIP3) to produce projected streamflows for the twenty-first century. They chose these ten GCMs because they adequately modeled the atmosphere–ocean climate oscillations that affect southern Alberta, i.e., the PDO, ENSO, and Arctic Oscillation. Shown in Fig. 12 are (a) projected flows for the South Saskatchewan River at Medicine Hat and (b) empirical cumulative frequency distributions for three selected years. If business as usual water usage and anthropogenic climate change continue, flows will continue to decline. The curves in Fig. 12b also suggest an increasing probability of extreme low flows.

An alternative approach to projecting future streamflows is the use of physically based hydrologic models with GCM-derived temperature and precipitation as predictors. This method has been applied to the South Saskatchewan River Basin (e.g., Lapp et al. 2009; Shepherd et al. 2010; Larson et al. 2011; MacDonald et al. 2011; Tanzeeba and Gan 2012), and all models projected declining surface water availability for the region. Given that two different methods (statistical versus dynamical) are projecting lower flows in the South Saskatchewan River Basin, there is reason for concern about future surface water supplies in this region where surface water is already over-allocated in some tributaries.

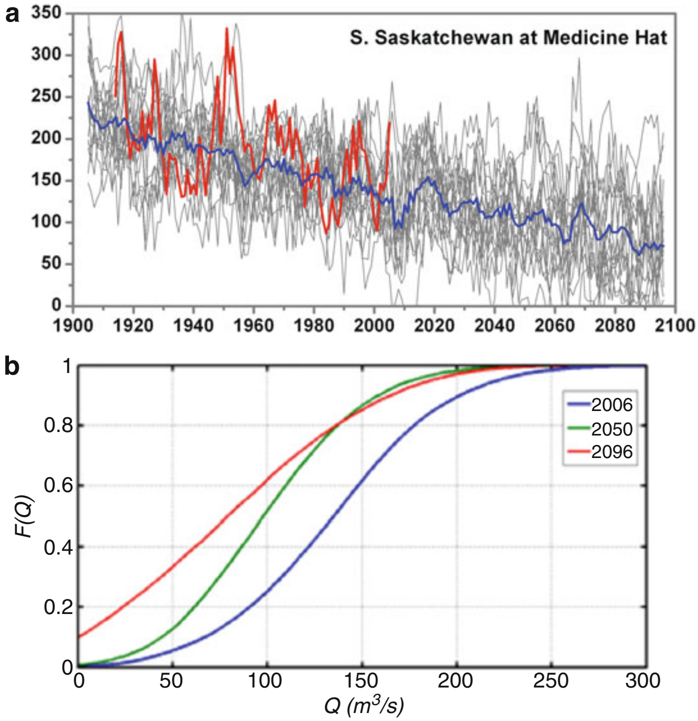

Fig. 12 (**a**) South Saskatchewan River twentieth-century simulations (1900–2005) and twenty-first-century projections (2006–2096 daily mean flows (m^3/s), averaged over the year, smoothed by five-point binomial filters) under the SRES B1, A1B, and A2 emission scenarios. The *red line* is the observed record, the *grey lines* are the individual model runs, and the *blue line* is the all-model mean of the GCM runs. (**b**) Empirical cumulative frequency distributions of projected lightly smoothed (5-year binomial smoother) annual discharges for the South Saskatchewan River

Climate Projections

An assessment of the vulnerability of the Canadian Prairies to climate change is not complete without scenarios of the projected changes in the regional climate as a consequence of anthropogenic global warming. For the purpose of this chapter, climate change scenarios were derived from four global climate models (GCMs) and two higher-resolution regional climate models (RCMs). These models are identified in Table 3. Output from these model runs was obtained from Canadian Climate Change Scenario Network (CCCSN), which is the Canadian repository for climate model output.

The modeling of twenty-first-century climate is based on scenarios of future greenhouse gas (GHG) emissions. For the Fourth IPCC Assessment Report (AR4), the climate model projections were based on the SRES (Special Report on Emission Scenarios) GHG scenarios, labeled B2, A1B, and A2 (Table 3). The “best case” B1 scenario is optimistic and highly unlikely to transpire given recent and historic

Table 3 List of chosen climate models

Model	Country	Resolution	# Twenty-first-century runs			PDO correlation
			B1	**A1B**	**A2**	
CGCM3.1(T63)	Canada	2.8° × 2.8°	1	1	0	0.82
ECHAM5/MPI-OM	Germany	1.875° × 1.865°	2	2	1	0.82
MRI-CGCM2.3.3	Japan	2.8° × 2.8°	5	5	5	0.83
NCAR-PCM	USA	2.8° × 2.8°	2	2	2	0.84
CRCM4.2.3	Canada	0.44° × 0.44°	0	0	1	NA
PRECIS1.8.2	UK	0.44° × 0.44°	0	1	0	NA

GHG emissions and the failure of national governments to achieve a global agreement for the mitigation of climate change. Emission scenario A1B represents the "most likely" future anthropogenic climate forcing; it assumes a mix of technological developments with some use of fossil fuels. SRES A2, the "worst case" or "business as usual" scenario, characterizes a future where socioeconomic trends carry on as at present.

The CCCSN provides output for 65 IPCC-AR4 GCM experiments and for seven runs of RCMs. Reducing this large array of model output to a manageable subset of plausible climate change scenarios, was based on two criteria: (1) projections that span the full range of simulated climate and (2) models that are able to reasonably simulate the ENSO and PDO, since these sea surface temperature oscillations account for much of the interannual to decadal variability in the climate of western Canada. The three scatter plots in Fig. 13 provide a summary of projected changes in mean annual temperature and total annual precipitation, relative to the climate of the baseline period 1971–2000, for the three future time periods 2020s (2011–2040), 2050s (2041–2070), and 2080s (2071–2100). Data from the 65 GCM and seven RCM experiments are plotted. The solid blue lines show the median projected increases in temperature and precipitation. As the twenty-first-century advances, the projected changes increase in magnitude, precipitation by 15–20 % and temperature by 5 °C. The range of values, the departures from the median, also increase reflecting increasing uncertainty in future concentrations of atmospheric greenhouse gases and in the response of the climate system to these higher levels of GHGs.

Figure 13 highlights the 14 chosen experiments: four GCMs by three emission scenarios, plus two RCM runs using single emission scenarios. The output from the selected experiments spans the range of future climates projected by the full set of IPCC-AR4 and RCM model runs.

Whereas this use of scatterplots to display and select output from climate models is common, the second method and criterion applied here is not common but considered necessary given the large degree and impact of internal climate variability in western Canada. Table 3 indicates that for the chosen GCMs, there is a high correlation between modeled and observed characteristics of the ENSO and PDO. These correlations are from Lapp et al. 2011, who evaluated the full set of

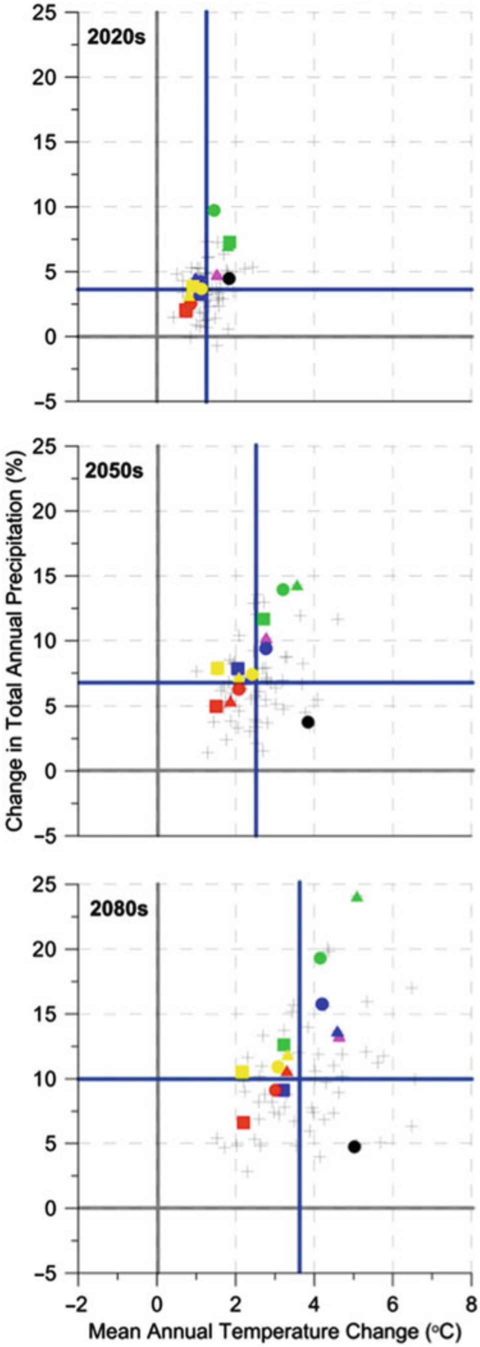

Fig. 13 A scatter plot of change in total annual precipitation (%) versus change in mean annual temperature (°C) from 1971 to 2000 for three future time periods, 2020s, 2050s, and 2080s, as projected by 65 GCMs and seven RCM experiments. The subset of 14 experiments chosen for further analysis is represented with colored symbols: *Green*, CGCM3.1(T63); *Blue*, ECHAM5-OM; *Red*, MRI-CGCM2.3.2a; *Yellow*, NCAR-PCM; *Magenta*, CRCM4.2.3; *Black*, PRECIS1.8.2; SRES GHG emission scenarios: ■ – B1; ● – A1B; ▲ – A2

IPCC-AR4 GCMs in terms of their capacity to simulate the spatial and spectral patterns of the ENSO and PDO. Since the spatial domain of RCMs is limited to a subcontinent and does extend to the oceans, this type of analysis is not applicable.

Whereas the colored symbols in Fig. 13 give the projected changes in annual temperature and precipitation averaged over the Canadian Prairies, the climate model output is available for thousands of point locations on a coarse grid for the GCMs and a much finer grid for the RCMs (the resolutions are given in Table 3). Therefore, the projections for each combination of climate variable, future time period, GCM, RCM, and GHG scenario can be mapped. As an example, Figs. 14 and 15 contain maps of projected total annual precipitation and mean annual temperature for the 2050s, relative to the 1971–2000 baselines, and for the three SRES GHG emission scenarios. While there are discrepancies among models, most of them project reduced precipitation in the western and southern prairies and increased precipitation toward the east and north. The temperature projections are much more consistent with a gradient from smaller to larger increases in temperature from southwest to northeast.

Implications for Adaptation Policies and Practices

Historically prairie agriculture has been sustained through the adjustment of land use and management systems to climatic variability (e.g., drought, early frosts, storms) and to take maximum advantage of soil and water resources. The process of adaptation has occurred episodically in response to periodic water scarcity and to changing markets, technology, and transportation systems. Adjustments have included major changes in farming practices and a significant degree of rural depopulation with the abandonment and consolidation of farms. Given a relatively high adaptive capacity and the historical adaptation that established and sustained commercial agriculture in this dry cold climate, the rural economy and communities could withstand much of the anticipated future change in mean climate.

If the degree of anthropogenic climate change exceeds the historical experience, further adaptation will be required. Adaptation in response to changes in mean temperature and precipitation is a familiar process; prairie agriculture became established by adapting crop and livestock production to a cold climate and low annual precipitation (less than 330 mm over a large area). These adaptations included the development of frost- and drought-tolerant crops or cultivars, adjusting the timing of seeding and harvest and, where water supplies permit, irrigation. Agriculture, and irrigation in particular, accounts for more than 70 % of the consumptive use of surface water (Coote and Gregorich 2000). An expansion of irrigated land is often cited as an effective adaptation to the increased summer aridity anticipated under global warming.

The preceding climate model projections suggest that the future climate of the Canadian Prairies will be warmer and even wetter, but the currently warmest and driest areas will be warmer and drier and currently cooler and wetter areas will be warmer and wetter. The best case scenario for this region, where crop, pasture, and

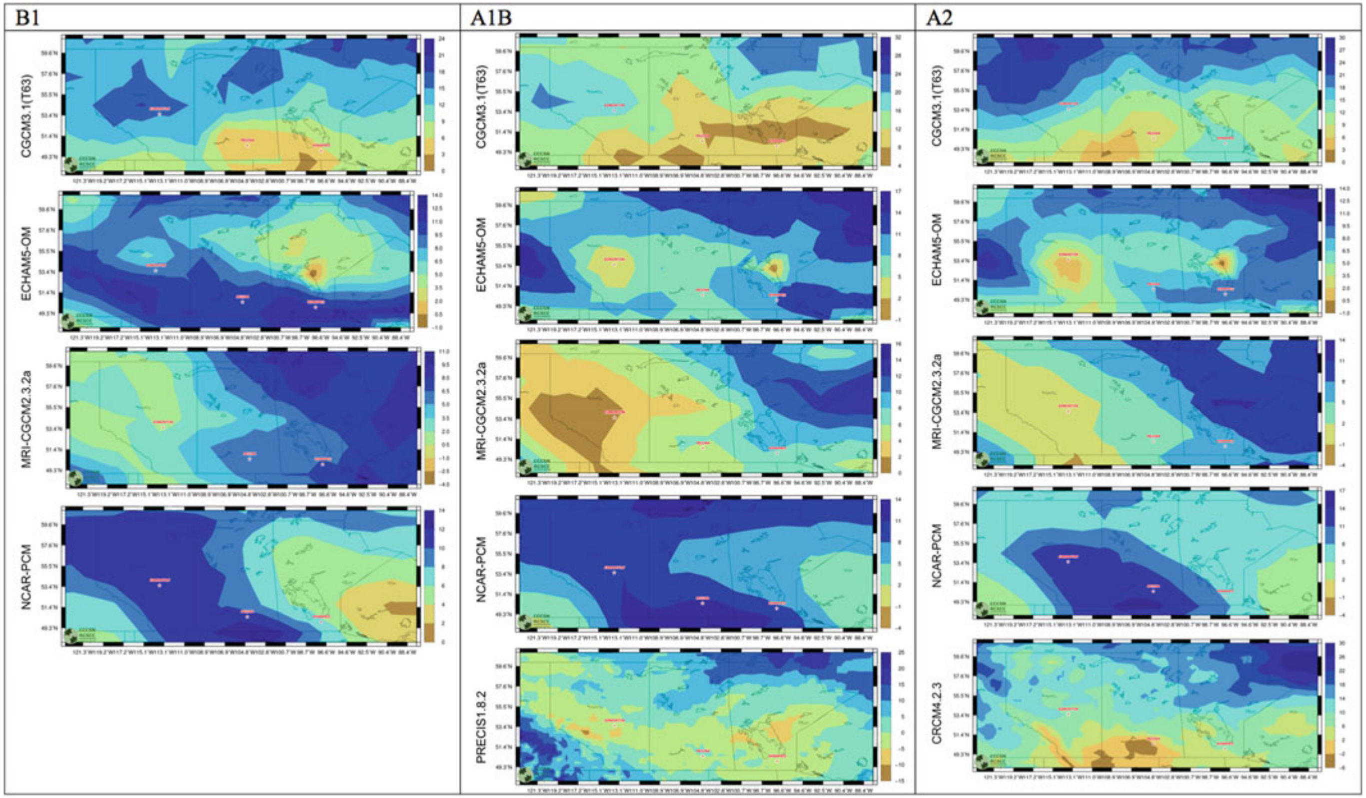

Fig. 14 Projected changes in mean total precipitation for the 2050s (relative to 1971–2000). The climate models and SRES emissions scenarios are identified across the top and along left margin of each map

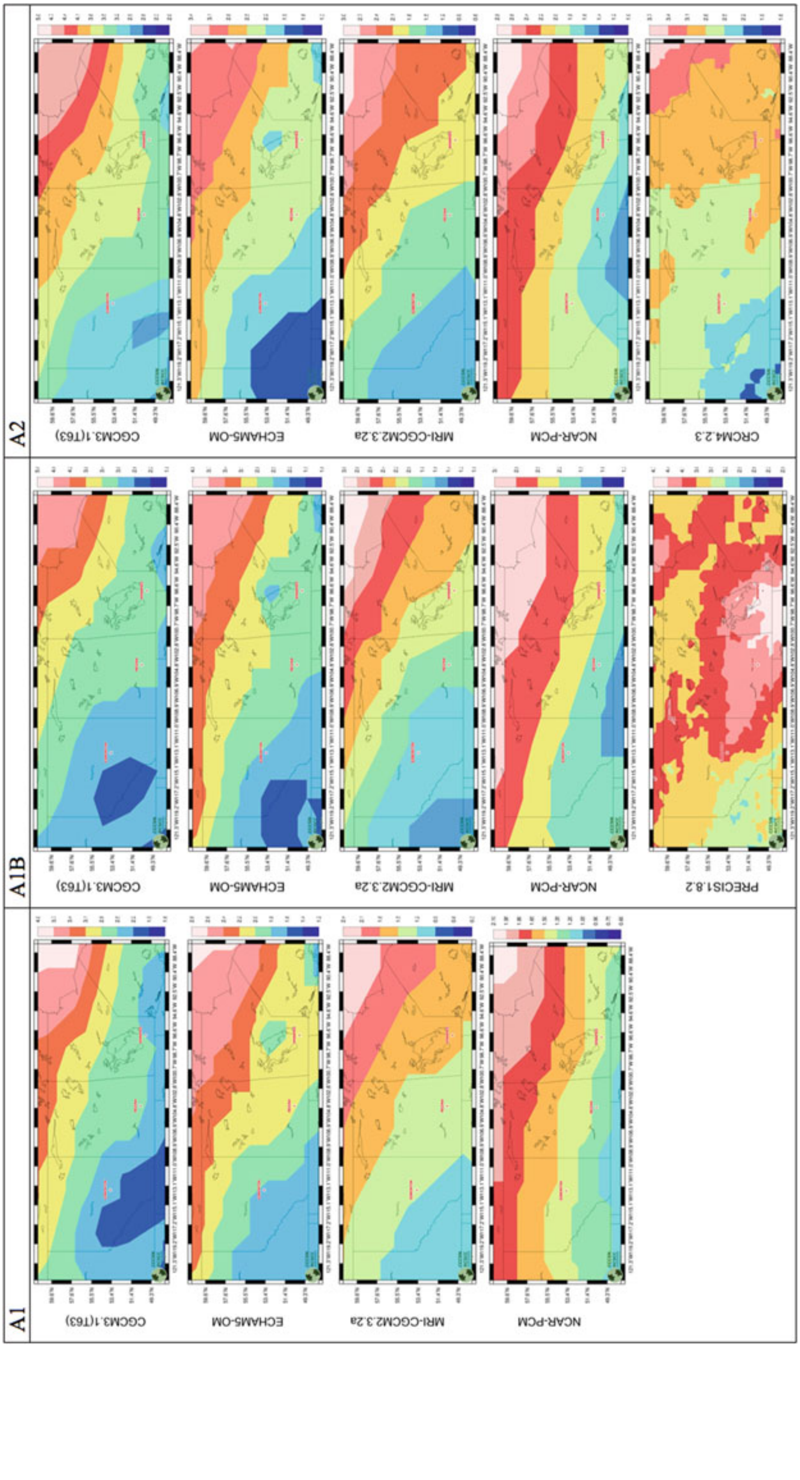

Fig. 15 Projected changes in mean annual temperatures for the 2050s (relative to 1971–2000). The climate models and SRES emissions scenarios are identified across the top and along left margin of each map

forest productivity is limited by the length of the frost-free growing season, is projections of enhanced precipitation with moderate increases in temperature and water loss by evapotranspiration. Higher productivity would result from the longer growing season, higher temperatures and concentrations of CO_2, elevated water use efficiency, and accelerated growth and maturation of crops before peak summer aridity. Higher temperatures will result, however, in potentially higher rates of evapotranspiration and, for more hours per year, cause water loss that exceeds any marginal increase in precipitation. A warmer growing season is also a more favorable environment for exotic pests, weeds, and disease vectors. These problems have technological solutions, although these technologies may be costly relative to agricultural revenues from extensive farming.

Whereas changes in average conditions can be addressed with familiar strategies, the more challenging circumstances are insufficient soil and surface water either seasonally to annually (drought) or in the longer-term (aridity) if certain thresholds are exceeded. The most severe recent drought in western Canada was during the period 1999–2003. Throughout western Saskatchewan and central and northern Alberta, most climate stations recorded the least precipitation for any single year in 2001 and for any three-year period during 2001–2003. As the impacts of drought in 2001–2002 rippled through the economies of Alberta and Saskatchewan, the loss in gross domestic product (GDP) was about $4.5 billion (Wheaton et al. 2008). A media survey by Wittrock and Wheaton (2007) showed that the most common adaptive responses were related to crops, livestock, and then water and economics. Spring and late summer were peak times for the discussion of adaptation. Innovative adaptations included water sharing agreements and modification of farming equipment. Even with considerable adaptation, negative impacts of this drought were considerable, and adaptations were costly (Wheaton et al. 2008). This suggests that some thresholds for adaptation capacity may have been exceeded for this drought. Yet the paleoclimate record, including the tree-ring reconstruction in this chapter, indicates that the worst droughts withstood by the modern economies and communities were of short duration compared to prolonged dry periods recorded by the tree rings. The greatest climate risk to the Canadian Prairies is the recurrence of drought of longer duration and/or severity than has occurred since Euro-Canadian settlement of the region.

As drought persists, soil and surface water deficits grow with increasingly serious consequences. Thus, duration is probably the key determinant of drought impacts. Nemanishen (1998) described the challenge of "Coping with Consecutive-Year Droughts":

> Modern farming technologies and practices now enable farmers to cope with single-year droughts. Most of the light lands in the drought prone areas are now either community pastures or seeded to permanent cover. Yet even with modern technologies, the current wheatlands are not able to yield sufficient returns to justify cropping in the second drought year. During the consecutive-year droughts, the precipitation deficit accumulates and leads to the depletion of the soil moisture in the root zone to a depth of a metre or more. . . . There is no technology, apart from irrigation, which can sustain either cereal grain or hay production during extended drought periods in the Palliser Triangle.

Even irrigation is ineffective under conditions of prolonged hydrological drought. Groundwater is an alternative to surface water as, in other parts of the world, it is the major source of irrigation water. However, shallow aquifers are sensitive to climate change and variability. Deeper groundwater is less responsive to climate variation, but in western Canada, it tends to be of poor quality, with high concentrations of dissolved minerals. There are few existing strategies other than government-funded assistance programs to sustain agriculture and rural communities through a drought of unprecedented duration that likely will exceed the coping capacity of prairie producers and agricultural institutions. Sustained drought, which occurred in the centuries prior to introduction of European agriculture to the Canadian Prairies, is almost certain to reoccur. The key questions are when and to what extent will global warming amplify the severity (intensity and duration). As discussed earlier in this paper, drought in western North America has been linked to large-scale anomalies in atmosphere–ocean circulation and specifically the ENSO and PDO. Thus, a scientific question of considerable relevance and intense investigation is how will the warming of the oceans and atmosphere, and the loss of arctic sea ice, modify the frequency and intensity of ENSO and the PDO and the strength of the teleconnections to regional climate variability? Even in the absence of this knowledge, we at least know that when a long and/or intense drought transpires in the coming decades it will occur in a warmer climate where demand for water from natural and human systems will be intensified.

Conclusion

Traditional cultures and economies are tied to the annual and seasonal cycles. The term ‘climate’ is from the Greek *klima* meaning inclination, referring to the sun’s declination, which varies on an annual cycle and is the cause of seasonality. Even today, as illustrated here using the case of the rural communities in the Canadian Prairies, modern economies are adapted mostly to seasonal and interannual variability, the scale with which we have the most experience. This adaptation involves familiar strategies and the corresponding policies, programs and best practices. Familiar agricultural practices include storage of water and irrigation to compensate for seasonal and interannual variability in the availability of water.

There are, however, other modes of climate variability requiring a different set of adaptations. Rural communities have less experience, and therefore fewer adaptation options, in dealing with decadal to multi-decadal modes of climate variability and with unprecedented climate extremes. These scales of climate variability and extreme events require adaptations that generally are not supported by existing policy and programming. This chapter examined decadal modes of climate variability and the adaptations required to minimize the impacts of prolonged drought and excessive moisture. If, in the short-term, natural variability continues to dominate the regional climate regime, then we should at least recognize the significance of inter-decadal variability and that there may be two sets of appropriate adaptations according to phase of the PDO, and the tempo of other teleconnections. But as we move forward through this century, the anthropogenic signal is likely to become increasingly apparent and expressed not only in terms of rising average temperatures, but also as a shift in climate variability and the severity of extreme weather events.

The most common perception of anthropogenic climate change is a monotonic upward trend in temperature resulting from a perturbation to the earth's radiative balance. This view reflects a simplified reporting of climate science and the scientific basis of climate projections – models that simulate the global response of the climate system to a change in external forcing. As important as the degree of climate changes is the timing – major climate impacts could occur with minimal changes to annual averages and totals if the distribution of heat and water shifts between seasons and years. Equating regional climate change to global warming is problematic, where changes in local temperatures and precipitation depart from the weather expected in a constantly warming world. Sun and Frank (2012) suggested, "It is time to look seriously at an alternative hypothesis, which is that the defining feature of global warming will be changes in the magnitude of climate variability." This alternative conceptualization of climate change certainly facilitates the communication and planning of adaptation in regions like the Canadian Prairies.

Abstract

This chapter addresses the biophysical dimension of adaptation. A framework is developed and applied to evaluate options for adaptation in different and relevant Italian agricultural cropping systems. Adaptation options rely on the identification of alternate cultivars optimally adapted to expected climate conditions, building on crops' intraspecific biodiversity. The aim is to remove or at least reduce the vulnerability of current production systems by identifying alternate cultivars optimally adapted to expected climate conditions, without altering the pattern of current species and production systems.

A new approach is proposed to (i) evaluate indicators of expected thermal and hydrologic conditions within a specific landscape and production system, (ii) identify the cultivar-specific thermal and hydrologic requirements for the optimal growth of a set of cultivars, and (iii) identify as options for adaptation the cultivars for which expected climate conditions match the climatic requirements. A robust methodology is provided to assess adaptive capacity, relying on mechanistic simulation models and on the identification of cultivar-specific climatic conditions required for optimal development and yield.

The approach is demonstrated through three case studies on (a) rainfed agriculture, (b) irrigated herbaceous crops, and (c) irrigated fruit crops. For rainfed agriculture, we have identified cultivars adapted to climate predicted for the period 2021–2050. For irrigated crops, we have evaluated adaptability for irrigation schedules ranging from optimal to severely reduced water depths. Options for adaptations of herbaceous and fruit crops have been identified as a combination of cultivars and irrigation schedules.

Introduction: Impacts, Stressors, Vulnerability, and Adaptation

The Mediterranean Basin is currently affected by a decreasing trend in precipitation up to −15 % per decade (1979–2005), while at the same time annual temperatures are increasing in the range of 0–0.5 °C per decade, and further increases in temperature and reductions in rainfall are reported by projections of future climate change (Trenberth et al. 2007). Further, an increase in temperature variability (heat waves, precipitation extremes, increase in the number of warm spell days) has been observed in the last decade, the increase has caused reduced harvest worldwide (Tank and Konnen 2003; Coumou and Rahmstorf 2012). Impacts on agricultural crops due to reduction in water resources and increasing temperature might be larger in the Mediterranean area than in other regions (Ventrella et al. 2012).

Literature documents a lively debate about the definition of adaptation of agricultural systems particularly about the integrated assessment of climate stressors, vulnerability, and resilience toward the evaluation of climate impact on agricultural systems (Collins and Ison 2009). IPCC (2007) provides a synthesis on the assessment of impacts of climate change, the vulnerability of natural and human environments, and the potential for response through adaptation.

Several studies show that climate change is generally problematic for agricultural production economies but vulnerability can be reduced through adaptation by building upon several opportunities (Smit and Skinner 2002). Olesen et al. (2011) illustrated perceived risks and foreseen impacts on European agriculture and described observed and predicted adaptation responses.

Highlights of studies on vulnerability and adaptation of agricultural production systems are given in Table 1. In general, the approach is to measure impacts as changes in yield in response to indicators of climate variability, with the impact modulated by vulnerability. There are significant conceptual and methodological differences in the studies summarized in Table 1. However, Xu et al. (2012) defined vulnerability as having three elements: exposure (to climate stress), sensitivity, and adaptive capacity. Ventrella et al. (2012) specifically evaluated the potential of irrigation and fertilization toward the mitigation of climate impacts. Reidsma et al. (2010) evaluated the adaptive capacity of agricultural crops by comparing the yield response to spatial versus temporal climate variability. Challinor et al. (2013) reviewed predictions on the evolution of agriculture, with many studies addressing the assessment of adaptation options. Supit et al. (2012) assessed potential and water-limited yield of four selected European crops under different emission scenarios and time scales, assuming no variation in crop types. Mainuddin et al. (2013) compared the impacts on rainfed rice using different climate scenarios and evaluated specific options for adaptations to conclude that climate impacts could be offset by adaptation. Jagtap and Jones (2002) evaluated the yield response for different cultivars and planting dates but did not evaluate explicitly the relevance of such differences toward vulnerability and adaptation. Challinor et al. (2009) noted the adaptation opportunities of intervarietal differences in phenological cycle in response to the thermal regime. Meza et al. (2008) proposed double cropping as option for adaptation evaluating the introduction of new hybrids better adapted to future climate.

In this chapter, climate is regarded as an independent (external) forcing factor (i.e., stressor) with impacts being modulated by the vulnerability of each production system:

$$\text{Impact} = \text{Vulnerability} \times \text{Stressor}$$

In this logic, adaptation is an intervention aiming at reducing or removing factors of vulnerability. Options toward adaptation can include changes in currently grown crops, time of planting, irrigation management, locations, and environmental and farm management. Although there has been considerable research on farmer habits, there has been little quantitative analysis on farmers' individual adaptation decisions, especially addressing the site-specific characteristics of adaptation processes (Below et al. 2012).

The concept above has been articulated through case studies on three of the main production systems in Italy (Table 2): rainfed agriculture (grape vine and olives),

Table 1 Review of studies about vulnerability and adaptation to climate change

Author(s)	Main objectives
Ventrella et al. 2012	The impacts of predicted climate change, and the possible beneficial effects of adaptive strategies, such as irrigation and fertilization, were evaluated for winter durum wheat and tomato crop using the Decision Support System for Agrotechnology Transfer (DSSAT) v4.0 crop model
Challinor et al. 2009	GLAM model simulations were used, together with an observed data set and a simple analysis of crop cardinal temperatures and thermal time, to estimate the potential for adaptation using existing cultivars
Challinor et al. 2013	Different methods to identify geographical hot spots of vulnerability (for drought and heat stress) to climate change were illustrated. The uncertainty of predictions and assessments was evaluated by combining climate scenarios with alternate agro-meteorological models
Reidsma et al. 2010	The adaptation of farmers and regions in the European Union was analyzed to prevailing climatic conditions, climate change, and climate variability in the last decades (1990–2003) in the context of other conditions and changes. They compared (1) responses in crop yields with responses in farmers' income, (2) responses to spatial climate variability with responses to temporal climate variability, (3) farm level responses with regional level responses, and (4) potential climate impacts (based on crop models) with actual climate impacts (based on farm accountancy data)
Jagtap and Jones 2002	An operational procedure to predict soybean yield and production was developed and tested by linking the CROPGRO-soybean model with a low-resolution regional database of weather, soils, management, and cultivars. Different planting dates were considered depending on soil moisture conditions and management practices but independent on cultivars
Olesen et al. 2011	The body of knowledge on vulnerabilities of crops under present climate, estimates of impacts on selected crops, possible adaptation options, and adaptation observed so far was reviewed. Observed adaptation responses in Mediterranean environmental zones by introducing new and more suitable cultivars were documented
Meza et al. 2008	Evaluate the impacts of climate change scenarios on the productivity of two maize cultivars in central Chile using Ceres Maize in DSSAT v 4.0. They evaluate the possibility of double cropping as a response to changes in the length of the growing season
Xu et al. 2012	Explain the observed patterns of vulnerabilities also in terms of different adaptive capacities in a semiarid area of southern Alberta. They quantitatively assess the vulnerability of an agricultural system by coupling the agricultural yields with the climatic stressors

irrigated herbaceous crops (maize and tomato), and irrigated fruit crops (pears, peaches, apricots, and kiwi). They represent 48.8 % of total Italian crop productions and 37.9 % of its value (Table 2).

A very significant determinant of the vulnerability of these production systems to climate variability is the crop response to water and temperature stress (Table 3). The vulnerability of the examined cropping systems to identify option for adaptation based on the use of cultivars adapted to projected climate conditions was investigated.

Common suggestions for addressing climate change-related concerns include the use of alternate cultivars to avoid drastic changes in current production systems.

Table 2 Statistics of Italian productions of the main agricultural systems investigated in this study (After FAOSTAT 2011 http://faostat.fao.org/site/339/default.aspx)

Production system	Crops	Value (% of total)	Production (% of total)	Value ($\$ \cdot 10^6$)	Production ($t \cdot 10^3$)
Rainfed agriculture	Olives	20.9 %	17.2 %	2,548	3,182
	Grapes			4,067	7,116
Irrigated herbaceous crops	Maize	11.3 %	26.2 %	1,382	9,753
	Tomatoes			2,199	5,950
Irrigated fruit crops	Pears	5.6 %	5.4 %	379	927
	Peaches			891	1,637
	Apricots			145	263
	Kiwi fruit			352	431
Total		37.8 %	48.8 %	11,963	29,259

This approach relies on the significant intraspecific differences of resilience to climate-related stresses (Reyer et al. 2013).

