Foreword

Climate change is one of the most pressing challenges mankind currently faces, being a matter of great concern to people living in both industrialized and developing countries. Due to its scope and its implications to the economy of countries, to properties, and to human health and well-being, it is essential to make sure that we are able to adapt to climate change.

But even though the need for adaptation is a perceived one and in many parts of the world, urgent action in the field of climate change adaptation is needed, there is a paucity of scientific publications which tackle the subject matter of climate change adaptation in a holistic way.

In an attempt to address this problem and at the same time provide a contribution to foster a better understanding of the various aspects of climate change, the International Climate Change Information Programme (ICCIP)—in cooperation with Springer—have prepared this landmark multivolume reference work. This handbook is aimed at fostering a broader understanding of what climate change is, what it means to people, and how its impacts on the environment and ecosystems can be reduced via climate change adaptation strategies.

Consistent with its editorial aims, this Handbook is structured along four parts:

Part I. Climate Change Impacts and Management (handling climatic, physical, human, and biodiversity impacts on land and water ecosystems)

Part II. Policy and Climate Change (handling policy measures, planning procedures, and concrete action to cater for adaptation efforts)

Part III. Climate Change Adaptation, Agriculture, and Water Security (handling concrete examples of adaptation efforts in the field of agriculture and water capture, storage, and use)

Part IV. Climate Change Adaptation Technologies (presentation of examples of technologies which allow adaptation to be pursued and implemented in the short and medium term)

A set of cross-cutting issues have been included across all parts, such as the socioeconomics of climate change, resilience, trade, growth, development, justice, poverty, health, populations, security, international politics, the UN process, democracy, education, as well as information and communication. Although the

Handbook is on the one hand grounded in the best science and meets the highest scientific standards, it aims on the other hand to be inclusive methodologically and be practice based.

Specialists from across the world have provided a wide range of contributions addressing many of the variables associated with climate change adaptation with examples, case studies, and projects from all geographic regions. Their efforts are commendable since their willingness to document and disseminate their ideas, approaches, and projects via this Handbook makes it a very rich publication.

I want to thank all the authors who contributed to this Handbook for their time and effort. It is hoped that this Handbook may not only be used as a tool toward the greater understanding of different variables associated with climate change adaptation.

All in all, we have managed to produce a groundbreaking publication, which will hopefully provide practical assistance and support to climate change adaptation initiatives across the world. We also hope that it may serve as inspiration and guidance to many others, helping to tackle a problem which is global in its scope but often local in its impacts.

Walter Leal Filho
Editor-in-Chief

About the Editor

Professor Walter Leal (BSc, PhD, DSc, DPhil, DL, DLitt, DEd) is Professor and Head of the Research and Transfer Centre Applications of Life Sciences at the Hamburg University of Applied Sciences in Germany and holds the Chair of Environment and Technology at Manchester Metropolitan University, UK. He is a Review Editor at Working Group II (Climate Change Adaptation) at the Intergovernmental Panel on Climate Change (IPCC) and founding editor of the *International Journal of Climate Change Strategies and Management* and heads the International Climate Change Information Programme (ICIIP). He is also Editor-in-Chief of the *Climate Change Management* series with Springer.

Prof. Walter Leal serves on the editorial board of various journals. He has in excess of 300 publications to his credit, among which are groundbreaking books such as *Universities and Climate Change*, *The Economic, Social and Political Aspects of Climate Change*, and *Climate Change and Disasters Management*. He teaches environmental management, information, and climate issues at various European universities. He has over 20 years of research experience on all aspects of environmental information and education and has a particular interest in the connections between environmental management, sustainability, climate, and human behavior.

Section Editors

Abul Quasem Al-Amin is currently Associate Professor at International Business School, Universiti Teknologi Malaysia, Malaysia. His research interests include environmental modeling, economic sustainability, modeling on optimal pollution taxation for environmental aspects, ecological economics, and economics of climate change. He is currently associated with Conference in Cooperative Green Growth Modeling Forum (C2GMF), Greenhouse Gas Inventory and Research Center, South Korea, Asia Pacific Network for Global Change Research (APN), and Institute for Global Environmental Strategies (IGES), Japan, and has a particular interest in the connections between environmental management, sustainability, climate, and human behavior.

Suani Teixeira Coelho is a chemical engineer with master's and doctorate degrees in Energy from the University of São Paulo's Energy Graduation Program, where she is currently lecturer and thesis advisor professor on bioenergy. She is also thesis advisor professor at the Integrated Graduate Program in Bioenergy (USP/UNICAMP/UNESP). She was member of the U.N. Secretary-General's Advisory Group on Energy and Climate Change (AGECC) from 2008 to 2011 chaired by Kandeh K. Yumkella from UNIDO and Deputy Secretary at São Paulo State Environment Secretariat (2003–2006), where she was responsible for the international agreements of the State Secretariat. Prof. Coelho has published papers in and was a reviewer for technical journals such as *Energy Policy* and *Biomass & Bioenergy* among others. She has also published several books and book chapters including "Land and

Water: Linkages to Bioenergy” in *Global Energy Assessment* (IIASA, Cambridge University, 2013)

Harry Polo Diaz is Professor of Sociology and Social Studies and former Director of the Canadian Plains Research Center (CPRC) at the University of Regina. His fields of research include adaptation and vulnerability to climate change, water scarcities, and environmental governance in Canada and Latin America. He is author and coauthor of several publications on the human dimension of climate change.

Ilan Kelman is a Reader in Risk, Resilience, and Global Health at University College London, England, and Senior Research Fellow at Norwegian Institute of International Affairs, Oslo. His overall research interest is linking disasters and health, including the integration of climate change into disaster research and health research. His geographic areas of particular interest are islands, the Arctic, and mountains. His personal website is http://www.ilankelman.org.

Maris Klavins is Professor and Head of Department of Environmental Science at University of Latvia (Riga, Latvia). His research background is in chemistry, but recent interests are related to environmental pollution analysis, natural organic substances, climate change, and long-term environmetal change. Prof. Klavins is author of several books, has supervised more than ten doctoral theses, and is active in promoting environmental education concepts.

Justice Nyamangara is a Soil Scientist with a B.Sc. Agriculture Honours from University of Zimbabwe, M.Sc. Soil Science from University of Aberdeen (UK), and a Ph.D. in Soil Fertility and Environmental Pollution from the University of Zimbabwe. He is currently Professorial Chair of Environmental Science at Chinhoyi University of Technology (CUT) (Zimbabwe). Professor Nyamangara has also worked as a Scientist at the International Crops Research Institute for the Semi-Arid Tropics (ICRISAT) (2009–2014), Visiting Scientist at the International Center for Tropical Agriculture (CIAT) (2007–2008), Associate Professor and Deputy Dean of Agriculture at the University of Zimbabwe (2000–2009), and Principal Research Officer and Head of Crop Nutrition at the Department of Research and Specialist Services (Zimbabwe) (1990–2000). His research focuses on soil fertility, conservation agriculture, climate change, and environmental pollution. He has supervised or cosupervised more than 20 postgraduate theses, and has in excess of 100 publications to his credit.

Anirudh Singh is Associate Professor at the University of the South Pacific (USP) within the School of Engineering and Physics. He teaches courses in renewable energy and basic physics and leads the regional component of a multinational project in renewable energy. His research interests are renewable energy and climate change, with specific interest in the areas of biofuels, energy efficiency in buildings, and energy policy. His most recent publications include four book chapters in renewable energy and a perspective paper in biofuels. He is currently supervising one Ph.D. and three M.Sc. students.

L. Vargas received an Electrical Engineer diploma and an M.Sc. degree from Universidad de Chile, Santiago, in 1985 and 1987, respectively, and a Ph.D. degree in 1994 in electrical engineering from the University of Waterloo, Waterloo, Ontario, Canada. Since 1994, he has worked at the Electrical Engineering Department, Universidad de Chile, where currently, he is Associate Professor. Dr. Vargas has been involved in applied projects for the main electric companies and energy institutions in Chile as well as international agencies. His main research interests are in the areas of wind energy, supply and demand forecasting, regulation, and expansion planning of energy systems.

Acknowledgments

In the preparation of this Handbook, I need to thank many people and organizations. First and foremost, thanks are due to the authors for the willingness to share their know-how, their experience, and their work with an international audience. It is their inputs that have made this publication possible, and the richness of experiences combined with the diversity of perspectives documented here make this publication an invaluable one to anyone interested in the principles and practices of climate change adaptation.

Thanks are also due to the section editors for their hard work and support in checking all papers and for overseeing the revisions of the manuscripts. Their help was important and most appreciated.

My thanks also go to Dr. Mihaela Sima, whose support as editorial assistant was an important one, and to the editorial team at Springer, especially Annalea Manalili and Mary Baker, for their valuable support.

Part I

Climate Change Impacts and Management

A Methodological Framework for Building an Index for Vulnerability Assessment in Rainfed Agriculture

Aliou Diouf and Amadou Thierno Gaye

Contents

Abstract

This chapter presents a methodological framework to build an index for participatory vulnerability assessment of rainfed agriculture in Ngayokheme rural community, Senegal. Through a participatory approach, the chapter identifies components/resources of rainfed agricultural system, evaluated their exposure, sensitivity, and adaptive capacities to climatic and non-climatic stressors. A review of the main vulnerability indices developed in the literature highlighted gaps. And based on the weaknesses of the existing indices, a new index combining exposure, sensitivity,

and adaptive capacities is proposed. A tool for vulnerability assessment replicable in different contexts and accessible to all disciplines has been built. The vulnerability of the whole system of rainfed agriculture as well as each of its components was quantified using a participatory approach. The chapter attempts to provide a detailed framework for assessing vulnerability to climate change of the rainfed agriculture, in such a manner that all countries of the region can follow it. Climate change is affecting rainfed agriculture in Senegal. To mitigate impacts of climate change and increase the resilience of the sector, a good vulnerability assessment is required. This is why an index for assessing vulnerability to climate change of the rainfed agriculture has been suggested. This focused on strengthening the vulnerability evidence base to support climate change policy, advancing knowledge and training to understand climate change impacts, and implementing adaptation measures. The framework presented on this chapter could yield substantial benefits for Senegalese and other Sahelian countries.

Keywords
Index • Vulnerability • Assessing • Participatory approach

Introduction

The adverse effects of climate change on natural and human systems are becoming more and more severe and complex. This is why the question of understanding the level of vulnerability of natural and human systems has become a major concern and a challenge for the academic, political, and development practitioners' communities. Several studies on vulnerability analysis have been undertaken. Many of them were performed using the participatory approach. The participatory approach has emerged with the "Activist Participatory Research" during the 1960s. Ever since, several variants of participatory approach have been developed. Thus, in the 1970s, variants such as "Field Research on Farming Systems," "Participatory Research (PR)," "Rapid Rural Appraisal (RRA)," and "Agro-ecosystem Analysis" have emerged. Later, in the 1980s, other variants of the participatory approach were developed and strong. Thus, "Applied Anthropology" and "Participatory Rural Appraisal (PRA)" have emerged. The 1990s saw the emergence of Participatory Action Research (PAR) (Chambers 1994). The participatory approach has been experimented, initially in developing countries' rural areas, and has enabled community to share their perceptions and identify, prioritize, and appraise issues from their knowledge of local conditions (Rabinowitz 2013; Van Aalst et al. 2008). A participatory approach is a process in which every stakeholder in the intervention has a voice. Everyone who has a stake should be invited to the table. In a participatory approach, all stakeholders' voices are heard and respected and that everyone has some role in decision-making (Rabinowitz 2013).

Researches that have used participatory approach have proved useful because they have informed on how natural and human systems are vulnerable to climate hazards. However, these studies have failed to meet the needs of academia, policymakers, and practitioners to quantify the vulnerability in order to understand its severity level and plan responses to climate change effects.

To fill this gap, researches to quantify vulnerability to climate change have been made. The modelers have undertaken most of them and limited vulnerability assessment to analysis of climate change impacts on a number of sectors such as agriculture, health, water resources, forests, etc. However, these studies had shown some limitations related to the fact that impacts of climate change are measured on a limited number of parameters although studies generally focused on systems. So, understanding the vulnerability of such a system cannot be reduced to impact of climate change on few elements of the system. In addition, social, cultural, economic, and political aspects are barely considered in these models. This is why studies using modeling do not give a full measure of the vulnerability of a system.

In recent years, we have witnessed emergence of new studies trying to combine qualitative and quantitative approaches to vulnerability. These studies are to quantify the vulnerability using the participatory approach. They seek, through community participation, to provide a quantitative measure of vulnerability and to explain it. These researches are based on the definition of a conceptual framework that allows them to start identifying determinants or parameters of vulnerability. These studies propose models of relationship between parameters of vulnerability to calculate the value of the vulnerability and produce vulnerability indices.

According to the definition of vulnerability, several types of model relationship between the determinants have been proposed. However, most models that establish relationship between determinants of vulnerability do not accurately express the link between these determinants. Many models build on subtraction or addition relationship or combine both. However, these two types of relationship do not sufficiently reflect the relationship between the determinants of vulnerability. This arises the following question: which model faithfully expresses the relationship between the determinants of vulnerability?

The aim of the present chapter is to feed thought and efforts made to construct appropriate vulnerability index. More specifically, the present chapter proposes a methodological framework for building an integrated index to assess vulnerability to climate change of rainfed agricultural system in Senegal through a participatory approach. To do this, a review of approaches to vulnerability will be made in the first place. This review will be followed in a second phase of a critical analysis of computational models of vulnerability. In a third step, a model of the relationship between the various determinants of vulnerability will be offered, followed by a description of the methodological framework to construct the index of vulnerability.

Review of Vulnerability Approaches and Indexes

Climate change mainly is manifested in adverse effects on livelihoods in developing countries that are most vulnerable. The effects are often complex and difficult to understand. The need for understanding vulnerability justifies that of analysis and assessment of vulnerability.

Vulnerability has been abundantly analyzed and defined, especially in the climate change literature (Luers et al. 2003; Füssel 2009). However, first definitions arose from geography and ecology (Cutter 1996). Timmermann (1981) has provided to the scientific community with the first reference definition of vulnerability. He defined vulnerability as "the degree to which a system acts adversely to the occurrence of a hazardous event. The degree and quality of the adverse reaction are conditioned by a system's resilience (a measure of the system's capacity to absorb and recover from the event)." But it is in risk and disaster management and recently in environmental change and in development and environment areas that the word vulnerability is mostly used. Indeed, during the past two decades, the concept of vulnerability acquired an important place, especially with the IPCC Assessment Reports. Owing to the abundance of the analysis of the concept, further work on vulnerability assessment, including approaches, methods, and tools, had been undertaken and several conceptual and methodological approaches of vulnerability have been developed (Cutter 1996).

Despite this important scientific production, fundamental conceptual differences remain about definition and approaches of vulnerability. Broadly, there are three major schemes of vulnerability frameworks. The first one distinguishes biophysical and socioeconomic vulnerability (Füssel 2009). The second scheme recognizes external factors *that are not part of the system* and internal factors *that are part of the system.* A third scheme that can be presented as the most comprehensive deals with vulnerability as contextual (starting point) and vulnerability as an outcome (end point) (O'Brien et al. 2007; Brooks 2003; Füssel 2009; Kelly and Adger 2000; Turner et al. 2003 ; Maru et al. 2014). The key element on which the focus is put when explaining vulnerability of human or natural systems distinguishes these approaches.

Biophysical Approach

The biophysical approach highlights the key role played by external/natural hazards in the occurrence of vulnerability of human and natural systems. Thus, Gabor and Griffith (1980), Mendelsohn et al. (1994), Polsky and Esterling (2001), and Sanghi et al. (1998) have emphasized how cash income of farmers is affected by natural hazards. Adams (1989), Kaiser et al. (1993), and Olsen, Bocher, and Jensen (2000), Kurukulasuriya and Mendelsohn (2006) also studied the vulnerability of agriculture by linking climate change stressors to agricultural yields. Similarly, Martens et al. (1999) in health sector; Du Toit et al. (2001), FAO (2005), Xiao et al. (2002) in food security and water availability sectors, and Forner (2006) and Villers-Ruiz and Trejo-Vázquez (1997) in ecosystems sector studied climate change effects. All these studies put the focus on natural/external factors as causes of economic, social, agricultural, health, and vulnerability.

This approach has the advantages of providing relevant and measurable information. It helps to know the extent of the impacts of natural hazards on different natural systems. However, this approach often adopts a negativistic, futuristic, and quantitative perspective of impacts of climate change. In addition, this approach often has a negativistic and futuristic perspective of the impacts of climate change. The impact assessment focuses on the damage areas and is based on the predictions of climate models and other agricultural, economic, and health models. Thus, any comprehension of the current vulnerability is provided (Gabor and Griffith 1980). It also gives only quantitative data. Certainly very informative, this approach however does not demonstrate what these impacts mean for communities. For example, 50 % of lower yield due to climate change does not mean the same thing for a Senegalese farmer and for an American farmer. In the same vein, even if development of mosquitoes due to climate change can drive the resurgence of malaria, this increase will not have the same effect for two individuals or communities that have unequal access to health services and monetary income. This physical/natural approach does not take into account the adaptive capacities of systems having been affected by the climatic stimuli.

Social Sciences Approach

This approach emphasizes factors related to the socioeconomic and political status of individuals and communities, in short, the social system, including changes in status between individuals and communities (Füssel 2007, 2009). This approach considers that there are a variety of social status between individuals and between and within communities (Füssel 2007). These differences can be approached through gender, social and political class, education level, wealth, access to health services, natural resources, credit, agricultural inputs, technology, formal and/or informal social capital, etc. (Adger 1999). These factors are major social determinants of vulnerability (Allen 2003; Kelly and Adger 2000). This socioeconomic approach of vulnerability has the advantage of highlighting importance of internal resources available to an individual, a community, and a sector or system to reduce the negative effects of a shock. It shows that an individual, community, or system does not remain inert when it is attacked. It often responds to attacks drawing on its resources. The vulnerability is seen as an internal state of a system before the external forces of nature occur (Allen 2003).

The limitations associated with this approach are related to the low inclusion of natural/external factors. Yet, the role of the latter cannot be ignored when interpreting vulnerability. For example, two communities with similar socioeconomic conditions, but subject to natural hazards of different intensity and frequency, do not have the same level of vulnerability. Although socioeconomic factors are crucial in explaining the vulnerability, neglecting natural factors leads to a partial understanding of the vulnerability. Reconciling the two approaches seems to provide benefits to the full understanding of vulnerability.

Integrated Approach

However, although having obvious benefits in terms of vulnerability assessment, both biophysical and social approaches do not have less limitation from the perspective of an integrated assessment of the socio-environmental dimensions of vulnerability. Reconciling the two approaches seems to be advantageous to take the full measure of vulnerability. This is the main characteristic of the integrated approach that combines both social sciences and biophysical sciences approaches to determine vulnerability (Füssel 2007). In this regard, an adaptation of the IPCC definition of vulnerability can help reconcile the approaches of biophysical and social sciences into an integrated approach. The IPCC defines vulnerability as "the degree to which a system is susceptible to, or unable, to cope with the adverse effects of climate change, including climate variability and extreme weather conditions" (McCarthy et al. 2001, p. 995). While the IPCC definition specified directly to change climate, particularly to climate risks, an integrated approach of vulnerability needs to integrate biophysical and socioeconomic factors in addition to climate risks. The adaptation of IPCC conceptualization integrates internal and external factors and biophysical, socioeconomic, and climatic stressors. Vulnerability according to IPCC depends on the nature, extent, and rate of climate variation to which a system is exposed and the sensitivity and adaptive capacity of the system. The exposure parameter includes external factors, while sensitivity encompasses internal dimension as for adaptive capacity.

An Overview on Vulnerability Index

Based on these approaches, indices have been developed to better quantify and assess vulnerability level. Adger (1996, p. 49) developed a vulnerability index where vulnerability to climate variability is function of social vulnerability and environmental risk:

1. Vulnerability to climate variability = f(social vulnerability, environmental risk)

*where environmental risk can be indicated by the return period of a threshold physical hazard: Environmental risk = Impact * Pr*

where Pr = 1/R (Pr = probability and R = recurrence interval (years)).

Although this index takes into account the natural and social factors, the relationship between the parameters is not clearly established. It considers vulnerability as a function of social vulnerability and environmental risk, but does not clearly indicate the type of relationship between these parameters. In addition, the adaptive capacity parameter is not explicitly taken into account in the calculation of vulnerability. It is not clear whether it lies in social vulnerability or not.

Moss et al. (2001) determined vulnerability index (VI) by assigning a negative value to sensitivity and a positive value to adaptive. They establish relationship between parameters through this equation:

2. Vulnerability = (adaptive capacity)–(sensitivity + exposure)

This equation considers vulnerability as the difference between adaptive capacity and sum of exposure and sensitivity. This relationship model has a number of limitations. The relationship between sensitivity and exposure does not seem to be well translated by an addition as shown in this equation. The addition relationship links two parameters of a similar nature. However, sensitivity is totally different from exposure as sensitivity mainly refers to the internal structure system, while exposure is related to external factors. Also, the order of the parameters in this equation is not appropriate. Before talking about adaptive capacity of a system, it must have been exposed to and affected by a hazard. A system never adapts ex nihilo, it adapts to a hazard. So the exposure and sensitivity should come before adaptive capacity. That is why adaptive capacity should come after in the order of parameters, because it has to be deducted from the exposure and sensitivity, and not the contrary. In addition, the adaptive capacity plays an attenuator or dissolving role of effects of exposure and sensitivity. In this regard, the subtraction is not the best type of relationship.

Yohe et al. (2006) have developed indices of (aggregated outcome) vulnerability to climate change that vary according to different assumptions regarding climate sensitivity, development of adaptive capacity, and other calibration parameters. The aggregated vulnerability is calculated as

3. $Vi(t) = \frac{\Delta Ti(t)}{ACi(t)}$,

whereby $\Delta Ti(t)$ *is the projected change in national average temperature (i.e., a rational-scaled variable) and* $ACi(t)$ *is a normalized index of national adaptive capacity (i.e., an ordinal-scaled variable)* (Brenkert and Malone 2005).

This index has a specific climate and futuristic orientation. The risk in question here is a projected climate risk and is neither a current risk nor a non-climatic risk. Furthermore, the sensitivity parameter which is very important in the vulnerability of a system or sector is not integrated into the development of this index.

In summary, these indexes that have been developed have two main limitations. The first is related to the inappropriate nature of the relationship posed by these indices. The second limitation is related to the fact that these indices do not incorporate both natural and socioeconomic as well as the adaptive capacity of the whole area in question. In short, these indices are not based on a systemic approach of the systems studied. A third shortcoming of the indices is related to the fact that many of them are built for a national level and not do not take into account local specificities.

Methodological Framework for Building an Integrated Participatory Assessment Vulnerability Index

Conceptual Definitions

The development of a new vulnerability index in this study is yet based on the IPCC definition of vulnerability, but goes beyond. It is not focused exclusively on climate change as a hazard, but includes all significant factors that are sources of vulnerability for rainfed system at community level. The IPCC (2007) definition shows that vulnerability depends on three parameters: exposure, sensitivity, and adaptive capacity. However, the relationship between them is not specified (Fussel 2009). Before proposing the relationship between these three parameters and that result in a situation of vulnerability, it is important to make an analysis of these three parameters

Exposure. The first parameter of the vulnerability in the IPCC definition is identified by a group of words, namely, *the nature, magnitude, and rate of climate variations to which a system is exposed*. It is in this expression that the term *exposure* appears. So exposure is closely related to risk and hazard. Exposure is defined as the situation or position to which a system, a sector, a social group, or an individual is within the reach of a hazard. Being exposed is to be not sheltered from a risk; being exposed is to be in a situation where one is potentially reachable by a hazard.

One can note that exposure involves a hazard and a system. To be exposed, there must be a stressor and a stressed object. It also requires that the characteristics, nature, extent, and strength of the stressor allow it to reach the exposed system. However, it should be noted that exposure does not necessarily mean being in danger. People can be exposed without running the risk of being damaged, to see their physical or moral integrity affected. In addition, exposure can be assimilated to risk in the sole condition that there is a possibility of damage to the exposed element.

Sensitivity and impact. The second parameter of the IPCC definition of vulnerability is about sensitivity. Being sensitive is reacting (positively or negatively) if one is affected by an external force. A system is when it reacts and changes state regardless of the time, when it loses its trajectory, its identity, and its natural properties be it temporarily or permanently. Sensitivity is the susceptibility of a system to react, to respond to an attack, change positive or negative when the agent reached it. It mainly depends on the constitution of the internal structure of the system. The sensitivity is very important in the sense that regardless of the strength of a stimulus, if the system has no sensitivity, the stimulus can never be a risk, the system cannot be considered exposed.

Sensitivity is closely related to the impact which is the result of the sensitivity of a system and the nature of the shock that affects the system. The impact is a product of the sensitivity of a system and the intrinsic characteristics of stress (magnitude, force, rhythm, frequency of the stress).

Adaptive capacity. Adaptive capacity is defined as the set of resources available to a system to reduce the negative effects of stressors or to take benefit from them. It is a function of human resources, technology, social and cultural resources, access to information, and institutional, economic and financial, and physical and natural resources.

Vulnerability. Based on these conceptual definitions, it can be noted that the exposure and sensitivity when they increase or decrease tend to produce the same type of effect on a system. Their common growth increases the vulnerability of an element, while their decrease reduces vulnerability. However, adaptive capacity has an opposite effect on the vulnerability. Indeed, when the adaptive capacity increases, it tends to reduce vulnerability and vice versa. The relationship between exposure and sensitivity as well shows that if each increases by one unit, the resulting increase is more than the sum. The relationship is better expressed as a multiplication. Adaptive capacity does not play a role of subtracting the combined value of the exposure and sensitivity, but tends to diminish or invalidate effects produced by exposure and sensitivity. Adaptive capacity acts as divisor of the product formed by the exposition and sensitivity. In this regard, the best relationship that binds adaptive capacity to exposure and sensitivity is a division relationship. The division is the best relationship that leads a factor toward zero.

Given the relationship between exposure and sensitivity on the one hand and between these two parameters to adaptive capacity on the other, we propose to calculate vulnerability using the following formula:

$$V = {}^{E \times S}/_{Ac}$$

where

V = Vulnerability
E = Exposure
S = Sensitivity
Ac = Adaptive capacity

An adaptation of the IPCC definition that incorporates the nature of risks or hazard (continuous or discontinuous hazard) could lead to consider vulnerability as function of the magnitude and rhythm, or force and probability of a hazard, sensitivity, and adaptive capacity of the system.

Approach for Building the Integrated Index

Participatory Evaluation of Parameters of Vulnerability Through Focus Groups

To build the integrated index, the rainfed agriculture has been approached as a system. Our unit of analysis corresponds to community level. Designed as a system, rainfed agriculture then includes several components or resources, including climate. With farmers of Ngayokhème rural community as the study area, the various components of the rainfed system resources have been identified. These are climate, soil, water, seeds, fertilizers, mechanical equipment, draft animals, labor, the values attached to agriculture, vegetation, and slopes. In terms of hazards, it not only undergoes the weather but is also affected by economic nature and social, cultural, institutional, political, and biophysical vagaries. So to understand the vulnerability of agriculture, it is necessary to take into account all the resources but also all types of hazards.

Given the large number of organizations and the size of the study area, we had identified four zones based on socioeconomic and ecological criteria. Each zone comprised between four and six villages and hosted two gendered focus groups. In total, eight focus groups with men and women had been organized. The practical course of these grouped interviews relied on research protocols. These consisted of matrices drawn on the flipchart and pasted on the walls of the room where the focus groups were held. Each matrix contained as many columns and rows as identified components and stressors of rainfed agricultural system. Each stressor was crossed to each component to identify the impact. To mention each impact on the flipchart, we had to find a consensual response of all members of the group. Once the components and stressors of the farming system and the impacts are identified, the following step was to proceed with the evaluation of the parameters of vulnerability.

In a second stage of building the index, the determinants of vulnerability which are exposure, sensitivity, and adaptive capacity were assessed in a participatory way. The evaluation was made based on a scale from 0 to 5 which were defined with communities. The rating scale is defined by mutual agreement between the different actors. Each scale value represents a level of each of these three parameters. Level 0 corresponds to a total lack of vulnerability. Levels 1, 2, 3, 4, and 5 correspond, respectively, to 20 %, 40 %, 60 %, 80 %, and 100 % of vulnerability. However, the evaluation was conducted with a small number of farmers (05), compared with focus groups. Indeed, as the matter is to assign numerical values to these parameters, members of the focus group should have a certain level of instruction that enables them to fully understand the meaning of each level but also the parameters of the vulnerability. They should also be active farmers that have experienced effects of climate change and be able to remember them. As we worked with the Federation of Farmers Associations, persons meeting these criteria have been provided by the Federation. Reaching consensus on the value to assign to exposure, sensitivity, and adaptive capacity of each component or resource guided the evaluation phase of the vulnerability.

Weighting of the Components

The components of the rainfed agricultural system do not have the same weight. Each component had been attributed a weight. This weighting was done by consultation with experts in the rainfed system who have accumulated extensive experience in the study area but also with the local farmers with a certain level of education allowing them to assign weights to the various components. Experts comprised agronomists (03), agricultural extension agent (01), professor (01), practitioners (01), and leaders of farmers' organizations (04). They were called at first to correct or validate the component inventory of rainfed system identified by grassroots communities in the focus groups. And secondly, they assigned a weight to each component of the system on a scale of 100. For components, some changes in terms of merging were made. Indeed, the experts asked for a definition of the content of each component. Once this is done, no significant changes in terms of addition or removal of components have been made. The values assigned by each expert were averaged to obtain the weight of each component of the system.

After attributing value to exposure, sensitivity, and adaptive capacity of each component regarding the stressors that affect them, and after pondering each component, the equation has been applied to quantify the level of vulnerability of each component and the global vulnerability of the rainfed agricultural system by multiplying each component to its weight.

Discussions

The objective of this chapter was to propose a methodological framework for building a vulnerability index to assess vulnerability of rainfed agriculture.

The analysis of various studies and vulnerability assessments revealed several gaps due to their sector or inappropriate nature. Vulnerability to climate change has been analyzed and assessed in an exclusive climate perspective or at national level. This gives an incomplete understanding of the whole impacts of climate change. Indeed, climate change does not only act directly on the elements of the natural and human systems. It also affects them indirectly through other elements. This indirect action is not always taken into account by the study and assessment of vulnerability to climate change.

The index proposed here integrates both vulnerabilities to climatic and to non-climatic shocks. In this respect, it gives the full measure of vulnerability to climate change. In fact, it takes into account the direct and indirect impacts of climate change. The construction of this index which is based on a participatory approach has shown that the qualitative and quantitative approaches can be integrated. This index and the approach that enabled to build it are applicable in different contexts because of their flexibility to adapt to different environments.

Despite these advantages of this index, it should be noted some limits. The first relates to the lack of precision that is associated with values assigned to the exposure, sensitivity, and adaptive capacity as well as components of rainfed system. Another limit refers to the fact that there is no differentiation made between farmers. The integrated index is done at community level.

Conclusion

This tool for vulnerability assessment is replicable in different contexts and accessible to all disciplines. The vulnerability of the whole rainfed agriculture as well as each of its components was quantified using a participatory approach. This tool provides a detailed framework for assessing vulnerability to climate change of rainfed agriculture, in such a manner that it can be applied by all countries in the region. Climate change is affecting rainfed agriculture in Senegal. To mitigate the impacts of climate change and increase the resilience of the sector, a robust vulnerability assessment is required. This is why an index for assessing vulnerability to climate change for rainfed agriculture has been suggested. This chapter focused on strengthening the vulnerability evidence base to support climate change policy, advancing knowledge and training to understand climate change impacts, and implementing adaptation measures. The framework presented in this chapter could yield substantial benefits for Senegal and other Sahelian countries.

A Multi-model Framework for Climate Change Impact Assessment

Alireza Gohari, Mohammad Javad Zareian, and Saeid Eslamian

Contents

Abstract

The chapter aims to estimate the climate change impacts within a probabilistic multi-model framework. The suggested approach attempts to improve the reliability of the climate change impact assessment approach by considering the three main sources of uncertainty.

Climate change impacts on the climate variables in Iran's Zayandeh-Rud River Basin have been evaluated. Multi-model ensemble scenarios are used to deal with the uncertainty in climate change projection for the study period (2015–2044).

DOI 10.1007/978-3-642-38670-1_91

The probabilistic multi-model ensemble scenarios, which include the 15 GCMs, are used to project the temperature and precipitation for the near future period (2015–2044) under 50 % risk level of climate change.

Downscaled climate variables suggest that generally temperature will rise in the Zayandeh-Rud River Basin while the level of temperature increase varies between. The maximum monthly precipitation reduction will occur in winter. This can be of considerable importance for the basin having a semiarid Mediterranean climate in which winter precipitation is the main source of renewable water supply.

In the proposed framework, the uncertainties of GCMs, emission scenarios, and climate variability of daily time series are handled by the combination of change factors and a weather generator. Covering the full range of potential climate change, such framework can provide the valuable lessons to policy maker for adapting to climate change.

The Zayandeh-Rud River Basin has been constantly facing the water stress problem during the past 60 years. The results of the climate change impacts on the basin's climate variables can provide the policy insights for regional water managers to address well the water scarcity in the near future.

Climate change • Impact assessment • Climate variable • Zayandeh-Rud • Iran

Introduction

Climate change is a significant change in the weather conditions in long-time periods. It may be the changes in weather parameters or in the distribution of weather events (i.e., more or fewer extreme weather events). Climate change is considered as one of the major factors that will affect the water availability and life in the future (Bates et al. 2008; Eslamian et al. 2011).

Humans have been the significant contributors to greenhouse gas emissions by different industrial and household activities. The Intergovernmental Panel on Climate Change (IPCC) stated that in the Fourth Assessment Report of climate change (AR4), the air temperature increased by 0.74 °C from 1906 to 2005 (IPCC 2001).

Increased evaporation (resulting mainly from the higher temperatures), combined with regional changes in precipitation characteristics (e.g., total amount, variability, and frequency of extremes), has the potential to affect mean runoff, frequency and intensity of floods and droughts, soil moisture, and water supplies for irrigation and hydroelectric generation, which are the little effects of climate change in the recent years (Ghosh and Mujumdar 2009; Zhang et al. 2010; Eslamian et al. 2011).

Projections of climatic variables globally can be performed with General Circulation Models (GCMs), which provide the projections at large spatial scales.

These models are considered as the most credible tools for the projections of future global climate change (IPCC 2007).

An important limitation in the GCMs' application is the some sources that prevent from finality in the model outputs. These limits are often expressed as uncertainty (Moss and Schneider 2000). These include:

1. Estimating the amount of greenhouse gas and aerosol emissions is hard and has a lot of uncertainties (related to the emission scenarios) (Parry et al. 2004).
2. There are some uncertainties in GCMs (Sajjad Khan et al. 2006).
3. Global climate model sensitivities don't have the finality (Elmahdi et al. 2008).

The uncertainty in the global model configuration has long been recognized as one of the most important parts of the overall uncertainty, especially considering the first decades of the twenty-first century when the different emission scenarios do not lead to dramatically different climate responses (Benestad 2004).

To resolve these uncertainties, the different methods based on physical and mathematical relationships are presented in climate change modeling (Schaefli et al. 2007).

There are two general approaches for using of the GCMs. The first method is using a single GCM model for predicting future data (Jones and Thornton 2003; Guo et al. 2010). This may lead to an incorrect estimate of the calculated parameters in climate change models (Lee et al. 2011).

In the second method, multiple climate change scenarios are produced by the different GCMs to capture probable range of climate change impacts. This method helps to identify, better understand and more realistic modeling of the climate change (Medellin-Azuara et al. 2008; Kloster et al. 2010; Abrishamchi et al. 2012).

There are many researches in the literature for the use of multiple impact assessment models to better represent and manage these uncertainties (Tao et al. 2009; Lizumi et al. 2009; Tao and Zhang 2010; Daccache et al. 2011; Ozdogan 2011). In the recent studies, probabilistic outputs from ensembles of the GCMs models and emission scenarios have been used to achieve a better representation of uncertainties and comprehensive impact assessment. Some of them suggested that an average over the set of GCM outputs provides a dominant climate simulation related to any individual model (Bader et al. 2008; Liu et al. 2010). Elmahdi et al. (2008) have used seven AOGCMs from the IPCC third assessment report to project the future temperatures. They generated 1,000 samples of air temperature time series for uncertainty analysis and risk assessment of water demand.

This chapter aims to assess a multi-model framework for climate change impact assessment. In this framework, the uncertainties of GCMs and emission scenarios are handled by an innovated downscaling method (combination of change factors and a weather generator). The suggested approach attempts to improve the reliability of the climate change impact assessment approach by considering the three main sources of uncertainty as discussed earlier.

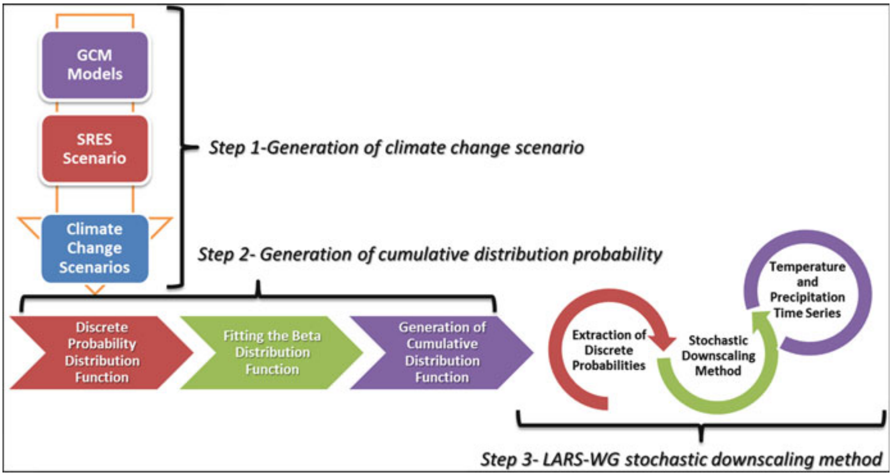

Fig. 1 Detailed flowchart of methodology

Methodology Outlines

In this study, the multi-model ensemble scenarios within the risk framework are used in order to manage uncertainty of the GCM outputs and emission scenarios. This probabilistic framework has been constructed by the combination of change factor and LARS-WG methods in the downscaling of ensemble GCMs. A detailed flowchart of this methodology has been shown in Fig. 1. According to Fig. 1, the major stages of this study consist of three steps: (a) generation of temperature and precipitation climate change scenarios by 15 GCMs for the case study, (b) generation of cumulative distribution function for climate change scenarios and extraction of climate scenarios corresponding to 50 % probabilities, and (c) generating temperature and precipitation daily time series by the LARS-WG stochastic downscaling method.

Climate Change Scenarios Generation

Generating climate change scenarios is the first step to achieve probable patterns of the future climate based on assumptions of future atmospheric concentrations. The AOGCM-derived scenarios of climate change are the most common scenario type in the impact assessments. In this chapter, 15 GCMs outputs under two emission scenarios (A2 and B1) from the Fourth Assessment Report (AR4) of the Intergovernmental Panel on Climate Change (IPCC) are used (IPCC 2007). The detailed description about these models is shown in Table 1. A2 scenarios assume rapid population growth coupled with slow economic and technological development until 2100. B1 scenarios are characterized by very rapid global socioeconomic growth and population rising until 2050 and then declining toward the end of the century.

Table 1 Description about 15 GCMs from the Fourth Assessment Report (AR4) IPCC

Model	Abbreviation	Center

CCSM3	NCCCSM	NCAR (USA)
CNRM-CM3	CNCM3	CNRM (France)
MIROC3.2	MIMR	NIES (Japan)
IPSL-CM4	IPCM4	IPSL (France)
GISS-E-R	GIER	NASA/GISS (USA)
BCM 2.0	BCM	Beijing Climate Center (China)
CGCM3 T47	CGCM	Canadian Centre for Climate Modeling and Analysis
ECHO-G	ECHO	Meteorological Institute, University of Bonn Meteorological Research
INMCM 3.0	INMCM	Russian Academy of Science, Institute of Numerical Mathematics
NCARPCM	NCRPCM	National Center for Atmospheric Research (NCAR), USA

In the first step, monthly temperature and precipitation variables for the baseline period (1971–2000) and future period (2015–2044) have been extracted from the Data Distribution Center (http://www.ipcc-data.org) (DDC) of IPCC. The values of difference for the temperature and relative change for precipitation between the 30-year monthly average baseline period and future period are calculated for each month. These values represent the climate change scenarios for the temperature and precipitation's 30-year monthly averages. Here, climate change scenarios in the future period to baseline period are created separately for the different AOGCMs under two emission scenarios.

Risk Assessment of Climate Change Impacts

There are the high levels of uncertainties in the results of the AOGCM climate change scenarios. These uncertainties affect the choice of method and the confidence that can hurt the results in the impact assessment studies. There are many methods for uncertainty management, for example, expression of the results as a central prediction, central prediction with error bars, known probability distribution function, a bounded range with no known probability distribution, and a bounded range within a larger range of unknown possibilities (OECD 2003). Here, a bounded range with known probability distribution (Gohari et al. 2013a) is used for managing uncertainties due to use of ten AOGCMs, which is created from the weighting of the AOGCMs. This probabilistic multi-models approach includes the three following steps.

Weighting the AOGCMs

The ranges of monthly climate change scenarios are not the same due to different abilities of the AOGCMs to local climate simulation. So, each of the 15 GCMs used in this study separately has been weighted based on the mean observed temperature-precipitation (MOTP) method. In this method, each AOGCM has been weighted based on the difference between average of temperature and precipitation simulated by AOGCM in the base period from corresponding observed value, following the study by Massah Bavani and Morid (2005):

$$W_i = \frac{\left(1/_{\Delta}T_{ij}\right)}{\sum_{j=1}^{15}\sum_{i=1}^{N}\left(1/_{\Delta}T_{ij}\right)} \tag{1}$$

where W_i is the weight of each model in month i and ΔT_i is the temperature and precipitation change field for GCM j in month i.

Probability Distribution Function (PDF)

In this step, probability distribution function (PDF) is made, where the X and Y values represent the temperature or precipitation monthly changes and the weight of corresponding AOGCM, respectively (Fig. 2). In order to produce a time series of temperature and precipitation for the future period, the temperature and precipitation long-term monthly averages are needed. Therefore, discrete probability distributions of climate change scenarios must be converted to continuous probability distribution. Due to a high correlation and having a low number of parameters, the two parameters beta distribution function as one of the best function can be fitted on these discrete distributions:

$$\mathrm{f(x)} = \frac{\mathrm{(x-a)^{p-1}(b-x)^{q-1}}}{\mathrm{B(p,q)(b-a)^{p+q-1}}} \qquad \mathrm{a \ll x \ll b;} \quad \mathrm{p,q > 0} \tag{2}$$

where x and p and q are the variable and shape parameters for beta distribution function respectively, and B(p, q), the beta function.

The values of p and q are changed to get the best fit based on the maximum likelihood estimation method. Here, the sum of squared error (Eq. 3) is used to show how well the beta function fits the data:

$$SSE = \sum_{i=1}^{n}\left(y_i - ¥_i\right)^2 \tag{3}$$

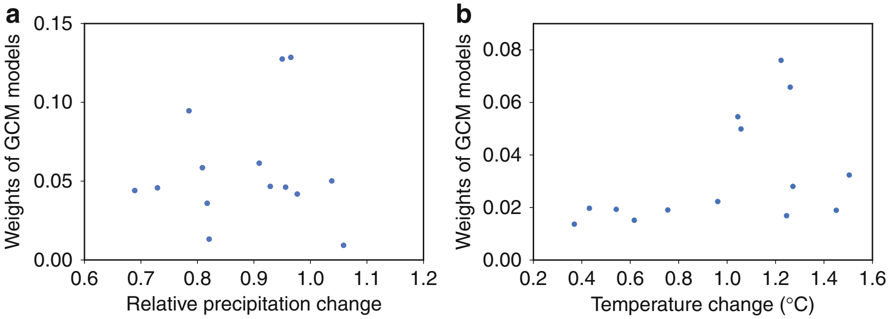

Fig. 2 Discrete PDFs, relating monthly temperature and precipitation changes to the weights of corresponding GCMs. Graph (**a**) shows the developed PDF of relative precipitation changes in May and graph (**b**) shows the developed PDF of temperature changes in February

where y_i is the data point, $¥_i$ is the estimation of beta function, and n is the number of data points ($n = 15$). The small size of sample data set can affect the goodness of fit. This is indeed a limitation of this type of assessment caused by having access to a limited number of GCMs.

Cumulative Distribution Function (CDF)

In this step, the developed PDFs are converted to CDFs. Cumulative distribution function (CDF) curve is made, where X and Y values represent the temperature or precipitation monthly changes and corresponding exceed probability (P_i). Since there is no possibility to use each point of these CDF in the impact assessment models, the monthly temperature and precipitation change scenarios have been extracted corresponding to 50 % discrete probabilities as a moderate-risk level of climate change (Fig. 3).

Stochastic Downscaling

The direct use of the AOGCM-derived climate scenarios could be impossible in impact assessment models due to large deviation of these model-derived downscale variables time series (i.e., temperature and precipitation, etc.) with real data. But long-term monthly averages of these variables are highly correlated to the real data (Semenov 2007). The downscaling techniques bridge the gap between the AOGCM outputs and required inputs by the impact assessment models (Wilby and Wigley 1997). One of the downscaling tools to generate daily climate scenarios is a stochastic weather generator (WG) (Wilks and Wilby 1985; Semenov 2007). A WG is a model, which has an ability to simulate synthetic time series of daily weather for the future by using predicted climate change scenarios from GCMs.

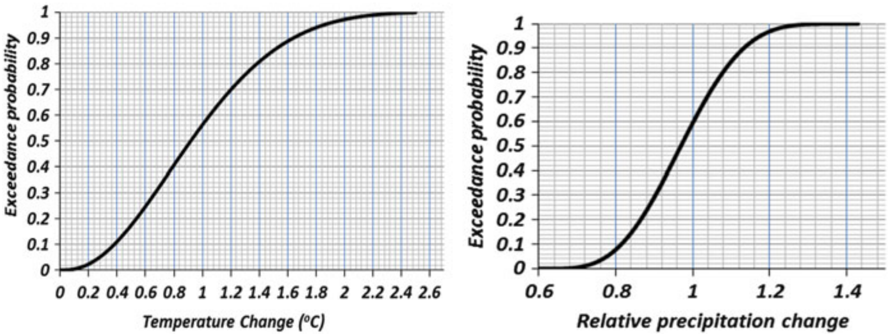

Fig. 3 Developed CDFs based on the presented PDFs in Fig. 2

LARS- Weather Generator

LARS-WG is one of the stochastic WGs that generate synthetic daily time series of minimum and maximum temperatures, precipitation, and solar radiation (Semenov 2007). The LARS-WG can generate the daily time series from monthly climate change scenarios. In the first step, the weather generator parameters calculate based on the probability distributions of locally observed daily weather variables (Semenov 2007). So, the semiempirical distributions of observed data such as frequency distributions calculate for the wet and dry series duration. Fourier series are used for describing the precipitation amount, solar radiation, and minimum and maximum temperatures. In the next step, LARS-WG generates synthetic weather data by combining a climate change scenario file for precipitation amount, wet and dry series duration, mean temperature, temperature variability and solar radiation with the resulting parameter files. In the final step, the observed data statistical characteristics are compared with those of synthetic data. A number of statistical tests (i.e., the chi-squared test, Student's t-test, and F-test) are used in this comparison to determine the differences between the distributions, mean and standard deviation values of the synthetic and observed data set (Semenov and Barrow 1997; Semenov et al. 1998).

In the present work, future daily time series of maximum and minimum temperatures and precipitation are generated for 2015–2044 based on observed daily time series and climate change scenarios for 50 % probabilities using LARS-WG. For generating 30 years daily time series, 300 years daily time series (10 × 30 years daily time series) for future period are generated by this WG and then the average daily values of these ten time series are calculated.

Case Study

The Zayandeh-Rud River Basin with an area of about 26,917 km^2 is located in central Iran (Fig. 4). In recent decades, due to high agricultural and industrial development potential, the basin has witnessed economic growth and increased

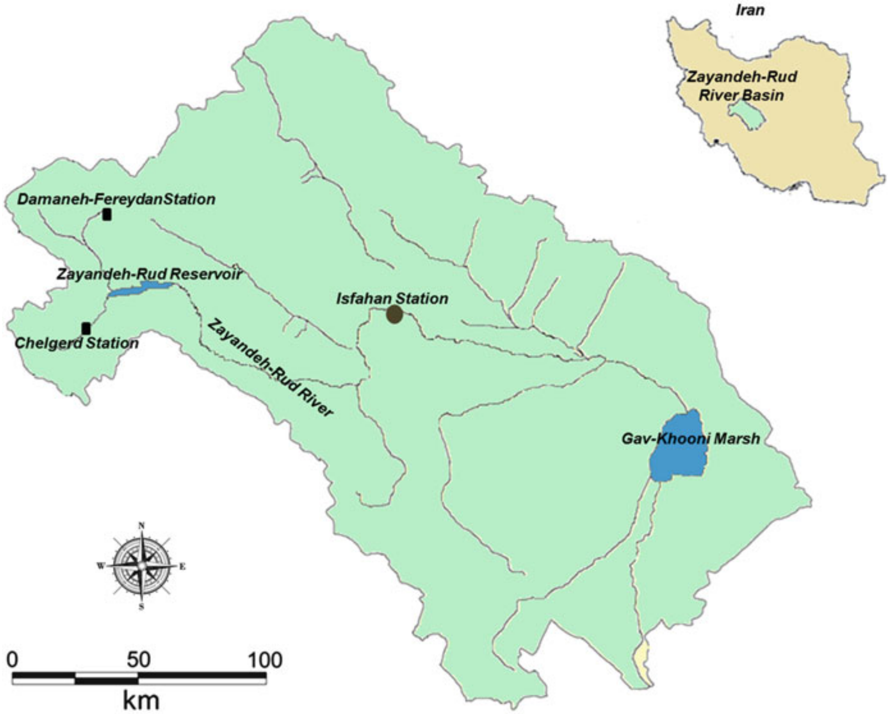

Fig. 4 Zayandeh-Rud River Basin

population (Madani and Marino 2009). Currently, more than 3.7 million people are living in the basin, making it the second most populated watershed in Iran. As the major water consumer, agriculture sector uses more than 73 % of water supply (Zayandab Consulting Engineering Co. Report 2008). Cultivation of high-water-demand crops (i.e., rice, corn, wheat, and barley) and low irrigation efficiency of 34–42 % contribute to the high agricultural water demands (Gohari et al. 2013b).

The Zayandeh-Rud River with an average flow of 1,400 million cubic meters (MCM), including 650 MCM of natural flow and 750 MCM of the transferred flow, starts from the Zagros Mountains in the west of the basin and flows into the Gav-Khooni Marsh in the east of the basin (Gohari et al. 2013b). The Gav-Khooni Marsh is recognized as an international wetland under the Ramsar Convention (1971). The river has been tapped for increasing water consumption within and outside the basin. This makes the river the most important water resource of the basin for its residents and their urban, industrial, and agricultural uses, as well as for the survival of the ecosystem of the Gav-Khooni Marsh.

Two climatological stations and a rain gauge station are selected in the study area. Table 2 presents the description of these stations.

Table 2 Brief description of the selected observation stations

Station name	Geographical position			Type of station
	Longitude	Latitude	Elevation (m)	
Damaneh-Fereydan	50° 29′	33° 01′	2,300	Climatological station
Chelgerd	50° 05′	32° 27′	2,300	Rain gauge station
Isfahan	51° 68′	32° 63′	1586	Climatological station

Impact of Climate Change on Climate Variables

Large Scale Climate Change Scenario for Temperature and Precipitation

The results of temperature changes for Isfahan synoptic station projected from ECHO-G model are presented in Table 3. Mean monthly temperature changes are generally expected to increase under climate change. Most GCMs suggest higher future temperatures in the study region while the range of expected temperature changes varies between months.

Uncertainty of Climate Change Projection

Weighting of AOGCMs

The weights of 15 GCMs for Isfahan station are shown in Table 4. The values of AOGCM weights vary between different months. The maximum weight is assigned to the CGCM3.0 model in July. The comparison of average weights of different models shows that minimum weight is assigned to the NCARPCM. The average monthly weights show that the maximum contribution of different months is related to July.

Probability Distribution Function

The discrete PDFs of climate change scenarios are developed for each month. The parameter estimation method is used to convert the discrete PDFs to continuous ones. Table 5 shows the values of SSE and beta distribution parameters for continuous temperature. The low values of SSE underline the suitability of beta distribution.

Regional Temperature and Precipitation Changes

Figures 5 and 6 respectively, show the estimated local (downscaled) temperature for Damaneh-Fereydan and Isfahan stations under climate change for various risk levels. Generally, temperature increases are expected for all months under climate change. But, the levels of increase vary between the months. The maximum

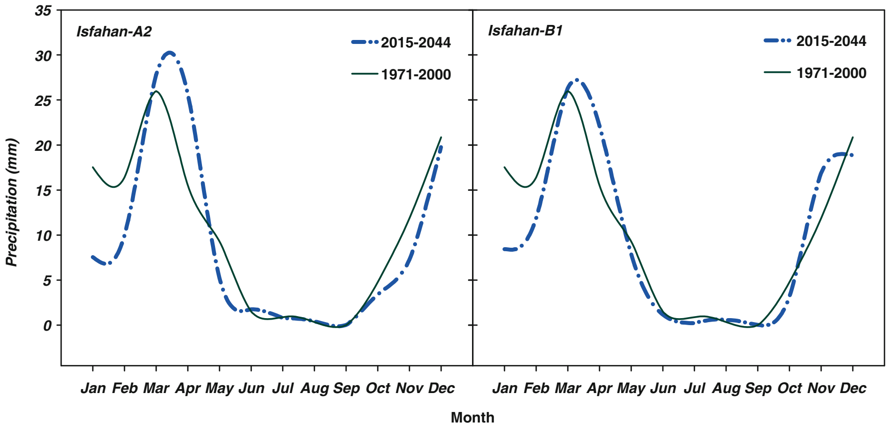

Fig. 8 Comparison of the baseline (1971–2000) and future (2015–2044) period 30-year monthly mean precipitation under A2 and B1 emission scenarios in Isfahan station

temperature changes in Damaneh-Fereydan are expected in spring and summer months, respectively, under A2 and B1, while maximum temperature change fields in Isfahan station are simulated in summer and fall months, respectively, under A2 and B1.

Unlike the results for temperature, the local precipitation changes do not show a general increasing trend (Figs. 7 and 8). The results show that the maximum monthly precipitation decreases in Isfahan and Chelgerd stations in January under A2 and B1.

The projected annual and seasonal changes of 30-year mean temperature and total precipitation were calculated under A2 and B1 (Tables 6 and 7).

With 5–15 % decrease in Chelgerd's precipitation and 0.58 °C increase in Damaneh-Fereydan's temperature at annual scale, the upper subbasin will face warmer and drier conditions under climate change. The results of Isfahan station indicate that the lower sub-basin will experience warmer (0.82–0.95 °C) and dryer (6–17 % reduction in precipitation) conditions than the upper subbasin in the future.

Conclusions

In this study, 15 GCMs are used under two emission scenarios to estimate climate change impacts on climate variables in the Zayandeh-Rud River Basin. To deal with the high uncertainty in the estimated temperature and precipitation changes under climate change, the weighted ensembles of GCMs' outputs were generated and climate change variables at 50 % risk levels (a medium-risk level) were estimated. The results suggest that generally temperature will rise in the study area while the level of temperature's increase varies between the months. Monthly precipitation changes do not show a general increasing or decreasing trend.