In Europe, Italy has the largest number of plant species; for instance, the biodiversity of Italian vegetable crops consists of 36 crops with 1,512 cultivars (nearly 8 % of total in Europe) (Elia and Santamaria 2013). Hundreds of cultivars of olive and grape vine are cultivated across a very broad range of climates worldwide; this implies a very significant potential for the adaptation of these production systems in Italy. It must be noted that adaptation by substitution of current cultivars leads to potential impacts on the current system of certification of high-quality types of oil and wine, which are linked to the current location of cultivars.

As regards irrigated agriculture, adaptation may be achieved through changes in irrigation management if water is not a limiting factor. Contrariwise, in a scenario of reduced water resources, intraspecific differences in yield response to water availability become as important as in rainfed agriculture. Moreover, management practices can be tuned to take advantage from regulation of plant development, which may increase water use efficiency. Reduced amounts of water may be applied to some crops to exploit the plant stress-sensing capacity to reduce unnecessary vegetative growth while maintaining fruit production with a reduced supply of water (Davies et al. 2002; Girona et al. 2005).

Intraspecific Biodiversity of Agricultural Crops: A Toolkit to Identify Options for Adaptation

Overview

A new approach has been developed to identify options for adaptation, which avoids the assessment of climate impacts on agricultural yields and does not aim at adaptation by mitigating impacts on current cropping patterns. Instead, the aim is to remove or at least reduce the vulnerability of current production systems by

Table 3 Crop responses to water and temperature stress

		Stressors	
		Water deficit	High/low temperature
Dry land agriculture	Olive	Olive is well known to be very resistant to drought (Bongi and Palliotti 1994; Giorio et al. 1999; Tognetti et al. 2004; Connor 2005), and the crop achieves acceptable yields while subjected to high irradiance and temperature and to prolonged water shortage	Excessive temperatures can negatively influence several reproductive processes (flower development, pollen viability, and the pollination process) and, consequently, fertilization and yield (Aguilera et al. 2013)
		The species has developed efficient physiological, biochemical, and morphological mechanisms of drought avoidance and tolerance. Avoidance involves mechanisms to reduce transpiration and to maintain root water uptake and high plant water potential as drought sets in. Other mechanisms increase tolerance to dehydration at low plant water potential as the drought deepens (Connor and Fereres 2005)	
		Significant yield differences among cultivars have been observed under drought conditions (Chartzoulakis et al. 1999)	
	Grapevine	Severe water deficit results in low sugar concentration as a consequence of restricted carbon assimilation (Matthews and Anderson 1988; Santesteban and Royo 2005). However, mild to moderate water deficit results in higher sugar level in fruits and in earlier ripening (Roby et al. 2004)	Heat stresses (T_{max} > 35 °C) during berry ripening are associated with lower photosynthesis rates and yield. High temperatures affect yield's quality and quantity through reduced fruit set and berries' size (Kliewer 1977); color development (Kliewer and Torres 1972) and of flavor ripening (Mullins et al. 1992) are inhibited, as well
		In Mediterranean climate, water stress in spring and early summer up to the beginning of ripening should be avoided. Restricted water availability in a later stage favors berry ripening by limiting late vegetative growth (Jackson 2008). Bonfante et al. (2012) showed a positive correlation between water stress occurring in the berry formation phase and wine quality (i.e., content of anthocyans, polyphenols, sugar, and titratable acidity)	

(*continued*)

Table 3 (continued)

		Stressors	
		Water deficit	High/low temperature
Irrigated herbaceous crops	Tomato	Water availability affects flower formation and fruit size. Water stress decreases the average number of flowers per truss and can severely reduce fruit set. Moreover, low water availability concurs in causing physiological disorders (e.g., blossom-end rot) (Kinet and Peet 1997)	High temperatures (36–40 °C) adversely affect the reproductive process, causing abscission of flowers or young fruits. At ripening, temperatures above 30 °C inhibit lycopene synthesis and may cause fruit disorders (e.g., sunscald) (Kinet and Peet 1997)
	Maize	Maize is very sensitive to drought at flowering (Otegui et al. 1995). NeSmith and Ritchie (1992) reported yield reductions over 90 % caused by water deficit during flowering	Warmer growing season can directly reduce yields. Heat stress in combination with drought is a common constrain during the anthesis and grain filling stages. The ability of pollen to germinate on silks is greatly reduced at temperatures above 32 °C (Basra 2001)
Irrigated fruit crops	Peach	Peaches are sensitive to water stress during some phenological phases, like flowering and fruiting (Xiloyannis et al. 2005)	Peach is very sensitive to spring frosts that can completely destroy fruit production (Steduto et al. 2012). Peach requires an appropriate thermal sequence (in terms of occurrence and level of high/low temperatures) for a proper formation of reproductive organs (Couvillon and Erez 1985)
	Pear	Pear's organs and tissues can withstand a certain degree of dehydration; thus, this species exhibits a drought resistance higher than other deciduous fruit trees such as peach, plum, or apple. Moderate water stress during the fruit-growing season or postharvest increases flowering in the following season (Naor 2006)	In pear higher temperatures accelerate the development of disorders like watercore (Sakuma et al. 1995)

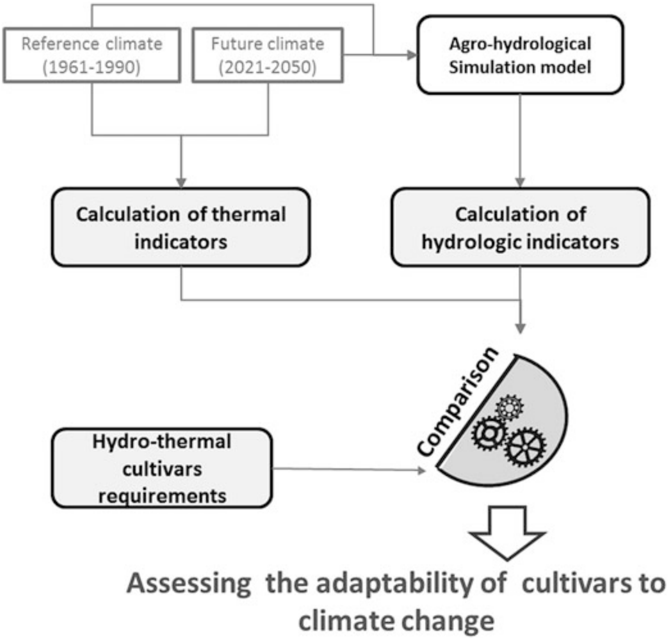

Fig. 1 Conceptual scheme of proposed approach to assess the adaptability of cultivars to climate by evaluating climate indicators against cultivar-specific climatic requirements

identifying alternate cultivars optimally adapted to expected climate conditions, without altering the pattern of current species and production systems (Menenti et al. 2008; De Lorenzi et al. 2013b).

The approach involves the following steps (Fig. 1):

(i) Evaluate indicators of expected thermal and hydrologic conditions within a specific landscape and production system.
(ii) Identify the thermal and hydrologic conditions required for the optimal growth of a set of cultivars relevant to the production system under consideration, i.e., cultivar-specific climatic requirements.
(iii) Identify the cultivars for which expected climate conditions match the climatic requirements (options for adaptation).

With this approach, options for adaptation have been evaluated in different Italian agricultural systems (Fig. 2 and Table 2) that are representative of the most important production systems: (i) a valley dominated by grape vine and olive orchards, with a significant presence of wheat (Valle Telesina); (ii) an irrigated district where cereals and horticultural crops are grown (Destra Sele); and (iii) an area of the Po Valley where fruit crops are intensively grown (Romagna).

Models of crop response to environmental forcing might be used for the evaluation of crop adaptability but are severely constrained by the very scarce knowledge

Fig. 2 Location of the investigated study areas within the Italian territory

on cultivar-specific values of model parameters (Craufurd et al. 2013), thus limiting analyses toward the potential exploitation of intraspecific biodiversity for adaptation. More robust assessments of adaptive capacity are achieved by relying on cultivar-specific climatic conditions required for optimal development and yield, as described in this chapter.

Downscaled climate scenarios have been used (Tomozeiu et al. 2014) to calculate indicators of soil water availability and thermal times and to evaluate the variability of crop phenology in combination with critical temperatures.

Cultivar-specific thermal requirements defining timing of each phenological stage have been estimated by combining phenological observations on different cultivars with the calculation of crop- and phase-specific thermal times. Critical temperatures have been determined on the basis of scientific literature and used to assess thermal hazard in different phenological stages (Fig. 3). The requirements on water availability of several cultivars for each dominant species in each production system have been derived from yield response functions to water availability through the reanalysis of experimental data sets.

Next, to identify options for adaptation, the compatibility of such requirements with the thermal and hydrologic conditions was characterized using the indicators mentioned above in a reference (current) and a future climate case. As regards hydrologic conditions, this compatibility assessment has been done at landscape scale in all soil units within each study area (Fig. 4). This has lead to maps of

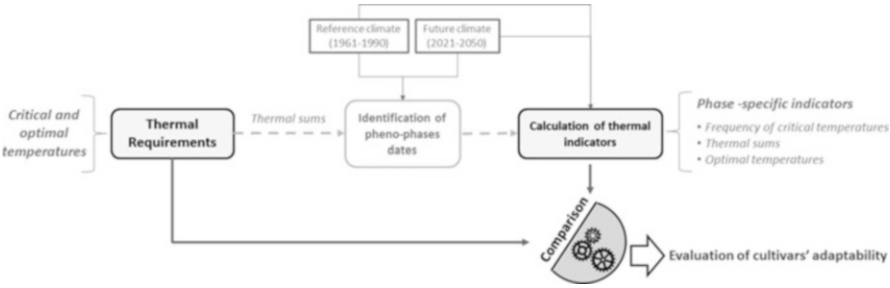

Fig. 3 Schematization of the procedure to evaluate adaptability on the basis of thermal requirements

locations where each crop is expected to be compatible with climate. When dealing with irrigated agriculture, different irrigation water management options were considered. Timing of phenological phases in both climates (reference and future) has been determined to evaluate the compatibility of the cultivars with the thermal regime (Fig. 3). The combination of these procedures has lead to identify both potential crop persistence and cultivar substitutions within the areas.

Climate. Two climate scenarios were considered: reference (1961–1990) and future (2021–2050) climate, the former from climatic statistics on observed variables and the latter from statistical downscaling of general circulation models (AOGCM). Climatic data consist of daily time series of maximum and minimum temperature and daily rainfall on a grid with a spatial resolution of 35 $\times$ 35 km (Villani et al. 2011; Tomozeiu et al. 2014).

Thermal indicators. Three types of thermal indicators have been used: (a) dates of occurrence of phenological phases for each year and for each cultivar, calculated by using cultivar- and phase-specific thermal requirements; (b) mean air temperature in a crop-specific period of time (optimal temperatures); and (c) extreme temperatures (critical) associated with severe impact on crop metabolism and yield.

Hydrologic indicators. The mechanistic model SWAP (soil–water–atmosphere–plant model) of water flow in the soil–plant–atmosphere system was used (Fig. 4) to describe the hydrologic conditions in response to climate and irrigation. In most areas, the model was calibrated and validated for the different crops. Crop-specific input data and model parameters were estimated on the basis of local experiments and of scientific literature and assumed to be generically representative of the species. The yearly time series for the reference and future climate were used as climate forcing. The soil hydraulic properties were estimated by means of pedotransfer functions as implemented in the HYPRES (hydraulic properties of European soils) database (Wösten et al. 1999) and measured on undisturbed soil samples in some cases (Basile et al. 2006). For irrigated crops, different irrigation scheduling options were simulated. Two indicators of soil water availability have been calculated using the numerical experiments: the relative soil water deficit ($RSWD_{soil}$) and the relative evapotranspiration deficit ($RETD_{soil}$) (De Lorenzi et al. 2010; Monaco et al. 2012; Alfieri et al. 2013b; Bonfante et al. 2013;

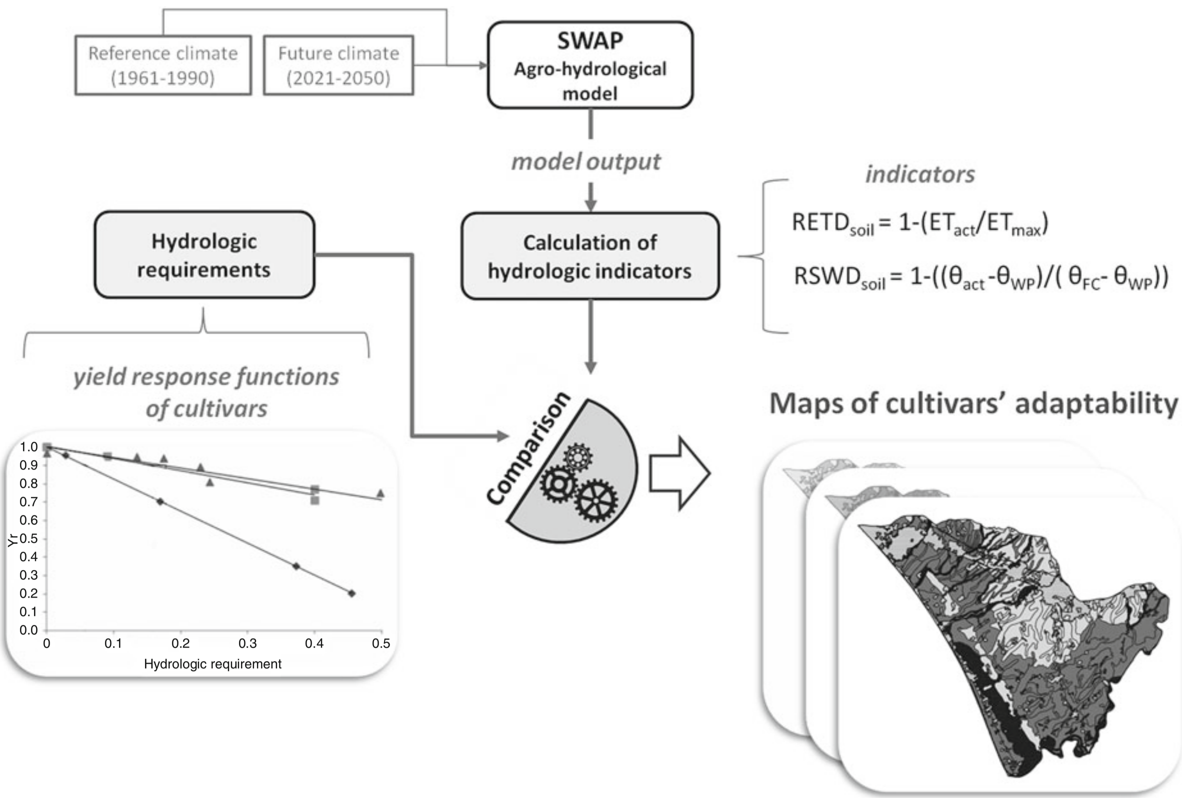

Fig. 4 Schematization of the procedure to evaluate adaptability on the basis of hydrologic requirements

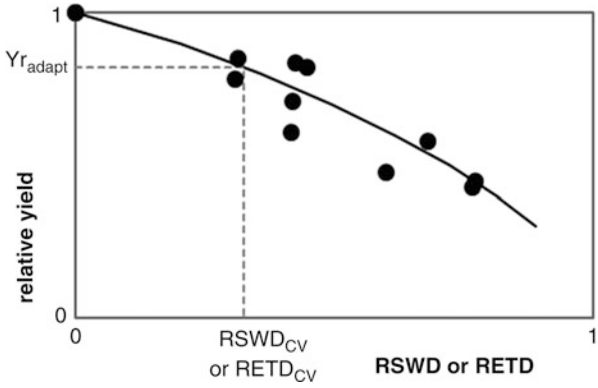

Fig. 5 Relative yield as a function of soil water availability indicators: relative soil water deficit (RSWD) or relative evapotranspiration deficit (RETD). The relative yield desirable for adaptation (Yr_{adapt}) and the corresponding values of the indicators ($RSWD_{cv}$ or $RETD_{cv}$) are shown

De Lorenzi et al. 2013a; Reyer et al. 2013). Daily values of these indicators were calculated for each soil unit.

Crop Climatic Requirements

Thermal requirements. Variety-specific phenology is used as a biological indicator to evaluate adaptability to the thermal regime. Three types of thermal requirements have been used: (a) thermal time required for completion of a specific phenological stage, (b) mean temperature required in a specified period of time, and (c) extreme minimum and maximum temperature, beyond which crops do not recover from thermal stresses.

Hydrologic requirements. Cultivar-specific hydrologic requirements have been derived from yield response functions to water availability for both irrigated and not irrigated crops (Fig. 5). The critical values of the indicators, namely, $RSWD_{cv}$ and $RETD_{cv}$, were defined by setting a threshold (acceptable) yield level. The required information was obtained from the reanalysis of experimental data sets, from both local experiments and scientific literature.

Adaptability Assessment

To identify which cultivars are adapted to expected thermal and hydrologic conditions, the thermal and hydrologic indicators have been evaluated against the cultivar-specific thermal and hydrologic requirements and the associated statistics. This evaluation has been repeated for multiple realizations of each climate case, and estimated probabilities have been associated with statements on the compatibility of a cultivar with expected thermal and hydrologic conditions.

The evaluation of hydrologic conditions ($RSWD_{soil}$ and $RETD_{soil}$) against hydrologic requirements ($RSWD_{cv}$ and $RETD_{cv}$) has been carried out for each soil unit within a study area, leading to soil-specific statements on adaptability.

For irrigated crops, cultivar adaptability was evaluated in relation with the hydrologic indicators corresponding to different irrigation scheduling options.

The evaluation of thermal conditions against thermal requirements has been carried out initially by comparing required mean temperatures with mean temperatures over the same period of time for all available yearly time series (reference and future climate). The dates of each phenological stage for each variety and each year have been estimated, and then the frequency of temperature extremes during critical phases, e.g., flowering and fruit formation, was evaluated. In a similar way as with hydrologic conditions, estimated probabilities of the compatibility with variety-specific requirements have been associated with expected thermal conditions.

Designing Adapted Production Systems with Data and Models

Climate Cases

Daily air temperature and precipitation time series for the reference and future climate scenarios have been produced within the Italian project "Agroscenari" (www.agroscenari.it). Data are available over a 35 × 35 km-resolution grid covering the entire Italian territory. The database consists of:

– Reference climate case, i.e., the period 1961–1990
– Future climate case consisting in 50 realizations of a year representative of the period from 2021 to 2050

Reference climate case. The reference climate has been produced by the "Unità di Ricerca per la Climatologia e la Meteorologia applicate in Agricoltura" (CRA-CMA) applying the "kriging with external drift" method (Wackernagel 1998) to the meteorological data included in the National Agro-meteorological Database (http://cma.entecra.it/Banca_dati_agrometeo/index3.htm). Daily meteorological data have been gridded at 35 × 35 km resolution for the period from 1950 onward (Esposito 2010; Table 4).

Table 4 Annual mean and standard deviation (in parenthesis) of meteorological variables at the reference nodes for each study area over the reference period (1961–1990) and future climate scenario (2021–2050)

	T_{min} (°C)		T_{max} (°C)		Rainfall (mm)	
	1961–1990	2021–2050	1961–1990	2021–2050	1961–1990	2021–2050
Valle Telesina	8.70 (0.40)	10.17 (0.28)	18.73 (0.51)	20.43 (0.33)	1069 (212)	912 (100)
Destra Sele	10.24 (0.38)	11.53 (0.28)	19.79 (0.53)	21.37 (0.28)	1035 (178)	838 (122)
Romagna	9.04 (0.37)	10.28 (0.30)	17.72 (1.05)	19.35 (0.40)	701 (133)	708 (110)

Future climate case. Daily values of maximum and minimum temperatures as well as precipitation data have been produced in two phases. At first the seasonal mean and standard deviation of the meteorological variables have been generated by a statistical downscaling model (SDM, Tomozeiu et al. 2007) starting from coupled atmosphere–ocean global climate models (AOGCMs) under emission scenario A1B (ENSEMBLE, Van der Linden and Mitchell 2009). The results are then used by a weather generator to produce 50 realizations of the daily values of the same variables for a year taken as representative of the period between 2021 and 2050. The work was carried out by the "Agenzia Regionale per la Protezione Ambiente" (ARPA-SIM) within the project Agroscenari (Tomozeiu et al. 2014; Table 4).

Hydrologic Indicators

Water balance analysis was performed using the SWAP model (Kroes et al. 2008). Assuming 1-D vertical flow processes, it calculates the soil water flow by integrating the Richards' equation:

$$C(h) \cdot \frac{\partial h}{\partial t} = \partial \left[k(h) \cdot \left(\frac{\partial h}{\partial z} + 1 \right) \right] \cdot \partial z - S(h) \tag{1}$$

where $C(h) = \partial\theta/\partial h$ is the soil water capacity, θ (cm^3 cm^{-3}) is the volumetric soil water content, h (cm) is the soil water pressure head, t (d) is the time, z (cm) is the vertical coordinate taken positively upward, k (cm d^{-1}) is the hydraulic conductivity, and S (cm^3 cm^{-3} d^{-1}) is the water extraction rate by plant roots.

Soil water retention is described by the unimodal $\theta(h)$ relationship proposed by van Genuchten (1980) and expressed here in terms of the effective saturation, Se, as follows:

$$Se = \left[\frac{1}{1 + (\alpha|h|)^n} \right]^m \tag{2}$$

with $Se = (\theta - \theta_r)/(\theta_0 - \theta_r)$, θ_r and θ_0 being the residual water content, respectively, the water content at $h = 0$, where α (cm^{-1}), n, and m are curve-fitting parameters.

Mualem's expression is applied to calculate relative hydraulic conductivity, k_r (Mualem 1976). Assuming $m = 1 - 1/n$, van Genuchten (1980) obtained a closed-form analytical solution to predict k_r at a specified volumetric water content:

$$k_r(Se) = \frac{k(Se)}{k_0} = Se^{\tau} \left[1 - \left(1 - Se^{1/m} \right)^m \right]^2 \tag{3}$$

where k_0 is the hydraulic conductivity at θ_0 and τ is a parameter which accounts for the dependence on the tortuosity and partial correlation between adjacent pores.

The condition at the bottom boundary can be set in several ways (e.g., pressure head, water table, fluxes, impermeable layer, unit gradient, etc.).

The upper boundary conditions when applying SWAP to agricultural crops are generally described by the potential evapotranspiration ET_p, irrigation and daily precipitation. SWAP simulates water uptake and actual transpiration according to the model proposed by Feddes et al. (1978), where root water uptake S is a function of the pressure head, h:

$$S(h) = \alpha(h) \cdot S_{\max} = \alpha(h) \cdot \frac{T_p}{|z_r|} \tag{4}$$

being z_r (cm) the thickness of the root zone and $\alpha(h)$ a semiempirical function of pressure head h, varying between 0 and 1. The shape of the function $\alpha(h)$ depends on four critical values of h, which are related to crop type and to potential transpiration rates. The actual transpiration rate T_a (cm d^{-1}) is computed by the integration of S over the root layer. The root depth is specified by the user as function of development stage.

The dependence of soil hydraulic properties on soil texture (Wösten et al. 1999) was established by making use of the HYPRES database (http://www.macaulay.ac.uk/hypres/) and evaluated against a limited number of measured water retention and hydraulic conductivity functions. It is this simple yet robust relationship between soil texture and van Genuchten parameters that makes this approach feasible to study large and complex landscapes.

The soil–water–atmosphere–plant model (SWAP) was applied to solve the soil water balance in both climate cases for each soil unit in the case study areas (Fig. 4). The ET_p was calculated by means of the Hargreaves and Samani (1985) formula and a crop coefficient.

Irrigation scheduling. In the case of irrigated agriculture, climate signatures and options for adaptation are strongly dependent on irrigation strategies. Six irrigation strategies have been evaluated for each climate scenario and for each soil using the model SWAP, i.e., optimal irrigation; 80 %, 60 %, 40 %, and 20 % of optimal water depths; and no irrigation. At first, the optimal irrigation schedule under the constraint that actual transpiration be equal to potential transpiration at all times has been calculated: this yields dates and water depths.

Next, increasing reductions have been applied to water depths keeping the same dates as in the optimal irrigation schedule. Finally, the hydrologic indicators and the effectiveness for each irrigation schedule was evaluated (De Lorenzi et al. 2013a).

Indicators were calculated from simulation runs in all soil units, to describe soil water availability. Namely, the relative soil water deficit (RSWD) and the relative evapotranspiration deficit (RETD) were determined, as follows:

$$\text{RSWD} = 1 - \frac{\theta_{act} - \theta_{WP}}{\theta_{FC} - \theta_{WP}} \tag{5}$$

where θ (m^3 m^{-3}) is the volumetric soil water content in the layer explored by roots, namely,

θ_{act} = actual soil water content
θ_{WP} = soil water content at $h = -1{,}500$ kPa (wilting point)
θ_{FC} = soil water content at $h = -33$ kPa (field capacity)

$$\mathrm{RETD} = 1 - \frac{ET_{act}}{ET_{\max}} \tag{6}$$

where
ET_{act} = actual crop evapotranspiration (mm)
$ET_{\max}$ = maximum crop evapotranspiration (mm), i.e., evapotranspiration at optimum soil water availability

Thermal Indicators

The response of plants to both mean and extreme temperature varies very significantly across phenological stages, and it is a well-established notion that plant development scales with thermal rather than actual time (Lawler et al. 2010). This concept has been applied to model the response to climate of global and continental vegetation (Huang et al. 2010). Accordingly, a three-tiered approach to characterize thermal conditions is applied:

– Calculate specific thermal times for each phenological stage.
– Calculate mean air temperature for each phenological stage.
– Calculate the frequency of extreme low and extreme high temperatures during the phenological stages most sensitive to either extreme conditions.

Thermal times. The start and end dates of each phenological stage have been estimated by matching cultivar- and phase-specific thermal requirements, as described below, with thermal times. Thermal time, expressed in terms of growing degree days (GDD) or growing degree hours (GDH), is calculated by means of phase-specific models forced from mean air temperature.

Mean air temperature. During specific phenological phases, e.g., ripening, mean air temperature is a significant determinant of the quantity and quality of yield. A notable case is grape vine with stringent cultivar-specific requirements (e.g., Jones 2006) identifying optimal conditions for growing a specific cultivar. Given the timing of phenological stages, estimated for each year of both the reference and future climate cases, mean air temperature for each phase is calculated.

Extreme temperatures. During early phenological stages, e.g., bud swelling and flowering, extremely low temperatures can halt crop development irrecoverably. Likewise, extreme high temperatures during ripening can compromise crop yield. Accordingly, the frequencies of air temperature lower than a minimum and higher than a maximum phase-specific threshold for each year, of both the reference and future climate cases, were calculated.

Determination of Cultivar-Specific Hydrologic and Thermal Requirements

Cultivar-specific *hydrologic requirements* were determined for many cultivars of the most representative crops of the selected case studies. Requirements were determined through the reanalysis of experimental data sets derived from scientific literature. To this purpose, the yield of each cultivar was expressed as a function of soil water availability measured by either RSWD or RETD.

The crop yield was expressed as relative yield (Yr) defined as:

$$Yr = \frac{Y_{act}}{Y_{\max}} \tag{7}$$

where

Y_{act} = actual yield

$Y_{\max}$ = maximum yield under given climate and soil conditions, i.e., the yield at optimum soil water availability

The relations between relative yield and soil water availability indicators were determined rearranging existing experimental data sets. Yr values were plotted against values of water availability indicators, and the yield response function was defined by a curve fitting to experimental data. A generic yield response function is shown in Fig. 5.

The level of relative yield below which yield reduction is unacceptable was thus identified for each cultivar and indicated as the set point for adaptation (Yr_{adapt}).

The value of the indicator (RSWD or RETD) corresponding to Yr_{adapt} was set as the cultivar-specific hydrologic requirement (RSWD_{cv} or RETD_{cv}). An error of estimation, due to the empirical relationship between Yr and soil indicators, was associated to each RSWD_{cv} (or RETD_{cv}).

Hydrologic requirements are summarized in Table 5 where values of RSWD_{cv} and RETD_{cv} span quite different ranges, between different species and also within the same species e.g., olive. Cultivar requirements, determined in a certain phase of crop cycle, were evaluated against hydrologic conditions calculated, by means of the simulation model, in the corresponding time period.

Thermal requirements. Required *thermal times* for completion of each phenological phase and for each cultivar are calculated starting from multiannual observations of start and end dates of occurrence of the phenological phases and the thermal times calculated as outlined above. In some cases, the Chilling requirements have been derived from the technical specifications of each cultivar provided by the producers. An example of phase-specific thermal time calculation for peach crop is summarized in Table 6 where the phases and the models used to calculate thermal requirements and the corresponding units of each considered thermal time are listed.

The dates of occurrence of each phenological phase were estimated by matching the calculated phase-specific thermal times with the thermal requirements for each cultivar and for each year for both the reference and the future climate cases.

Table 5 Range of hydrologic requirements across cultivars relevant to the productions systems of the three case studies

Area	Crops	$RSWD_{cv}$ range	$RETD_{cv}$ range
Valle Telesina	Olive (11 cv)	0.47–0.73	0.32–0.39
Destra Sele	Tomato (4 cv)	0.41–0.54	
	Maize (5 hybrids)		0.03–0.50
Romagna	Peach (2 cv)	0.29–0.30	

Table 6 Overview of thermal times used to estimate the dates of start and completion of phenological phases for peach cultivars

Phase	Thermal times model	Unit	References
Rest	Richardson chill unit	Chilling units (CU)	Richardson et al. 1974
Bud development and inflorescence emergence	North Carolina	Growing degree hours (GDH)	Shaltout and Unrath 1983
Flowering	Growing degree days	Growing degree days (GDD)	Bonhomme 2000
Fruit development	Growing degree days	Growing degree days (GDD)	Bonhomme 2000
Ripening	Growing degree days	Growing degree days (GDD)	Bonhomme 2000

Mean air temperature. Literature documents well-defined ranges of mean air temperature during specific phenological stages which identify optimal, cultivar-specific climatic conditions (e.g., Jones 2006; Mariani 2008). A data set on the optimal mean air temperature for a number of grapevine cultivars has been compiled and applied to identify suitable areas for each cultivar in the reference and future climate cases.

Extreme temperatures. Literature on critical low and high temperature during specific phenological stages was reviewed and compiled. The requirement applied was that such critical temperatures must not be exceeded. The frequency of occurrence of such events, estimated as described above, was used to assess the probability of irrecoverable impacts on crop development.

Assessing the Design by Measuring Adaptability

The Hierarchy of Criteria for Adaptability

Thermal requirements are critical determinant of adaptability since in case climatic conditions are not compatible with a cultivar thermal requirement, the crop under consideration will suffer severe impact on metabolism and yield, making hydrologic requirements irrelevant. To assess adaptability of a given variety, therefore, it is needed to assess whether expected climate meets the requirements by considering stressors in the following sequence:

1. Duration and dates of phenological phases
2. Mean temperature in specific phenological phases
3. Extreme temperature in specific phenological phases
4. Water deficit

Probabilistic Assessment of Adaptability

The assessment of adaptability is performed by evaluating whether the value of stressor indicators (S_i) is lower than requirements (R_i). The estimates of such requirements, however, are affected by a standard error of estimate (δ_{Ri}*) that needs to be taken into account. The error on the estimated R_i^m is indicated as a random variable δ_{Ri} with a normal distribution of standard deviation δ_{Ri}*.

Requirement R_i is therefore:

$$Ri = R_i^m + \delta_{Ri} \tag{8}$$

where R_i^m is the requirement estimated by experimental data and δ_{Ri} its associated standard error.

The probability distribution function of the requirement is:

$$f(R_i) = R_i^m \pm \frac{1}{\delta_{Ri}{}^* \sqrt{2\pi}} e^{-(Ri - Ri^m)^2 / 2\delta_{Ri}{}^{*2}} \tag{9}$$

When evaluating the adaptability for a specific cultivar in a specific year and environment, the uncertainty of the requirement estimation is taken into account by calculating the probability (P) that given a random value of the requirement (according to Eq. 9), the stressor indicator for that year (in a certain phase) is lower than the requirement value (Fig. 6).

The distribution over the reference and future climate of the probabilities calculated as explained above is evaluated. Medians M of P (over the years in either scenario) are then used to assess and quantify the adaptability of cultivars, and its spatial distribution, in the reference and future climate.