Upper subbasin precipitation especially in winter is known as the main resource of surface water in the Zayandeh-Rud River Basin. The results indicate that maximum monthly precipitation reduction (5–26 %) will occur in winter and annual precipitation is expected to decrease by 5–15 %. This can be of a considerable importance for the Zayandeh-Rud River Basin with semiarid Mediterranean climate in which winter precipitation is the main source of renewable water supply. Temperature rise will lead to more precipitation falling as rain, instead of snow, and the snowpack will melt earlier in the spring. The reduced snowfall due to increasing temperature in winter months will generally lead to more severe water shortages in such arid and semiarid regions under climate changes.

A Socio-Economic Evaluation of Community-based Adaptation: A Case Study in Dakoro, Niger

Olivier Vardakoulias and Natalie Nicholles

Contents

Abstract

Community-based adaptation (CBA) is gaining popularity as an approach to supporting vulnerable communities to adapt to the impacts of climate change, but in an environment of competing financial demands, to what extent is CBA economically efficient?

Empirical research from NEF Consulting (New Economics Foundation) using an extended social cost-benefit analysis (SCBA) of qualitative and quantitative data gathered from four communities compares and contrasts the benefits and

investment in CBA initiatives carried out by the Adaptation Learning Programme (ALP), implemented by CARE International in Dakoro, Niger.

The results suggest a high return on investment on ALP's CBA activities in Dakoro and an increase in the economic capital of communities (revenue and savings) as well as social and environmental capitals. Even only taking into account the benefits ALP has generated to date (over 4 years), findings suggest that for every £1 invested in communities, there has been a return of more than £4. In order to capture the future value of community-based adaptation, the evaluative model was extended further to forecast evolutions to 2020 using three core climate scenarios to evaluate the impact on the different forms of communities' capital under a no intervention scenario, compared to an intervention scenario. Even under a high discount rate, results remain positive and returns are high, proving that CBA is both an economic and socially effective approach to adaptation.

Keywords
Climate change • Community-based adaptation • Social cost-benefit analysis

Introduction

Climate change is one of the greatest threats facing poor and marginalized communities (Parry et al. 2007). As the possibility of keeping global temperature increase to 2 °C looks increasingly unlikely under current projections (IPCC 2013), societies will be faced with the challenge of adapting to the imminent impacts of climate change. The impacts of climate change will exacerbate existing challenges such as economic crises, natural disasters, environmental degradation, and conflict (Buhaug et al. 2008). This poses new challenges for development practitioners, policy-makers, and national and local governments, who will increasingly need to take into account future impacts of climate change. This will require building resilience and capabilities within communities to respond to the impact of climate change. With this in mind, new research conducted by NEF Consulting (New Economics Foundation) sought to answer the question of which adaptation strategies are the most effective and would therefore benefit from most investment.

Community-based adaptation (CBA) has been growing in popularity as an approach to supporting communities to adapt to the impacts of climate change (IIED 2009). The key aspects of the approach are a focus on both "hard" and "soft" adaptation strategies, the importance of action at all levels (community, regional, and national), embedding adaptation practices and actions into community life by codesigning approaches to adaptation, and stressing the importance of both quick win activities (such as disaster risk reduction measures) as well as building longer-term adaptive capacity (Ensor and Berger 2008). In short, CBA provides an effective, practical, and integrated approach which strengthens adaptive capacity and supports planning and implementation of DRR and climate-resilient development, informed by knowledge of climate information and risks. It seeks to address broader underlying causes of vulnerability which, if left unchallenged, would prevent the achievement of resilient outcomes (Ensor and Berger 2008).

There are a range of research methods which are suitable for testing the efficiency and effectiveness of adaptation strategies promoted as part of CBA, including both quantitative and qualitative methods (GIZ 2013). Social cost-benefit analysis (SCBA), including its variants like social return on investment (SROI), is widely regarded as one of the most appropriate methods for assessing effectiveness and efficiency from a socioeconomic perspective. By comparing the wider benefits (economic, social, and environmental) generated by an intervention against the costs, SCBA determines whether available resources are used in an efficient and effective way (Dreze and Stern 1987). This enables an analysis of which strategies are most effective in delivering intended change when compared against others.

This chapter presents the research conducted by NEF Consulting using a SCBA approach to evaluate and appraise the adaptation strategies promoted as part of the CBA approach by the Adaptation Learning Programme for Africa (ALP), implemented by CARE International in Niger. CARE International launched ALP in 2010 with the aim of identifying the problems faced by communities in the context of climate change, determining potential current and future solutions both for communities and the wider region, and building a robust community-based adaptation approach, which takes into account broader macro-institutional conditions and strategies, both regional and national. The ALP is carried out in four countries in Africa – Kenya, Niger, Mozambique, and Ghana. The program aims to generate learning on community-based adaptation to climate change in order to inform best practice for adaptation and development practitioners as well as local, national, and regional policy- and decision-makers (Fig. 1).

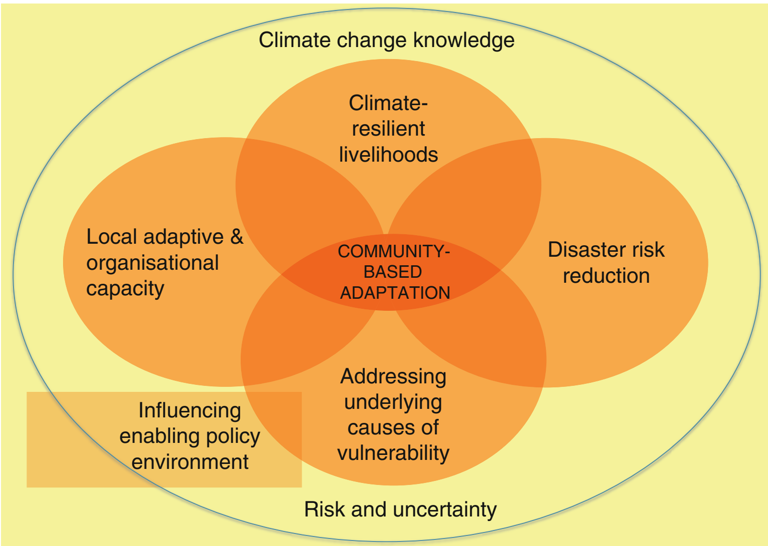

Fig. 1 Scope of Adaptation Learning Programme

Purpose of the Evaluation

In 2011, NEF Consulting carried out a socioeconomic analysis of community-based adaptation interventions carried out by ALP in Kenya. This created much interest and discussion in the efficiency and effectiveness of investing in community-based adaptation (Nicholles and Vardakoulias 2012) although the methodology used remained entirely forecastive. It was therefore agreed that a follow-up study using an evaluative approach to analyze ALP was needed to deepen understanding in this area. ALP started work in Niger in 2010 which meant that it was a good location for the study due to the longevity of the project. The objectives for the research were as follows:

- To use extended cost-benefit analysis methodology to conduct a socioeconomic analysis of community-based adaptation
- To analyze the results against the "broader" picture, i.e., comparing community based to no adaptation and/or to other development interventions that do not take adaptation into account

In addition to this, the assignment aimed to simplify the original cost-benefit model used in Kenya so that the approach, learning, and results could be used by ALP and local government stakeholders to make decisions about the allocation of funds for activities which support climate change adaptation.

Climate Change in Niger

Niger is one of the most vulnerable countries in the world and is highly dependent on climate conditions due to the nature of its geographical location and socioeconomic characteristics (Republique du Niger 2006). Niger's economy and the livelihoods of its population are highly sensitive to the impact of climate changes due to 40 % of its GDP being based on agriculture and 80 % of the population being dependant on agriculture for their livelihoods (World Bank 2013).

Over the years Niger has been consistently affected by droughts which are one of the drivers of vulnerability in terms of food crises, with no less than seven severe droughts since 1980 (World Bank 2013). This has resulted in successively undermining agricultural and livestock production on which most of the population depend. This is exacerbated by a number of other factors and risks including recurrent locust outbreaks, floods, desertification, land degradation, and poor resources and infrastructure to deal with these shocks. Figure 2 presents the economic impacts of these shocks from 1980 to 2010.

Climate vulnerability is therefore just one of many interrelated pressures – climatic, socioeconomic, institutional, and ecological – that Niger's agricultural sector experiences (World Food Programme 2010). It is also important to note that while agricultural production has increased as shown in Fig. 2, production per capita has been decreasing since the 1960s (Ozer 2007). Therefore, agricultural

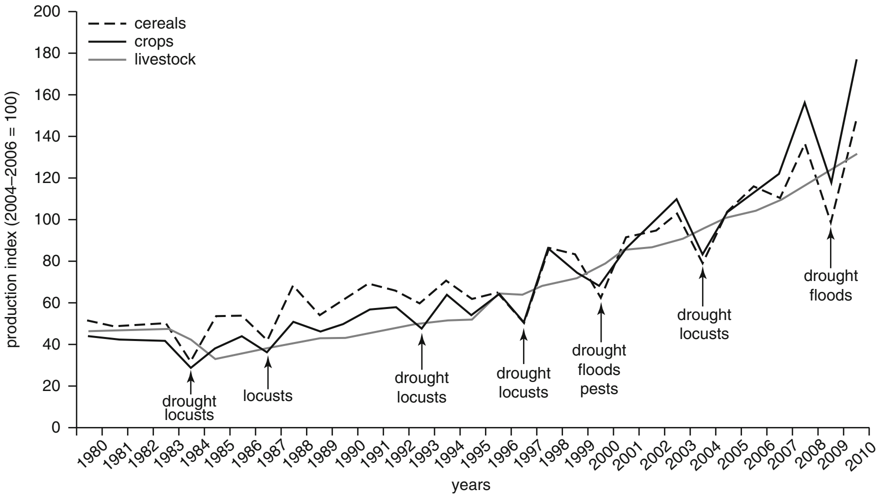

Fig. 2 Impacts of shocks on agricultural and livestock production in Niger (1980–2010)

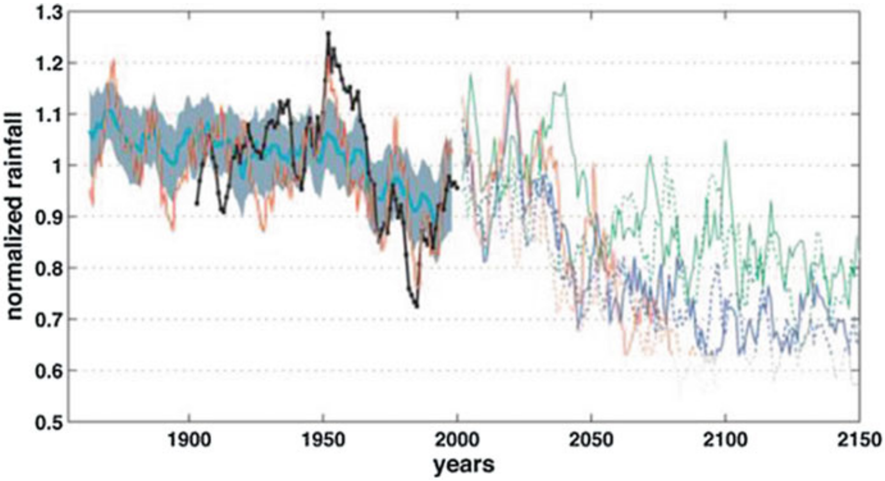

Fig. 3 Historical and projected rainfall patterns in the Sahel

production is not keeping up with population increase, which means that an increasing number of households are at risk of malnutrition.

In the Sahelian zone, there is broad agreement that there is a decreasing trend in rainfall since the mid-twentieth century (Held et al. 2005). However, after a dry period lasting until the 1980s, rainfall has been increasing ever since. It is important however that these average conditions do not hide the increase in extreme rainfall events, anomalies in rainy seasons, and the fact that due to the chaotic nature of the climate system, the current wetter period might not last. In fact some downscaled global models predict that there will be a slow but sure decrease in rainfall across the Sahel rather than an increase as well as changes in the seasonality of precipitations (Held et al. 2005; Yayé et al. 2013; Fig. 3).

Even if, as some downscaled models predict, overall precipitation will slightly increase or remain stable, all models agree on significant increases in mean temperature for the region. The impact of this increase in mean temperature on soil fertility and moisture is unlikely to be balanced out by the increase in precipitation. Furthermore, most models forecast a decrease in the length of growing period (LGP) and therefore a decrease in agricultural production as a consequence of temperature increase (Yayé et al. 2013). Looking at the overall picture, the climate projections for the Sahel region, coupled with population growth, are likely to increase existing vulnerability in Niger (Fig. 4).

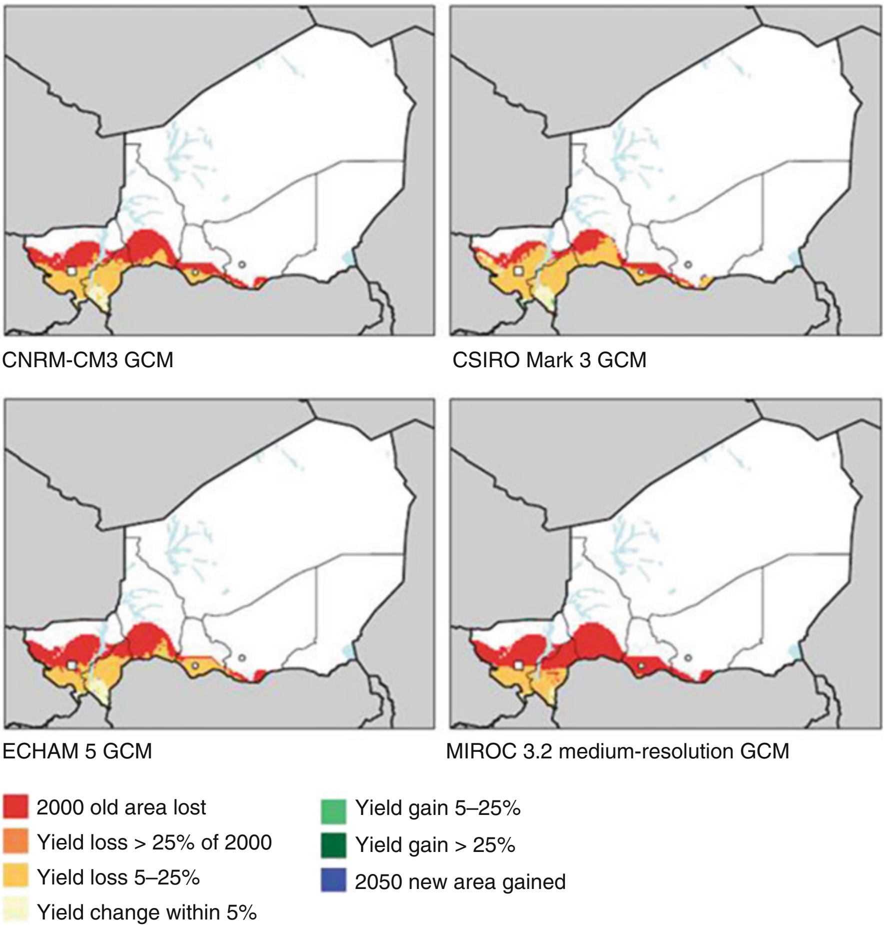

Fig. 4 Projected yields of rain-fed sorghum under different precipitation and temperature scenarios

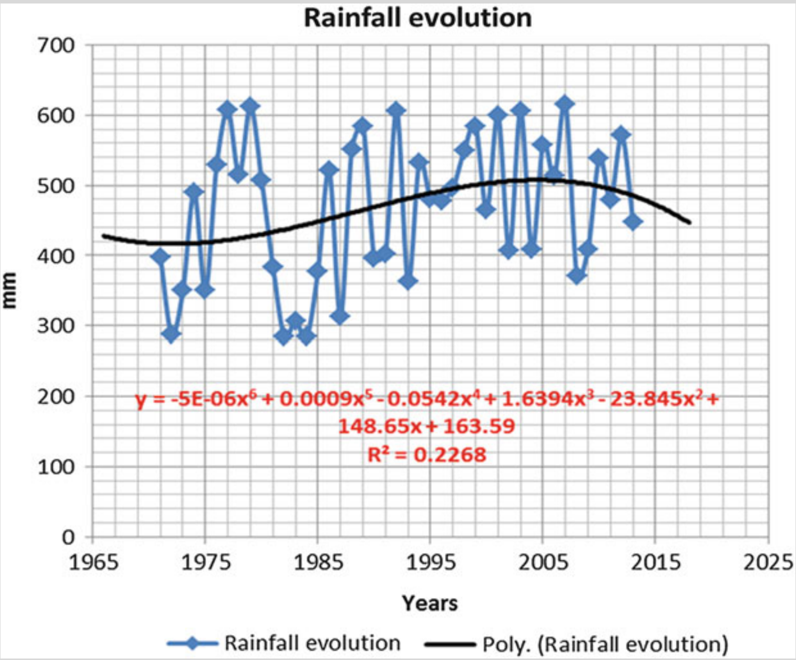
The department of Dakoro, where the ALP is operational, experiences precipitation anomalies typical of the Sahelian zone. The study was unable to find climate model forecasting for the region of Dakoro, but by looking at past historical records, it is clear to see just how vulnerable the region is. The province has been hit by six severe or catastrophic droughts between 1981 and 2000, this is equivalent to one severe or catastrophic drought happening every 4.8 years (World Bank 2013). The study took raw data from the weather station in Maradi (120 km south of Dakoro) and analyzed it revealing that precipitation patterns in the region are chaotic, demonstrating high vulnerability on a year-on-year basis (INS Niger 2010) (see Box 1). This presents a major challenge for rural communities who are dependent on rain-fed agriculture, as demonstrated by the economic analysis conducted by the World Bank which suggests that output of major crops is correlated to rainfall by a factor of 0.60 (World Bank 2013).

Box 1: Rainfall Evolution in the Region of Maradi (1965–2013)



The sample communities which are the focus of this research are therefore situated in a particularly vulnerable environment where the predominant form of agriculture is rain-fed and water resources are limited – particularly during the dry season of October to May.

Methodology: Understanding Change and Impact

This study takes a socioeconomic perspective of community-based adaption, which is not only useful in understanding the impact of CBA but also provides an effective framework for evaluation.

The three factors are interrelated; if people have enough access to resources and also have the skills and knowledge to use them in the most effective way possible, then they are less likely to need or deplete their resources when a shock occurs. It is this assumption that is tested in this evaluation (Fig. 5).

Following on from the study which was conducted in Kenya in 2011, this research combines a traditional cost-benefit analysis approach with the underlying principles of SROI (Lawlor et al. 2008). This results in a three-pronged approach to the methodology:

- Developing theories of change (ToC) through engagement with primary stakeholders and the ALP team
- Measuring quantitative social and economic capital evolutions using empirical research with primary stakeholders
- Assessing quantitative environmental capital evolutions and climate variability through extensive literature reviews and secondary desk-based research in order to fill gaps identified in empirical analysis

The evaluation is composed of two main components, modeling the resilience of communities to shocks relative to a business-as-usual scenario and then modeling how this resilience impacts on the long-term prospects of communities – relative to a business-as-usual scenario. In short, the evaluation analyzes the value created by ALP's interventions in economic, social, and environmental capital in comparison to investment.

ALP works in 20 communities across four communes in Dakoro; therefore, the study was undertaken in a representative sample of communities chosen for the ALP.

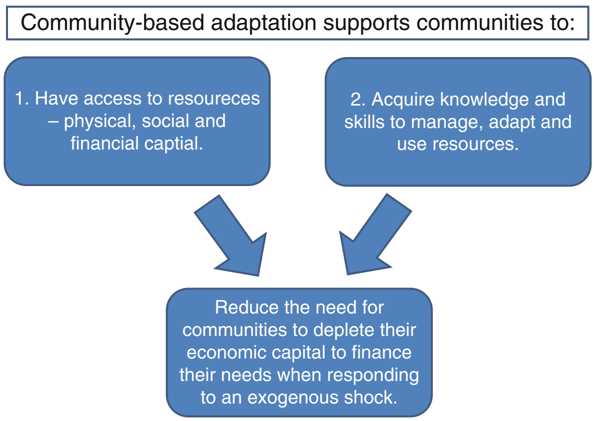


Fig. 5 ALP's framework for community-based adaptation

Table 1 Sample construction based on level of vulnerability

	Total households	D = extremely vulnerable	C = very vulnerable	B = vulnerable	A = moderately vulnerable	Total
Maiwassa	230	6	5	1	1	13
Dan Ijaw	124	1	4	2	1	8
Kouggou	49	0	1	2	1	4
Gomozo	81	2	2	1	1	6
Total	484	9	12	6	4	**31**

The communities chosen for the sample were Maiwassa, Dan Ijaw, Gomozo, and Kouggou. This was based on three key selection criteria, ethnic group, level of vulnerability, and proximity to the Tarka valley, as these factors are considered to have the most impact on the effectiveness of community-based adaptation. There are three main ethnic groups in the communities, Hausa, Fulani, and Toureg, with Hausa being the dominant group among the 20 communities. In order to ensure this distribution, two Hausa, one Fulani, and one Toureg community were selected. It was decided that the most feasible sample size would be 5 % of households within the communities, broken down by vulnerability levels.

The levels of vulnerability were defined by taking into account household income and assets, and the vulnerability categories were defined by communities themselves. Communities were asked to collectively determine and identify which households were to be classified as "extremely vulnerable" through to "moderately vulnerable" based on a number of criteria including amount of assets (land, livestock, tools, etc), agricultural production output, social position within the community, quality of housing, and nutritional coverage.

Vulnerability was assessed and weighted across the levels, this was to account for the fact that in some cases, 5 % resulted in less than a whole household (see Table 1).

Theory of Change

Qualitative data on how the four communities selected for this research experienced the impacts of climate change prior to the start of ALP in 2010 and in 2013 when this research was conducted was collected via stakeholder engagement. Communities were asked to retell their stories across a range of parameters including social and economic impacts. A counterfactual scenario was also explored to find out how communities felt they would have experienced climate change in the absence of ALP. This can be illustrated through a theory of change diagram which presents the need for ALP as expressed by the challenges induced by climate change (Fig. 6).

The *prevailing conditions* are the reasons why ALP intervenes in the communities because collectively they increase vulnerability to a climate shock. When a climate shock does occur, this often results in weakened economic capital (crop failure or weak livestock), and a vicious cycle of not being able to plan and develop strategies

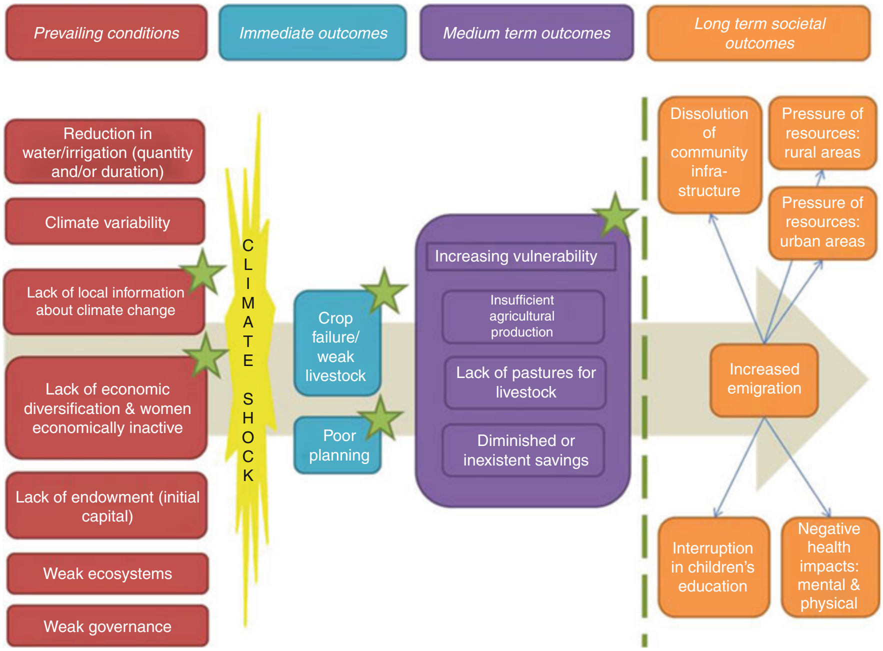

Fig. 6 Theory of change for business as usual

for forthcoming shocks ensues. These, alongside the prevailing conditions, increase communities' vulnerability from an economic perspective.

According to the communities, one of the longer-term impacts of increased vulnerability is rural to urban and peri-urban migration which can lead to a number of impacts including breakdown in community infrastructure, increased resource pressure on both urban and rural areas, interruption in children's education, and a detrimental impact on both physical and mental health.

ALP has clear strategies to prevent these longer-term outcomes from occurring: to increase communities' resilience to the uncertainty and impacts of climate change. Denoted by the green stars in Fig. 6, ALP intervenes to address the lack of local information about climate change, the lack of economic diversification, and women's economic role within communities. It then works to address weakened economic capital and poor planning, which is about focusing on the core needs of the community to build their resilience. This is where ALP is aiming to influence, as denoted by the line of accountability. The line of accountability is a tool that allows for understanding of ALP's sphere of influence and for better measurement of impact.

Once communities articulated the need for ALP's intervention, they then shared the social, economic, and environmental outcomes they had seen following the adoption and integration of adaptation strategies. Figure 7 presents the theory of change as captured through the stakeholder engagement.

ALP supports the process of action planning for community-based adaptation, which enables communities to decide on relevant and locally appropriate adaptation

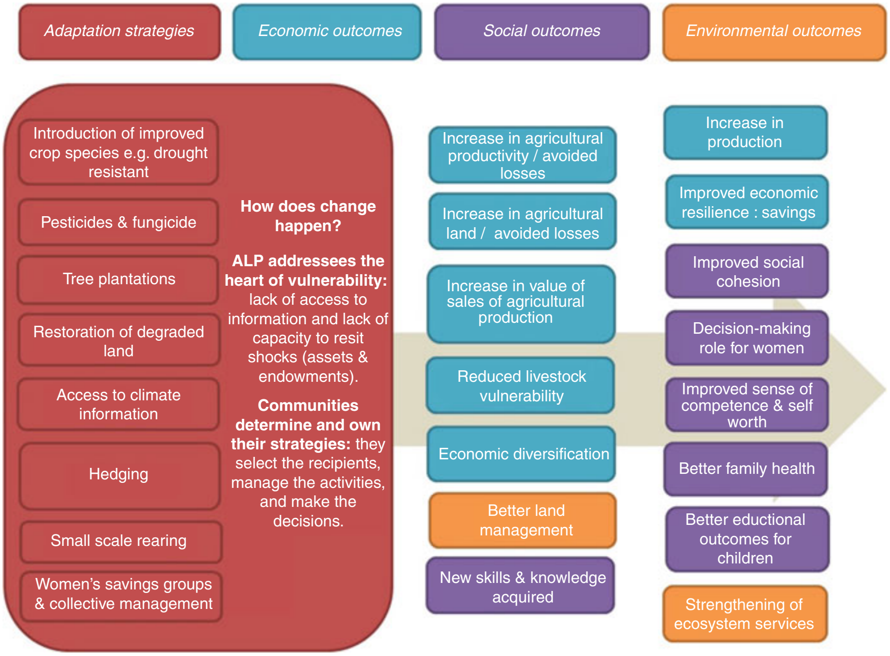

Fig. 7 Theory of change for community-based adaptation

strategies. Each community applies a mixture of adaptation strategies selected by them. Indeed, this point is crucial to understanding the theory of change: communities determine their own strategies, select the recipients, and make the decisions about who is responsible and how resources are allocated. These decision-making processes are informed by climate vulnerability and capacity analysis, and climate information in some form. Adaptation strategies are multiple and usually involve activities related to livelihoods, risk reduction, or advocacy initiatives. These aim to reduce vulnerability and risk and result in climate-resilient and more equitable livelihoods, which are adapted over time. Example strategies range from improving crops (such as drought-resistant crops), community-based hedging mechanisms (known as warranting), small-scale rearing (one or two goats), and women's collective savings structures.

The qualitative information to create the theories of change provided a guide for which hypotheses needed to be tested and evidenced through quantitative data collection. These hypotheses are that:

- Economic capital improves through increasing production (either agricultural productivity or land; increasing the value of sales or reducing livestock vulnerability), economic diversification (mostly where women undertake economic activities), and improving savings. All contribute to greater resilience from an economic perspective.
- Social capital improves through learning new skills and acquiring knowledge and making collective decisions. Communities reported having better relationships

and a sense of cohesion, improved sense of self-worth as a result of feeling more in control of their future, and better general educational and health outcomes for families and children. The decision-making role of women changed through ALP's work, as many of the strategies are run by women, and they reported enjoying their newfound role within their families. Interestingly, while the men showed support for the women's active participation and management of economic resources, women's increased independence (such as allowing women to go to the market) was not experienced in the same way across all the communities.
- Environmental capital improves through strategies that encourage better land management and the strengthening of ecosystem services. Tree plantations and the restoration of degraded land support the maintenance of critical ecosystem services in fragile ecosystems of the Sahel.

The hypothesis is equally that these three forms of capital interact in various ways. An improvement of ecosystem services, for example, underpins the economic sustainability of communities by preventing land degradation, which could reduce incomes from agriculture. Similarly, economic capital impacts on social capital, for instance, by preventing the breakdown of communities and/or emigration of youngsters from the communities. Finally, institutional empowerment can be a critical economic driver, by ensuring that communities are able to adapt and build resilience strategies in the future.

Environmental, Economic, and Social Outcomes

The research used a questionnaire to measure the quantitative change in economic, social, and environmental variables. The aim was to see whether the interventions carried out by ALP have affected broad economic, social, and environmental outcomes. These include communities' income from agricultural activities, education, health, social capital, and the key ecosystems on which communities rely. This required data collection which evidenced change in adaptive capacity and change in typical development outcomes. Change was measured using a retrospective approach to assess the level of capital before the start of the ALP (2009) to provide a baseline and then post intervention in 2013. This approach gives a measurement of "gross" change, in other words a level of change which does not take into account the counterfactual (what would have happened anyway) or the attribution of other actors/factors in influencing this change. Below is a summary of the key results for each type of capital.

Key Economic Outcomes

The communities in which ALP works in Niger are highly dependent on agriculture and livestock for their livelihoods as described earlier. The economic data collected therefore focused on the evolution of agricultural and livestock returns since the beginning of the ALP. In addition to this, savings and degree of diversification were also assessed.

The data collected in relation to agricultural activities shows three main findings: there has been an increase in productivity of all major crops, there has been an extension of agricultural productivity, and there has been an increase in agricultural revenue since the start of the program. Sorghum was the only major crop where a decrease in productivity was experienced, but it is difficult to ascertain why this might be. One possible reason might be that the increase in agricultural land might represent an extension into more marginal (less productive) land which can have an influence on overall productivity. Furthermore this slight decrease must be considered alongside a business-as-usual scenario (see section on additionally) (Figs. 8 and 9).

In addition to this, there has been an increase in agricultural returns across all crops during the same period, as represented in Fig. 10. It is important to note that

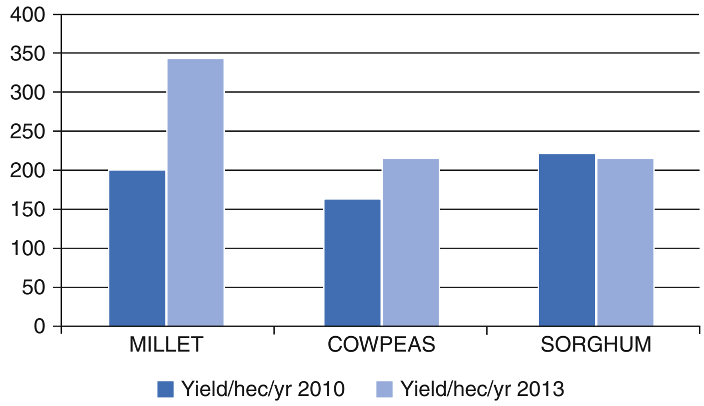

Fig. 8 Evolution of agricultural productivity (kg/ha/year)

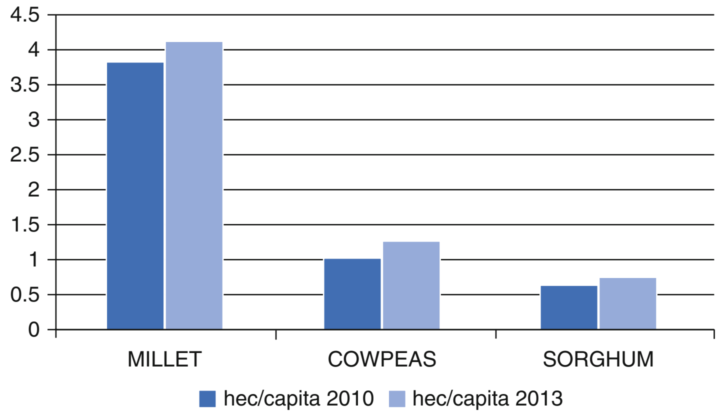

Fig. 9 Evolution of land tenancy

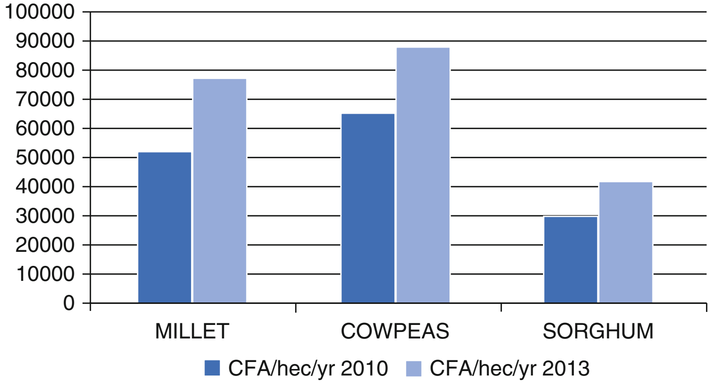

Fig. 10 Average returns per hectare

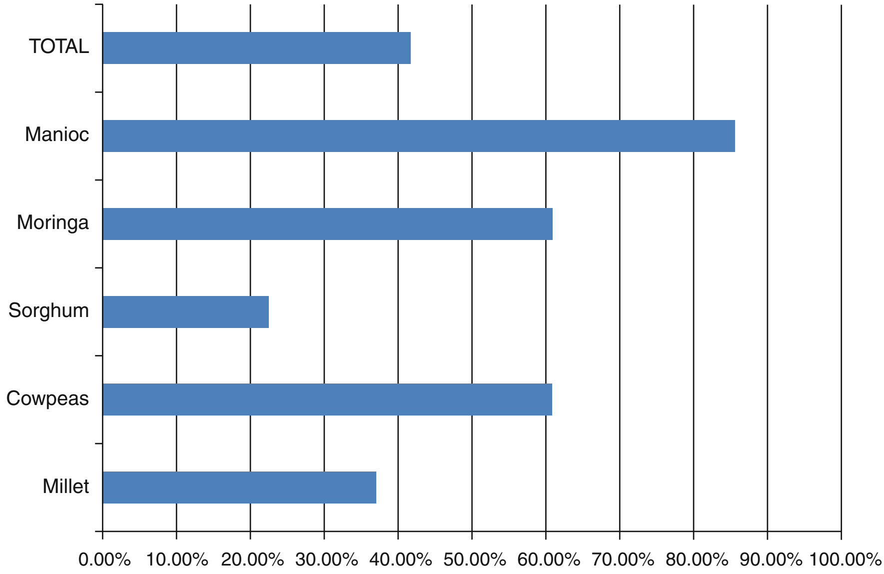

Fig. 11 Change in net revenue from crops

agricultural returns are different to agricultural yields. One of the reasons why agricultural yields per hectare may have increased more than actual agricultural productivity could be due to the impact of the warrantage system in Niger, an adaptation strategy which involves storing excess produce at the end of the rainy season and selling it on the market when prices are higher although this theory would need to be tested.

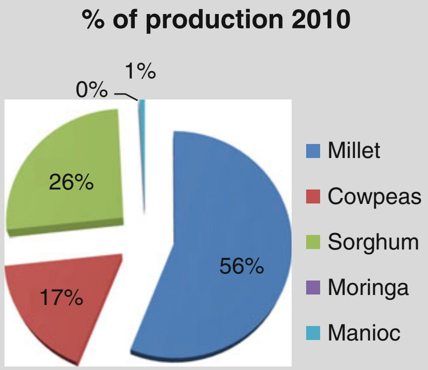
The combination of intensification, extensification, and warranting has resulted in a 41.8 % average increase in agricultural revenue between 2009 and 2013, as shown in Fig. 11. This figure is net of debt repayment and costs of production inputs.

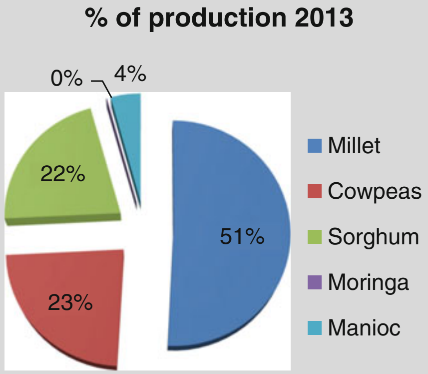
Crop diversification is another factor which has an impact on economic assets and therefore should be considered alongside intensification and extensification. Based on the data collected, only a very modest diversification of crops has taken place in the communities during the period under investigation (2009–2013), as presented in Box 2.

The development of livestock activities is a more complicated picture. While there seems to have been a slight decrease in total ownership of livestock – as determined by headcounts of cattle, goat, sheep, donkeys, camels, and poultry (see Fig. 12) – the total value of and revenue derived from livestock and poultry have increased (see Box 3).

Furthermore, a decrease in livestock headcounts can also be indicative of communities placing more emphasis on and investing more resources in agriculture. The two hypotheses are not mutually exclusive.

Box 2: Structure of Agricultural Production





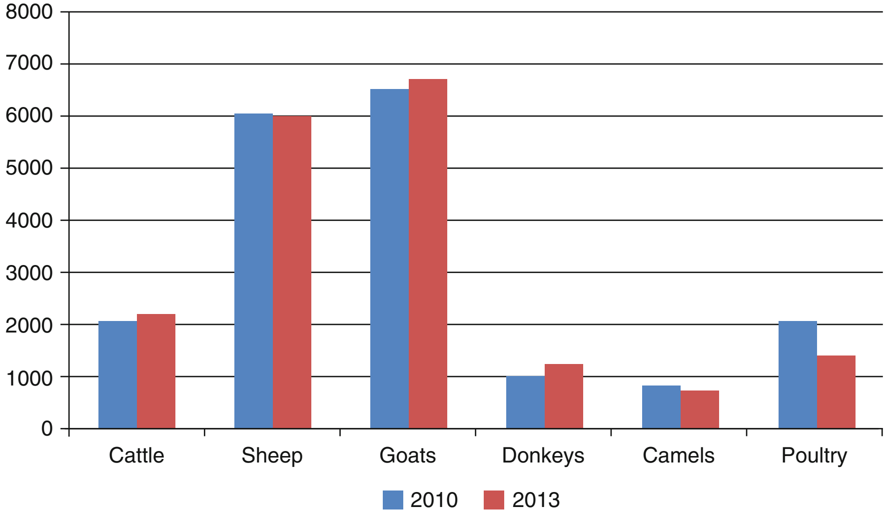


Fig. 12 Total livestock and poultry expressed in headcounts

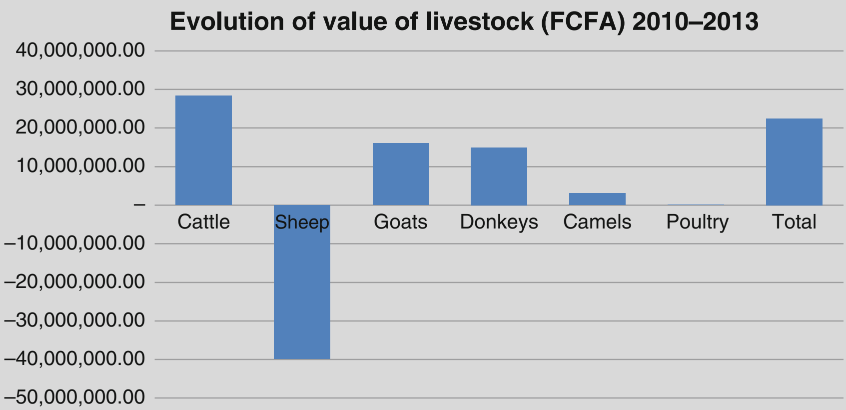
Just like with agricultural production, the evolution of livestock headcount and livestock revenue needs to be compared against the counterfactual. A decrease of livestock headcount could be considered as a negative evolution only if the counterfactual scenario is a stable or increasing number of livestock. However, in many circumstances, a business-as-usual trend might actually consist of a greater decrease of the stock. In this case, anything over and above this decrease could be considered a positive impact.

The main economic findings are presented in Table 2.

On average, the empirical data suggests that there has been a positive evolution of yearly household budget as well as yearly savings, albeit to a lesser extent. These findings are in line with existing development literature which suggests that the ability of the poorest households to save is very low. This is due to the fact that a household with a low income is more likely to spend extra income rather than save it, so although savings do increase with income, they do not do so proportionally.

Finally, households were asked to estimate how much time they would need to replace lost income and assets following a significant drought event pre- and post-ALP intervention. This was done by asking communities how much time it took them to replenish their stocks after the last drought event and how much time they thought this would have required if ALP had been operating during the last drought event. Responses suggest a faster recovery rate of nearly half the time following ALP.

Box 3: Average Income from Livestock and Evolution of Value per Type of Animal (FCFA, 2013)



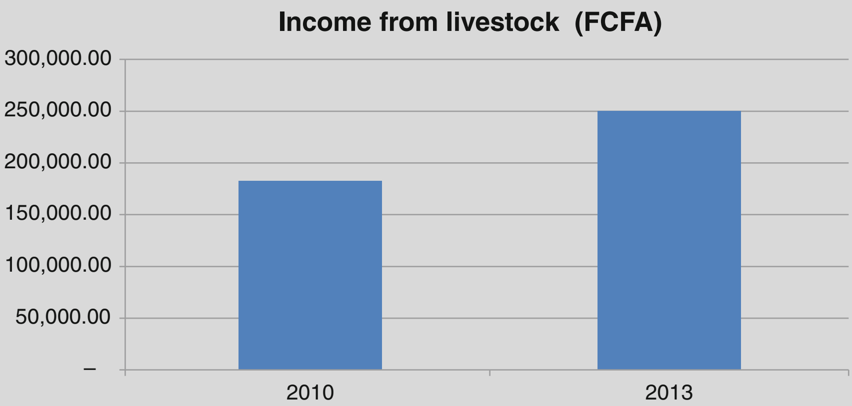


Table 2 Main economic findings

	2009 (pre-ALP)	2013 (post-ALP)	% change
Average yearly household budget *(FCFA 2013)*	266,449	399,353	+49.8
Average yearly savings, including in-kind savings *(FCFA 2013)*	63,083	86,056	+36.4
Average time required to replenish lost income and assets after a drought	4.6 years	2.5 years	−44.7

Social Outcomes

The main focus of ALP's work is on generating social outcomes. The empirical work was therefore aimed at capturing these social outcomes based on the theory of change which had been developed with the community. When measuring social outcomes, some are easy to quantify based on established academic methods – such as health and education – while other softer social outcomes such as social capital, institutional capital, or changes in gender dynamics are harder to quantify. However, such soft indictors should not be overlooked due to the difficulty in quantifying them as they are no less important in building resilience or in enhancing development more broadly. Institutional strengthening, for example, can create positive externalities such as community members' participation in decision-making as well as broader economic outcomes. Another example is women's economic empowerment which is known to drive socioeconomic change. Furthermore, it is widely acknowledged that building resilience is not just about creating changes in material conditions but is a multidimensional process which involves the flexibility of institutions, of social structures, and of collective knowledge and skills in communities. The changes in social outcomes are presented in Table 3 below.

The indicators which have been used for health and education are the ones which are well established in the respective fields of health and education economics. Quality-adjusted life years (QALYs) were calculated by asking sample households to rank their health condition both on physical and mental health grounds (see Box 4). To capture a change in education, the number of children attending school was combined with the average school attendance in order to obtain the extra school years gained (Fig. 13).

Social capital was measured by assessing the evolution of solidarity circles of households, i.e., the number of other households directly supporting the livelihoods of the sample households. An enlargement of this circle is used as a proxy indicator for social capital within communities. Subjective indicators were also used to capture the community perceptions of changes in the evolution of women's role on decision-making structures and the evolution of trust in household and community adaptive capacity.

Table 3 Evolution of key social variables

Type of outcome	Indicator	% evolution (2009–2013)
Health	Quality-adjusted life years (QALYs)	+128
Education	Number of children attending school >6 months per year	+33
Social capital	Number of persons in the "solidarity network" of the household	+23
Gender (and institutional capital)	Five-point scale on the extent to which women have an influence in community and household decision-making	+112
Adaptive capacity	Five-point scale on the extent to which community members believe in their capacity and knowledge to establish resilience strategies in the future	+258

Box 4: Quality-Adjusted Life Years

The QALY is a measure of the value of health outcomes. Since health is a function of length of life and quality of life, the QALY was developed as an attempt to combine the value of these attributes into a single index number. The basic idea underlying the QALY is simple: it assumes that a year of life lived in perfect health is worth 1 QALY (1 year of life $\times$ 1 utility value $=$ 1 QALY) and that a year of life lived in a state of less than this perfect health is worth less than 1. QALYs are therefore expressed in terms of "years lived in perfect health": half a year lived in perfect health is equivalent to 0.5 QALYs (0.5 years $\times$ 1 utility), the same as 1 year of life lived in a situation with utility 0.5 (e.g., bedridden) (1 year $\times$ 0.5 utility). QALYs combine subjective data (e.g., self-stated physical and mental health conditions) with objective data (e.g., life expectancy) to measure the disease burden associated with different health conditions. It can also be used for measuring the value of different health conditions – notably in cost-benefit analysis – through a combination of the empirical data obtained and measurement of the "statistical value of life."

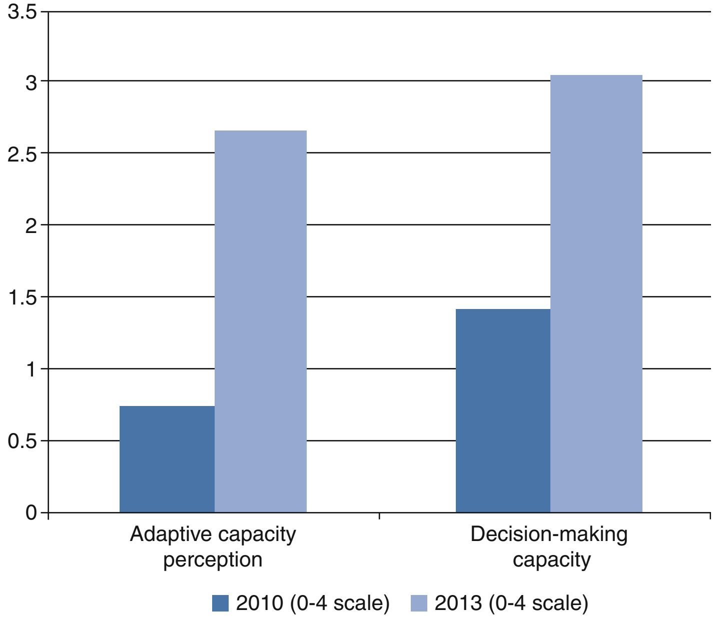

Fig. 13 Change in perception of adaptive capacity for men and women and decision-making for women only

Table 4 Evolution of key environmental indicators

Outcome	Indicator	Evolution (2009–2013)
Avoided deforestation and reforestation	Number of trees planted or maintained	+64,165
Improved land management	Hectares of degraded lands restored	+1,575.6

Key Environmental Outcomes

The two environmental outcomes which were measured in this research both relate to desertification which is the greatest ecological threat facing Sahel ecosystems. ALP has tried to address this challenge through building the capacity of households to implement sustainable land management techniques, providing resources for reforestation, avoiding further deforestation, and restoring of degraded lands.

The environmental outcomes are intricately linked to the ecosystem services that are directly supporting the socioeconomic livelihoods of the communities. For example, reforestation and deforestation can directly provide resources such as timber and fodder to communities. Equally, sustainable land management and the restoration of degraded lands can avoid a further extension of agricultural land to less productive spots. Finally, both can affect microclimate patterns in the communities. The results of the environmental outcomes are presented in Table 4.

According to the data, the number of trees maintained (not deforested) or planted since the start of the program amounts to approximately 64, 165 in the four communities. This equates to an average of 75 trees per household. A total of 1,575 ha of degraded lands have been restored. This represents an average of 1.85 ha per household.

Measuring Additionality

The outcome data presented so far is only representative of "gross impact," i.e., the total impact across different forms of capital before you take into account what would have happened in the "counterfactual" or if a business-as-usual approach had been followed and ALP had not implemented CBA approaches in Dakoro. Determining the counterfactual makes it possible to estimate the role of the ALP in creating outcomes. This allows for calculation of the "net" or "additional" impact.

Due to the nature of the number of active stakeholders in Dakoro, this study asked communities to list the organizations and actors that contributed to the changes observed and to estimate the proportion of contribution from these different actors to the outcomes. The results are presented in Table 5 below.

It is interesting to note that communities perceive the impact of ALP differently for each outcome. ALP is perceived to have had the most impact in creating positive

Table 5 Proportion of contribution of different organizations operating in the area

	Economic impacts	Social impacts	Environmental impacts
Local government	9	7	8
ALP	**53**	**55**	**60**
Other NGOs	15	14	11
State programs	15	18	14
Community actions	8	6	7
Total	100	100	100

environmental outcomes rather than social or economic ones. It is also important to note that there is a risk of social desirability of answers in this sort of exercise, meaning that respondents answer according to what they think the interviewer wants to hear, and it is possible that respondents in this research provided socially desirable answers. However, it is also worth noting the value of subjective questions which provide an opportunity for communities to share their perspective and perception. These answers therefore are assumed to be indicative and they are fed into the analysis of the counterfactual.

While these results are important and a useful exercise, they do not capture evolution due to climate variability. 2009 was a bad year overall for average rainfall and duration of the rainy season. The four following years were relatively good which might explain in part the increase in agricultural and livestock revenue and, by extension, the improvement in social and environmental conditions in the communities (see Box 5).

Therefore it is important to capture the counterfactual; in order to do this, two methodological approaches were considered:

Option one: using national-level data on the evolution of agriculture and livestock production and productivity and comparing this data to observed changes in ALP communities

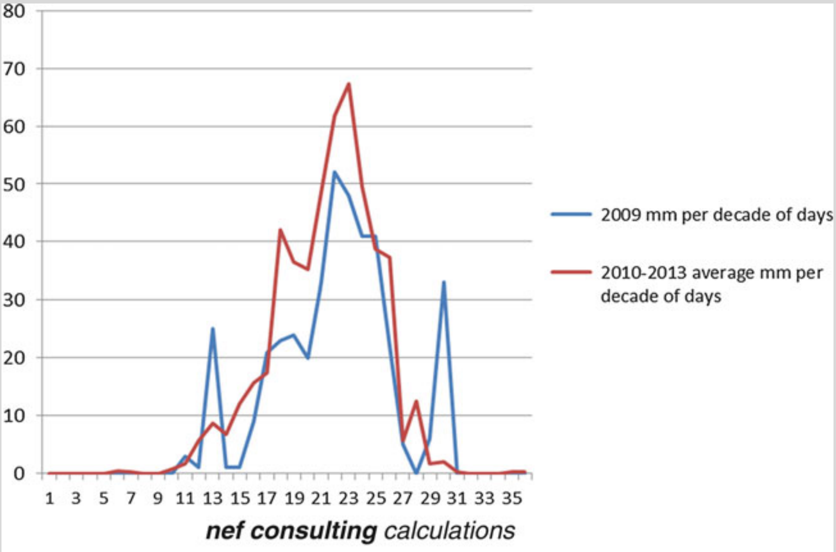
However this approach could involve substantial biases. Firstly, national (or even regional) data can mask substantial disparities in production and productivity among different sites and locations, for example, comparisons between production in marginalized communities and production in areas with relatively intensive/modern practices. This means that aggregate averages might be poor proxies for understanding what would have happened in marginalized communities in Dakoro in the absence of ALP. Secondly, as articulated earlier, despite an increase in total agricultural production throughout the past three decades, the existing evidence suggests that production per capita has been decreasing (Ozer 2007). Given that the data gathered by this research is for household-level agricultural production, it is neither comparable to per capital production nor aggregate production figures. Therefore, benchmarking the change in agricultural production, relative to national-level data, was excluded due to a lack of directly comparable data.

Box 5: 2009 Versus Post-2010 Rainfall Patterns

Rainfall evolution (2009–2013)

	mm of rain	Days of rainfall (events with >5 mm)
2009	409	44
2010	539	59
2011	479	44
2012	571	52
2013	448	43

Rainfall pattern and variability



Option two: using regression analysis to understand the extent to which evolving climate patterns might have determined the increase in production and productivity

This method can be used to estimate the extent to which the observed increase in production can be explained by weather patterns across different years and therefore provide an estimation of the production that should have been expected had the intervention not taken place. Despite this approach being more robust, it is important to stress that regression analysis is dependent to a great extent on the quantity and quality of available data. For instance, although climate patterns are sufficiently documented, the occurrence of other external shocks, such as locusts, is poorly reported – beyond whether they occurred or not. However, this approach was considered less imprecise than option one.

Due to the limits of the first option, this study used regression analysis to determine the contribution of climate evolutions to agricultural production and livestock. This was done by using a historical data series for the region of Maradi, the closest possible to Dakoro (see Figs. 14 and 15).

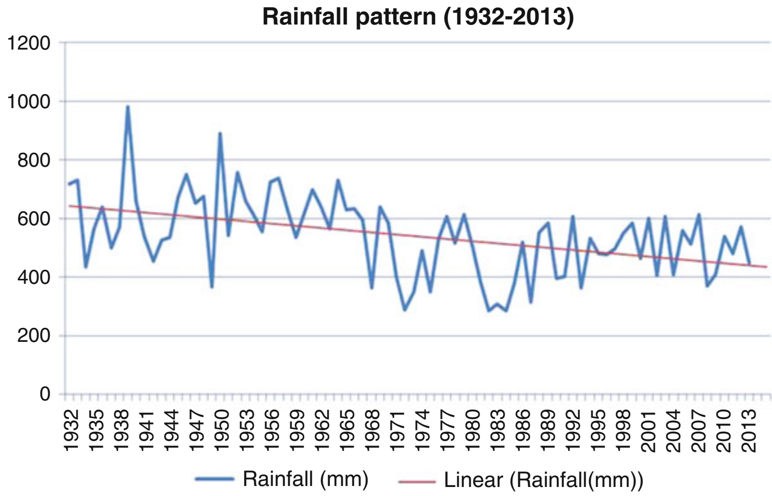


Fig. 14 Rainfall pattern Maradi (1932–2013)

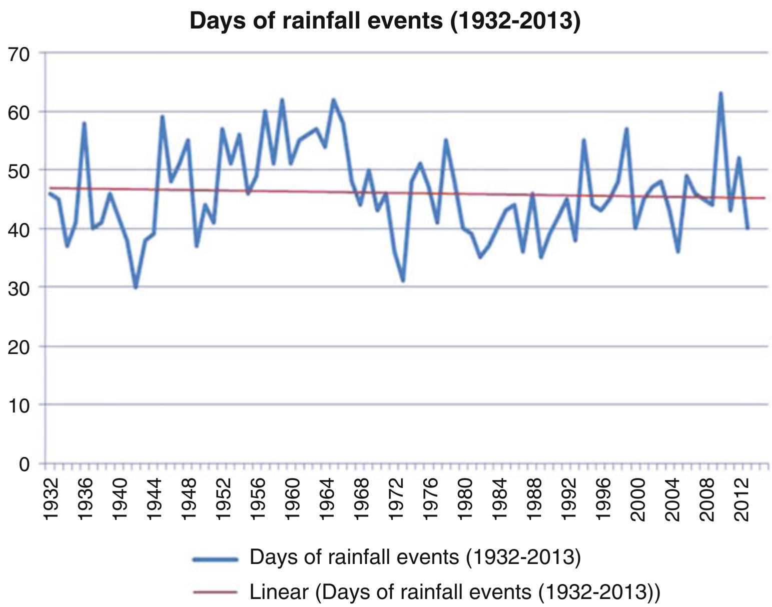

Fig. 15 Days of rainfall events Maradi (1932–2013)

Table 6 Measurement of the counterfactual for major crop production (expressed in kg)

Crop	Production 2009	Estimated 2013 production under BAU	Actual production 2013 (ALP)	Gross impact of ALP	Net impact of ALP
Millet	267,053.88	271,733.88	307,584.03	+40,530.16	+35,850.16
Cowpeas	81,993.42	86,673.42	141,207.48	+59,214.06	+54,534.06
Sorghum	123,304.26	127,984.26	129,470	+6,165.74	+1,485.74

The results suggest that for each extra mm of rainfall, 120 additional units of agricultural output are generated. Conversely, a decrease of 1 mm in rainfall induces a loss of 120 units of output. By using this coefficient for the period 2009–2013 in the sample communities, it was determined that agricultural production for the three major crops (millet, sorghum, and cowpeas) should have been expected to increase by 3.75 % throughout the period 2009–2013, compared to 30.80 % as the findings suggest. As such, the net increase (impact due to ALP) is of the order of 27 %. Taking into account the contribution of other actors to the program, ALP has directly contributed to a 13.8 % increase of agricultural production. Table 6 presents the counterfactual for all major crops and the net impact of ALP.

A similar approach was replicated to determine the quantitative link between livestock returns and rainfall patterns. The coefficients determined for economic capital were then transposed to social and environmental capital to calculate net impact. Although not a precise approach, this was deemed to be the most robust way of assessing the business-as-usual scenario and environmental capital evolution. The net economic, social, and environmental impacts of ALP, factoring for counterfactual and attribution, are presented in Table 7 below.

Approach to Social Cost-Benefit Analysis

Determining what is included and excluded from a socioeconomic analysis is of critical importance in order to understand the results of a social cost-benefit analysis. The approach taken in this analysis can be summarized as follows:

- **To include not only strict economic outcomes but also broader social and environmental outcomes**. Such an approach therefore considers three forms of capital (economic, social, and environmental) rather than just one. This requires the monetization of social and environmental outcomes in order to be compared like-for-like with economic outcomes and with investment in the program. Although monetization of nonmarket goods entails uncertainties, excluding these from the analysis means that an entire range of benefits become automatically invisible. In short, while accepting the shortcomings of "pricing the priceless," this analysis takes the stance that an imprecise number is better than excluding outcomes which matter to communities.

Table 7 Net outcome incidence per indicator per form of capital

	Outcome	Indicator	Outcome incidence	Deadweight	Attribution	Net outcome incidence
Economic benefits	Agricultural revenue	Net evolution of revenue	£153,273.72	0.27	0.53	£21,857.25
	Livestock revenue	Net evolution of revenue	£74,397.87	0.27	0.53	£10,609.34
	Total savings (stock)	Stock of savings (money and nature/ livestock)	£30,312.49	0.27	0.53	£4,322.64
Social benefits	Health	Quality-adjusted life years gained	70.80337673	0.27	0.53	10.10
	Education	School years gained	93.08	0.27	0.53	13.27
	Social capital	Additional funds provided to other community members	£60,013.52	0.27	0.55	£8,912.67
	Empowerment	Increased confidence in making adaptation decisions	0.384615385	0.27	0.55	0.057119665
	Gender empowerment	Decision-making capacity within household	0.323076923	0.27	0.55	0.047980519
Environmental benefits	Avoided land degradation	Hectares under improved land management	1,576	0.27	0.60	255.6992197
	Avoided deforestation	Number of trees planted or maintained	34,649	0.27	0.60	5,622.853735

- **To focus on a restrictive set of outcomes that can reflect broad aggregates or the “big picture” for communities and decision-makers rather than an exhaustive list**. This means not focusing on the turnover of hedging schemes or the impacts of micro-lending within the community, for example, investigating instead whether and to what extent this set of micro-interventions have influenced broad aggregates such as revenue, health, or education. This responds to a need to replicate the analysis in different contexts, which is made possible by establishing a common set of outcomes that can be used in other contexts.
- **To consider not only strict typical disaster risk reduction outcomes but equally more classic development outcomes**. Indeed, the frontiers between an adaptation intervention and a development one are blurred and often artificial. As such, it is sensible to consider whether and to what extent adaptation enhances human development and vice versa.
- **To create the framework for the analysis in the spirit of community-based adaptation**. The outcomes and impacts have been co-determined through a bottom-up process, and only then complemented with objective indicators, in order to measure what matters.

Table 8 outlines the variables used in the SCBA, as well as valuation approaches and sources. An overview of the process is presented in Fig. 16 below.

As outlined earlier, this analysis considers both the counterfactual and the potential contribution of other actors, including the autonomous strategies of communities, to the outcomes identified. The benefits generated by the intervention are then compared to the financial investment of ALP in the communities. Financial costs include both programmatic expenditure and management costs associated with these.

Time Delineation

The study involved running two distinct modeling simulations:

- A strict **evaluative simulation** that focuses only on the costs borne and benefits generated throughout the period 2010–2013.
- An analysis **combining evaluative data with a forecast to 2020**. While the results of the former can be considered more reliable and the latter more hypothetical, there is a clear rationale for forecasting potential impacts into the future.

Firstly, benefits do not suddenly cease to occur as a consequence of artificial time delimitations. For instance, the impacts of the introduction of improved crop varieties are unlikely to stop happening this year. As such, analyzing up to 2013 only may considerably underestimate the benefits generated by community-based adaptation. Indeed, one of its key characteristics is the focus on sustainability: by embedding new practices, knowledge, and skills into community structures, community-based adaptation aims precisely to ensure the sustainability of adaptation beyond the time span of ALP’s intervention.

Table 8 Description of variables used in the social cost-benefit analysis

Category	Variable	Indicator	Data collection method	Monetary valuation proxy	Source for valuation proxy
Economic	Agricultural revenue	Net returns to agriculture (market and subsistence)	*Empirical*	Market value	Empirical
	Livestock revenue	Net returns to livestock (market and subsistence)	*Empirical*	Market value	Empirical
	Savings	Monetary and in-kind stock of savings	*Empirical*	Market value	Empirical
Social	Health	Quality-adjusted life years (QALYs)	*Empirical*	Statistical value of life approach (average GDP per capita of Niger for a full QALY, i.e., year in perfect health)	Miller (2000)
	Education	Extra years of schooling	*Empirical*	Returns to primary education for an extra year of schooling	Psacharopoulos and Patrinos (2002)
	Social capital	Number of individuals in the solidarity circle	*Empirical*	Value of goods donated to other households within the community per year	Empirical (questionnaire application)
	Women's participation	Increased participation of women in decision-making	*Empirical*	Willingness-to-accept compensation exercise	Empirical (focus groups)
	Community empowerment	Increased confidence in implementing adaptation strategies	*Empirical*	Opportunity cost of time (hourly minimum wage) for participation in community actions and decision-making	Empirical
Environmental	Avoided deforestation and reforestation	Number of trees planted/ maintained	*Empirical*	Value of timber	World Bank (2009)
				Value of fodder	
				Value of tCO2eq emissions sequestrated	
	Restoration of degraded/ desertified lands	Hectares of land restored	*Empirical*	Value of land per hectare (market price)	Empirical

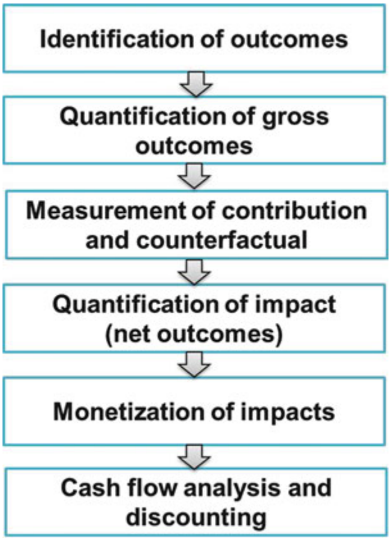

Fig. 16 Flow diagram illustrating the social cost-benefit analysis process

In short, although an evaluative model may be perceived to be "safer" in terms of deriving conclusions on strategies that are already in place, forecasting into the future can, despite complexities, depict a better representation of the magnitude of benefits.

Forecasting and Uncertainty

Forecasting into the future requires a consideration of likely climatic evolutions over the next 7 years. Indeed, the evolution of economic capital (and, by extension, social and environmental capital) is critically dependent on climate variables – most importantly rainfall patterns. As evidenced earlier, however, the rainfall and temperature patterns in Dakoro are far from linear and do not point to a clear trend. Similarly, the available data does not show clear trends in the distribution of rainfall during the rainy season as well as demonstrates potential interruptions to the start/end dates of the rainy season.

Numerous scenarios are therefore required in order to forecast uncertainty and the evolution of capital, and these need to be based on historical data. These scenarios are outlined in Table 9.

A "no drought" scenario was excluded from the analysis. This is because Dakoro has experienced six severe or catastrophic droughts in the past 29 years. This represents a frequency of one drought every 4.8 years, on average. It is also synonymous with a 20 % probability of drought occurrence per year.

Through datasets of the Nigerien climate center Agrhymet, the study was able to determine the impacts of shocks on agricultural production for the region of Maradi. Through an econometric analysis, the impact of the level of rainfall on agricultural production and livestock was estimated. The coefficients derived

Table 9 Different scenarios for a forecastive analysis

Scenario	Description
Replicating the 1980s scenario (worst case)	An average rainfall of 411.5 mm per year throughout the period and four major drought events – three of which consecutive
Replicating the 1990s scenario (moderate case)	An average rainfall of 489 mm per year throughout the decade and one major drought event
Replicating the 2000s scenario (best case)	An average rainfall of 495.2 mm throughout the decade and one major drought event

allowed for forecasting the evolution of production under a business-as-usual scenario (what would have happened without ALP) compared to the evolution of production post-ALP. While, evidently, community-based adaptation does not shield nor exempt communities from shocks, a higher level of savings and other initial conditions prior to the shock mean that the reduction can be less dramatic and that communities are apt to bounce back more rapidly, as evidenced earlier.

Findings

Table 10 presents the results of the evaluative analysis for the four communities combined. The results suggest that under any discounted rate, the intervention yields highly positive returns even if not taking into account further impacts beyond 2013.

More importantly, even if accounting *only* for economic returns, cost-benefit ratios range from 1.9 to 2.06. That is, even when social and environmental impacts are left out of the equation, the intervention still yields between £1.9 and £2.06 per pound invested. Further, returns are still positive at the highest discount rate of 12 %, with economic capital representing most of the value (see Fig. 17).

When forecasting over a longer time span, the benefits of the program increase even further (see Table 11) and this is due to a combination of two factors:

1. The investment period of ALP ends in 2014, while benefits continue to accrue to communities. The net benefits therefore increase compared to costs, which remain stable after 2014.
2. A critical assumption in the model is that the time required to recover from a drought post-ALP is approximately half that required in a no intervention scenario (2.5 years vs. 4.6 years). This substantially increases the output gap between the business-as-usual and the intervention scenario. It also means that the worse the climate scenario, the higher the returns generated by community-based adaptation (see Table 11). When relaxing this assumption, by assuming that the same time is required to recover regardless of the intervention, then returns are still positive, albeit lower.

Table 10 Results of evaluative analysis (time span: 2010–2013) *in £2013*

	Net present value (net discounted benefits)	Cost-benefit ratio
0 % discount rate	£184,129.84	4.45
5 % discount rate	£158,044.91	4.34
12 % discount rate	£129,330.39	4.19

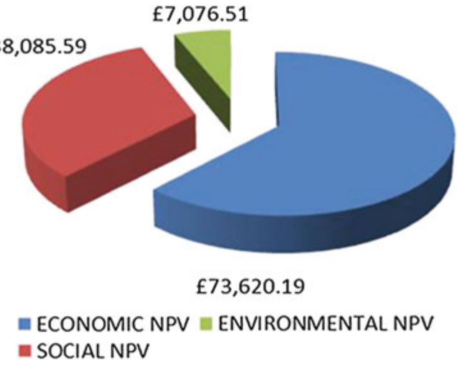

Fig. 17 Net present value of different capitals under a 12 % discount rate

Table 11 Results of combined evaluative and forecastive analysis (time span: 2010–2020) *in £2013*

		Net present value (net discounted benefits)	Cost-benefit ratio	Economic C-B ratio only
The 1980s scenario (worse)	0 % discount rate	£399,413.48	9.8	4.5
	5 % discount rate	£340,751.38	8.5	3.9
	12 % discount rate	£230,426.50	6.1	2.8
The 1990s scenario (moderate)	0 % discount rate	£321,080.23	7.9	3.6
	5 % discount rate	£273,922.99	6.8	3.1
	12 % discount rate	£185,235.10	4.9	2.3
The 2000s scenario (best)	0 % discount rate	£286,934.97	7.06	3.2
	5 % discount rate	£244,792.66	6.1	2.8
	12 % discount rate	£165,536.28	4.4	2.06

These results need to be put into perspective. Table 12 compiles the results of a sample of previous cost-benefit analyses on adaptation and DRR programs. The results from this analysis suggest that ratios ranging from approximately £4 to almost £10 per pound invested are indicative of a highly socially profitable investment. Indicatively, the ratios found in this study are indeed higher than the

Table 12 Indicative cost-benefit ratios of a sample of DRR and climate adaptation interventions

Country	Type of intervention	Cost-benefit ratios	Source
Nepal	Adaptation	1.13–2.04	Willenbockel (2011)
Nepal	DRR	1.55–5.81	White and Rorick (2010)
India	DRR	3.17–4.58	Venton (2004)
Sudan	Adaptation	2.4	Khogali and Zewdu (2009)
Malawi	Adaptation	37.3	Tearfund (2010)
Belarus, Georgia, and Kazakhstan	DRR	3.1–5.7	World Bank (2008)
Kenya	Adaptation	0.93–3.13	Nicholles and Vardakoulias (2012)

ratios of all previous analyses except for one, which suggests an extremely high result $37.3 per $1 invested. However, this analysis does not consider explicitly the counterfactual and attribution, which means that results might overestimate the benefits of the program compared to costs. Further, this comparison is only indicative. Indeed, these studies are not comparable like-for-like: first and foremost because the outcomes they consider are different and second because the time frames considered are highly variable among different analyses.

Conclusion

This research aimed to answer the question: is community-based adaptation an efficient and effective approach to climate change adaptation? While previous research conducted by NEF Consulting, published in the report *Counting on Uncertainty* (Nicholles and Vardakoulias 2011), was based on a solely forecastive approach (the impacts of strategies which had not yet taken place), this research is based on solid, evaluative data. The findings from this suggest that returns are considerably higher than the ones which were previously predicted. Returns on investment range from £4 to almost £10 per £1 invested, which is high by any standard. There is a high level of confidence in these results for two main reasons:

1. The sensitivity analysis conducted suggests that even if considering strict quantitative economic benefits only, returns are still positive. As such, even for those skeptical of monetization (i.e., those who do not place confidence in nonmarket valuation), the fact that economic returns are positive on their own is sufficient to consider community-based adaptation as cost-effective.
2. This analysis has taken into extensive consideration both the counterfactual and the contribution of other actors in achieving the outcomes identified in the field. It is therefore highly unlikely that impacts are overestimated or inflated.

Considering the breath of positive outcomes presented in this analysis, community-based adaptation approaches appear to present multiple dividends: not only does a community-based approach enhance the decision-making capacities of communities at a local scale but equally impacts considerably on "hard" outcomes, such as increase of agricultural production. This means that a community-based approach seems to increase the "uptake" of adaptation and development activities, e.g., the introduction of improved seed varieties.

Similarly, community-based adaptation impacts on overall development of communities. Indeed the benefits considered in this analysis are based on typical development outcomes such as health and education. The findings suggest that community-based adaptation responds both to short-run disaster mitigation measures and long-run development needs.

Finally, the approach and findings from this study have led to a number of recommendations for future upscaling of the analysis and design of adaptation strategies:

- Replicate the analysis to appraise and evaluate different adaptation strategies. Comparing results across different adaptation interventions could indicate the most cost-effective adaptation strategies.
- Determine a common set of outcomes which should be considered when evaluating adaptation interventions. Only this would allow a robust comparison of different socioeconomic appraisals.
- Take note that wide uncertainties regarding climate variables, such as future rainfall and temperatures patterns, mean that different scenarios need to be considered when forecasting the impacts of adaptation interventions into the future. This especially holds for analyses at a local level, where climate uncertainties are considerably high.

Adaptation as Climate Risk Management: Methods and Approaches

Paul Bowyer, Michaela Schaller, Steffen Bender, and Daniela Jacob

Contents

Abstract

This chapter highlights the benefits of framing adaptation to climate change as an issue of climate risk management and describes a number of methods and approaches that may be applied in the process of developing adaptation strategies. A key consideration when developing adaptation strategies is to have a sound understanding of how a given system functions in response to changes in

both climate and non-climate factors, and thus the need for a causal model which represents this understanding. There are a range of methods and tools that may be applied to assist with developing this system understanding in a climate risk assessment, and a number of these are described here. Moreover, given that adaptation planning is to a large degree about forward planning, all adaptation strategies will need to appropriately consider the implications of uncertainty on their likely effectiveness. This chapter provides a discussion of the ways in which adaptation strategies can be developed and decisions made when appraising different adaptation strategies. As such, it provides a basis upon which users can assess how they may approach adaptation as an issue of climate risk management and select and apply suitable methods. It provides a useful accompaniment to any practitioner or organization, as they proceed on their adaptation journey.

Keywords
Risk management • Climate change • Adaptation • Climate information • Impact assessment • Adaptation assessment • Robust decision making • Uncertainty

Introduction

Adaptation is an iterative process of defining a problem, planning and implementing action, and monitoring and reviewing these actions, in the light of new or changing risks, regulations, policies, and/or new information about a given system response. Adaptation action involves making changes in management practices and business systems in order to reduce the potential for harm or negative consequences and maximize or exploit any opportunities or positive consequences that may arise under climate change (Adger et al. 2007). These actions may range in size from relatively small changes, or larger transformations, depending on the size and scale of the adaptation problem.

Adaptation will need to take place in order to cope with the impacts of climate change over the shorter term, e.g., due to climate variability and extremes, and to ensure that business objectives are able to be met over the longer term, and thus will involve long-term forward planning. Moreover, adaptation to climate change is not just about thinking in terms of how the climate may change in isolation. Adapting to the impacts of climate change should be integrated into all climate-sensitive areas that an organization may have, and thus any adaptation actions will need to fully consider the non-climate factors that are key to understanding the impacts of climate change in their proper context. Only by doing this will a sound foundation be laid for developing adaptation measures and strategies. Dealing with adaptation as part of an overall organizational risk management strategy should ensure that climate impacts are not considered in isolation, and make it easier to address adaptation as an issue of risk management.

It is also important to state that adaptation may not be successful. The success of adaptation will depend on a wide range of factors including the size and/or complexity of the problem, good governance structures, adequate resourcing, a sound understanding of system function, and appropriate incentives (Moser and Boykoff 2013). Chief among these factors will be the size and complexity of the problem. The larger the changes in climate and associated impacts, the less likely it is that adaptation will be successful as physical, technical, and social limits of adaptation are approached (Dow et al. 2013). This discussion leads to a suitable definition of adaptation as:

> Adaptation involves changes in social-ecological systems in response to actual and expected impacts of climate change in the context of interacting nonclimatic changes. Adaptation strategies and actions can range from short-term coping to longer-term, deeper transformations, aim to meet more than climate change goals alone, and may or may not succeed in moderating harm or exploiting beneficial opportunities. Moser and Ekstrom (2010)

Adaptation is about forward planning in both the short and long term and as such involves large uncertainties: these include uncertainty about the possible future climate, uncertainty about the possible future development of human society, uncertainty in understanding the sensitivity of a given system to changes in climate and non-climate factors, and uncertainty around the effectiveness of any adaptation strategies that may be implemented. These uncertainties need to be appropriately considered when developing adaptation strategies. These characteristics of adaptation make a risk management framework particularly well suited to dealing with adaptation (Jones and Preston 2011). This chapter provides an overview of the risk management process within an adaptation context, a summary of key issues, and methods and approaches that may be applied at the risk assessment and adaptation appraisal stages of the risk management process. As such, this chapter provides a useful accompaniment to any practitioner or organization, as they proceed on their adaptation journey.

What Is Risk and the Risk Management Process?

The International Standards Organization (ISO) 31000 (2009) defines risk as the "Effect of uncertainty on objectives." Organizations will have a wide range of objectives which operate under conditions of uncertainty, and the impact that this uncertainty has on being able to successfully meet objectives is the focus of the risk management process. These objectives include strategic objectives, such as the reputation of an organization with its stakeholders; operational objectives such as meeting certain levels of service provision, e.g., ensuring a reliable water supply to a city or region; and objectives relating to compliance with legal and regulatory requirements, e.g., chemical concentrations in industrial effluents or water discharge temperatures. All of these kinds of objectives may be influenced in some way by changes in climate.

In this chapter, the ISO 31000 (2009) calculation of risk is used, being the combination of the likelihood of an event and its consequences:

$$\text{Risk} = \text{Likelihood} * \text{Consequences}.$$

If the likelihood of a given event is assessed as being zero, then there is no risk; likewise if there are no consequences from an event, then the risk is also zero. Generally, when the likelihood and consequences are higher than the greater the risk, however, things are more complicated than this, as the significance of a given level of risk is what matters to organizations, when deciding whether the risks need treating.

The consequences of an event may be positive, which may sometimes be referred to as opportunities, or negative, which may be referred to as threats or vulnerabilities. In this chapter, threats and opportunities are used to refer to negative and positive consequences, respectively. An organization may face more than one event which presents a risk to the achievement of objectives, and managing one risk may have implications for the management of other risks, and so it is important to consider risk interactions – this is particularly relevant for reducing the potential for maladaptive strategies. The likelihood of an event can be assessed in qualitative or quantitative terms.

In the context of risk and vulnerability, it is worth stating that in the climate adaptation research arena, a lot of effort has been devoted to investigate the vulnerability of various countries and communities to climate change, to the extent that it has become a widely applied method (Malone and Engle 2011). For adaptation in practice, a risk management framework can incorporate vulnerability analyses as part of a risk assessment.

Regardless whether the risks that a given organization may face have positive or negative consequences, in order to adapt to climate change, a coherent framework is needed within which these risks can be managed. The risk management process provides such a framework. The ISO 31000 (2009) defines the risk management process as the:

> Systematic application of management policies, procedures, and practices to the activities of communicating, consulting, establishing the context, and identifying, analysing, evaluating, treating, monitoring, and reviewing risk. (ISO 31000 2009)

The various stages involved in the risk management process and their interconnections are shown schematically in Fig. 1. The focus of discussion in this chapter is on the risk assessment stage and assessing adaptation measures as part of the risk treatment stage (Fig. 1).

What Are the Benefits of a Risk Management Approach?

There are various reasons as to why adopting a risk management framework to address adaptation to climate change is attractive and powerful; these include (adapted from ISO 31000 2009; Jones and Preston 2011):

- **It is all about uncertainty**: adaptation to climate change is characterized as operating under uncertainty and deep uncertainty, in relation to the future development of climate and socioeconomic systems, and what this may mean

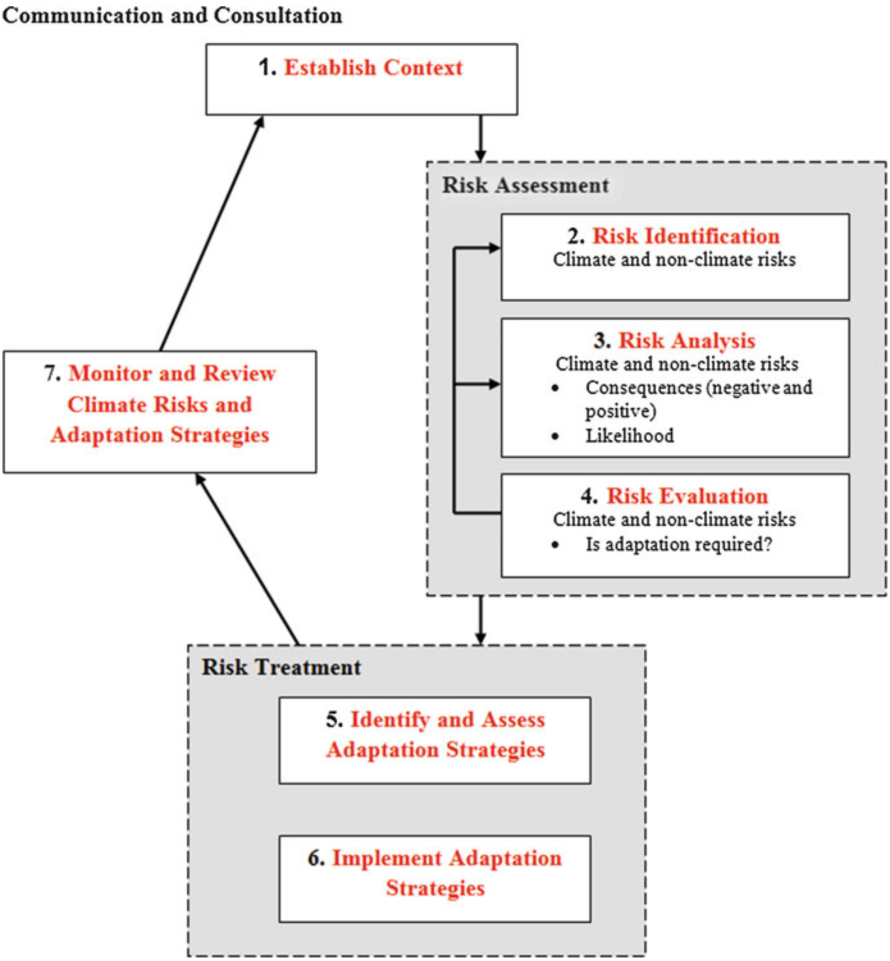

Fig. 1 Adaptation as a process of risk management. The various stages involved in the risk management process and their interactions, as applied to climate change adaptation (*Source*: Adapted from the ISO 31000 (2009) risk guidelines. The risk management process may not proceed in a linear process from step 1 through 7, and in practice steps 3 and 5 may be performed in combination. The steps are separated out simply to enable clarity of explanation

for a given organization. A risk management framework involves explicit consideration of uncertainty in climate risks, their likelihood, and consequences.

- **It is solution focused**: adaptation is about taking action in the real world, reducing threats, and seizing opportunities presented by climate change. This means finding and implementing effective solutions. The risk treatment stage in the risk management process makes this focus on finding solutions explicit. In addition, in relating the level of risk determined in the risk analysis to what is significant for an organization, a rational basis is provided on which to stimulate action.

- **Communication and consultation is integral**: key to developing effective solutions is establishing the proper context for identifying risks, having sound causal models of how a system functions, and identifying and being able to implement adaptation strategies. All these activities demand that there is effective communication and consultation with a range of people, to ensure that the right people are on board in gaining knowledge and understanding, formulating and asking the "right" questions, and identifying practical adaptation strategies and any potential for maladaptation.
- **It is a well-established method:** risk management is not new, and many businesses and organizations will already have risk management strategies in place. As such, it may be possible to incorporate climate risk existing mechanisms rather than requiring new mechanisms to be implemented. This familiarity can aid the uptake and mainstreaming of adaptation into all relevant business activities and can increase the chances of considering climate as an additional factor in managing risks.
- **It is an iterative process**: adaptation takes place in a dynamic environment where external and internal factors change over time, there are deep uncertainties, and new information is developed which may be brought to bear in informing decision making. As such, adaptation is a continual process and as such requires an iterative process.
- **It is flexible**: a range of different methods may be applied to the discovery and generation of information in relation to climate impacts and considering and planning adaptation options. Thus, the risk management process can be tailored to the information needs and level of detail required to analyze a particular adaptation problem.
- **Facilitates a learning environment**: while a range of different methods can be applied in carrying out a risk assessment (described in section "Methods and Tools for Climate Risk Assessment"), it is the case that the very act of committing to a process of considering how changes in climate (and other factors) may impact on business objectives can provide an environment in which much learning about how an organization operates is obtained. In addition, where the adaptation problem involves a range of stakeholders with different values and perspectives, the process provides a forum in which these issues can be discussed, networks built, and knowledge shared and contested, thus facilitating social learning (Yuen et al. 2013). The process will also generate learning about which factors were instrumental in being able to engage with stakeholders, and possibly arrive at mutually agreeable adaptation strategies.

That a risk management process provides an attractive framework for approaching adaptation is also evidenced by its use in other countries, for example in the UK (Willows and Connell 2003). Adopting a risk management framework was also one of the recommendations from the US national research project, *America's Climate Choices* (NRC 2010), which sets out the direction in which the USA should deal with climate change.

Methods and Tools for Climate Risk Assessment

In order for an organization to assess how their business objectives may be affected by changes in climate, and other non-climate factors, and thus understand how large a threat or opportunity may exist, methods and tools are needed with which an evidence base can be generated to help answer these questions. Understanding how a given system responds to climate and non-climate factors is central to successful adaptation planning. The greater the understanding of how a given system functions, the more guidance there is as to which factors could be acted upon in order to manage the risk and thus aid the search for, and development of, successful adaptation strategies. Consequently, all risk assessments need a causal model that links the changes in climate and non-climate factors to the risks. These models can vary from conceptual to quantitative impact models (Jones 2001; Jones and Preston 2011).

It is the case that there will be many adaptation problems and issues that are so complex that there will not be existing quantitative impact models available for a given system. Thus, it may be necessary to develop a new model, or modify existing models, if a quantitative approach is sought. Alternatively, an adaptation problem may be so complex and poorly quantified that it will be necessary to generate conceptual models whereby the way in which expected changes in climate may impact a system is thought through, using methods such as brainstorming sessions, workshops, and logical reasoning.

The choice then as to which method or tool to use will depend upon a number of factors, chief among which will be the complexity of the adaptation problem (which may mean a complex or more simple method is pursued), the available resources (time, financial, expertise), and the nature of the uncertainty involved in the problem (ISO 31010 2009).

While it should be clear that the kinds of climate risks that organizations face are generated by both climate and non-climate factors, there is a focus, in this section, on describing those methods and tools that may be used to investigate what the impact of changes in climate may have on a given system. It is important to state, however, that this is not an exclusive focus, for example, the use of scenarios for forward planning can be applied to both climate and non-climate factors. Moreover, many of the methods can make use of and may even in some way depend on the use of socioeconomic and sociopolitical data. A wide range of statistical data of past changes in economy and society, as well as some projections of future changes, e.g., population change, are available from various national governments and international organizations, for example, the UN and the World Bank.

Scenarios and Scenario Planning

Adapting to climate change and variability essentially means developing plans or strategies that are able to reduce the negative consequences and maximize any positive consequences that may occur. This clearly implies the need to think about the future and how a given system may function or respond, under future conditions of changed climate and non-climate factors. It is not possible, however, to predict the future with certainty and as such there is uncertainty as to what the future may hold. The use of scenarios is one way of dealing with this uncertainty (Rounsevell and Metzger 2010). The value of scenarios as a forward planning tool is to consider the effect that different plausible futures might have for the achievement of business objectives. Scenarios are used in various economic sectors, and perhaps one of the most successful examples of the development and use of scenarios is Royal Dutch Shell Plc, who, through the use of scenarios, were well prepared to respond to the oil price shock of the 1970s (http://www.shell.com/global/future-energy/scenarios.html). Other examples of scenarios are those developed by the International Energy Agency (IEA) (http://www.iea.org/publications/scenariosandprojections/), the World Business Council for Sustainable Development Vision 2050 (http://www.wbcsd.org/vision2050.aspx), and the IPCC Special Report on Emissions Scenarios (SRES) (Nakićenović et al. 2000).

Scenarios may be defined as:

> A plausible and often simplified description of how the future may develop, based on a coherent and internally consistent set of assumptions about driving forces and key relationships. IPCC (2007)

Scenarios are, thus, not predictions about how the future will turn out, rather plausible possibilities or alternatives that may appear. As such, they serve as an aid to critical thinking when developing strategies or policies to manage or ensure success under different futures. In other words, they provide a framework for asking questions such as: How would our existing strategy work under different future conditions? How might alternative strategies perform under future conditions? Scenarios may be qualitative or quantitative, and often the two are combined, with a qualitative scenario being used to run a quantitative simulation model under the assumptions contained in the qualitative scenario. For example, global climate models are used to generate quantitative scenarios or projections, of how a range of different climate variables may change in the future, based on the assumptions in the SRES qualitative scenarios. Qualitative scenarios are normally accompanied by a "storyline," which provides a narrative description of how a given scenario materializes.

In adaptation planning, the need for developing scenarios will most likely center around developing scenarios in relation to changes in the non-climate factors, for example, how a water supplier would be able to meet a possible rise in water demand of 25 % over the next 25 years. The need for an organization to develop customized climate scenarios (based on climate models) is likely very low, since there are a number of climate scenarios which are available and as such may be used as "off-the-shelf" products, which can then be tailored according to the needs of a given organization. The task then is linking these scenarios which describe different plausible futures to a model of how a given system functions.

Scenarios thus offer a potentially powerful means of supporting adaptation planning, but key to the process is the accurate identification of the key driving forces, how these are then characterized, and the avoidance of bias in thinking about uncertainties (Reed et al. 2013).

Making Use of Climate Information

What Kinds of Climate Information Are There?

Essentially there are two main kinds of climate information of relevance to adaptation planning, derived from observational and modeled data. Observational data are clearly most useful for learning about past and present changes, while modeled data can be used for both learning about the past and also possible future climates. Using these two sources, it is possible to generate information relating to basic changes in climate variables, e.g., surface air temperature, climate indices, and extremes, for example number of days when summer maximum temperature is >25 °C, and to generate projections of possible future climates.

Deciding which kind of climate information to use will depend largely on the time horizon over which a given adaptation strategy may be operative, and the available expertise and resources. If time or planning horizons are relatively short, i.e., the next one or two decades, then adapting to recent climate variability and trends based on observed data may be sufficient. When the lifetime of a given strategy or action has implications for many decades, the performance of adaptation measures should be investigated across a range of climate change scenarios, and modeled climate information will be needed. The focus in this section is on the use of modeled climate information for informing adaptation planning.

Simulating Future Climates

In order to be able to assess future climate risks, it is necessary to have some idea as to how future climate may change, and for this some kind of model is needed. The most sophisticated tool for this is to make use of global climate models (GCMs). It is, however, also possible to simulate or construct future climates using synthetic data (e.g., Lempert and Groves 2010). Performing a climate risk assessment however is not simply about changes in climate, it is also necessary to understand what effect or impact possible changes in climate may have on a given system of interest. In the following sections, some of the main methods and tools that may be used to assess climate risks are described, and the various issues that are associated with their use and application discussed.

What Is a Global Climate Model?

A global climate model (GCM) is a numerical representation of the various processes that take place in the Earth's atmosphere, ocean, cryosphere, and land surface. These models are based on well-established physical laws and observations of physical processes. They simulate, for example, incoming and outgoing radiation, cloud formation and atmospheric and ocean circulation, and they also try to simulate the interaction of these various processes (McGuffie and Henderson-Sellers 2005). GCMs are highly complex and are extremely computationally demanding, making the use of supercomputing a prerequisite. GCMs solve these various processes mathematically at a series of grid points in the atmosphere and ocean, and across the land surface, and as such have both horizontal and vertical resolution. Because of the complexity, GCMs are only currently tractable when run at relatively coarse spatial resolutions, on the order of 100–300 km.

How Is Future Climate Model Information Generated?

Future climate will be largely determined by the concentration of greenhouse gases (GHGs), and aerosols in the atmosphere, and the changes this leads to in the functioning of the Earth system. Future atmospheric concentrations of GHGs and aerosols will be determined in large part by human activities. In order to be able to simulate future climates, it is necessary to make some assumptions about the way in which human activities will be organized in the future, and thus produce plausible scenarios of how concentrations of GHGs and aerosols may develop. The IPCC Special Report on Emissions Scenarios (SRES) (Nakićenović et al. 2000) represents a major activity which has formed the basis for the generation of a large number of climate model simulations. These scenarios make various assumptions about, for example, global human population development, how our economic affairs will be organized, what technologies might be employed, and the fossil fuel intensity of human activities. Recently, a new set of emissions scenarios has been developed by the science community to try and address some of the constraints that use of the SRES scenarios placed on the climate simulations. These new scenarios are called the Representative Concentration Pathways (RCPs) and take a different philosophical approach to that of the SRES (Moss et al. 2010; van Vuuren et al. 2012). Whereas the SRES scenarios assumed a given pathway of socioeconomic development would lead to a particular level of emissions, the RCPs do not. Instead, many different development pathways may be consistent with the level of emissions and thus concentrations of GHGs and aerosols, under the RCP scenarios. A new set of socioeconomic scenarios have been developed, called the shared socioeconomic pathways (SSPs), which may be used in conjunction with the RCPs (O'Neill et al. 2013). Using these emissions or concentration scenarios with global climate models allows future climate projections (or scenarios) to be made, which are conditional upon the assumptions made in a given emissions scenario. In this way, it is possible to obtain quantitative information on the way in which future climate may evolve.

What Kind of Information Can These Models Generate?

Global climate models can be used to generate information for a few months ahead and these are known as seasonal forecasts; for the next decade – these are known as decadal predictions; or for many decades ahead, i.e., 20–100 or more years – these simulations are known as multi-decadal or centennial projections.

To date, most focus in adaptation planning has tended to use multi-decadal projections, which is a function of the relative maturity of this field, and data availability, compared to the seasonal and decadal projections. Seasonal forecasts do have some skill in some parts of the world and are used to help people adapt particularly in less developed nations (Lizumi et al. 2013). Decadal predictions on the other hand also have some skill in predicting certain climate variables and phenomena in certain parts of the world and/or at the global scale. However, these predictions are very much an experimental research area (Meehl et al. 2009). As such, despite their clear appeal in terms of the time horizon, a major amount of progress is needed in this area before they may be suitable for assisting with typical adaptation planning problems (Tollefson 2013).

Deciding which climate model data to use, and for which emissions scenarios, will depend upon the nature of a given adaptation problem, and specifically the associated planning horizon. Clearly, if there is a business decision that needs to be made which is climate sensitive but can be adjusted within a short time period, then using observed data, statistical relationships, or learned experience may be a suitable approach, rather than using modeled data. If, however, there is a business decision whose lifetime will extend over a couple of decades or more, then climate change and climate models will need to be consulted and incorporated into the planning and decision-making process.

Downscaling Global Climate Model Data

Global climate model outputs are not particularly well suited to the kinds of questions related to adaptation planning, owing to their coarse spatial resolution. In order to bring the results of global climate models closer in line with the needs of users, the global climate data may be downscaled (Fowler et al. 2007; Jacob et al. 2013). There are two main approaches to downscaling climate information to the regional level, dynamical and statistical downscaling. Dynamical downscaling proceeds through the use of regional climate models, whereas statistical downscaling can proceed via a range of methods, for example, regression analysis. A precondition for all downscaling, however, is the realistic representation of large-scale circulation patterns from the driving GCMs.

Uncertainty in Climate Model Information and How to Deal with It

Uncertainty in climate model information stems from three main sources: natural or internal variability, model uncertainty, and emissions uncertainty (Hawkins and Sutton 2009). This issue is discussed in more detail in the chapter by Bowyer et al. (2014) in this volume.

The most common way in which uncertainty is quantified is through the use of probability. This can mean specifying a percentile range or possible variation to be expected, through to generating full probability density functions (CCSP 2009; Collins et al. 2012). The way in which uncertainty is quantified is important for the meaning that may be attached to the results of any model or statistical analysis, and thus how this may be used and interpreted in informing the adaptation decision support process.

Given the sources of uncertainty in climate modeling, when generating data that may be used in support of adaptation planning, one would ideally have data available that were generated from multiple different climate models which had each been run multiple times, exploring a very wide range of uncertainty in parameter values. This would also ideally be done for a range of different future emissions or concentration scenarios. Unfortunately, because of the large compute time required to run GCMs, this is not practical at the present time, although progress is being made (Sexton et al. 2012).

What options exist for dealing with this uncertainty? One approach for which suitable data are currently available is to make use of what are known as multi-model ensembles (MME). Because different international climate modeling centers have different models, and structure them in certain ways, combining these simulations into an ensemble is one way in which uncertainty can be explored in the climate modeling. A multi-model ensemble is then a collection of different climate model simulations obtained from a number of different models. Overall, the MME approach does not explore a lot of variation in uncertain process parameters, with typically only a small number of simulations being performed with each model. As such, this approach provides a limited quantification of uncertainty (Stainforth et al. 2007).

An additional way in which uncertainty can be dealt with is to generate what is known as a perturbed physics ensemble (PPE). In this approach, a single climate model is used, in which a large number of model parameter values are varied across their plausible range of values, and the climate model run for each instance. This approach allows the generation of a large number of model versions, each one being part of the ensemble. There are, however, very few examples of such PPEs being generated, owing to the fact that they are so time consuming to generate (Sexton et al. 2012).

Climate Indices and Extremes

Both observed and modeled data can be used to obtain information on changes in climate indices and extremes (defined as any change above a commonly accepted statistical measure of rarity, e.g., 95th or 99th percentile). In relation to adaptation planning, it is often the case that direct experience of, or information related to, extremes can often provide the stimulus for action, in that the direct experience of an extreme weather event creates a so-called window of opportunity (Adger et al. 2007), raising awareness of climate risks, and that action may be needed to address them.

Often, information relating to extremes is presented in the form of indices, e.g., the number of summer days with mean temperature above 25 °C. Information on climate indices and extremes can be used to form either a quantitative or qualitative assessment of what the changes may mean, or indicate, for being able to meet business objectives, either in the past or in the future. It is also worth stating that the use of observed changes in indices and extremes, and any trends in these, can be very powerful in raising awareness of climate change, establishing an evidence base, and helping build a case for the need for adaptation. If the observational data sets can show a clear trend of change, then this can often be sufficient evidence to stimulate adaptation action.

Climate indices contain information relating to changes in climate variables, which may be of relevance to different economic sectors, for example, in the energy sector, the number of cooling degree days and heating degree days is used to help plan and manage energy demand. Indices may be derived or calculated directly from climate observations or modeled data.

Information on changes in extremes is highly in demand particularly for future time periods, from, for example, insurance companies. Figure 2 provides examples of ways in which climate extremes may change under a changed climate. Possible changes in the mean, variability, and shape of climate statistics will lead to different possible changes in the frequency and magnitude of extremes. It should be clear from Fig. 2 that even relatively small changes in the climatology of a given variable can have significant implications for the frequency and magnitude of extreme events (Coumou and Rahmstorf 2012; Rahmstorf and Coumou 2011).

Simulating the Impacts of Climate Change

While the use of climate change data may be of use to develop a broad understanding of possible ways in which a system may be affected under climate change, for example, as part of risk identification, or a preliminary risk screening exercise, the question that really needs to be answered however is: How will a given system be impacted by these changes in climate, and thus the ability of an organization to meet its business objectives? This section provides a discussion of some of the main methods and approaches that can be used to develop an understanding of how a given system functions.

Modeling Climate Impacts

A powerful way of obtaining more detailed information on the way in which a given climate-sensitive system may respond to changes in climate is through the use of environmental modeling tools, which may also be referred to as climate impact models (Challinor et al. 2009). These may be either statistically or physically based models and are used to model various environmental systems and economic sectors, e.g., water, agriculture, forestry, coastal systems, energy, and food. Impact models will typically be driven by climate variables, and other system relevant variables, and may offer some scope for the inclusion of socioeconomic variables. These models may be used to perform sensitivity analyses (discussed in section "Model Sensitivity Analysis"), to try and understand better the way in which a given system responds to climate, and should ideally be able to simulate or integrate the action of adaptation measures or strategies on the system function (Lempert and Groves 2010).

Using impact models can often be a very resource-intensive approach, particularly if a number of climate model simulations, or ensembles, are to be investigated to quantify uncertainty. This need not be the case, however, but careful consideration should be given to the level of detail that is needed in order to answer the kinds of adaptation questions or problems that may exist, and thus using impact models may only be deemed necessary for particularly significant risks.

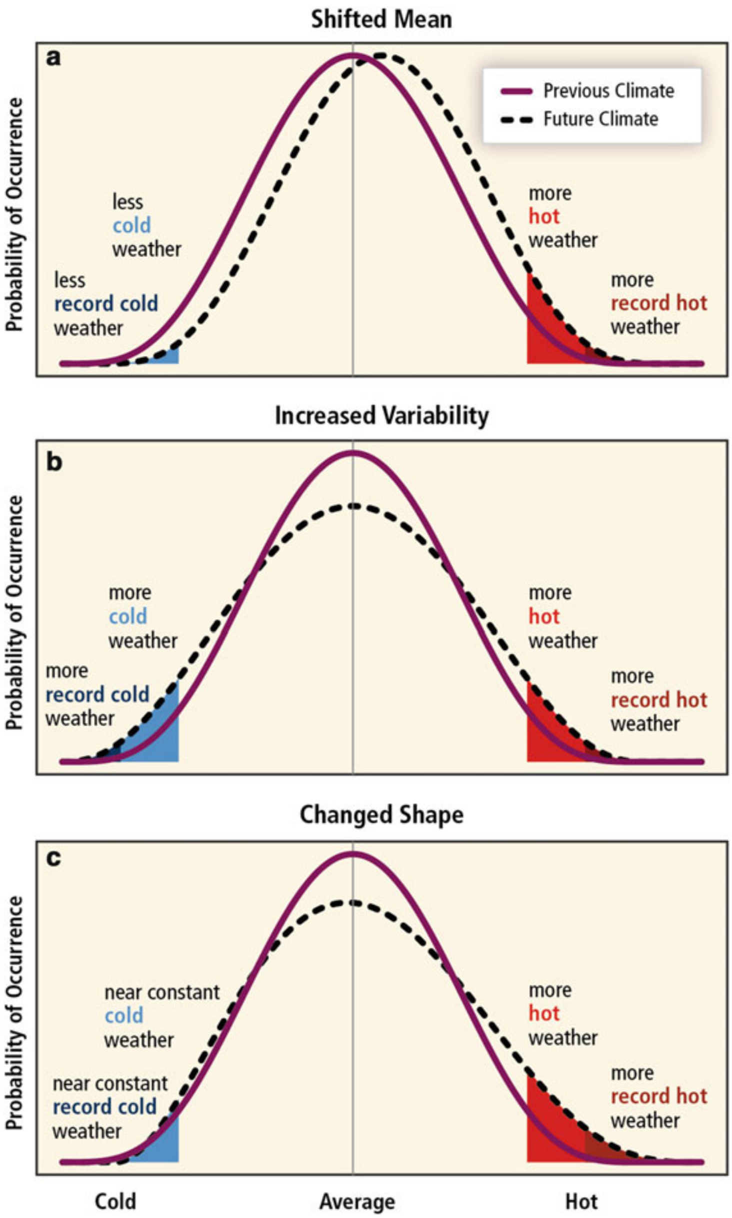

Fig. 2 The effect of changes in temperature distribution on extremes. Different changes in temperature distributions between present and future climate and their effects on extreme values of the distributions: (**a**) effects of a simple shift of the entire distribution toward a warmer climate, (**b**) effects of an increased temperature variability with no shift of the mean, and (**c**) effects of an altered shape of the distribution, in this example an increased asymmetry toward the hotter part of the distribution (*Source*: IPCC (2012))

Model Sensitivity Analysis

A model sensitivity analysis quantifies the way in which the model output responds to variation in the model inputs, and can be used to determine the relative importance of the model parameters in driving variation in the model output (Saltelli et al. 2000). Using a given impact model, sensitivity experiments can be conducted where a wide range of known or expected variation in the relevant climate and non-climate parameters is explored and then analyzed to see how the given system (model) responds. This could be done with modeled climate data, or a less resource-intensive approach would be to generate synthetic climate data. Sensitivity analysis can be used to help identify those factors which are most important to control or which have most influence on the functioning of a system, and thus can be very instructive in the search for adaptation measures or strategies. Moreover, it may be possible to explore the efficacy of potential adaptation measures across a large range of possible futures, using a sensitivity analysis. This would serve to highlight where, or under what conditions, a given adaptation measure may be suboptimal or less robust. This kind of information is potentially very informative in the process of selecting adaptation measures.

Model sensitivity analysis provides a powerful means of learning about the functioning of a system and is less resource-intensive than generating an ensemble of impacts based on a climate model ensemble. The results of a model sensitivity analysis can also be used to generate what are known as impact response surfaces.

Climate Impact Response Surfaces

Model sensitivity analyses can lead to the identification of a set of model parameters which are most influential in driving the system response. Using this approach, it may be possible to generate a functional relationship between a small set of model parameters and the system response (Fronzek et al. 2010). In so doing, it is possible to generate what is known as a climate impact response surface, which represents this functional relationship. This system response could be a threshold value of high relevance to a given business objective. For example, it may be necessary to have a certain water level in a river to allow transportation of manufactured goods or river water temperatures which may place a constraint on the availability of cooling water for power stations (van Vliet et al. 2012). An impact response surface could be used to investigate how often in the future this threshold level would be exceeded, and thus help support decisions in relation to developing adaptation measures. An example of an impact response surface is shown in Fig. 3.

This method provides a rapid, quickly updateable and reusable tool for understanding the effects of changes in climate on the system response. As new climate data sets become available, they can simply be plotted over the existing surface (assuming no change in the functional relationship), and analyze if new information leads to any change in the exceedance of a valued threshold. This attractive feature of reusability and being easily updateable as new climate information becomes available or, as business objectives change, means that this approach

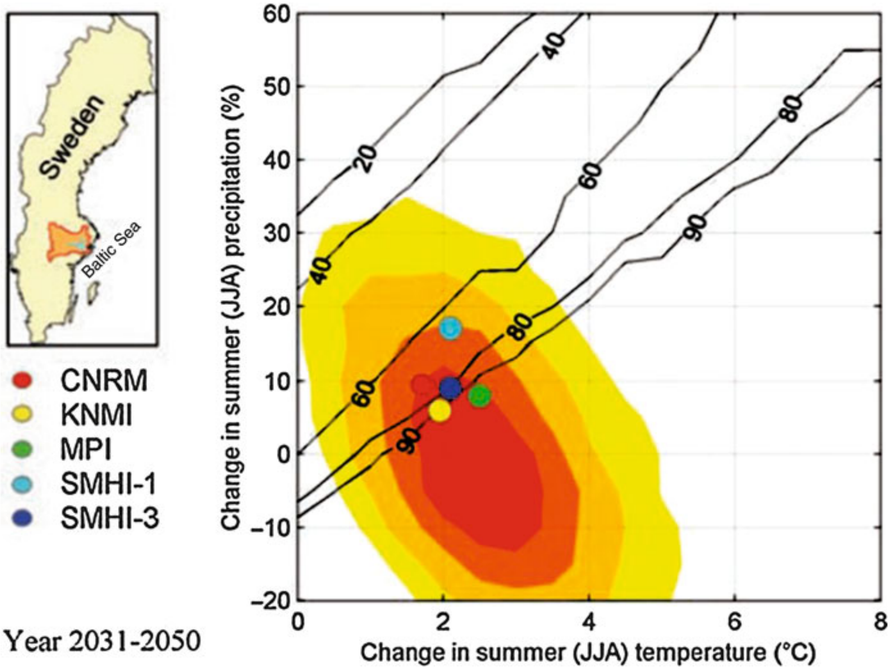

Fig. 3 An example impact response surface for Lake Mälaren in Sweden. Diagonal *black lines* are the likelihood in percent of summer water level being below the target operating threshold for a consecutive period of 50 days for the change in summer temperature and precipitation. Climate projections for the time period 2031–2050 are shown as probability density plots in the colored area, which encloses approximately 90 % of all projected outcomes. The *colored dots* are projections from regional climate models (*Source*: van der Linden and Mitchell (2009))

may represent a good return on any investment made to develop such tools, and is easily incorporated and used as part of an iterative review process of climate risk management.

This approach is most suitable for systems whose response is driven very strongly by a few climate variables, e.g., in the water and forestry sectors (Prudhomme et al. 2010; McDaniels et al. 2012). Also, the accuracy of these surfaces compared to a full modeling approach should be assessed and reported. Also consideration of the uncertainty in the modeled response itself needs to be considered in the sense that a different impact model may give a different surface. These response surfaces serve to highlight visually when business objectives may be vulnerable, or alternatively, where a particular risk may become worth exploiting. Challenges arise when this response surface cannot be defined with less than four parameters, because one of the big attractions of response surfaces is the rapid assessment that visualization provides. With more than three parameters, visualization becomes difficult.

Decision Making Under Uncertainty

The foregoing discussion has focused on a range of methods and tools that may be applied at the risk assessment stage of the risk management process, in order to establish a basis upon which the significance of any risks can be assessed. Any risks which are deemed to need treating will then require an adaptation strategy and will need to appropriately consider the issue of uncertainty.

Because of the various sources of uncertainty in adaptation decision making, it is simply not possible to accurately predict what the future world will be or look like. The only credible way of acknowledging and dealing with this uncertainty is to explore as wide a range of different possible futures as possible. The task then is to endeavor to understand what this may mean for the functioning of a given system, and the effect it may have on an organization being able to successfully meet its business objectives, and thus planning and implementing adaptation strategies. Moreover, it is also a fact that developing an effective adaptation strategy will also need the approval of a range of different stakeholders, who will have different values and priorities. As such, developing an adaptation strategy is not simply about having an evidence base and information but obtaining stakeholder engagement and buy-in. This adds another layer of uncertainty to the process, such that it may be said that adaptation takes place under conditions of deep uncertainty. Lempert et al. (2004) characterize deep uncertainty as being the situation where "decision makers do not know or cannot agree on (1) the system models, (2) the prior probability distributions for inputs to the system model(s), and their interdependencies, and/or (3) the value systems used to rank alternatives."

Given this reality, an organization is faced with the question of how best to make decisions in these circumstances. Should an organization seek to predict the future and strive to optimize an adaptation strategy around what is determined to be the "most likely" future? Or, instead, should an organization acknowledge that pursuing an optimizing approach is highly vulnerable to futures different from what was considered to be most likely, and accordingly seek robust adaptation strategies that perform reasonably well across a range of different possible futures?

This section discusses the implications of deep uncertainty for developing adaptation strategies, whether to optimize, or hedge and seek robust decisions (Weaver et al. 2013). In addition, a discussion of the robust decision-making framework is provided.