The Climate Adaptation Information System (CAIS)

The calculation of the thermal and hydrologic indicators for the production systems and environmental and climatic conditions examined in this study requires the following tools (Fig. 7) based on the modeling approach described above:

Development of an information system and of a user interface for modeling engine based on the SWAP code (3.2.26 version porting for LINUX operating system, http://www.swap.alterra.nl) by using different climate forcing. This step is based on an automatic procedure to run the model iteratively with different crop,

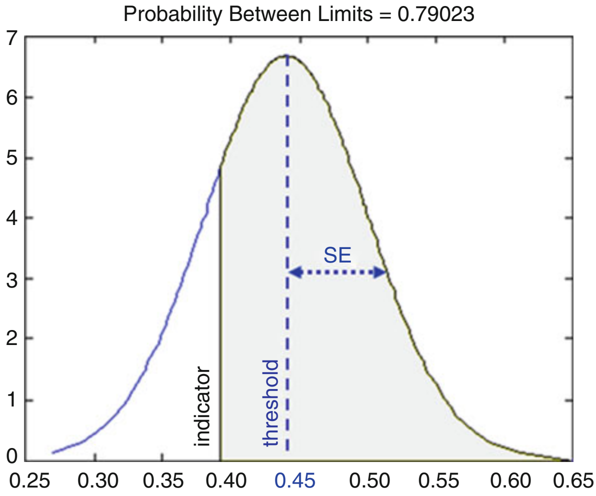

Fig. 6 Probability distribution function of the estimated requirement. *Shaded area* indicates the probability P that the (thermal or hydrologic) indicator is lower than the threshold requirement

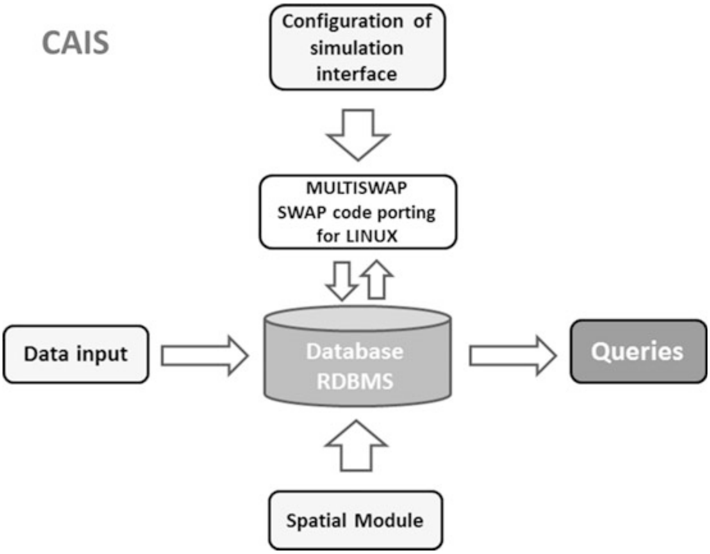

Fig. 7 Simplified scheme of the Climate Adaptation Information System (CAIS)

soil data, and meteorological input data. The system (called MultiSWAP) allows to execute the SWAP model for all custom calculation cells which have been identified in the study areas. It provides a configuration panel to design and execute all the simulations in one run.

Architecture of the database and of the procedures to populate it. Crop, meteorological, and soil data for the areas under study can be available in different formats, i.e., tables and vector formats (points and polygons). This step is based on

GIS (geographical information system) procedures to process and harmonize the different input data sets to the format required by the first step. In particular, spatial interpolation of point variables (i.e., meteorological data) and intersection of vector and raster layers are necessary. A specialized spatial interpolation module to interpolate meteorological data based on GStat code (Pebesma and Wesseling 1998) has been implemented.

Procedures and algorithms for data query and analysis on the output database to generate the required indicators, accordingly to user-defined criteria. They allow to (i) perform calculations on outputs, (ii) aggregate outputs on spatial and temporal scale, (iii) calculate statistics on the matching between user-defined requirements and simulated values, and (iv) display on a web interface the results of geo-located queries on maps.

The information system is based on an automated web infrastructure (Fig. 7).

Case Studies

The approach described above has been applied and refined by carrying out three case studies (Table 7).

Case Study 1: Valle Telesina

The "Valle Telesina" is a 20,000 ha complex landscape located in South Italy in the Campania region, which has a complex geology and geomorphology, and it is characterized by an E–W elongated graben where the Calore River flows. The valley is surrounded on both the Southern and Northern sides by the Matese massif. Camposauro Mountain is the dominant relief that reaches up to 1,390 m asl. The main crops are grapevine (6,448 ha) and olive (3,390 ha).

Vulnerability challenges. Olive (*Olea europaea* L.) is a typical sclerophyllous species, native plant in the semiarid Mediterranean climate. During the last 500 years, olive growing has extended all over the world but remains mainly a crop of the Mediterranean Basin (Connor 2005). In this area, olive is generally cultivated in rainfed conditions under the minimum viable rainfall and therefore

Table 7 Overview of case studies

Cropping system	Area	Ha	Lat long	Crops	Environment
Rainfed agriculture	Valle Telesina	20,000	41 N, 14E	Olive, grapevine	Hilly region
Irrigated herbaceous crops	Destra Sele	22,000	40 N, 14E	Maize, tomato	Coastal plain
Irrigated fruit crops	Romagna	20,000	44 N, 11E	Fruit crops (peach, apricot, pear, kiwifruit)	Plain

Table 8 Thermal requirements of grapevine varieties estimated using concurrent phenological observations and climate data in the period 1992–2003 (Scaglione et al. 2008)

Grapevine varieties	Thermal requirements	Ranges
Fiano	1625	1575–1625
Trebbiano tosc.	1650	1625–1675
Falanghina	1736	1711–1761
Aglianico	1804	1779–1829
Catalanesca	1865	1840–1890
Malvasia di Candia	1880	1855–1905
Forastera	1950	1925–1975
Guarnaccia	1980	1955–2005

vulnerable to climate variability and change, particularly to amount and distribution of precipitation. The adaptability of 11 olive cultivars was evaluated using hydrologic indicators and requirements.

Grapevine (*Vitis vinifera* L.) is cultivated all over the world mainly in rainfed conditions but also with irrigation and supplemental irrigation practices. This crop is very sensible to environmental conditions (soil type, thermal regime, water availability), particularly as regards grape and wine quality (sugar, acidity, polyphenols, anthocyans, etc.). Soil water availability in response to climate is strongly dependent on soil type (Bonfante et al. 2011, 2012).

Thermal regime largely influences which cultivar may better adapt to climate (Amerine and Winkler 1944), since it is a strong driver of metabolism (Kriedman 1968; Seguin and Cortazar 2005). Generally, grapevine shows a very selective adaptation to the temperature regime during fruit formation and ripening stage. The quality of grapes and wine is strongly dependent on mean air temperature, and ranges of average growing season temperatures are known (Jones 2006).

Thermal indicators. This case study was focused, as regards grapevine, on mean air temperature during the growing season (April–October). Given the morphology of the study area, the spatial distribution of mean air temperature must be determined. The dependence of air temperature on elevation was determined by regression analysis and applied to downscale air temperatures over the study area. At a later stage, a new method was developed using time series of MODIS TIR data to downscale gridded climate data on air temperature (Alfieri et al. 2013a).

Thermal requirements of nine grapevine cultivars, typical of the Campania region, are shown in Table 8, as defined using the Amerine and Winkler index (AWi). The latter was calculated as:

$$AWi = \sum_{DoY=91}^{DoY=304} T_m - 10 \tag{10}$$

where T_m is the mean air temperature.

The probability distribution of the stressor (thermal time) was estimated from observed frequencies for the two climate cases (1961–1990 and 2021–2050). Then the integral of the distribution within the ranges defined by thermal requirements was calculated to evaluate the probability of adaptation (shaded bar in Fig. 8).

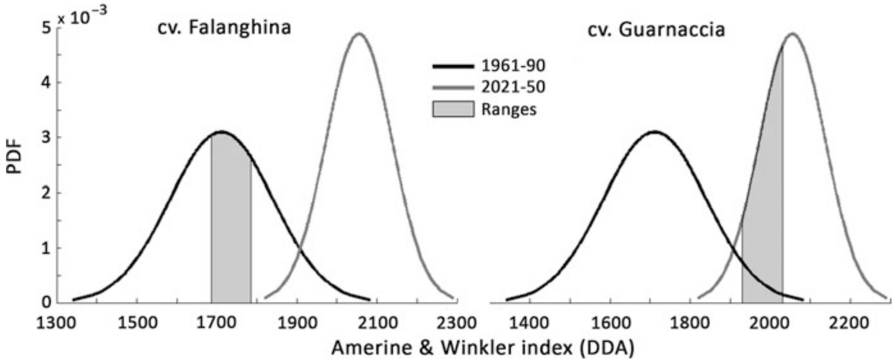

Fig. 8 Amerine and Winkler index distributions in the reference and future climate, compared with the thermal requirement of two cultivars (Falanghina, Guarnaccia); *shaded area* indicates the probability that either cultivar is compatible with reference and future climate conditions

An increase of the Amerine and Winkler index is foreseen under future climate conditions (Fig. 8): this increase reduces the adaptability of some cultivars (e.g., Falanghina, an important variety in the Campania region) and improves the adaptability of some others (e.g., Guarnaccia). A particularly significant consequence is the displacement within the Valle Telesina of areas optimally suited for a specific cultivar. This does not appear when using statistics derived for a single location with the gridded climate data. Therefore, the spatial distribution of air temperature and of the Amerine and Winkler index was estimated and the assessment of adaptability repeated. The spatial distribution of adaptability based on the spatial distribution of the index (Fig. 9) shows that there will still be areas suitable to grow the Falanghina, although such areas will cover a significantly smaller fraction of the Valle Telesina and will be located at higher elevation. On the other hand, the area suitable to grow new varieties, such as the Guarnaccia, will expand very significantly (Fig. 9).

Olive. Water availability during the summer was evaluated using the *hydrologic indicators* calculated with the SWAP model for the reference and future climate cases.

Soil information was derived from an existing soil map at 1:50,000 scale (Terribile et al. 1996). The area includes 47 soil mapping units (SMUs) and about 60 soil typological units (STUs). The available water capacity (AWC, Fig. 10) calculated to 100 cm soil depth is lower in the SMUs located at high elevation because of the smaller soil depth (around 40–60 cm).

Daily values of the hydrologic indicators RSWD and RETD were calculated for each STU and for each year in the reference (1961–1990) and future climate (2021–2050) and then averaged over the period of time applied to the estimated hydrologic requirements. According to the available experimental data set, RETD values were averaged over the whole year, whereas RSWD values were averaged over shorter periods (namely, over the months when irrigation was applied).

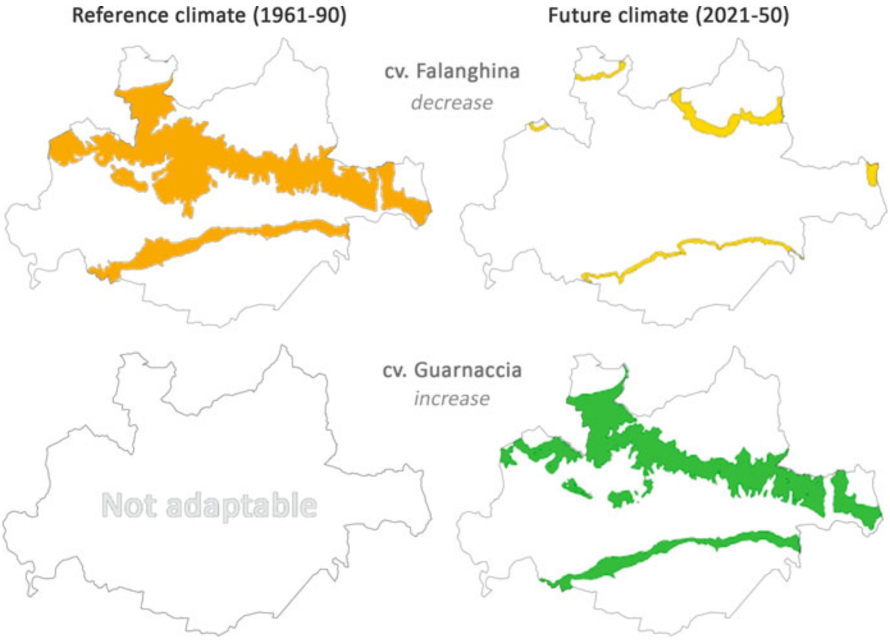

Fig. 9 Maps of areas suitable for the Falanghina (*top*) and Guarnaccia (*bottom*) grapevine varieties under the reference (*left*) and future (*right*) climate cases

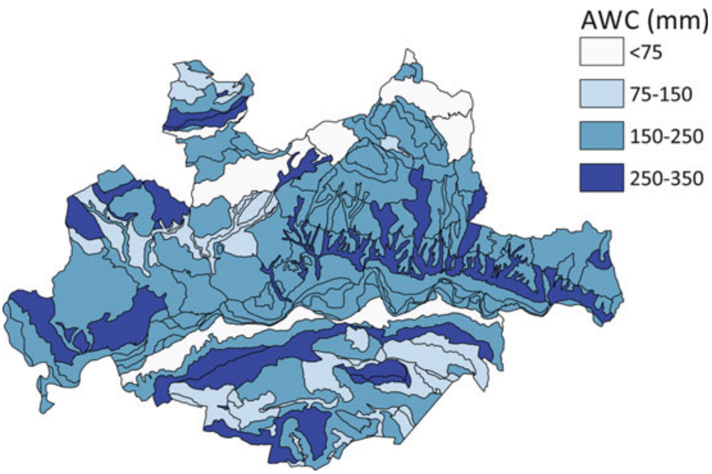

Fig. 10 Available soil water capacity (AWC) in 47 soil mapping units of Valle Telesina

Table 9 Cultivars' specific hydrologic requirements of relative soil water deficit ($RSWD_{cv}$) and relative evapotranspiration deficit ($RETD_{cv}$). Standard errors of requirements and determination coefficients of regressions are reported

Olive cultivar	Values	SE	R^2	Reference
	$RSWD_{cv}$			
Manzanilla fina	0.469	0.104	0.67	Correa-Tedesco et al. 2010
Leccino	0.619	0.028	0.84	Tognetti et al. 2004
Frantoio	0.659	0.048	0.69	Tognetti et al. 2004
Maiatica	0.673	0.022	0.93	d'Andria et al. 2008
Nocellara del Belice	0.695	0.045	0.75	Tognetti et al. 2004; d'Andria et al. 2008
Itrana	0.708	0.062	0.63	d' Andria et al. 2008
Ascolana tenera	0.712	0.037	0.84	d'Andria et al. 2008
Kalamata	0.726	0.062	0.67	Tognetti et al. 2004; d'Andria et al. 2008
	$RETD_{cv}$			
Arbequina	0.315	0.033	0.88	Iniesta et al. 2009
Cobrancosa	0.353	0.015	0.97	Fernandes-Silva et al. 2010
Picual	0.393	0.006	0.98	Moriana et al. 2003

In the study area, most olive groves are currently grown under rainfed conditions. The level of relative yield attained under these conditions was thus identified for each cultivar and indicated as the set point for adaptation (Yr_{adapt}), i.e., the yield level below which yield reduction is unacceptable.

A database of cultivars' *hydrologic requirements* ($RSWD_{cv}$ or $RETD_{cv}$) and their associated errors was set up (Table 9).

Adaptability assessment. For each cultivar, SMU and year the probability (P) of $RSWD_{soil}$ (or $RETD_{soil}$) being lower than $RSWD_{cv}$ (or $RETD_{cv}$) was calculated taking into account the error distribution. Subsequently, the median (M) of the P values for each climate period and SMU was calculated. These M values were pooled into a single distribution whose quartiles (Q) were determined and used to set adaptability ranges. The quartile Q1 had a rather low value (0.005) and very close to the minimum value (0.00) so the following ranges have been considered: from minimum value to Q2 (0.00–0.16), from Q2 to Q3 (0.16–0.67), and from Q3 to the maximum value (0.67–1.00).

The adaptability assessment for cultivars Itrana and Frantoio is shown in (Fig. 11). The adaptability in the future climate was lower than in the reference climate for both cultivars, since a higher soil water deficit occurred in the 2021–2050 period (data not shown). The medians M of the probabilities of adaptation were in the 0.67–1.00 (Q3 to maximum value) and 0.16–0.67 (Q2–Q3) ranges, respectively, for cv. Itrana and Frantoio in the major part of the valley in the reference climate (1961–1990). In the future climate, there was a shift of the median values toward the lower ranges: 0.16–0.67 for cv. Itrana and 0.00–0.16 for cv. Frantoio.

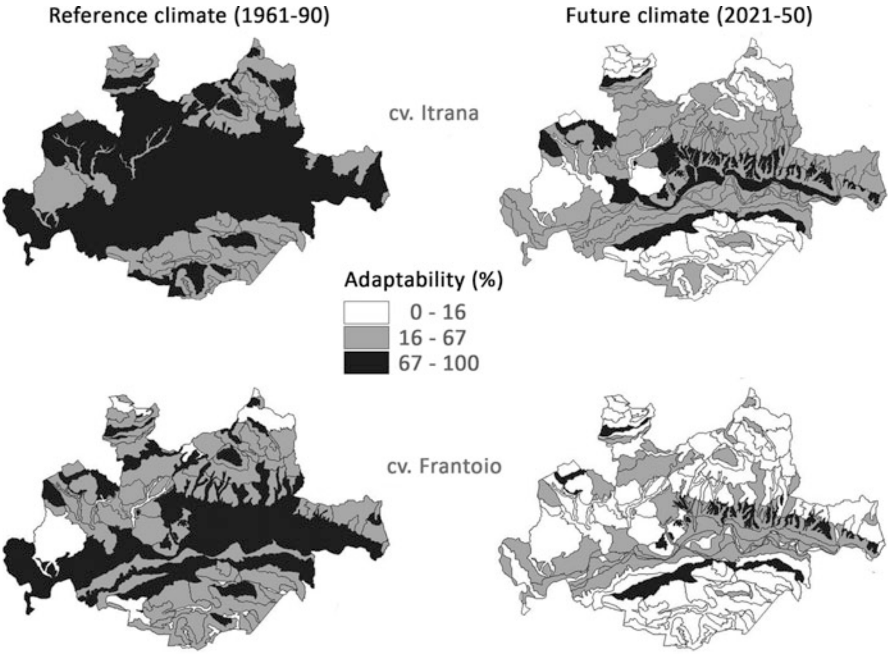

Fig. 11 Probability of adaptation of olive cv. Itrana and Frantoio in the reference (1961–1990) and future (2021–2050) climate in the 47 soil mapping units of the Telesina Valley considering the quartile ranges determined

Table 10 Percentage of the study area where cultivars are adapted with probability > Q3 in the reference (1961–1990) and future climate (2021–2050)

	Percentage of total area > Q3	
Cultivar	1961–1990	2021–2050
Manzanilla	0	0
Leccino	21	4
Frantoio	40	6
Maiatica	53	9
Nocellara	58	13
Itrana	66	14
Ascolana	62	19
Kalamata	68	19
Arbequina	0	0
Cobrancosa	12	0
Picual	44	37

In the reference climate, cv. Kalamata, Itrana, Ascolana, Nocellara, Maiatica, and Picual were adaptable in most of the area above Q3 (Table 10); this means that, for these cultivars, the median M of the probabilities of adaptation was higher than 0.67 in the major part of the valley. The other cv. showed a lower adaptability.

Case Study 2: Destra Sele

The study area "Destra Sele" (22,000 ha) is located in Southern Italy, in the Sele River plain (Campania Region, Province of Salerno). Destra Sele is characterized by five different geomorphic systems (dunes, hills/foothills, conoids, terraces, alluvial plains) with heterogeneous soil parent material that originated very different soil types: mollisols, alfisols, inceptisols, and entisols. The soil spatial variability is very high; thus, 23 STUs and 20 SMUs were identified. The irrigation scheme (15,000 ha) is managed by the consortium "Destra Sele," a state-controlled association of farmers. At present the available water resources fulfill farmers' water demand.

Maize and vegetables crops (tomato, fennel, cauliflower) are grown in the "Destra Sele" area. In this case study, we focused on processing tomato and maize. In the Province of Salerno, maize is grown on 2,450 ha, and the yearly grain production is 13,900 t (ISTAT 2012). Processing tomato is grown on 1,100 ha in the Salerno Province, and the yearly production amounts to 62,000 t (ISTAT 2012).

Vulnerability challenges. In Italy, both maize and tomato are among the crop with the most intensive use of agricultural land, with a high input of water and fertilizers. Maize is rather vulnerable to reduced water availability, and it is most sensitive (i.e., highest potential yield loss) to water stress during pollination, followed by grain-filling and vegetative growth stages. As regards tomato crop, a proper water management is a key factor to obtain high fruit yields. A prolonged water deficit limits growth and reduces yield; fluctuations in soil water content may induce physiological disorders. On the other hand, excess water may determine both reduction in fruit quality and yield and a negative environmental impact, such as nitrogen leaching.

Signature of climate change. Irrigation strategy determines whether and how the climate signal is observed. In a future (and warmer, as foreseen) climate scenario, if water availability would not be limited, the increase in crops' water demand could be fully met by irrigation, and the influence of a (moderately) warmer and drier climate on production could be offset by higher irrigation volumes. The climate signal would thus translate into higher water consumption.

In a more realistic future scenario, water availability will be limited and a suboptimal quantity of water will be delivered to crops, and the climate signal would translate into a soil water deficit. Under water shortage conditions, irrigations are scheduled according to the constraints of irrigation schemes: the signature of climate will thus depend on the matching between irrigation schedule and crop water requirements.

Moreover, intraspecific differences in crop water requirements and resistances to stress influence crop response to climate. Therefore, the interplay of water management strategies and cultivars' hydrologic requirements was explored.

Definition of irrigation strategies. Different irrigation scheduling options were defined and evaluated using the model SWAP, as described above. Schedules were designed for each climate case (1961–1990 and 2021–2050) and for each soil (23 STUs), from optimal irrigation to different levels of deficit irrigation.

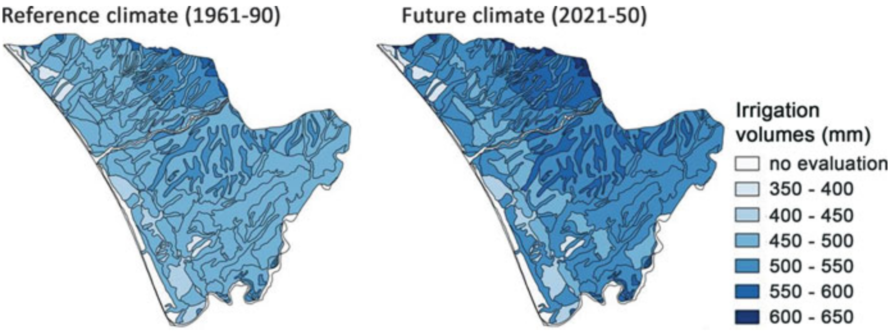

Fig. 12 Spatial patterns of seasonal irrigation volumes for a maize crop at optimal irrigation scheduling in the reference (1961–1990, *left*) and future (2021–2050, *right*) climate

Seasonal irrigation volumes were calculated in each STU, in the reference and future climate. For maize (Fig. 12), seasonal irrigation volumes, averaged over the 23 STU, increased by 8.8 % from reference to future climate for the optimal irrigation case. On average the largest differences in irrigation volumes were obtained in systems of hills/foothills and terraces and in the central portion of the alluvial plains. The increase was smaller for tomato: mean irrigation volumes increased by 2.7 % for the optimal irrigation case. The climate signal was thus different for the two crops. Irrigation volumes in maize and tomato varied due to their inherently different water requirements and to a small shift in their crop cycle, which interacted with the rainfall distribution.

Effectiveness of irrigation. The effectiveness of each irrigation schedule was calculated as the marginal increase of transpiration per unit of irrigation volume:

$$\mathrm{IP} = \Delta Tact/Ir = (Tact_{Ir} - Tact_{Ir\ 0})/Ir \tag{11}$$

where

IP is irrigation performance

$Tact_{Ir}$ (mm) is the seasonal crop actual transpiration for each irrigation case (i.e., 100 %, 80 %, 60 %, 40 %, and 20 %)

$Tact_{Ir\ 0}$ (mm) is the seasonal crop actual transpiration with no irrigation (0)

Ir (mm) is the seasonal irrigation volume applied for each irrigation case

In both climate cases, the irrigation performance was always higher for the maize crop. Optimal irrigation gave the lowest IP, which increased when reducing irrigation volumes up to 40 % of optimal irrigation. The tomato crop had a higher vulnerability to water shortage, with the maximum irrigation effectiveness at 60 %, with a noticeable decline at lower irrigation volumes.

Hydrologic indicators. Soil water availability was described by means of the hydrologic indicators $RSWD_{soil}$ and $RETD_{soil}$. Due to the definition of the irrigation strategies (i.e., optimal irrigation and proportional reduction of water depths in deficit irrigation schedules), the hydrologic indicators' values for each soil and for the same irrigation schedule were similar in the two climate cases (Fig. 13).

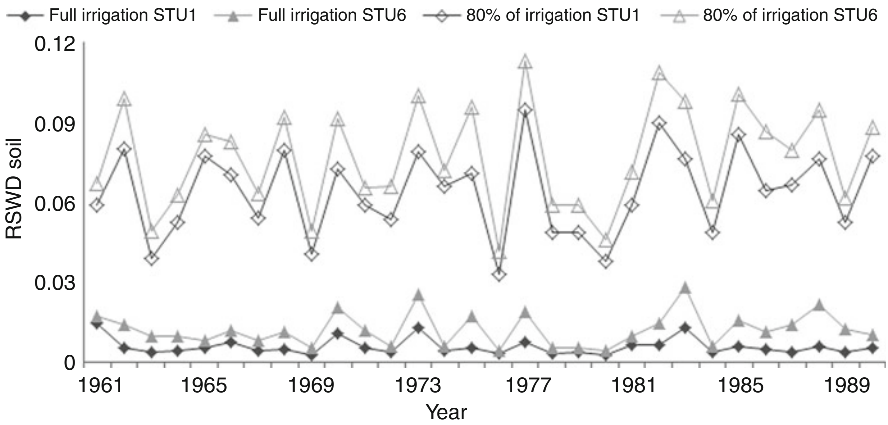

Fig. 13 Reference climate: hydrologic indicator $RSWD_{soil}$ in the maize crop, calculated for soil typological units (STUs) 1 and 6 at two irrigation levels (optimal irrigation and 80 % of optimal volume)

$RSWD_{soil}$ values are averages of daily data throughout the crop cycle. STU 6 showed a higher sensitivity to the reduction of irrigation volume. Within each soil, the interannual variability was significant, particularly at the 80 % irrigation level.

Hydrologic requirements were determined for five maize hybrids and four processing tomato cultivars (Table 11). Maize hybrids of FAO maturity class between 600 and 800 are commonly used in the study area.

Yield response functions of maize cultivars were represented by a linear regression model (Djaman et al. 2013). The yield set point for adaptation $Yr_{adapt} = 0.9$ was applied. The corresponding value of RETD was applied as the cultivar-specific hydrologic requirement ($RETD_{cv}$) (Fig. 5).

The available data set on tomato cultivars allowed to represent yield response functions to relative soil water deficit (RSWD) according to a threshold-slope regression model. The value of the indicator (RSWD) corresponding to the threshold of the response function was set as the cultivar-specific hydrologic requirement ($RSWD_{cv}$). An error of estimation, due to the empirical relationship between relative yield and water availability data, was associated to each $RSWD_{cv}$ (or $RETD_{cv}$).

In Table 11, values of $RSWD_{cv}$ and $RETD_{cv}$ span quite different ranges. Besides intraspecific differences in crop responses to water availability, this is due to the different phases of the crop cycle in which the requirements were determined.

Adaptability Assessment

Probability of adaptation. By comparing soils' indicators with cultivars' requirements, the adaptability was evaluated for all cultivars, soil mapping units, and climate cases, at irrigation levels 100 %, 80 %, and 60 %. The potential spatial distribution of maize hybrids and tomato cultivars was thus assessed in the study area.

Table 12 Probability of adaptation: quartiles of the distributions of the medians

	Maize	Tomato
Q1	0.01	0.93
Q2	0.97	0.99
Q3	1	1

The ranges of the probability of adaptation were estimated for all cultivars (Table 12).

The second quartile (Q2) of each distribution was set as the lower limit for full adaptability. A cultivar was considered adaptable, therefore, when the median of its probabilities, in a soil and in a given climate case, was equal to or higher than Q2. In analyzing the probabilities of adaptation of tomato cultivars, the data values higher than Q2 were grouped, being the Q2 value (0.99) quite close to Q3 and to the maximum value.

As regards maize's probability distribution, the medians of a 25 % subset lay in a wide range of probabilities (i.e., $0.01 < P < 0.97$), from almost fully adaptable (medians close to Q2 = 0.97) to very low probabilities of adaptations (medians close to Q1 = 0.01). Another subset of medians showed probabilities of adaptation close to zero (i.e., lower than Q1).

Evaluation of cultivars' adaptation. At optimum soil water availability, all cultivars were adaptable (i.e., medians always higher than 0.97 and 0.99, for maize and tomato, respectively). However, in the future climate, the full adaptability could be maintained by increasing irrigation volumes, as discussed previously. Therefore, adaptability was assessed in a more realistic future scenario, i.e., at increasing scarcity of water resources. In both crops, adaptability resulted to be strongly dependent on soil hydrologic properties and cultivar biodiversity.

Figure 14 shows the spatial distribution of the adaptability of two maize hybrids (Manuel and Dekalb C5740RR) at 80 % irrigation level. Manuel resulted to be

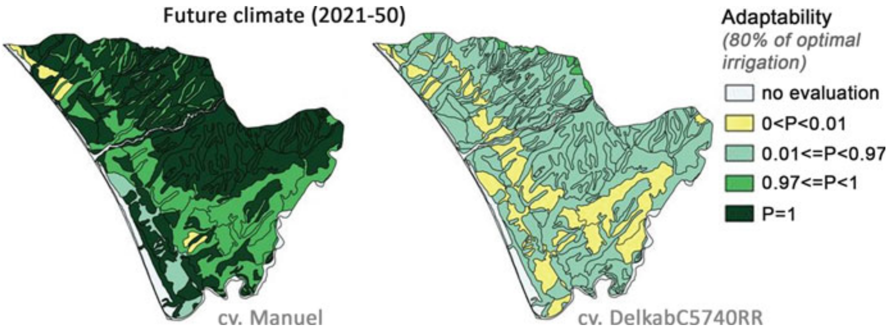

Fig. 14 Extent and distribution of adaptability of maize hybrids Manuel (*left*) and Dekalb C5740RR (*right*), at 80 % irrigation level in the future climate (2021–2050) in the soil mapping units of the "Destra Sele" area. The probability ranges are set according to quartiles

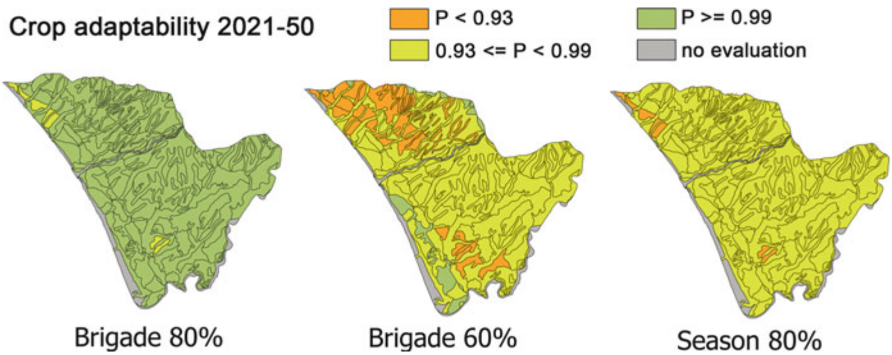

Fig. 15 Extent and distribution of adaptability of tomato cultivars Brigade (*left* and *center*) and Season (*right*) at 80 % and 60 % irrigation level in the future climate (2021–50) in the mapping units of the "Destra Sele" area. The probability ranges are set according to quartiles

adaptable (i.e., medians higher than 0.97) in 94 % of the total area and in some dunelike mapping units was not adaptable. The Dekalb hybrid, at 80 % irrigation level, was adaptable only in 8 % of the area. The choice among hybrids would therefore allow to sustain current crops' production at irrigation performances values higher than at optimal irrigation. At lower irrigation level (60 %), both hybrids were not adaptable (map not shown).

As regards tomato, the spatial distribution of adaptability for two cultivars (Brigade and Season) is shown in Fig. 15. The cultivar Brigade proved to be quite resistant to water shortages, being adaptable (i.e., medians higher than 0.99) at 80 % irrigation level, in 98 % of the area (Fig. 15, left); some dunelike areas, as with maize hybrids, were unsuitable. At the same water regime, cv. Season was adaptable with a lower probability (i.e., $0.93 \leq P < 0.99$) in the same area (Fig. 15, right).

With scarcer irrigation water (60 %), the probability of adaptation was $0.93 \leq P < 0.99$ in 83 % of the area for cv. Brigade (Fig. 15, center) and in 5 % of the area for cv. Season (map not shown). Due to the hydrologic requirements of the cv. Brigade, the highest irrigation performance (IP = 0.75) could thus be achieved, although at the expense of a decrease of the probability to attain optimal yield (0.93 vs. 0.99).