To Hedge or Not to Hedge: That Is the Question

In the context of using climate information to support adaptation planning and decision making, there are two alternative decision frameworks that are applied, a predict-then-act framework and a robust decision making (RDM) framework (Weaver et al. 2013):

1. **Predict-then-act**: this has been the most commonly adopted framework, under which optimal strategies are sought which seek to maximize the expected utility of a given adaptation strategy. This framework relies on the ability to predict the "most likely" future (Lempert et al. 2004). To determine the "most likely" future requires that probabilities are assigned to model predictions.
2. **Robust decision making**: this framework has more recently gained traction in the adaptation arena (Lempert et al. 2006; Lempert and Groves 2010; Kunreuther et al. 2013). This framework seeks to minimize the regret associated with a given adaptation strategy, by evaluating a number of different strategies and selecting that strategy which performs relatively well compared to the alternatives, across a large range of possible futures. This relative performance measure is the robustness criterion and, because it does not seek to provide an optimal outcome under one "most likely" future, provides a hedge against uncertain futures. The performance criterion is the level of robustness offered by a given strategy, in the sense that it fails to meet its objectives on fewer occasions, or is less sensitive to uncertainties, than the alternative strategies.

Deciding which of these two frameworks is most suitable for application essentially comes down to how seriously a given adaptation strategy is, or may be afflicted by, the issue of deep uncertainty. Clearly, deep uncertainty will be more or less important depending on the decision context and nature of the uncertainty associated with a given strategy. If the strategy does not affect external stakeholders, has a short decision lifetime, has flexibility, and/or is a no, or low regret, option, then the predict-then-act framework may be suitably applied. If, however, the strategy has a long decision lifetime, has limited flexibility, and/or involves external stakeholders, then an optimal strategy designed under the predict-then-act framework may be too vulnerable or risky in the face of futures different from what was considered most likely when the decision was made. In addition, pursuing a predict-then-act approach will also be more vulnerable to the occurrence of surprises. In these cases, a robust decision-making framework is likely to be more suitable. It is worth stating that there may also be pragmatic reasons for adopting one or the other decision framework.

Robust Decision Making

Under the robust decision-making framework, one accepts that there are multiple plausible futures, and seeks to explore how a given business objective may fare under a range of different futures (Weaver et al. 2013). The approach starts first with the candidate adaptation strategies and then uses a modeling framework which samples a range of uncertainty in the main decision relevant system driving variables to generate a large number of scenarios. The question then asked is, under

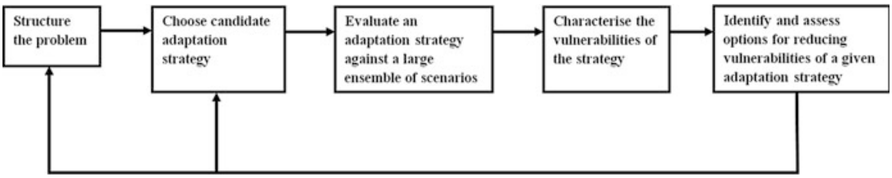

Fig. 4 Steps involved in a robust decision-making analysis (*Source*: Adapted from Lempert and Groves (2010). In operation, the RDM method combines steps 3 and 5 of the risk management process (risk analysis and adaptation option appraisal))

what future conditions would a particular adaptation strategy fail to meet its business objectives, as represented by some performance criterion (Lempert and Groves 2010)? The RDM approach is an iterative method which tests out different candidate adaptation strategies, seeking to characterize the vulnerabilities associated with each and using this information to inform and identify alternative strategies that may be more robust. The RDM approach is summarized schematically in Fig. 4.

As originally conceived, RDM was a quantitative computational model approach (Lempert et al. 2006) and as such can require a lot of resources. However, the principles involved in the approach can be equally well be applied to qualitative conceptual models of how a given system functions, which provides a much less resource-intensive approach, as recently demonstrated by McDaniels et al. (2012).

Conclusion

Framing adaptation as an issue of climate risk management provides a range of attractive features which should ensure adaptation can be understood and acted upon within existing management structures. A range of different issues are involved at the different stages and these need proper consideration in adaptation planning. There are several different methods and tools available that may be applied to help carry out a risk assessment, in order to generate an evidence based upon which the significance of climate risks can be assessed, and the necessity of treating them analyzed. Key to the risk assessment stage is having or developing a causal model which explains the way in which changes in climate can lead to impacts on the activities of a given organization and thus understanding how a given system functions. This understanding is central to the search for effective adaptation strategies.

Developing adaptation strategies also involves a range of different issues, not the least of which is how best to develop a strategy in the face of deep uncertainty. The two main approaches of predict-then-act and robust decision making can equally well be justified in practice, depending on the exact nature of the uncertainty associated with a given adaptation problem and strategy. The key issue in thinking about adaptation and making decisions is that it is an analytical process which needs to draw on a wide range of different expertise and stakeholder involvement. At different stages of the adaptation process, different information, skills, and approaches are needed. A risk management framework provides a well-established method which can accommodate all these different aspects.

Abstract

This chapter attempts to illustrate the socioeconomic implications of climate change on alpine and cross-country skiing, golf, snowmobiling, and nature parks at a local and regional level. A transdisciplinary approach is used to create a framework for adaptation responses relevant to the Laurentian and the Eastern Townships regions. Participatory Action Research (PAR) process through social analysis tools and techniques www.sas2.net (SAS^2) leads to better comprehension of perceived changes and business realities, recognition of climate risks, and identification of actions to manage CC-related risk. This process establishes an environment for dialogue, transparency, and progressive awareness about spatial and temporal repercussions for subsectors and regions. Consequently, growing concerns relate to the need to plan adaptation solutions by combining them to other significant business challenges. Interests now focus on feasible adaptation responses to the current effects and projected climate, along with its interrelated socioeconomic risks. The main aim here is to outline a more personalized approach by encouraging business-driven solutions, in such a manner that it can be used as a model to other tourism regions in the province of Quebec.

Adaptation process • Climate change • Collaborative Participatory Action Research (PAR) • Regional tourism regions Businesses • Transdisciplinary • Quebec • Canada

Introduction

A 2011 report by the National Round Table on the Environment and the Economy (NRTEE) suggests that climate change (CC) could cost Canada roughly CAN$5 billion per year by 2020 and from $21 billion to $43 billion per year by mid-century. As a highly climate-dependent industry, tourism will be significantly affected by global warming (Becken and Hay 2012). One key way to reduce the impact on operating costs is adaptation (REDD 2011).

Even though Northeast America is not considered a CC vulnerability hotspot for tourism, other scientific fields are gathering significant evidence of environmental transformation across Canada and Quebec (Allard and Lemay 2012; Ouranos 2010a). Some of these changes will have important impacts on seasonal, nature-based recreation and sports tourism (MDDEP 2012; Simpson et al. 2008; Scott et al. 2007a; Scott and Jones 2007).

Climate change (e.g., the changing hydrological cycle) and related physical and environmental effects (e.g., regional water and snow scarcity) trigger cascading repercussions on local businesses, destinations, and regions (REDD 2011). As provincial supply extends over the entire southern portion of Quebec, opportunities and risks will arise from climate variability and conditions that are extreme in terms of magnitude, frequency, and intensity, particularly in major economic regions such as *the Eastern Townships and Laurentian regions, that offer golf, alpine, and cross-country skiing, snowmobile trails, and parks.*

The nature-based and sports activities provided by tourist operations play a crucial role in regional and local economies (Ministère du Tourisme du Québec 2012, 2009; CQRHT 2010; Scott et al. 2008; ASSQ et al. 2008). CC can thus be considered a threat, and tourism managers and operators should plan accordingly to reduce their exposure (NRTEE 2012).

Uncertainty about the current and future climate conditions will alter visitation and participation rates (Scott et al. 2011). Predicted CC scenarios, such as changes in precipitation patterns and temperatures, and the increased occurrence of natural hazards such as heavy rains and intense storms, flooding, as well as indirect consequences of biodiversity loss and vector-borne diseases will have major implications for tourism (Scott et al. 2002; Bourque and Simonet 2008).

In the past years, severe meteorological and hydrological phenomena have affected outdoor tourism operations in Quebec and tested decision-making and response mechanisms. Highly unpredictable and variable conditions (i.e., heat waves) in Northeastern Canada led to early closure of ski resorts, with an 8 % decrease in attendance over the previous year (Archambault and Germain 2012). A small consolation for Quebec, the National Ski Areas Association (NSAA and RRC Associates 2012) found that the 2011–2012 season ended in a major frequency drop, making it the worst in 20 years, with visits to Northeast USA down to 20 %.

Interviews conducted by analysts from the Transat Chair in Tourism (University of Quebec at Montreal) with ski resort managers show a marked change in attitude: for example, in the last decade most operators used different ad hoc adaptation strategies that focused primarily on marketing and snowmaking, despite limitations and sustainability of the last approach. As the awareness of the long-term nature of CC grew, ski resorts have developed their own adaptation strategies that tend to focus on technology, activity diversification, and resort partnerships (alliances) as a means of coping with changing snow conditions (Archambault and Germain 2012).

The changing climate presents opportunities for industry transformation. As pointed out by the NRTEE, *Just as businesses must readily manage financial and regulatory uncertainty, they must also understand the risks and potential opportunities presented by a changing climate and position themselves to respond appropriately.*

Recent circumstances call for new sustainable operational and management skills (McBean 2012; IPCC 2012; Ministère du Tourisme du Québec 2012 – PACC 2013–2020). Despite the fact that environmental impacts can affect the value and supply chain and natural assets (McBean 2012; NRTEE 2012; Gössling et al. 2012; Felmate et al. 2012; Vescovi et al. 2009; Scott and Jones 2006a, 2007), the tourism industry still does not fully grasp the need to adapt (Weaver 2011; see Bramwell and Lane 2007).

In many cases, tourism coverage in CC literature is virtually nonexistent or is discussed too generally to help key players develop adaptation strategies or measures (Scott et al. 2012). Knowledge of appropriate adaptation mechanisms for specific outdoor recreation and tourism sectors is very limited (Agrawala 2007; Scott and McBoyle 2007; Pelling 2011) or else restricted to specific regions such as Quebec. The best way to involve partners in adaptation strategies is to create a partnership between local and regional associations, universities, and different levels of the government, thereby combining tourism expertise with the latest climate science knowledge.

This chapter presents an integrated collaborative approach to adaptation. Ouranos – a consortium on regional climatology and CC adaptation – and industry associations from the private sector joined forces in a program (including collaborative Participatory Action Research [PAR]) that aims to initiate dialogue on climate risk and create a flexible, realistic framework for local and regional adaptation responses.

This exploratory study is original in many ways. It used a five-step plan to achieve three research objectives: (1) scenarios/estimates, (2) workshops, (3) questionnaire, (4) benchmarking, and (5) brainstorm sessions. The article focuses on steps 2 and 5 of the study. Results from each step informed subsequent steps. The workshops were based on the modeling results. The strategic orientations of the workshops provided a basis for the questionnaires, helped target adaptation strategies and best practices outside Quebec, and validated individual, local initiatives. Results from the first four steps were reported at two regional brainstorming sessions, where discussion centered on critical strategic orientations for adaptation to CC and the future of this project.

The following chapter will discuss the process analysis and research project management, the stakeholder interaction, the workshop techniques and methods used, the quality and relevance of results, and the benefits of collaborative research in decision making.

In conclusion, recommendations are highlighted for future projects using an action-based learning system to address climate risk and adaptation responses in a transdisciplinary research context. It is expected that this type of collective brainstorming will generate adaptation solutions that will lead to the creation of interactive documents through ongoing, collaborative authorship.

Literature Review

Climate: Tourism

Despite increased global awareness of the significant impact of climate change (CC) on tourism, practical and effective responses remain limited (Becken and Hay 2012, p. 1; Berrang-Ford et al. 2011). In the last decades, research to better understand CC and its implications has intensified. Investigations started as early as the 1960s through weather-/climate-related and tourism-/recreation-related articles in research journals and lasted throughout the 1970s (Scott et al. 2005a). In 1970 Mandauer (as cited in Scott et al. 2012, p. 60) noted that the effects of weather on tourist regions and the extent of weather-related effects on tourists were still largely unknown.

Today, some experts feel that, while research publications on climate change or climate/weather in the context of tourism display a more mature approach (Scott et al. 2005a), the research field is not sufficiently developed (Fisher 2007). Knowledge advancement is weakened by sparse weather and climate data and a geographical research imbalance largely dominated by northern countries (Fisher 2007). According to Kajàn and Saarinen (2013) despite more prolific output in the late 1990s, these observations still hold true today.

Climate Trends and Environmental Change

Changes have been observed both in mean conditions and also in the frequency and intensity of weather and climate patterns across the province (Ouranos 2010a; Allard and Lemay 2012). In southern Quebec, recent trends show decreased snowfall patterns especially during the freeze-up cycle (Duguay et al. 2006; Brown 2010). Estimates show that between 1981 and 2004, the summer season has lengthened by an average of 0.8 days per year (Yagouti et al. 2006; Julien and Sobrino 2009). With average temperatures above the climate normals of 1961–1990, the last 12 years have been the warmest on record (Ouranos 2010a; Allard and Lemay 2012; WMO 2012).

Further alteration of climate conditions could intensify the hydrological cycle, as well as drought, snow, and ice distribution patterns (Prowse et al. 2007; Allard and Lemay 2012). More frequent low-pressure systems, decreased ice cover duration, soil thawing, and rising mean that sea levels are already affecting southern Quebec. These physical conditions weaken infrastructures and the built environment (Bleau 2012; Allard et al. 2008), biodiversity, ecosystems (Berteaux et al. 2010), and communities (Savard 2010).

Impact Assessments on Recreation and Sports Tourism

Numerous studies have evaluated the risks that climate change poses to tourism and outdoor recreation in environments similar to those in Quebec (New England – Dawson and Scott 2007; Scott et al. 2008; Dawson et al. 2009; Ontario – Scott and Jones 2006a, b; Jones and Scott 2006a; McBoyle et al. 2007; Brown and Hunt 2007; Finland – Sienvanen et al. 2005).

In Canada and the United States, the most vulnerable sectors are the snow-dependent ones such as alpine skiing (Scott et al. 2003, 2008; Dawson and Scott 2007; Hamilton et al. 2007; Shih et al. 2009), snowmobiling, and cross-country skiing (McBoyle et al. 2007; Scott et al. 2011; Blangy et al. 2011). However, CC scenarios have shown increased participation in various peak and shoulder season activities, events, and festivals (Scott et al. 2005b), visits to provincial and national parks (Richardson and Loomis 2005; Scott et al. 2007b; Jones and Scott 2006a, b), and golf (Scott and Jones 2006a, b; Scott et al. 2011), that would generate economic benefits. Still, further studies are needed to ascertain how the tourism industry must change in order to reduce the risks and sustainably increase the benefits (Dawson and Scott 2010).

Quebec has made little progress in understanding how CC will affect the socioeconomics of regional recreation and sports tourism. While the impact remains hard to quantify (Scott et al. 2005a), two studies addressing the relationship between outdoor activities (alpine skiing and golf) and future climate scenarios revealed preliminary results (Singh and Bryant 2006; Scott et al. 2007a). Although incomplete, these studies clearly identified the risks of snow dependency for ski resorts and the benefits for golf courses. Further investigation is required as neither study assessed the direct relationship between climate, recreation, and the economic impacts on regional tourism.

As previously mentioned, research has documented the current and anticipated effects of CC on seasonal sport and outdoor recreation (Abegg et al. 2007; Moen and Fredman 2007; Scott et al. 2009), also has highlighted the importance of adaptation and mitigation strategies (Agrawala 2007; Scott et al. 2007a, 2011; Dawson and Scott 2010), and identified some obstacles to implementation (Lemieux and Scott 2011). However, further multidisciplinary research is needed to assess vulnerabilities, inform tourism leaders – businesses, nongovernment and government bodies, and academic institutions – of the costs and advantages of adaptation, and provide them with the tools and insight to make targeted decisions on adaptive responses to climate change.

Adaptation

Adaptation to climate change refers to an action-oriented process and the resulting strategies and initiatives (Smit and Pilifosova 2001). It is defined by the Intergovernmental Panel on Climate Change (IPCC) as the “[a]djustment in human or natural systems to actual or expected climate change or their effects in order to moderate harm or exploit beneficial opportunities” (IPCC 2007), and by the United Nations Development Program (UNDP) as “a process by which strategies to moderate, cope with and take advantage of the consequences of climatic changes are enhanced, developed, and implemented” (UNDP 2005). CC means not only protecting against the negative impacts of climate change but also taking advantage of any socioeconomic benefits it may bring (EEA 2013, p. 14). Ouranos (2010b) adds that adaptation affects all levels of decision making (individual, local, regional, national, and international) and requires a global and integrated approach, as issues often intersect and extend beyond administrative and territorial boundaries.

Frameworks and Adaptation Planning

According to Scott et al. (2012), tourism industry adaptation research and practices lag 5–7 years behind other economic driver sectors. Several countries have conducted or are currently conducting large-scale research projects on the adaptation needs of sustainable tourism. Yet, according to a OECD/UNEP 2011 poll, only 2 out of the 18 countries surveyed had a tourism adaptation policy either at the planning or implementation stage (Scott et al. 2012).

Several of the countries studied were committed to creating knowledge and awareness among tourism players (OECD/UNEP 2011). However, tourism strategies with concrete climate adaptation measures are still either rare or nonexistent (Ministère du Tourisme du Québec 2012; Felmate and Thistlethwaite 2012). As pointed out by Berrang-Ford et al. (2011), despite studies on the adaptation of tourism practices to climate variability, most publications merely describe human intentions and environmental vulnerabilities with no tangible actions from stakeholders (Becken and Hay 2012). Apparently, the private sector in most countries is not yet fully integrated into adaptation policy processes (EEA 2013, p. 8) even though various impacts and vulnerabilities emerge at local and regional levels (Adger et al. 2007; Frankhauser 2009; Swart et al. 2009).

As stated in the European Environment Agency's (EEA) latest report from 2013, this is because national frameworks and research activities often fail to prioritize economic- and business-related topics. However, practical case studies on Canadian and US businesses show that they recognize the benefits of acting now to prepare for future climate realities. For instance, Whistler Blackcomb Holdings Inc. has its own mitigation/adaptation strategy. The benefits of such strategies consist in protecting value, reducing existing weather- and climate-related risks, and creating value by strengthening market position (NRTEE 2012, p. 6). Still, information on the obstacles to implementing private-sector measures and initiatives at the local or regional level is limited, as national plans and strategies often fail to relate to the needs of these organizations.

So far, it is acknowledged that Canadian companies have made little effort to implement strategies and measures to effectively manage the increasing climate risk (REDD 2011; NRTEE 2012). Given that new published tourism development frameworks (2012) at both federal and provincial levels have left out adaptation to CC, the adaptation actions taken by tourism operators are mostly reactive or voluntary. However, consistency across ministries and agencies is now supported by the provincial Ministry of Sustainable Development, Environment, wildlife and Parks through the 2013–2020 Government Strategy for Climate Change Adaptation.

Introducing a Collaborative Approach

Studies on tourism and CC adaptation recommend tourism stakeholders to work hard to identify relevant adaptation strategies with respect to activities, products, or destinations (Wilson 2006; Nicholls and Holecek 2008). Stakeholder discussions will be more effective if supported by the best available climate change data and industry impact scenarios (Wall and Marzall 2006). Other researchers also suggest that adaptation planning must be an ongoing process and continue at different levels, including at the territorial level (Wilson 2006; Scott and McBoyle. 2007).

In tourism, the process can be beneficial whether it takes place at the subsector level (i.e., skiing) or at the destination level (i.e., Mont-Tremblant). Integrating adaptation strategies into decision-making mechanisms and capacity building is a highly variable and complex process, given that the sector includes many stakeholders, diverse business models, territories, and resource needs (Scott 2006; Scott et al. 2009; EEA 2013, p. 19). For example, adaptation strategies for a golf course may involve water use restrictions, while for a four-season resort, these may be associated with energy, water, insurance costs, or competitiveness.

Dubois and Ceron (2006) have pointed out that once potential climate change impacts are known, it is easier and more efficient to focus on adaptation strategies. Ongoing discussions with stakeholder groups at the regional and sectoral levels may provide more valuable information of how businesses can adjust and what incentives are required for feasible implementation (Simpson et al. 2008). According to the NRTEE, decision makers – from operational managers to directors – should broaden their outlook by considering climate risk. Ideally, working in partnership will provide for increased knowledge, data access, sharing best practices, implementing adaptive measures, and becoming advocates for policy change.

In this sense, a holistic approach, such as collaborative Participatory Action Research (PAR), is required to help subsectors adapt. PAR is built on mobilization and knowledge transfer and exchange, with all players, including the researchers, sharing responsibility for gathering knowledge and committing to community involvement (Anadon 2007). The challenge of PAR is for all players – subjects and researchers alike – to make flexible use of the tools involved in a way that structures the approach within an analysis context that is still undefined (Dubost and Lévy 2003; Blangy 2014). Chevalier and Buckles (2013) participatory social system analysis techniques (SAS^2) provide such a methodological framework. A number of the techniques from their set of 50 can be applied to tourism (Chevalier et al. 2011; Blangy et al. 2010). An action-based learning system allows partnerships to be created and skills to be developed in order to discuss issues and strategies and integrate techniques. Over time, participants are empowered to engage in further dialogue and develop sector-based competencies (Chevalier and Buckles 2013).

Methods

The approach used in this study is original in many respects. Its success is due to the following factors:

- An ambitious and clearly defined specifications and program
- Intellectual and financial input from the private sector, including strong expectations regarding the deliverables for each step of the project

- Two pilot regions representing Quebec tourism in terms of products, visitation, and geographic location
- The involvement of expertise for all five steps of the project: scientists from different disciplines (socio-anthropology, climate science, and tourism), consultants, regional tourism managers, local and provincial government representatives, and sectoral associations
- The emphasis on participatory workshops and brainstorming sessions involving experts in workshop design and facilitation
- A five-step project plan (scenarios and estimates, workshops, questionnaires, benchmarking, brainstorming sessions) that allowed the group to learn, share, and jointly produce knowledge

Study Scope and Objectives

The purpose of this study was to provide participants with a *greater understanding of* the climate issue by using not only climate and tourism scenarios but also peer-reviewed *adaptation case studies* and overseas research projects. Also, the aim was to learn about *the climate perceptions and seasonal business realities of subsectors* regarding the more recent climate conditions. Finally, *an adaptation dialogue* was engaged based on learning and transparent discussions by sharing experiences and subsector and regional transformations, expected to take place by 2020–2050 (cf. Table 1).

The goal of the above-mentioned process was to enable participants to recognize the risks of climate change (CC) and identify regional and local adaptation initiatives by making use of current scientific information. Raising awareness of CC is expected to improve how public and private tourism stakeholders adapt to new realities and provide the first major, multilevel recommendations for Quebec's tourism industry.

Table 1 The three study objectives and the five steps to move forward

Three objectives	Five steps
Assess potential socioeconomic impacts of CC	1. Evaluate current and future impacts on tourism and the economy, using climate scenarios and daily attendance (1998–2008) data
Assess climate perceptions within pilot regions and sectors, and identify relevant adaptation strategies	2. Organize five participatory workshops to assess CC perceptions of impacts/risks and probability of recurrence
	3. Conduct online questionnaires and phone interviews to validate workshop results (154 managers across all 5 outdoor activities)
	4. Benchmarking: identify best practices and adaptation strategies for Quebec
List potential adaptation measures and formulate recommendations for the tourism industry	5. Organize two regional (PAR) brainstorming sessions with the Laurentian and Eastern Townships representatives

To achieve these goals, a working group met in 2010, consisting of the Transat Chair in Tourism of University of Quebec at Montreal (ESG UQAM), as well as 19 businesses from the Quebec tourism industry organized into sectoral associations, the Ouranos consortium, and the Research Chair in Global Change and Tourism at the University of Waterloo.

The Chair in Tourism initiated and coordinated the project. For many years the Chair has been gathering intelligence on the Quebec tourism industry. Ouranos, the consortium on regional climatology and adaptation to CC, played an important role in the development of this project assessment by providing output from the Canadian Regional Climate Model as well as climate-related expertise to the tourism experts. This information is an essential building block for the assessment and development of local and regional adaptation strategies.

Cooperation agreements were signed by the Chair and several sectoral associations (golf, camping, cross-country and alpine skiing, snowmobiling, and nature parks), who together funded the research along with the Natural Resource Canada.

Two pilot regions, the Laurentian and the Eastern Townships, were selected for their diversified and mature seasonal products. This allowed us to investigate the complexity and severity of the related socioeconomic risks and opportunities to unfavorable weather and climate conditions and to determine the extent of CC impacts on the above-mentioned nature-based and recreation sectors.

The Laurentian tourism region covers 20,559 km^2 and is located in southwestern Quebec. The region is strongly influenced by its geography and settlement history. From a demand perspective, the Laurentian region has the third highest visitation levels in Quebec, with 2.9 million tourists in 2008 (Montreal and Quebec City rank first and second in terms of total visitors). The Eastern Townships tourism region covers 10,200 km^2 (about 0.6 % of the province) and is located in southern Quebec, adjacent to the US border (Vermont). With 2.6 million tourists per year, the Eastern Townships is the fourth most visited tourism region in Quebec (Ministère du Tourisme du Québec 2009).

The following focuses on steps 2 and 5 of the project, in which researchers engaged in ongoing dialogue, shared knowledge, and built joint strategies with businesses (Fig. 1, Table 1).

Participatory Workshops

To implement a participatory approach, socio-anthropologist Jacques Chevalier from Carleton University (Ottawa), an expert on Participatory Action Research, was called upon (www.participatoryactionresearch.net). The originality of his approach lies in the flexible use of a wide variety of group facilitation techniques combined with fact-based thinking and analytical methods, so that the process satisfies the needs and working methods of all stakeholders.

Although the sectoral and regional workshops had different yet complementary designs, they yielded comparable results. The workshop structure was based on

Fig. 1 The five steps process of the project

a progression that participants could readily understand: *What we know; What we can expect; What we are already doing; What we could do together*. Participants at the sectoral workshops explored in detail what factors hindered or promoted the development of snowmobiling and cross-country skiing. They worked on sector-specific strategic orientations in the areas of communication, diversification, trail access, snowmaking, and club and ski center organization. Participants at the regional workshops shared their perspectives on CC and discussed the likelihood that such changes will recur.

The workshop exercises were supported by visual aids (radar and Cartesian graphs), analysis software, stories, and a combination of plenary and small group sessions (Table 2). These activities provided participants with an opportunity to analyze extreme weather events and their perceptions of CC, share their knowledge, and study both their individual strategies and the means of developing future collective strategies.

Participants compared their current status with their target status by using the evaluation wheel or radar graph. Each spoke of the wheel represented one of the strategic orientations and conferred a score of 0–5. The gap between the current and target statuses indicated by the wheel-enabled participants to assess the work required to develop new strategies and put them into action. The discussion focused on *Where we are now* and *Where do we want to go from here* and how collective strategies can be improved.

Three regional and two sectoral workshops were organized over the 3-month off-season between March and May 2011. Each workshop involved between 10 and 16 participants, for a total of about 100 participants. Those participants involved in

Table 2 SAS^2 workshop techniques used and relating to examples from Figs. 2 to 4

Telling the story	Timeline: tell a story of gradual CC and extreme weather events from the past
	Cartesian graph: understand CC perceptions through probability and magnitude of impact (+/−) on seasonal products
Monitoring and project evaluation	The Socratic wheel: define the criteria, indicators, and information needed to measure current, ongoing, and expected progress in achieving project results
	The Roman Carousel/projections: visualize what can be expected if current trends continue (climate phenomenon perceptions and probabilities)
Diagnostics and problem solving	Force fields: identify ways to act on key contributing and mitigating factors
	Validation: discuss additional evidence and the stakeholder involvement required to better understand the problem and make plans
Working together	Negotiation fair: assess what stakeholders can expect from each other and negotiate those expectations, then plan concrete actions to meet those expectation, and resolve key problems

the brainstorming sessions were leaders – presidents of sectoral, regional, or local associations – along with provincial government bodies that promote local economic development and support entrepreneurship, managers, tour operators, and so on.

At the very first regional workshop, cross-country skiing and snowmobiling associations (which are especially affected by CC) asked that the first workshops be devoted to their sectors. Less affected subsectors – golf, parks, and camping – were prepared to wait for their turn. Participants received an illustrated report of the workshop content, complete with pictures and graphs showing the processes, techniques, and validated results (Blangy et al. 2011).

Regional Brainstorming Sessions

After this fourth benchmarking step, results were summarized and compiled into reports, fact sheets, and PowerPoint presentations intended for all stakeholders. This CC information package was used at the regional sessions that comprised the final phase of the study and served as a basis for elaborating new tools for the industry: video clips on such topics as climate system, impacts, extremes, and adaptation, analyses by the Tourism Intelligence Network, case studies, and brochures for sectoral associations.

At this stage of the adaptation process, the goal of pursuing the collaborative approach with local and regional actors was to deepen insights on adaptation at the regional level (i.e., the Laurentian and the Eastern Townships). Both sessions focused on transferring newly acquired information to stakeholders from earlier phases. The workshops and questionnaires revealed that it was imperative to bring stakeholder knowledge up to date and create a common basis for discussion, so an information package was created and distributed to participants from both pilot regions. These included commonly used terminology from adaptation and climate sciences and two summary tables (see Bleau et al. (2012) and Tables 25 and 26). The latter showed the impacts and consequences – both positive and negative – of CC on winter and summer practices collected from workshops (Blangy et al. 2011), web questionnaires of 154 managers, and phone interviews.

This information package required several weeks of work because of the large amount of information collected during earlier steps, as well as the tools and methods used. In addition, it was agreed that the methodology should be flexible to match ground reality. These sessions led actors to define adaptation actions for their territories and determine who would implement them. At this stage, concepts of flexibility and time scales (short, medium, long) were important to continue a dynamic process of gradual adaptation. These sessions promoted awareness building and problem solving rather than firm decision making.

Brainstorming session participants were asked to select two strategic orientations (themes) from among the seven orientations that were ranked in order of importance in the workshops and to outline possible regional actions. This exercise was followed by negotiation fairs, at which participants discussed both their needs and the services they could offer. The outcome of this process was a set of recommendations and possible specific actions involving major future actors.

The above approach generated a regional vision around the two selected axes and helped identify obstacles and strengths for each region, while creating the first set of broad recommendations for the tourism industry. However, the brainstorming sessions did not reflect the full territorial offer because major actors were missing.

Finding

Results provided multiple insights, both tangible and intangible, regarding the data and participatory processes in general. Here the focus is solely on the workshop and brainstorming session results.

Process Outcomes

This project was primarily successful because of the participatory approach, the care taken to design and facilitate workshops and report the data.

Workshop design is crucial to the success of the participatory process. The workshop facilitator also plays an important role, provided that he/she has the tools to foster dialogue. A similar workshop design made it possible to compare and confirm data trends. From the three regional workshops, five identical strategic orientations emerged, while two other orientations revealed the different regions' climatic and geographical differences.

The workshops' visual aids saved a great deal of time and energy. In a single day, the sectoral groups made a diagnosis, identified factors that hinder or promote their activities, developed adaptation scenarios, and wrote a draft strategic decision-making plan.

The social analysis tools and techniques developed by Chevalier (Chevalier et al. 2011) helped participants to set forth perceived environmental changes and business realities, recognize climate risks, and identify actions to manage CC-related risk. The workshops helped clarify adverse consequences for each sector, created a sense of ownership, gave people a chance to share knowledge and build bridges, and developed links between communities and operators so they could work at the regional level.

Participants reportedly enjoyed the workshops and felt they created a strong sense of momentum for future activities. Several leaders within each group voiced a strong motivation to pursue discussions on urgent strategic orientations.

Qualitative and Quantitative Results

The workshops generated a concrete, comprehensive overview of the perceptions, sources of change, strategic orientations, and actions that subsequently provided the basis for identifying and grouping best practices and facilitating brainstorming sessions. More specifically, the seven strategic orientations became guidelines for the pilot projects chosen by the two regions.

During the Participatory Action Research (PAR) process, stakeholders were able to specifically identify both recent climate impacts and their direct and indirect consequences for various spheres of business. Mobilized stakeholders also identified seven areas for strategic intervention and four regional measures.

What We Know and What We Can Expect

Workshop participants were asked to tell their story and list climate and environmental trends hindering or promoting their business. The Cartesian graph used for this exercise helped stakeholders clarify their own CC perceptions by looking at the probability of occurrences and the magnitude of impacts (positive or negative) on seasonal products in the future (see Bleau et al. 2012; Blangy et al. 2011).

Climate changes can have negative repercussions for sectors offering winter products and positive effects for those operating mainly in warm or summer periods. Despite these findings, there were more negative impacts from CC on winter activities (i.e., climate shifts, rising temperatures, more rainfall, and extreme events), and these outnumbered the positive summer impacts reported by some businesses. Yet, all participants perceived a high probability that identified environmental changes for both seasons will intensify by 2020 (Fig. 2).

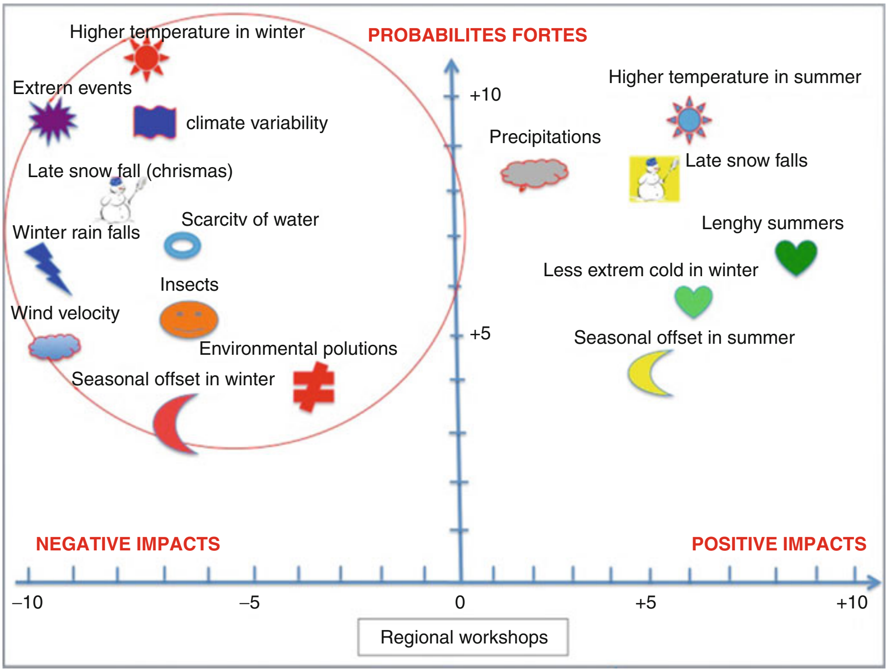

Fig. 2 Perceptions of CC: broad trends, future probabilities, and nature of impacts

Sectoral and regional workshop participants identified repercussions that are already affecting their day-to-day operations. Faced with socioeconomic and environmental challenges at all levels, businesses are adapting reactively to these conditions.

For example, tourism operators must deal with seasonal offset and increased freeze/thaw cycles, increasingly frequent mechanical breakdowns, changing employment conditions, increased snowmaking demand, the changing geography of native species, greater use of natural sites (golf courses and camping grounds), and pressure due to energy and water resource limitations and costs.

Factors Hindering or Promoting the Development of Cross-Country Skiing and Snowmobiling

The force field analysis was performed for the cross-country skiing and snowmobiling sectors (Fig. 3). This tool identified key contributing and mitigating factors (i.e., economic growth and maintained practices). Participants also estimated their degree of control over these factors.

For operators and entrepreneurs, the level of control and flexibility remains highly variable. Results show that real estate development, equipment, and

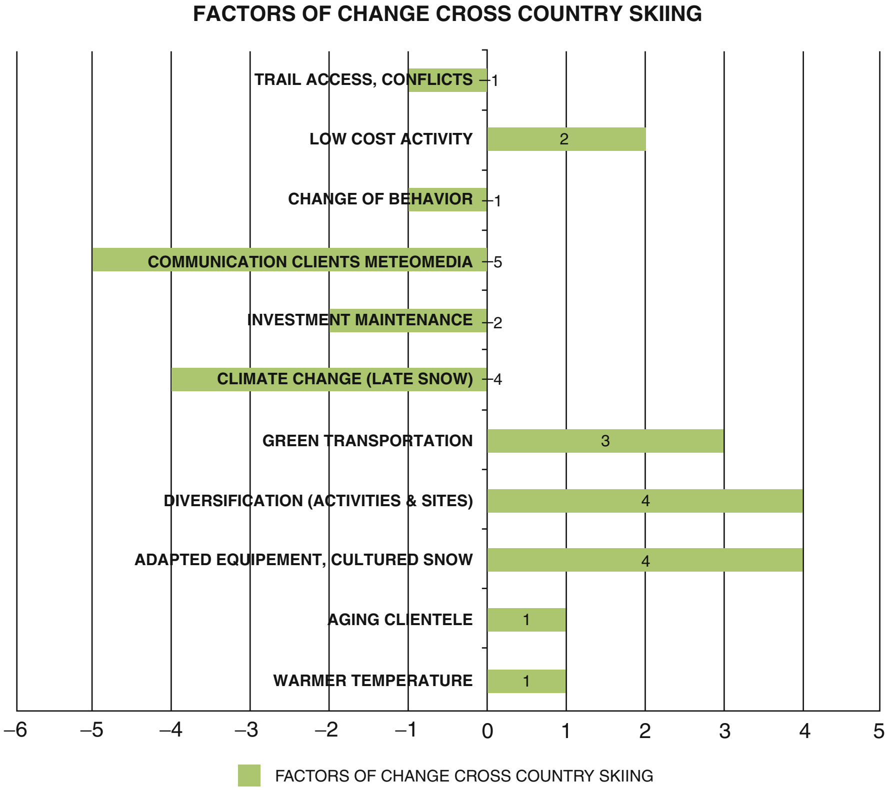

Fig. 3 Force field analysis: factors that hinder and promote the development of cross-country skiing

investment can easily be controlled. Conversely, aspects associated with global temperature (freeze/thaw cycles, rain, and their consequences) appear to be uncontrollable, thus proving that CC is not the main factor generating growth or disrupting operations.

Climate change adds to the range of challenges that tourism sectors are already facing or will be forced to address in order to remain competitive and maintain sustainable growth (Table 3). Operators do not necessarily consider the climate as a strategic risk, even though it affects their businesses at a number of levels they cannot control, such as technical, human, financial, environmental, strategic, image, reputation, and customer levels.

Results from the workshops and questionnaires confirm how each of the four sectors (camping, golf, nature parks, and alpine skiing) rated the challenges. Only alpine skiing mentioned CC as a major concern. Although nature parks indicated severe impacts on cross-country skiing participation in their response to the questionnaire, CC does not appear in their top three concerns. This may be due to a lack of awareness of the subject.

Table 3 Top three challenges faced by operators (questionnaire results)

	Camping	Golf	Nature parks	Alpine skiing
First	Evolving trends and customer habits	Aging population	Labor shortage	**Climate change**
Second	**Climate change**	Competition between destinations or companies	Competition between destinations or companies	Evolving trends and customer habits
Third	Competition between destinations or companies	**Climate change**	Evolving trends and customer habits	Labor shortage

What We Are Already Doing

The perceived and actual changes mentioned in the above exercise encouraged participants to identify strategies already implemented in their businesses and to think of new ones they wished to jointly develop. Six of the strategies listed were selected as being the most relevant, and these were ranked in order of priority, discussed, and illustrated in an action plan (Fig. 4): (1) communication and education; (2) environmental and social responsibility; (3) research, development, innovation, and technology; (4) diversification and maintenance of product quality; (5) planning and infrastructure; and (6) changes to climate policies, practices, and reserve funds.

Small differences were observed between the two regions, based on their different characteristics. Participants from the Northern Laurentian, who are farther and more isolated from the outbound markets (Montreal), insisted on building reserve funds to promote private initiatives. In the Eastern Townships, numerous environmental practices aimed at reducing the ecological footprint have already been implemented and deserve to be highlighted in this study as a source of inspiration for other Quebec regions.

Regarding communication, participants emphasized the need to improve in this respect and provide customers with real-time, accurate information on both regional and daily climate variations.

With regard to environmental responsibility, they agreed on the importance of reducing their ecological footprint and specifically on improving water supply management. On the research/development front, more detailed complementary studies should be conducted, focusing on costs-benefit analyses and snowmaking for cross-country ski centers. Finally, the diversification strategy consisted of designing a four-season concept, developing a multi-activity approach, and combining products in order to compensate for income lost due to changes in seasonal patterns and extreme events.

Although participants had varying needs, this technique was useful to reach common ground in six distinct areas and to think about ways of improving current

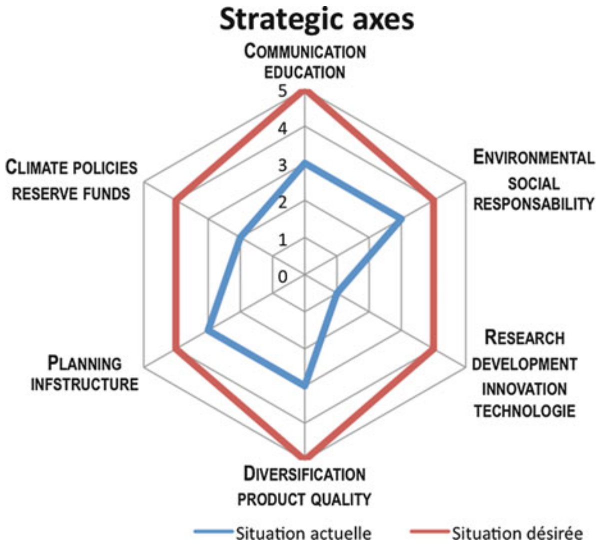

Fig. 4 What we are already doing – existing and possible future adaptation strategies

measures and developing potential adaptation actions to reach the desired scores. Based on the strategic orientations, participants concluded that mitigation actions are far more numerous than adaptation actions, but they recognized that they often confuse the two.

What We Could Do Together

A draft action plan was established based on the radar graph and resulting discussions. This plan included a list of collective activities for improving existing adaptation measures and implementing future ones. Sector-specific adaptation actions were outlined for each of the six strategic orientations. The subsector workshops arrived at this stage more quickly than the regional ones because of their expertise in the area and the fact that they shared common interests.

Brainstorming Sessions: Synthesis of the Five-Step Plan

The final step of this study consisted of regional brainstorming sessions. To obtain the first strategic adaptation framework specific to both the pilot areas, the two groups agreed to select two urgent strategic orientations out of the seven proposed.

Despite the unanimous concern over water scarcity, given the absence of major actors, the Eastern Townships participants agreed to focus on a combined diversification and communication/education (weather extremes) strategy rather than choosing the environmental one. The group concluded that the variations in physical environments, micro-climates, and cross-sector issues prevented them from creating an exhaustive regional view of localized adaptations. Instead, they chose to integrate existing mechanism and policies, in order to accelerate early adaptation to CC at the local level.

As for the Laurentian, that group worked on diversification/maintenance of product quality and research/technology. The need to optimize water supply management to maintain product and service quality was a widespread concern. The alpine skiing, golf, and camping sectors feared that restrictive measures will soon be imposed by local governments. Given the current fact of water variability, a regional cross-sectoral committee was proposed to address this matter.

The brainstorming sessions revealed an individual, territorial approach to adaptation and a need for more concerted action. It also highlighted that weather instability and extremes are major concerns for most nature-based and sports operators because weather forecasts can disrupt people's destination decisions and activity planning and thus affect attendance.

A summary of the discussions yielded two lists of potential adaptation measures for different geographic areas and time frames that were later validated by participants. Initiatives were proposed by public and private stakeholders and actors that could support these actions, some were local (i.e., subregional), while others were regional.

This fifth phase of the five-step plan was followed by ongoing dialogue with regional leaders in order to implement the options that had been prioritized by both regional tourism associations (RTA). Local development bodies emphasized the importance of encouraging tourism entrepreneurs to integrate climate risks in their business plans, in order to prepare for climate/weather uncertainties. The Laurentian RTA has taken a leadership role in educating its outdoor operators on CC impacts and adaptation. Growing awareness and ownership has encouraged local and regional authorities to integrate CC risk management into existing internal policies affecting tourism operations and management. As a result of these outcomes, the tourism in Quebec is now encouraging the research unit to continue the PAR process with other seasonal practices at the national level.

Discussion

This section will focus on the research project structure and management. Discussion will center on how to move from the initial, top-down model to a more flexible and continuous bottom-up approach as a means of addressing adaptation and action implementation in tourism (Fig. 5). Lessons learned throughout the collaborative process and adaptation measures are also featured. Finally, in order to move forward past this initial project, research needs are highlighted by refining tourism and climate scenarios and optimizing knowledge and subsector education in order to promote understanding of regional territorial challenges for adaptation decision making in nature-based and sports tourism.

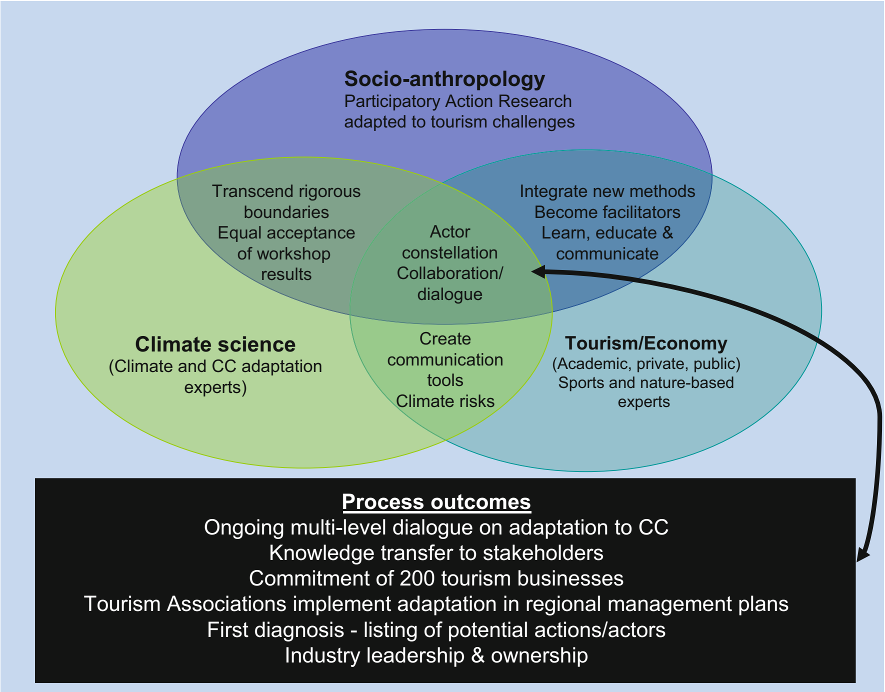

Fig. 5 Transdisciplinary process for progressive learning and management

Project Structure and Management

The use of a traditional structure to manage interconnecting phases and tool production generated many questions with respect to the framework's flexibility, continuity, efficiency, and deadline requirements. This first collaborative experience with private-sector stakeholders has underlined the necessity of involving the industry during initial brainstorming sessions to determine research project objectives and pinpoint adaptation challenges and expectations. This unbiased partnership optimizes trust and the connection between research and practical transformational outcomes. It is argued that this allows the sector to expand knowledge on more critical natural tourism areas, implicate missing subsectors (such as agro-tourism and outfitters), promote greater involvement from nature parks, and include assessment of horizontal issues (i.e., employment, energy supply).

The deliverables for each phase of the research project were planned from the outset. Over the course of the 3-year project, some tasks had to be dropped and others modified because it took more time than anticipated to orchestrate workshops and brainstorming sessions, bring objectives in line with industry expectations, and analyze the vast quantities of data (Table 1 and Figs. 2, 3, and 4). Other tasks were added to address varied levels of awareness and terminology comprehension and the time it was expected users would likely devote to reading complex academic reports.

Communications had to be adjusted to take into account stakeholders' varying skills and awareness levels. Although this step was crucial to a collaborative framework, it was also time-consuming and left less time for data analysis. Coproducing documents means frequently retrieving data and communicating end results to core team leaders who send out the new information. The type of document was therefore called into question and adapted in order to better broadcast and downscale findings to tourism associations, operators, and managers and involve other players.

It is highly suggested by the co-researchers to integrate more flexible media – teaching materials, podcasts, and visual presentations – into the existing scientific reports and technical canvas, as a more malleable data presentation format can well mitigate these inconveniences.

Furthermore, increased trust in the co-researcher unit can facilitate the collection of private primary data, and the more flexible, user-oriented approach will encourage industry leadership and foster ownership of results and tools by improving communication skills and expertise. Also, data retrieval methods that authorities and managers can easily access and understand played a key role in recovering information. In other words, interactive co-construction of synthesis documents from workshops increased accuracy of data retrieval and maintained exchanges between involved parties between interconnecting steps (Figs. 1 and 5).

Subsector and regional experts are best suited to defining the complex business interconnections, needs, and challenges with regard to climate conditions (REDD 2011). It is recommended by Bleau et al. (2012) to set up a permanent CC committee composed of tourism practitioners and researchers (private and public) to elaborate strategic orientations and address significant socioeconomic threats. The ongoing partnerships created through this committee would foster knowledge and information sharing, thereby creating an environment that is conducive to more far-ranging tourism management and policy planning, strategic document formulation, business coaching and education, innovative research, and funding assistance.

Researcher Stance

The project's originality lies in involving a large number of private-sector stakeholders and obtaining their financial support, social engagement, and overall acceptance of adaptation-related PAR techniques. Also, by gathering expertise from a variety of disciplines in order to achieve research objectives, consultants, experts, and researchers had to become more open to flexible structures and visions. Figure 5 illustrates the transdisciplinary overlaps required to connect knowledge systems. The degree of participation, action, and research is often not decided in advance (Hughes 2008). While some tourism experts learn to use new methods and become SAS (Social Analysis Systems) facilitators, climate scientists work on accepting empirical data in the context of social science analysis. Skills are developed in all three disciplines to present climate data in plain language and construct practical tools that are better adapted to the industry.

The collaborative approach linked fundamental questions from the research units to the researcher stance. Researchers and stakeholders were asked to go beyond their familiar scope and boundaries in order to engage knowledge systems and change existing mechanisms (Fig. 5). As stated by Couture et al. (2005), the research documents a process of change and is supported by a constellation of actors who become co-researchers. This innovative approach uses a wide variety of group facilitation techniques combined with fact-based thinking and analytical methods so that the process satisfies the needs and working methods of all stakeholders (Chevalier et al. 2013).

As argued by Daniels and Walkers (2001), an excellent facilitator is key to a successful process. He/she sets the tone for interaction and ensures that the social and physical space is tailored to the participants' needs. Frequent turnover of research personnel hindered not only workshop facilitation but also data analysis and recovery. Expertise in workshop facilitation must be developed as stakeholders wish to continue applying SAS, tools, and techniques.

PAR Process

Customizable SAS techniques were used to design workshops that were adjusted to the multilevel (i.e., global to local) CC context. Indeed, the participants' growing concerns can now be channeled into planning adaptation solutions that are integrated with other contemporary business issues. In other words, adaptation strategies must take other current challenges into account rather than addressing climate change in isolation.

Regional planning should consider all types of enterprises and destinations since CC consequences affect decision making at all levels. Findings show that adaptation strategies are customized in accordance with the pilot areas, the type of recreation and sport businesses located there, and their ability to adapt. Moreover, regions must consider the diversity of products offered in order to assess vulnerability (supply) and make medium- and long-term adaptation decisions (Climalptour 2011). Companies that start by assessing product and service vulnerabilities have a strong focus on risk management and bottom-line protection.

Mobilizing Stakeholders

It comes as no surprise that tourism stakeholders are displaying an increasing interest in current and future CC impacts on seasonal practices, as current information concerning climate change for Quebec's industry is scarce to nonexistent.

Tourism stakeholders recommend pursuing an action-based learning system to guarantee a dynamic, strategic regional plan for the future. The workshops met with widespread satisfaction, providing a forum for equitable and creative discussion of climate issues. It was found that they helped educate stakeholder networks by connecting knowledge from different disciplines. Moreover, informed leaders play a key role in disseminating this integrated CC and adaptation information to their colleagues. On the contrary, Muro and Jeffrey (2006) criticized the difficulty of observing actual learning outcomes of participatory processes.

The process proved difficult at times, in part because various stakeholders had different understandings of the problem, agendas, and priorities. Initially stated by O'Brien (2009), research results also show that values and interests play an important yet seldom-discussed role in climate change responses and influence the adaptation strategies that are prioritized by different groups.

Strategies and Measures

Even if operators do not consider CC to be a strategic risk, it nevertheless affects their businesses on a number of uncontrollable levels. Their response to the lack of current information about weather and climate variations therefore consists of flexible packages, investment in technologies, partnerships, and product diversification. While there is nothing inherently wrong with these strategies, as the first step, the tourism industry needs to focus on improving adaptation capacity and its ability to assess vulnerabilities in areas of great natural and economic value.

Entrepreneurs in pilot regions generated solid information that led to seven strategic development interventions and a list of potential adaptation measures containing 30 new initiatives. The dynamic nature of these outcomes means they can serve as a starting point for a second collaborative research project. Regional tourism associations (RTA) have taken the lead by implementing adaptation in existing practices and mechanisms such as management plans (Fig. 5).

Current local reactive and voluntary adaptation actions can be found in the final report (Bleau et al. 2012). In practice, there were more mitigation than adaptation measures. This can be largely attributed to the fact that first provincial framework on CC overlooked the adaptation aspect of business planning.

While inspired by international initiatives, the business sector found them difficult to transpose into their own socioeconomic context, because of the Quebec-specific nature of national/regional/local structures, geography, and cross-sector issues. Given the current lack of government incentives, their main concern remains funding sources for future sustainable projects.

Research Needed to Integrate Adaptation

Future uncertainty makes planning a difficult task for small and medium-sized businesses and regions. Based on the results of the PAR process, six elements were identified as essential to provide future support to policy and managerial decision making at all levels: (1) ground proofing (comparing case studies);

(2) quantified information from cost/benefit studies; (3) connections between local businesses/destinations and regions; (4) transformational change in existing mechanisms and business models; (5) applied tools for users; and (6) government bodies, associations, and business coaching.

Conclusion

A collaborative research model developed specifically to better understand the impacts of CC on Quebec's nature-based and sports tourism has highlighted fruitful elements for further exploration. The transdisciplinary approach resulted in a learning process that led to team building and an exchange of methods and techniques. Overlaps between disciplines are key focuses to the progressive adaptation of the tourism sector (Fig. 5). The project's first diagnosis has clarified the benefits of adopting a more flexible framework, developing continuous partnerships, and co-constructing interactive documents for regional and local adaptation responses.

Throughout this project and hereafter, a sustained effort to democratize climate science knowledge for multilevel tourism stakeholders has improved their understanding of adaptation and risk management. Indeed, CC has become a motive for combined efforts to rethink core aspects of the tourism industry as a whole in light of recent extreme events and future uncertainties. The outcome of this research project calls into questioning the old economic development model and puts forward a new model that repositions the industry with a focus on combined economic growth and sustainability.

Committed participants now focus on evaluating both individual and regional assets to improve and personalize territorial decision making. Also, prudent risk management suggests companies should recognize outcomes and consider ways to anticipate the effect of long-term climate trends. Furthermore, researchers must take a nuanced approach when interpreting climate and tourism scenarios, as both their results and scientific forecast tools are often called into question. In fact, financial institutions are increasingly taking CC into account when granting and guaranteeing loans. Already considered at risk by these institutions, the tourism sector is sensitive to climate conditions. It is therefore in the interest of these companies to put forward innovative CC adaptation strategies to minimize the associated risks and take advantage of potential economic opportunities.

More than 200 businesses and 300 participants from different tourism subsectors took part in this collaborative process to raise awareness and mobilize the industry. The tourism sector expects guidance in the adaptation process. Pilot regions and subsector leaders have become knowledge ambassadors and wish to use existing synergies and identified potential adaptation responses to make further progress. While Quebec's tourism sector is inherently dynamic and flexible, it also foresees the need to draw in other regions and get the provincial government involved.

The role of the Transat Chair in Tourism is to develop research expertise to ensure knowledge advancement and support seasonal activities in the adaptation process in order to ensure collaboration and education. As a leading partner, the Chair hopes to build partnerships with other tourism regions (both here and abroad) to develop efficient coping strategies and pursue dialogue on sustainable development and tourism in the context of CC.

An Analytical Framework for Investigating Complex Institutions in Climate Change Adaptation: The Institutional Environment Matrix

Sining C. Cuevas, Ann Peterson, and Tiffany Morrison

Contents

Abstract

This chapter introduces the institutional environment matrix (IEM), a diagnostic and planning framework designed to analyze complex institutional environments and determine the institutional fit of climate change adaptation responses. The framework argues that the institutional environment is comprised of rules, social structures, and organizations. It establishes the vital role of institutional arrangements in characterizing the functions and functional interdependencies of institutions. The IEM framework has a dual layer design that allows complex

institutional relationships to be examined across scales. The institutional environment layer is a comprehensive inventory of institutions that outlines institutional complexities. The institutional matrix layer is the system of institutional arrangements that determines the functional interdependencies of institutions. The matrix explores institutional interplay in relation to several general institutional functions: reducing uncertainty, connecting individuals to society, fostering adaptive capacity, and mobilizing resource utilization. By providing a structure to examine complex institutional relationships, the IEM is a significant innovation for assessing the institutional fit of and interplay between existing and planned climate change adaptation responses. This framework may also be used as an analytical tool in adaptation planning and evaluation.

Institutions • Institutional environment • Climate change adaptation • Analytical framework

Introduction

Urban and rural systems are increasingly subject to complex and uncertain problems such as climate change, biodiversity loss, land-use conflict, pandemic disease, and rapid market fluctuations. These problems challenge the abilities of societies to manage change in traditional ways. Subjective perceptions, cross-sectoral misunderstandings, and technological contingencies only increase this challenge (Gunderson and Holling 2002; Crowder et al. 2006). Institutions play a critical role in ensuring successful adaptation to rapid and unpredictable change yet are one of the least examined and ambiguous aspects of climate change adaptation (O'Riordan and Jordan 1999; Adger 2000; Adger et al. 2005a, b).

Following the works of North (1990) and Ostrom (1990), several facets of institutions have been examined in the literature (Young 2002; Sabatier 2007; Oberthür and Stokke 2011). Recently, of particular interest to scholars are the linkages between institutions, climate change, and adaptation with studies addressing the effects of institutional barriers and constraints on adaptation (Inderberg and Eikeland 2009), the fundamental functions of institutions in facilitating climate change adaptation (Rodima-Taylor 2012), and the institutional requirements for adaptation (Adger et al. 2005a). Yet, despite these works, the research area is still in its infancy, as evidenced by a number of competing frameworks.

To analyze these institutional concerns more effectively, scholars have developed a variety of frameworks to examine the role of institutions in the context of climate change adaptation. These analytical frameworks are differentiated by how they define institutions – in essence, whether they consider institutions as rules, social patterns of behaviors, or organizations. In other words, the types of analysis that can be performed using these frameworks are bound by the frameworks' institutional perceptions.

For example, one framework that focuses on organizational institutions examines the institutional linkages between and among public, private, and civil society institutions and the significance of institutional partnerships in enabling adaptation. It provides a tool to analyze organizational partnerships and the impacts of these associations on the access of vulnerable social groups to resources (Agrawal 2008). Another framework that defines institutions in terms of rules, customs, and norms concentrates on the intrinsic characteristics of institutions in influencing the behaviors of individuals and in fostering collective action. Essentially, this framework deals with understanding and assessing the ability of institutions to raise the adaptive capacity of society (Gupta et al. 2010).

This raises two significant issues. First is the disharmony in defining institutions in the context of climate change. Research has focused on institutions as rules and social structures (O'Riordan and Jordan 1999; Eriksen and Selboe 2012) and also as organizations (Agrawal et al. 2008; Vallejo 2011). Therefore, as climate change research advances, there is a discrepancy on how the concept of institutions is founded. Second is the inability of the frameworks to simultaneously analyze the various facets of institutions. If these gaps are not addressed, it can lead to a divergence in institutional concepts and the direction of research.

To address the first concern, a conceptual framework was developed that defines institutions as a triad of rules, social structures, and organizations in the context of climate change adaptation. Thus, institutions are the commonly known and acknowledged rules, social structures, and organizations founded on common belief systems that transform individual acts and expectations into collective actions; convert personal values into social norms and shared beliefs; and define the formal and informal behavioral systems of human existence. As an extension of this endeavor, this chapter develops an analytical framework that helps to examine the complexity of the triad institutions in climate change adaptation responses.

Institutional interventions formulated and implemented to adapt to climate change bring either conflict or harmony into existing institutions and arrangements (Young 2002; Nilsson et al. 2012). A framework that can be utilized to examine the relationships between and among rule-based, social structure-based, and organizational institutions is useful in planning for and evaluating the effects of these institutional changes. Moreover, the efficiency and success of adaptation responses rest on how they fit in the institutional environment and institutional arrangements that are in place (Theesfeld et al. 2010). Every case has a unique institutional environment or *array of institutions that influence and affect climate change adaptation behaviors and decisions*. Therefore, the institutional fit of the adaptation measures, i.e., *whether adaptive institutional interventions are synchronized or in harmony with the existing institutions*, is vital to effectively implement an adaptation response. The more fitting the adaptive institutions are with the other institutions in the system, the better each institution performs and, thus, the more relevant each one becomes.

This chapter is divided into two major parts. The first establishes the theoretical foundations of the framework by presenting the concept of institutions as rules, social structures, and organizations in the context of climate change adaptation (Institutions in Climate Change Adaptation Planning); examining the concepts of institutional

Table 1 Definition of key terms

Term	Definition
Rule-based institutions	Constraints that structure political, economic, and social interactions and determine decisions, actions, information, payoffs, and actors in various conditions and situations (North 1990; Ostrom 1990)
Social structure-based institutions	Self-sustaining, salient patterns of social interactions (Aoki 2007) that form individual and social expectations, relations, conduct, interactions, and behavior (Agrawal 2008)
Organizational institutions	Structures of power that form the social, economic, legal, and political organizations of a society (O'Riordan and Jordan 1999; Acemoglu and Johnson 2005)
Institutional arrangements	Structures of the rules that govern human decisions (Tang 1991) or the specific guidelines designed to facilitate social interactions (Klein 2000)
Institutional fit	State where the adaptive institutional interventions are synchronized or in harmony with the existing triad of institutions – rules, social structures, and organizations
Institutional interplay	Interactions and reactions between and among institutions that build institutional linkages, relationships, and interdependencies
Functional interdependencies	Relationships built resulting from the interactions among the arrangements that allow institutions to perform their functions
Institutional environment (IE)	Comprehensive inventory of the differing institutions – rules, social structures, and organizations – that may influence adaptation responses
Institutional matrix (IM)	System of institutional arrangements that determines the functional interdependencies of institutions
Institutional environment matrix (IEM) framework	A planning and diagnostic framework designed to analyze institutional environments and determine the institutional fit of climate change adaptation responses

Sources: North (1990), Ostrom (1990), Tang (1991), O'Riordan and Jordan (1999), Klein (2000), Acemoglu and Johnson (2005), Aoki (2007), and Agrawal (2008)

arrangements (Institutional Analysis and Institutional Arrangements); and classifying institutional functions (Institutional Functions). The second part synthesizes these concepts (Institutional Environment Matrix Framework) to form a framework termed as the institutional environment matrix (IEM). In developing the IEM, this paper adopts the definitions established by other authors and develops some new definitions befitting the context in which they are used (Table 1).

Institutions in Climate Change Adaptation Planning

There are varying notions of what constitutes an institution. Institutions are rules, procedures, conventions, and protocols in rational choice, economics, and game theory; moral templates, cognitive scripts, and frames of meaning in sociology and

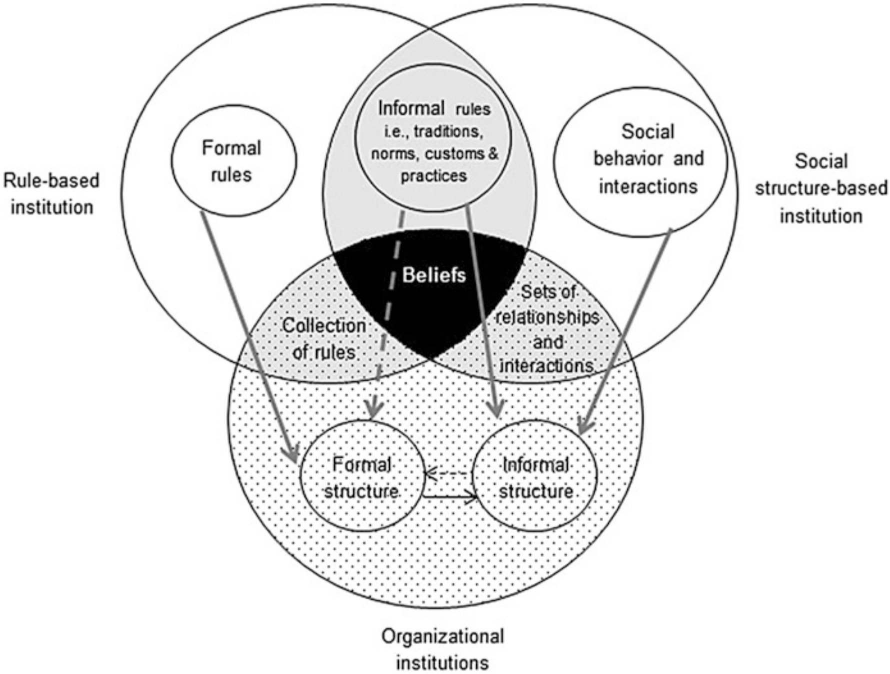

Fig. 1 A conceptual framework for institutions in the context of climate change adaptation (Source: Authors)

anthropology; and organizations in comparative politics and state theory (North 1990; Jordan and O'Riordan 1997; O'Riordan and Jordan 1999; Markvart 2009).

In climate change adaptation, institutions should have a synthesis of definition that has cross-disciplinary relevance. Therefore, institutions are the commonly known and acknowledged rules, social structures, and organizations founded on common belief systems that transform individual acts and expectations into collective actions; convert personal values into social norms and shared beliefs; and define the formal and informal behavioral systems of human existence. Hence, rules, social structures, and organizations are all institutions.

The core relationships among the three forms of institutions are illustrated in the Venn diagram (Fig. 1). Rules, social structures, and organizations are linked through a system of beliefs that allow them to exist and continue to persist as institutions. The beliefs associated with rules and organizations are significant components shaping the self-enforcing expectations, which consequently affect behavior and motivate individual actions (Greif and Kingston 2011). The belief system itself is a part of what constitutes social structure-based institutions (Nelson and Sampat 2001; Nelson and Nelson 2002).

Rule-based and social structure-based institutions are further linked through informal rules. This linkage is shown in the overlap between the spheres representing rule-based and social structure-based institutions (Fig. 1). Together with formal rules, informal rules such as practices, norms, and traditions comprise part of the rule-based institutions.

Formal rules define the hierarchical structure, decision-making powers, contracts, and property rights allocation in the political and economic systems (Pejovich 1995). Meanwhile, informal rules determine individual interactions and are engraved in society's culture and heritage (North 1990; Hasan 2000; Hodgson 2006). These same social patterns of behaviors are the elements that form social structure-based institutions (Nelson and Sampat 2001; Aoki 2007).

The conceptual framework considers organizations as an assembly of rules and contracts that operate through some type of relationship among individuals. This perception interlaces organizations – perceived as a "collection of rules" (March et al. 2011, p. 239) – with the rule-based institutions. Organizations rely on the norms and patterns of behaviors to be implemented (Hodgson 2006), which tie organizations to the social structure-based institutions.

The formal and informal structures of organizational institutions are rationalized by the formal rules and social customs, values, and beliefs, respectively (Meyer and Rowan 1977; Shafritz et al. 2005). Formal rules are the written and legally sanctioned rules, whereas informal rules are represented by the unwritten social patterns of interactions and behaviors (Nabli and Nugent 1989). Formal rules are usually applied, managed, observed, and monitored by formal political, legal, and government institutions. Conversely, informal institutions fall under the private realm (Williamson 2009).

Formal structures have a special relationship with informal rules (illustrated by the broken arrow linking the two factors) (Fig. 1). Formal organizations are created and legitimized by formal rules, whereas the relationships among the members of formal organizations are typically governed by informal rules. Hence, "in every formal organization, there arise informal organizations" (Shafritz et al. 2005, p. 205), thereby forming an additional linkage between formal and informal organizations (indicated by the broken arrow between the two entities). This relationship denotes that informal organizations do not directly affect the structure, composition, or creation of formal organizations. However, informal organizations are defined as collective behaviors (in the form of organized groups of people) that influence the choices and decisions of the formal organizations' members. Meanwhile, formal organizations directly affect informal organizations through the formal rules they implement or the actions they perform (solid arrow in Fig. 1). In essence, "the root of informal systems are imbedded in the formal organization itself and nurtured by the very formality of its arrangements" (Shafritz et al. 2005, p. 205). For example, a formal organization that funds the activities of an informal organization may influence the latter to become formal itself, especially if formality is a requirement to gain further financial assistance. Alternatively, the funds provided may have allowed the informal organization to expand its operations, with the transition to a formal structure being essential to continue these new activities.

This unified definition of institutions is vital in analyzing linkages among climate-adaptive institutions. Climate change impacts include extensive aspects of human existence (i.e., social, economic, political, ecological, and environmental).

Hence an amalgam of ideas from various disciplines befits the concept of institution in the climate change adaptation context. This synthesized definition should be further investigated, particularly in relation to how rules, social structures, and organizational institutions function together in systems where adaptation responses are applied.

Institutional Analysis and Institutional Arrangements

Institutional arrangements are critical to address the climate change challenge as adaptation "never occurs in an institutional vacuum" (Agrawal et al. 2008, p. 2). The success of adaptation practices rests on specific institutional arrangements, such as well-defined property rights that address resource access and risk exposure (Agrawal 2008). For example, building a seawall would not depend only on the physical construction of the structure itself, the costs associated with it, or the science that projects the rate of sea level rise. It also would be affected by the rules governing property (Caldwell and Segall 2007), including the agreements on the allowable height, thickness, and length of the structure; the social norms of the communities affected by the predicted sea level rise and storm surge; and the rights of private property owners. Therefore, developing suitable adaptation responses entails institutional arrangements that enable these measures to be implemented (Rodima-Taylor 2012, p. 12).

Arrangements in Rule-Based and Social Structure-Based Institutions

Institutional analysis assumes that institutional change will affect some areas of reality that already are exposed to existing institutions. Therefore, the environment where the institutional changes (e.g., the creation of new policies or amendments in prevailing regulations) are to be implemented must be understood first before the possible consequences of such changes can be determined (Theesfeld et al. 2010). More importantly, intensive institutional analysis involves understanding the detailed working rules and norms that influence people's decisions (Ostrom 2011).

In **rule-based** and **social structure-based** institutions, these rules exist at three levels, namely, operational rules, collective-choice rules, and constitutional-choice rules (Ostrom 1990). Among the three, constitutional-choice rules are the most extensive. They are the basis of all rules – the set which determines who and what (specific rules) are authorized to create the other levels of rules. Next in the hierarchy are the collective-choice rules – the rules created to resolve conflicts, impose decisions, and formulate or transform operational rules (Ostrom 1990). Essentially, they are the rules which underpin operational rules (Tang 1991). Lastly, operational rules are those that directly influence the daily decisions about who oversees the actions of others and how or who takes part in which situation, what information must be given, what are the participants allowed to do, and what rewards or penalties will be designated to various sets of acts and consequences. Operational rules are typically known as policies (Ostrom 1990).

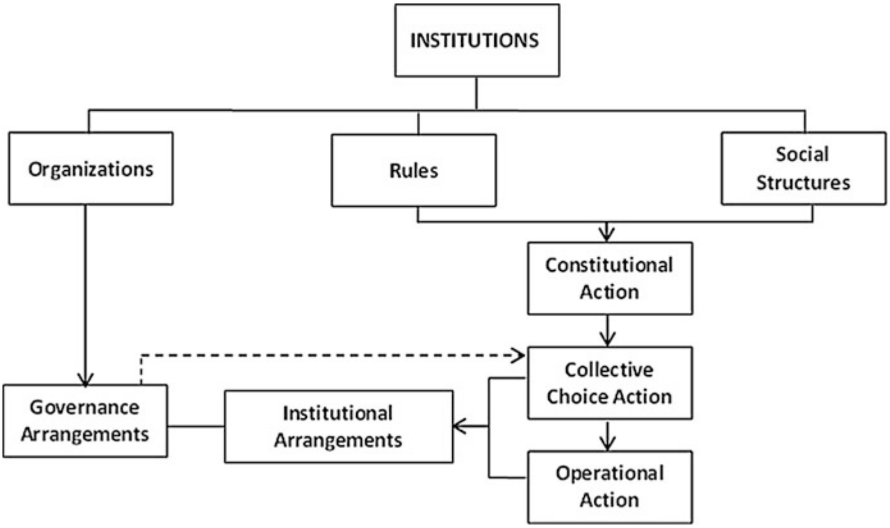

Fig. 2 Institutions and institutional arrangements (Source: Authors)

Ostrom's (1990) classic text, "Governing the Commons," identified specific processes at each level of rules. Operational rules cover appropriation, provision, monitoring, and enforcement; the collective-choice level encompasses policy-making, management, and mediation of policy decisions; and the constitutional level includes formulation, governance, adjudication, and modification of constitutional decisions. Through these rules, institutions are able to affect and influence individual and collective actions. For instance, operational rules, such as those that specify fishing technologies permitted at a particular fishing ground, constrain and predict operational actions. Similarly, collective-choice rules are translated into collective-choice actions and constitutional rules into constitutional-choice actions (Schlager and Ostrom 1992). These levels of rules form the categories of institutions (Feder and Feeny 1991). The constitutional-choice rules comprise the constitutional order, whereas the *collective-choice rules and operational rules constitute institutional arrangements* (Fig. 2) (Feder and Feeny 1991; Tang 1991).

Institutional arrangements are the structure of rules governing human decisions (Tang 1991) or the specific guidelines which facilitate social interactions (Klein 2000). Institutional arrangements are also sets of rules or agreements with a common objective (e.g., contract) that preside over the activities of people. For instance, a group of farmers may enter into an agreement to jointly purchase agricultural inputs or supply products to buyers, thus forming a producer's organization (Eaton et al. 2008). Institutional arrangements likewise identify an individual in relation to others within the group that she/he belongs to, as well as with those outside the group. For example, in property regimes, the property relation between individuals is defined by the interest of one that is protected by virtue of the right and the duty of others to follow the arrangement (Bromley and Cernea 1989). Institutional arrangements, therefore, guide individual behaviors toward collective actions.

Arrangements in Organizational Institutions

In terms of **institutional organizations**, institutional arrangements involve the system of (organizational) units that plan, support, and/or implement programs, practices, and actions. These arrangements include the linkages between and among organizations at different administrative scales (national, regional, state, provincial, and local) or sectors (economic, political, legal, social). They also represent relationships between government and nongovernment units such as households, communities, and civic organizations (Mattingly 2002). As institutions, organizations are governing structures that motivate collective behaviors and actions (Nelson and Sampat 2001; Williamson 2009), while institutional arrangements are the **governance arrangements** (Klein 2000; Kooiman 2008). Institutional arrangements oversee the relationships and interactions between, among, and within groups of individuals and, thus, influence the variability of commitments of institutions to governance (Klein 2000; Andersson and Ostrom 2008). These ideas are significant because they link organizational arrangements to the rule-based and social structure-based arrangements (Fig. 2). To illustrate, policy goals depend on the set of dominant actors and ideas in the area and when these policy debates and decision-making occur. Governance arrangements then determine the aims and the general implementation preferences of policies, regulations, and state-society interactions (Howlett 2009).

Institutional arrangements allow multiple types of linkages between and among institutions (Heikkila et al. 2011). As guidelines, they are the means by which institutional interplay (i.e., in the form of functional interdependencies or consequences of institutional design and management) is implemented (Young 2002). Accordingly, institutional interplay refers to the interactions among institutions that build institutional relationships (Young 2002). Institutional interaction is determined by the impact of one institution on another, thereby exhibiting causation (Gehring and Oberthur 2009; Oberthür and Stokke 2011). Thus, the effect or interaction will not be observed without a stimulus and a receiver. The stimulus is the source institution (independent variable), and the receiver is the target institution or system (dependent variable) (Gehring and Oberthur 2009). For example, an introduced institutional adaptive measure (the independent variable) will interact with the existing institutions in the system (the dependent variable). Institutional interplay, however, is not one directional. Interplay involves functional interdependencies (Young 2002; Linnér 2006) and thus includes mutual influences or effects. Although the interaction may be triggered by a stimulus, the outcomes or institutional linkages are the result of the institutional integration. Therefore, the interplay exists in the . institutional environment comprised of the adaptive institution and the other existing institutions.

Institutional interactions may be complementary, neutral or coexisting, counterproductive, conflicting, or overlapping (Gunningham and Grabosky 1998; Young 2002; Nilsson et al. 2012). In relation to the triad institutional concept introduced in this chapter, institutional linkages encompass relationships within, between, and among laws, policies, regulations, traditions, norms, practices, government units, civic organizations, and community groups, among others. Institutional linkages must be understood to determine how institutions influence adaptation practices and responses (Agrawal 2008). Consequently, institutional functions in the context of this institutional definition should be determined to understand the institutional fit of adaptation responses.

Institutional Functions

Institutions are crucial in promoting successful adaptation to climate change. They influence key decisions in the system, shape the direction of adaptation efforts, frame the adaptive capacities of systems, and enable collective action toward attaining the adaptation goals (Næss et al. 2005; Agrawal et al. 2008; Eriksen and Selboe 2012). Institutions accomplish these tasks through their innate characteristics and the functions they perform.

Institutions, as rules, social structures, and organizations serve the same functions, thus they are interdependent. These institutional functions can be classified into four main types, namely, reducing uncertainty (by forming individual and social expectations), connecting individuals to society, fostering adaptive capacity, and mobilizing resource utilization. These functions are performed by all institutional types, thereby, strengthening the interconnections among these institutions (Fig. 3).

The different characteristics of rules, social structures, and organizations limit their respective capabilities to perform some of these functions. For example, organizations (as a collection of rules and bundles of relationships and interactions) can establish systems of power and authority and identify the people included and excluded from the organization. However, the entirety of organizations, including their characteristic as "actors" (Gupta et al. 2010), constrains the organizations' ability to create rights and entitlements but promotes their capacity to deliver external resources into the system (Table 2).

Reduces Uncertainty

Institutions **reduce uncertainty** by forming individual and collective expectations and by developing a constant structure of social interactions (North 1990; Ostrom 1990; Kirsten et al. 2009; Brousseau et al. 2011). They also provide stability and predictability by *establishing the power and authority systems* (O'Riordan and Jordan 1999; Acemoglu and Johnson 2005; Berman et al. 2012) and *creating rights and entitlements* (Ostrom 1990). Institutions also *identify inclusions and exclusions* by determining which actions are permissible and the conditions by which to undertake certain activities (North 1990; Ostrom 1990; Klein 2000). By outlining constraints, institutions set up the boundaries for each individual and society as a whole (Ostrom 1990). For example, as an institution, property rights form expectations that the claims to the property would be respected and be abided by all, thereby reducing the uncertainty associated to these claims (Bromley and Cernea 1989).

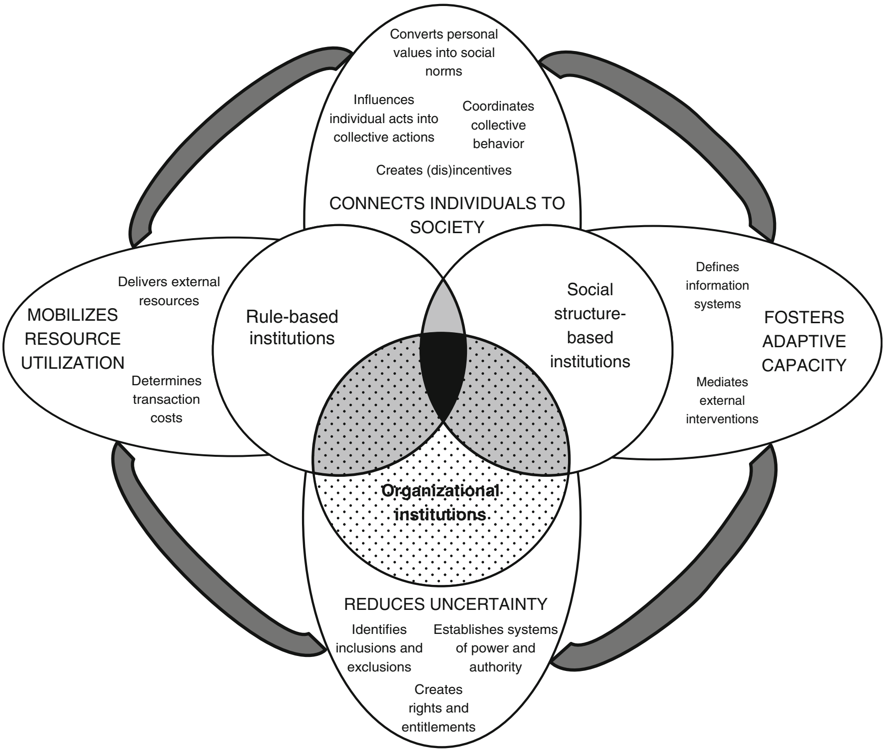

Fig. 3 Functions of institutions (Source: Authors)

Connects Individuals to Society

Institutions **connect individuals to society** by giving everyone a shared identity (Jentoft 2004). They *convert personal values into social norms and shared beliefs* as individuals get emotionally attached and identify with the institutions. This function is specifically attributed to social structures, informal rules, and informal organizations. Thus, institutions become the social standard for understanding and reacting to circumstances, which accordingly become the source of people's compliance and submission to institutions. As such, institutions *influence and transform individual acts and expectations into collective action*s (Kirsten et al. 2009).

Institutions also *create the incentive structure* that determines the actions of people as individuals and as a society (Agrawal 2008). Incentive structures incorporate behavioral patterns that encourage actors to change norms and practices, implement the changes, uphold the changes, and stand by the decisions to change (Biermann 2007; Gupta et al. 2010). Thus, incentive mechanisms enable individuals to choose how to respond efficiently to goals and objectives such as those of climate change adaptation (Young 2002). Conversely, institutions also influence

Table 2 Institutional functions by type of institution

Functions of an institution	Types of institutions					Features/ descriptions
	Rules		Social structures	Organizations		
	Formal	Informal		Formal	Informal	
Reduces uncertainty						
Establishes systems of power and authority	✓	✓	✓	✓	✓	Actors and actions involved in decision-making; who has the authority and what kind of authority
Identifies inclusions and exclusions	✓	✓	✓	✓	✓	Scope and jurisdiction of actors (who) and actions (what) allowed and constrained
Creates rights and entitlements	✓	✓	✓	×	×	Claims, privileges, etc. to resources, i. e., access rights, management rights
Connects individuals to society						
Converts personal values into social norms and shared beliefs	✓	✓	✓	✓	✓	Social principles, beliefs, and philosophies
Influences and transforms individual acts and expectations into collective actions	✓	✓	✓	✓	✓	Plans and programs for collective efforts and actions
Creates (dis) incentives for individual and collective actions	✓	✓	✓	✓	✓	Rewards and penalties; payoffs on actions
Coordinates individual or collective behaviors	✓	✓	✓	✓	✓	Management of multiple efforts

Means of delivery of external resources	×	×	×	✓	✓	Actors facilitating access to outside resources (who and for whom)
Determines transaction costs of activities and decisions	✓	✓	✓	✓	✓	Integration of multiple efforts; internal costs (financial or otherwise)

Sources: North (1990, 1994), Ostrom (1990), O'Riordan and Jordan (1999), Jentoft (2004), Acemoglu and Johnson (2005), Pfahl (2005), Agrawal (2008), Adkisson (2009), Dorward and Omamo (2009), Kirsten et al. (2009), Gupta et al. (2010), Greif and Kingston (2011), and Berman et al. (2012)

behaviors by providing disincentives or penalties to various actions and consequences (Ostrom 1990). Thus, choosing to conform to institutional arrangements becomes attractive.

Institutions are also the *means by which people coordinate their beliefs*, *interactions*, *and activities*, thereby affecting how individuals and society make decisions (Pfahl 2005; Adkisson 2009; Greif and Kingston 2011). For instance, the local governing body in the Carteret Island in Papua New Guinea (i.e., the Council of Elders) organized the voluntary relocation of community households to the main island of Bougainville (Rakova 2009). Labeled as one of the first climate change refugees, the Carteret people were forced to leave their homes due to the accelerated sea level rise and the worsening extreme coastal events in the area (Boano et al. 2008). The Council formed a nongovernment organization, named Tulele Peisa, which designed and administered the Carterets Integrated Relocation Programme (CIRP) (Rakova 2009; Boege 2011). In this case, the organizational institutions such as the Council of Elders and the Tulele Peisa were vital in planning and mobilizing the relocation efforts. The community's norms and traditions authorized the organizations (specifically the Council of Elders) to make decisions for the whole community. Meanwhile, the CIRP guided the people on how to follow through with the community resettlement. Thus, the social and cultural norms, organizations, and formal policies all affect how an individual, a household, and/or a community responds to climatic and other stressors (Young 2002).

Fosters Adaptive Capacity

Institutions are critical in **building the adaptive capacities of systems** (Berman et al. 2012; Pradhan et al. 2012). They *affect information systems* (Dorward and Omamo 2009) and strengthen the ability of vulnerable communities to prepare for the impacts of climate change. They influence the flow of information, the types of studies undertaken, and the interpretations made from the research results (March and Olsen 1996). Moreover, they influence the kind of information to be disseminated (Ostrom 1990) and how this knowledge is disseminated (Agrawal 2008).

Institutions are *mediators of external interventions* that affect how individuals, communities, and social groups utilize assets and resources (Agrawal 2008). Institutions provide leadership, facilitate negotiations, and create networks with other institutions such that external interventions can be systematically filtered, effectively absorbed, accepted, or refused (Agrawal 2008; Rodima-Taylor 2012). For example, a culture of solid community ties suggests an accommodating attitude for external interventions promoting community-based management; but the reverse can be expected if individualism is the norm.

Mobilizes Resource Utilization

In mediating external interventions, organizational institutions are the *means by which the external resources that facilitate adaptation are delivered*, and they accordingly administer access to such resources. These resources may be information, technical inputs, and/or financial support. Institutions "mediate the extent to which climate change affects communities" (Pradhan et al. 2012, p. 9); therefore, they are crucial to the successful implementation of externally facilitated adaptation strategies (Agrawal 2008).

Institutions matter because they *determine the cost of transacting* activities (North 1994) and are comprised of "transaction-cost–reducing arrangements" (Kirsten et al. 2009, p. 43). Transaction costs pertain to the costs incurred from the activities that lessen the risk of transaction failure such as planning, negotiating, creating, monitoring, and enforcement of an agreement. These also include the costs of maladaptation, bargaining, and other operations related to governance and securing the commitment of actors to the contracts (Kirsten et al. 2009). Institutions will fail to reduce transaction costs if the institutional context where the transactions take place is in disarray (Theesfeld et al. 2010).

Similarly, a weak institutional environment, specifically in terms of legal frameworks, makes it difficult to enforce contracts and agreements that exchange goods and services and to coordinate activities (Eaton et al. 2008). The norms and practices existing in the system also affect the cost of transactions. For example, if bribery is the custom, then people may bribe corrupt law enforcers to accomplish their goals. Costs would include resources (e.g., money, time, and people) in bribing transactions plus the regular expenses incurred in undertaking such tasks. If the rule of law is upheld, then bribing will be useless and the associated costs will not exist. Likewise, if cheating is the norm, then there will be additional costs to prevent other parties from cheating. The effectiveness and efficiency of actions and activities depend on the institutional environment and arrangements in place.

Interdependencies and linkages among institutions occur through these functions. These associations are the product of the interactions between and among institutional arrangements (Young 2002). In this sense, functional interdependencies can be defined *as the relationships between institutions resulting from the interactions among arrangements that allow institutions to perform their functions*. These linkages are explored in the IEM framework that analyzes the institutional environment in adaptation responses.

Institutional Environment Matrix Framework

The proposed framework incorporates two layers, the **institutional environment** (**IE**) **and institutional matrix** (**IM**) (Fig. 4). The institutional environment focuses on a specific type of system, a particular adaptation goal, or a type of adaptation strategy. It is a *comprehensive inventory of the differing institutions – rules*, *social structures*, *and organizations – that may influence adaptation responses*. This layer assumes that examining the institutional environment in assessing and planning for climate change adaptation responses is a significant feat. For instance, the coastal management and governance arrangements in the East of England showed that there exist:

> three central government departments, four regional bodies, five statutory agencies, four ad-hoc groupings, seventeen local authorities, and four forums with an interest in coastal planning, but not necessarily working together. . .. five sets of overlapping plans, fourteen designations of coastal sites and landscapes, a mix of management bodies, many organizational cultures, un-coordinated organizational activity at different scales, and overlapping jurisdictions, responsibilities and functions. (Nicholson-Cole and O'Riordan 2009, p. 373)

Analyzing or planning for adaptation responses incorporates an exhaustive assessment of the institutional environment in which these responses have been or will be applied. This is important in institutional analysis because the number of institutions in a given system is directly related to the rate and complexity of the institutional linkages (Young 2002).

The institutional matrix (IM) can analyze the interactions among the arrangements. It is defined as the *system of institutional arrangements – including operational and collective-choice rules and governance arrangements – that determines the functional interdependencies of institutions*. This layer examines the various

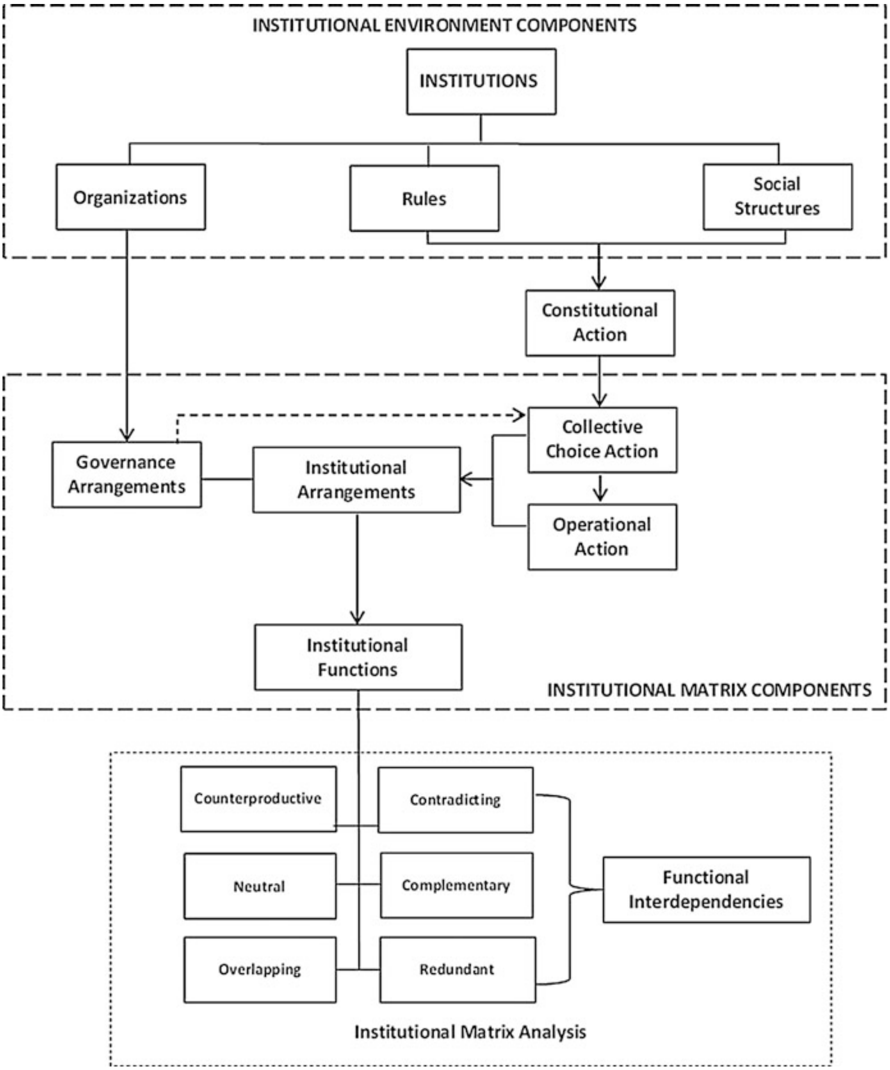

Fig. 4 Institutional environment matrix (IEM) framework (Source: Authors)

relationships among the institutions and assumes that institutions affect an adaptation response via the institutional arrangements that enable institutions to perform their functions.

The IE and the IM stages are closely linked, such that the IM is dependent on the information provided by the IE. This relationship, however, is one directional. Significant IE analyses can be done even without proceeding to the IM level, but the reverse is not possible.

Various institutional interactions, like complementary, neutral, and counterproductive relationships, are realized from the IM layer. Complementary interaction indicates beneficial associations such that institutions perform better because of the creation or existence of the other (Gunningham and Grabosky 1998). Conversely, counterproductive interactions result when institutional arrangements either destabilize or weaken one another, thus impeding the ability of institutions to perform their functions effectively. Neutral interaction suggests that institutions just simultaneously exist in the institutional environment without interacting with each other. The institutions neither improve nor worsen each other.

Contradicting relationships arise when institutions are mismatched, thereby creating situations in which institutional arrangements are not attuned with each other. This institutional linkage forms tensions and conflicts among institutions and the corresponding elements that function within these institutions (Nicholson-Cole and O'Riordan 2009). Overlapping associations involve disputes in jurisdictions (Davis 2006), especially when institutions have similar mandates (Aggarwal 2005). Institutional overlaps are common and more significant in a high-frequency institutional environment where there is a high density of institutional arrangements operating in a single system (Young 2002). Lastly, redundancy signifies complete duplication of all institutional functions (Fig. 3).

All the relationships, except redundancy, may exist in a single or multiple types of institutional functions. Policy 1 may be counterproductive with Policy 2 in establishing systems of power and authority but may be complementary in creating incentives for individual and collective actions. Likewise, there might not be any connection (neutral) between the two on defining information systems on climate change and adaptation. These linkages can be thoroughly examined using the institutional matrix analysis, which is further explained in the succeeding sections.

Institutional Environment (IE)

The IE layer (Table 3) is comprised of formal rules (FR), social structures (SS), formal organization (FO), and informal organization (IO). Formal rules represent the written laws, policies, and regulations, whereas social structures are the traditions, norms, and practices affecting social collective behaviors. This framework incorporates informal rules in the social structure-based institutions, following the notion that they are linked. Formal organizations are the groups legitimized by the formal rules, whereas the informal organizations are those sanctioned by informal rules. The institutions comprising the IE may have been created to address a variety of issues, some of which may not be related to climate change. These rules, social structures, and organizations have particular arrangements that can affect climate change adaptation decisions, hence their inclusion in the IE. Take the case of Carteret climate change refugees.[1] The adaptation response – community relocation – involves property institution and property right arrangements, both of which have been existing and working in the systems long before climate change concerns emerged.

Table 3 Institutional environment framework layout

Institutional systems: complex system/adaptation response	Institutional environment			
	Formal rules (FR)	Social structures (SS)	Formal organizations (FO)	Informal organizations (IO)
	FR1	SS1	FO1	IO1
	FR2	SS2	FO2	IO2
	FR3	SS3	FO3	
	FR4			

Source: Authors

In this hypothetical case (Table 3), the institutional framework identifies four formal rules (FR1, FR2, FR3, FR4); three social structures (SS1, SS2, SS3); three formal organizations (FO1, FO2, FO3); and two informal organizations (IO1, IO2) that affect the adaptation response. All types of institutions are included in this layer regardless of scale. For example, FR1 may be a national program, FR2 a regional regulation, and FR3 and FR4 local policies. This is possible because the IE layer assumes that the institutions existing in various scales may simultaneously affect (or be affected) by the same adaptation response(s) through their arrangements. These institutional arrangements cut across differing scales, and they structure the relationships and functional interdependencies of institutions. The arrangements associated with each institution are critical in determining the extent of the institution's influence in the decision-making process (Fig. 5).

For instance, the Environmental Protection Act 1994 (EP Act) – an act primarily concerned with environmental pollution in the state of Queensland, Australia – can influence local authorities' responsibilities and decisions. Though a state law, the EP Act specifies the responsibilities of local governments in notifying administering authorities of violations at the local level (EP Act, Part 8 [2]). (Commonwealth of Australia 1994).

Thus, the IE layer is composed of all institutions that may affect climate change adaptation, regardless of the scale at which the institution primarily operates. In contrast, the institutional matrix layer is limited to a single scale analysis – only those institutional arrangements that cover the scale (federal/national, state/regional/territory, provincial/local) being analyzed will be examined. In the previous hypothetical case (Table 3), while FR1 is a national program and FR2 is a regional regulation, only those arrangements affecting the local scale will be included in the matrix if the scale of analysis is local. These notions are further elaborated below.

[1]People were forced to leave their homes and resettle elsewhere because of climate change-related events.

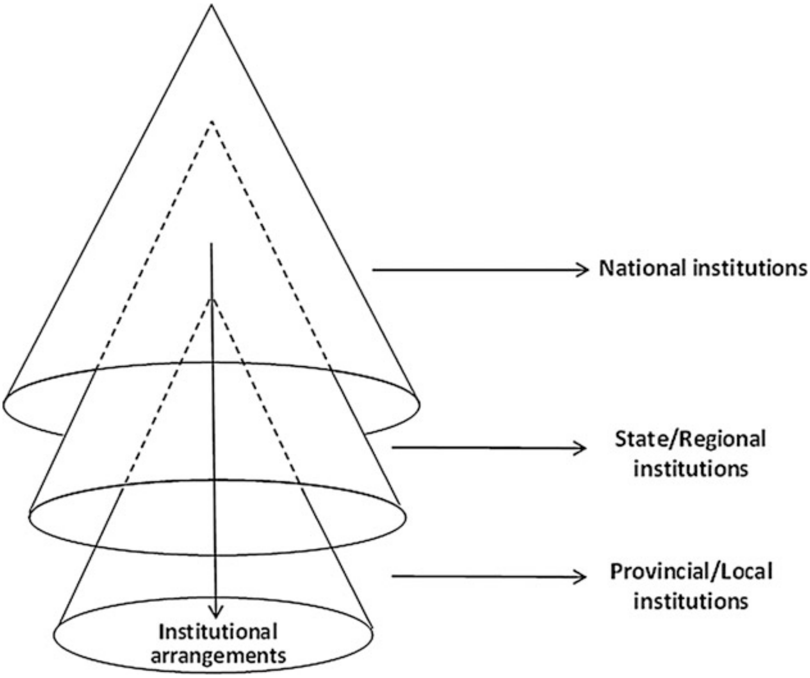

Fig. 5 Multilayered institutional linkages (Source: Authors)

Institutional Matrix (IM)

From the IE, the analysis progresses to the individual institutional arrangements in the institutional matrix (IM). The IM is dependent on the set of information provided by the IE stage, and those institutions identified in the environment are incorporated in the matrix (Table 4). In this hypothetical case, the IM analysis focuses on the local scale.

The functions are the source of interdependencies among institutions, which are vital elements of the IM layer. Institutional interplay is observed by analyzing the institutional arrangements that shape these functions. With this, the institutional functions compose the row headings, and they are the categories by which the institutional arrangements are organized in the IM cells.

Framework Analyses: Vertical and Horizontal

The framework offers two types of analyses – vertical and horizontal. Vertical analysis (Table 5) shows the influence of individual institutions on the adaptation response by examining each institution's function. As the hypothetical case has a local scale, only local arrangements will be included in the matrix. The vertical analysis of the formal rules indicates that the national program (FR1) incorporates

Table 4 Institutional matrix (IM): an institutional framework for adaptation analysis

FUNCTIONS OF AN INSTITUTION	TYPES OF INSTITUTIONS											
	Formal Rules (FR)				Social Structures (SS)			Formal Organizations (FO)			Informal Organizations (IO)	
	FR1	FR2	FR3	FR4	SS1	SS2	SS3	FO1	FO2	FO3	IO1	IO2
Reduces uncertainty												
Establishes systems of power and authority												
Identifies inclusions and exclusions												
Creates rights and entitlements												
Connects individuals to society												
Converts personal values into social norms and shared beliefs												
Influence and transforms individual acts and expectations into collective actions												
Creates (dis)incentives for individual and collective actions												
Coordinates individual or collective behaviors												
Fosters adaptive capacity												
Defines information systems												
Mediates influence of external interventions												
Mobilizes resource utilization												
Means of delivery of external resources												
Determines transaction costs of activities and decisions												

Notes: The function "creates rights and entitlements" does not apply to organizations, while the function "means of delivery of external resources" does not relate to formal rules and social structures. The cells are shaded accordingly.

local arrangements that establish systems of power and authority, identifies inclusions and exclusions, influences and transforms individual acts and expectations into collective actions, coordinates individual or collective behaviors, and defines information systems. The regional regulation (FR2) performs the same tasks in addition to determining transaction costs of activities and decisions. The IM vertical analysis also outlines the dominant institution in the institutional environment. In the example, the local policy FR3 is the most influential among all four formal rules (Table 5).

An empty cell signifies that the institution does not perform the associated function at the specific scale in question. However, this does not imply that the institution does not implement the function at all. For example, FR1 may not create rights and entitlements at the local scale but may have such arrangements in either the national or regional scales. This aspect is the major difference between the IE and IM layers. Although cross-scale investigation is possible in the IE, this cannot be done in the IM. Overall, the vertical analysis shows the extent of the institution's influence on the adaptation response. It also compares its functions across institutions in a specific scale.

The horizontal analysis is more complicated as it studies the functional interdependencies of institutions and assesses the relationships across various institutions based on their functions. In the hypothetical case (Table 6), the institutional linkages of all 12 institutions are illustrated in relation to the function "establishes systems of power and authority." The cells in red are negative relationships,

Source: Authors

specifically counterproductive and contradicting. Conversely, the green cells are positive associations, particularly the complementary type. Neutral and overlapping relationships are white and yellow, respectively. With regard to structuring power and authority systems, some of the possible interpretations of the matrix are as follows:

1. Formal rules generally have negative relationships with informal organizations.
2. Informal organizations are in harmony with the social structures.
3. Formal organizations typically have overlapping jurisdictions with one another.
4. Informal organizations typically have overlapping jurisdictions with one another.
5. Formal rules are generally counterproductive or contradictory to social structures.
6. The national program, FR1, has relationships only with social structures and other formal rules. It does not affect organizations, whether formal or informal.
7. The national program, FR1, contradicts with the regional regulation, FR2.
8. The national program, FR1, complements the local policy, FR3. As the national program and the regional regulation have a negative relationship, it is consistent that FR2 and FR3 are also contradicting each other. Thus, the regional regulation has a negative linkage with all other formal rules.
9. Local policies FR3 and FR4 overlap.
10. Both local policies are not attuned with the existing local norms, SS2, but are neutral to the local practices, SS1 and SS3.

Other assessments can be gleaned from this example. This type of analysis can be duplicated to the other functional classifications, thereby creating the overall assessment of the linkages between and among institutions. The matrix, thus, enables a planner or analyst to structurally examine complex institutional relationships, thus, possibly effectively evaluate and plan adaptation responses to climate change.

Conclusion

Institutions in climate change encompass rules, social structures, and organizations. The institutional dimension of climate change adaptation involves an intricate web of relationships between and among these institutions. In analyzing the complexity of institutions, a number of factors need to be considered such as institutional functions and interplay, as well as issues of scale (national, state, regional, and local) and jurisdiction. Thus, a purpose-built framework that can perform these kinds of analysis, such as the institutional environment matrix (IEM) framework, is needed.

The IEM adopts a dual-layered approach in examining the various institutions that directly or indirectly influence adaptation decisions and responses in a particular system. Institutions are intrinsically complex; hence a single layer analysis cannot cover the intricacies involved in an institutional analysis. Furthermore, this design allows institutions to be examined across scales and provides an easy transition toward a single scale analysis.

The dual layer design of the IEM allows the institutional environment and arrangements to be extensively studied. The IE layer includes all kinds of institutions in the environment regardless of scale, identifies the dominant institutions in the system affecting adaptation responses, and outlines the complexity of institutions in the institutional environment. Meanwhile, the IM layer enables a scale-focused analysis by dealing with particular institutional arrangements. The matrix allows for complex analysis of institutional linkages and interactions through the vertical and horizontal analytical approaches. By using these techniques, the functional interdependencies of institutions can be identified and institutional interplay can be explored.

The institutional dimension of climate change adaptation is motivated by the need to design or redesign arrangements to address the risks and impacts of climate change (Young 2002). Accordingly, the IEM framework helps identify whether the existing institutions hinder effective adaptation, especially when there are negative relationships among the institutional arrangements. This condition may warrant modifying or replacing the arrangements such that institutions will fit more effectively in the institutional environment. When new institutions need to be introduced into the system, the IEM framework may be useful in developing arrangements that will be compatible with the existing ones. This will help avoid mismatches among institutions and thus minimize conflicts.

This chapter has outlined a theoretical tool that can be used in adaptation planning and evaluation. However, the real value of the framework lies in its applicability in empirical cases. The need for further research in this area is vital.

Abstract

In recent years the population of the Hindu Kush Himalayas (HKH) has been confronted with rapid social, economic, demographic, and political changes. In addition, the region is particularly vulnerable to climate change. However, there is a scarcity of cohesive information on the state of the environment and on the socioeconomic situation of the approximately 210 million people who reside in the HKH. Specifically, data on livelihood vulnerability and responsive behavior is lacking. To address this gap the International Centre for Integrated Mountain Development (ICIMOD) has developed the *Vulnerability and Adaptive Capacity Assessment* (VACA), a research tool to explore livelihood vulnerability to environmental and socioeconomic change as well as adaptive capacity in the mountain context. As part of the *Himalayan Climate Change Adaptation Programme* (HICAP), ICIMOD has carried out a representative quantitative survey that interviewed about 6,100 households in three sub-basins in the HKH region: the Upper Indus sub-basin in Pakistan, the Eastern Brahmaputra sub-basin in India, and the Koshi sub-basin in Nepal. The chapter discusses the operationalization of vulnerability in the VACA questionnaires, the research design of the VACA survey, and first findings for the three sub-basins.

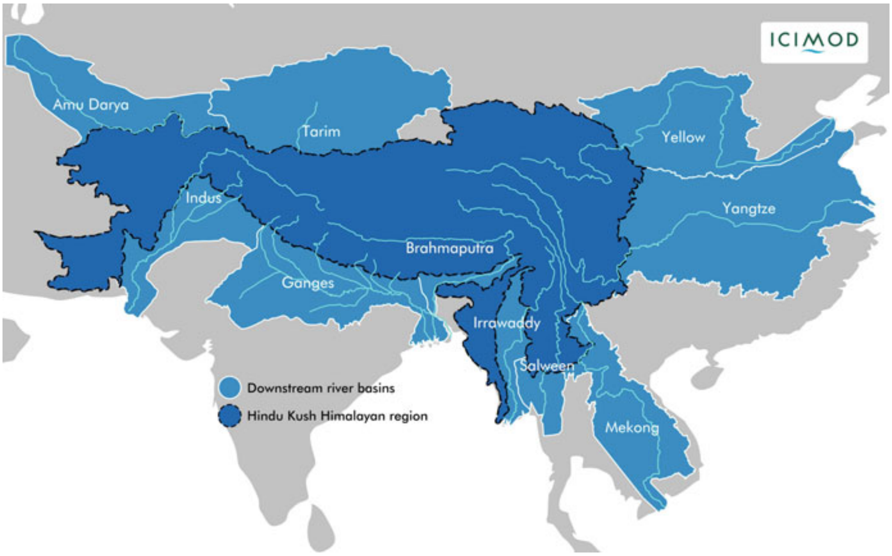
Hindu Kush Himalayas • Climate change • Livelihood vulnerability assessment • Survey research

Introduction

The Hindu Kush Himalayan (HKH) region extends across parts of eight countries: Afghanistan, Bangladesh, Bhutan, China, India, Myanmar, Nepal, and Pakistan (see Map 1). It is one of the poorest areas of the world: almost one-third of its approximately 210 million people lives below the absolute poverty line (Hunzai et al. 2011; Gerlitz et al. 2012). A significant proportion of mountain people reside in difficult terrains, far from the centers of commerce and power, and exert little influence over the policies and decisions that influence and shape their lives (Khalid and Kaushik 2008).

In recent years, the population of the HKH region has been confronted with rapid social, economic, demographic, and political changes. In addition, the region has experienced rapid environmental changes, and it is widely believed that the HKH region will be one of the planet's hot spots of future climate change impacts (Maplecroft 2011). Like other mountain regions, the Hindu Kush Himalayas have experienced above-average warming (IPCC 2007; Nogues-Bravo et al. 2007), which has led to glacial retreat, area reduction, and negative mass balance (Yao et al. 2012). The glaciers are important sources of water for springs and rivers, particularly during the dry season. The contribution of snowmelt to the runoff of major rivers varies from 10 % in the Eastern Himalayas to 60 % in the Western Himalayas (Vohra 1981). A modeling study by Immerzeel et al. (2010) simulated a



Map 1 The Hindu Kush Himalayan region (Source: ICIMOD)

mean decrease in upstream water supply between the periods 2000–2007 and 2046–2065 of 8.4 % for the Upper Indus, 17.6 % for the Ganges, 19.6 % for the Brahmaputra, and 5.6 % for the Yangtze. The cascading of effects from high- to low-altitude areas implies that impacts will be greater at lower elevations, e.g., increased runoff at high altitude could lead to floods and increased sand deposition on agricultural land at lower altitudes (Tse-ring et al. 2010). However, available studies are limited to isolated parts of the HKH region and may not be representative of the region as a whole (for detailed discussion of changes in temperature pattern for the Hindu Kush Himalayan region, see Eriksson et al. 2009; Xu et al. 2009; Shrestha and Devkota 2010). A lack of notable trends is observed in most of the precipitation studies in the HKH region (Shrestha et al. 2000; Shrestha 2009; Dimri and Dash 2011). In the Eastern Himalayas, climate change impacts are manifested in loss and fragmentation of habitat, reduction in forest biodiversity, degradation of wetland and riverine island ecosystems, decline in forage and fodder resources, reduction in agrobiodiversity, increase in forest fires, soil fertility degradation, changes in land use pattern, and increased variability in agricultural productivity (Tse-ring et al. 2010). Mountain communities and their livelihoods are sensitive to such changes, which will have a variety of impacts on human well-being. Nonetheless, there is a scarcity of data on the state of the environment in the Hindu Kush Himalayan (HKH) region, on the socioeconomic situation of its residents, and specifically on livelihood vulnerability to environmental and socioeconomic change and associated responsive behaviors. To address this gap, the International Centre for Integrated Mountain Development (ICIMOD) has developed the *Vulnerability and Adaptive Capacity Assessment* (VACA), a household survey to explore vulnerability and adaptive capacity in mountain contexts.

As part of the *Himalayan Climate Change Adaptation Programme* (HICAP), ICIMOD has carried out a representative quantitative study interviewing about 6,100 households of almost 280 settlements in three sub-basins in the HKH region: the Upper Indus sub-basin in Pakistan, the Eastern Brahmaputra sub-basin in India, and the Koshi sub-basin in Nepal. The aim of this survey was to assess livelihood vulnerabilities to environmental and socioeconomic changes, drivers of vulnerability, and the capacities of the people of the HKH region to adapt to these changes. It is intended that the VACA will help to identify and promote adaptation actions and strategies at the community level, enable the mapping of target areas and groups for interventions, and serve as a baseline for further in-depth studies.