Case Study 3: Romagna

The *study area* is about 58,800 ha in the alluvial plain of Emilia-Romagna region (Italy), located within the cities of Lugo, Faenza, and Imola. Most of cultivated area is dedicated to fruit crop production (peach, apricot, pear, and kiwi).

Emilia-Romagna is the first region for peach (*Prunus persica* L.) cultivation in Italy. The crop represents more than 30 % of the regional agricultural area with 24,375 ha and 498,378 t of total production (ISTAT 2011). The subhumid climate of the area is particularly favorable for peach cultivation, while irrigation is a determinant for productivity since it improves the crop yield, fruit size, and quality (Battilani and Ventura 1996).

Vulnerability challenges. Fruit trees have different response to temperature and water availability depending on phenological development. The knowledge of peach cultivars' development cycle and timing and duration of phenological phases is important to define cultural practices, such as thinning, pruning, fertilization, phytosanitation, and irrigation and to identify the cultivars most adapted to a specific climate. Our objectives are:

– To describe the changes of phenological phases of several peach cultivars between reference and future climate by estimating timing and duration of phenological phases.
– To evaluate the consequent impact on the frequency of occurrence of extreme maximum and minimum temperatures that determines adverse effects on cultivars during specific phenological phases. This requires at first the characterization of thermal requirement for critical phases.

Thermal requirements. Time of phenological phases is regulated by the temperature range and by the cultivar response to temperature (Boonprakob et al. 1992). Cultivar-specific thermal requirements for each phenological phase were estimated by means of phase-specific thermal times using 3 years of phenological observations (2009–2011) on different cultivars (May Crest, Big Top, Stark Red Gold, and Royal Glory) within the "Romagna" study area. Thermal requirements were calculated by phase-specific models (Table 6) using meteorological observations at a ground station located at Imola. Baseline temperature for GDD calculation was set at 10 °C.

Table 13 Estimated changes (days) in the dates of peach phenological stages; positive values indicate later dates; negative values indicate earlier dates

Cultivars	Rest completion	First flowering	Full bloom	Fruit developed	Ripening
May Crest	6.7	−9.8	−10.1	−12.3	−12.4
Stark Red Gold	5.9	−9.2	−9.3	−14.8	−16.2
Big Top	6.1	−9.1	−9.9	−14.1	−15.6
Royal Glory	5.8	−9.1	−13.3	−14.6	−15.8

Two different requirements on critical temperature were considered:

1. High temperatures above which photosynthesis is reduced to a level that no appreciable growth occurs (Richardson et al. 1982).
2. Average temperature that determines 10 % bud kill after 30 min exposure was set to −2.7 during flowering and −2.5 during fruit development (Proebsting and Mills 1978).

Dates of occurrence of phenological phases. The dates of occurrence of each phenological stage were calculated in both reference and future climate using the cultivar- and phase-specific thermal requirements. The results (Table 13) indicated for future climate a delay in rest completion of about 6 days for all the cultivars. The flowering is anticipated by 9–10 days. Earlier ripening was also predicted, and the difference was larger for medium and late cultivars (respectively 15 and 16 days) than for early cultivar (12 days).

A Student's *t*-test was performed to evaluate the significance of the differences between the dates calculated for two climate cases (at the 5 % significance level) giving a good significance for all the phases and cultivars (except for Big Top ripening date).

Lopez and De Jong (2007) found that peach fruit size increased with the number of days between full bloom date and a reference date (defined as the date on which 80 % of sliced fruits have hardened pits near their distal end, plus 10 days). Thus peach was negatively affected during years with high spring temperatures since trees could not supply resources rapidly enough to support their maximum potential fruit growth rates. A shorter duration of phenological phases, therefore, can have consequence on fruit production even if, in our knowledge, current scientific research is still insufficient to give a quantitative description of the process in terms of thermal requirements.

Cultivars' adaptability to extreme temperatures. The frequency of crop-specific critical temperatures for each phase and cultivar has been calculated for reference and future climate taking into account predicted shift in timing and duration of phenological phases.

In the future climate case, the probability of occurrence of critical minimum temperature increases (Table 14) during flowering due to the effect of phase advancement, which exposes the crop to colder climate. Thus, the exposure to critical minimum temperatures is larger for earlier cultivars (May Crest).

The increase of mean temperature predicted for the future climate case increases the frequency of maximum critical temperature during fruit development and more significantly during ripening (Table 14). On the other hand, predicted earlier ripening reduces the impact of high critical temperatures (Fig. 16). High standard deviation suggests a large interannual variability of extreme events in the future climate case.

Conclusions and Perspectives

The work summarized in this chapter shows that the intraspecific biodiversity of agricultural crops has indeed the potential to offset the impact of climate variability and change without altering the current production systems. The assessments of adaptability of the production systems analyzed in the case studies (rainfed agriculture, irrigated herbaceous crops, and irrigated fruit crops) apply to the differences between a reference (1961–1990) and a future (2021–2050) climate case. For each crop evaluated, the adaptability of several alternate cultivars was assessed, although quantitative thermal and hydrologic requirements could be determined for relatively few cultivars in relation with the number of known and widely used cultivars for each crop. This is due to a generally insufficient documentation of climate conditions in literature on field trials of agricultural crops. To some extent, the inaccuracy of estimated thermal and hydrologic requirements is accounted for by the error of estimate and its distribution taken into account in the probabilistic assessment of adaptability as proposed and applied in the studies described in this chapter.

Climate stressors have different impacts on crop development, namely, extremely low and extremely high temperatures may halt crop development irrecoverably when occurring in specific phenological phases. Accordingly, adaptability should be evaluated by considering climate stressors in the sequence: (1) duration and dates of phenological phases, (2) mean temperature in specific phenological phases, (3) extreme temperature in specific phenological phases, and (4) water deficit.

The case study on rainfed agriculture did show that extensive substitution of olive and grapevine cultivars would be needed under predicted climate conditions. This would allow the preservation of the current production system but at the price of significant investments.

The case study on irrigated herbaceous crops did show how closely the choice of cultivars and the design of irrigation schedules are related. In addition to predict climate, changes in the available water resources should be estimated and irrigation strategies developed accordingly. Specifically, moderate deficit irrigation schedules and the choice of cultivars resistant to moderate water stress provide real options to adapt to scarcer water resources for irrigation.

The case study on fruit crops demonstrated that the dates of phenological stages must be evaluated first as a function of climate in order to assess the impact of

extreme temperatures and irrigation water use. Particularly, it was shown that interannual variability of phenological stages has a significant impact on irrigation water requirements.

Acknowledgments The work was carried out within the Italian national project AGROSCENARI funded by the Ministry for Agricultural, Food and Forest Policies (MIPAAF, D.M.8608/7303/2008).

The authors are grateful to colleagues at CNR-ISAFOM for supplying some cultivars' data sets: dott. Riccardo d'Andria, Dr. Antonella Lavini, and dott. Giovanni Morelli for olive and Dr. Cristina Patanè for tomato. The contribution of CRPV (Research Center for Crop Production, Cesena, FC, Italy) that provided data on fruit crops is also acknowledged.

Glossary

Climate change Statistically significant variation either in the mean state of the climate or in its variability, persisting for an extended period (typically decades or longer)

Climate variability Variations in the mean state and other statistics (such as standard deviations, the occurrence of extremes, etc.) of the climate on all temporal and spatial scales beyond that of individual weather events

Adaptation Options to Improve Food Security in a Changing Climate in the Hindu Kush-Himalayan Region

Sarah Marie Nischalke

Contents

Abstract

This paper analyzes the food security situation in the Hindu Kush-Himalayan region (availability, access, utilization, and stability) and new challenges, emerging from climate and socioeconomic change. It addresses the challenge, particularly for policy makers, which of the various adaptations presented by science to choose and implement. All dimensions of food security will be affected by climate change impacts. Currently many different autonomous and

planned adaptations are happening independently in the region and are not assessed or supported in a coordinated way. Prioritization is needed to effectively prepare the farm and food systems for changes to come.

The list of identified priorities contains, first, planned adaptations for short-term improvements in disaster preparedness (early warning systems, natural protection, and insurance schemes) and, second, adaptations that with a long-term perspective test and upscale options for local water storage and maintenance. The third priority is diversification of agriculture with a focus on localized climate- and nutrition-sensitive farming (crop diversity and climate-resistant crops with good nutritional performance). The fourth priority is to enable rainwater harvesting on household level through dissemination of knowledge on simple technologies and quality management. The fifth priority is to enable autonomous adaptation in the form of making better use of remittances and nonagricultural income sources to increase livelihood security.

Keywords
Hindu Kush-Himalaya • Mountain food security • Climate change • Adaptation options

Introduction

The Hindu Kush-Himalayan (HKH) region, which hosts one of the poorest and most vulnerable communities in the world, is highly dependent on agriculture and, of late, is facing major climate change as well as socioeconomic stress. All dimensions of food security, availability, access, utilization, and stability are affected. Mountain farmers from Yunnan (China), the Far West and Midwest in Nepal, to Assam in India report problems of low productivity and too much and too little water in an area that already is a topographically challenging terrain for agriculture. Farmers practicing predominantly rainfed agriculture struggle with the erratic climate, a late onset of monsoon, droughts, and flooding. Despite the condition of natural capital resources, migration leads to labor shortages and a restructuring of farming systems in the region. Cash crops of low labor intensity often serve as relief (tea in Assam, tobacco in Yunnan, fruit trees in Central Nepal) and move the system away from food self-sufficiency. Climate and sociocultural change also impact food prices, potentially deteriorating livelihoods and devaluating food entitlements because of an increased dependency on purchased foods (ICIMOD 2008). In addition, nutritional practices in mountains already have strong limitations, and nutritional environments often do not meet necessary requirements for nutritional security (Ebi et al. 2007).

The challenge, particularly for policy makers, is which of the various options and adaptations presented by science and practitioners to choose and implement. To improve food security, the choice should not fall between the different dimensions of food security but for the development of integrated strategies, for example, the promotion of climate- *and* nutrition-sensitive crops.

By reviewing recommendations for HKH, six categories of adaptation options were identified: (1) *Information management and research*: connecting scientific and local knowledge and recommending coordinated databases/research designs and new communication channels all to enhance knowledge management; (2) *Institutional and social innovation*: exploring options to respond to the increased complexity of systems through redefinition of social capital, farming and institutional flexibility, and new approaches in agricultural development and investment; (3) *Modification of agricultural practices*: suggesting usage of high-yielding varieties, tree crops, bioorganic farming, climate-resilient farming systems, and no-regret adaptation strategies to improve food security and strengthen resilience; (4) *Water resource management*: exploring different technologies of demand, supply, and quality management, including IWRM and rainwater harvesting; (5) *Financial security*: investigating adaptation potential of crop insurance scheme, microfinance, and migration; and (6) *Livelihood diversification and integrated approaches*: combining adaptation strategies with a focus on strengthening and diversifying livelihoods beyond agriculture.

There is no time to wait for perfect knowledge and a panacea does not exist but a need to act now and to prioritize. A prioritization can help the different HKH countries in strategizing adaptations for the mountains to improve food security. The analysis for this chapter is based on primary data, collected for the Himalayan Climate Change Adaptation Programme (HICAP), a collaboration among the institutions CICERO, ICIMOD, and UNEP GRID-Arendal. With the help of the Vulnerability and Adaptive Capacity Assessment (VACA) framework, developed in 2012, quantitative data was collected from five river basins in China, India, Nepal, and Pakistan (Upper and Eastern Brahmaputra, Koshi, and Upper Indus; data from Salween and Mekong basin is still under processing) to assess livelihood vulnerability and adaptive capacity and promote adaptation strategies to strengthen community resilience. This data was confronted by secondary literature on climate projections and adaptation options for HKH mountains in order to develop policy priorities in adaptation.

Scientific Gaps in the Analysis of Mountain Food Security and Adaptation

Though the literature on food security in the HKH region is vast and diverse, most of it has little relevance to mountain areas as it does not tackle the specificities of these *fringes of production* and provides little information on specific adaptation strategies tailored to these areas. This is due to the marginal role of mountains in national food security and negligible votes in these areas.

Digging through the plethora of literature on food security issues in the HKH countries makes one thing clear – there are three approaches to the topic of adaptation, which shelter a conflict in themselves: Do we prepare farmers for the unpredictable or do we prepare farmers for the predicted? Or do we improve agricultural techniques without putting emphasis on climate change, so that adaptation only is a positive side effect from technological progress? Adapting to the predictable assumes that strategies can be based on climate, crop simulation, and economic modeling. Estimates and research provide indicators for policy recommendations and planned adaptations mostly in the form of new technologies (Hussain and Mudasser 2007; Pandey et al. 2003; Kalra et al. 2007). The second camp bases its assumptions on uncertainty and the need to be well prepared for the unpredictable (Aase et al. 2010; Nadeem et al. 2012; Su et al. 2012). Instead of focusing on crop development, it means to strengthen capacities and flexibility, to extend knowledge and skills, to improve livelihoods, to increase diversity, and to reduce vulnerabilities, so that the strength to cope with stress and adapt to new circumstances increases. A comparative study in the Horn of Africa has shown that farmers with very limited capacities are not capable to adapt agricultural practices to new circumstances (Kristjanson et al. 2012). The third camp just deals with technical aspects of agricultural techniques, water availability, or productivity either without referring to climate change impacts or mentioning it in a subordinate clause only (Abrol 1999; Joshi et al. 2007; Quadir et al. 2007; Sharma 2009). One conflict pole was found in the fact that adaptation is highly complex and localized and needs locally adapted solutions, whereas for planned adaptation, a broad outreach and synergies, transferability, and upscaling are crucial.

Food Security Situation in HKH Mountains: Distinct from Food Insecurity in the Plains

For planning adaptation options, it is important to understand the root causes of food insecurity, their socioeconomic dimensions, as well as direct and indirect impacts of climate change on food production. Food security defined as “when all people, at all times, have access to sufficient, safe and nutritious food to meet their dietary needs and food preferences for an active and healthy life” (FAO 2009) is an acute problem in mountain areas. Half of the 58 most alarming countries in the Hunger Index have mountainous terrain (FAO 2012).

The challenges of ensuring food security are more daunting in mountains than plains due to limited arable lands, harsh climates, difficult terrain, and unfavorable biophysical conditions and because they are characterized by inaccessibility and fragility combined with political and social marginalization. In Nepal, for instance, food insecurity has become a concern in Mid- and Far-Western Hill and mountain districts. Food security has been a constant concern in other parts of the HKH region (Dame and Nuesser 2011). In many places, the average food self-sufficiency of rural HHs is between 3 and 6 months only. Besides limitations of arable land and land fragmentation, other reasons are declining, and stagnant agricultural productivity rates in predominantly rainfed agriculture and land use change at the cost of food production as well as a declining carrying capacity of the forests and rangelands (Nautiyal et al. 2007; Tulachan 2001). But also poor infrastructure and prices as well as deficient nutrition practices and seasonal disruptions in availability constrain food security. Further downstream, in the plains large populations are confronted by limited land resources and growing water stress, which provides more explanation why 51 % of the region's population is food-energy deficient (Rasul 2012). Around 150 million people in HKH mountains (Hunzai et al. 2011) are poor due to limited income-generation opportunities and exhibit high malnutrition rates.

The mountain farm households with small landholdings are increasingly exposed to economic, physical, and social risk and highly vulnerable to climate change and extreme weather events. Despite the challenging terrain for agriculture, farmer communities in the HKH mountains have established semi-subsistence farms that used to be well adapted to microclimates and make use of the ecosystem services that the Himalayas provide (crops, forest products, medicinal herbs, honey, etc.).

The HICAP research showed that more than half of the farming households do not even own 0.64 ha farmland that FAO (2010) estimates as necessary to enable a farmer to self-sufficient production, not to speak about setting up a social safety net or having an income source. Rural households without land are the most vulnerable to food insecurity; they usually lease land or use share-cropping arrangements. The diversity in crops and diets is low in most districts, and people consume on average the smallest number of food groups compared to the lowlands and urban areas. Even though the average quantity produced in cash crops (330 kg year) is low, it is perceived as a silver bullet to boost agricultural incomes that are threatened by environmental change. The farming systems used to be characterized as labor-intensive low-input systems. Now cash crop production fosters intensification. Chemical fertilizers replace soil fertility management, herbicides replace intercropping systems (Murray 2010), and diversification as a coping strategy of the region is gradually replaced by monocultures. Hence, these "new" systems need to be reevaluated under climate change conditions.

The farming systems are under immense stress due to shifting of flowering and ripening times and delayed sowing, and often replanting seeds is required to get a viable output. Because most of the agriculture in HKH is rainfed, water security is vital in order to achieve food security. Only 15 % of households in Eastern Brahmaputra basin (India) and 44 % in Koshi basin (Nepal) use irrigation, and many face severe water problems already. In Koshi water is sufficient only on an average of 4.6 months and in Eastern Brahmaputra for 3.2 months. Less availability of water for drinking, cattle, and agriculture requires adaptations.

Because people rely less on subsistence production, access to food has changed its face as well. In India, purchased food contributes to 46.8 %, and in Nepal 42.7 %; in Pakistan, food consumption in the mountain states contributes to 63.1 %; and almost 15 % would not be food secure without public distributions or food aid (see Table 1). Farmers depend less on environmental conditions and weather but become more vulnerable to market developments and prices as well as stability in labor markets and business revenues. Price hikes become a double-edged sword. While cash crop revenues increase, more has to be spent on food. While food prices go down for household consumption, also the cash crop revenues go down. Volatile global food prices result in higher real prices in the medium term.

Table 1 Percentage contribution of sources to household food consumption in the last 12 months HICAP PVA

Basin	Self-produced	Bought from store	Food aid NGO/IO	Food received from friends/ relatives	Food subsidies/ PDS	Shared crop on leased land	Others
Brahmaputra (India)	34.39	51.02	0.11	0.82	8.95	2.08	2.53
Koshi (Nepal)	53.67	44.20	0.23	0.68	0.14	0.9	0.18
Indus (Pakistan)	29.81	64.70	5.20	0.13	0.07	0	0
Total	**40.84**	**50.99**	**1.10**	**0.64**	**3.95**	**1.24**	**1.16**

In 2008/2009 this burden became visible, when the world saw a major food price crisis, where prices in South Asia and China skyrocketed and many farmers struggled to feed their families.

Maintaining a healthy nutritional status is extra challenging for mountainous populations. The growing seasons are short, the lean periods long. Plant growth is reduced due to cold temperatures, and only limited varieties of crops can grow on rough terrain. Nutritional security is threatened by monotonous diets, low dietary diversity (especially during winter), hard work, and compromised hygiene. The high work burden of women and lack of knowledge prevent good child feeding and caring practices, and existing gender roles and family hierarchies also lead to food deprivation of females (de Schutter 2012). The burden of disease from miserable hygiene and sanitation conditions and unsafe water is substantial. A large number of households use open pits as toilet facilities and open springs for drinking water. The steep slopes and harsh conditions reduce access to the often poor-quality health services. Stunting (height for age) as the indicator of chronic malnutrition is very high in mountains. In Nepal stunting prevalence in mountainous regions stands at 61.0 %, reaching up to 70 % in hot spots, as compared to the hills (46.4 %) and Terrai (43.5 %) (National Planning Commission 2013). In China stunting rates have been reduced to 9.4 %, but geographical variation is immense. In some mountainous states such as Guizhou or the district of Guangnan (Yunnan – 21.2 %), stunting rates cross 30 % (Zhao et al. 2013).

The most food insecure households are the ones with very little or no access to land and a high dependency on wage labor for income, a high dependency on rainfed agriculture and subsistence farming, and a small crop and income diversity. Many of them face severe water problems and labor shortages on their farms and are highly indebted. The resilience of farm households to shocks ranging from family sickness to price shocks, livestock disease, flooding, drought, or erratic rain is very low. Consequentially, the number of households with low capacity to cope with or adapt to climatic, environmental, or socioeconomic events is high. People lack knowledge and adequate responses and have no backup (food stocks, savings, insurance). These households have little capital and endowments that can be translated into food entitlements and find themselves in a situation of cumulative vulnerability: weak endowment structure, low income profile, frequent encounter with shocks, and land degradation or low productivity, which result in a very poor food and nutrition security situation.

Climates of Food Insecurity

The IPCC report projects rising temperatures, high rainfall variability, and increases in extreme weather events for Asia, which are likely to result in declining agricultural productivity, especially of cereals. Water and agriculture will be the most vulnerable sectors affected by climate change. Agriculture in HKH will be hit particularly by changes in water sources (Cruz et al. 2007). Douglas (2009) refers to peak flows in major rivers, which are likely to change, and food crops to be disrupted by variation in monsoon onset and duration and frequency of floods and droughts. Stresses will multiply due to urbanization and industrialization trends, which put pressure on resources, land use and cover, biodiversity, and human health. Crop yield decreases particularly for South Asia are projected at up to 30 %.

However, IPCC lacks data on assessments for the HKH mountain region because hydrometeorological information for historical time series is scarce and weather stations are too few. However, they are important parts of the earth's ecosystem, providing services not only to mountain communities but also to lowland populations (Beniston 2003). The Himalayas, also known as the third pole, have a crucial role in storing water through 50,000 glaciers, glacial lakes, and permafrost. HKH is one of the richest and most varied ecosystems, known for its variety in altitudinal vegetation belts with an abundant high biodiversity, but climate change effects are understudied. And food security depends on both availability of water and biodiversity. Rigorous research and policy advocacy are the needs of the day (Singh et al. 2011).

At first sight climate change adaptation in mountain areas suggests a strong focus on availability and market access as the natural capital resources here are the most dominant "currency" and livelihoods beyond subsistence widely depend on infrastructure and accessibility of marketplaces. There is no disaggregated data for mountains, but especially with regard to availability, yields of rainfed production of corn (40 %), rice (10 %), and wheat (5 %) are projected to decline (Singh et al. 2011). Livestock productivity is also likely to be affected by degrading animal health and declining milk yield.

Overall, the natural conditions for agriculture are projected to change. Cruz et al. (2007) point out that high temperatures enhance transpiration of plants and lead to increases in water demand and change soil texture. The evolution of weed species in warmer temperatures, vertical migration of species, reduction in winter kill of insects, and speeding up of pathogen growth rates (abetting diarrheal diseases and malnutrition) will pose further challenges to agricultural productivity and food security in mountains. It is not likely that negative effects can be outbalanced by longer growing seasons, improved timings of threshold events in crop development, or CO_2 fertilization. High temperatures also put pressure on transport and storage infrastructure, which is deficient in the region.

Decreasing agricultural output directly hit the rural poor, who depend on it for livelihood, while urban poor will suffer from future food inflation because they have to purchase food stocks. The new dependency on cash crops is likely to increase vulnerability to markets and prices in context of climate change (ICIMOD 2008), which will devaluate food entitlements if livelihood security deteriorates. At the same time nutrition is endangered to worsen through destroyed crops, livestock, and other livelihoods. However, new agricultural opportunities in the form of higher crop and diet diversity could also have positive effects on nutrition. All in all, it is expected that the health environments will change: with increased incidents of flooding or water scarcity because the risk of water-related diseases rises (Adshead et al. 2010; Ebi et al. 2007) and can adversely affect nutritional absorption. Therefore, an eye should be kept on impacts of climate change on nutrition practices (diversity) and sanitation as well as potential related adaptation options in the mountains. Competition for resources and land might add further pressures because people from flood-affected and arid areas are likely to move to the hills and mountains (e.g., in Bangladesh the Chittagong Hill Tracts) (Singh et al. 2011).

Socioeconomic Change in Mountain Communities and Implications on Food Security

Farm households in HKH face transformation in social structure that also affects the farming system's structure. An increasing dependency on purchased food shows that households cannot or do not want to sustain their household requirements from own production anymore. Farmers allocate resources differently; invest less time, labor, and money in subsistence agriculture; and focus more on off-farm employment or business activities. Impacts of climate change (declining yields and water sources, food insecurity, etc.) are one reason, but farmers are also more aware of opportunities outside their location and abroad. Communication technologies such as mobiles, radio, the Internet, and television promise income opportunities and a different future, and reduced transport costs enable people to travel. One effect is that many people migrate.

Migration is not new to this region, but it currently happens to an unknown extent and to a rising number of destinations. It is becoming the number one adaptation measure, boosted by the economic upturn in urban centers, e.g., in the Gulf countries and Southeast Asia. 15 % of the 200 million laborers worldwide come from HKH countries and many of them from mountain regions (Banerjee et al. 2011). This was reflected in the HICAP data, which showed that off-farm employment has become a popular livelihood strategy (see Table 2). In 2010 households in India received remittances from abroad of 55 billion USD, 51 billion in China, 9.4 billion in Pakistan, and 3.5 billion in Nepal. Migration is a challenge, but as a source of social and financial remittances, it also provides benefits (ibid.). Not only does it help to fulfill basic needs (e.g., food), but it can also support people

Table 2 Households with employment outside the farm (in percent, female participation in brackets) HICAP PVA

Migration and off-farm employment	India (Eastern Brahmaputra)	Nepal (Koshi)	Pakistan (Upper Indus)
Migration for work (inside the country)	**11** (3)	**18** (6)	**21** (>1)
Migration for work (abroad)	**1** (>1)	**24** (1)	**4** (>1)
Off-farm employment (business) for at least 10 months/year, at least one family member	**26** (3)	**19** (8)	**37** (3)
Off-farm employment (salary) for at least 10 months/year, at least one family member	**24** (11)	**32** (8)	**54** (8)

to recover from disaster (reconstruct houses and rebuild livelihoods after floods), prepare for disaster (invest in irrigation in drought areas, boats in flood areas), and adapt to climate change (purchase drought-resistant seeds or technology). In HKH migration is a highly engendered process (up to 40 % of males absent) and leads to feminization of agriculture and the whole mountain economies. The drudgery on women increases and negatively affects agricultural outputs, time allocation for food preparation, and caring of children and livestock. Especially if migrants are in poorly paid employment, remittances do not compensate for the missing male workforce and the money is not sufficient to employ laborers – so people are at risk to be less food secure than before. In contrast, if remittance earnings are good and women become the de facto heads of households, they tend to take better decisions for child nutrition and spend more on education and health of children. But often enough then agriculture is abandoned. Nowadays agriculture is perceived as a "socially demeaning occupation" in the region, meant for the illiterate (Hoermann et al. 2010, p. 7). The shift from subsistence to market orientation and out of agriculture shows this change in values. Agriculture as it used to be is not viable anymore, and in many places it does not provide income to fulfill material needs and health and education requirements.

Adaptation Options to Improve Food Security in HKH

Nowhere else in the climate change discourse is the issue of adaptation more present than in food production and security. Here also a trend from single technological solutions toward structuring adaptation along the value chain from production to consumption can be seen (Douglas 2009; Jhoda 1996) to tackle institutional, structural, and economic weaknesses of the food system. One reason is that the need to develop innovative forms of production and distribution or storage has been recognized. Integrative approaches such as the food-water-energy nexus (Rasul 2012) are also recommended to address the high interdependence of food, water, and energy security. Even though climate change adaptation has not much been investigated through the gender lens, women's contribution in agriculture and as food managers is more and more recognized and investigated (Krishnaraj 2006; Rao 2006).

Table 3 Applied coping strategies by households in three river basins (in percent, in the last 10 years) HICAP PVA

Coping strategy	Eastern Brahmaputra (India)	Koshi (Nepal)	Upper Indus (Pakistan)
Given up planting certain types of crops (livestock)	15 (2)	16 (9)	22 (18)
Introduced new crop or livestock varieties	11	17	30
Changed grazing practices	>1	7	16
Changed farming practices, e.g., delayed sowing/harvesting	14	15	33
Taken on new off-farm activities/ migrated for work	23	15	20
Farmland was left fallow/farming abandoned	3	11	6
HH invested in irrigation (community investment)	6	7	2
Community invested in irrigation	4	3	9
HH invested in disaster preparedness	10	5	13
Community invested in disaster preparedness	3	1	9
Have done nothing	76	51	4

Farmers are struggling to maintain availability in food security in the context of climate change and environmental degradation. The perceived changes are also reflected in adaptations in the investigated river basins, where the research showed that coping practices are applied (see Table 3). Most common is the change in farming practices (21 %): delayed sowing (especially paddy) and harvesting but also resowing of crops such as maize, barley, buckwheat, or vegetables. Traditional staple crops such as paddy, maize, or wheat are given up (18 %), and livestock varieties such as cattle and goats are abandoned by 10 % of households. The percentage of adaptations in disaster preparedness and irrigation also shows that people mostly move forward individually. Communities expressed the need for systematic support to develop community strategies in water and disaster management. Because farmers lack knowledge and resources, a large number of households have not applied any strategies.

Adaptation, defined as "an adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities" (IPCC 2001), is found in forms of very different sets of strategies in the literature on HKH to spread or transfer risk and improve food security. The adaptation approaches can be divided into holistic approaches that remain rather general and combine different adaptation strategies (integrated farming system approaches, farming flexibility, institutional innovation, etc.) and the specific ones that have been evaluated or piloted and often are described as complementary with other options to be effective (climate-resistant crop varieties, crop insurance and microfinance schemes, water storage and harvesting infrastructure). Many issues are already taken up by institutions such as the International Centre for Integrated Mountain Development (ICIMOD), but open questions for policy makers remain which to prioritize, how to identify and disseminate the best simple low-cost technologies, and how to reach the most vulnerable groups with low capital profiles. Six categories of adaptation options were identified, which will be introduced in the following:

1. Information and knowledge management
2. Institutional and social innovation
3. Modification of agricultural practices
4. Water resource management
5. Financial security (crop insurance schemes, microfinance, etc.)
6. Livelihood diversification and integrated approaches

Information and Knowledge Management

Participatory information management aims at capacity building of farmers and wants to train "climate managers" whose knowledge will be based on agroclimatic zones, climate models and simulation in the form of weather forecast, agro-advisory services, and the establishment of mini agro-met observatories (Pande and Akermann 2008). Information such as market developments and specific weather codes, which recommend farming practices based on conditions of droughts (drought code) or floods (flood code), can be communicated through these risk managers, crop-weather watch groups, or village knowledge centers (Swaminathan and Kesavan 2012).

In addition participatory management of resources (collective vegetable planting, breeding crop varieties with desirable properties of stress resistance, management of forests) and indigenous knowledge (bio-farming, water conservation, etc.) can establish climate-resilient farming systems. However, before information management can take off, knowledge management is required. As long as research is producing data that is of high uncertainty and not shared or coordinated, how can risk or climate managers be provided with adequate information? Coordinated research and databases are suggested. A cross-regional database on land use, demography, infrastructure, water resources, and best practices can improve risk assessment for disaster preparedness (Sharma and Sharma 2010). To improve adaptive capacity, disaster management capability of institutions and efficient communication systems and logistics are needed.

Coordinated research on early warning systems, refined flood and water level forecasting (GIS), and upgraded flood planning and vulnerability maps are required. Karki (2011) recommends a transboundary IWRM database for Pakistan and the region for long-term documentation and the assessment of climate change impacts and adaptation measures. Research and farmer's ground realities need to be linked through participation and information backed up by scientific knowledge to increase resilience and improve food security. Having databases is not sufficient; dissemination and access to the information need to be thought out in detail.

Institutional and Social Innovation

Institutional and social innovation is one response to the information and communication gap between policy makers, researchers, and farmers. The problem of the high uncertainty of data and predictions, the question of local applicability, and the low reliability of institutions trigger responses such as farming flexibility, redefined social capital, or institutional adaptation. Farming flexibility as a form of adaptation aims at identifying “uncommitted potentialities” in farming systems, using the example of Manang (Nepal) to expand spaces of opportunities and increase adaptive capacity (Aase et al. 2010). The critical question of this approach remains, who is going to or supposed to identify the many different localized potentialities? One form of flexibility can also be the use of new local social institutions (Chaudhary et al. 2012), where participatory setups for agricultural and disaster management are used. Community-based biodiversity management (setting up home gardens, group funds) and participatory plant breeding and variety selection of stress-tolerant crops and livestock are at the center of this approach.

As precondition for effective adaptation, institutional flexibility is as much required as on community level (Bartlett et al. 2010). Many autonomous adaption options are available, but building and expanding basic infrastructure at local level will be indispensible such as expansion and refurbishing of irrigation or improvement of water storage infrastructure. Capacity building is needed on all levels to develop parallel strategies for autonomous adaptations and for drafting and implementing effective national adaptation plans. Also “alternative” paths need to be considered. In Chinese agriculture, where conventional approaches dominate, the lack of a redefinition of social capital is described as missed opportunity to enable coping with pressures of modernization; often much more conform to sustainable rural livelihoods. “Sharing local knowledge” could become a distinctive form of asset in addition to the other five capital forms (Shiro et al. 2007).

Modification of Agricultural Practices

The focus is put on investment in science and technology, and recommendations range from climate-friendly and biodiversity-based organic farming practices to the testing and dissemination of high-yielding varieties in the mountains. The investment into fruit tree species that are more resistant to climate stress is suggested as well as the establishment of sustainable agricultural systems and no-regret adaptations that are needed for sustainable development. Bhatt’s (2012) emphasis is put on diversified crop rotations, mixed cropping, integrated agroforestry systems with leguminous crops, and limited synthetic fertilizer usage. Local low water-demanding crops and animals suitable for the climate should be promoted and genetic material be preserved in local seed and grain banks. Other authors recommend high-yielding varieties for mountains (Hussain and Mudasser 2007) and targeted breeding, where genotype selection is based on weather extremes for autumn crops and erratic rain and temperature changes for spring crops (Mall et al. 2006).