The following sections describe the operationalization of vulnerability in the VACA questionnaires in the form of the Multidimensional Livelihood Vulnerability Framework for the HKH region, document the research design of the VACA survey in the three sub-basins, and discuss some first findings on exposure and coping mechanisms.

Theoretical Background: The Operationalization of Vulnerability in the VACA Tool

The Concept of Vulnerability

While the term "vulnerability" is used widely in development and adaptation contexts, there is no standard definition of vulnerability, and usage of the term varies considerably. Nonetheless, definitions of vulnerability tend to fall into two categories. The first category draws on the natural hazards literature and defines vulnerability as a function of the internal characteristics of a population or system that mediate the extent to which that population or system experiences harm as a result of exposure to an "external" *hazard* (Wisner et al. 2004). In this formulation, the risk of an undesirable outcome (e.g., a complex disaster) is a function of and results from the interaction of hazard and vulnerability. While this conceptualization of vulnerability may include local geographical and environmental factors that mediate risks/outcomes, it is strongly rooted in social and political processes and tends to take an actor-oriented approach (Wisner et al. 2004; Cannon and Müller-Mahn 2010; Miller et al. 2010). The vulnerability of a system to hazards associated with environmental change is linked with the wider political economy of resource use (Adger 2006). Generally, this approach tends to adopt socially defined scales, namely, household, community, and region (Miller et al. 2010).

The second category is associated to a large extent with the Third and Fourth Assessment Reports (TAR and AR4 respectively) of the Intergovernmental Panel on Climate Change (IPCC 2001, 2007), whose glossaries define vulnerability as:

> The degree to which a system is susceptible to, or unable to cope with, adverse effects of climate change, including climate variability and extremes. Vulnerability is a function of the character, magnitude, and rate of climate variation to which a system is exposed, its sensitivity, and its adaptive capacity. (IPCC 2001, p. 995, 2007, p. 883).

Put more simply, the IPCC definition views vulnerability as a function of *exposure*, *sensitivity*, and *adaptive capacity* (Hahn et al. 2009). It differs from the natural hazards approach in viewing vulnerability as a function of both "internal" factors (sensitivity and adaptive capacity) *and* "external" factors (exposure to shocks and stresses). The latter are the various climate hazards associated with climate change and variability to which a system or population is exposed. The IPCC defines exposure as "the nature and degree to which a system is exposed to significant climate variations" (IPCC 2001, p. 987) and sensitivity as "the degree to which a system is affected, either adversely or beneficially, by climate related stimuli" (IPCC 2001, p. 993). Adaptive capacity is defined as "the ability of a system to adjust to climate change (including climate variability and extremes) to moderate potential damages, to take advantage of opportunities, or to cope with the consequences" (IPCC 2001, p. 982).

In fact, the IPCC definition of vulnerability is structurally similar to the natural hazards definition of risk; the IPCC essentially replaces the term "risk" with "vulnerability" and the term "vulnerability" with sensitivity. The "character, magnitude, and rate of climate variation to which a system is exposed" takes the place of hazard, and the concept of adaptive capacity is added to address the fact that many manifestations and impacts of climate change will unfold over time-scales that are long enough for people to anticipate, plan for, and respond to these changes.

In its recent SREX report, the IPCC (2012, p. 32) defines vulnerability as "the propensity or predisposition to be adversely affected" and describes exposure and vulnerability as the determinants of risk. While the IPCC Fifth Assessment Report (AR5) has not been released at the time of writing, this suggests that the IPCC may be moving away from the definition of vulnerability in the glossaries of the previous two assessment reports and toward the more established natural hazards definition of vulnerability as a component of risk.

Nonetheless, this most recent IPCC definition of vulnerability is very vague. This may signify a desire on the part of the authors to accommodate multiple ways of defining and treating vulnerability, recognizing the diverse ways the concept has been used in the climate change literature, without contradicting the earlier IPCC glossary definition.

For the operationalization of vulnerability in the VACA questionnaire, the definition in the glossaries of the IPCC TAR and AR4 is used. This definition has been widely adopted and has been used to frame a growing number of studies that range from local-scale studies with the unit of analysis being the household (Eakin and Bojórquez-Tapia 2008; Pandey and Jha 2011; Notenbaert et al. 2012; Sonwa et al. 2012) to global-scale studies that examine the relative vulnerability of individual countries (Yohe et al. 2006a, b; Allison et al. 2009). Other studies apply this approach at the national or subnational scale to analyze the relative vulnerability of individual states or districts (O'Brien et al. 2004; Brenkert and Malone 2005; Malone and Brenkert 2008). Common to all these definitions are the key concepts of exposure, sensitivity, and adaptive capacity (Miller et al. 2010). While recognizing the diverse and evolving definitions of vulnerability in the literature, the authors choose to use the widely recognized IPCC TAR/AR4 definition, reflecting its widespread adoption by researchers and practitioners in recent years.

Mountain Specificities

Mountain regions are characterized by a variety of specific features that have to be taken into account if one wants to measure vulnerabilities in the HKH region. These *mountain specificities* on the one hand enable human activities and on the other constrain such activities (Jodha 1992, 1997, 2001; Körner et al. 2005). "Enabling features" include a high diversity of resources, species, and cultures, as well as diverse niches for specific livelihood activities and products, associated with a great range of human adaptations. "Constraining factors" include environmental and social fragility, marginality, and limited accessibility. Within the mountain specificities framework, inaccessibility captures all elements of distance and mobility as well as the availability of risk management options. Marginality is defined as the lack of social and political capital, which often results in difficulties in securing tenancy rights over land and in gaining access to social services such as credit, education, and health. Fragility is understood as the diminished capacity of a social or ecological system to manage shocks. The social dimensions of fragility in the mountains occur due to scarce, scattered, and periodically unavailable livelihood resources. Ecological fragility is linked with low carrying capacities coupled with topography (slope and relief). On the other hand, the concepts of diversity, niche, and adaptive capacity seek to capture different coping abilities and strategies that emerge from the natural resource management patterns, livelihoods, and cultural practices of a given community.

Mountain areas are challenging and demanding living spaces, and mountain communities have a long history of adapting to extreme conditions. Nonetheless, traditional adaptation mechanisms are often insufficient to cope with recent socioeconomic and environmental changes (Jodha 1997), which have considerably increased the challenge for mountain people to secure their livelihoods (O'Brien and Leichenko 2000). In developing countries, economic development in mountain regions already lags behind that of lowlands, foothills, and urban areas (Tanner 2003; Barrera-Mosquera et al. 2010). Climate change is expected to exacerbate existing challenges faced by mountain people and their environments, to intensify some existing hazards, and to result in the emergence of new hazards (Sonesson and Messerli 2002; O'Brien and Leichenko 2000; Macchi and ICIMOD 2010). These processes will intensify the exposure component of vulnerability. The sensitivity component will include environmental aspects embedded in the biophysical features of a region and social elements that are closely linked to the nature and range of available livelihood options (Jodha 1997) as well as the access to resources (Adger and Kelly 1999; Brooks and Adger 2005; Macchi et al. 2011).

The Multidimensional Livelihood Vulnerability Framework for the HKH Region

For the operationalization of vulnerability in the VACA questionnaire, the authors follow the precedent established by a number of recent studies, as discussed above, and use a framework based on the established IPCC definition of vulnerability, in which vulnerability is defined as a function of *exposure*, *sensitivity*, *and adaptive capacity* (IPCC 2007), the relationship between which is defined as follows:

$$\text{Vulnerability} = f\,(\text{Exposure} + \text{Sensitivity} - \text{Adaptive capacity})$$

Within this framework, the authors use household-level indicators to capture key socioeconomic drivers of sensitivity, aspects of adaptive capacity, and the extent to which households have been exposed in recent years to evolving environmental hazards that are likely to be influenced by climate change, as well as socioeconomic hazards. Sensitivity is viewed as a factor that makes people or systems more likely to experience harm when exposed to a hazard or stress (i.e., the focus is on the negative aspects of sensitivity, with any “positive” aspects of sensitivity that allow people to recognize and respond to changes in a timely manner being associated with adaptive capacity). Adaptive capacity is a quality that allows people and systems to increase their ability to cope with external (e.g., climate) stresses and hazards and to expand the range of conditions under which they can sustain themselves and their livelihoods. Adaptive capacity thus reduces vulnerability to hazards that recur or unfold over periods of sufficient duration to allow people and systems to respond and adapt to change (Brooks 2003).

To estimate the vulnerability of a “system” (e.g., an individual, household community, district, or country), it is necessary to identify the factors that contribute to the three elements of exposure, sensitivity, and adaptive capacity and capture these factors using indicators. These indicators can then be combined to create a composite vulnerability index.

Here the authors build on the methodology developed by Hahn et al. (2009), who developed a *livelihood vulnerability index (LVI)* that focuses on quantifying the strength of current livelihood systems and the capacity of communities to alter livelihood strategies in response to climate-related exposures. The LVI combines the sustainable livelihoods approach (Chambers and Conway 1992; Scoones 1998) with the measurement of vulnerability as defined by the IPCC. Rather than taking a model-driven, impacts-based approach to the measurement of vulnerability, the LVI uses primary data from household surveys. The LVI consists of seven major components: sociodemographic profile, livelihood strategies, social networks, health, food, water, natural disasters, and climate variability. Each of these major components comprises a number of indicators or subcomponents and is associated with one of the elements of vulnerability (i.e., exposure, sensitivity, or adaptive capacity).

This LVI framework has been adapted to a mountain context for application to the HKH region, reflecting the need to address the *mountain specificities* discussed.

The resulting Multidimensional Livelihood Vulnerability Framework for the HKH region (MLVF-HKH) incorporates indicators that are relevant in mountain contexts, such as physical accessibility, environmental stability, and social networks which refer to the constraining characteristics inaccessibility, fragility, and marginality. It also addresses the fact that climate change will not act in isolation from other stresses by taking into account economic shocks (e.g., unemployment or the failure of a business). The MLVF-HKH forms the basis of the VACA questionnaire. To operationalize the MLVF-HKH, its subdimensions were broken down into measurable indicators. These indicators are captured by specific questions within the VACA questionnaires. Table 1 gives an overview of the main dimensions, subdimensions, and indicators of the MLVF-HKH.

Research Design: The Implementation of the VACA Survey

The Survey Instrument

The *Vulnerability and Adaptive Capacity Assessment* (VACA) research tool consists of a settlement and a household questionnaire. The *Multidimensional Poverty Assessment Tool* (MPAT), created by IFAD (see Cohen 2009), provided a conceptual basis for the development of these questionnaires, while the structure and content of the questionnaires is based on the MLVF-HKH described above. The VACA questionnaires also incorporate elements from the *Vulnerability Assessment Mapping* (VAM) survey created by the World Food Programme (WFP) and the *Nepal Living Standard Survey* 2002/2003 (NLSS). These elements provide the questions for the sections on household food and nonfood consumption and accessibility, respectively. The thematic areas covered by the VACA include household consumption, food security, water security, health and health care, access to basic facilities, accessibility, housing, education, assets, exposure to shocks, medium-term climatic and environmental changes, and coping behavior. The VACA questionnaires were piloted by local partner institutions in India, Nepal, and Pakistan. Feedback was used to tailor the tools to local contexts and the practical requirements of surveys.

Study Site Selection

The Himalayan Climate Change Adaptation Programme (HICAP) focuses on the three major river basins of the HKH: the Indus basin, the Ganges basin, and the Brahmaputra basin. The three basins were selected based on expected significant impacts that climate change will have there. The selected basins show different degrees of dependency on meltwater from snow and glaciers (Vohra 1981), which is crucial if one wants to analyze the impact of global warming on snow and glaciers as well as the associated downstream implications.

Table 1 Multidimensional Livelihood Vulnerability Framework: dimensions, subdimensions, and indicators

Main dimensions	Subdimensions	Indicators
Adaptive capacity	Sociodemographic status	Dependency ratio
		Educational attainment of HH head
	Access to resources	Agricultural land per head
		Livestock per head
	Livelihood strategies	Primary sector livelihood diversity
		Secondary and tertiary sector livelihood diversity
		Yearly amount of remittances per head
		Cash crops diversity
	Social networks	Political influence on the local level
		Ease to borrow money
	Physical accessibility	Time to reach the next market center
		Time to reach the next hospital
		Time to reach the next bus stop
Sensitivity	Well-being	Total per head consumption
		Communication and transport assets
		Affordability of health care
		Extent of indebtedness
	Health and sanitation	Frequency of serious illnesses
		Access to improved sanitation
		Access to improved source of drinking water
		Perceived quality of drinking water
	Food security	Food self-sufficiency
		Months HH had sufficient food
		Food crops diversity
		Diet diversity
	Water security	Time to reach primary water source
		Months of water sufficiency for HH needs
		Severity of water conflicts
		Months of water sufficiency for crops and livestock
	Coping strategies	Short-term livelihood diversification coping strategies implemented
		Average time to recover from shocks in relation to combined severity
		Medium-term coping strategies implemented
	Environmental stability	Majority of agricultural land flat or sloping
		Majority of agricultural land irrigated land
		Quality of soils of majority of land
		Quality of wall material of dwelling
		Degree to which dwelling can withstand extreme weather events

(*continued*)

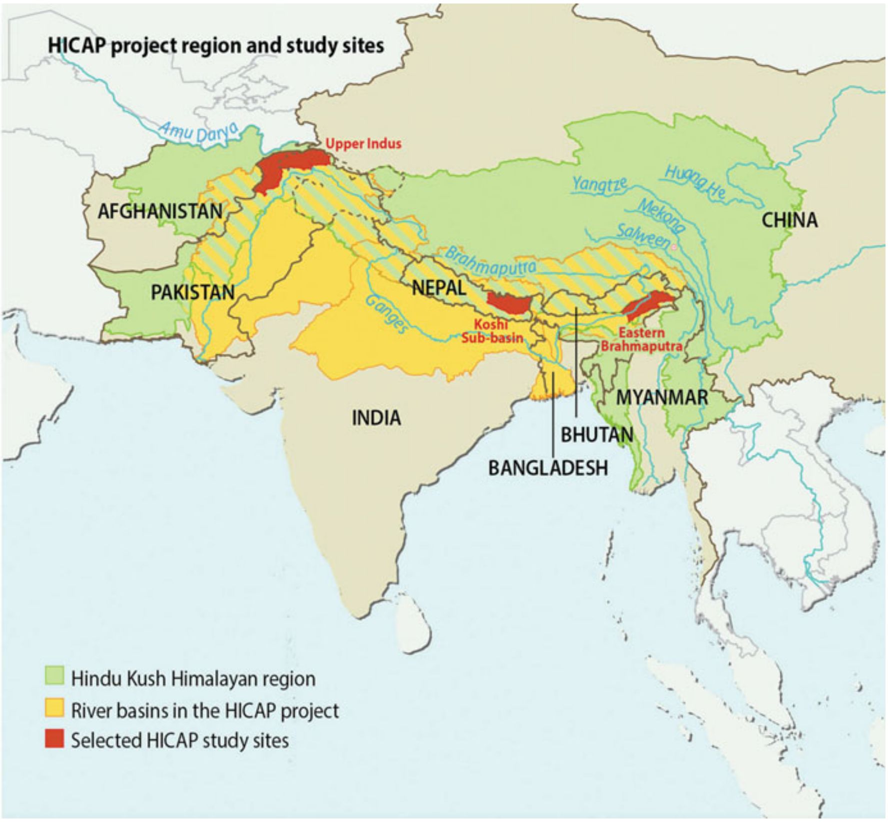
Table 1 (continued)

Main dimensions	Subdimensions	Indicators
Exposure	Short-term exposure	Environmental shocks during the past 12 months
		Combined damage in US$ caused by environmental shocks during the last 12 months
		Socioeconomic shocks during the past 12 months
		Combined damage in US$ caused by socioeconomic shocks during the last 12 months
	Medium-term exposure	Perceived change in frequency of certain climatic events over the last 10 years
		Perceived change in severity of certain climatic events over the last 10 years
		Perceived new climatic or environmental conditions over the past 10 years
		Perceived change in temperature over the past 10 years
		Perceived change in precipitation over the past 10 years

Within the three river basins, sub-basins were selected based on the following criteria: (1) representativeness of the HKH region, (2) availability of data (gauging stations, secondary data, etc.), (3) population density (vulnerable communities), (4) accessibility, and (5) land use pattern. Out of six potential sites, the VACA was conducted in the following three sub-basins: the Upper Indus sub-basin in Pakistan, the Koshi sub-basin in Nepal, and the Eastern Brahmaputra sub-basin in India (see Map 2).

Sample Design

The selection of households for VACA data collection within the three sub-basins followed a three-staged random sampling procedure. In the first step, there was a purposeful selection of districts within the sub-basins based on the following seven criteria: (1) a substantial proportion of land that can be characterized as hilly or mountainous (some plain and foothill district areas were selected as a control group); (2) prior environmental hazards such as floods, flash floods, or droughts; (3) representativity in terms of ecological, ethnic, livelihood, and socioeconomic aspects; (4) expected vulnerability to future climate change impacts; (5) being part of the HICAP feasibility study (2009–2010); (6) availability of operational partners to conduct the VACA survey; and (7) the security situation and accessibility. Expert opinions from ICIMOD, regional research institutes, and local partner institutions were sought for the final selection. In the second step, a random selection of settlements within the selected districts took place. In the third step, there was a random selection of households within the settlements. One enumerator from each survey team was asked to stand in the center of the settlement and randomly select a direction for the first interview. The other interviewers were asked to start from the



Map 2 The VACA study sites (Source: ICIMOD)

periphery of the settlement and progress in a random direction. The enumerators walked in the respective directions, counting houses until they reached a prior given number. This was the first house to be surveyed. If a household was empty, then the enumerator moved to the next closest household. This procedure was continued until the quota for the settlement was accomplished. In each selected district, the sample size required to ensure representativity at district level was surveyed – in many cases approximately 385 households. The number of households surveyed per settlement was proportional to the total population. Overall, 6,096 households of 279 settlements were interviewed. Table 2 presents the details of the samples in India, Nepal, and Pakistan.

Field Work

VACA survey fieldwork was undertaken between October 2011 and April 2012. In Pakistan, the interviews were conducted from October until mid-November 2011.

Table 2 VACA sample size by country, state, and district for India, Pakistan, and Nepal

Sub-basin (country)	State/province/ development region	District	Sample size (HH)	Sample size (settlement)
Eastern Brahmaputra (India)	Arunachal Pradesh	East Siang	375	23
		Lower Dibang	380	19
		Lohit	330	20
	Assam	Dhemaji	390	20
		Lakhimpur	390	20
		Marigaon	386	14
		Tinsukia	396	18
	Total		2,647	134
Upper Indus (Pakistan)	Khyber Pakhtunkhwa	Chitral	383	10
	Gilgit-Baltistan	Hunza-Nagar	376	12
		Gilgit	380	5
	Total		1,139	27
Koshi (Nepal)	Central Mountains	Dolakha	385	18
	Central Hills	Kavrepalanchowk	385	16
	Eastern Hills	Khotang	385	18
		Udaipur	385	24
	Eastern Terai	Sunsari	386	18
		Siraha	384	24
	Total		2,310	118

The data collection was done in collaboration with the Aga Khan Support Programme (AKRSP). In India, data were collected between November 2011 and end of March 2012 in collaboration with Aaranyak. In Nepal, the survey was conducted from December 2011 to February 2012. Here, the data collection was done in collaboration with the Nepal Development Research Institute (NDRI) and the Koshi Victim's Society (KVS). Each field team consisted of the enumerators, field supervisors, and a local coordinator. The enumerators were responsible for conducting the interviews. The field supervisors oversaw the work of the enumerators, provided clarifications, checked completed questionnaires, and managed local logistics. The local coordinator managed the implementation of the VACA in the respective sub-basins.

The VACA implementation comprised the following generic steps: an orientation and training session, pre-survey preparation, settlement and household survey, post-survey revisit, and data entry and compilation. Orientation and training were conducted separately in each of the sub-basins. These sessions involved discussions with the field team on issues such as objectives of the study, research design, sampling method, survey technique, ethics, confidentiality protocol, and questionnaires. Where survey questions contained technical terms which did not have synonyms in the local language, the entire field team agreed upon a common definition. The training session included test interviews in villages, which were supervised by the field supervisors. The training sessions were followed by debriefing sessions to collect feedback from enumerators, field supervisors, and local coordinators and provide clarification.

Prior to the field work, the field teams briefed the community elders or villages leaders about the aim and content of the study. As VACA required detailed information about various aspects of a household, original survey protocol required that interviews should be conducted with the functional head of the household, irrespective of the person's age or gender. The enumerators explained the objectives of the survey to the respondent and obtained a verbal consent before continuing with the interview. An interview was left incomplete if the respondent refused to provide the verbal consent. The enumerator recorded the refusal and moved to the next closest household. In the case of the settlement questionnaire, the head or a senior member of a rural or urban public institution was interviewed.

On average, a household interview required 1 h and 20 min, ranging from 30 min to two and a half hours. The interviews were conducted in the primary local language of the sub-basin. The completed questionnaires were collected and random plausibility checks were carried out by the field supervisors. In cases of discrepancies, enumerators revisited particular households to seek clarifications. The household and settlement questionnaires were entered in a data entry mask. After entering the data, plausibility checks were performed to control for entry errors and inconsistencies to guarantee the quality of the data.

Challenges in the Field

Several challenges were encountered during the implementation of VACA. People in the HKH region generally associate the collection of data with imminent development interventions. Such perceptions can create expectations of forthcoming benefits in return of their participation. Prior to the interviews, enumerators told the respondents and community elders that VACA would not lead to any immediate direct development intervention. They pointed out that since the tool captures significant issues of the household and the community, the study will contribute to more informed policy and development planning at various levels.

The spatial and temporal synchronization of the survey proved to be a challenge. In some study areas, the process was delayed because of adverse weather, the farming cycle, availability of enumerators, and sensitive security situations. Due to cultural sensitivities and general curiosity among people in the communities, it was difficult to conduct one-on-one interviews with female respondents. Often, the female respondent was surrounded by men, women, or children from the same household or neighborhood. Under such circumstances, the respondents were often reluctant to respond frankly to culturally sensitive issues. Sometimes, onlookers tried to influence the respondent's opinion. The presence of female enumerators was able to resolve this to a limited extent.

First Findings of the VACA Survey

Methods

The following analyses were based on VACA household data from India, Nepal, and Pakistan. The findings consist of weighted descriptive analyses of basic indicators for short-term and medium-term exposure as reported by the surveyed households, and the identification of coping strategies deployed to deal with the stresses to which these households were exposed. The presented percentages and means were differentiated by sub-basin.

Short-term Exposure and Coping Strategies

One section of the VACA questionnaire deals with short-term exposure to environmental and socioeconomic shocks as well as coping behavior applied by the households to deal with the events mentioned. Figure 1 presents the three most common environmental shocks during the last 12 months prior to the interview that households of the three sub-basins reported. In both areas water-related events seem to have played a significant role: on the one hand people faced too much water in the form of floods in the Upper Indus sub-basin and Eastern Brahmaputra sub-basin[1] (19 % and 17 %, respectively). On the other hand there was too little water which resulted in droughts in the Eastern Brahmaputra sub-basin (16 %) and irrigation problems in the Koshi sub-basin (22 %). A considerable number of the households of the Koshi and Upper Indus sub-basins reported erratic rainfall (16 % and 14 %, respectively). In addition to water-related stresses, a significant percentage of households in the three sub-basins had to deal with livestock diseases (32 % in Eastern Brahmaputra, 22 % in Koshi, and 11 % in Upper Indus).

The three most common socioeconomic shocks which were reported by the households are shown in Figure 2. It becomes apparent that people of all the surveyed sub-basins were confronted with quite similar socioeconomic problems, although to a different extent. In all three areas family sickness was the most common socioeconomic stressor (63 % in Eastern Brahmaputra, 43 % in Koshi, and 36 % in Upper Indus), followed by electricity shortage (38 %, 33 %, and 32 %, respectively). In addition, debts were one of the frequently mentioned socioeconomic problems both in the Koshi sub-basin and in the Eastern Brahmaputra sub-basin (30 % and 16 %, respectively), while about seven percent of the households in the Upper Indus sub-basin were confronted with poor access to markets.

[1]The authors would like to emphasize that the presented information was obtained by the respondents. In the reference period, neither local nor national authorities have declared a drought in the Eastern-Brahmaputra sub-basin.

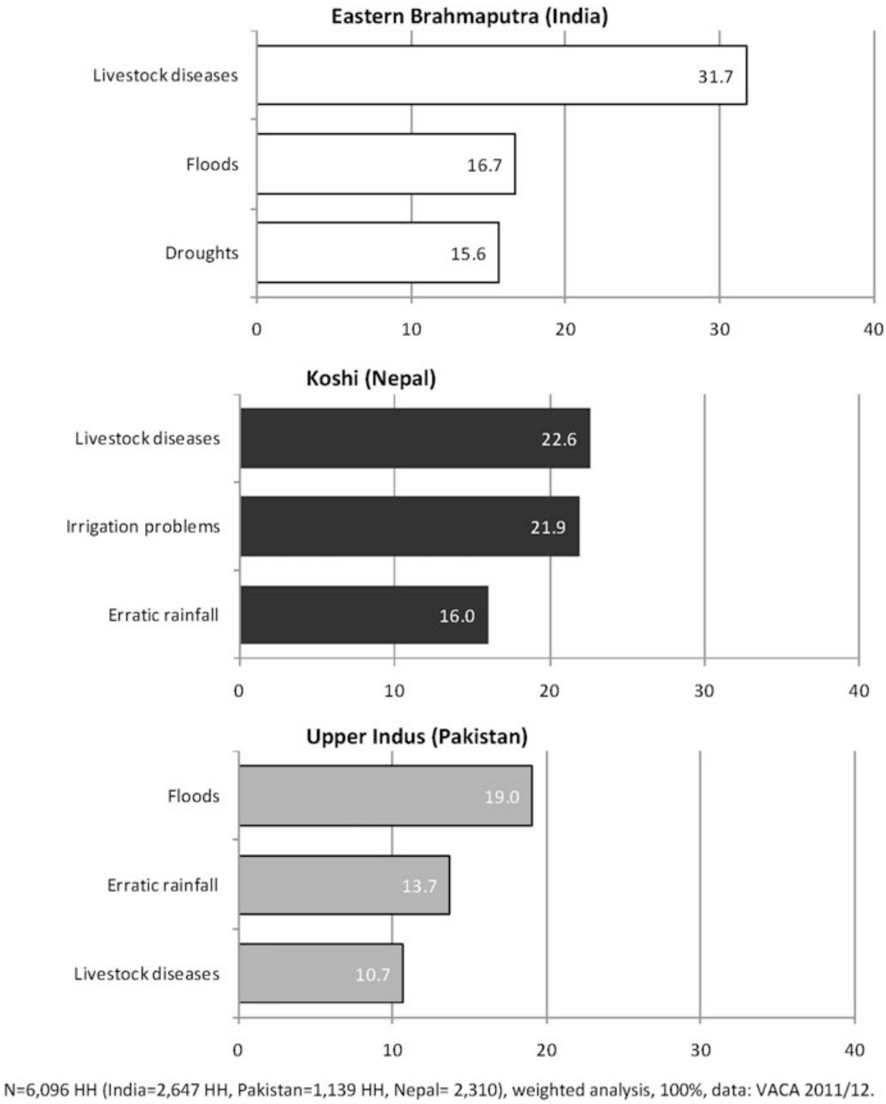


Fig. 1 The three most common environmental shocks during the last 12 months by sub-basin (in % of HH)

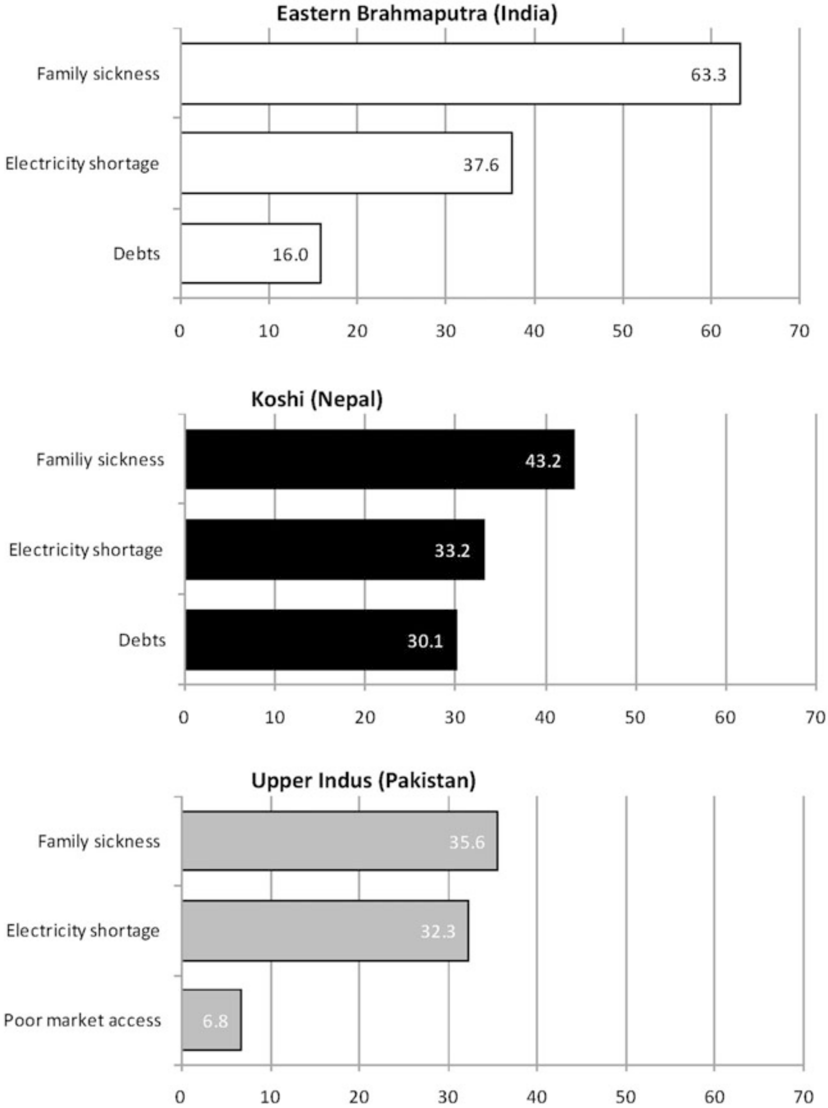
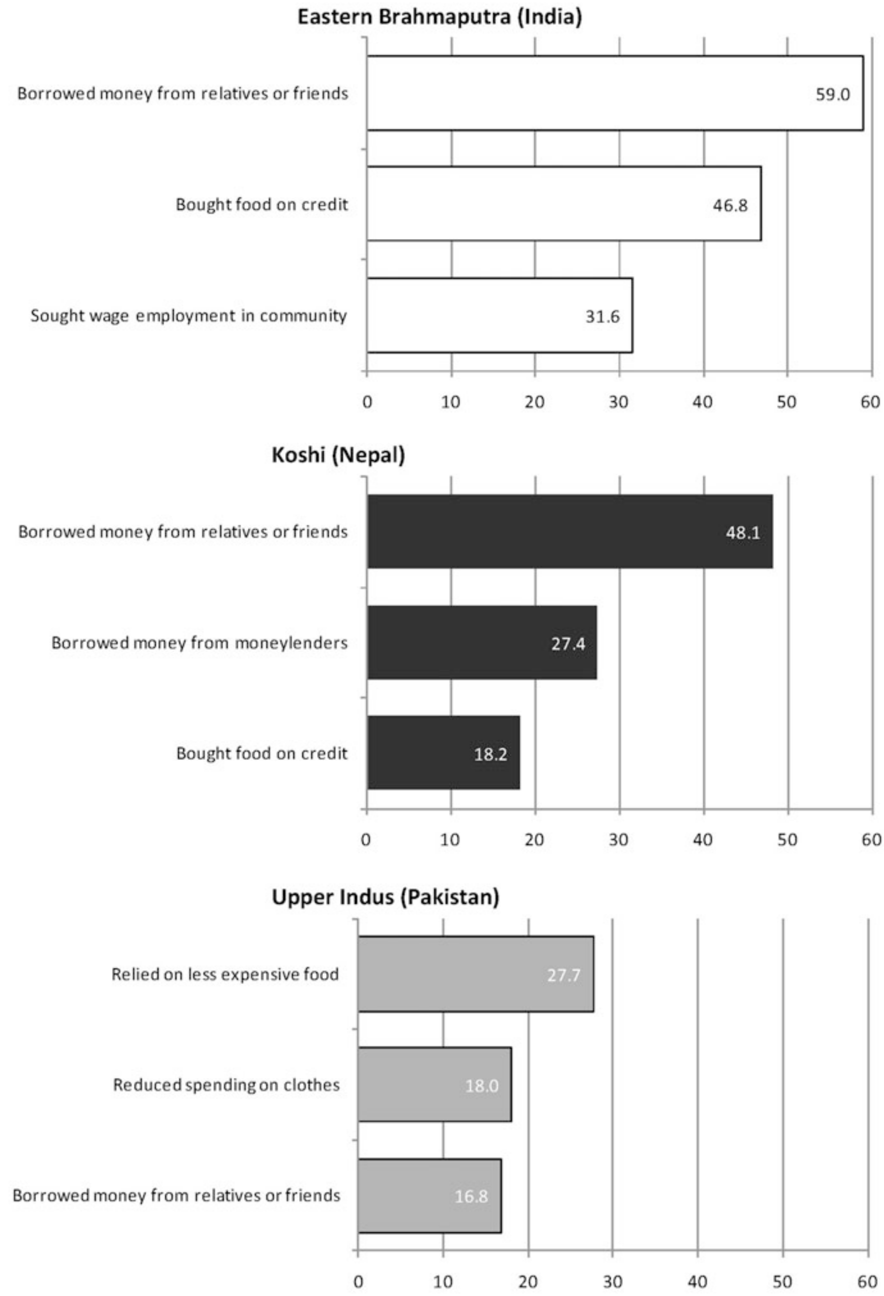
The VACA questionnaire records a broad variety of strategies employed by households to cope with short-term exposure. Figure 3 presents the three most common coping strategies that were reported by the people of the three sub-basins. One of the basic strategies to cope with short-term shocks that households of all three sub-basins applied was borrowing money from relatives or friends (59 % in Eastern Brahmaputra, 48 % in Koshi, and 17 % in Upper Indus). In addition,



N=6,096 HH (India=2,647 HH, Pakistan=1,139 HH, Nepal= 2,310), weighted analysis, 100%, data: VACA 2011/12.

Fig. 2 The three most common socioeconomic shocks during the last 12 months by sub-basin (in % of HH)

one-fourth of the people of the Koshi sub-basin have taken loans from money-lenders (27 %). A significant percentage of households of the Indian and Nepalese sites reported that it has bought food on credit (47 % and 18 %, respectively), which is just another form of borrowing money. It can be assumed that this



N=5,855 HH (India=2,571 HH, Pakistan=985 HH, Nepal= 2,299), weighted analysis, 100%, data: VACA 2011/12.

Fig. 3 The three most common coping strategies to deal with shocks by sub-basin (in % of HH) type of coping is related to the indebtedness which is one of the major socioeconomic problems reported by the households of the Koshi and Eastern Brahmaputra sub-basins. In the Upper Indus sub-basin, the reduction of spending on basic goods like food (28 %) and clothes (18 %) is another relevant coping strategy. In the Eastern Brahmaputra sub-basin, almost one-third of the households reported that they have sought wage employment to deal with short-term exposure.

Medium-term Exposure and Coping Strategies

The VACA questionnaire includes a section for recording medium-term exposure, i.e., perceived environmental and climatic changes during the 10 years prior to the survey. Figure 4 shows the percentage of households that has observed changes in their environment as well as in temperature and precipitation patterns, differentiated by sub-basin. Almost all households of the Upper Indus sub-basin reported that they have experienced changes in all of the three aspects. Though the respective percentages in the Eastern Brahmaputra sub-basin and the Koshi sub-basin are significantly lower, still a broad majority has observed environmental and climatic changes.

If households reported that they have experienced changes, they were asked to describe the changes that they have perceived. This was done separately for changes in the environment, changes in temperature patterns, and changes in

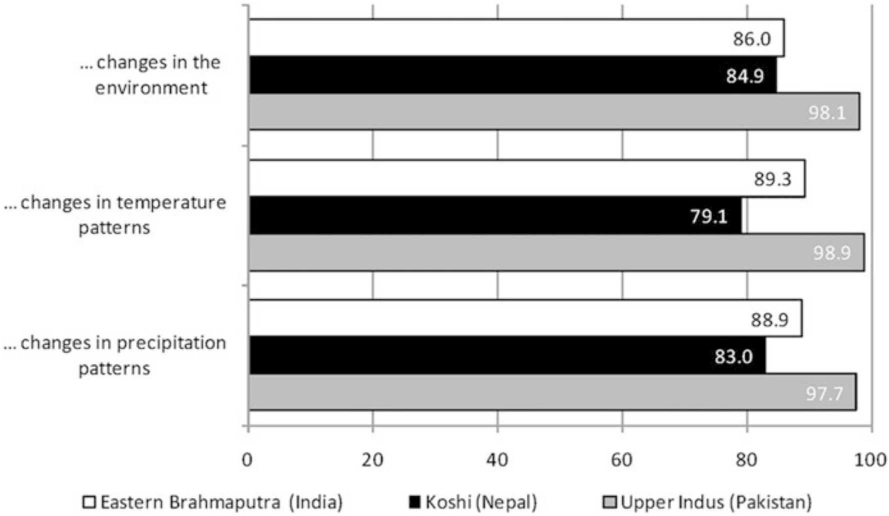


Fig. 4 Households which have observed the following changes over the last 10 years by basin (in % of HH) N = 6,094 HH (India = 2,646, Pakistan = 1,139 HH, Nepal = 2,309), weighted analysis, 100 %, data: VACA 2011/12

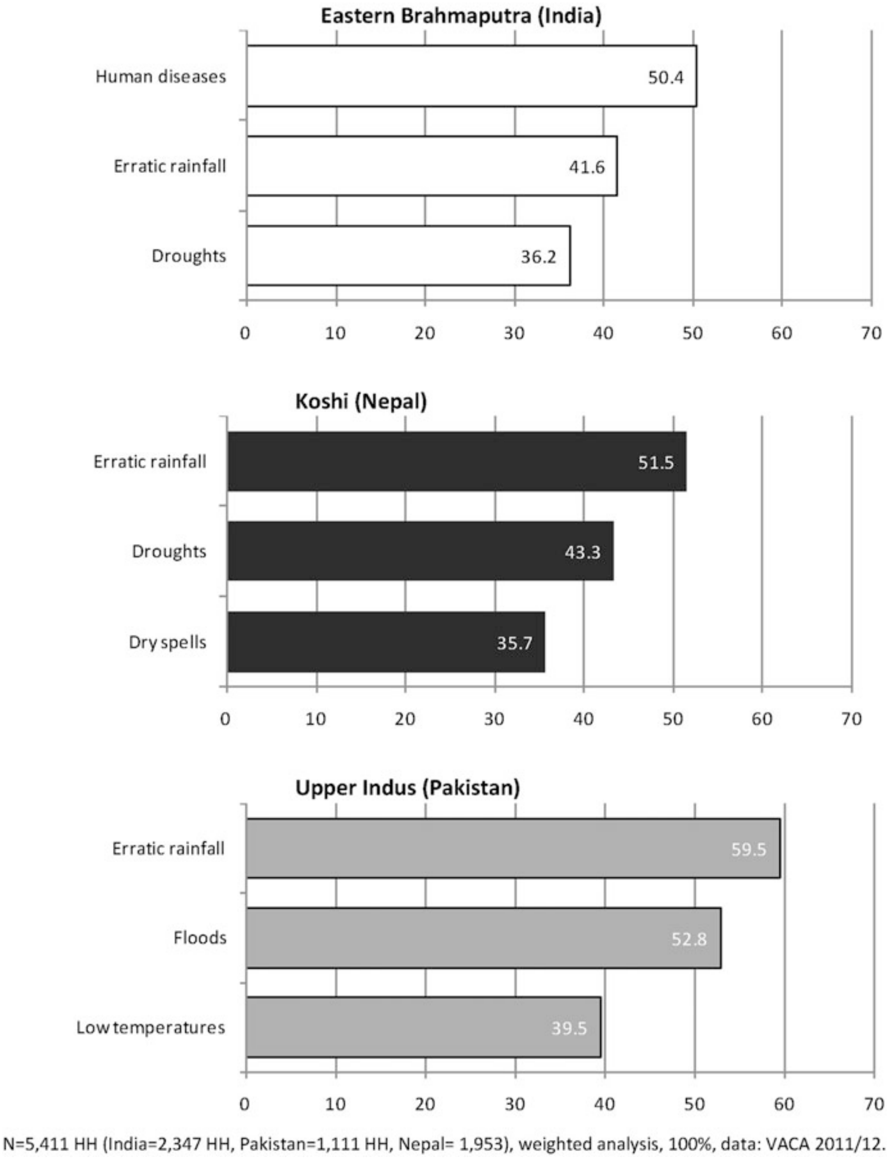

Fig. 5 The three most common new events observed in the environment over the last 10 years by sub-basin (in % of HH)

precipitation patterns. Figure 5 illustrates the three most commonly reported new environmental stressors during the last 10 years. Again, several of the stressors were water related: too much water in the form of floods in the Upper Indus sub-basin (53 %) and too little water in the form of droughts (43 % in Koshi, 36 % in Eastern Brahmaputra)[2] and dryspells (36 % in Koshi). In addition, a significant percentage of households in the three sub-basins reported erratic rainfall (60 % in Upper Indus, 52 % in Koshi, and 42 % in Eastern Brahmaputra). Irrespective of water-related stressors, a large number of households in Upper Indus have observed extraordinary low temperatures over the last 10 years (40 %). It should be pointed out that the most frequent new event reported by the people of the Eastern Brahmaputra sub-basin were human diseases (50 %).

Figure 6 shows the three most common strategies employed by households to cope with new environmental and climatic conditions over the last 10 years. Overall, the percentage of households in Nepal reporting that they have applied any coping strategy is lower than in Pakistan and India. People of all three sub-basins applied quite similar measures: a primary strategy in all three sub-basins was giving up planting certain kinds of crops (28 % in Upper Indus, 22 % in Eastern Brahmaputra, and 17 % in Koshi). In the Upper Indus sub-basin and the Koshi sub-basin one of the most common practices was to change farming practices (28 % and 12 %, respectively), i.e., bringing forward or delaying sowing and harvesting. In the Koshi sub-basin and the Eastern Brahmaputra sub-basin, a significant percentage of households introduced new crops and varieties (15 % and 11 %, respectively). Apart from farm-related coping strategies, in the Eastern Brahmaputra sub-basin almost one-fourth of the households took on new off-farm activities to deal with medium-term exposure.

Discussion

Because of the limited availability of historical time series data on temperature and precipitation in the HKH region and the marked microclimatic variation in altitude and aspect (Singh et al. 2011), a direct comparison of perceptions of climatic medium-term exposure in the three sub-basins with hydrometeorological data is difficult. Available climate data indicate a moderate warming, while data on precipitation do not show any statistically significant trends. Climate models for the region generally predict increasing temperatures and greater amounts of precipitation than at present to the middle of the century (Singh et al. 2011). Nevertheless, people's perceptions can be useful as proxies for missing climate data at the local level and as a supplement for scientific data (Macchi et al. forthcoming).

In all three sub-basins, perceptions of climatic and environmental short-term and medium-term exposure are mainly water related. Unpredictable precipitation and changes in water availability have direct impacts on primary sector activities which make up a large part of the livelihoods of the population of the study sites. Changes in precipitation timing (e.g., changes in the onset of summer and winter monsoon)

[2]The authors would like to emphasize that the presented information was obtained by the respondents. In the reference period, neither local nor national authorities have declared a drought in the Eastern-Brahmaputra sub-basin.

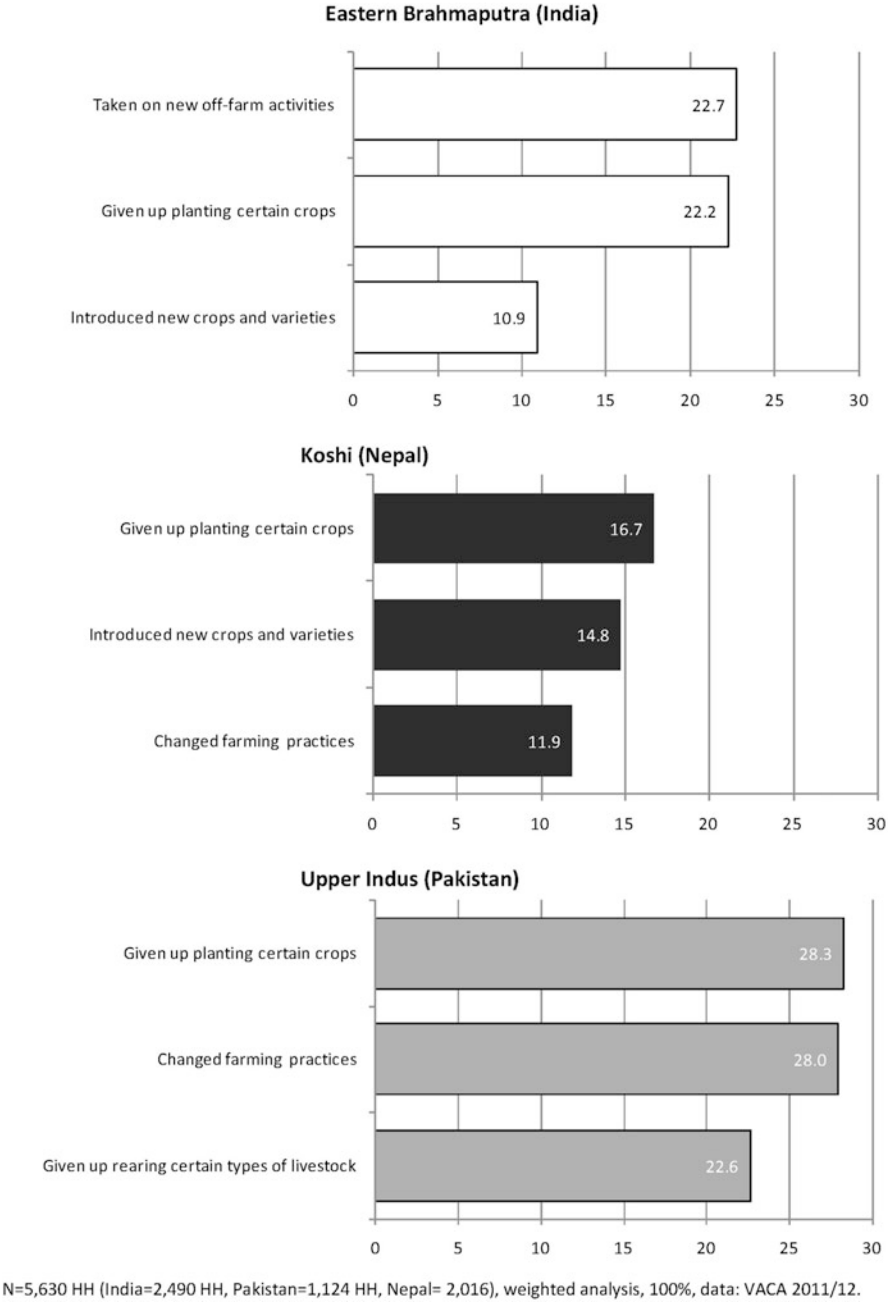

Fig. 6 The three most common coping strategies to deal with environmental changes over the last 10 years by sub-basin (in % of HH)

and overall water availability in a region where people are greatly dependent on agriculture, both for subsistence and for growing cash crops, result in uncertainty regarding the timing of crop production which can lead to lower productivity and even crop failure (Bartlett et al. 2010; Gentle and Maraseni 2012). Furthermore, erratic precipitation patterns affect rangelands and forests and thus have impacts on the grazing of livestock and the availability of non-timber forest products (Gentle and Maraseni 2012).

The main short-term coping strategies reported by the households of the three sub-basins were borrowing money and reduced consumption of basic goods. According to Corbett (1988), these are primary coping strategies applied to deal with disasters, which are, when exhausted, followed by the disposal of productive assets (e.g., sale of livestock or agricultural land). Taking loans places additional stress on families, promotes exploitation, and is pushing poor households toward indebtedness and a vicious cycle of poverty (Gentle and Maraseni 2012). This is actually reflected in the relatively high number of households that have reported indebtedness as one of the main socioeconomic shocks. Furthermore, these short-term coping strategies are not sustainable in view of predicted climate change associated with increasing temperatures and an increase in the frequency and magnitude of extreme events (Nogues-Bravo et al. 2007; IPCC 2012) as they deplete the asset base and thus render households even more vulnerable to recurring shocks.

Although a vast majority of the households in the three sub-basins have perceived climatic and environmental changes during the last 10 years, the percentage of households that have applied medium-term coping measures was relatively low. These results are in line with other findings of recent studies from the region that show that people often do not react to perceived changes because they lack resources, information, and/or government support (Gentle and Maraseni 2012; Gambhir and Kumar 2013; Colom and Pradhan 2013; Zaheer and Colom 2013). The most important medium-term coping strategies employed by households included giving up certain crops, changing farming practices (e.g., earlier sowing or harvesting), and introducing new crop varieties. While the first two strategies are reactive and may lead to decreased productivity and thus increase vulnerability, the latter could be regarded as a proactive adaptation measure, given that farmers have anticipated changes and therefore adjusted their farming practices accordingly. A recent qualitative study by Macchi et al. (forthcoming) in Nepal and Northwest India provides an example of mountain farmers who took advantage of new opportunities offered by increasing temperatures: the farmers grew millet and certain fruits at altitudes where they had not thrived before or cultivated more than one crop cycle per year.

Given the rather low percentage of households that addressed change in a proactive manner and the fact that most of the observed response mechanisms to change were natural resource based and therefore highly susceptible to changing climatic conditions, awareness rising and capacity building at all levels of society (from government institutions to households), improved communication of tailor-made information, and a synergy between adaptation and development interventions are essential. This, again, requires assessments of the location-specific situation and the specific needs of all stakeholders.

Conclusion

The people of Hindu Kush Himalayas are confronted with rapid socioeconomic, demographic, and environmental changes. To explore their vulnerability and adaptive capacity, the International Centre for Integrated Mountain Development has developed a survey instrument (VACA questionnaires) and had collected data of almost 6,100 households of three of its regional member countries as part of the *Himalayan Climate Change Adaptation Programme (HICAP)*. This chapter presented the methodology of the VACA study, i.e., the operationalization of livelihood vulnerability in the VACA questionnaires and the research design of the VACA survey. At the end, the usefulness of the assessment was illustrated by presenting preliminary findings.

At the moment, the project is ongoing and several tasks are performed. One of them is the development of a multidimensional livelihood vulnerability index (MLVI) for the HKH region, which allows an effective way of describing and comparing of livelihood vulnerability and its trigger across the study sites. Besides, the data provide a rich basis for the quantitative analysis of various research questions, such as the causes and effects of vulnerability and adaptive capacity. In this regard, it seems fruitful to have a closer look into short-term and medium-term exposure and the respective coping strategies: who is doing what and with what kind of results?

The survey data will provide a baseline for further in-depth studies, both qualitative and quantitative, and interventions that are planned within HICAP. Based on VACA, it will be possible to identify relations and interdependencies on an aggregated level, while in-depth studies will help to explore the underlying mechanisms. Given the lack of household-level data on vulnerability and adaptive capacity in the studied river basins, VACA can provide significant insights for the adaptation planning at the district level. In addition, the survey data will be linked up with available metrological and environmental data as well as information on hazards in the respective sub-basins. In that sense, VACA is one of several pillars within the mixed-method approach chosen for HICAP.

Acknowledgements The research for this chapter has been done as a part of the Himalayan Climate Change Adaptation Programme (HICAP), a joint program coordinated by the International Center for Integrated Mountain Development (ICIMOD), Center for International Climate and Environmental Research – Oslo (CICERO), and United Nations Environmental Programme (UNEP) GRID-Arendal. HICAP is funded by the Norwegian Ministry of Foreign Affairs. The authors express their gratitude to the colleagues of ICIMOD, CICERO, and UNEP for their guidance and comments. Climate Change and Displacement in Bangladesh: Issues and Challenges

Nour Mohammad

Contents

Abstract

The purpose of this chapter is to explain and come to an understanding of the causes of forced migration and climate displacement due to the climate change in the present era of globalization. Environmental crisis along with the increasing impacts of climate change in Bangladesh has become an important cause of cross-border migration to South Asian countries. This chapter attempts to focus on migration and climate displacement in Bangladesh. The research is based upon theoretical sources and empirical data. The consequences of such movement of population in South Asian context will generate a range of destabilizing sociopolitical, economic, and climate change impacts in the future. Bangladesh is commonly recognized as one of the most climate-vulnerable countries on earth and is set to become even more so as a result of climate change. This chapter underlines that climate displacement is not just a phenomenon to be

addressed at some point in the future; it is a crisis that is unfolding across Bangladesh now. Sea-level rise and tropical cyclones in coastal areas as well as flooding and riverbank erosion in mainland areas, combined with the socio-economic situation of the country, are already resulting in the loss of homes, land and property which are common phenomenon in Bangladesh. Among the many causes of vulnerability of people, cross-border migration due to climate change might increase the susceptibility of people to climate change in South Asian countries. This chapter examines the details of legal framework of current and future causes of climate displacement in Bangladesh. It further analyzes existing government policies and programs intended to provide solutions to climate displacement and relief to climate displaced persons and emphasizes that rights-based solutions must be utilized as the basis for solving this crisis.

Climate change • Displacement • Environmental migrants • Vulnerability • Policy • Bangladesh

Introduction

Climate change is one of the most serious threats in the present world. It will affect all of us but will have a disproportionate impact on millions of poor rural people of developing countries. It puts more people at risk of hunger and makes it more difficult to reduce the proportion of people living in extreme poverty. For development work to be effective, we must help poor rural people cope with and mitigate the impact of climate change. The concept of climate and displacement is not a new phenomenon and can be traced back to earlier deliberations on environmental displacement, which were particularly prominent during the 1990s. Climate change has emerged as the greatest threat faced by human beings in the modern world (Clime Asia 2009). The adverse effects of climate change destabilize the human displacement, economic development, human security, and people's fundamental right (UNDP 2007). Climate change, environmental degradation, and migration are among the key topics that dominate the international and national political arena today. Environmental migration is a reality that can no longer be overlooked. Millions of people have already been displaced as a result of climate change and climate-related natural disasters like *Alia* and *Sidr* in Bangladesh. The affected people are also moving from one place to another because of environmental disaster and not able to continue their livelihood anymore. The Red Cross research shows that more people are now displaced by environmental disasters than by war. The United Nations University predicts that 50 million people globally will be displaced by environmental crises by the year 2010. According to other experts in the relevant field, there could be as many as 200 million displaced worldwide by 2050. Although these numbers are expertly researched estimates, even the predictions on the lowest end of the scale are immense.