Aggarwal et al. (2004) base their no-regret adaptations on augmenting production through biotechnology and increased income from innovative agricultural enterprises (value addition). However, the dissemination of high-yielding varieties brings about the risk of an increased amount of fertilizer, pesticides, and water and implies a high environmental risk. Generally, genotype selection and breeding should always be done in cooperation with the local communities. As tree species (Lu et al. 2012) can be more resistant to climate stress than field crops, improve soil fertility, and conserve water and nutrient cycles, planting trees (fruit, fodder, carbon), which is less labor and input intensive, could be one long-term solution for the restructuring of agriculture in HKH.

Water Resource Management

Water seems to become the issue for food security in mountains, where infrastructure maintenance and feasibility for the topography are most important factors. The main objective is storage of water through natural and artificial reservoirs. One option is to use existing infrastructure, e.g., reviving of dying springs (based on experiments from Sikkim, India). There micro springs, located in farm fields, were revived and used as source of piped water (through gravity flow), fed by groundwater, and recharged by rainwater and infiltration (Tambe et al. 2012). In order to "capture rain where it rains" (Pandey et al. 2003, p. 53), the development of microcatchments is necessary to make use of available runoff, aiming at extending storage periods (in the Global North harvested water is stored for up to 1,000 days). This includes the restoration of traditional village tanks, ponds, or earthen embankments that still exist, for example, in India, and are often not well maintained (sediments). Treatment of (polluted) rainwater, e.g., through solar filtration, might also be needed along with restoring decentralized facilities or recreating freshwater fisheries. Local cheap and farmer-oriented solutions to water scarcity also need to explore innovative technologies such as roof water harvesting for drinking, shallow aquifers using treadle pumps, fog collection, and micro-irrigation for cash crops (sprinkler, drip irrigation, or bubble irrigation as used in Pakistan). Farming practices need improvements such as soil moisture retention through traditional mulching or new plastic film technologies, and recharge areas of spring and groundwater require protection (restrictions for cattle, closed spring boxes) (Merz et al. 2003).

Sharma (2010) and Laghari et al. (2011) follow a broader integrated water resource management approach. Sharma supports an approach that combines simple indigenous structures with large sectoral or multipurpose reservoirs and watershed management. Simple low-cost options such as rainwater harvesting are an important priority to capture water for domestic use (rooftop storage). Watershed management is needed along with water-conservation techniques for rainwater harvesting and soil moisture storage, which can lead to increased soil infiltration, recharging groundwater. Laghari recommends aquifers for artificial groundwater recharge due to a good storage capacity and reservoir management to solve the problems of sedimentation. Waste water infrastructure and water pollution prevention strategies e.g., in form of legislation are required. In addition green approaches to farming are needed that improve water productivity, promote suitable crops to surface and groundwater and integrate livestock or fisheries to increase value per unit of water. The water issue, supply, demand, and quality management is complex and needs well-planned IWRM with a strong focus on rainwater harvesting and other locally tested low-cost options for the diverse areas in HKH. Policy needs to foster planned adaptation in order to solve issues of irrigation, storage, and maintenance and improve farming practices while meeting the high uncertainty.

Financial Security

Adaptation strategies of financial security that transfer or spread risk are still underexplored. Migration enhances the overall capacity of households to adapt to climate change and can positively influence resilience for those left behind through a reliable flow of remittances. Remittances can enable smooth consumption, positively influencing food security, and often bring back entrepreneurial and agricultural skills as well as nutritional knowledge (Barnett and Webber 2010). However, the loss of labor in agriculture can adversely affect food security, so that channeling of remittances and support in climate-smart investment decisions are needed.

Agrawala and Carraro (2010) show how channeled resources (microfinance) at subnational level in Bangladesh have responded to needs of disaster preparedness and the agricultural sector. Microfinance there is targeted at reducing vulnerability to weather and climate risks (water management, agriculture, fisheries, forestry, and health) and contributes to adaptation through supporting the accumulation and management of assets. Critical points remain that microfinance usually targets the economically active poor, has high monitoring and administrative costs, and is not suitable as a long-term solution. In microfinance flood risks and general management of hazards are absent and crop production risks neglected. The Climate Change Cell (2009) has investigated the potential of crop insurance products to strengthen financial security and spread risk in agriculture in Bangladesh (production of yield, price, and market asset). The weather index-based insurance scheme came out as the most affordable and accessible to rural poor and the most practical to implement. However, insurance remains a business and not an income opportunity. Problems to be solved are lack of reliable data on weather patterns, crop yields, and land record systems, lack of insurance consciousness and poverty of farmers, lack of trained personnel, and limited financial resources.

Livelihood Diversification and Integrated Approaches to Adaptation

Because often government services are not responsive to climate change threats, livelihood diversification is an important adaptation strategy, which addresses underlying causes for vulnerabilities and can spread risk within agriculture and outside. Macchi et al. (2011) show the need for knowledge on climate-adapted crops and multiple cropping, water harvesting structures, and livelihood diversification options. Because living conditions determine adaptive capacity, flexible income-generation strategies are needed along with resilient resource management institutions, enhancement of knowledge and skills, and social capital (Bhandari and Grant (2007) to cope with constraints of insufficient agricultural land, insufficient labor within families, and lack of access to ecological agricultural services.

An integrated approach to adaptation (Gurung and Bhandari 2009) needs to be localized. For Nepal tested recommendations included sustainable intensification, considering water management and integrated trainings on marketing and agricultural techniques, livestock health management, and new business models (community-based), including cooperatives and crop insurances. In water resource management especially the rehabilitation of infrastructure (e.g., irrigation canals) was important for growing HVPs. Tree planting (fodder, timber, fruit) through forest user groups and the SALT practice for multipurpose cropping proved to be successful as well. Agricultural livelihoods need to become more resilient, and opportunities in the form of new enterprises (selling milk, etc.) should be explored. Last, climate change needs to be mainstreamed across the institutional landscape, so that it enables the efficient implementation of adaptation activities.

Prioritizing Adaptation Solutions: Disaster Preparedness, Water, and Climate-Smart Livelihoods

The analysis of the food security situation in HKH and current trends in climate and agriculture strongly suggest certain priorities for adaptation. The communities already experiment, so do researchers and policy makers in a rather uncoordinated way. Ideally, adaptation is done in an anticipatory rather than responsive way. People should at least be prepared to respond and develop a kind of adaptive thinking. The social acceptability and socioeconomic affordability is one major concern as well as it being endogenous to society and contingent on ethics, knowledge, attitudes to risk, and culture (Adger et al. 2009). A two-pronged strategy is suggested, which supports technologies and actions through planned adaptation based on current trends and needs of communities and upgrades knowledge for autonomous adaptation, strengthening farmers' overall adaptive capacity and flexibility. It can be seen as a quantum jump to single out priorities for planning adaptation, jointly tackling different dimensions of food security. For policy makers in the HKH region, these should be:

Priority List for Policy Makers

I. Planned adaptations:
   1. Short-term improvements in disaster preparedness (early warning systems, natural protection, and insurance schemes)
   2. Adaptations that with a long-term perspective test and upscale options for local large-scale water storage and maintenance
   3. Diversification of agriculture with focus on localized climate- and nutrition-sensitive farming

II. Supporting autonomous adaptation (contributing to I.1-I.3):
   4. Enabling rainwater harvesting on HH level through dissemination of knowledge on simple technologies and quality management
   5. Enabling efficient investment of remittances and other income sources in order to increase livelihood security, including access to food and nutrition (social organization/investment)

The first priority, a planned adaptation, tackles stability of ecosystems and nutrition and health environments. The projections for extreme weather events, water scenarios, and the high exposure to disaster in many areas in HKH require, first of all, improved risk assessment and disaster management capability to minimize human death, disease, and losses. Therefore, vulnerable areas need to be identified and prioritized in planned adaptation (vulnerability, flood, and drought maps), flood forecasting needs to be improved, and early warning systems need to be tested and installed in disaster-prone areas. For flood- and drought-prone areas, insurance systems should be supported and monitored and communication systems (institutional and communities) improved.

The second priority is a planned adaption and focuses on availability and stability of food production. The projections and current experiences of reduced water sources, decreased reliability in precipitation, and competition for resources suggest an integrated water resource management strategy, where local water storage is of highest priority, aiming at testing and upscaling large-scale water storage solutions (reviving existing infrastructure, installing aquifers, etc.). Additionally, improved maintenance, increased water productivity (irrigation techniques, crops), and conservation (water sources) should be promoted on district level. The aim is to improve long-term water security for agriculture and other purposes.

The third priority is a planned adaptation option that addresses challenges for agriculture such as disaster, water stress, temperature stress, and intensification stress resulting in decreasing productivity and nutrition performance. It tackles the availability and utilization of food and implies a policy reorientation toward climate and nutrition performance of agriculture instead of a profitability-first approach. Livelihood options also need to be evaluated and promoted according to their performance under climate change stress (traditional field crops, cash crops, tree crops, medicinal herbs, livestock, etc.) and nutrition and resource intensity (work, inputs such as water, fertilizer, etc.) and not only based on market value. Because biodiversity is important to spread risk and increase resistance and nutrition security, agricultural policy should discourage the silver bullet philosophy of monoculture cash crop systems in mountains. The integration of local knowledge and innovative approaches of collective management will ensure higher effectiveness and affordability of strategies. More coordinated research, including the compilation of existing techniques, is needed to give recommendations on climate-smart agricultural solutions for mountains.

The fourth and fifth priorities support autonomous adaptations and provide an increase in flexibility and adaptive capacity, which will help to achieve priority one to three. On the household level, water scarcity can be reduced with the help of rainwater harvesting technologies. It requires the dissemination of knowledge on simple technologies along with quality management and the provision of access to credit and technology are needed. This priority touches upon all dimensions of food security at household level. The support of social organizations might be useful to initiate installation of water solutions on community level, e.g., during winter. Best practice examples are known from Nepal, where communities jointly invested in infrastructure.

The fifth priority aims at enabling autonomous adaptation in the form of making better use of remittances and nonfarm-based income sources in order to increase livelihood security, tackling the dimensions of access to food and better nutrition. Knowledge on investment options and credit facilities need to be provided to encourage people to set up innovative agricultural or nonagricultural enterprises. Education is needed on how to best fulfill nutritional needs with available assets, because higher incomes do not automatically ensure better nutritional practices. Especially women are in need of knowledge of where to invest in order to become more efficient food and risk managers under changing circumstances (disaster management, farm management, nutrition, etc.). If remittances are used for investments in climate-smart agriculture, disaster preparedness (insurance), or irrigation, it can create win-win situations because the farmer, the farming system, and the community might benefit. Also social organization (e.g., water or women self-help groups) can be encouraged to jointly invest in irrigation systems, crop insurances, etc. Appointed climate change managers or knowledge centers could also help in spreading information.

Overall, a parallel approach of information and knowledge management is needed to fill knowledge gaps on climate-resilient farming systems and mountain nutrition. Information management needs coordinated communication, reliable research results, and proactive governance, whereas knowledge management requires intensified and tested localized research with regard to crop varieties, farming practices, water management, or financial insurance schemes. The final destination should be autonomous learning and exchange and transferability in the form of planned adaptation.

Conclusion

The food security situation in the Hindu Kush-Himalayan region is serious, and climate and socioeconomic change pose new challenges to its four dimensions (availability, access, utilization, and stability). This chapter identified adaptation priorities and showed that no panacea exists and a flexible approach should be followed in farming, institutions, and science. Policy reorientation will only be brought forward by well-informed policy makers backed up by research, development, and community support. Only a mixed approach of promoting tested climate-smart technologies and strengthening capacities of farmers (in and outside of agriculture) seems promising in order to spread risk and prepare farmers for the unknown. Adaptation options need to be reevaluated for local circumstances before implementation, and increased flexibility and capacity of institutions and farmers can help mountain communities to handle uncertainty and to spread out as much as possible.

Much remains to be done in terms of mainstreaming adaptation to climate change within the national policy-making processes of the HKH countries. Policy makers need targeting, and, to facilitate this, scientific research must be translated into appropriate language, practices, and timescales. Combining planned adaptation and fostering autonomous strategies by making use of scientific and local knowledge can prevent a science-first approach as well as free falling into the unknown transformation state.

ICIMOD with the help of CGIAR (Research Program on Climate Change, Agriculture and Food Security) is piloting and developing a concept of climate-smart villages for the mountain areas. It could become a role model for knowledge exchange and strategy development and through that provide an experimental ground for planned adaptation but will need institutional support to out- and upscale climate smartness in livelihood systems to improve food and nutrition security in HKH.

Adaptation Strategies Against Salinity-Induced Vulnerability in Coastal Bangladesh

Mustafa Saroar

Contents

Abstract

Both climatic and non-climatic factors' induced salinity in coastal plains has posed a formidable challenge for livelihood security of natural resource-dependent coastal population in Bangladesh. This chapter is aimed to identify the broad adaptation strategies that are more likely to be employed by coastal people against salinity to secure their livelihood.

This study heavily draws on quantitative inquiry. Field data and information were collected through a semi-structured questionnaire from 225 respondents selected randomly from salinity-affected three coastal villages located around swampy mangrove forests – *Sundarbans* in Bangladesh. For data analysis various statistical tools, especially multinomial logistic regression (M-Logit) model, were used.

Subsistence agriculture, fisheries, open water fishing, and extraction of both timber and non-timber forest products from *Sundarbans* have appeared as the dominant sources of livelihood which are seriously impacted by salinity

W. Leal Filho (ed.), *Handbook of Climate Change Adaptation*,
DOI 10.1007/978-3-642-38670-1_48

intrusion. Against the impacts of salinity, respondents have adopted almost a dozen of specific strategies and a couple of more they might adopt in the future as well. However, broadly there are three strategies they might eventually employ. M-Logit models have predicted that whether respondents would prefer *crop agriculture and allied jobs* over *saline shrimp farming* or *intensification of resource extraction from Sundarbans* would be significantly determined (LR chi-square = 308.17, pseudo $R^2 = 0.86$, $p < .001$) by factors such as socio-demographic (education [$p = .001$], occupation [$p = .02$], NGO's membership [$p = .00$], power in local polity [$p = .03$]), economic (farm size [$p = .002$], disaster recovery period [$p = .00$]), adaptive behavioral (seasonal migration [$p = .00$], shrimp-harvest failure [$p = .05$]), and spatial/locational (attachment to the locality [$p = .049$], tidal inundation of cropland [$p = .005$], land suitability for cropping [$p = .08$]) aspects. In line with these findings, suggestions are provided.

The policy implication of the study is if measures were taken in line with findings, it would help the poor and marginalized coastal population to better adapt with the impacts of salinity on their natural resource-based livelihood.

Adaptive capacity • Adaptation strategies • Coastal livelihood • Salinity intrusion • Bangladesh

Introduction

This chapter has twofold objective: firstly to identify the impacts of salinity intrusion on the livelihood security of natural resource-dependent communities living in the south-west part of Bangladesh and secondly, to identify the factors that influence the coastal inhabitants' adaptation preference against salinity intrusion to secure their livelihood. Presence of salinity in soil, subsoil water table, and surface water bodies is not a new phenomenon along the shoreline of Bangladesh coast. However, over the decade due to accelerated sea level rise and tidal influence, the area under saline zone has been expanding very rapidly. Accelerated sea level rise induced by climate change is no more a contested issue as it is already accepted as a reality in the National Adaptation Programme of Action (NAPA) of Bangladesh (GOB 2005). Even the Intergovernmental Panel on Climate Change (IPCC), the authoritative global body on climate research, in its various assessment reports has warned that Ganges-Brahmaputra-Meghna (GBM) delta in general and the coastal Bangladesh in particular would experience sea level rise (SLR)-induced various problems including salinity intrusion (IPCC 2001, 2007). Some of the models projected that Bangladesh might experience almost of one-meter SLR by the end of this century (World Bank 2000; Agrawala et al. 2003). Bangladesh is one the 22 coast-lying countries most susceptible to climate change-induced SLR (Nicholls 1995; Middleton 1999; Oppenheimer and Todorov 2006). Globally 170 million populations would be affected by SLR-induced events, including salinity intrusion. Almost 35 million of them would be from coastal Bangladesh alone. One-fifth of the country might go under saline water (Warrick et al. 1996). Drawing from the study of Ahmed and Alam (1998), World Bank (2000) has shown a projected [high-end scenario] SLR of 30 cm and 50 cm for the years 2030 and 2050 along the Bangladesh coast. For every year average rise is 1 cm. However, projected SLR of 14 cm, 32 cm, and 88 cm along the Bangladesh coast for the years 2030, 2050, and 2100, respectively, is shown in National Adaptation Programme of Action (NAPA) for Bangladesh (GOB 2005, 2009).

Therefore, climate change and SLR are considered to be the most pressing problem against which the people of Bangladesh in general and the coastal people in particular have to adapt in this century and beyond (GOB 2008). Adaptation involves some processes and actions in order to better cope with, manage, or adjust to some changing condition, stress, hazard, risk, or opportunity (Smithers and Smit 1997; Fankhauser et al. 1999; Smit and Pilifosova 2001; Brooks et al. 2005; Smit and Wandel 2006). In climate change context, IPCC conceptualizes adaptation as adjustment in natural or human systems in response to actual or expected climate stimuli or their effects, which moderates harm or exploits beneficial opportunities (McCarthy et al. 2001). Adaptation can be reactive or anticipatory based on the timing of adaptive response. Anticipatory adaptation involves taking measures well before the occurrence of the actual event (Smith 1997; Wilbanks et al. 2007). Adaptation can be private or public depending on whether the private individual or government agency is making effort to adapt to it (Adger et al. 2005). However, private and public adaptations are not mutually exclusive but rather often mutually reinforcing. Government program for exposure minimization often encourages private adaptation (Mimura 1999; Nicholls et al. 1999).

Like the citizen of any coast lying nations, the people of the coastal Bangladesh have only three options to deal with the vulnerability of SLR-induced events including increased intrusion of saline water in soil, subsoil water table and in surface water bodies. These options are protection, accommodation, and retreat (Klein et al. 2001; Tol et al. 2008). Protection involves construction of hard structure to minimize the exposure to increased salinity (Mimura 1999; Nicholls et al. 1999). However, taking this kind of measure is often beyond the private means because coastal populations are mostly natural resource-dependent marginalized people. Accommodation involves decreasing sensitivity through enhancing adaptive capacity (Adger and Barnett 2009; Adger et al. 2009). People having accommodative attitude would try to overcome the salinity-induced threats on livelihood without permanently evacuating their usual place of living. The last option "retreat" or pulling back to a safer place is basically evacuation which might involve relocation to a new place often faraway from the original one. Experts already warned that for a land-scarce country like Bangladesh which may even loss one-third of her landmass due to SLR, retreat may not be a sustainable solution. They put higher emphasis on adaptation in situ, i.e., encouraging people to be accommodative with the SLR-induced events including salinity. Practical manifestation of accommodative behavior is the adaptive livelihood. For following adaptive livelihood, people need to have adequate information about the likely change of climatic parameters which may affect their livelihood (Perry 2007; Collins and Kapucu 2008; Leal Filho 2009). Similarly, they need to have physical, social, cultural, and other forms of capital, assets, and organization (Blaikie et al. 1994; Smith 1997; Kelly and Adger 2000; de Hann and Zoomers 2005; Adger 2006; Blennow and Persson 2009; Saroar and Routray 2010; Wolf et al. 2010). Then again their past behavior of adaptation against similar threat on livelihood also influences the future course of action as regards adoption of adaptive livelihood (Patt and Gwatta 2002; Grothmann and Patt 2005; Grothmann and Reusswig 2006).

Bangladesh despite being a coastal nation, information on factors that govern the people's choice of adaptive behavior against the SLR-induced event especially against the burgeoning threat of salinity intrusion is still a gray area of existing body of knowledge. Only scanty of research on identifying the changes in the hydrometeorological processes (Ali 1999, 2003; Islam et al. 1999; Singh et al. 2001; Karim and Mimura 2008; Vineis et al. 2011; Bhuiyan and Dutta 2012; Pethick and Oxford 2013), identifying the locations particularly at risk (Castro-Ortiz 1994; Huq et al. 1998; Ali 1999, 2003; Saroar and Routray 2010; Rahman et al. 2011; Brammer 2014; Kulatunga et al. 2014), and characterizing and quantifying the impacts is available (Nicholls et al. 1995; Agrawala et al. 2003; Faruque and Ali 2005; Hoq 2007; Alvi and Dendir 2011; Ahamed 2013). Although, some scholars, for instance, Cannon (2002), Ahmed (2005), Ali (2006), Hoq (2007), Alvi and Dendir (2011), Habiba et al. (2012), Penning-Rowsell (2013) and Alam and Rahman (2014), have investigated the various aspects of current copping strategy against current natural calamities and hazards, none of them quantitatively assessed the influence of various factors that govern the people's adaptation preference for ensuring livelihood security. These are the gray areas of existing body of knowledge which this research would like to address.

Sea Level Rise and Impacts of Salinity in Coastal Bangladesh: A Succinct Review

Bangladesh, a tropical low-lying country, is historically prone to various hydrometeorological disasters such as floods, cyclones, tidal surge, and salinity intrusion (Islam et al. 1999). Climate change-induced SLR is going to extend this list. Numerous studies already have indicated that apart from its own direct impacts, SLR may even give synergistic effect to amplify the devastating power of currently occurring disasters that ravage the country recurrently (Castro-Ortiz 1994; Nicholls et al.1995; Huq et al. 1998; Ali 1999, 2003; Ali Khan et al. 2000; World Bank 2000; Singh et al. 2001; Cannon 2002; GOB 2006, 2009). In fact, the geographic location and geomorphological condition of Bangladesh have made it one of the most vulnerable countries to SLR in general and salinity intrusion in particular. Bangladesh is located at the interface of two different environments. The Himalaya is in the north and the Bay of Bengal is in the south. The interface between freshwater and saline water had been stable due to downward flow of freshwater from the Himalaya. Due to lower flow of water from the upstream and the accelerated SLR accompanied by strong tidal influence, the saline zone has been moving landward (further inland) from the shoreline of the Bay of Bengal. Now almost one-third of Bangladesh is under tidal excursions (Ali 1999, 2003; Rahman et al. 2011; Brammer 2014; Kulatunga et al. 2014). The country has 19 coastal districts in three distinct coastal zones. These are western, central, and eastern coastal zones.

Given the projected scenarios of SLR, salinity intrusion is now considered to be the most important single factor that may severely affect the livelihood security of the coastal inhabitants. In fact, increased salinity would interact with other hazards such as coastal flooding/inundation and storm surges in the low-lying coastal areas of Bangladesh. Nicholls (1995) and Nicholls et al. (1995) have shown that a one-meter rise in sea level and a 15 % increase in precipitation would inundate 71 million people. The SLR may also result in drainage congestion and water logging in the delta during high flow periods in the three major river systems in Bangladesh. Such a massive scale inundation will have severe impacts on agriculture and forestry, food security, human health, transport and infrastructure, and settlement and housing. Thus Bangladesh is shown as rank 1 in terms of the number of population likely to be affected by climate change and SLR effects.

Salinity intrusion has appeared as one of the important direct effects of climate change-induced SLR and other extreme events. Anticipated SLR would produce salinity impacts in three fronts: surface water, groundwater, and soil (Huq et al. 1998). Increase in salinity intrusion and increase in soil salinity will have serious negative impacts on agriculture (Faruque and Ali 2005). Because already about one million hectares of arable land is affected by varying degrees of soil salinity (DOE 2007), more adverse impacts are projected for the coming decades by Paul and Roskaft (2013). The presently practiced rice varieties may not be able to withstand increased salinity (Ahmed 2005; Ali 2006; Ahamed 2013). This might have serious repercussion on future food security and livelihood as agriculture is and continues to be the most dominant occupation in coastal areas. Increased salinity might affect the forestry and horticulture as well. The IPCC Working Group II has indicated in their fourth assessment report that for a 1-m rise in sea level, the "Sundarbans" mangrove forest is likely to be lost. Similar assertion is made by Organisation for Economic Co-operation and Development [OECD] in its study done by Agrawala et al (2003) and World Bank (2000).

Likewise, increased salinity in tandem with storm surge will cause reduction in fish production – another important avenue of coastal livelihood (Choudhury et al. 2005). In fact, for the last 2 decades or so, both freshwater and brackish water aquaculture, particularly shrimp farming in the coastal areas, are becoming popular and considered to be a lucrative business. Increase in salinity and coastal surge may not only jeopardize this lucrative business but may even arrest this trend (CARE 2003; Afroz and Alam 2013). This will also have serious implication on coastal livelihood. Although SLR itself is a slow onset event, scientific evidences warned that with accelerated SLR, the surge (both wave and cyclonic) height would increase significantly much like the same way as frequency and intensity of cyclonic events would increase (Ali 2003; Kulatunga et al. 2014). This is alarming as evidenced by the recent two cyclonic events such as *Sidr* and *Aila* which took place in 2007 and 2009, respectively, that brought about one-third of the south-west coastal floodplain under salty water for about 2 years. The accumulation of salt layer above the topsoil made the soil unsuitable for most of the agricultural crop production and even for keeping as pastureland. Almost after 5 years, partial recovery of productively of soil has been reported in few pockets of areas that experienced higher rainfall in the recent 2 years.

Finally, it can be reasonably assumed that accelerated SLR along the Bangladesh coast is likely to enhance the risks of coastal flooding, salinity intrusion, storm surge, and even catastrophic cyclone (Ali Khan et al. 2000; Singh et al. 2001; Bhuiyan and Dutta 2012; Kulatunga et al. 2014). Each of these will have network of impacts on coastal topography, morphology, social, economic and physical infrastructures. These all ultimately will affect the livelihood avenues of coastal population (CARE 2003; Thomalla et al. 2005; Afroz and Alam 2013). But the question remains. Are these impacts such as flooding, salinity intrusion, and storm surge, etc. new phenomena to the people of coastal Bangladesh? Simple answer is – these are not new. To impacts of these will be felt new indeed. They may feel the character, frequency, and magnitude of flood/coastal inundation, storm surge and salinity intrusion quite differently than the usual flood, seasonal salinity intrusion with which they are accustomed to. The coastal peoples are experienced in coping with normal flooding. For years they know when the flood water will pass through their farmlands and settlements. They know the duration (often very short lived) and character of flooding, i.e., slow/rapid onset-pick-recede. As they know the behavior of such flooding, they prepare their activity rosters, cropping calendars, and lifestyles and cope with the flood. Much like the same way, they get used to with the periodic salinity intrusion caused by tidal influence. They even use that brackish/saline water to culture shrimp on a seasonal basis alongside normal crop agriculture (Afroz and Alam 2013).

However, in the event of SLR, the inundation by salt water would be perpetual; it will increase over time and never get recede. Lowlands, farmlands, and even settlements and other physical and social infrastructures may gradually be abandoned over time. Likewise, salinity intrusion may permanently settle over farmlands, causing surface, subsurface water, and even soil completely saline. Such permanent salinity will not only seriously impede the agricultural productivity but also will damage the housing and other physical infrastructures. Further, crisis for freshwater for drinking will also be felt over time. Arguably one might say people will adapt in the future much like the same way as their ancestors did in the past. However, one needs to be mindful that adaptation does not take place automatically; certain factors govern the people's preference for adaptive response toward livelihood security (Scoones 1998; Adger et al. 2003; de Hann and Zoomers 2005; Pelling and High 2005). This study examines the influence of various factors on people's adaptation preference in coastal Bangladesh against the impacts of SLR in general and the salinity intrusion in particular.

Materials and Methods

Selection of Study Area, Respondents, and Survey Procedures

The whole coastline of Bangladesh are susceptible to multiplicity of disasters, and recent empirical evidence and scientific studies have warned that people of the south-west part of coastal Bangladesh are more vulnerable to various hydrometeorological disasters including cyclones, storm surges, salinity intrusion, and tidal floods (Castro-Ortiz 1994; Huq et al. 1996; Ali and Chowdhury 1997; Ali Khan et al. 2000; World Bank 2000; Singh et al. 2001; Karim ad Mimura 2008; Brammer 2014). This vulnerability may even increase in the changing context of climate; especially the accelerated SLR might amplify the devastating effects of many of these already occurring disasters. Dacope Upazila (subdistrict) of coast-lying Khulna District which is flanked in the south by the swampy mangrove forest (global heritage *Sundarbans*) and the Bay of Bengal was selected for empirical study (Fig 1). As the study site, two villages of Sutarkhali Union Parishad (lowest tier of local government unit in Bangladesh) were selected. The whole study area is separated from the mangrove swamp Sundarbans by Vodra River. Numerous other small rivers, canals, creeks, and brooks are in the study area which are important source of livelihood. The typical hydrological characteristic of this area is most part of lowland go under tidal water during high tides; therefore, two times each day many areas go under tidal flooding and such flooding by saline water takes severe form in the cyclonic period. Especially onrush of cyclonic surges often brings huge quantity of salt water from the Bay of Bengal and often the water get trapped and a thick layer of salt almost permanently settles over the land which seriously undermine the productivity of soil for cultivation.

As a survey instrument, mostly a semi-structured questionnaire was used to collect data and information. A total of 235 respondents were selected randomly for taking interview from where 225 responses were considered valid and used for this research. The survey was conducted during March to June in 2011. Interviews were done through administering Bengali version of semi-structured questionnaires. Three focused group discussions were conducted; these are male group, female group, and mixed group. Each group comprised of 10–12 members.

Result and Discussion

Climatic Disasters and Intrusion of Salinity

The entire area is historically prone to multiple natural hazards such as coastal flooding, cyclones, storm surges, salinity intrusion, and prolong/torrential rainfall. Apart from these, acute scarcity of freshwater for irrigation and drinking during dry season due to salinity intrusion is a major hazard. Although there are differences in the process of formation, timing of onset, duration of events, and even in devastating powers among these hazards, each has the ability to cause unprecedented

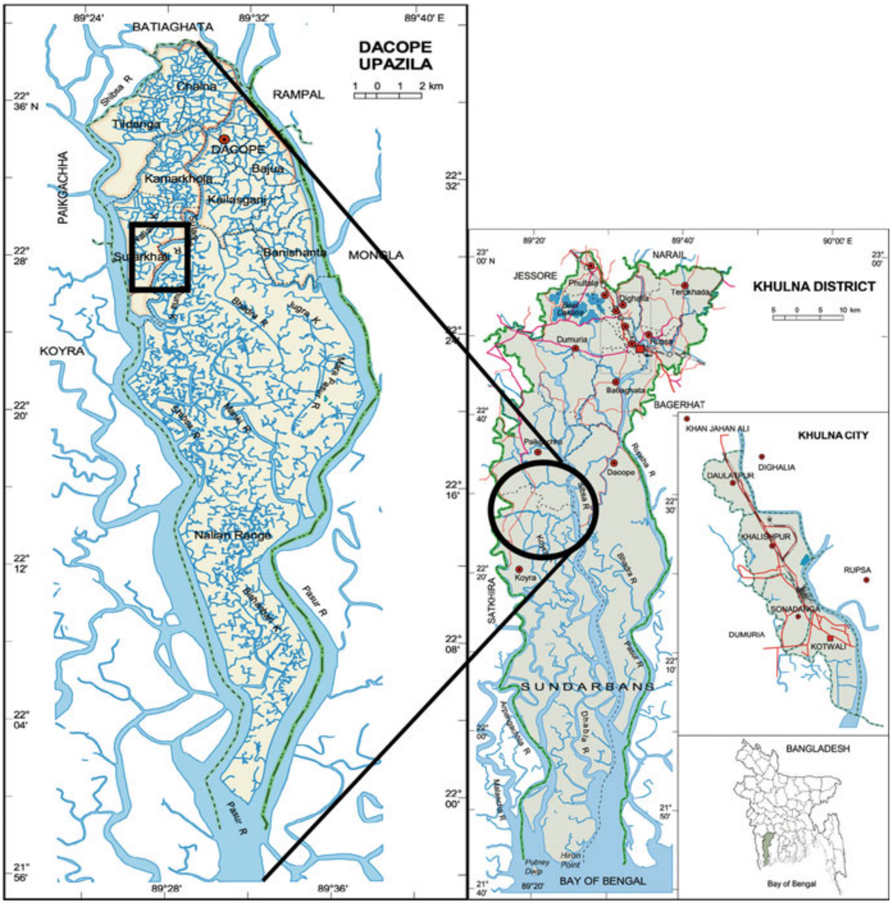

Fig. 1 The study site Sutarkhali Union (inside rectangle) in context of Dacope Upazila (inside circle) and Khulna District

damage to wealth, property, and other kinds of human well-being. In fact, ultimate impacts are felt on livelihood security. Although a very diverse portfolio of occupational engagement is observed in the study area and most peoples heavily depend on natural resource-based livelihood, some occupational groups are more affected than the others. Focused group discussion and other informal conversation with the respondents unveil that impacts of cyclone and surge are very universal. Direct impacts of cyclone and surge are felt by the respondents irrespective of their occupational engagement. The study area is located in the cyclonic path. The respondents have experienced several devastating cyclonic hits in their lifetime. Most recent of such events are category 4 cyclones – *Aila* and *Sidr*. The cyclone *Sidr* hit in the month of May 2007 and *Aila* struck in November 2009. Although the death tolls were not so high due to numerous reasons including good preparedness, the damages of property, assets, and livelihood avenues were unprecedented.