The concept of migration is not a new one; it has been developed for thousands of years ago. This phenomenon is new because there are more and more people that are forced to flee their homes due to environmental factors and natural disaster related to climate change. The complex interdependence between these phenomenon and the potential consequences of the failure to tackle them in time are beginning to attract increasing public and scientific attention. The manifested political commitments to the pursuit of sustainable development, environmental protection, and the respect, protection, and fulfillment of human rights and even more so to their interlinkages are often limited by narrow geopolitical interests when action becomes necessary. Bangladesh is widely recognized to be one of the most climate-vulnerable countries in the world. It is found that in every year, natural disaster frequently happens, which causes loss of life and damage to infrastructure and economic assets and adversely impacts on lives and livelihoods, especially of poor people (BCCSAP 2008). Climate change is considered to be a critical global challenge and recent events have demonstrated the world's growing vulnerability to climate change. The impacts of climate change range from affecting agriculture to further endangering food security, to rising sea levels and the accelerated erosion of coastal zones, and to increasing intensity of natural disasters, species extinction, and the spread of vector-borne diseases (United Nations Permanent Forum on Indigenous Issues 2007). Bangladesh has developed some facility for dealing with the impacts of climate change at the national level and policy response options has been mobilized that deal with vulnerability reduction to environmental variability and most recently to climate change in particular (Saleemul Haq. Ayers 2007).

Climate Change and Bangladesh

Bangladesh is one of the largest deltas in the world which is highly vulnerable to natural disasters because of its geographical location, flat and low-lying landscape, population density, poverty, illiteracy, lack of institutional system, etc. In other words, the physical, social, as well as economic conditions of Bangladesh are very typical to any of the most vulnerable countries to natural disasters in the world. The total land area is 147,570 km^2 and consists mostly of floodplains (almost 80 %) leaving major part of the country (with the exception of the northwestern highlands) prone to flooding during the rainy season. Moreover, the adverse affects of climate change especially high temperature, sea-level rise, cyclones and storm surges, salinity intrusion, heavy monsoon downpours, etc. has aggravated the overall economic development scenario of the country to a great extent (Anne Katrien 2012). Climate change is an important issue in the effort for global peace. The global temperatures and sea levels are changing day by day. The whole world is apprehended about the unnatural changes occurring in global climate. The issue of global climate change that we are facing is more pressing than ever (BCCSAP 2009). In Bangladesh the climate change is affecting the human life and economical development and causing displacement of human being. Due to global warming, the country has experienced unusual changes in seasons and faces unexpected rains, dry spells, temperatures, and other symptoms of changes in global weather patterns.

Bangladesh's vulnerability to climate change lies mainly in its density of population and that a large part of its area consists of low-lying coastal areas and expansive floodplains. Now Bangladesh has a population of 163 million people (Bangladesh Demographic Report 2013). While the country's population has been increasing, on the one hand, its forests are being depleted on the other (Jahangir Alam 2009). An increasing world population and harmful industrialization by the developed countries are the main causes of climate change. The severity of storms, droughts, rainfall, floods, and other natural disasters has been increasing in developing countries like Bangladesh in particular, due to climate change. Global warming threatens our agriculture also, which is the backbone of a country. Every year, natural disasters occur like *Sidr* and *Alia* causing havoc effects on Bangladesh agriculture, touching every corner of the country. Due to lack of resources and other causes, Bangladesh does not have the capacity to ensure that appropriate measures are taken to mitigate the damage (Ahamed 2008).

The coastal areas of Bangladesh and the coastal people are mostly affected by the climate change and they are losing ponds, lakes, dams, and forestry due to natural disaster. National and regional varieties of fish are being lost due to such climate disaster. Specialists have consensus that 54 varieties of fish in Bangladesh have already been lost due to climate change and natural disaster, and forest and animals are also being lost. Most of the people in Bangladesh are living in rural areas and lead a very poor life. According to the Water Development Board, there is a total of 11,000 km of embankment that the Water Development Board developed, of which around 250 km were damaged by water surges during cyclones *Sidr* and *Alia*. The existing embankment at Moheshkhali under Cox's Bazar District requires a 4.5 m height increase to protect against storm surges and sea-level rises due to the effects of climate change. Any future embankments should be designed to be 2–4 m higher than the existing ones. Due to climate change, the weather in Bangladesh has changed. Water levels have fallen, temperatures have risen, and the incidence of floods, dry spells, and cyclones have all increased, affecting both people's lifestyle and the crops. At least 30 rivers, including the Padma, the Gomti, and the Teesta, have dried up. And most of the other rivers in Bangladesh are being lost because they are being filled with soil. Parts of northern Bangladesh are becoming desert. Geological and biological changes in the area are threatening normal life (Shamsudoha and Chy 2009). Bangladesh needs technological and economic support to survive the effects of a changing climate. Just as important is the proper handling of any foreign funds Bangladesh may get, since we know that corruption is another large barrier to our prosperity.

Causes of Climate Change and Displacement: The Present Scenario

The main causes of environmental deterioration or devastation forcing people to move from their natural habitat are many and varied. The primary causes of climate displacement in Bangladesh tidal height increases in the coastal areas and riverbank erosion in the mainland areas. The secondary causes of displacement are tropical cyclones and storm surges in the coastal regions and river flooding in the mainland. The main scenario sites of displacement have been in the coastal areas and in the river delta regions in the mainland. Bangladesh has 64 districts of them 24 coastal and mainland districts have already producing climate displaced peoples (Climate displacement Report 2012).

Impacts related to climate change could be divided into two distinct drivers of migration:

(a) Long-term climate processes (for instance, sea-level rise, salinization of agricultural land, desertification, soil erosion, water scarcity)
(b) Short-term extreme climate events and extreme weather events (for instance, flooding, hurricanes, storms)

According to International Organization for Migration (IOM), climate change is likely to affect the movement of people in at least four ways: (i) the intensification of natural disasters like both sudden and slow onset leading to increased displacement and migration; (ii) the adverse consequences of increased warming, climate variability and of other effects of climate change for livelihoods, public health, food security, and water availability; (iii) rising sea levels that make coastal areas tumble down; and (iv) competition over scarce natural resources potentially leading to growing tensions and even conflict and, in turn, displacement. The consequences of climate change (including its effects on migration) will be most severe for the developing world like Bangladesh. Particular areas including the Asian mega deltas have been identified as "hotspots" where greater revelation and sensitivity to climate change combine with limited adaptive capacity to suggest that impacts will be most significant (IOM 2008).

The proposed working definition of migrant by the International Organization for Migration (IOM) is that environmentally induced migration or environmental migrants to encompass people who move as a result of natural or human-made disasters as well as those who migrate because of deteriorating environmental conditions. According to this definition, environmental migrants are those "Environmental migrants are persons or groups of persons who, for reasons of sudden or progressive changes in the environment that adversely affect their lives or living conditions, are obliged to have to leave their habitual homes, or choose to do so, either temporarily or permanently, and who move either within their territory or abroad."

This definition is inclusive of all persons who have an environmental factor as the major cause of migration and acknowledges that environmentally induced migration can be internal as well as international and a short- or long-term phenomenon, due to sudden or gradual environmental change, without ignoring other intervening political, economic, and social factors.

One of the most basic issues in climate change and environmentally induced migration is that it is an international issue or process, but not a regional or local issue. The international community has the responsibility to provide adequate measures for prevention, adaptation policy, and mitigation community in order for the mostly affected countries to reduce their vulnerability to the impacts of environmental disasters and manage the development of environmental processes. The local and national authorities have no power to engage in proactive intervention to reduce the crisis of climate change. Environmentally induced migration is rarely mono-causal. The cause-consequence relations are increasingly complex and multifactorial (Myers and Kent 1995). A growing number of people flee because of multiple causes of injustice, exclusion, environmental degradation, competition for scarce resources, and economic hardship caused by dysfunctional states. Some people leave voluntarily, some flee because there is no other choice, and some may make the decision to move before they have no other choice but to flee. The different degrees of force and the complex set of influencing factors blurs the traditional concepts of migration and displacement, creating confusion among the academia and the international community about whether to talk about migration or displacement in the case of people fleeing disasters and environmental degradation (Tina 2008).

There is a scientific perception that the effects of the climate change are frustrating; many of the natural environmental hazards already faced by Bangladesh in every year (McAdam and Saul 2010) are sudden-onset events including floods, cyclones, storm surges, waterlogging, salinity intrusion, and riverbank erosion and slow-onset events such as coastal erosion, sea-level rise, saltwater intrusion, etc.

Bangladesh's vulnerability to natural hazards leads to climate displacement – the forced displacement of individuals and communities from their homes and lands. This is as a result of both "sudden-onset events" such as floods, cyclones, and riverbank erosion as well as "slow-onset processes" such as coastal erosion, seal-level rise, saltwater intrusion, changing rainfall pattern and drought, etc. (Siddiqui 2011).

Alarmist prediction is that some 30 million people will be displaced from Bangladesh by 2050 as a result of climate change (McAdam and Saul 2010). It is projected that six million people have already been displaced by the effects of climate hazards in Bangladesh.

However, human displacement and migration is a multi-causal phenomenon even in cases where climate change is a predominant driver of migration; it is usually compounded by social, economic, political, and other factors. Resource, social network, cultural ability to cope with change, individual's attitude, position in family decision making, and gender contribute to decision to migrate or not (Matthew 2010).

It is estimated that 60,000 deaths from climate-related natural disasters occur every year (UN News Service 2007) and that 30 million people worldwide are being displaced because of serious degradation of environmental conditions, natural disasters, and depletion of natural resources. This figure is expected to soar by the middle of this century. While there are no authoritative global figures on the number of people who will move for environmental reasons in the future, the Stern Review provides an estimate of 150–200 million becoming permanently displaced due to the effects of climate change by the year 2050 (Stern 2006).

However, the international community is largely ignoring the issue that may potentially become one of the greatest global demographic and humanitarian challenges for the twenty-first century (Myers and Kent 1995).

Climate Displacement in Bangladesh: Future Situation

Bangladesh has total 64 districts, of which 24 districts are coastal and mainland from which people are displaced. Bangladesh having 160 million people is highly vulnerable to climate change and displacement due to sea-level rise (Rabbani 2009). Twenty-eight percent of the population of Bangladesh lives in the coastal regions of the country (Rafiqul Islam 2007).

Climate change is one of the greatest challenges for the world today. The effects of climate change will aggravate many of the natural hazards faced by Bangladesh in every year, including all of the natural hazards currently leading to climate displacement: flooding, tropical cyclones, storm surges, salinity intrusion, and riverbank and coastal erosion and SLR. The Intergovernmental Penal of Climate Change (IPCC) has provided that climate change and global warming are likely to lead to an increase of rainfall, rise in the frequency of flash floods and large-area floods, earlier melting of snowpacks and melting of glaciers, frequent and intense droughts, intense tropical cyclones, rising sea levels, frequent and intense storm surges, and intense inland rainfall and stronger winds (IPCC 2007). Sea-level rise from climate change is anticipated to worsen many of these processes and to subsume up to 13 % of Bangladesh's coastal land by 2080 (Pender 2008).

Heavier and more erratic rainfall in the Ganges-Brahmaputra-Meghna system is likely to lead to further riverbank erosion resulting in mass displacement in the mainland areas of Bangladesh. Besides, erratic rainfall is also likely to lead to overtopping and breaching of embankments resulting in widespread flooding in both urban and rural areas. In addition, it is likely to lead to increasing droughts, especially in the drier northern and western regions of Bangladesh which record significantly less rainfall causing the destruction of crop yields and severe disruption to livelihoods (IPCC Third Assessment Report 2001). Erratic rainfall is likely to lead to increasingly frequent and severe landslides in the hill regions of Bangladesh triggering human exodus. As the Himalayan glaciers continue to melt, it is likely that there will be higher river flows in the warmer months of the year, followed by lower river flows and increased saline intrusion after the glaciers have shrunk or disappeared (Displacement Solution Report in Bangladesh 2012).

The difficulty inherent in predicting the future impact of climate change on displacement in Bangladesh means that any attempt to quantify the exact number of climate displaces should be treated with some caution. However, as all of the key current drivers of displacement are expected to increase in both frequency and intensity due to climate change, it is highly likely that the number of climate displaced due to existing factors will continue to increase in the future in Bangladesh. In addition, the number of climate displaced is likely to rise even higher due to secondary and as yet unforeseen effects of climate change (Haque 1996).

Existing Potential Policies and Institutional Frameworks in Bangladesh

Bangladesh, being one of the most vulnerable countries, has adopted a number of policies and institutional frameworks over the recent years. These measures have been undertaken to combat frequent natural disasters and the adverse effects of climate change.

Policies and Institutional Framework on Environment in National Level

The Government of Bangladesh has adopted a number of national policy and framework for the protection of environment and natural disaster. National Environmental Policy 1992 and the Coastal Zone Policy 2005 deal with the adverse effects of disasters and environmental problems (Roy 2012). But there is no clear indication about the problems of population displacement. In terms of guiding strategies on the environment, among the key documents is the National Environmental Management Action Plan 1996, the more recent National Capacity Self-Assessment (NCSA) for Global Environmental Management 2007, and the sector-specific environmental policies such as the National Water Policy 1999 and the Guidelines for Participatory Water Management. All of these documents are understandably focused on meeting Bangladesh's current environmental challenges and make few specific references to the migration effects of environmental change and degradation (although the NSCA refers to the problems of displacement by river-bank erosion, rural-urban migration, and the potential for out-migration from coastal zones). In contrast, policies on disaster management such as the Draft National Plan for Disaster Management 2008 do make reference to displacement and specific vulnerabilities related to migration, such as problems faced by families who are left behind when men out-migrate following an event (Walsham et al. 2012).

The institutional framework of Bangladesh consists of different disaster management committees at different levels comprising government, nongovernment, voluntary, and other relevant stakeholders. The National Disaster Management Council (NDMC), headed by the Prime Minister, is established to provide guidance towards disaster risk reduction and emergency response management in Bangladesh and is the highest-level forum for the formulation and review of disaster management policies. The Inter-Ministerial Disaster Management Coordination Committee is responsible for implementing disaster management policies and the decisions of the NDMC and is assisted by the National Disaster Management Advisory Committee (Roy 2011). The Ministry of Food and Disaster Management is the focal ministry for disaster management in Bangladesh. Its Disaster Management Bureau (DMB) is mainly responsible for coordinating national disaster management interventions across all agencies. In 2000 the government published "Standing Orders on Disaster" which provides a detailed institutional framework for disaster risk reduction and emergency management and defines the roles and responsibilities of different agencies and committees (BCCSAP 2008).

Existing Policies and Institutional Mechanisms on Climate Change in Bangladesh

The Government of Bangladesh has taken many steps to address adaptation to climate change including the establishment of a 45-million-dollar Climate Change Fund, the development of the Bangladesh National Adaptation Programme of Action in 2005 (NAPA), and the Bangladesh Climate Change Strategy and Action Plan 2009 (Fatima and Anita 2010).

The National Adaptation Programme of Action in 2005 (NAPA)

The Government of Bangladesh has adopted the National Adaptation Programme of Action in 2005 (NAPA) prepared by the Ministry of Environment and Forests. The NAPA aimed to accumulate the understanding of the current state of affairs from discussions with appropriate stakeholders from four subnational workshops and one national workshop (MOEF 2005). The NAPA was prepared keeping in mind the sustainable development goals and objectives of Bangladesh where the importance of addressing environmental issues and natural resource management with the participation of stakeholder in bargaining over resource use, allocation, and distribution was recognized (BCAS 2008). The NAPA recognizes that Bangladesh will be one of the most adversely affected countries due to climate change especially because of Bangladesh's "low economic strength, inadequate infrastructure, low level of social development, lack of institutional capacity and a higher dependency on the natural resource base."

The NAPA suggested adopting the following measures for Bangladesh to adverse effect of climate change including variability and extreme events based on coping mechanisms and practices. The suggested future adaptations are (MOEF 2005):

(i) Reduction of climate change hazards through coastal afforestation with community participation
(ii) Providing drinking water to coastal communities to combat enhanced salinity due to sea-level rise
(iii) Capacity building for integrating climate change in planning, designing of infrastructure, conflict management, and land-water zoning for water management institutions
(iv) Climate change and adaptation information dissemination to vulnerable community for emergency preparedness measures and awareness rising on enhanced climatic disasters
(v) Construction of flood shelter and information and assistance center to cope with enhanced recurrent floods in major floodplains

(vi) Mainstreaming adaptation to climate change into policies and programs in different sectors (focusing on disaster management, water, agriculture, health, and industry)
(vii) Inclusion of climate change issues in curriculum at secondary and tertiary educational institution
(viii) Enhancing resilience of urban infrastructure and industries to impacts of climate change
(ix) Development of eco-specific adaptive knowledge (including indigenous knowledge) on adaptation to climate variability to enhance adaptive capacity for future climate change
(x) Promotion of research on drought-, flood-, and saline-tolerant varieties of crops to facilitate adaptation in the future
(xi) Promoting adaptation to coastal crop agriculture to combat increased salinity
(xii) Adaptation to agriculture systems in areas prone to enhanced flash flooding in North East and Central Region
(xiii) Adaptation to fisheries in areas prone to enhanced flooding in North East and Central Region through adaptive and diversified fish culture practices
(xiv) Promoting adaptation to coastal fisheries through culture of salt-tolerant fish special in coastal areas of Bangladesh
(xv) Exploring options for insurance and other emergency preparedness measures to cope with enhanced climatic disasters

In 2005 NAPA identified some adverse impacts of climate change, many of which link with climate displacement such as scarcity of freshwater due to less rain and higher evapotranspiration in dry seasons, drainages congestion due to higher water level in the confluence of the rise of sea level, riverbank erosion, frequent flood and widespread drought, and salinity in the surface, ground, and soil in the coastal zone due to migration; however, these links were not expressed in concrete terms. The document also stated that a potential long-term consequence of the "adaptation to agriculture systems in areas prone to enhanced flash flooding" project would be that "people might get a means to continue with farming, instead of migrating to cities after the flood."

Bangladesh NAPA has moved from the urgent needs to wider adaptation requirement to address medium- and long-term climate issues. It gave emphasis on four basic national security issues of Bangladesh, i.e., (a) food security, (b) energy security, (c) water security, and (d) livelihood security (including right to health) and respect for local community on resource management (Haque 2011).

The Climate Change Strategy and Action Plan in 2009 (BCCSAP)

Bangladesh Climate Change Strategy and Action Plan is the most recent document formulated by the government aiming to address the adaptation and mitigation to build the capacity and reliance of the country to climate change for a period of decade 2009–2018. The plan was prepared in 2009 focusing on a 10-year program to encounter the potential challenges and variation condition (BCCSAP 2009).

BCCSAP identifies all the climate-induced hazards, including flood, drought, salinity intrusion, cyclone and storm surge variations in temperature and rainfall, etc., and their associated impacts on different sectors. BCCSAP identifies a set of activities/measures under the following six major themes:

(i) Food security, social protection, and health
(ii) Comprehensive disaster management
(iii) Infrastructure
(iv) Research and knowledge management
(v) Mitigation and low carbon development
(vi) Capacity building and institutional strengthening

The BCCSAP recognizes that "Bangladesh is one of the most climate vulnerable countries on earth and will become even more so as a result of climate change" (IPCC Third Assessment Report 2001) and highlights the many risks of the effects of climate change that have led to displacement, including floods, tropical cyclones, storm surges, and droughts.

It states that increased riverbank erosion and saline water intrusion in coastal areas "are likely to displace hundreds of thousands of people" and that if sea-level rise is higher than currently expected and coastal polders are not strengthened and/or new ones built, "six to eight million people could be displaced by 2050 and would have to be resettled."

The BCCSAP provides that "it is now evident that population in many parts of the country will be so adversely affected [by climate change] that they will have to move out. . .The process of migration of climate change-affected people, both inside and outside the country, need[s] to be monitored closely. . .and adequate institutional support should be provided for their proper resettlement."

In addition to these two mechanisms, there are some existing traditional climate change-related fund mechanisms in Bangladesh to address the issue of climate change. Bangladesh Climate Change Trust Fund (BCCTF) based on revenue from the national budget, within a legal mandate by the Climate Change Trust Act passed in Parliament in 2010. At the same time, an alternate Bangladesh Climate Change Resilient Fund (BCCRF), which was formerly known as the Multi-donor Trust Fund (MDTF), was created to pool funds from the country's development partners.

Bangladesh Climate Change Trust Fund (BCCTF)

The Bangladesh Climate Change Trust Fund is a "block budgetary allocation" of US$ 100 million each year for 3 years (2009–2012). The Climate Change Act provides that an amount equivalent to 66 % of the total fund is being spent for the implementation of BCCSAP while 34 % will be maintained as a "fixed deposit" for emergencies. The interest accrued on the 34 % fixed deposit will also be spent on project implementation. Funds from the BCCTF can be used to finance public sector and 10 % for nongovernment projects, and it is not mandatory to spend the total grant within a given financial year (Munjurul et al. 2006).

Bangladesh Climate Change Resilience Fund (BCCRF)

Bangladesh Climate Resilience Fund (BCRF) has also been created by the government for supporting actions to address climate change. Mainly international development partners of Bangladesh are contributing to create this fund. In April 2008, a UK-Bangladesh Climate Change Conference was held in Dhaka. The development partners expressed their view for the urgency of establishing a "financial mechanism" to assist Bangladesh in combating the impacts of climate change. Subsequently, the London Climate Change Conference was organized jointly by Bangladesh and the UK in September 2008.

However, finally in May 2010, DPs in Bangladesh Development Forum (BDF) agreed the establishment of BCCRF which would be managed by the Government of Bangladesh (GoB). World Bank is providing "fiduciary" support to the BCCRF with an objective of handing it over to the GoB in the next 3 years. By this time the BCCRF has received an approximate amount of 200 million USD from different DPs including UK, EU, Denmark, Sweden, and Australia. An amount of 90 % of the total amount would be spent by different ministries while the rest 10 % would be managed by PKSF to support initiatives taken by NGOs and Bilateral Development Partners (Hoque 2007).

Sectoral Adaptation Policies

Bangladesh has developed a good number of sectoral adaptation policies since 1990. Considering the fact that Bangladesh is highly susceptible to climate change, only one sectoral policy on the coastal zone has considered climate change (BCAS 2010). The National Water Policy (NWP) was formulated in 1999, considered firstly short-, medium-, and long-term perspectives for water resources in Bangladesh. The NWP was followed by the National Water Management Plan (NWMP) in 2001. Though there is a huge effect of climate change on water resources in Bangladesh, the NWP does not mention the climate change issue at all. However, the NWMP identifies climate change as one of the future elements affecting supply and demand of water. The National Environmental Management Action Plan (NEMAP), which was published in 1995, does not illuminate climate change. Similar to NEMAP, the National Land Use Policy (NLUP) and the National Forest Policy (NFoP) do not make direct reference to climate change. Climate change was not also addressed in the Poverty Reduction Strategy (PRS) papers until recently. The present PRS recognizes the threat of climate change and its adverse impacts on the development process. It understands the need for integration/mainstreaming. Integration/mainstreaming of adaptation measures into other policy areas and the implementation of the adaptation projects were identified in the NAPA (BCAS 2010).

Institutional Mechanisms

There are many departments in Bangladesh working for institutional mechanisms for climate change. The Ministry of Environment and Forests (MOEF) is mainly responsible for policy formulation on climate change and its adaptation while the Climate Change Unit (CCU) and Department of Environment (DOE) implement projects and programs under NAPA and BCCSAP at the community level. The National Steering Committee on Climate Change (NSCCC), chaired by the Minister of MOEF, is composed by secretaries of all climate-affected ministries, divisions, and representatives of civil society and business community. The National Environment Committee under the ministry is expected to mainstream climate change into national development planning. Climate Change Focal Points (CCFP) in various ministries are expected to provide collaboration. Five technical working groups have been constituted for adaptation, mitigation, technology transfer, financing, and public awareness (Country Summary Report 2010).

Climate Change and Internal Displacement: International Legal Framework

Bangladesh ranks as the country most at risk of natural disaster. The displacement occurs in the immediate, sudden onset such as flood, cyclones, and riverbank erosion, etc.; the people move from one place to another place and seek to return to their homes as soon as they can, but sometimes it is quite impossible to return to their homes when the areas are repeatedly inundated. Displacements due to sudden onset are predominantly localized in Bangladesh. The people living in the vulnerable areas are very poor and lack resources; they do not move to a long-distance place and do not have any support from the networks of other countries. They remain in their home country and qualify as an internal displacement.

Guiding Principles in Internal Displacement (1998)

The guiding principle on internal displacement is one of the promising initiatives at the international level to promote and provide protection and assistance for internally displaced person (IDPs). These principles fill a major gap in the international protection system for the rights of IDPs and the obligation of governments and insurgent forces in all phases of displacement. They offer protection before internal displacement occurs (i.e., protection against arbitrary displacement), during situations of displacement, and in postconflict return and reintegration.

The United Nations officially first dealt with internally displaced persons in 1972, but did not define who exactly would be considered to be internally displaced. ECOSOC res. 1705 (LIII), 27 Jul. 1972. *Para.* 1 of resolution 1705 provides that "The Economic and Social Council urges Governments, The United Nations High Commissioner for Refugees, specialized agencies and other organizations associated with the United Nations and nongovernmental organizations concerned, to provide the assistance required for the voluntary repatriation, rehabilitation and resettlement of the refugees returning from abroad, as well as persons displaced within the country."

Francis Deng, nominated as Special Representative of Secretary-General on the human rights issues related to internally displaced persons by Commission on Human Rights in 1992, further refined the existing definitions. In 1998, he submitted a set of "Guiding Principles on Internal Displacement" to the Human Rights Commission.

The needs of the IDPs stem from twofold danger (Geissler 1999):

(a) Whenever persons are forced to leave their homes or places of habitual residence, multiple human rights violations, such as acts of violence, armed attack, torture, disappearances, or rape, are committed on them.
(b) There is no clearly defined institutional protection for IDPs and have only little coordinated ad hoc responses.

Several initiatives have been taken to address the plight of internally displaced persons more efficiently. In the quest for a more effective response, the international community has concentrated its efforts along two main lines, that of identifying an appropriate normative framework and that of developing effective institutional arrangements. The Representative of the Secretary-General on internally displaced persons, Mr. Francis Deng, has been catalytic to these initiatives and, more generally, to stimulating a better understanding of the numerous complex issues associated with internal displacement.

A number of international bodies, guidelines, and standards also exist which specifically protect the rights of displaced persons. These include the Guiding Principles on Internal Displacement, the *Pinheiro Principles*, the United Nations Inter-Agency Standing Committee's Guidelines on Human Rights and Natural Disasters, the Human Rights Council Resolution 7/23 and 10/4 on Human Rights and Climate Change, the 1951 Geneva Convention, the Code of Conduct for the International Federation of the Red Cross and Red Crescent Societies and NGOs in Disaster Response Programmes, the Responsibility to Protect of the International Commission on Intervention and State Sovereignty, and the Humanitarian Charter of the Sphere Project.

The United Nations Principles on Housing and Property Restitution for Refugees and Displaced Persons (the Pinheiro Principles) (UN Sub-Commission 2005). There are 23 principles recognizing the right to be protected from displacement, right to housing and property restitution, right to nondiscrimination, right to equality between men and women, right to privacy and respect for the home, right to peaceful enjoyment of possessions, right to voluntary return and safety, right to freedom of movement, etc.

The United Nations Inter-Agency Standing Committee's Guidelines on Human Rights and Natural Disasters (IASC 2006) ensures that displaced persons or those otherwise affected by natural disasters do not lose the rights of the population at large, and at the same time, they have particular needs which call for greater protection and assistance measures. It also states that protection is not only limited to securing survival and physical security but also encompasses all aspects of civil, political, economic, social, and cultural rights as afforded by international standards.

The Human Rights Council Resolution on 28 March 2008 adopted its first resolution 7/23 (HRCU 2008) and on 25 March 2009 adopted another resolution *10/4 on Human Rights and Climate Change*, recognize the relationship between human rights and climate change, and also climate change-induced displacement. It also recognizes that climate change is a global problem and that it requires global solution. The Human Rights Council has taken the decision to hold panel discussions on the relationship between climate change and human rights in order to contribute to the realization of the goals set out in the Bali Action Plan.

The 1951 Refugee Convention while not providing protection for persons fleeing environmentally harm and natural disaster could be useful in narrow circumstances whereby victims are entitled to protection under the principle of *non-refoulement*. This would prevent a government's return of a person from their country regardless of legal status, where the person's life or integrity are at risk or where return would subject the person to cruel, unusual, or degrading treatment.

The Code of Conduct for the International Federation of the Red Cross and Red Crescent Societies and NGOs in Disaster Response Programme affirms that the humanitarian imperative comes first and without any discrimination and that disaster-affected victims will be recognized and treated as dignified humans.

The doctrine of responsibility to protect was first established in 2001 by a group of prominent human rights leader comprising the Report of the International Commission on Intervention and State Sovereignty on the Responsibility to Protect which aims to develop "global political consensus about how and when the international community should respond to emerging crises involving the potential for large-scale loss of life and other widespread crimes against humanity."

The said doctrine reaffirms that the primary responsibility for the protection of its displaced people, but that in situations where this is not possible or not being done, the international community will intervene which includes scenarios of overwhelming natural or environmental catastrophes.

The Humanitarian Charter and Minimum Standards of the Sphere Project is structured around the three core principles of the right to life with dignity, the right to protection and security, and the right to receive humanitarian assistance. The minimum standards ensure that affected persons have access to at least the minimum requirements of water, sanitation, food, nutrition, shelter, and healthcare in order to satisfy their basic right to life with dignity. Although these guidelines and instruments are not legally binding, they provide a *soft law* approach to dealing with the issue of displaced persons. It should be mention here that most of these instruments only cover displacement caused by natural disasters and do not take into account displacement caused by environmental degradation such as desertification or movement caused indirectly by climate change. It is predicted that the majority of climate change-induced displacement be caused indirectly, and therefore, there is an urgent need to formulate a framework for the protection of their rights (Fitma et al. 2010).

Conclusion

Climate change poses a dreadful challenge for all countries, but its major impact will be on developing countries like Bangladesh. Climate displacement in Bangladesh, which is increasing day by day due to climate change, increases the frequency and intensity of the natural hazards that are already leading to displacement in Bangladesh. It is very essential to take effective and appropriate arrangement to make a durable solution to this growing issue. However, migration policy should be better integrated into the national development agendas as well as development cooperation. Development cooperation can help vulnerable communities living in absolute poverty to mitigate the impacts of environmental degradation and climate change and to reduce their vulnerability to the effects of such phenomena. Development strategies must in the future also pay more heed to the sustainability of development plans in the light of foreseeable climate impacts at local level. For example, the agricultural development of a region likely to be strongly affected by drought in the future should be reevaluated (Committee on migration, refugee and population 2008).

Climate change and climate change-related effects have a horrific impact not only on the environment but also on the human inhabitants. The number of natural disaster is growing together with the number of people who are migrating from one place to another place due to climate change. If the process is continued, between 50 million and 350 million climate migrant will be expected by 2050. The existing policies and institutional mechanism should be reviewed for better disaster responses. The primary responsibility goes to the government to address the immediate and future displacement crisis in Bangladesh. The capacity of the government and other national and international concerned authority has to plan and implement adaptive program to meet the challenge of climate change. Proper training, education, and awareness program has to be undertaken for the capacity building. Additionally proper implementation of the policies and guidelines needs to be ensured for better displacement of the person. Every attempt should be taken by the concern authority to find domestic solution to displacement, in the event that domestic solution is no longer viable. The international environmental law as well as international human rights law can play a vital role as appropriate mechanisms are crafted to support developing countries in their response to the adverse impacts of climate change. The international community has also taken the matter as an urgent and calls for political will to make it happen.

Climate Change and Health in Colombia

Tam Tran, Salua Osorio Mrad, and Gilma C. Mantilla

Contents

Abstract

As the impacts of climate change become more widely acknowledged, federal governments are beginning to address the subject in the national agenda. However, the difficulty in determining the magnitude and impacts of climate change has led to challenges in policy-making. This chapter seeks to create a

comprehensive understanding of how Colombia and the federal government have made important advances in implementing a climate change framework with a focus on health.

This chapter will provide context on the role and responsibilities of the government before discussing the climatic conditions of Colombia and how climate change is impacting the country, especially on the health sector. Such discussion will justify why climate change is a major current and future priority for the country. The chapter will then examine the existing climate change policy framework and ongoing projects that are targeted toward climate and health. This chapter will show that there is still a need to improve the capacities and interest of the public health research community by improving the evidence and knowledge about climate change impacts, vulnerability, and risk. Understanding Colombia's national circumstances will allow other countries and decision-makers to potentially use Colombia as an example to define their own health and climate change agendas.

Introduction

With the annual carbon dioxide maximum having recently exceeded 400 ppm, the IPCC reports have agreed that climate change will likely impact society but there is a great deal of uncertainty on the extent and timing of such impacts. Developing countries currently and will continue to experience the most negative impacts. Many countries lack the necessary resources and do not have an existing framework to create federal policies to respond to climate change. Furthermore, it is anticipated that public health will be highly impacted by climate change but the health sector currently lacks the federal support and resources to create and tailor policies accordingly.

Climate change and health issues have recently become a large concern globally and they are starting to be addressed in many developing countries. A climate change policy framework, with a focus on health, will be provided on Colombia because of the progress that has been made within the country and by the government. Brief pertinent background information on the political structure of Colombia will be illustrated so context can be provided on the role and responsibilities of the government. The chapter will then discuss the climatic conditions of Colombia and how climate change is impacting the country, especially in the health sector. Such discussion will justify why climate change is a major current and future priority for the country. The chapter will then examine the existing climate change policies, with a focus on climate change and health policies, in Colombia where advances have been made.

The hope is that by illustrating existing federal policies in a developing nation, other developing nations may also learn and replicate the successes of Colombia's policies within their own respective countries. By demonstrating the progress that has been done within Colombia, the goal is that other countries may eventually use similar Colombia's climate change framework to define their own health and climate change agendas. Providing information on a government's current capabilities and how climate change impacts each nation is crucial because without such background, context cannot be provided to justify why federal policies should be prioritized or enforced.

This chapter utilized governmental documents, publications from major organizations, and scientific articles to discuss the current policies in Colombia. The authors of this chapter relied on peer-reviewed publications, when available, but this was not often possible because of the lack of available publications on the Colombian policies. The greatest efforts were thus made to utilize documents published by the Colombian government in an attempt to ensure accuracy on Colombia's status. By doing so, this allowed less limitation in illustrating the current political framework in Colombia.

Background

Despite contributing only 0.2 % of the total global carbon dioxide emissions, Colombia is considered highly vulnerable to the negative social, economic, and environmental impacts of climate change (Ideam 2010). Certain climate change impacts are already occurring in the country based on studies such as the Integrated National Adaptation Project (INAP) conducted by the Institute of Hydrology, Meteorology, and Environmental Studies of Colombia (IDEAM); the Institute of Marine and Coast Research (INVEMAR); the Corporation for the Sustainable Development of the Archipelago of San Andrés, Providencia, and Santa Catalina (CORALINA); and the National Institute of Health (NIH) (World Bank 2012). Colombia has been cited as a leader in developing climate change policies (Comstock et al. 2012).

Colombia is a party to the United Nations Convention on Climate Change and has signed and ratified the Kyoto Protocol (European Commission 2009). As part of its commitments to the Convention, Colombia published its First National Communication (NC-1) in 2001, identifying malaria and dengue fever/DHF as climate-sensitive diseases of primary concern (IDEAM 2001). The Second National Communication (NC-2) was published in 2010 and updated the greenhouse gases inventory, the climate change scenarios, and the national policies and plans associated with mitigation and developed a method to estimate vulnerability to compare the different sectors, ecosystems, and institutions (Ideam 2010). Colombia is currently developing the Third National Communication.

The main national environmental authority in Colombia is the Ministry of Environment and Sustainable Development (MEDS), which is responsible for the climate change agenda (MinAmbiente). The IDEAM, affiliated with MEDS, is responsible for producing and managing the scientific and technical information on the environment (IDEAM 2001). IDEAM is the country's leading agency for climate change and is responsible for producing United Nations Framework Convention on Climate Change (UNFCCC) documents and relevant supporting material (IDEAM 2001).

The main health authorities in Colombia are the Ministry of Health and Social Protection (MSPS) and the National Institute of Health (NIH). The Ministry is responsible for directing the health-care system and social protection through policies on health promotion, prevention, treatment, and rehabilitation (MinSalud). It is also responsible of the inter-sectoral coordination to develop the public health policy (MinSalud). The National Institute of Health (NIH), affiliated with the MSPS, promotes scientific research, innovation, and formulation of studies according to the public health priorities. NIH is the lead institution on the public health surveillance system (Ministerio de Salud y Protecciòn Social 2012).

Using governmental documents and scientific publications, this chapter will provide insight on how climate change impacts Colombia and health, and governmental actions on this subject. Background will first be provided on the climate in Colombia and how climate change impacts health.

Climate

Colombia is located on the equator and is thus affected by the intertropical convergence zone, ITCZ (Ideam 2010). The migration of the ITCZ is the dominant factor in controlling the annual hydroclimatic cycle and corresponds to the trade winds movement (Poveda et al. 2005). The average annual precipitation in Colombia is 3,000 mm but varies drastically in different parts of the country due to the geography and topography (Ideam 2010). While temperatures range from very hot to very cold, the temperatures show minimal seasonal variation at the same altitude (World Bank 2011b). Most of the climatic differences are due to the differences in elevation.

The spatial variability is controlled by Colombia's geography, such as the eastern Pacific and western Atlantic oceans, the Andes mountains, atmospheric circulation over the Amazon basin, and soil and vegetation moisture contrast (Poveda et al. 1999). The Choco jet, a westerly at 5°N, and the easterly San Andres jet at 12–14°N are low-lying jet stream that affects climate variability (Poveda et al. 2005).

ENSO, the El Niño Southern Oscillation phenomenon, is a major driver in the climate and the hydrological cycles at interannual timescales in the Pacific (Poveda et al. 2005). It has particularly strong impacts on the northern regions of South America (Poveda et al. 2005). During El Niño events, Colombia is more likely to experience droughts, reduced rainfall, and increased air temperature (Poveda 2009). During La Niña, Colombia generally experiences wetter conditions (World Bank 2011b). ENSO occurs later and is weaker in the east than in the western and central part of Colombia (Poveda 2009). ENSO affects the ITCZ in northern South America by causing a decrease in convection by a weaker land-sea thermal contrast and extra subsidence over the ITCZ (Poveda 2009). In recent years, from 2009 to

2011, El Niño caused the reservoirs for water supply to drop to critical levels, whereas La Niña resulted in heavy rainfall that led to landslides and major floods and maximized the capacity of reservoirs (Barriga 2011).

According to IDEAM, Colombia has five major climatic regions: hot (with elevations below 900 m below sea level), temperate (900–1,980 m), cold (1,980–3,500 m), high-altitude grasslands (the so-called paramos, 3,500–4,500 m), and areas of "permanent" snow (above 4,500 m) year (Colombia dashboard: climate baseline). Under the Holdridge classification, 60 % of the Colombia territory is warm humid, 8.9 % is warm dry, 7.65 % is warm very humid, 4.63 % is template humid, 4.13 % is template dry, 2.76 % is cold humid, and 2.17 % is very cold humid (Atlas climatológico de Colombia: Segunda Parte). The remaining categories do not exceed 1 % (Atlas climatológico de Colombia: Segunda Parte). The hot region experiences temperatures from 24 °C to 38 °C and alternates between dry and wet interannual seasons (World Bank 2011b). The temperate has an annual temperature range between 19 °C and 24 °C; there are two wet seasons, from April to June and October to December, and two dry seasons from January to March and July to September (World Bank 2011b). The cold zone has an average temperature range between 10 °C and 19 °C and the wet seasons are bimodal, occurring from April to May and September to December (World Bank 2011b).

Climate Change Impacts

In the last 20 years, the temperature has increased by 1 °C (Colombia overview). From 1974 to 1998, the temperature change in the Central Andes was 0.34 °C, 70 % greater than the average global temperature change (European Commission 2009). Precipitation has increased in Colombia by 5 % from December to February (World Bank 2011b). Precipitation is decreasing in the north while increasing in the south (Blanco and Hernández 2009). In central Colombia, rainy seasons have recently been occurring earlier, with positive anomalies for intense rainfall events and consecutive dry days (Colombia dashboard: climate baseline).

As aforementioned, climate change is currently and will further impact Colombia in the future. The Pacific Decadal Oscillation, PDO, is expected to enter a negative phase in the upcoming years (Barriga 2011). This will likely result in more frequent La Nina events and wetter than average conditions, thus prolonging the rainy period cycle (Barriga 2011). Extreme climatic events and variability are predicted to increase (Barriga 2011). The long 2005 drought period led to projections that the savannah region will expand in Colombia (European Commission 2009). Snow-covered regions are likely to completely vanish and over half of the moorland may disappear (World Bank 2009). This will result in a loss of natural resources, especially water (World Bank 2009). A simultaneous increase in the rainy season could result in higher risks of flooding (World Bank 2009). These climate change forecasts will be especially problematic for the future of Colombia because the country already suffers from water shortages and land instability in the Andes (Slunge 2008). Along with drastically affecting land settlements and economic activities, climate change is expected to negatively impact those in poverty and will thus challenge the country's Millennium Development Goal of reducing poverty (Côté et al. 2010).

Using 1971–2000 as a base period, climate change scenarios have projected an increase in the mean temperature of 0.13 °C per decade for 1971–2000 (Climate change). The multi-model ensembles have predicted that the average air temperature will increase to 1.4 °C for 2011–2040 and 2.4–3.2 °C from 2041 to 2070 and for 2071–2100 (Climate change). In the next century, the total amount of precipitation will reduce between 15 % and 36 % for much of the Caribbean and Andean regions and increase around the Pacific Region (Climate change). Predictions have indicated that there may be a rise of 40 and 60 cm of sea level in the Caribbean and Pacific Coasts, respectively, compared to the base period (Impactos del cambio climático del nivel nacional; World Bank (2013b).

Based on these results, the following socioeconomic sectors and natural systems were identified as the most vulnerable: costal zones, water resources, glaciers, highland Andean ecosystems and associated forest cover, soils and land undergoing desertification, the agricultural sector, and human health due to an expected increase in exposure to tropical vector diseases such as malaria and dengue (IDEAM 2001). INAP, based on the NC-1 results, identified areas of primary concern: high mountain ecosystems (notably moorlands), insular and coast areas, and human health (World Bank 2012). These topics were selected as topics of significant concern due to their high vulnerability to climate variation and their importance for human populations (World Bank 2012).

The INAP project has made several important advances in response to climate change by producing important results regarding water and carbon cycle in high mountain ecosystems; glaciological mass balance related to interannual climate events such El Niño and La Niña; planning models of land use that incorporate climate change impacts through an "Adaptive Ecological Territorial Structure" (EETA); the establishment of the system of observation of the oceans (GOOS) in the Caribbean based on the installation of physical and biological monitoring stations; supporting the implementation of a marine protected area in the area of Corales del Rosario, San Bernardo, and Isla Fuerte; development of a management system for managing groundwater reserves in the San Andres; and implementation of a monitoring system of coastal erosion (World Bank 2011a).

Climate Change Impacts on Health

Most of the evidence of the impact of climate and climate change on health is on communicable diseases, mainly vector-borne diseases (Epstein 1997). The information available in Colombia is regarding malaria, dengue fever, leishmaniasis, and leptospirosis. There are also some preliminary studies about acute respiratory disease (ARD). Recent information has been released in Colombia on how climate change impacts health so this chapter will provide an update on published information.

Malaria is a protozoal disease caused by infection with *Plasmodium* spp. and is transmitted to humans through the bite of an infected female mosquito, *Anopheles* species. Of the four known parasite species that cause malaria, three are found in Colombia: *Plasmodium vivax*, *Plasmodium falciparum*, and *Plasmodium malariae* (Blanco and Hernández 2009).

Malaria transmission is highly sensitive to climate conditions. Temperature is a significant driver and determines their reproduction and maturation rates for both the mosquito vector and the *Plasmodium* parasite (Blanco and Hernández 2009). The parasite is unable to develop in its vectors when ambient temperature is below 18 °C (Olano et al. 2001). Rainfall and humidity provide essential environmental characteristics for juvenile mosquito development (breeding sites) and adult survivorship (Blanco and Hernandez 2009; Wernsdorfer and McGregpr 1988). Consequently, it is expected that climate change will affect malaria transmission dynamics (Blanco and Hernández 2009).

Approximately 13 million Colombians live in regions with endemic malaria transmission (MSPC 1996, 2000, 2003a, b). Malaria incidence is mostly rural (Valero-Bernal 2006). The annual parasite index (total infectious/population at risk) increased from 6.2 (2008) to 7.9 (2009) to 11.48 (2010) to 6.3 (2011) (INS). Approximately half of malaria cases are concentrated in two states; 75 % of them are reported by 44 municipalities (World Bank 2011a). The Colombian Pacific coast (with an area of about 72,000 km^2 and almost 2.2 million inhabitants) typically concentrates 10-30 % of the total malaria cases in Colombia for the last 50 years, with 24 % in 2008 (Rodríguez et al. 2011). The Urabá-Sinu and Bajo Cauca region (43,400 km^2 and 2.5 million inhabitants) comprised of 60 % of total cases in 2010 and the Amazon-Orinoquia region concentrated nearly 8 % (Rodríguez et al. 2011).

Even though malaria is a highly complex multifactorial disease, some studies have demonstrated a significant relation between the occurrence of ENSO and the increase in malaria cases in South America (Barnston et al. 1997, Gagnon et al. 2002). Several studies on Colombia's nationwide malaria situation showed a significant association between ENSO and increases in the number of malaria cases (e.g., Poveda and Rojas 1997; Bouma et al. 1997; Poveda et al. 2001; Mantilla et al. 2009). Poveda and Rojas (1997) reported evidence of the association between malaria epidemics and the occurrence of the warm phase of ENSO (Poveda et al. 2001). Based on malaria morbidity profiles observed over the period from 1960 to 1992, Bouma et al. (1997) suggested that malaria cases are likely to increase by 17.3 % during El Niño years and by 35.1 % in the post-Niño years. Poveda et al. (2001) stated that the El Niño event intensifies the annual cycle of Colombia's *P. falciparum* and *P. vivax* malaria cases in endemic rural areas as a consequence of the concomitant anomalies in the normal annual cycles of temperature and rainfall. More recently, Mantilla et al. (2009) further reinforced these observations by showing that ENSO is a significant predictor of the number of malaria cases in Colombia, particularly in lowland regions along the Pacific and Atlantic coasts.

Other studies have also quantified projections in the number of expected malaria cases. In a study by Blanco and Hernández (2009), they used the IPCC scenarios to predict the climate change impacts on temperature and precipitation. Based on those scenarios, the study calculated the additional increase in malaria cases based on the 6-year disease period from 2000 to 2005 (Blanco and Hernández 2009). During this 6-year period, *P. falciparum* had 184,350 cases; for a 50-year scenario, cases are expected to increase by over 19,000 cases and nearly 57,000 cases over a 100-year scenario (Blanco and Hernández 2009). During the same 6-year period, *P. vivax* had 274,513 cases; for a 50-year scenario, cases are expected to increase by over 16,000 cases and over 48,000 cases over a 100-year scenario (Blanco and Hernández 2009).

According to the results of INAP (World Bank 2011a), the impact of temperature and precipitation varies from region to region. Temperature is the key determinant for malaria transmission in the Pacific zone, precipitation for the Orinoquia zone, and both temperature and precipitation for the Atlantic zone. Forecasts were made using dynamic models. In the medium term (2015), the model suggested increases of 6–15 cases per 1,000 habitants assuming constant socioeconomic and entomological conditions. For the long term, the model suggested a strong increase in the number of cases until 2040 where the prevalence starts to decrease.

Dengue is a viral and urban disease transmitted to humans through the bite of an infected female mosquito, *Aedes aegypti* (Padmanabha et al. 2012) The mosquito species are particularly susceptible to environmental conditions, an important factor in dengue transmission (CDC 2010). The viability and reproductivity of mosquitoes are dependent on temperature, precipitation, and humidity (CDC 2010). Higher temperatures have been noted to reduce the life cycle of the virus in the vector (CDC 2010). As temperature increases, mosquitoes will have a higher likelihood of transmitting dengue fever to humans (CDC 2010). Four dengue serotypes exist worldwide and Colombia is at risk for all four serotypes (WHO 2009).

The report conducted by Bello Pérez (2011) showed that 75 % of the national territory, located at altitude of 1,800 m, has conditions of temperature, relative humidity, and rainfall suitable for dengue transmission. This is distributed in 620 endemic municipalities with a total population of 23,607,414 people at risk. 80 percent of the disease burden is recorded in 100 endemic municipalities. Since its reemergence in the 1970s, dengue transmission has presented a wide geographic expansion and intensification in the Colombian territory. This phenomenon was especially evident during the last decade. There was an increasing trend in the number of municipalities where dengue cases were recorded annually, from 402 municipalities with endemic transmission in 1999 to 621 municipalities in 2009 (Vigilancia Rutinaria). In 2010 Colombia experienced the largest epidemic in the history of the country, with a total of 147,426 cases of dengue in total, 221 confirmed deaths, and a case fatality rate of 2.26 % (Vigilancia Rutinaria).

There are mix reports on the effect of temperature on dengue fever. It has been suggested that herd immunity, rather than temperature, is the limiting factor on transmission intensity (Blanco and Hernández 2009). Other reports have linked disease transmission to temperature. The larval mosquito matures over a specific temperature threshold and freezing temperatures will kill the eggs (Poveda et al. 2005). Moderately high temperatures can accelerate the larval stage, causing smaller mosquitoes that feed more frequently (Poveda et al. 2005). With climate change, temperature ranges are expected to shift geographically and may allow transmission of dengue fever into new locations. The aforementioned study by Blanco and Hernández (2009) included predictions on the additional increase in dengue fever based. During the 6-year period from 2000 to 2005 which was used as their base study, there was a total of 194,330 dengue cases recorded (Blanco and Hernández 2009). For a 50-year scenario, cases were expected to increase by over 41,000 cases and over 123,000 cases for a 100-year scenario (Blanco and Hernández 2009).

The INAP report (World Bank 2011a) included a summary of the dengue fever situation in Colombia. The use of climate and dengue models currently has limited impacts on controlling dengue fever. Colombia has focused on intervention strategies that focus on dengue vector production because it is easier to control the transmission dynamics. INAP uses a targeted approach to determine how climate change affects dengue fever in the country by understanding four key processes. First, INAP recognizes that water insecurity and high costs affect human behavior; improper storage due to instable conditions can lead to increased vector production. Climate change is expected to further increase the cost and instability of water, which will require people to have better water storage. Second, the density of people and displacement are significant considerations. Cities with more than 150,000 people constantly suffer dengue fever, suggesting that epidemics are amplified by high population density. Human migration between cities can spread transmission. Third, property size and precipitation affect dengue fever dynamics because close quarters increase the density of the population, thus causing a higher risk of human contact. Furthermore, living in cities with water storage containers reduces seasonal variation and changes how mosquitoes have seasonal production. Lastly, variation in temperature and height affects mosquito interaction. Overall models suggest that human adaptation to water uncertainty will have a larger impact on dengue risk for regions above 1,200 m and below 600 m compared to the intermediate regions. Larval mortality is generally greater at 24–26 °C than 20–22 °C or 28–30 °C. Currently, dengue fever activities are based on local health authorities. The present control activities for epidemics are often expensive because they require vector control resources and short-term intervention strategies, e.g., spraying insecticides during epidemics. While these methods have not been very effective, the increase in population immunity has led to reduced epidemics, creating a false sense of success. More effective control strategies will require more spatiotemporal adaptation to water insecurity access, a risk assessment of dengue fever, and connecting the ongoing work at a local and national level.

Leishmaniasis is caused by *Leishmania* species and is vectored by sand flies, the *Lutzomyia* species (Cardenas et al. 2006). Of the three forms of the disease, cutaneous comprises 95 % of reported leishmaniasis cases in Colombia (Valderrama-Ardila et al. 2010). The disease distribution can occur in different climates and habitats, with the Andean region having the highest disease rates (Valderrama-Ardila et al. 2010). Leishmaniasis has been linked to ENSO cycles in northeastern Colombia (Cardenas et al. 2006). During El Niño, the rate of incidence increases because of the dry conditions (Cardenas et al. 2006). In contrast, during La Niña, the rate decreases because of the wetter season (Cardenas et al. 2006). The number of cases reported in the country has increased significantly from 6,500 cases per year in the 1990s to over 16,000 cases per year by 2006 (Valderrama-Ardila et al. 2010). As the climate warms in the future, it is suggested that this will lead to ideal conditions for *Leishmania* development (Cardenas et al. 2006).

Climate variability has also been demonstrated to affect rodent-borne diseases in Colombia, including leptospirosis. Humans and susceptible animals acquire disease by contact with surfaces, water, or food contaminated with urine infected by the bacteria. The most common reservoirs are rats, dogs, wild animals, cows, and pigs. The incidence of leptospirosis depends on the environmental and climatic conditions influencing the dynamics of the rodent population, size, and behavior. In 1995, there was a significant outbreak of leptospirosis, in Colombia along the Caribbean coast (Cardenas et al. 2006; Pappas et al. 2008). From 1990 to 1995, the El Niño period was linked with a long drought period (Epstein 1997). However, the drought period ended with an extreme rainfall that marked the beginning of a La Niña period, which lasted from 1995 to 1996 (Epstein 1997). As a result, rodents left their burrows and caused an increase in leptospirosis outbreak (Epstein 1997).

For other diseases like acute respiratory disease (ARD), most of the information is from studies conducted in Bogotá by Alcaldía Mayor de Bogotá et al. (2011). The epidemic peak of acute respiratory disease develops between the months of March and June and is associated with phenomena like intensification of rainfall, changes in ambient temperature, and changes in the circulation of respiratory viruses. However, in the winter season of 2010, the torrential rains presented since June and became stronger in August and extended until November. This resulted in flooding in the rainy season, which began in August, and an increase in cases of ARD in Bogotá from this month was observed.

For other types of diseases in Colombia, the effect on climate change on health is inconclusive. There is the general belief among the health sector that climate can be associated with the increase in some diseases but further research will be required.

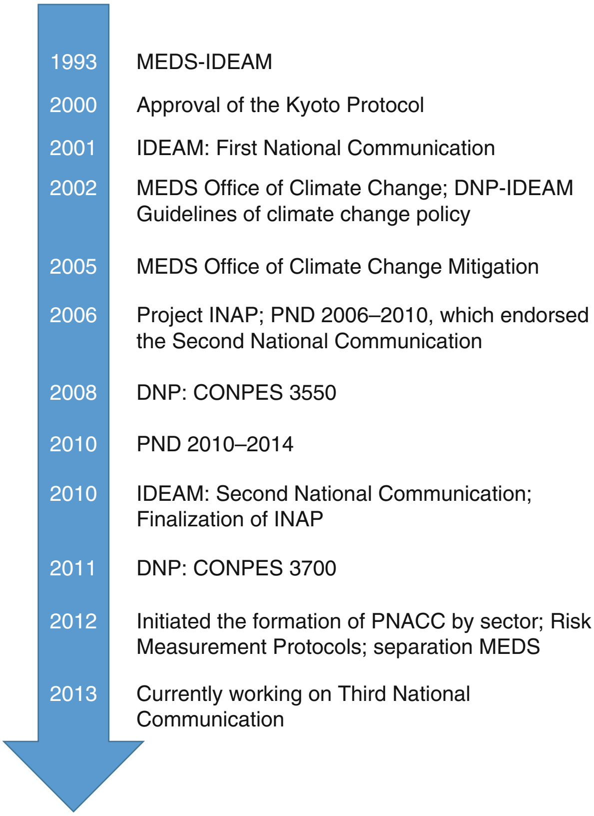
Policies on Health and Climate Change

In recognition that climate change will impact all sectors, the Colombian government is encouraging a multi-sectoral approach to programs and policies. A summary on climate change policies that are relevant to the health sector responding to climate change impacts will be provided as a framework (see Fig. 1).