The entire area turned into a death valley. Thousands of homesteads were simply washed out; thousands of hectares of cultivable lands were underwater for many months as the trapped water could not pass away due to drainage congestion. People took refuge in uplands, embankments, and along the highways. They had to depend on outside assistance even for two meals a day for a year or so. The agricultural field, the fishponds, and shrimp *gheers* could not be utilized for the next 3 years as the salt layer was too thick on the bed of ponds, *gheers*, or in the cropland.

Unlike cyclone and storm surge, the impacts of salinity intrusion-induced freshwater crisis are not equally felt by different occupation groups in the study area. Impacts of freshwater crisis due to high salinity in water are more felt by people engaged in agricultural and other on-farm activities. These impacts are rather less felt by people engaged in nonagricultural activities such as small business, petty trade, and transportation.

Salinity Intrusion: A Dominant Cause of Threatened Livelihood

The coastal region as a whole and the study area in particular are in shortage of freshwater for crop cultivation (irrigation), fodder production, fish culture, and human consumption and similar domestic uses. It is primarily because the entire study area experiences severe crisis of fresh (non-saline) water throughout the winter season due to salinity buildup. Salinity in soil and water starts to build up after the month of October and reach in its peak in the month of April. Acute salinity in subsurface water table and in soil seriously impedes the cultivation of most winter crops including winter-season rice. Most parcels of farmlands are kept fallow throughout this winter due either to lack of freshwater irrigation or presence of extreme salinity in soil and water table. In other parts of the country hand tube well/shallow tube well with a maximum depth of 50–100 m is enough to ensure year-round sufficient supply of fresh (non-saline) water; in the study area, however, this depth range from 200 to 300 m entails higher cost. Moreover, the presence of hard rock layer in that depth makes it difficult to draw freshwater. The reasons of the presence of saline water throughout the subsurface water column could be attributed to lateral movement of seawater in addition to infiltration of saline water from surface sources. During high tide, saline water that accumulates in the surface water bodies, such as natural depressions, creeks, brooks, and canals is trapped and conserved by influential peoples to use in their saline water shrimp farms. Furthermore, few syndicates of influential shrimp farm owners are responsible for on-purpose ingression of salt water in the locality throughout the year, which severely affects the crop agriculture, horticulture, vegetable production, freshwater fish culture, and even production of animal fodders.

While conducting household survey through questionnaire, the respondents were asked to identify the major impacts of salinity on various aspects of their livelihood security. Almost 60 % of respondents face severe shortage of freshwater for drinking. Similarly 55 % of the respondents encounter difficulty in finding freshwater for irrigation. Lower yield in rice production is experienced by more than 50 % of respondents due to higher salinity in soil and water. Other impacts that the respondents feel due to higher salinity are presented in Tables 1 and 2. From the

Table 1 Impacts of salinity on livelihood of coastal population

The 10 most important impacts of salinity intrusion that negatively affects livelihood	Count[a]	Percent of responses	Percent of cases[a]
(i) Severe shortage of freshwater for drinking	133	12.1	59.9
(ii) Freshwater crisis for irrigation	124	11.3	55.9
(iii) Lower yield in rice production	115	10.5	51.8
(iv) Difficult to produce winter vegetable	107	9.7	48.2
(v) Reduced labor demand in dry season	103	9.4	46.4
(vi) Cannot grow most fruits	94	8.5	42.3
(vii) Shortage of fodder as no pastureland	89	8.1	40.1
(viii) Damage of building materials	85	7.7	38.3
(ix) Low catch in open water bodies	75	6.8	33.8
(x) Increased workload of women fetch water	71	6.5	32.0
(xi) Diarrhea and skin diseases	64	5.8	28.8
(xii) Cannot use paddy residuals for roofing	40	3.6	18.0
Total responses	1,100	100.0	495.5

[a]Multiple responses ($N = 222$; three cases are missing)

Table 2 Livelihood activities/inputs impacted by salinity in the study area

Assets and activities	Impact of salinity buildup and water stress condition
Aman (wet-season) rice	Increasing level of salinity and water stress condition affects growing to flowering stage of *Aman* rice
Boro (winter) rice	Acute high salinity restricts planting of *Boro* rice
Summer-season vegetables	High salinity affects planting of most summer vegetables during April to May
Winter-season vegetables	High salinity affects planting and growth of most winter vegetables during November to February
Culture fisheries/shrimp *gheer*	Although salinity has little impact, water stress condition affects productivity
Fish catch/fishing	Water stress condition and increase level of salinity render lower yield in open water bodies
Collection of fuel wood	Illegal extraction of fuel wood from mangrove forest *Sundarbans* increased due to lack of availability of biomass/paddy residuals
Cattle/goat rearing	High salinity degrades the pastureland during dry season and creates shortage of fodder
Poultry/duck (swan) production	Nonavailability of natural food due to increased salinity which affects subsistence poultry/duck rearing
Wage labor	Due to higher salinity, no winter paddy (*Boro*) production demand for labor is the worst
Water for drinking and domestic uses	Freshwater crisis prevails round the year but it is acute due to salinity in dry winter
Housing/settlements	Salinity severely affects building materials used in plinth, floor, and roof
Public health and sanitation	Prevalence of waterborne diseases, i.e., skin infection, diarrhea due to use of high saline water

summary of the multiple responses, it is evident that on an average almost five impacts are felt by each family due to higher salinity in soil and water.

Appraisal of Future Threat of Salinity Intrusion on Livelihood Security

Threat appraisal is contingent on both external and internal factors. External factors include source of threat itself (stressor or perturbation), probability of occurrence of the event, and the magnitude of the threat. Internal factors include person's level of familiarity with the event, perception and belief about the possible occurrence of the event, and comprehension of the impact (fear) from such event (Leiserowitz 2006; Fussel 2007). Threat appraisal is not something which cannot be changed; it changes indeed over time based on new information. Threat appraisal often influences the adaptive behavior (Maddux and Rogers 1983; Grothmann and Patt 2005). However, for appraising current as well as future threats, having knowledge about the causes/sources of the threats is fundamental. Respondents were asked to identify the cause of the accelerated pace of intrusion of salinity. They identified five causes of increased salinity in soil and water (Table 3). On average each respondent has identified three causes of intrusion of salinity.

Considering the reality of future SLR, dynamic nature of salinity, and the changing local land use and landscape, the respondents were also asked to identify the future scenario of salinity problem. How the respondents appraise the future threats of salinity on their livelihood is shown in Table 4. Well above two-third (68 %) of respondents appraised that impacts may be severe. Almost one-fourth (23.6 %) of them appraised that the impacts may increase but would not be severe. Very small number (8.4 %) of the respondents does not think that impacts of salinity would increase further and could appraise future threat.

Adaptive Livelihood Against Accelerated Pace of Salinity Intrusion

The entire study area experiences severe crisis of fresh (non-saline) water throughout the winter season. In fact, after the month of October, salinity both in surface

Table 3 Key causes/sources of intrusion of salinity in the study area

Most important causes/sources of intrusion of salinity	Count[a]	Percent of responses	Percent of cases[a]
(i) On-purpose ingression of saline water for shrimp culture	178	24.6	80.2
(ii) Cyclonic surges push saline water overland	174	24.1	78.4
(iii) Storing of saline water in illegally occupied canals	154	21.3	69.4
(iv) Strong tidal influence	147	20.3	66.2
(v) Siltation in riverbed allows saline water to travel further inland during high tide	70	9.7	31.5
Total responses	723	100.0	325.7

[a]Multiple responses ($N = 222$; three cases are missing)

Table 4 Appraisal of threat of future sea level rise with current awareness

The respondents were asked to appraise the overall threat from accelerated level of salinity; their responses are as follows:		
	No. of responses	% of responses
(i) Impacts of salinity may not increase	19	8.4
(ii) Impacts may increase but would not be severe	53	23.6
(iii) Impacts may be severe	153	68.0
Total	225	100
Mean		1.4
Standard deviation		0.6
N		225

water bodies and subsurface water table increases tremendously. Higher level of salinity persists for 4–5 months. Only after the onset of rainy season/monsoon, the level of salinity starts to decline. Acute salinity in subsurface water table and in soil does not permit cultivation of most winter crops including winter-season (*Boro*) rice. Even the shortage of animal/cattle fodders is acute throughout the winter due to higher salinity in soil. During this period to earn a living, a significant proportion of peasant farmers used to go for fishing in nearby rivers and canals located in and around the Sundarbans and in the Bay of Bengal. Furthermore, a significant proportion of people used to enter mangrove forest *Sundarbans* to collect both timber and non-timber forest products, such as honey, wax, sea grasses, fish, crab, etc. Seasonal diversification of livelihood is getting popular among the respondents. Many families, most of which are NGO beneficiaries, switch to cultivation of winter beans, legumes, nuts, and roots. Basically, with the assistant of extension workers of NGOs and agricultural department, the small and peasant farmers have been trying to adapt with the salinity and water stress condition by switching to cereals and crops that demand low water and can tolerate moderate level of soil salinity (5–10 dS/m). For instance, as winter-season rice (*Boro*) production is difficult, many farmers have been trying to cultivate sunflower, beans, sesame seed, and watermelon. Furthermore, some of them have adopted aeroponics vegetable production in handing bases made of recycled small plastic drums, buckets, bottles, canes, etc. Although in most cases productivity is less than normal, the peoples are happy that this production meets their own consumption need. The respondents believe that if they could be supported with drought- and saline-tolerant rice varieties with other agricultural implements, they could effectively adapt to the salinity problem even in a changing climate.

After agriculture and related farm activities, fishing is one of the dominant sources of livelihood. In fact, a significant number of poor and marginalized families heavily depend on both inland and marine fishing for their livelihood. The small fishers catch fish round the year in the open water bodies, canals, and rivers in and around swampy mangrove forest *Sundarbans*. As most of the small and marginalized fishers work as fishing workers in commercial trawlers, their marine fish-catch-based livelihood depends on the mercy of relatively rich commercial fish merchants, especially during the dry winter. During winter, the commercial fish merchants employ manpower to catch marine fishes in the offshore and in the deep-sea areas of the Bay of Bengal. This activity allows many unemployed youth to earn their living throughout the dry winter since they cannot sell their labor in the crop agriculture, which is heavily impacted by the water stress condition and higher presence of salt in soil and water. In fact, as the levels of salinity are increasing and prospect for crop agriculture is diminishing during dry season (November to April), a growing proportion of poor and marginalized people are being forced to enter swampy mangrove forest *Sundarbans* to catch fish in the bay, rivers, and canals located in and around this mangrove swamp. It means the *Sundarbans* mangrove swamp is going to experience higher pressure in the years to come.

Although increased salinity is a problem in general, a handful of rich and influential farmers have been considering increased salinity as an opportunity. Over the last 2 decades or so, many rich farmers have switched to saline/brackish shrimp farming practice. The lowlands that go under saline water have comparative advantage for saline/brackish water shrimp cultivation. Although saline shrimp culture has tremendous revenue potential, good harvest is highly variable and uncertain because of the presence of higher risk of production failure (Afroz and Alam 2013). Production failure or harvest failure in shrimp farms is mostly associated with viral attacks, climatic variability such as temperature increase, and coastal flooding, tidal surges, and even prolonged dry condition. This kind of production risk is difficult to assume by small farmers. Only the rich farmers go for this venture. This saline shrimp farming has scale economy; the larger the farm size, the higher the return and also the lower the production cost. Small- and medium-sized farmers cannot go for this venture. Again these shrimp farms only require small number of labors as compared to crop agriculture in a similar size farm. Therefore, conversion of crop agricultural fields into saline water shrimp farms has negative impact on rural employment market. Despite various social and environmental bearings, a growing number of rich and large farm owners have been switching to saline/brackish water shrimp farming and this trend may continue (Paul and Roskaft 2013).

As regards severe shortage of salt free freshwater, the people have been adopting two types of measures. The first one is related to use of pond-sand filter (PSF) technology for removing basically physical impurities. The PSF is a package type slow sand filter unit developed to treat surface water, usually pond water for domestic water supply. Treated water from a PSF is usually bacteriologically safe or within tolerable limits. With direct supports from local NGOs, community people have installed PSF unit near the bank of pond where they preserve rainwater throughout the rainy season. During winter when freshwater is very scarce due to the presence of excessive amount of salt in tube well water, the water from this PSF is collected on a community-managed rationing system. The other method that they have started lately is the rainwater harvesting through installation of simple harvesting apparatus on the roofs of their dwelling units. Throughout the rainy season they collect rainwater and preserve it in plastic containers. For preserving

water they use plastic drums that they used earlier for stocking fish while fishing in the bay or rivers in and around *Sundarbans*.

Given the reality of SLR, the increasing trend of salinity, and their own appraisal about the threat of salinity in their livelihood, the respondents were asked to identify their main adaptation pathways. Although there are more than a dozen of specific strategies/action areas, broadly three types of responses have emerged (Table 5). Nearly about half of (51.1 %) the respondents want to continue crop agriculture and allied farm jobs anyway for their livelihood. Despite knowing the limitations of continuing agriculture in the future, they want to be with it because for most of them it is the only skill that they have. They believe in general that acquiring a new skill to fit with the changing context probably would be difficult for them in this juncture of their lifecycle. Almost one-third (30.7 %) of the respondents cannot precisely determine what they would probably do to secure their livelihood. However, one thing they are expecting to do is intensification of resource extraction from swampy mangrove forest *Sundarbans* and from the nearby Bay of Bengal apart from temporary outmigration. Looking into their responses, it seems that they are guided by short-sighted views; they fail to take into account of the impacts of climate change and SLR on the availability of resource of the *Sundarbans* mangrove swamp in the years to come. It is important because various earlier studies, for instance, World Bank (2000) and OECD (Agrawala et al. 2003), have estimated that almost half of the *Sundarbans* mangrove swamp would be lost before the middle of this century due to increased salinity and accelerated SLR. However, many of these respondents have been diversifying their portfolio of earning from various sources. The remaining 18 % of respondents express their willingness to either switch or (if already started) continue saline water shrimp farming. In coastal areas, increased adoption of shrimp farming means increased incidence of unemployed labor (Paul and Roskaft 2013). On the other hand, climate change-induced SLR and increased salinity would lower the earning of people from *Sundarbans* mangrove swamp and the nearby Bay of Bengal. Therefore the poor and marginalized people would be affected by double exposures of shrinking employment opportunity in shrimp farm sector and shrinking income from mangrove swamp *Sundarbans* and its adjoining bay areas.

In the following sections, it is attempted to quantitatively assess the characteristics that are associated with the people willing to adopt various (three) broad strategies for adaptation against the impacts of salinity on their livelihood. These strategies are (a) continue crop agriculture and allied farm jobs anyway, (b) switch to or continue with saline shrimp farming, and (c) intensification of resource extraction from the *Sundarbans* and its adjoining bay area (Table 5). Characterization of these groups would help identify the driving factors that govern their adaptation preference against the impacts of SLR and salinity on their livelihood. This is done through multinomial logistic regression model (M-Logit) because the dependent variables are categorical and mutually exclusive and the independent variables are interval, categorical, and binary variables (Hair et al. 2006). Details of variable selection and model specification are presented in the section below.

Modeling the Adaptation Preference Against Salinity

The categorical dependent variable "adaptation preference" has three mutually exclusive options of response such as "continue crop agriculture and allied farm jobs anyway," "intensification of resource extraction from *Sundarbans* swamps," and "switch to or continue with saline shrimp farming" (Table 5). As the options of response do not reflect a very precise ordering, multinomial logistic regression (MLR) model is used rather than ordinal/ordered logistic regression (OLR). Here the reference category is "continue crop agriculture and allied farm jobs anyway," which is compared with the other two. The independent variable (predictor) list includes various asset holdings; socio-demographic, cultural, and organizational factors; access to informational resources; adaptive behavioral aspects; and spatial/location factors and exposure potential. These independent variables have been selected from reviews of pertinent literature which are shown in Table 6.

Before running the MLR model, bivariate correlation is performed, and due to strong collinearity ($r > 0.90$) "total land holding" and "yearly income" are not used in the M-Logit model. Similarly, cross-tabulation for each categorical/binary independent variable with the dependent variable broad adaptation preference is performed. The independent variables which have zero count/frequency or count/frequency less than five in any cell of cross-table (matrix) were excluded from the model to avoid "floating point overflow" problem – a systemic problem that renders the modeled output less dependable. Finally, after running the model, factors that significantly explain the variations in respondent's preference for "intensification of resource extraction from Sundarbans" and "switch to or continue with saline shrimp farming" over "continue crop agriculture and allied farm jobs anyway" are identified. These outputs are analyzed to identify various interventions to build resilient coastal community against accelerated pace of salinity intrusion.

Model Output I: Who will prefer saline shrimp culture over crop agriculture?

M-Logit model depicts that respondents' preference for "switch to or continue with saline shrimp farming" over "continue crop agriculture and allied farm jobs anyway" as a strategy for livelihood security against SLR and other factors that induce salinity is statistically significantly (LR chi-square = 308.17, pseudo $R^2 = 0.86$, $p < .001$) determined by many demographic, social-economic, adaptive behavioral, and locational factors (Table 7). Most dominant factors are educational attainment ($p = .001$), duration of living in that locality ($p = .049$), experience of (shrimp)

Table 6 List of independent variables used in M-Logit model

Variables in detail[a]	Variable	Coding
Age of respondent (year)	Age (year)	
Education of respondent (year of schooling)	Education (year school)	
Family size (no. of members)	Family size (no. mem)	
Catching fish from swampy Sundarbans areas	Duration of fishing (year)	
Recovery period of damage caused by a cyclone	Recovery period (year)	
Duration of living in that coastal locality	Duration of living (year)	
If experienced harvest failure of shrimp (d)	Loss from shrimp	If frequent, 1; otherwise, 0
If homestead is on *khas* (govt.) lowland (d)	Location of homestead	If yes, 1; otherwise, 0
If most close relatives live in the same locality (d)	Relatives stay nearby	If yes, 1; otherwise, 0
If wage laboring is the main occupation (d)	Main occupation	If labor, 1; otherwise, 0
If cropland goes under tidal water during high tide (d)	Land submerse by tide	If yes, 1; otherwise, 0
If avoid giving ransom to pirates in *Sundarbans* (d)	Avoiding ransom	If always, 1; otherwise, 0
If seasonally migrate to outside locality for earning (d)	Seasonal migration	If always, 1; otherwise, 0
If member of any social group or NGO (d)	Membership of NGO	If yes, 1; otherwise, 0
If experience frequent embankment failure (d)	Embankment failure	If yes, 1; otherwise, 0
If abandon land frequently for high salinity (d)	Abandoning land	If yes, 1; otherwise, 0
If only plant rice in the wet season (d)	Only wet-season rice	If yes, 1; otherwise, 0
If frequently adapt to acute scarcity of freshwater (d)	Freshwater scarcity	If yes, 1; otherwise, 0
If has good connection with local political clout (d)	Political connection	If yes, 1; otherwise, 0
If always follow radio bulletin for early warning (d)	Follow radio bulletin	If yes, 1; otherwise, 0
Farm types based on landholding	Farm landholding	Small

If a respondent increases his/her educational attainment by one unit, the relative chance of preference for "switch to or continue with saline shrimp farming" over "continue crop agriculture and allied farm jobs anyway" is expected to increase by a factor of 1.9 given the other variables in the model are held constant. It means educated people have two times higher probability to engage in saline shrimp culture if impacts of salinity become perpetual. Similarly, respondents who have never experienced harvest failure while culturing saline shrimp have about 20 times higher probability to prefer saline shrimp farming over crop agriculture and allied jobs if salinity problem becomes perpetual. By contrast, however, respondents who do not have experienced submersion of cropland by high tides are 0.034 times less likely to prefer saline shrimp farming over crop agriculture and allied jobs even if salinity problem becomes perpetual. Similarly, respondents who do not have experienced problems in double cropping a year are 0.162 times less likely to prefer saline shrimp farming over crop agriculture and allied jobs. Almost same way, smallholders (respondents) show their negative gesture to prefer saline shrimp farming over crop agriculture and allied jobs.

Model Output II: Who will prefer intensification of resources' extraction from Sundarbans over crop agriculture?

The model output shows that duration of fishing ($p = .00$), recovery period of cyclonic damage ($p = .00$), bonding with relatives ($p = .06$), types of occupation ($p = .02$), security concern ($p = .04$), membership of NGO ($p = .00$), seasonal migration ($p = .00$), power in local polity ($p = .04$), and farm/landholding size ($p = .08$) are the significant predictors of respondents' preference for intensification of resource extraction from *Sundarbans* over continue crop agriculture and allied farm jobs anyway as a broad strategy of adaptive response (LR chi-square = 308.17, pseudo $R^2 = 0.86$, $p < .001$) (Table 7). Other factors have very limited influence in this respect (Table 7: Model II).

For every one-year increase of experience of fishing of respondents in and around swampy mangrove forest Sundarbans, the probability to prefer "intensification of resource extraction from Sundarbans" over "continue crop agriculture and allied farm jobs anyway" is expected to increase by a factor of 1.3 given the other variables in the model are held constant. It means people who have been earning their livelihood from fishing in the open water (in and around swampy mangrove forest Sundarbans and adjoining bay area) are more likely to intensify their resources extraction if salinity increases. Similarly, respondents who have never migrated out seasonally for earning have about 14.70 times higher probability to prefer "intensification of resource extraction from Sundarbans" over "continue crop agriculture and allied farm jobs anyway" if salinity problem becomes perpetual. Much like the same way, respondents who are not members of any social group/ NGO have about 16.30 times higher probability to prefer "intensification of resource extraction from Sundarbans" over "continue crop agriculture and allied farm jobs anyway."

By contrast, however, respondents who suffer frequently from cyclonic storm are 0.16 times less likely to prefer "intensification of resource extraction from Sundarbans" over "continue crop agriculture and allied farm jobs anyway." In fact, to expedite the recovery period, they do not want to rely on Sundarbans-based aquatic resource extraction since making a good earning from those sources/ activities is highly uncertain. Moreover, immediately after the havoc caused by cyclonic storms, they often lack equipments and gears to go for fishing; also people avoid fishing at that time as fish feed on dead body of human beings and animals. Rather they try to migrate out to get job both in urban sector activities and in rural areas outside the coast where there is demand for wage labor. Similarly, respondents whose most of their close relatives do not stay close to their village are 0.18 times less likely to prefer "intensification of resource extraction from Sundarbans" over "continue crop agriculture and allied farm jobs anyway." It is because they have go for fishing or other resource extraction from Sundarbans for months; during their absence, their relatives often look after their families. For families whose close relatives stay away, the main earning member tries not to earn living from offshore fishing, but rather works in the locality as wage labor. Similarly, respondents who could not avoid giving ransom to pirates who kept them hostage while they were fishing in the Sundarbans area are 0.2 times less likely to prefer "intensification of resource extraction from Sundarbans" over "continue crop agriculture and allied farm jobs anyway" even if salinity increases. It is because the amount of ransom that they have to give in one time often is higher than what they earn in a year from fishing and other resource extraction activities from Sundarbans and its adjoining areas. Similarly among the respondents who do not have good connection (kind of patron-client relationship) with local political elites are 0.15 times less likely to prefer "intensification of resource extraction from Sundarbans" over "continue crop agriculture and allied farm jobs anyway" even if salinity increases. It is because while securing pass from the local forest department's office for entering swampy Sundarbans, often they have to pay 5–10 times more than the government revenue. But if they were backed by the ruling-party elites, they have to pay little more than the government revenue. Therefore, those who do not have good connection with local political elites often prefer working in crop agriculture and allied jobs. However, it is not very apparent why smallholders (respondents) have shown less interest for resource extraction from Sundarbans even if salinity will increase in the years to come. Probably they have failed to understand the damage that salinity may cause to their crop agriculture-based livelihood.

Policy Implications and Concluding Remarks

From the analysis of the foregoing findings, it could be interpreted that educated peoples are more likely than uneducated/less educated people to prefer adoption of saline water shrimp culture if salinity problem becomes perpetual. This finding confirms with the very fundamentals of risk-taking behavior of educated people. In fact, saline water shrimp production is a very lucrative business. However it needs capital and entrepreneurial skills to run efficiently. Then again there are lots of risk of harvest failure. For instance, viral attack, extreme weather conditions, such as high temperature, and submersion of shrimp production farms by cyclonic surges often cause harvest failure. Therefore, educated people may take into account these risk factors. Despite the risk of harvest failure, for those who have never experience such failure, it is very likely that they would use their skills, knowledge, and expertise and might continue to produce saline shrimp in the event of perpetual increase of salinity in the water and soil.

On the other hand, although at current level of salinity many respondents who do not experience very frequent inundation of their cropland by tidal water or who can make use of land for both wet and dry season rices/crops express their desire to continue crop agriculture and allied farm jobs, in practice when salinity would be perpetual, would they be able to strict to their current thinking? It is really a big question mark. Similarly, those who are smallholders and who do not have political connection, for them it is really hard to switch to shrimp farming. For this group who have shown their negative gesture toward saline shrimp, they are rational as well. As it is mentioned earlier that saline shrimp business involves a lot of risks and frequent harvest failures are very normal, except the large shrimp farm owners who have farm size within the range of 10–100 hectares, the marginalized or small farm owners with farm size below one hectare cannot afford the risk of harvest failure. Therefore, it is not unlikely that small farmers/smallholders would try to be strict to their ancestors' occupation of crop agriculture and allied jobs no matter how severe the salinity impacts would be. Another reason is that it is the crop agriculture and allied jobs with which they are habituated and they have limited sets of skills around these activities. Getting involved in a new venture like saline shrimp farming is different from their mind-set of occupational engagement. Therefore, even if salinity problem gets perpetual in the changing scenarios of climate and

SLR, very small fraction of the total coastal population would go for saline shrimp farming. Instead, from close consultation with many smallholders, it is revealed that they want saline-tolerant rices and other crop varieties to continue their known occupation in this juncture of their life.

From model II it is found that a large majority of the population who are mostly landless or posses very small amount (less than 30 decimals) of cultivable land and who are used to with fishing in the open water (rivers, canals, and bay in and around swampy mangrove forest Sundarbans) for generations are more likely to intensify their fishing in those areas in the event of lower catch due to increase salinity in water and soil. Similarly, poor people who have been extracting other resources such as *golpata* (nypah palm), honey, wax, and crab from Sundarbans for generations would also intensify their efforts to cope with the lower abundance of those forest products (both timber and non-timber). This would be the situation for few other groups of people. For instance, those who are not used to with seasonal migration to urban areas or in other resourceful rural areas outside the coastal zone would probably look for earning from swampy mangrove forest. In fact, the model result shows that this group might appear in the future as a major threat for the sustainability of resources of Sundarbans, because their intensions for extraction of these resources seem like very unsustainable. Therefore, it is very good time to explore the possibility of diverting this increasing stream of resource exploiters to unban sectors or other areas where there is seasonal demand for wage labors. In this connection, measures could be taken to enhance their existing skills, diversify their skills, and give them new set of skills through participatory training and capacity building projects. In this regard, both government and nongovernment entities such as private enterprises and NGOs could cooperate.

Almost similar situation would be created by poor people who are not member of any social groups or NGOs. Earlier findings (model II) reveal that this group of people have more inclination to exploit resources from swampy mangrove forest of Sundarbans if job opportunity gets reduced in the crop agriculture and allied sector due to increased salinity. Therefore, it could be argued that NGOs should consolidate their current awareness campaign as regards protection of global heritage site Sundarbans and at the same time could launch special programs of natural resource management for the coastal community. In this connection, the roles of donors and government agencies also must match with the changing demand of the protection of coastal resources without not undermining the livelihood avenues of poor and marginalized population.

There are positive sign as well as regards lowering dependency on resources of the swampy mangrove forest Sundarbans. Few distinct groups of people from poor and marginalized category who used to rely on both wage laboring in the agricultural sectors and resource extraction (specially fishing) from rivers, canals, and bay located in and around Sundarbans have started to go outside locality for urban sector jobs. This is not really a kind of seasonal migration but rather migration to avoid uncertainty of income from natural resource-based activities in the post disaster (e.g., cyclonic) period. One episode of cyclone of 3/4 category causes unprecedented damage to property and resources of poor and marginalized people.

It also destroys the places of resource extraction and fishing grounds and also seriously disrupts the transportation and communication channels of resource flow. Moreover, there is common prejudice among the coastal people that in the post disaster, especially in the post cyclonic periods, the fish in the rivers, canals, and bay located in and around Sundarbans feed on dead body of human beings and animals. Therefore, almost for 6 months in the post disaster period, poor fishers do not go for fishing as the demand for fish is less and so as the price. Therefore, many poor and marginalized people who used to depend on Sundarbans-based resources for livelihood in the normal period of life have shown strong inclination to move out for earning from urban sectors to expedite the recovery period in the post-disaster situation. This is because, in the post disaster situation, as the scope for resource extraction gets reduced, more and more poor and marginalized people would look for alternate avenues from urban sectors as the rural crop agriculture and allied activities would suffer from the accelerated pace of salinity as well. This behavior in fact opens up new opportunities for intervention to protect resources of Sundarbans and at the same time to ensure sustainable livelihood for the poor and marginalized population who used to depend on the abundance of natural resources of Sundarbans. In this respect a fresh program of capacity building that suits with the requirements of the urban sector's jobs could be launched in cooperation with business, NGOs, and local government agencies. Apart from this climate-compatible coastal physical infrastructure development program could be launched to give the poor and marginalized people an easy access to nearby urban centers for making their livelihood.

Acknowledgments This chapter is an outcome of both an academic research and evaluation study of an action project which was partly funded by Nabolok in Khulna; the author gratefully acknowledges it.

Adaptation to Climate Change Effects Among Rural Women in Savannah and Forest Zones of Oyo State, Nigeria

Nathaniel S. Sangotegbe, Janet O. Obayomi, and John O. Oluwasusi

Contents

Abstract

The study assessed adaptation strategies to climate change effects among rural women in savannah and forest zones of Oyo State, Nigeria. A total of 117 rural women were randomly selected from the two randomly selected LGAs in the

state. Data were collected through a structured interview schedule. A higher percentage in the savannah (88.2 %) than the forest (67.8 %) was in their active years (20–50 years). About 41 % (savannah) and 32 % (forest) had no formal education. Awareness of climate change was high (78.7 % and 69.6 %, respectively), while farming-related activities were the main livelihood. Also, 93 % admitted that climate change had a severe influence on their livelihoods through reduction in the amount of rainfall on their farmland. Respondents adopted different strategies such as multiple cropping, crop rotation, changing planting periods, storage of water for future use, and diversifying into other areas of livelihood to adapt to climate change effects. However, there was also a significant difference in the influence of climate change ($t = 4.605$, $p = 0.000$) and adaptation strategies ($t = 6.637$, $p = 0.000$) between the women in the two ecological zones. Adequate funding and locality-specific climate change-related information on adaptation strategies are recommended to be made available across the two ecological zones of the state.

Keywords
Climate change • Adaptation strategies • Rural women • Nigeria

Introduction

Climate change is one of the major environmental problems facing humanity. It is the cause of the mixture of extreme adverse phenomena such as drought, flood, and heat and cold waves. The problem of climate change in the world affects Nigerians and rural women most especially since they form the majority of producers and processors of agricultural crops, Nigeria being an agrarian society. At the same time, the change from traditional to intensive agricultural systems largely contributes to climate change. Land use changes, flooding areas for rice and sugarcane production, burning crop residues, raising ruminant animals, and using nitrogen fertilizers are all activities that release greenhouse gases into the atmosphere.

Developing countries are hard hit by climate change, particularly countries which depend largely on rain-fed agriculture. Climate change affects changes in plant growth and in production by promoting the spread of pest and diseases, increased exposure to heat stress (Fischer et al. 2002), changes in rainfall patterns, greater leaching of nutrients from the soil during intense rains, greater erosion due to stronger winds, and more wildfires in drier regions (Akonga 2001).

For Nigeria, climate change poses a great challenge to livelihoods and remains the overriding priority impetus to the promotion of sustainable economic development. Several authors have reported the negative impacts of climate change, most observed as change in weather patterns, increased rate of desertification, flooding, coastal erosion, increased water pollution and reduction in crops and livestock productivity, and consequently, lower income (Adejuwon 2004; Titilola et al. 1996; Nwajiuba et al. 2008; Ogbuehi et al. 2008)

According to IPCC (2001) projections for the humid tropics, rainfall is expected to increase in Southern Nigeria. However, in view of the expected increase in evaporation and evapotranspiration, there is likelihood of localized drought in parts of this humid area of the country. The effects of climate change to date have been small, but are projected to progressively increase in all countries and regions. In Nigeria, climate change often appears very obscure but it is real. According to Ihedioha (2007), parts of the outcome of climate change in some parts of the Nigerian economy are situational.

The gender-related impacts of climate change have also received some attention in the literature. Generally, the causes of climate change are closely related to struggles over resources between men and women in rural areas, but women are particularly affected because of their socially ascribed roles. Also in Nigeria, the altered rain patterns which disrupt planting seasons and adversely affect crop yields resulting in devastating consequences for livelihoods and economic security have been noted by indigenous peasant women. The end result of this is increased hunger and poverty to most rural women in Nigeria.

There are numerous significant linkages between gender and agriculture. Gender aspects in agriculture affect access to and control over resources, with consequences for food security as well as for market and policy decisions. In many countries, women's access to land is limited. At the same time, they account for 70 % of agricultural workers and 80 % of food producers (Fresco 1998). Bzugu and Kwaghe (1997) reported that women form the highest proportion of the economically active population in rural Nigeria and play an important role in agricultural activities, particularly in subsistence food production, where they contribute an estimated 60–80 % of the total labor used. Corroborating Bzugu and Kwaghe, Mabogunye (2010) asserted that an estimated 54 million of Nigeria's 78 million women are based in rural areas and make a living from the land. Also, because of their labor- and time-intensive work in order to care for their families, the share of women hit by poverty is high. Their responsibility for using and preserving land for food and fuel production and the resulting dependency on the soil make them vulnerable to climate change effects and consequences. Also it may be necessary to compare the degree to which climate change impacts the lives of rural women in the different ecological zones of Nigeria. This would be of great importance to develop principles and procedures to protect and encourage women in two of the distinctively different agroecological areas to national climate change mitigation and adaptation programs and projects. It has also become imperative to look into the extent and various ways by which change in climate has adversely affected livelihoods in the two ecological zones of the study area.

Oyo is one of the 36 states in Nigeria and it lies in the western part of the country. The state is divided into two ecological zones (rainforest to the south and savannah to the north) and is well suited for food crop production, as farming is being practiced by both men and women of the area. The bulk of food consumed in the southwestern part of Nigeria is being produced by farmers in Oyo State, while Oke-Ogun, in the savannah zone of the state, has been labeled the food basket of Southwestern Nigeria (Sangotegbe et al. 2011). Therefore, the assertion of Oluwasegun and Olaniran (2010) that Southwestern Nigeria is a region that feeds more than 45 % of the nation's population implies that the contribution of the Oyo to the nation's food security is significant. While the savannah zone favors mainly arable crops such as sorghum, maize, cowpea, and yam with some parcel of land, which supports tree crops, the forest zone favors the cultivation of some tree crops like cocoa and oil palm, alongside other crops as cassava, maize, and yam. Women are directly involved in the cultivation, processing, and marketing of these crops, especially the arable crops in both zones. However, processing and marketing are their important roles for cocoa and oil palm enterprises.

Objectives of the Study

The following specific objectives were achieved:

1. Assess the socioeconomic characteristics of the rural women in the study areas.
2. Determine the livelihood activities of respondents in Oyo State.
3. Compare the influence of climate change on the women's activities in the two ecological zones.
4. Identify the various adaptation strategies adopted by women in the two ecological zones of the study area.

Review of Relevant Literatures

Implications of Climate Change for Agriculture

Greater poverty impacts agriculture hugely since it hampers human energy/effort to plant and restricts capacity to afford necessary inputs. Smith (2006) notes that over 40 % of the world's people are unable or barely able to meet their needs for survival. Attainments of the Millennium Development Goals (MDGs) may therefore have been overtaken by events as the expiry is around the corner. It will result in greater poverty, wider discrepancy between rich and poor, sea level rises, and more precarious livelihoods challenging survival. Already, 2.7 billion people try to live on £1 or less per day. Smith (2006) argues that action on climate change is integral to poverty reduction. Such action requires both mitigation of the rate of change (Keller et al. 2005) and adaptation to that which does occur. Stabilizing CO_2 at 450 ppm (requiring cuts of 60–90 % in GHG emissions before 2100) may limit the mean global temperature rise to 2 °C. Mitigation of climate change is affordable; to stabilize at 450 ppm CO_2 would cost 1–4 % of global average GDP over 50 years. Kyoto protocol implementation would cost 0.1 % of GDP over 10 years.

Concept of Adaptation to Climate Change

Different authors have come up with different definitions of adaptation to climate change. Burton et al. (1998) define it as all those responses to climate change that may be used to reduce vulnerability. According to Burton (1997), adaptation to climate is the process through which people reduce the adverse effects of climate on their health and well-being and take advantage of the opportunities that their climatic environment provides. Downing et al. (1997) asserted that adaptation is synonymous with "downstream coping." Füssel and Klein (2002) defined it as all changes in a system, compared to a reference case, that reduce the adverse effects of climate change. IPCC (2001) defined adaptation to climate change as adjustment in ecological, social, or economic systems in response to actual or expected climatic stimuli and their effects or impacts. This term refers to changes in processes, practices, or structures to moderate or offset potential damages or to take advantage of opportunities associated with changes in climate. It involves adjustments to reduce the vulnerability of communities, regions, or activities to climatic change and variability. Adaptation strategies to climate change in this study are being viewed as a combination of adjustment and/or responses within the human capacity, put up to reduce the undesired impacts of climate change on the livelihood of the people, making use of the opportunities within the local environment.

Gender and Climate Change

There are numerous significant linkages between gender and agriculture. Gender aspects in agriculture affect access to and control over resources, with consequences for food security as well as for market and policy decisions. In many countries, women's access to land is limited. Patrilineal inheritance customs regulate land ownership and property rights and thereby influence control over land and food sovereignty. At the same time, women make up 54 % of the agricultural labor force worldwide, significantly more in the Global South. For example, 80 % of female employees and self-employed in sub-Saharan Africa are working in the agricultural sector.

Women make up a large number of poor people in communities that are highly dependent on local natural resources for their livelihood and are disproportionately vulnerable to and affected by climate change. Zabbey (2011) opined that women's limited access to resources and decision-making processes increases their vulnerability to climate change. Additionally, women in rural areas in developing countries have greater responsibility for household water supply, energy for cooking and heating, and for food security. Thus, women are negatively affected by drought, uncertain rainfall, and deforestation. Again, because of their roles, unequal access to resources, and limited mobility, women in many contexts are disproportionately affected by natural disasters, such as floods, fires, and coastal erosion (Zabbey. 2011).

Women are the main producers of the world's staple crops, providing up to 90 % of the rural poor's food intake and producing 60–80 % of the food in most developing countries. Maize, sorghum, millet, and groundnut yields have a strong association with the year-to-year variability of ENSO (El Niño-Southern Oscillation) in Africa. For Southern Africa, the productivity is expected to drop by 20–50 % in extreme El Niño years (Stige 2006). If global climate changes move more toward El Niño-like conditions, crop production in Africa will decline (Stige 2006). Insect outbreaks could increase due to changes in climate. For example, locust outbreaks in China are associated with cold and wet periods, floods, and droughts (Stige 2007). Climate variability, according to Stireman et al. (2005), also affects the relationships between parasite and host, and parasitoids are key agents of control of herbivore populations. An increase in pest outbreaks would not only reduce crop and milk yields but also add to the number of hours and resources women had to invest in pest control.

However, women are not just helpless victims of climate change, they are powerful agents of change and their leadership is critical. Women can help or hinder in dealing with issues such as energy consumption, deforestation, burning of vegetation, population growth and economic growth, development of scientific research and technologies, and policy making, among many others.

Methodology

The study was carried out within Oyo State. The two major ecological zones in Oyo State are the forest and savannah. Oyo State is located within the western region of the southern part of Nigeria. It covers a total of 27,249 km^2 of landmass. Oyo State enjoys the characteristic West African monsoon climate, marked by distinct seasonal shifts in the wind pattern. Between March and October, the state is under the influence of the moist maritime southwest monsoon winds, which blow inland from the Atlantic Ocean. This is the raining season. The dry season occurs from November to February, when the dry northeast trade dust harmattan winds blow from the Sahara desert. The state thus is characterized by two climate seasons, raining season and dry season.

Oyo State was stratified into rainforest and savannah zone (Table 1) being the two ecological zones in the state. In the rainforest zone, Saki West and Ido LGAs were purposively selected for being most predominantly savannah and rainforest, respectively. Of 10 wards in each of the LGAs, 30 % were selected, to give a total of six wards. Twenty-three villages were selected in all, while a total of 117 rural women were sampled. Table 1 presents the summary of the sampling procedure.

Structured interview schedule was used to obtain information from the women. Primary data were obtained on socioeconomic characteristics of respondents, livelihood activities, awareness of climate change, and impact of adaptation strategies to climate change effects. The level of awareness of climate change was measured by using a three-point scale indicating whether the selected impact items have increased (2), no change (1), or decreased (0). Perceived effects of climate change in the two area were measured in terms of yes = 0 or no = 1. Perceived

Table 1 Distribution showing sampling procedure and sample size in the two ecological zones of the study

Ecological zones	No. of wards	30 % of wards	No, of villages	10 % of villages	No. of household sampled per village	Total no. of respondents sampled
Savannah zone (Saki West local government area)	10	Ajegunle	51	5	5	25
		Keli	51	4	5	20
		Ogidigbo	41	4	4	16
Forest zone (Ido local government area)	10	Omi-Adio	30	3	7	21
		Akufo	29	3	5	15
		Apete	39	4	5	20
Total	20	6	241	23	31	117

effect of climate change was then operationalized as negative and positive, using the mean effect score as the benchmark. Adaptation strategies adopted by rural women in coping with the effect of climate change were measured as respondents indicated “yes” or “no” to a list of adaptation strategies employed and not employed, respectively. Scores of 1 and 0 were assigned to “yes” and 0 to “no.” An index of each of the influence of climate change effects and adaptation strategies was then obtained and abstracted to interval levels of measurement. The mean scores of influence of climate change as well as farmers’ level of adaptation strategies were then compared, each between women in savannah and forest zones of the state, as stated in hypotheses 1 and 2, respectively.

Conceptual Framework

Figure 1 below presents the conceptual framework that relates the negative effects of climate change and their adaptation strategies to these effects. This is not to imply that climate change is only associated with negative consequences. However, the study focuses on only the various negative effects of climate change against which rural women in the two ecological zones have developed adaptive measures. The framework borrows from a number of frameworks that have been used in analyzing risk, vulnerability, and poverty (Smith et al. 2005 and Hoddinott and Quisumbing 2003). The socioeconomic characteristic of an individual has an influence on the various forms of livelihood activities (livelihood strategies) a typical rural dwellers engages in. In recent years, farming is becoming a far less potent source of livelihood in the rural areas of many sub-Saharan African nations; therefore, multiplicity of these activities has become a trend. It is therefore expected that, for example, membership of social organization could avail a rural dweller access to credit facilities and extension education. These and many more opportunities derivable from being members help an individual to diversify into other forms of livelihood

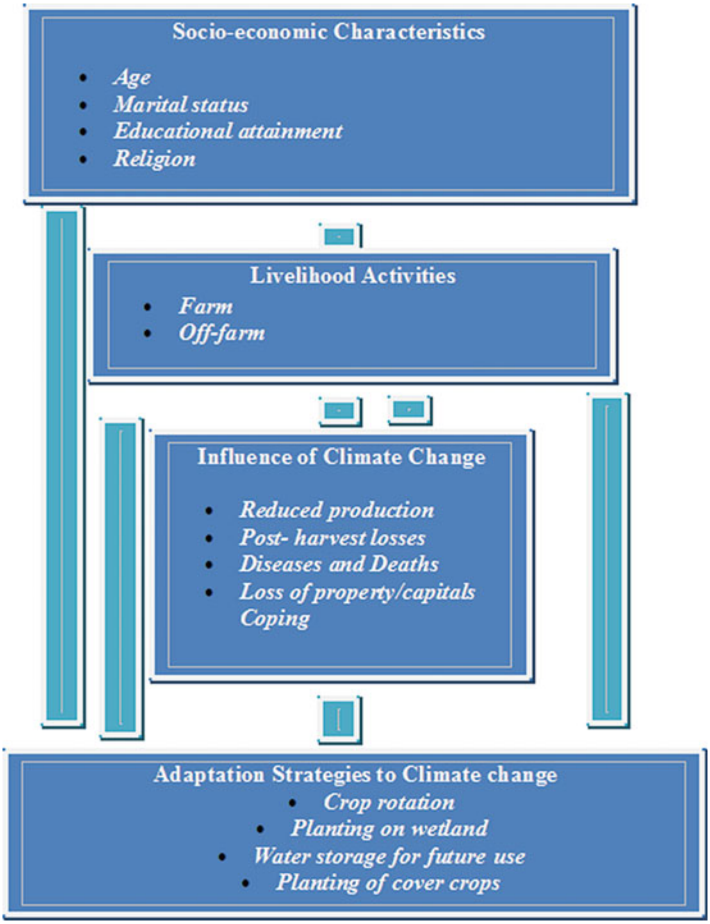

Fig. 1 Conceptual framework for adaptation strategies to climate change of women in two ecological zones of Oyo State. Source: Authors' idea

activities, since assets (in this case, social asset) determine to a large extent an individuals' livelihood activity in terms of number and type. Smith et al. (2005) support this notion by positing that in the rural communities, the capacity to resist poverty and improve livelihoods often depends on the opportunities offered by natural resource-based production systems as conditioned by wider economic, institutional, and political environment. Bebbington (1999) posited that these assets are not simply resources that people use in building livelihoods but they are also assets that give them capabilities. For example, possession of human capital is not only the means people produce more and more efficiently, it also gives them the capability to engage more fruitfully and meaningfully with the world (Sen 1997).

The framework also establishes a direct and vice versa relationship between these livelihood activities and the influence climate change has on the people.

This is because climate-related shocks often affect stock of livelihood assets, which eventually have their tolling effects on livelihood activities. These often result in reduced production, poor health, insecurity, loss of capitals, poor harvest, and post-harvest losses. On the other way round, these resultant effects of climate change affect the extent to which the people are engaged in one form of livelihood activity or the other. For example, a woman farmer with poor health condition (an example of influence of climate change) has less human capability to work and therefore limit her engagement in livelihood activities and even her holding of assets. At the last level of the framework are the adaptation strategies to climate change of rural women which are a function of the kind of influence climate change has on their livelihood activities. This partly agrees with Smith et al. (2005) that depending on the assets (as a proxy for activities) the people have access to which defines livelihood activity opportunities, a household will then choose a set of adaptation strategies to climate change effects. Bebbington (1999) posited that assets are not simply resources that people use in building livelihoods but also gives them capabilities. Adaptation strategies are also directly influenced to a very large extent by some socioeconomic characteristics such as educational status, membership of social organization, and access to credit facilities. Also, the level and how effective are the adaptation strategies of the people, to a large extent, impact upon their livelihood activities and assets in terms of extent of use (for activities) and value and number (for assets) for building resilience against climate change effects.

Results and Discussion

Table 2 reveals that 26.2 % and 19.3 % of the respondents were 30 years and below in savannah and forest zones, respectively, while 33 % and 30 % falls within middle-age range of 41–50 years. The mean age of the women in savannah zone was 40 years, while those from forest zone were 43 years. The result implies that more of the rural women from savannah zone (88.2 %) are in their active age of 20–50 years when compared with respondents from forest zone (67.8 %); hence, they can actively engage in productive activities and thereby contribute effectively to food production in Nigeria. The result also shows that 80.3 % and 63.4 % of the respondents from savannah and forest zones respectively were married. This implies that since women in the two zones were predominantly married, this could influence the adaptation strategies of the majority through spousal supports and thereby reduce the effects of climate change on their activities.

Also, 41 % and 34 % of the respondents from savannah and forest zones respectively do not have formal education, while 32.8 and 32.1 % respectively had primary education. This shows that there is a very large case of illiteracy, as level of literacy was low. Accessing relevant information through the use of the modern-day ICTs as well as the print media may therefore be difficult for the respondents. The result further shows that 55 % and 44 % of the respondents from the respective zones were Christians, while 42.6 % and 53.6 % were Muslims. The result reveals that 52.6 % and 66 % of the women in savannah and forest zones

Table 2 Distribution of respondents according to their socioeconomic characteristics

Variables	Savannah zone		Forest zone

respectively belongs to various religious groups in their communities and this constitutes a greater proportion compared with other social groups in the zone. This is a clear indication that most of the women will have quick access to information about their community, family, and other areas of concern. Also women join voluntary formal groups to be better informed and for economic gains.

Livelihood Activities Engaged in by Respondents

Table 3 reveals that in the savannah zone, 41.0 % of the respondents were fully involved in crop farming, while 18.0 % are occasionally involved. Few of the women (6.6 %) were fully engaged in rearing of animals, while 50.8 % of the women occasionally rear livestock such as goats, sheep, and fowl. About one third (34.4 %) of the

Source: Field survey, 2011

women also reported significant involvement and direct marketing of their farm products such as cassava, maize, palm produce, etc. These are farm products cultivated by the women or by their husbands, thereby eliminating the position of middlemen and more profits are made. The results agree with Dercon and Krishnan (1996), Bryceson and Jarnal (1997), Little et al. (1998), and Barret and Webb (2001) who argue that farming on its own rarely provides a significant means of survival in rural areas of low-income countries including Nigeria. Rural livelihood diversification also serves as means of spreading risks associated with climate change among respondents in the study area. The result also shows that majority of the respondents do not engage in hired labor activities (77 %), fish farming (95.1 %), and harvesting of farm produce (95.7 %). The implication of this is that these activities are considered for the men folk since it requires lot of energy.

Table 3 further shows that of all the farming-related livelihood activities in the forest zone, larger proportion of the respondents were fully engaged in crop farming (51.8 %), crop processing (30.4 %), and marketing of farm produce (51.8 %). Also, none of the respondents was fully involved in livestock rearing, gathering and sales of fuelwood, fish farming, fish processing, and hired labor work. This implies that majority of the women in the zone derived their living through farming; hence, their survival depends on agricultural land which must be rich and fertile in order to increase productivity. The result concurs with the study of Asunmgha and Nwosu (2006) and Ajeih and Uzokwe (2007) that women play a leading role in agricultural enterprise, contributing about 58 % in southwest and 88 % in north-central zones, with involvement in virtually all activities, namely, hoeing, planting, weeding, harvesting, transporting, storing, processing, marketing, and domestic chores.

Influence of Climate Change on the Livelihood Activities of the Respondents in the Two Zones

Table 4 reveals that majority (80.3 % and 100 %) of the respondents residing in savannah and forest zones respectively had experienced an increase in intensity of sunlight over the years. The result shows that majority of women in savannah zone (63.9 %) and 100 % of women in forest zone also experienced decrease in the frequency of rainfall. In a study in the northern part of Nigeria, Ojo et al. (2001) showed a decrease in rainfall in the range of about 3–4 % per decade since the beginning of the nineteenth century. The result also reveals that 63.9 % of women in savannah zone and 82.1 % in forest zone lamented an increase in incidence of pest and diseases, while very few (6.8 % and 1.6 % of women) in these zones reported that there is no change being witnessed. This implies that change in climate favors emergence of pest and disease which feeds on farmers' crops leading to decrease in farm yield and consequently lower income of the farmers. WHO (1990) supported this view that adequacy of food production could be affected by reduction in the quantity of water available for irrigation, loss of farmland through rise in sea level, changes in crop yield, livestock production, and geographical shifts in the agroclimatic zones suited to the successful cultivation of

Table 4 Distribution of respondents' awareness on climate change

Variables	Savannah zone						Forest zone					
	Increase		Decrease		No change		Increase		Decrease		No change	
	F	%	F	%	F	%	F	%	F	%	F	%
Increased intensity of sunlight	49	80.3	11	18.0	1	1.6	56	100	–	–	–	–
Increased frequency of rainfall	21	34.4	39	63.9	–	–	–	–	56	100	–	–
High incidence of pest and diseases	39	63.9	18	29.5	4	6.8	46	82.1	9	16.1	1	1.6
High incidence of skin and airborne diseases	40	65.6	7	11.5	14	23.0	14	25.0	12	21.4	30	53.6
Heat stress on human productivity	46	75.4	6	9.8	9	14.8	52	92.9	–	–	8	13.1
Reduced availability of forest products	12	19.7	41	67.2	8	13.1	1	1.8	44	78.6	11	19.6
Increased cases of soil erosion and flooding	8	13.1	21	34.4	32	52.5	4	7.1	18	32.1	34	60.7
Reduced availability of portable water	8	13.1	45	73.8	8	13.1	34	60.7	20	35.7	2	3.6
Loss in crop productivity	42	68.9	12	19.7	7	11.5	33	58.9	14	25.0	9	16.1
Loss of animal productivity	46	75.4	6	9.8	9	14.8	33	58.9	14	25.0	9	16.1

specific crops. The study further revealed that 67.2 % and 78.6 % of the respondents from savannah and forest zones respectively reported a decrease in availability of timber and other forest products such as mushrooms, snails, breadfruit, and so on. A large number (68.9 % and 58.9) of the women in the respective zones reported increasing cases of crop losses and declining animal productivity. The implication of this is that there would be a decrease in supply of animal protein to the community which could lead to insufficient protein, deficiency diseases, and low income with consequent poverty being on the increase. Kurukulasuriya et al. (2006) and Ole et al. (2009) asserted that analysis of 9,000 farmers in 11 African countries predicted falling in farm revenues with current climate scenarios. Also Butt et al. (2005) predicted future economic losses and increased risk of hunger due to climate change.

Adaptation Strategies to Climate Change

Due to the influence of climate change on livelihood activities, women in the two ecological zones of the study employ different adaptation strategies to climate change effects on their activities. The study reveals that adaptation strategies employed by the respondents to various extremes of climatic variables varied across the two ecological zones of Oyo State. In the savannah zone, for example, the most important adaptation strategies included water storage for future use, diversification into other activities, and changing planting dates. This establishes the low level of water available for the crop plants, as well as for other livelihood and domestic activities of the rural women in the study area. It also implies the irregular rainfall annual calendar. On the other hand, while diversification into other activities was the most used adaptation strategies to climate change, practicing multiple cropping and changing planting dates were also important adaptive measures against climate change effects. These results are in line with Molua (2008), Rudolf and Hermann (2009), and Apata et al. (2009) who reported that main strategies for reducing climate risk is to diversify production and livelihood systems like soil and water management measures.

In the two zones, however, the least adopted adaptation strategies to climate change included rearing snail and/or grass cutter, use of fertilizer on farmland, as well as planting of *Jatropha* to help conserve water through reduction of evapotranspiration. The low-level adoption of use of fertilizer may be due to low access to production resources which very often are the cases in sub-Saharan Africa. This is in line with Ajani (2008) who asserted that despite significant contributions of women to economic development and the household, overall, they have less access to land, capital, credit, technology, and training than men do. This significantly entrenches poverty in the female gender. It also agrees with Sangotegbe et al. (2012) who reported lack of access to fertilizer as an important constraint limiting food crop farmers' adaptive capacity to climate change in Oke-Ogun, an area in the savannah region of Oyo State (Table 5).

Table 5 Distribution of respondents according to adaptation strategies to climate change in savannah zone

Adaptation strategies	Savannah			Rainforest		
	F	%	Rank	F	%	Rank
Crop rotation	27	44.3	5	37	66.1	4
Planting of trees	20	32.8	8	8	14.3	11
Cultivating wetlands (Akuro)	25	41.0	7	14	25.0	8
Planting early maturing crop	15	24.6	9	17	30.4	7
Use of fertilizer on farmland	6	9.8	13	11	19.6	10
Practicing multiple cropping	30	49.2	4	39	69.6	2

Hypothesis 1

Ho$_1$ There is no significant difference in the influence of climate change on rural women in the two ecological zones.

Result shows that there is a significant difference in the influence of climate change on the activities of rural women in the two ecological zones (t = 4.605, p = 0.000), with the effects being more in the forest zones. The implication of this is not far from the fact that savannah zone experiences shorter duration of rain period with longer period of dry season than forest zone which enjoys abundance of rain. This could mean more hardships to the rural women in this zone (savannah), many of whom depend on the natural sources for water and other resources as sources of livelihood and household energy needs (Table 6).

Hypothesis 2

Ho$_2$ There is no significant difference between the levels of adaptation strategies adopted by rural women in the two ecological zones.

The findings further reveal that there is significant difference between adaptation strategies adopted by rural women in the two ecological zones (t = 6.637, p = 0.000), with the forest zone adopting a higher level of adaptation measures than their savannah counterparts. This may be expected since rural women in the forest zone of the state experienced higher effects of climate change. It should however be noted that majority of the adaptation strategies being adopted to reduce climate

Table 6 *t*-test analysis of the influence of climate change on rural women in the two ecological zones

Variables	Mean	Degree of freedom	t-value	p-value	Mean difference	Standard deviation	Decision
Savannah	8.10	116	4.605	0.000	8.11	2.160	Significant
Forest	16.21						

Table 7 *t*-test analysis on adaptation strategies adopted by rural women in the two ecological zones

Variables	Mean	Degree of freedom	*t*-value	*p*-value	Mean difference	Standard deviation	Decision
Savannah	13.202	30	6.637	0.000	5.129	4.303	Significant
Forest	18.331						

change effects on the activities of women are those within their very limited economic power. It therefore suggests that the higher level of adaptation strategies were informed by the higher level of effects in the forest, rather than being indicative of higher level of access to resources (Table 7).

Conclusion and Recommendations

Women in the two agroecological zones are engaged in farming-related activities as their means of livelihood although very few of them engage in non-farming-related activities such as trading, hair-plaiting, tailoring, pottery, craft work, and tie-dye. The result of the research reveals that majority of the respondents in the two zones agreed to have been highly affected by climate change, in their various livelihood activities. Influence of climate change on respondents' livelihood activities and adaptation strategies adopted against climate change effects were both higher in the forest than in savannah zones of the state. However, adaptive capacities of the women were limited as strategies to climate change were restricted to those within the limited local resources available to the rural women in the two ecological zones of Oyo State.

Recommendations

Based on the results and conclusion of the study, the following recommendations are important:

1. Government should provide irrigation facilities especially in the drier region of the state (savannah zone) so as to boost agricultural activities during dry season.
2. The use of alternative energy fuel such as biofuel for domestic and household cooking should be encouraged among women.

3. Affordable technology that will adequately help rural women to cope with negative effects of climate change such as improved planting material, drought-resistant crop, planting early maturing varieties, and cultural means of reducing infestation of pest and diseases should be within the reach of the rural women.
4. Rural women should be encouraged to form groups where they can get access to short- term credit facilities at lower interest rates to help finance agricultural production and as such improve their lives and that of their family.
5. The Nigerian government should develop a gender strategy, promote women representatives as official focal points, invest in gender-specific climate change research, and establish a system for the use of gender-sensitive indicators and criteria for governments in national adaptation planning.

Abstract

Adapting to climate change is the most serious challenge facing our species. The scale is global, trajectory of onset uncertain and impacts potentially catastrophic (IPCC 2013). As further evidence emerges and as the scramble to adapt to the 'new normal' intensifies, persistent problems, past failures and new challenges have the potential to converge in a perfect storm. In response, extension and advisory service (EAS) providers have a key role to play as a critical link between farming populations and sources of new information and tools, so that practices can be appropriately adapted. This chapter outlines the challenge of adapting to climate change, identifies past and present points of EAS engagement, and proposes future responses, with a focus on the constraints and conditions of smallholder farmers in the tropics, and the natural resource base upon which agriculture depends.

Keywords

Agriculture extension and advisory services • climate change adaptation • human capacity development • information communication technologies • policy coordination • scaling interventions • systems research • technology switching points • technology transfer/dissemination

Introduction

Since the domestication of crops and the emergence of sedentary societies, adapting to climate change is the most serious challenge our species has faced. The scale is global, the potential impacts catastrophic, the time frame of onset largely unknown, and the threat of delayed action real (IPCC 2013, 2014). As further evidence emerges, we will have to continually redefine our understanding of problems and formulate responses.

Extension and advisory service (EAS) providers have a key role to play as a critical link between farmers and sources of new information and tools and in aiding farming populations to anticipate and adapt their practices in response to the challenges of climate change. Public extension systems will need to improve, to change the perception that they are unimportant and outdated. Private-sector interests will need to adjust and respond to shifting opportunities, and nongovernmental organizations (NGOs) and donors will need to join forces with others to achieve broader impact. As the scramble to adapt to the *new normal* intensifies, persistent problems, past failures, and new challenges have the potential to converge in a perfect storm. In response, all involved in agricultural adaptation will need to elevate the level and quality of their efforts.

This chapter outlines the challenge of adapting to climate change, identifies past and present points of EAS engagement, and proposes future responses, with a focus on the constraints and conditions of smallholder farmers in the tropics and the natural resource base upon which their livelihoods depend.

Box 1: Definitions of Key Terms Used in This Brief in the Context of Climate Change

Vulnerability: "[T]he degree to which geophysical, biological and socio-economic systems are susceptible to, and unable to cope with, adverse impacts of climate change" (IPCC 2007a).

Resilience: "The ability of a system and its component parts to anticipate, absorb, accommodate, or recover from the effects of a hazardous event in a timely and efficient manner. . ." (IPCC 2012).

Adaptation: "In human systems, the process of adjustment to actual or expected climate and its effects, in order to moderate harm or exploit beneficial opportunities. In natural systems, the process of adjustment to actual climate and its effects. . ." (IPCC 2012).

Mitigation: The efforts undertaken to "reduce anthropogenic [greenhouse gas] emissions or to enhance natural sinks of greenhouse gases" (IPCC 2007b).

The *New Normal*: The Biophysical Forces

Before they can prepare for and respond to global climate change, EAS providers must first understand the essential nature of climate change and the associated challenges. The rapid 20–25 % downturn in precipitation across the West African Sahel that occurred around 1970 and lasted through the 1990s provided a glimpse of what the future may hold. Global climate change, however, will be different.

In the current context, and barring the onset of abrupt climate change, we are unlikely to see such a sudden shift. Climate change is a process that will continue well into the next century with impacts felt over the next millennium. Climate change is also nonlinear and highly complex, with layers of feedback loops and unknown "tipping points" that, when exceeded, offer no retreat. Moreover, changes will continue on multiple fronts – air temperature and volume and patterns of precipitation, as well as other weather features. Climate change should also be understood as permanent; there will be no return to prior conditions over the course of individual human lifetimes (IPCC 2013).

Unlike challenges we have confronted in managing natural resources in the past, in the case of climate change, we have neither the means to readily affect the near-term rate or direction of change nor sufficient knowledge to anticipate the long-term synergistic effects within linked physical and natural resource systems.

Climate change will exert increasing pressure on our ability to meet other major challenges, feeding the world's growing population, which is expected to reach 9.6 billion by 2050, being paramount (UNDESA 2013). The environmental impacts of meeting rising food demand will be intensified as global warming and changes in associated climate features amplify the stressors placed on vulnerable and overburdened natural resource systems, leading to unknown interactions and feedback in the complex web of relationships among social, environmental, economic, and food systems with "uncertain consequences" (Ericksen et al. 2009). This situation is particularly troubling for people who are surviving on already degraded systems.

EAS providers will need to contend with the effects of two dimensions of climate change: ***climate change trends*** *and* ***weather disruption****.*

Climate Change Trends (Slow-Onset Systemic Changes)

Greenhouse gases: Increased concentrations of greenhouse gases (GHGs) prevent solar radiation reflected from the earth's surface from escaping the atmosphere. Carbon dioxide (CO_2) is the primary GHG emitted through human activities. The agricultural sector is a significant contributor to the problem. Taken together, the deforestation associated with agricultural expansion and direct and indirect energy use (including food transportation, processing and preparation), the agricultural sector is responsible for roughly one third of all GHG emissions (IPCC 2007b; USEPA 2006). To avoid triggering significant climate change, the upper limit of atmospheric CO_2 concentration is estimated to be around 350 ppm (Hansen et al. 2008). Concentrations have been rising steadily, 2 ppm per year over the past 15 years, and reached 400 ppm in May 2013 (NOAA 2013). At this rate, CO_2 levels are on track to meet the IPCC's most pessimistic projection for 2100 (IPCC 2013). Such high levels of CO_2 are expected to have a catastrophic effect on the planet's ecosystems. One hope is that if we can reduce future GHG emissions, we can mitigate the risk of even more distant changes to the climate. But even if all additional emissions were eliminated, 15–40 % of the warming effect from past emissions will continue for the next 1,000 years (IPCC 2013). And we have barely begun the serious work of reducing emissions.

Global warming: The primary outcome of rising atmospheric levels of CO_2 is an increase in land and sea surface temperatures – global warming. Historical records show a close tracking of air temperatures with atmospheric CO_2 levels (see Fig. 1). Over the past 60 years, average global air temperature has risen by 0.7 °C; temperatures over landmasses and in the high latitudes have risen by double this amount (IPCC 2007a, 2013). Decadal warming–cooling cycles in the south Pacific, currently in a cooling phase, are thought to be responsible for the recent slowdown in the rise of global air temperatures (Kosaka and Xie 2013). When the effect subsides, more rapid warming will likely occur.

Rising air temperatures trigger important secondary effects: These include (i) changes to seasonality, especially the onset and duration of warm seasons in northern latitudes; (ii) changes in the onset and duration of rainy seasons in the mono- and bimodal rainfall areas of the tropics; (iii) melting of the polar ice caps, northern latitude ice shields, and high-altitude glaciers worldwide, leading to changes in the timing and volume of freshwater discharge and rising sea levels; and (iv) more water cycling through the climate system (since warmer air carries

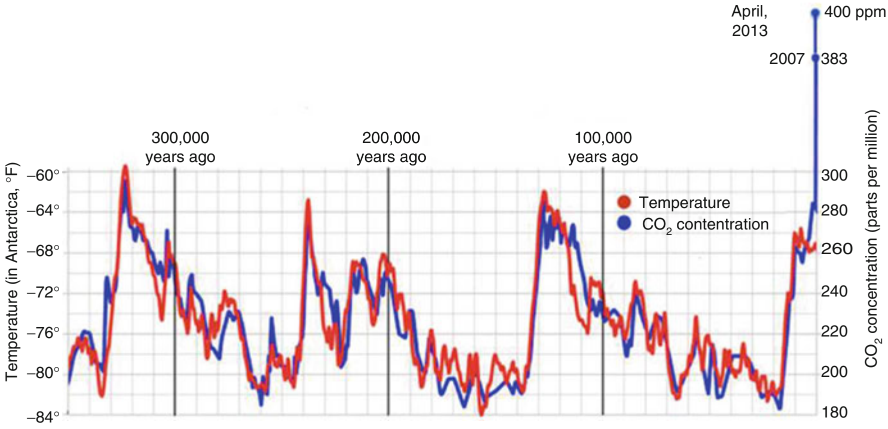

Fig. 1 CO_2 and global temperatures (Source: Modified from Southwest Climate Change Network, The University of Arizona (www.southwestclimatechange.org/figures/icecore_records), modified from Marian Koshland Science Museum of the National Academy of Sciences (www.koshland-science-museum.org))

more moisture), but with nonuniform distribution – in general, wet areas are projected to get wetter and dry areas drier.

Tertiary impacts of these changes on agriculture: These include (i) disruption of plant–pollinator and pest–predator relationships, altering the geography of pests and diseases, caused by rising air temperatures and changes in seasonality; (ii) higher daytime and nighttime temperatures affect plant maturation and plant respiration – the resulting yield declines (e.g., see Lobell and Asner 2003; Peng et al. 2004; Easterling and Apps 2005) will erase any positive effects on photosynthesis from higher concentrations of atmospheric CO_2 (see Fig. 2); (iii) by 2100, average growing-season temperatures are projected to exceed the temperature tolerances for many crops in locations where they are now grown (see Battisti and Naylor 2009; Gourdji et al. 2013); (iv) the decline and eventual loss of glacial water sources will drastically affect the systems that depend on these for irrigation, especially in high-population areas in Asia; and (v) rising sea levels will inundate low-lying coastal areas and islands, causing increased saltwater intrusion in coastal river and groundwater systems, eventually displacing tens of millions of people in flood-prone areas and potentially affecting a tenth of the world’s population – those living within 10 m of sea level (McGranahan et al. 2007).

Our understanding of when, where, and how these changes will be felt is still nascent (IPCC 2014). These general trends, however, will continue as long as we continue to emit substantial amounts of GHGs and long after. The very act of feeding the world’s population (agriculture) is a major source of emissions, and this effect will likely increase, not decrease, as we struggle to increase food production by the required 60–70 % by 2050 (FAO 2009; USAID 2013).

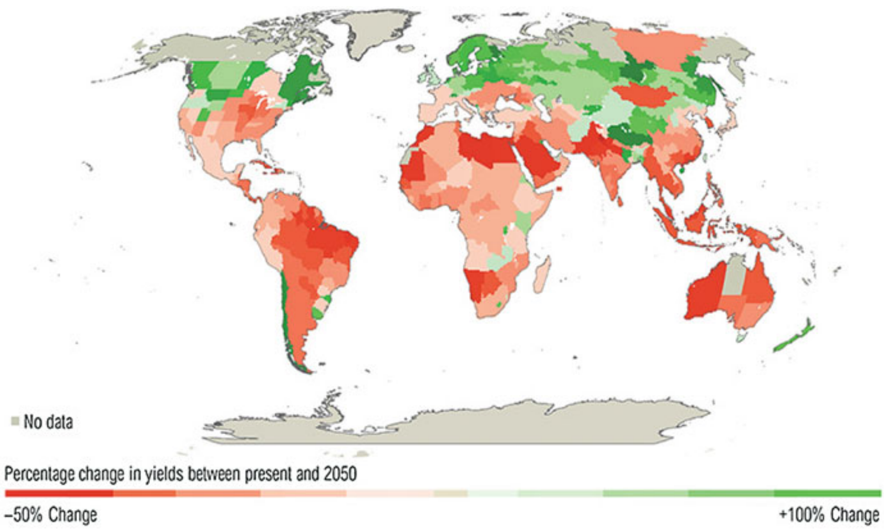

Fig. 2 Projected impact of a 3 °C temperature increase on crop yields (Source: World Bank 2010)

Weather Disruption (Extreme and Aberrant Weather Events)

More frequent and severe and at unpredictable times and places: Severe weather events – droughts, floods, hurricanes/cyclones/typhoons, and heat waves – are occurring with increased frequency, duration, and severity (IPCC 2012). The additional moisture carried by warmer air and the increased energy stored in the oceans (i.e., 90% of the solar energy trapped by GHGs) are leading to more intense and frequent storm events, as well as the systemic changes to rainfall described above (IPCC 2013). Extreme heat events in areas such as West Africa, for example, which typically occur once in 20 years, are predicted to occur every 2 years by the end of the century (IPCC 2012), and historically rare, once-in-50-years, once-in-100-years, and once-in-300-years events will become commonplace (see Fig. 3). EAS providers will increasingly be called on to assist with relief efforts for affected populations in the wake of these unpredictable and severe weather events (Shepherd et al. 2013).

Depletion and reduced resilience: Increasingly disruptive weather patterns will wear down the resilience of human systems and lead to the ecological restructuring of natural systems. Productivity will decline in some areas; natural resources and financial reserves will be depleted and unavailable for investment in long-term welfare improvements. Countries whose economies depend on rain-fed agriculture will be especially vulnerable; for example, in the Africa region, between 1960 and 2000, gross domestic product tracked closely with the rise and fall of annual rainfall levels (Barrios et al. 2003). At the farm level, investments in agricultural enterprises, especially those that depend on vulnerable local resources (such as seasonal water sources), will become increasingly risky.

Implications for Smallholders and the Rural Poor

Global climate change has sobering implications for natural resource management (NRM) and our long-term ability to feed ourselves. It also calls into question our continued ability to rely on agriculture for long-term poverty reduction and economic growth (World Bank 2008, 2010).

One of the hallmarks of the vitality of rural communities and smallholders is their ability to respond and adapt to changes that affect their livelihoods. Older villagers and more experienced farmers have noted changes in local climate and weather for several decades. Changes that are compounding the effects of expanded crop production and meeting fuelwood needs, leading to soil erosion and declining fertility through reduction and abandonment of fallow periods, increased insect pressures and incidence of disease, all related to the intensification of resource extraction (Bryan et al. 2009; Ebi et al. 2011; Gbetibouo 2009).

The fewer assets that rural families have – human, financial, natural, social, political, physical – the more challenging it becomes for them to cope with change and the longer it takes for them to recover from even modest shocks. Many communities and households already struggle to survive due to ongoing degradation of natural resources. The negative impacts of climate change trends and weather disruptions will further deplete the natural and financial assets of the rural poor, increasing their vulnerability (Barrett and McPeak 2006).

Collectively, legal tenure systems in many countries also undermine farmers’ control over natural resources. Ineffective national policies and local management structures further weaken farmers’ ability to manage natural resources, increasing their vulnerability to climate-induced trends and shocks. In contrast, within the

Box 2: The Lessons of Hurricane Mitch

The events in the aftermath of Hurricane Mitch in Central America in 1998 illustrate the importance of timing and scale. Families who had previously resisted planting live contour barriers to stem runoff and erosion lost their hillside plots in the hurricane while neighboring plots were protected by well-spaced vetiver hedges and rock barriers. A large multiagency research project on farmer responses to Hurricane Mitch found that plots under conservation agriculture practices sustained 58–99 % less damage, retained 28–38 % more topsoil, and suffered two to three times less surface erosion than conventionally managed plots. Seeing the differences, households that had previously resisted changing NRM practices immediately began to demand training and the adoption of *new* practices and technologies soared (World Neighbors 2000).

Lesson 1: Efforts to bring about behavioral change should to be targeted at the appropriate scale – in this case, hillsides within a watershed.

Lesson 2: Use observable evidence of climate change to focus farmers' attention on the importance and interrelations of NRM practices and agricultural management alternatives – i.e., capitalize on the teachable and learnable moments.

context of climate change, there is a growing need to link individual agricultural decisions with larger landscape and land-use management challenges.

Individuals and communities can be slow to implement changes in NRM, especially in locations with high proportions of vulnerable households and where there are no immediately observable benefits in productivity (Marenya and Barrett 2007; Shiferaw et al. 2009). Unfortunately, the benefits of most changes in NRM take time to manifest and are easily masked by seasonal stresses. Changes in local weather patterns, including more frequent severe events, will push smallholders to take up new NRM practices more quickly. Indeed, disasters can trigger rapid, widespread behavioral change that EAS providers must be prepared to capitalize on (see Box 2).

The Challenges of Climate Change for EAS Providers

The nature and range of professional challenges facing EAS providers will increase as the cumulative effects of climate change manifest themselves, including helping vulnerable farmers and rural communities to:

(a) ***Adapt*** their livelihoods to current and future changes in local weather conditions and the evolving status of natural resource systems.
(b) Strengthen the (bio)physical and social ***resilience*** of natural and human systems to withstand and recover quickly from increasingly frequent and severe weather events.

(c) ***Mitigate*** risks of further climate change by conserving existing carbon stocks, reducing CO_2 emissions from agriculture, and helping to sequester atmospheric CO_2 in trees and soil organic matter.

EAS Key Challenge No. 1: Determining the Technological and Adaptive Practice Switching Points

Extension and research programs must determine what proportion of limited human and financial resources to allocate to landscape-level versus farm-level interventions and within these different scales they must help farmers and rural communities to determine the timing, nature, and location of specific adaptive changes. The challenge lies in helping farmers and rural communities transition from current to anticipated future conditions, while keeping in sight the context of location-specific problems, appropriate scale and time frame, and availability of resources. To effect landscape-level changes in NRM, EAS providers will need to work with and through multi-stakeholder decision processes, help broker agreements, strengthen management structures, and mediate conflicts. There will be some hard choices to make.

Specific decisions related to climate change adaptation may include:

- When to switch to varieties and crops with greater tolerance to emergent climate change stressors
- When to modify or switch land-use systems (e.g., from annual crops to perennials more tolerant of droughts and intensive rainfall)
- When to transition from rain-fed production to supplementary irrigation as the frequency and length of dry spells increase
- When to augment and increase the capacity of drainage systems to handle extreme rainfall events
- When to shift use of land types – for example, moving from drought-prone uplands to better watered lowlands or moving out of increasingly flood-prone riparian areas
- When to diversify out of agriculture and ultimately abandon certain areas as they become untenable as zones of production

Making these choices for specific locations and at different scales will be difficult. The optimal timing for adaptive responses is never obvious, as it depends on local and external resources and costs; individual, social, and institutional capabilities; evolving markets; and national policy frameworks. Individual technology and management choices offer benefits under specific ranges of conditions and are suboptimal in others. Once taken, some choices may preclude following other action pathways. Some options involve significant lead times – e.g., for irrigation system development – that must be anticipated if they are to deliver full benefits as needs arise. Different choices offer varying degrees of robustness in their ability to meet a range of possible climate futures. And in all cases, there are limits to adaptation.

EAS Key Challenge No. 2: Enhancing Effective Technology Exchange, Adaptation, and Dissemination

EAS providers must enhance and facilitate technology exchange, adaptation, and dissemination to match the need for continual climate change adjustments. For guidance, EAS providers can learn from past and present examples of how others have adapted to significant changes in under climatic conditions, including indigenous responses, as well as draw lessons from formal research efforts relating to new or best-bet responses relevant to projected conditions. The ability to skillfully identify and efficiently assess, modify, test, and exchange useful technologies and practices from around the world will be increasingly important in adapting to climate change impacts as research systems struggle to keep pace with new and evolving problems (e.g., Ramírez-Villegas et al. 2011). One immediate challenge is the lack of a unified global agricultural knowledge system, leaving us collectively ill-prepared to rapidly draw upon and utilize the wealth of agricultural knowledge that has been generated over the course of human history.

EAS Providers: Bringing It All Together

It will be imperative for EAS providers to step more fully into a facilitating role. The EAS tools and tested practices to help farmers assess and implement climate change-related adaptations, necessary to maintain viable agriculture-based livelihoods, are early in their development. Moreover, while responding to the risks and impacts of climate change, traditional concerns for poverty reduction, economic growth, and food security cannot be abandoned. Fortunately, because of the close coupling of human and natural systems within agriculture, there are potential synergies between the various objectives; many adaptive measures can be viewed as "no risk" or "no regrets" (Heltberg et al. 2009) – i.e., changes that will strengthen overall resilience and enhance productivity regardless of when and whether anticipated climate-induced shocks materialize or not, for example, building up soil organic matter, maintaining year-round vegetative and/or residue cover, and investing in improved water-harvesting and conserving practices in dry areas.

The challenges of climate change call for stronger integration of NRM and agricultural EAS (Hunt et al. 2011; Johnson et al. 2006; Swanson 2008). However, few public-sector extension systems are structured to facilitate close integration of these efforts. There are exceptions, such as Malawi, where the same public-sector extension field agents support the full range of crop, livestock, fisheries, forestry, and irrigation programs. Having a single point of entry at the community level offers the potential of coordination between various initiatives. The downside, however, is that the demands placed on individual field agents to be knowledgeable across the entire spectrum of agricultural activities far exceed their training and the programmatic support they are offered (Simpson et al. 2012); this can lead to the overloading of frontline workers and confusion at the field level.

Closer functional linkages will also need to be (re)established between EAS and research programs, currently missing from most extension programs. Closer relations will allow EAS programs to benefit fully from research contributions, while research programs will benefit from a clearer understanding of the needs, challenges, and progress made by farming communities in adapting to climate change.

The management of local opinion regarding adaptation to the *new normal* will likely also become part of the EAS portfolio. Escalating conflict, avoiding panic and destructive short-term behaviors, as well as addressing the despondency of indigenous populations losing a sense of *place* are real concerns. Engendering trust and credibility with local populations will be key.

All in all, the levels of knowledge and skills required by frontline EAS providers to match various opportunities with site-specific needs, as well as EAS program flexibility and responsiveness, surpass any that are currently in place, yet define the path forward in preparing for life under the *new normal*.

The Road Ahead

The approximately 2.5 billion smallholder farmers (IFAD 2013) who manage a majority of the nearly 22.2 million square kilometers of the earth's surface under agriculture (Zomer et al. 2009) represent a tremendous force in our ability to utilize NRM practices to help mitigate the negative impacts of future climate change, and they form a large part of the target domain for EAS programming. Using agriculture as an engine for economic growth, poverty reduction, increased food security, and now also for adaptation to climate change is predicated on effecting widespread behavioral change involving the adoption of more productive, less wasteful agricultural technologies and management practices. But working on these themes with farmers and the rural poor under the *new normal* – in a context of continual and increasingly disruptive change – is a daunting new challenge. To effect behavioral change, EAS providers will first need to address the issue of helping farming populations understand that the *new normal* really is a departure from the past and that responding to it will require adoption of truly adaptive measures and not simply belt tightening and coping until conditions return to the way they used to be.

To respond to the breadth of challenges of adapting to climate change, EAS providers will need to (i) reconsider their strategies and operational frameworks for engaging rural populations, (ii) increasingly work with groups at appropriate scales, (iii) overhaul training curricula, (iv) maximize use of advanced information and communications technology (ICT), and (v) advocate for supportive policies. The remainder of the chapter addresses each of these issues in turn.

Evolving Strategies and Frameworks

The systemic nature of global climate change will require use of commensurate systems thinking to proactively engage the quadruple climate change challenge of mitigation, adaptation, decreased vulnerability, and increased resilience within the agricultural sector. The abandonment of support for the farming systems research and extension (FSR/E) paradigm by donors in the early 1990s has regrettably been accompanied by a nearly complete loss of formal systems analysis in applied agricultural research and extension practice. The payment for environmental services (PES) framework offers a conceptually rich subset of value chain development activity but has encountered stiff challenges in bringing *environmental externalities* into the marketplace. Watershed management and the *wild west* environment of the carbon-offset markets are probably the two PES action areas most relevant to EAS climate change efforts. Transaction costs and, in the case of carbon offsets, the costs of measurement, reporting, and verification systems have been barriers to widespread smallholder involvement.

One can hope that we are in a transitional phase and that more holistic climate change vulnerability assessment and adaptation planning procedures will become central features in development efforts. Given the nature and breadth of changes that are taking place under the *new normal*, it is difficult to envision how appropriate responses will be forthcoming without engaging in systems thinking and consideration of interactions.

Under the *new normal*, systems thinking will need to engage more broad-based system principles that hold over a wider range of conditions and recognize that the process of continuous change will not allow exhaustive investigations of individual, location-specific, system interactions. For example, precise recommendations on optimal intercropping associations (e.g., spacing, plant populations and planting patterns) will quickly become irrelevant with any significant change in rainfall or temperature, whereas basic principles relating to soil organic matter management, protection of critical water sources, and competitive and facilitative plant interactions can be applied by farmers in endless configurations across a range of climate regimes (e.g., Altieri 1987; Francis 1986; Gliessman 1990; Vandermeer 1989). Fortunately, within the domain of NRM-oriented agriculture, many land management principles confer broad-based, system-level benefits that allow farmers to contribute simultaneously to mitigation efforts while making needed adaptive responses and enhancing the resilience and profitability of their farming systems.

In the context of the *new normal*, the greatest advantage of the formal research system is the capacity to engage in anticipatory analysis, development, and dissemination of responsive technologies – for example, the development of new heat- and drought-tolerant maize varieties and the development of submergence-tolerant rice varieties by the international agricultural research centers (Cairns et al. 2013; Septiningsih et al. 2009). In contrast, formal research and EAS processes will likely prove too slow in responding to the real-time and disparate needs for more nuanced management adjustments by farmers in specific contexts. Continued practice of promoting prescriptive, general recommendations focusing on short-term optimization will become increasingly ineffective. The need to rely on and feed farmers' inherent adaptive capacities to fit tools and practices to local applications, the focus of much effort in the 1980s and 1990s in developing participatory methodologies, will need to be an integral part of EAS operational strategies.

Working with People

Regardless of the source of innovations, most EAS providers will need to engage in iterative cycles of experimentation and learning as they begin to work with rural communities in testing high-potential adaptation practices, preferably while risks are low. Consistent, ongoing EAS support in NRM-centric agriculture will be critical to give communities the confidence and skills to implement effective mitigation and adaptation efforts. Most technical options will require capacity strengthening and the support of broad-based community engagement.

In spite of the challenges, the nature of climate change impacts is such that strengthening social capital for collective action and strengthening the local knowledge base on local ecosystem functioning are essential parts of an adaptation strategy. In general, communities have a deep attachment to the areas where they live. Their collective history of environmental knowledge provides them with important assets for managing local natural resources. The shared knowledge and relationships of trust with one another and known points of opposition are the foundation for establishing effective comanagement structures, especially if they are fortified by strong community organizations, technical support for sustainable resource use, and policies codifying local resource rights (Brunckhorst 2010). Ferse et al. (2010) found that community involvement in environmental design for access, use, and protection of natural resources resulted in more adaptive, flexible management and more resilient ecosystems. Furthermore, when social networks included a mix of actors in the same watershed, those actors who had links to additional sources of information were able to bring new perspectives and opportunities that helped to improve management responses (Bodin et al. 2006).

EAS Education and Training

To help prepare EAS practitioners for the challenges described in this chapter, preservice education programs will need a major overhaul, and a process of regular in-service updates will need to be established. Recently, the importance of investing in tertiary (college-level) agricultural education has come back on the development agenda. But given the past neglect, needs vastly exceed the available resources and must be redressed if we are to begin taking the worldwide human resource crisis in agriculture seriously. One of the common findings of recent EAS assessments is the aging population of public-sector EAS staff; on average the members are within a decade of retirement (e.g., Simpson and Dembele 2011; Simpson et al. 2012; Simpson and Singh 2013). The gaps that will be created by retirement, combined with the current gaps and weaknesses in the EAS education and training system, will exert themselves for years to come, just as the pressures for a more capable EAS workforce are making themselves felt. Though particularly acute in Africa (e.g., Eicher 2004), the neglect of human resource development is by no means an African crisis alone (BIFAD 2003). There is now an opportunity to address this underinvestment in education by revitalizing national training programs to prepare the next generation of EAS practitioners for the challenges of responding to conditions under the *new normal*.

Information and Communications Technology (ICT)

The potential contributions of technological innovations to support sustainable development efforts have been promoted for over a decade (NRC 2002). Outside of the research community, however, little progress has been made. In contrast, the Famine Early Warning System Network (FEWS NET), one of the longest-lived programs involving applied advanced technologies, will likely see increased use in the decades ahead. To help capture the geographic and temporal dimensions of climate change impacts, climate and crop models, remote sensing, and geographic information system (GIS) technologies all have important roles to play in assisting policy-makers and research and extension program managers in targeting their respective efforts.

One example of combining the predictive capability of climate and crop modeling with soil and geographic data is the collaborative work undertaken by Catholic Relief Services, the International Center for Tropical Agriculture (CIAT), and the International Center for Maize and Wheat Improvement (CIMMYT) in Central America in the “Tortillas on the Roaster” project (Eitzinger et al. 2012). Developing an integrated assessment framework led to the identification of three major types of interventions and the ability to target these to specific geographic locations (see Box 3). One of the outcomes of this project was the capability to predict the effect of climate change on Central American maize and bean production in particular locations based on soil quality. This type of information can be immensely valuable in geographic and technical targeting of EAS programming.

Other ICT tools are equally valuable. Weather information and the use of radio and text messaging services have the potential to assist farmers in accessing real-time information for intra-seasonal management decisions. Early warning systems, such as FEWS NET (USAID) and the United Nations Food and Agriculture Organization Global Information Early Warning System, will become increasingly valuable tools for national decision-makers, donors, and emergency response agencies in gaining the lead time necessary to prepare response measures for slow-onset emergencies. For populations at risk, warning systems focused on rapid-onset emergencies, such as floods and typhoons, are in place and under development in South and Southeast Asia. In combination, the analytic power, communication reach, and immediacy of these ICT tools will become increasingly important for EAS programs.

Box 3: Three Major Types of Interventions Identified by the “Tortillas on the Roaster” Project

Adaptation spots: Areas where yield reductions of the crops in the model, in this case maize and beans, are expected to be 25 % and 50 % by the 2020s and 2050s, respectively. In adaptation spots, EAS for agriculture can be used to *promote locally appropriate adaptation practices*.

Hot spots: Areas where yield reductions of the crops in the model are expected to be >50 % by the 2050s. In hot spots, EAS would support *diversification of livelihoods and transitioning out of current, vulnerable livelihood systems*.

Pressure spots: Areas with potential for ≥25 % gains in production. The problem is that most of these pressure spots are forested or protected areas at risk of incursion by agriculture. Pressure spot interventions require support from EAS for *natural resource protection and sustainable management* and offer potential targets for PES (payment for environmental services) interventions (Fig. 4).

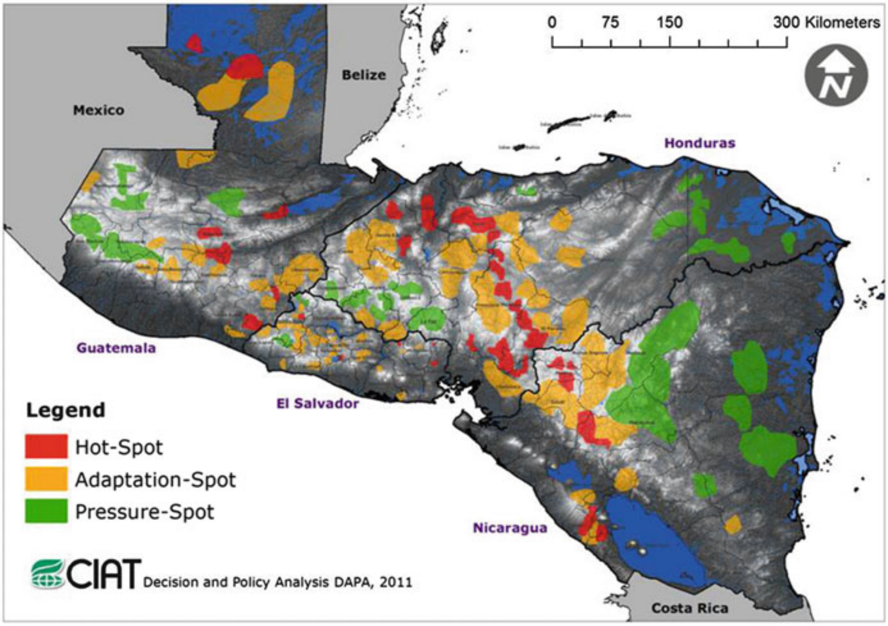

Fig. 4 Climate change impact on bean-producing areas in Central America

Importance of Policies

Few national EAS programs have launched initiatives aimed specifically at assisting farmers in adapting to climate change. The reasons for this warrant further investigation. At the policy level, however, there are growing indications of positive changes within national agricultural investment plans toward large-scale climate change adaptations. The *Plan Maroc Vert* (the Moroccan Green Plan) is one such example. Cast in terms of an economic growth and poverty reduction strategy, the Plan responds to a steady 30-year decline in rainfall levels by, among other things, assisting smallholder producers to transition from hillside annual crop production to higher value tree crop production, especially olives, almonds, and figs, which are tolerant of increasingly arid conditions. Accompanied by investments in structures to prevent soil erosion, these plantations will help farmers maintain and improve their livelihoods in the face of environmental change. The US$ 300 million investment under the US Millennium Challenge Corporation Moroccan compact, supporting the establishment and rehabilitation of 120,000 ha of hillside agroforestry plantations, is one of the first major investments in implementing *Plan Maroc Vert*, to which other donors are also contributing (Cooper et al. 2013).

Another example is the Malawi Greenbelt Initiative, with an initial target of bringing one million hectares under irrigation and strategic plans for developing 228,000 ha (Government of Malawi 2010). The initiative is primarily justified as an economic development effort aimed at exploiting surface water resources to increase high-value agricultural production and strengthen food security. The initiative stands to make major strides in assisting producers to transition to systems less exposed to the immediate risks of climate change.

These examples illustrate the type of policy decisions and the level of investments that governments must make in preparing for anticipated climate change impacts. Investments in EAS training programs and other support services are also needed to maximize benefits. To support implementation of *Plan Maroc Vert*, the Moroccan government has drafted a new national extension strategy. The Malawi Greenbelt Initiative called for the training of an additional 1,000 extension agents, with plans for hiring an additional 400 staff members over 4 years (Government of Malawi 2010). The sheer size of these undertakings and the need to mobilize resources are such that planning horizons must be lengthened to investment cycles of 10–15 years or more.

Agricultural policies involving subsidies are designed to influence farmer behavior in securing national food security objectives. These policies, however, can work against extension efforts to assist farmers to transition to more diverse, resilient production systems, leaving farmers more vulnerable to climate change trends and shocks (e.g., Simpson et al. 2012; Chinsinga et al. 2011). Decision-makers will need to review their policy frameworks closely with an eye to climate change adaptation to eliminate inconsistencies and identify leverage points.

Policy changes can also have dramatic effects in terms of facilitating farmer investments in NRM. For example, Niger's new Forest Code in 2004 recognized customary resource rights and the right to collect and use forest products. The granting of secure tenure rights, removal of punitive fines, and addition of a new source of technical assistance resulted in one of the most dramatic transformations of land cover in the region, with five million hectares, nearly half of the country's agricultural land, being converted to agroforestry management systems in less than a decade (Stickler 2012). In the process, farmers greatly increased their resilience to climate change impacts.

Best Prospects: Extension and Advisory Services Under the *New Normal*

The future of agriculture under the *new normal* is defined by increasing risks and uncertainties. The ideas presented here are by no means exhaustive, but are intended to focus attention on key issues, stimulate thinking, identify directions, and urge action at the appropriate pace and scale. There is an urgent need to make progress in climate change mitigation, preparing for adaptation, and to decrease vulnerability and increase resilience within the agricultural sector.

Recommendations for EAS providers:

1. EAS programs need to identify and be well informed about the essential nature of climate change risks and impacts, including the geographic zones of impact and likely trajectories of onset, the relative magnitude, level of certainty, likely timing, and location of slow- and rapid-onset risks.
2. Within the target locations for various types of risk, EAS providers must assess the vulnerability and resilience of human populations and natural resource systems in order to prioritize the allocation of resources. Use of a systems approach to identify linkages – involving at a minimum human/social, climate/environmental, financial/food security dimensions – is critical.
3. Based on assessed needs, EAS programs must identify any available multi-win, no-regrets, and robust options and demand that research institutions begin the hard work of assessing and screening available technologies for their fit under likely future conditions and identify technology gaps now so that appropriate responses will be available when needed. Issues that need to be taken into account by EAS programs include how to:
   (a) Match appropriate actions at the requisite scales and locations and plan for the temporal sequencing of responses
   (b) Determine social and organizational requirements to support technical choices
   (c) Develop market and nonmarket incentives for farmers and other stakeholders to stimulate behavior change
   (d) Mediate potential policy distortions that may increase smallholder risk
4. To identify potential technical and social alternatives, EAS providers must establish and aggressively engage in national and subregional platforms for networking and exchange of experiences and become skilled in tapping into

cross-regional and global resources. At the field level, learning from and building upon indigenous responses will be vital.

5. Technology transfer efforts need to be accompanied by streamlined procedures for technology release combined with the freedom to actively encourage and facilitate experimentation with new technologies by farmer groups.
6. EAS providers should participate in the identification and use of ICT applications (e.g., early warning systems) for various target audiences.
7. EAS education and training programs must be significantly upgraded so that field and management staff members are prepared for the risks of climate change. Critical areas include a sound understanding of climate change dynamics, a broad systems orientation, technical competency, and methodological expertise.
8. EAS program directors will need to engage more intensively in policy formation and review, with a view to incorporating plans for climate change adaptation and providing support for producer populations that may be at risk. Policy-makers must prioritize investments in EAS programs and related support services to help farmers make difficult transitions.
9. Programmatic divides between ministries must be identified and removed, in order to capitalize on potential operational synergies among EAS programs (e.g., crops, forestry, livestock, etc.). National EAS programs must also actively seek collaboration with actors outside of government who can help to increase the scale of impacts of EAS efforts.
10. Perhaps most challenging of all will be efforts to bring field-level coordination and coherence to public- and donor-funded initiatives and to help orient private-sector actors to emerging climate change adaptive opportunities. Design and implementation of national strategies should involve coalitions of public- and private-sector actors with donors and NGOs.

The list of needs is long and the demands are high, but the stakes are higher still. All those involved will be challenged to elevate their efforts. Our continued ability to feed the planet depends on the outcome.

Acknowledgments This chapter is based on a longer work by the authors (Simpson and Burpee 2014) produced through support of the USAID funded Modernizing Extension and Advisory Services project.

Agriculture and Climate Change in Southeast Asia and the Middle East: Breeding, Climate Change Adaptation, Agronomy, and Water Security

Ijaz Rasool Noorka and J. S. (Pat) Heslop-Harrison

Contents

Abstract

The agriculture of Southeast Asia and the Middle East is under threat due to vagaries of abiotic stress including climate change and water-related factors. With a particular focus on the challenges facing non-industrialized and developing countries, this paper attempts to create a framework for policy makers and planning commissions as well as increasing national and regional water stress awareness. The study elaborates the agriculture eminence, water provision, conventional water usage, and adverse consequences of water status under the changing climatic conditions and urban or industrial development. The study addresses the nature of problems, regional issues, current barriers, farmer's perceptions, and concrete efforts to save regional agriculture for sustainable food security. The consequences

of climate change, water stress, and salinity have affected huge areas of developing countries from an economic and resource security perspective that leads to disaster and unstable law and order issues. Long-term planning over timescales beyond the human lifespan and anticipation of threats and opportunities is required. Consequently, an emergency plan is also needed for international, national, and regional footprints including procedures for climate change mitigation and to implement inclusive plans to combat prevailing poverty, social changes, and allied anticipated risks. It elaborates the attempts to provide a framework for policy makers and political understanding to check the hidden but viable issues relating risks of climate change in local and global scenario. It is concluded that a viable charter of climate proofing and domestication is the way to success from on-farm-to-lab and lab-to-field outreach to mitigate declining food issues. The regional and international collaborative efforts are focused to modernizing crop genetics, agronomy, field-to-fork scrutiny, and adaptation training to increase quantity and quality of food with sustainable use of water.