Climate Change Policy Framework

Along with Colombia's international commitments, Colombia has made several advancements in linking policies with climate change in the National Development Plan (PND) from 2006 to 2010 and 2010 to 2014. The National Economic and

Fig. 1 Milestones in climate change adaptation and mitigation



Social Policy Council (CONPES) 3550 and 3700 articulated support for these plans and the the Basic Adaptation Concepts (ABC), included in PND 2010–2014, outlined the conceptual framework for climate change adaptation. These documents have provided the fundamental concepts for the different sectors, including health, when integrating climate change into their sector's agenda.

The PND of 2006–2010 endorsed the NC-2 and identified the necessity to support Clean Development Mechanism (CDM) projects, to seek options for reducing greenhouse gases (GHG) emissions, and to call for a national climate change policy and a comprehensive action plan on the issue (IDEAM 2001). The policy defined the institutional framework to coordinate the actions proposed therein (Plan Nacional de Desarrollo 2006–2010). The PND of 2010–2014 focuses its attention in relation to climate change in the following issues: National Plan for Climate Change Adaptation, Strategy for Disaster Financial Protection, Forest Policy and Avoided Deforestation (REDD+), and Colombian Strategy of Low Carbon Development (Sostenibilidad ambiental y prevención del riesgo).

The National Adaptation Plan 2010–2014 is coordinated by the Department of National Planning (DNP) with the support of the MEDS and IDEAM and is intended to reduce risk and socioeconomic impacts associated with climate variability and change (ABC: Adaptación bases conceptuales). It consists of four phases from 2012 to 2014 (ABC: Adaptación bases conceptuales). The Basic Adaptation Concepts (ABC), by the DNP, represents the first part under this plan and consists of four sections (ABC: Adaptación bases conceptuales). It is intended to build a conceptual framework for climate change adaptation for the country and establish guidelines to be followed during the formulation process for the different sectors and territories (ABC: Adaptación bases conceptuales). The first section explains the context that the National Adaptation Plan of Climate Change (NAPCC) was developed under, the second presents a conceptual framework that explains adaptation concepts, the third presents the main reasons to promote adaptation in Colombia, and the last defines the necessary guidelines for planned adaptation (ABC: Adaptación bases conceptuales).

CONPES 3550 was published on November 2008, with the main objective to define general guidelines that will strengthen the comprehensive management of the environmental health (DNP 2008). CONPES 3550 is oriented to prevent, manage, and control adverse health effects that result from environmental factors (DNP 2008). It serves as a basis for the formulation of the Comprehensive Environmental Health Policy (DNP 2008).

CONPES 3700 of July 2011, as stated by the DNP (2011), is a strategy to configure an inter-sectoral coordination mechanism to facilitate and promote the formulation and implementation of policies, plans, programs, incentives, projects, and methodologies in climate change. This will allow the inclusion of climate variables as determinants for the design and planning of development projects. CONPES 3700 is currently establishing the Climate Change National System (SNCC). The SNCC will consist of an Executive Committee of Climate Change (COMECC), a Financial Management Committee, a steering group, an advisory group, and four permanent subcommittees (sectoral, territorial, international affairs, and climate change studies and information production). The COMECC will be responsible for giving guidance and guide discussions on climate change at the national level and for ensuring the implementation and evaluation of policies, plans, and programs on the subject. Similarly, it will allow socializing at the highest level of government. The Financial Management Committee's main function will be to give technical feasibility and manage funding sources for projects submitted by the sectors, territories, or agent developers of adaptation and mitigation projects that do not have financial resources for its implementation. The permanent subcommittees will collect, analyze, and coordinate information, recommendations, and actions of the subjects in charge. They are to discuss and define studies and sectoral and territorial policies.

In addition to the national efforts, there are international efforts in Colombia as discussed by Côté et al. (2010). The Climate Change Mainstreaming Project was implemented between January 2009 and January 2010. It was implemented with assistance from UNDP, a 100,000 USD budget, and a four-person team. The project consisted of four stages. From January to March 2009, climate risks were assessed and a climate profile was produced; these were presented to the UN agencies and national entities to gain support. The second step occurred between April and July 2009 and resulted in the evaluation of risks and opportunities of climate change in national policy documents, development plans, UN plans, and UN projects, with an especially detailed analysis provided on the UN Development Assistance Framework (UNDAF). The third phase occurred during July, August, and November 2009; this organized public activities to present and gain feedback on previous efforts. This phase resulted in building capacities and the organization of a National Dialogue. The final phase, from September 2009 to January 2010, resulted in the publication of the Evaluation of Climate Risks and Opportunities in the Colombian UNDAF (2008–2012); in addition, it also involved correspondence with the IGCC and UN Agencies.

The project resulted in a risk and opportunity assessment of climate change in national policy, development plans, and UN projects (ALM 2011). Along with identifying stakeholders and UN initiatives in climate change issues and producing workshops, the Inter-agency Group on Climate Change of the Colombia UN Country Team was also created (ALM 2011). A UNDP methodology was produced for the evaluation of climate change risks and opportunities: "Quality Standards for the Integration of Adaptation to Climate Change into Developing Programming" (ALM 2011). It is intended to allow for the screening of climate change implications on projects and uses four "standards" (ALM 2011). This methodology was piloted in Colombia as a part of the Climate Change Mainstreaming Project and resulted in the recommendation of adaptation measures (ALM 2011). The principal aim for Colombia is to now launch a mechanism that will assimilate climate risks into a development assistance agenda (ALM 2011).

Using this framework, the Colombian Adaptation Plan will mainstream and integrate climate change considerations into the national agenda to develop capacities to face climate change challenge as further discussed by Côté et al. (2010). These adaptation measures are being implemented in high-priority regions, including the Caribbean islands and the Colombian mountain range, and in fundamental sectors, e.g., health and agriculture. Regional and local communities are now creating their own climate change adaptation plans, such as in the Coffee Belt and Capital Regions.

Climate and Health Policy

Climate change adaptation policies are targeted toward increasing research and building resilience (Ceron 2012). National public entities must incorporate an adaptation strategy to climate change into their agenda (Ceron 2012). The strategies should comply with the methodology defined by DNP, MEDS, and IDEAM (ABC: Adaptación bases conceptuales). In turn, the MEDS will support these public entities and require them to develop adaptation plans (ABC: Adaptación bases conceptuales). INAP is the most important health and climate change project and will be discussed in detail with brief insight on other ongoing governmental initiatives.

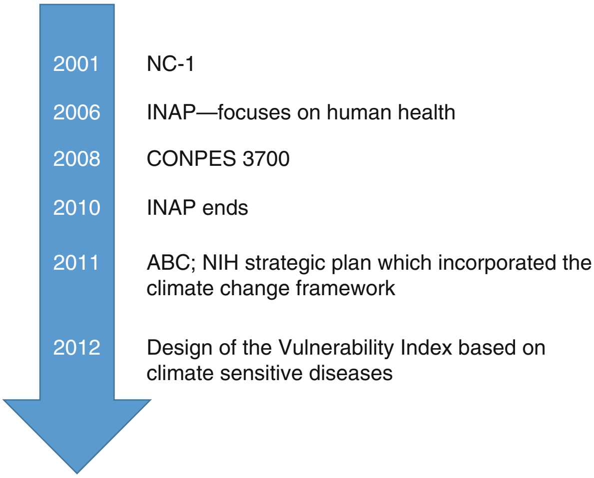


Fig. 2 Milestones in climate change and health policy

INAP was based on the TF Grant Agreement 056350 with 14.9 million USD (World Bank 2012). This project was partially founded by the GEF-World Bank and was coordinated by IDEAM and Conservation International-Colombia (Ideam 2010). This project had support from Accion Social, World Bank, IDEAM, Global Environment Facility, CORALINA, INVEMAR, and NIH (World Bank 2011a). The project was intended to span over the course of 5 years, from 2006 to 2011 (World Bank 2009). The objective of INAP was to support the Colombian government in implementing novel adaptation measures and policy options in anticipation of the impacts of climate change in high mountain ecosystems, Caribbean island areas, and human health (Ideam 2010).

INAP resulted in the opportunity for the health sector and the NIH to begin including climate change and the climate as a factor of consideration for the current and future status of health (World Bank 2011a). It allowed the incorporation of climate change into the NIH strategic plan 2011–2014 (World Bank 2011a). In addition, it provided the opportunity to participate in the CONPES document 3700 (World Bank 2012). INAP opened the discussions among the different sectors to face climate change impacts by allowing better understanding in the dynamics and effects of climate change (World Bank 2011a) (see Fig. 2).

Under INAP, Colombia proposed an Integrated Malaria and Dengue Surveillance and Control System, in order to avoid the potential negative impacts of climate change on human health in its territory (World Bank 2012). Some of the specific goals of this project included: (a) to strengthen the capability of the Colombian Institute of Hydrology, Meteorology and Environmental Studies to produce and disseminate continuous and reliable climate information relevant to the health sector and (b) to incorporate epidemiological, entomological, sociodemographic, and climatic data in the malaria and dengue surveillance system for proper understanding of malaria transmission and to regularly evaluate the spatiotemporal risk of infection in specific pilot sites and to develop locally adapted malaria and dengue control strategies (World Bank 2011a).

Furthermore, there have been efforts in Colombia on the vulnerability assessment front by including the most relevant findings from INAP as well as lessons from several other adaptation projects. The NIH is working on the development of a Vulnerability Index. The purpose of the vulnerability index is to guide the health sector adaptation plans, according to the DNP guidelines. The vulnerability index will allow identification and prioritization of adaptation measures. The conceptual framework is under construction and defines vulnerability as a function of sensitivity and adaptive capacity.

As stated by Ceron (2012), sensitivity consists of: (i) disease burden of climate-sensitive diseases and (ii) climate-sensitive risk factors associated to those diseases and that cannot be directly intervened by human action. A list of disease events that are sensitive to climate has been identified, including influenza, cholera, asthma, cardiovascular diseases, etc. A criterion was created to guide which diseases to focus in the Vulnerability Index in Colombia. The diseases must be a relevant public health burden in Colombia and there must be evidence that the diseases are impacted by climate. There must be at least 5 years of information from the surveillance system and information from other sources. It is also necessary that response to the disease is possible in the short and long term. The risk factors will be identified from literature review and expert focus groups. The diseases will also rate the sensitivity of the risk factor to the climate.

The adaptive capacity consists of governance and anthropogenic risk factors that are sensitive to climate, e.g., using bed nets with malaria (Ceron 2012). The conceptual framework should be consistent with DNP guidelines and its construction should include the participation of different sectors and institutions.

There are also local efforts to address the impacts of climate change on health, most notably in Bogotá, the capital city of Colombia whose population exceeds seven million inhabitants (DANE 2013a). As of 2011, several problems have been identified with climate change in Bogotá, including: increased risk of mortality due to the recurrence of extreme events, increase in diarrheal diseases due to changes in water supply, changes in patterns of viral circulation due to temperature and rainfall variation, changes in food security, effects of heat waves on morbidity and mortality, and increase in vector-borne diseases (Alcaldía Mayor de Bogotá et al. 2011). As a result, Bogotá has created a district environmental health policy that includes an intervention line related to climate change.

This intervention line has five main axes, as described by AlcaldÚa Mayor de Bogotá et al. (2011). First, there will be research development on the effects of climate change on health. Second, the plan will implement adaptation and mitigation processes to prevent further decline in health. Third, this will include the surveillance of events related to climate variability and change. Fourth, the plan will improve joint inter-institutional and inter-sectoral collaboration for the design of adaptation and mitigation measures. Lastly, the plan will strengthen community participation to reduce vulnerability.

Conclusion

Colombia has made important advances in implementing climate change adaptation and mitigation projects. Like many other developing countries, initial efforts and projects were concentrated in climate change mitigation and greenhouse gases inventory in response to the interests of information from UNFCCC. Even though these projects were responsible for introducing the topic, it is not until 2006 that the first national adaptation project (INAP) was developed. Since then, the federal government is slowly addressing the subject in the national agenda, which is being led by the National Planning Department (DNP).

The DNP has mainstreamed and integrated climate change into the National Development Plan. The department is also currently defining the strategy to configure an inter-sectoral coordination mechanism to facilitate and promote the formulation and implementation of policies, plans, programs, projects, and methodologies in climate change. This will allow the inclusion of climate variables as determinants for the design and planning of development projects. Given the prioritization process that will be required at the time of defining resources allocated for climate change adaptation, the leading role of DNP will be the key to successfully incorporating climate change adaptation into national policies.

Understanding and measuring vulnerability and risk to climate change is the first step in formulating and implementing adaptation plans. Although the initial efforts in Colombia were in identifying and implementing adaptation measures directly, the health sector has now focused on understanding and measuring vulnerability as one of the lessons learned from the INAP project. Despite the advances in Colombia, there is still a need to improve the capacities and interests of the public health research community and decision-makers and to further use climate information as another method of improving policies.

Climate Change and Urban Development in Africa

Asfaw Kumssa, Aloysius C. Mosha, Isaac M. Mbeche, and Enos H. N. Njeru

Contents

Abstract

Climate change poses a major threat to sustainable urban development in Africa. Changes in the frequency, intensity, and duration of climate extremes (droughts, floods, and heat waves, among others) will affect the livelihoods of the urban population, particularly the poor and other vulnerable communities

who live in slums and marginalized settlements. Extreme changes in weather patterns will increase incidences of natural disasters and impact on all key sectors of the economy, including the urban economy, agriculture and forestry, water resources, coastal areas and settlements, and health. In Africa, where livelihoods are mainly based on climate-dependent resources and environment, the effect of climate change will be disproportionate and severe. Moreover, Africa's capacity to adapt to and cope with the adverse effects of climate variability is generally weak. This chapter examines the relations between climate change and urban development in Africa and looks at the role and effect of climate change on urban development. It also assesses the available policy options for adaptation and mitigating climate change effects in urban Africa.

Keywords
Africa • Climate change • Urban development • Adaptation and mitigation policies

Introduction

Climate change is one of today's emerging threats and challenges to humanity. The signs are visible, while its adverse effects are felt across both the developed and developing nations. The high incidences of flooding and intense rainfall (Trapp et al. 2007), drought and heat waves, cyclones, hurricanes, and the frequent erratic weather patterns, which have exacerbated poverty, displacement, and hunger among millions of people, are partly attributable to climate change (Pall et al. 2011). The term climate change has been defined as a statistically significant variation in either the mean state of climate or in its variability, persisting for an extended period (WMO 2012). The major causes of climate change include natural variations in sunlight intensity and human activities, which have led to an increase in greenhouse gases and a steady rise of the earth's temperatures.

Global warming, which entails a rise in the earth's temperature, is caused by the use of fossil fuels such as wood, coal, oil, and petrol, among other industrial processes that have led to a buildup of greenhouse gases such as carbon dioxide, methane, nitrous oxide, and chlorofluorocarbons (IPCC 2007). Human activities that are related to biomass burning during shifting cultivation and domestic fuel are responsible for increasing greenhouse gases in Africa.

Besides rendering traditional agriculture across African countries less profitable, climate change has driven an unprecedented number of people into cities as they search for alternative livelihoods (Barrios et al. 2006). The resultant urban population increase has exerted pressure on urban services and resources such as urban space, urban water supply and infrastructure, and sanitation systems. Apart from posing a daunting challenge to urban planners and policymakers (Thynell 2007; Choguill 1999), climate change has become a major national, regional, and international problem and has limited human capabilities and undermined the international communities' efforts to attain the Millennium Development Goals (MDGs). Consequently, UNDP has declared climate change "the defining human development issue of our generation" (UNDP 2007, p. 1).

This chapter looks at the relationship between climate change and urban development and examines the impact of climate change on urban development in Africa. It also assesses available policy options for adaptation and mitigating climate change effects in urban Africa.

Climate Change and Its Impacts

The Intergovernmental Panel on Climate Change (IPCC) has declared that "warming of the climate system is unequivocal, as is now evident from observations of increase in global average air and ocean temperatures, widespread melting of snow and ice and rising global average sea level" (IPCC 2007, p. 30). Consequently, warming of the climate will not only hinder the achievements of MDGs and sustainable development, but it will also increase the risk of violent conflicts and therefore adversely affect human security (Barnett and Adger 2007). Therefore, concerted efforts are required to tackle climate change since failure to address this challenge will result in diminished future prospects for humanity.

UNDP (2007) reports that average annual global temperatures have been rising by 0.7 °C (1.3 °F) since the industrial revolution. The report also notes the rapid rate at which CO_2 concentrations are increasing, leading to rising air temperatures. It is expected that with the rise in temperatures, droughts will be frequent as rainfall patterns change. In the next 100 years, climate-induced temperatures in Africa could increase by between 2 °C and 6 °C (Hulme et al. 2001). This will have adverse effects on agricultural productivity and food security. It will also mean less water for poor people, increased floods, and a rise in sea level, thereby posing a great threat to coastal regions and small island nations (Tacoli 2009). The rise in temperatures will also increase incidences of diseases such as malaria (in areas that were originally malaria free) and other communicable diseases.

Unfortunately, climate change disproportionately affects the poor and poor countries since it impacts on the very resources that the poor depend on, e.g., agriculture, forests, rivers, and lakes. Most importantly, poor countries are extremely vulnerable to the adverse effects of climate change due to their low physical and financial capacity to withstand the economic shocks triggered by climate change (Ward and Shively 2012).

Worsening climatic conditions, coupled with other factors such as political and ethnic conflicts, erosion of traditional safety nets, and the deteriorating physical infrastructure, besides the absence of general security in rural areas, have forced some people to migrate to urban areas, exerting further pressure on cities and compounding their socioeconomic problems (Choguill 1999). As centers of innovation, cities have the capacity and the technical know-how of dealing with climate change. Unfortunately, they are also the major contributors to greenhouse gases. City-based commercial, industrial, and domestic refrigeration facilities, for instance, discharge large amounts of gaseous emissions (Mosha 2011). There is therefore a need to critically examine the role of cities vis-à-vis the process of climate change and its impacts.

Urbanization and Urban Development in Africa

As people migrate from the rural areas to urban regions, global settlement patterns are gradually changing. For instance, in 2008, 3.3 billion people lived in urban areas, a number that is expected to reach 4.9 billion by 2030. Despite being the least urbanized continent in the world, Africa has the highest urbanization rate of 3 % per annum. In 2007, the African urban population was 373.4 million, a figure that is projected to reach 759.4 million by the year 2030. It is further projected that more than 1.2 billion Africans will be living in urban areas by the year 2050 (UN-HABITAT 2008).

Table 1 profiles the past, current, and projected urban population by subregion between 1980 and 2030. From the data, northern Africa and southern Africa are the most urbanized regions in Africa, while East Africa is the least urbanized (but nevertheless the most rapidly urbanizing region).

This rapid urbanization can be explained by both the natural growth of the urban population (the net excess of births over deaths in urban areas) and the rural–urban migration. On the other hand, Potter (2012) argues that rapid urbanization in Africa is due to the reclassification of small rural settlements as urban areas, while others (Zachariah and Conde 1981; Kelley 1991) argue that rural–urban migration is the main contributor to urbanization in Africa.

Rural–urban migration has been triggered mainly by both the pull-and-push factors (Barrios et al. 2006) as well as past development strategies adopted by African countries, including socialist-leaning development policies and structural adjustment programs, which are biased against rural and agricultural development (Hope 2009). A dismal consequence of these policies is that the nonagricultural population now exceeds the available nonagricultural employment, leading to *over-urbanization* (Hope 1998).

African urban economies (weakened by institutional problems such as extreme centralization, rampant corruption external factors, and unfair global trade practices) have failed to absorb the growing urban populations. As a result, in most cities of Africa, shanty towns and squatter settlements have developed along the periphery of the major cities (Mosha 2011). The poor who live in these areas face tremendous economic and social hardships since they do not have access to basic human services such as shelter, land, water, safe cooking fuel and electricity, heating, sanitation, garbage collection, drainage, paved roads, footpaths, street lighting, etc. (Tacoli 2009; World Bank 2009).

Urban areas in Africa host major government agencies and the private sector. These sectors contribute significantly to economic growth and create much-needed employment. According to the UN-HABITAT (2008), urban areas account for about 55 % of Africa's GDP. They therefore play a pivotal role in

Table 1 Percentage of African population residing in urban areas by subregion, 1980–2030

Region	1980	1990	2000	2010	2020	2030
Africa	27.9	32.0	35.9	39.9	44.6	50.0
Eastern Africa	14.4	17.7	21.1	24.6	29.0	34.8
Northern Africa	44.4	48.5	51.1	53.5	56.8	61.3
Southern Africa	31.5	36.7	42.1	47.1	52.3	57.9
Western Africa	29.2	33.0	38.4	44.1	50.1	56.1

Source: UN-HABITAT 2008

the production of goods and services, besides generating employment for the growing urban populations. Unfortunately urbanization in Africa is not accompanied with an increase in economic growth or improved living standards. This is a unique phenomenon, which the World Bank has called "urbanization without growth" (Fay and Opal 2000; Barrios et al. 2006). This pattern of "urbanization without growth" is the result of inappropriate policies that could not cater for properly managed and planned urban development. In developed countries, urbanization took root during the industrial revolution. At a time when there was "redundant" labor in the rural areas, there was an increase in demand for labor in urban areas (Potter 1995). The same cannot be said about the process of urbanization in Africa.

The process of urbanization in Africa is usually highly influenced by the movement of people displaced by drought, famine, ethnic conflicts, civil strife, and war. Acute levels of urban poverty and haphazard urban settlements are also common characteristics of urbanization in Africa. The poor live in poor neighborhoods where they face dire economic and social hardships. Most are uneducated and unskilled workers who have migrated to urban areas, encouraged by the push-and-pull factors associated with rural–urban migration.

Women and children are most affected according to Bartlett (2008), who says that children under the age of 14 are 44 % more likely to die due to urban environmental problems compared to the rest of the population. Bartlett further argues that "globally children under five are the victims of 80 % of sanitation-related illnesses and diarrhoeal diseases, primarily because of their less-developed immunity and because their play behaviour puts them into contact with pathogens" (2008, p. 505). The immediate challenges facing slums could be addressed through provision of basic services such as water, sanitation, and affordable housing. However, the long-term policy response should focus on economic growth, poverty reduction policies, and institutional capacity building, as well as on improved governance.

If properly managed and planned for, urbanization could be an engine of economic growth and industrialization. However, without a proper policy in place, urbanization will contribute to the rising urban poverty, proliferation of slums, regional inequalities, and degradation of urban infrastructure and environment. As a result, some African cities could become centers of crime and slum settlements rather than being engines of industrialization and economic growth.

The Impact of Climate Change on Urban Development in Africa

With erratic rainfall and frequent drought, rural dwellers in the continent find it very difficult to work on their farms. Therefore, they abandon their rural settlements and migrate to urban areas in search of better opportunities.

Unfortunately, the urban economy is weak and cannot absorb these environmental refugees (Barrios et al. 2006). It is estimated that by the year 2050, there may be as many as 200 million environmental refugees, people who are forced to move due to environmental degradation (Myers quoted in Tacoli 2009). The migrants are generally younger, landless men with few dependants (Tacoli 2009). Unfortunately, most of these migrants are lowly farmers with limited skills and education. They therefore cannot secure employment in the urban economic sector. Consequently, they almost always end up in slums and shanty towns.

Besides being the most marginalized, these settlements are also prone to flooding and landslides and have very limited or no social amenities such as running water, electricity, proper health care, and infrastructure. The largest slum in East Africa, Kibera, is located about 5 km southwest of Nairobi. It has about 250,000 people but has no proper sanitation and garbage collection systems, toilet, and infrastructure. Kibera is heavily polluted by human refuse, garbage, and other wastes, including human and animal feces, courtesy of the open sewage system and the frequent use of "flying toilets." This poor sanitation, combined with poor nutrition among residents, accounts for the many illnesses and diseases in Kibera.

Climate change will eventually lead to a rise in sea level and threaten small island nations and coastal areas, especially those located near the sea. With nine of the world's ten most populated cities located in the coastal zones, the effect of a rise in sea level on the population and ecosystem of these cities will be enormous (UNEP 2005). The major and direct impact of sea-level rise on coastal ecosystems will be erosion, submergence, and increase in salinity (Armah et al. 2005). It is estimated that more than 600 million people (10 % of the world's population) live in coastal regions that have an elevation of up to 10 m (about 2 % of the world's land area) above the seal level. Out of this, 360 million live in urban areas (13 % of the world's urban population) and about 247 million live in low-income countries (McGranhan et al. 2007). With the rise in sea level, coastal towns will be susceptible to cyclones, typhoons, hurricanes, and floods. It is projected that a 3–4 °C rise in temperature will expose between 134 and 332 million people to coastal flooding (UNDP 2007).

Desertification due to drought and man's actions, especially in the Saharan and Sahelian environment, results in sand and dust storms that could affect urban communities in many ways. Apart from the inconvenience and the disruption of transport and communications infrastructure, the increased risk of health-related problems such as respiratory diseases will continue to plague the continent.

Many African cities will experience severe water shortages as the ravages of climate change, especially due to persistent droughts, continue to deepen. Large cities such as Lagos, Nairobi, Dar es Salaam, and others have a permanent water crisis. Unfortunately, women and children have to bear the burden of walking long distances in search of water. Assuming that current levels of investment in the sub-Saharan African urban water supply and sanitation continue over the next 20 years, as many as 300 million people in African cities will be without proper sanitation; and 225 million will be without potable water supply by 2020 (World Bank 1996).

Besides the physical hazards from floods, droughts, and hurricanes, health-related risks will be on the rise as impacts of climate change bite deeper. Heat stress and respiratory distress from extreme temperatures might combine with air quality decreases to create higher mortality in urban areas. Changes in temperature, precipitation, and/or humidity will result in water- and vector-borne diseases. Less direct risks are expected as well; these include negative effects on livelihoods, food supplies, the psychological state of people, or access to water and other natural resources. The urban populations exposed to disease, such as dengue fever and malaria, already killing people in sub-Saharan Africa, are spreading to urban centers located in previously safe higher latitudes and altitudes (Wilbanks et al. 2007). The highland cities of Nairobi and Harare are a case in point (IPCC 2007).

The geographical distribution of some infectious diseases will be altered, as warmer average temperatures permit an expansion of the area in which malaria, dengue fever, filariasis, and other tropical diseases are likely to occur. It should be noted that many of these health risks are already evident among most urban populations of Africa, even in the absence of full-blown effects of climate change, and are related to such factors as age, gender, socioeconomic status, and access to health services. Extreme weather events will likely create new health hazards and disrupt public health services, thereby leading to increased disease incidences.

Infrastructure in urban areas is already showing evidence of destruction due to climate impacts such as flooding and sea-level rise. Some of the most vulnerable infrastructures include industrial plants; equipment for producing and distributing energy; roads, ports, and other transportation facilities; residential, institutional, and commercial properties; and coastal embankments. The economic consequences of these impacts are severe. For instance, in Uganda, the record-breaking rains of 1997 destroyed 40 % of the country's 9,600 km feeder road network. Similarly, between 1997 and 1998, a prolonged drought in the Seychelles led to the closure of the Seychelles Breweries and the Indian Ocean Tuna Company (Mosha 2011).

Rather than alter existing infrastructure, cities would probably choose to abandon it and relocate in upland areas at a cost of billions of dollars. People and jobs will be forced to relocate, and land use will change dramatically.

Adaptation and Mitigation Policies: Implications for Urban Development in Africa

Urban governments play a critical role in climate change adaptation and in mitigating (reducing) greenhouse gas emissions. They however need a supportive institutional, regulatory, and financial framework, backed by their highest decision-making organs. In addition, low- and middle-income nations need the backing and full support of international agencies (Satterthwaite 2007).

Emission of GHGs is one of the major policy issues that need to be addressed (APF 2007). Urban authorities in Africa should have in place policies aimed at reducing carbon emissions, but this should be reciprocated by a commitment to the reduction of global greenhouse emissions. For these policies to be effective, there must be incentives that recognize the development needs of urban authorities. Africa has legitimate energy needs, hence the problem of carbon emission in her urban centers. Policies encouraging clean energy technologies should be formulated and encouraged through capacity building and financial support from national governments. International partnership should also be established in a bid to bolster these efforts.

Most African urban centers are located within the tropics or subtropic regions where solar energy and hydropower are abundant. Policies encouraging development of Africa's vast solar energy potential and hydropower should be enacted. The World Bank and the African Development Bank Clean Energy and Development Investment Framework should be fully implemented as a mitigation measure.

To mainstream adaptation to climate change in urban areas, the strategy should be a continuous process, which addresses both current climate variability and extremes and future climate risks. Africa's urban authorities should take actions that link climate change adaptation to disaster risk management.

A number of African countries such as Botswana, South Africa, Uganda, and Kenya have put in place national policies for disaster management that address issues such as prevention, mitigation, preparedness, response and recovery, and development (Mosha 2011). In Uganda, for instance, the government has created a climate change unit within the Ministry of Water and Environment to coordinate all climate change concerns and spearhead policy formulation in the country (Magezi 2011). At the local and urban authority levels, cities such as Cape Town have developed a municipal adaptation policy (MAP) that includes proper management and control of water supplies, storm management, bushfires, and coastal zones (Hope 2009). Similarly, the city of Durban has also came up with a climate change adaptation strategy that includes human health, water and sanitation, coastal zones, food security and agriculture, infrastructure, and cross-sectoral activities.

Many African countries have now recognized that policies on climate change adaptation and mitigation need to shift from a purely environmental concern to addressing a growing threat to sustainable development. Managing both current and future climate risks should be an integral part of development processes at both the national and regional levels and should involve a cross-sectoral approach that is reflected in the budget, thus the need for greater attention by ministries of finance and national planning.

Urban authorities in Africa should adapt to climate change impacts through:

- Increased efforts to improve access to climate data
- Investment and transfer of technologies for adaptation in key sectors

- Developing and implementing best practices for screening and assessing climate change risks in development projects and programs
- Mainstreaming climate factors into development planning and implementation
- Providing significant additional investment for disaster prevention

For Africa to adapt to the impacts of climate change, it will need development partners to deliver on their commitments. Assisting Africa's development through its largely unexploited hydropower potential will help to meet her objective of increasing energy access while limiting GHG emissions. Compensation for avoiding deforestation could also be introduced so as to limit GHG emissions, but this will require an understanding of the factors that encourage deforestation. Incentives to landholders could also be considered in a bid to discourage deforestation.

Policies that build on existing strategies to support adaptation to climate change are among the most likely to succeed. Growing evidence suggests that mobility, in conjunction with income diversification, is an important strategy for reducing vulnerability to environmental and non-environmental risks (Tacoli 2009).

Some of the climate change problems envisaged include drought, desertification, land degradation, floods and the rise of sea level. It is projected that between 75 and 250 million people in Africa will not have access to freshwater by 2030 (IPCC 2007). Climate stress usually overlaps with other factors in determining migration duration and composition. It is therefore important that socioeconomic, political, and cultural factors are integrated into the adaptation policies.

The high vulnerability of urban systems and their impact on climate can be reduced through adaptation and mitigation measures based on known technology and design methodology. To counter climate change disasters, African urban authorities must have preparedness programs and plans, ingredients often lacking in most African cities (WMO 1994).

African urban centers located along the coast and river deltas (or estuaries) are highly exposed to flooding due to their proximity to the sea (e.g., Free Town, Alexandria, Cairo, Beira). In this regard, mitigation measures required include designing and building appropriate flood shelters, improving and expanding sewerage and drainage systems, and putting in place an information system on climate change effects and responses (WMO 1994).

Governance is an important element in climate change risk exposure. Urban authorities with limited incomes or assets are the most exposed. This is because they lack quality infrastructure and have poor disaster-preparedness provisions for planning and coordinating disaster response. Besides, the extent to which the poor can buy, build, or rent "safe" housing in "safe" sites and the degree to which the local government creates an enabling environment for local civil-society action to address these issues are limited (Satterthwaite 2007). Most urban authorities in Africa cannot afford the requisite cost of reducing the impact of climate change.

Climate change health adaptation and mitigation measures required in African urban centers include putting in place an information system that profiles air conditions, observation networks and programs, and impact assessments and predictions. Bioclimatic GIS can be a useful tool in urban planning and design and can be used in predicting climate change impact on mortality.

In terms of the impact of climate change on planning and architecture, there is need to take into account proper use of materials and architectural detailing, as well as drafting plans that maximize on outdoor spaces. Climate-sensitive designs should be done in a way that protects the environment from pollution. Architects and planners should use widely available knowledge and information on climate, while urban climatologists need to simplify the language in which climatic data is availed to planners and architects. Planning and building codes should be made public and their objectives clearly set out. A specific design guide that incorporates climate information is required.

In a nutshell, the key to adaptation is competent, capable, and accountable urban governments that understand how to incorporate adaptation measures into aspects of their work and departments (Satterthwaite 2007).

Conclusion

Climate change is both a threat and a challenge to Africa. Climate variability affects agricultural production and influences hunger, health, access to water, and consequently food security and poverty in the continent. Prolonged droughts and floods, which are associated with climate change, impact negatively on the livelihoods of farmers, making traditional agriculture across Africa less profitable. This in turn results in a number of people from rural areas migrating to cities in search of better livelihoods.

The increased urban population in turn exerts pressure on urban services and natural resources such as urban space, urban water supplies, infrastructure, and sanitation systems, creating a challenge for urban planners and policymakers. The effects of climate change must therefore be factored into African countries' urban policies and unequivocally address the current and emerging urban challenges, especially the rapid urbanization, poverty, informality, and safety.

While Africa is the most vulnerable and most affected by climate change, it has the weakest coping mechanism and less financial and human resources. The support of the international community to help Africa build the requisite capacity to adapt to climate change is therefore very crucial.

Municipal governments and urban authorities should design policies that are sensitive to energy saving, fewer sprawls, and climate-resilient infrastructure, especially with respect to drainage, flood control, housing, sanitation, transport, and water distribution systems. In the USA, for example, the 2005 Energy Policy Act creates policies and incentives for developing renewable energy. The Act aims to enhance and expand domestic energy production. Brazil's government instituted the Incentives for Small Hydro Facilities policy to exempt small hydro facilities (those which produce less than 30 MW) from paying financial compensation for the use of water resources.

To encounter the expected climate change disasters, urban authorities must also have preparedness programs and plans. Urban policies in Africa should also emphasize and focus on new techniques and methods of seasonal prediction, early warning systems, monitoring, and risk management.

Climate Change Governance: Emerging Legal and Institutional Frameworks for Developing Countries

Martin Oulu

Contents

Abstract

Climate change is a relatively new governance area in which policy and practice tend to precede theory or advance simultaneously. Establishing effective legal and institutional frameworks is crucial to its management. This chapter conducts a comparative analysis of the climate change governance frameworks of four developing countries, namely, the Philippines, Mexico, South Africa, and Kenya, all of which have enacted or propose climate change legislations,

strategies, and related institutional structures and have decentralized governments. These are contrasted with the UK, the first to globally enact a framework climate change law. The results indicate that despite being time- and resource consuming, enactment of stand-alone framework climate change legislation is preferred over piecemeal amendments to relevant laws. Another key finding is the overwhelming adoption of mainstreaming as an important approach to managing climate change. Moreover, both adaptation and mitigation are considered equally important, mitigation being seen as a function of adaptation. This disabuses the notion that developing countries do not or should not focus much on mitigation. Institutionally, establishment of (often) a new high-level cross-sectoral climate change coordinating institution domiciled in the office of and/or chaired by the head of state is common. Such institutions offer general policy guidance and are supported at lower levels by an advisory panel of experts and a technical administrative secretariat. Procedures to ensure clear coordination between the central and devolved governments are in many instances outlined. Climate finance sources and management strategies are mixed. Sharing of experiences and strong support for national climate change legislations under ongoing post-Kyoto negotiations are recommended.

Keywords
Climate change • Governance • Policy • Legal and institutional frameworks • Developing countries

Introduction

Warming of the climate system is unequivocal as per the Fourth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC 2007). Atmospheric carbon dioxide concentration recently hit the 400 parts-per-million mark. While developing countries' contribution to the greenhouse gas (GHG) emissions is negligible, they suffer most from the impacts of climate change because they lack the necessary institutional, economic, and financial capacity to cope (Huq et al. 2003). The vulnerability, coupled with the pressing need to grow their economies in order to reduce poverty levels, has traditionally underlined many developing countries' focus on adaptation efforts at the expense of mitigation. The situation is however steadily changing as many now strive to reduce their emissions by integrating emission reduction strategies into regular socioeconomic policies in pursuit of low-carbon development paths (cf. Reid and Goldemberg 1998). Their motivations are myriad: (i) mitigation is seen as a function of adaptation, that is, it offers opportunities for enhancing development and boosting adaptive capacity, (ii) opportunity to leapfrog into newer low-carbon technologies, (iii) promise of access to international climate finance, and (iv) the ideological commitment to show leadership.

The crosscutting nature of climate change has seen mainstreaming being widely advocated as an important approach to its management (cf. Oulu 2011).

Mainstreaming is the integration of climate change vulnerabilities or adaptation into some aspect of related government policy (IPCC 2007). Its potential benefits, dimensions, and assessment criteria have been extensively discussed (cf. Huq et al. 2003; Klein et al. 2007; Lasco et al. 2009; Mickwitz et al. 2009) and implementation guidelines published (cf. UNDP-UNEP 2011). It can be operationalized *horizontally* by different policy sectors or departments, *vertically* at different hierarchical administrative levels, and *internationally* by embodying multilateral cooperation (Persson and Klein 2008). The three dimensions highlight the multilevel and complexity of climate change governance. Nevertheless, addressing climate change is ultimately a local-scale affair. While international efforts are crucial, it is individual countries which determine relevant policy by translating both local and global goals into either adaptation or mitigation actions. Doing so requires effective national climate change policies, legislations, and institutions. In fact, advancing domestic climate legislations can help create the necessary conditions for an international deal (Townshend and Mathews 2013). Some even consider creation of durable regulatory frameworks and institutions as more important than the choice of particular programs (Stavins 1997). Yet, even as literature places governance at the center of future adaptation and mitigation efforts, many national governments have paid little attention to legislations and institutions (Agrawal and Perrin 2009).

This chapter conducts a comparative analysis of the climate change governance structures of four developing countries with decentralized government systems, namely, the Philippines, Mexico, South Africa, and Kenya. In particular, it focuses on the legal and institutional frameworks with the aim of identifying emerging best practice. These are contrasted against the UK, a developed country and first globally to enact a framework climate change law. The UK is often touted as having both the "hardware" (institutions) and "software" (necessary knowledge) (Persson 2004), key ingredients in dealing with climate change. The chapter is organized into five sections. After the Introduction, section "Climate Change Governance: Role of Law and Institutions" examines the role of law and institutions in climate change governance. The individual country governance structures are analyzed in section "Individual Country Governance Frameworks," while section "Synthesis of Emerging Climate Governance Best Practice" provides a synthesis of the emerging legal and institutional frameworks. Section "Concluding Remarks" makes some concluding remarks.

Climate Change Governance: Role of Law and Institutions

Governance is a fuzzy concept with many definitions but no consensus. Some view governance as a political process of setting explicit societal goals and intervening in their achievement, translating into a generic term for the coordination of social actions rather than an antonym for government (Fröhlich and Knieling 2013). Three dimensions of governance are distinguished (Homeyer 2006; Herodes et al. 2007): policy (the nature and implementation of policy instruments), politics (actor constellations), and polity (institutional properties), each with a continuum of possible subdimensions. The vagueness of the term nonetheless allows for its use in a variety of disciplines and contexts. In climate change, it encompasses a broad range of forms of coordination of adaptation and mitigation characterized by cross-boundary, multilevel, multi-sector, and multiagency settings as well as long-term challenges and uncertainty (Fröhlich and Knieling 2013). Climate change is, essentially, a "wicked" problem (Balint et al 2011) or "super wicked problem" (Lazarus 2008). Its enormous interdependencies, uncertainties, and conflicting stakeholders lack a single problem formulation or solution. Moreover, the longer it takes to address it, the harder it becomes, while those best positioned to do so have the least immediate incentive to act, making its governance a complex reality. The field is also still a relatively new area in which policy and practice tend to precede theory or advance simultaneously. Lack of middle-range adaptation theories to help frame policy debates and absence of comparative empirical studies to support policy interventions are glaring challenges (Agrawal 2008).

Domestic climate change legislation has traditionally been viewed as something for governments to enact after an international agreement has been reached to support implementation. However, there is a growing global trend in which individual countries, states, or even cities are unilaterally implementing their own climate change regulations. While this could be attributed to frustrations with stalled United Nations (UN) climate agreements, it is also indicative of a growing recognition of the crucial role of domestic legislations and measures (Stavins 1997). By disregarding the so-called matching principle (cf. Butler and Mecey 1996), these countries are rebutting the skeptics' claim that it is self-defeating for a country to act alone on climate change. Apart from the possibility of regulation at lower jurisdictional level triggering regulation at a higher (international) level (Engel and Saleska 2005), the inclination toward domestic climate change legislations also signal a "portfolio" approach in which a suite of different plans spread risks across individual countries (Vance 2012). Many developing countries are beginning to implement national emission reduction actions, fully aware that it is in their self-interest to do so and make their economies climate resilient even in the absence of a global deal or sufficient action by developed countries (Townshend and Mathews 2013). Some have even suggested that combined emission savings from such national actions may be greater than those attained by industrialized countries (Reid and Goldemberg 1998). Clearly, the ongoing Durban Platform negotiations should involve a formal recognition of and active support for the advancement of national climate legislation.

Modes of environmental governance are variously categorized. Regulation or *command and control* is the most common approach. Literature is also awash with many types of "new" or "newer" policy instruments (NEPIs) which include market-based instruments, eco-labels, and voluntary agreements (Jordan et al. 2005). They have been hailed as able to offer cost-effective alternatives, provide dynamic incentives for technological change, address distributional equity concerns, and raise revenue (Stavins 1997; EEA 2005). Despite the "frenzy" surrounding the apparent popularity of NEPIs, regulation still dominates. Barring noncompliance may be the only means of ensuring environmental integrity. Importantly, many of the NEPIs require legislation to be effective (EEA 2005; Jordan et al. 2005; Herodes et al. 2007). But legislation also has its challenges and the nature varies greatly. Subsequent amendments, limited budgets, financial conditionality, delays in operationalizing regulations, vested interests, and simple nonenforcement can render a seemingly strong legal mandate mere symbolic aspirational statement. Successful climate change legislations must therefore be simultaneously flexible in certain respects and steadfast in others (Lazarus 2008). They should incorporate institutional design features that significantly insulate implementation from vested political and economic interests. Such design features should include precommitment strategies which deliberately make it hard, though not impossible, to change the law in response to emerging concerns and insights, as well as those intended to keep the statute on course over time. Examples include requirements for consultation with other agencies, scientific advisory committees, and stakeholders; judicial review provisions; and preemption triggers that accommodate competing interests while exploiting the resulting tension to further climate change policy.

Institutions are systems of rules and decision-making procedures that give rise to social practices, assign roles, and guide interactions (Gupta et al. 2010). Categorized into public, civil society, or private sector, institutions are humanly created formal and informal mechanisms which shape social and individual expectations, interactions, and behavior initiatives (Agrawal and Perrin 2009). They play a major role in assisting countries anticipate and respond to climate change by structuring the distribution of risks, constituting and organizing incentive structures, and mediating external interventions into local contexts. Effective adaptation-enhancing institutions encourage the involvement of a variety of perspectives and actors, allow continuous learning and behavior change, and can mobilize resources (Gupta et al. 2010). Fragmentation, conflicting mandates, and capacity challenges plague many developing country institutions.

Individual Country Governance Frameworks

The Philippines

Climate Change Vulnerability and Government Structure

The Philippines is an archipelagic country in Southeast Asia classified as lower middle income by the World Bank. Due to its location in the Pacific Ring of Fire, it is prone to earthquakes and active volcanoes and is ranked highest in the world in terms of vulnerability to tropical cyclone occurrence (Yumul et al. 2011; RoP 2011). The country lies within the Intertropical Convergence Zone (ITCZ), a source of heavy rains and storms. Its geography and location therefore puts it at a high risk from sea level rise (Lofts and Kenny 2012). The Philippines and similar small island developing states are particularly vulnerable to global environmental change (Pelling and Uitto 2001; IPCC 2007; Yumul et al. 2011; Guillotreau et al. 2012). Their disproportionate natural resource dependency and extensive coastlines expose them to high climate change risks. The country's GHG emission in 2000 was 21,767.41GgCO_2e (RoP 2011).

The 1987 Philippine Constitution provides for a unitary multitiered government (Diokno 2009; Manasan 2009). The country is divided into 15 administrative regions and two additional autonomous regions, Mindanao and Cordillera. The president is the head of state and government, and the bicameral legislature is made up of the Senate and the House of Representatives. Devolved local government units (LGUs) consist of provinces each subdivided into cities, municipalities, and barangays – the smallest political unit. They have authority over natural resource management, pollution control, and environmental protection but are under considerable supervision by higher-level government in areas like budgeting and legislation.

Legislative Framework

Well aware of its particular vulnerability to climate change, the Philippines developed the comprehensive *Climate Change Act of 2009*, the first in the developing world and second globally after the UK. The Act aims to "mainstream(ing) climate change into government policy formulations, establish(ing) the framework strategy and program on climate change, creating for this purpose the Climate Change Commission" (RoP 2009, p. 1). The unequivocal intent to systematically mainstream climate change is noteworthy, suggesting that the mainstreaming mantra is slowly finding its way from academia into policy and, hopefully, practice. Both adaptation and mitigation measures have since been implemented through formulation of a Framework Strategy and Program on Climate Change (2010–2022) and the National Climate Change Action Plan (2011–2028), but with no emission reduction targets. Interestingly, the Framework Strategy "treats mitigation as a function of adaptation" (RoP 2010, p. 17). That is, it recognizes the mutually beneficial relationship in which mitigation strategies offer opportunities for enhancing adaptive capacity. The close interrelation between climate change and disaster risk reduction (DRR) is particularly evident in the Philippines. As such, the Climate Change Act integrates DRR into climate change initiatives, while the Disaster Risk Reduction and Management Act 2010 considers disasters as inclusive of climate change impacts (RoP 2010).

Institutional Framework

Climate Change Commission

The Climate Change Act (2009) establishes the Climate Change Commission (CCC) as the sole policy-making body charged with coordinating, monitoring, and evaluating climate change-related programs and action plans. It is chaired by the president of the republic and is administratively located in the Office of the President, making it very high level. This arrangement has several potential advantages. First, it enhances the profile of and puts climate change firmly and high up on the national agenda. Second, it is a way of procuring and maintaining the political will and commitment to implement climate change actions by the executive. From a political ecology perspective, climate change is inherently political (cf. Eriksen and Lind 2009). Making the president by law the head of the premier climate change outfit does not automatically translate into political will. Rather, political competition potentially does the trick. That is, the incumbent will be motivated to bring to bear his or her political and executive powers on climate change programs as a way of endearing oneself to the electorate. The Act can, therefore, by design or default, create climate change champions out of the president, the executive, and the ruling political party or coalition. Champions play a critical role in rallying necessary support and educating the public on climate change (cf. Roberts 2008). Third, although enhancing mainstreaming, listed as the first function of the Commission, should essentially happen at all levels, the higher the better as this allows greater possibility of integration at lower political and administrative levels. The high-level status of the Commission gives the convening powers necessary to integrate climate change horizontally and vertically across all levels of governance.

The Commission is made up of three other Commissioners who must be climate change experts. It is supported by a broad-based, cross-sectoral, and cross-departmental *advisory board* with representatives from relevant government ministries, local government, academia, the private sector, and civil society. Involvement of key stakeholders enhances the quality of climate change policies and their implementation but could also pose a challenge as it might prove difficult to reconcile the myriad of interests at play. Nevertheless, the Commission is mandated to meet once every 3 months or as often as deemed necessary, an arrangement which could help resolve any deadlocks in good time. Infrequency of meetings can impede the functioning and effectiveness of institutions.

The day-to-day running of the Commission is assigned to a secretariat, the *Climate Change Office* headed by the Commission's vice chairperson. In addition, a *Panel of Technical Experts* provides technical advice to the Commission in climate science, technologies, and best practices for risk assessment and enhancement of adaptive capacity. Surprisingly, the experts are to be permanently employed by the Commission. Without a clear definition of what particular "technical advice" they are to provide and for how long, it would be cost-effective to make the panel ad hoc. Nevertheless, the panel of experts incorporates a science- and evidence-based approach to climate change management.

Other Institutions

Government ministries and agencies are assigned specific roles based on their core mandates in the Climate Change Act. For example, the Department of Education is to integrate climate change into the primary and secondary education curricula, while government financial institutions are required to give preferential financial packages for climate change-related projects. Some of the specified roles and responsibilities are, however, quite restrictive and do not allow for an innovative interpretation of their mandates with regard to climate change. Local government units (LGUs) are at the forefront in formulating, planning, and implementing local climate change action plans. The Joint Congressional Oversight Committee is to monitor implementation of provisions of the Act and recommend any necessary legislation.

Climate Finance

Climate finance is crucial to addressing climate change. All relevant government agencies and local government units are to allocate adequate funds from their annual budgets for the implementation of their respective climate change programs and plans. No special fund is set up although the Commission is authorized to accept financial support from local and international sources. No carbon trading schemes are to be set up or funding expected from such, a cautious move given that they have not benefitted the intended developing countries and their underlying logic for net emission reductions has been questioned (cf. Mulugetta 2011; Reddy 2011; Bond et al. 2012). International funds, though often necessary, should complement, not replace, domestic resource mobilization.

Mexico

Climate Change Vulnerability and Government Structure

Mexico, a Latin American country bordering the United States of America (USA), is categorized as upper-middle-income economy by the World Bank (2013). Its GHG emissions are quite high, about 616 Mt CO_2e in 2010 excluding land-use change (Höhne et al. 2012) and ranked eleventh globally (Vance 2012). Its climate is projected to become drier and warmer, with several hydrological regions highly vulnerable to decreased precipitation and higher temperatures (IPCC 2007). This makes major economic support sectors vulnerable to climate change (Liverman and O'Brien 1991). For example, the agricultural sector employs more than a third of its growing population, yet only one-fifth of the country's cropland is irrigated. Rainfed agriculture supports subsistence farmers and provides most of the domestic food supply. Frequent droughts already reduce harvests and jeopardize food and energy security. About one-fifth of Mexico's electricity is hydroelectric, hence susceptible to reduced water levels. Significant mismatch between water supply and population will see increased problems for cities and industrial production.

Mexico is a three-tier federal government with 31 relatively autonomous states and a federal district which encompass Mexico City (Rodríguez and Ward 1994; Lankao 2007; Höhne et al. 2012). The president is the head of the federation and government, the bicameral legislature (Congress) is made up of the upper and lower chambers, while the judiciary is divided into federal and state systems. Unlike other Latin American countries, the president is directly elected for a single 6-year term. From the state, lower levels of devolution include the municipality (*municipio*) and municipal council (*ayuntamiento*). Although the devolved units are supposedly autonomous, the hegemonic nature of the ruling party often muzzles such autonomy, for example, in financial resources (cf. Höhne et al. 2012).

Legislative Framework

The General Law on Climate Change (Ley General de Cambio Climático) was enacted in 2012, making Mexico the most recent country and third globally to enact a framework climate change law. The law seeks to facilitate the transition to a competitive low-carbon emission economy by consolidating the institutional framework across the three levels of government, regulation of adaptation and mitigation actions, and promotion of research, innovation, and technology transfer. It fulfills Mexico's Cancún pledge to voluntarily reduce its emissions to 30 % by 2020 and 50 % by 2050 (based on 2000 baseline), conditional on international financial support. This is in addition to generating 35 % of the country's electricity from renewable sources by 2024. The 2020 target is considered the most stringent for a developing country, and Mexico is the only developing country so far to set itself an absolute reduction target by 2050 (Höhne et al. 2012). Mechanisms for gradual establishment of market-based instruments and emission trading are included (IDLO 2012). The General Law of Ecological Balance and Environmental Protection (LGEEPA), Mexico's framework environmental law, was amended in 2011 to incorporate some climate change provisions, including the authority of environmental agencies to formulate and execute mitigation actions (Ruffo and Vega 2011). However, the enactment of the comprehensive General Law on Climate Change has incorporated and harmonized many such provisions.

Institutional Framework

The General Law on Climate Change establishes an institutional framework that emphasizes the need for a transversal, cross-sectoral approach to climate change and the critical importance of wide stakeholder participation (IDLO 2012). They include the following.

Intersecretarial Commission on Climate Change (Comisión Intersecretarial de Cambio Climático, CICC)

Originally administratively established in 2005 (Höhne et al. 2012), the CICC became embedded in the 2012 climate change law. Charged with formulating national climate change policies, coordinating actions across the federal government, and ensuring mainstreaming and participation of key stakeholders, the CICC is composed of several relevant government ministries. Similar to the Philippines' Climate Change Commission, the CICC is chaired by the president of the federation who may delegate this function to the minister responsible for environmental matters. It could not be established if the CICC is administratively located in the Office of the President. As already discussed under section "Institutional Framework" of the Philippines, making the president by law the chairperson and therefore directly the head of the premier, the climate change coordinating institution has positive ramifications for climate change management. Again, mainstreaming is clearly stated as one of the key objectives of the Commission and the law. The CICC is to have several permanent Working Groups, including one on Reducing Emissions from Deforestation and Forest Degradation (REDD). Deforestation is a major source of GHG emissions in Mexico and therefore an appropriate target area. Linked to the CICC is the *Council on Climate Change* (Consejo de Cambio Climático, CCC), a permanent consultative body comprised of representatives from the private sector, civil society, and academia. Its objective is to foster broad stakeholder participation, collaboration, and support for climate change policies and actions (IDLO 2012). It can be equated to the Philippine's Climate Change Commission's *Advisory Board*.

National Institute of Ecology and Climate Change (Instituto Nacional de Ecología y Cambio Climático (INECC))

INECC is the main public agency responsible for climate change policy development and evaluation (IDLO 2012). Specifically, it is to prepare, conduct, and evaluate the national climate change policy; design market-based instruments; prepare an emissions inventory; and build scientific and research capacity. Its management is under a governing board comprised of heads of several ministries and chaired by the sectoral minister responsible for environmental matters. It has a director general appointed by the president and chairperson of the CICC. The INECC's functions and composition are similar to the Philippine's Climate Change Office (CCO). However, the similarity of its functions to and unclear relation to the CICC might create institutional conflict if clear coordination and communication mechanisms are not put in place.

Other Institutions

The National System for Climate Change (Sistema Nacional de Cambio Climático, SNCC) is a permanent communication and coordination mechanism between the federal government and devolved governments. Made up of the CICC, CCC, INECC, state governments, LGU representatives, and the Congress, it is aimed at promoting the cross implementation of the national climate change policy (IDLO 2012). In a decentralized system such as in Mexico, clear coordination and communication between different governance levels are very crucial for the effective implementation of a crosscutting policy issue like climate change. The Evaluation Committee (Coordinación de Evaluación, CE) reports to the SNCC and is an expert body made up of the head of INECC and representatives from the scientific, academic, and technical communities charged with periodically and systematically evaluating progress on implementation of aspects of the climate change law.

Climate Finance

The General Law on Climate Change establishes a *Climate Change Fund* (Fondo Para el Cambio Climático) aimed at sourcing and channeling funds from public and private sectors, at both national and international levels (IDLO 2012). This is in addition to annual budgetary allocation and proceeds from carbon trading. The CICC is legally mandated to establish an emission market, including a regulating agency (Höhne et al. 2012).

South Africa

Climate Change Vulnerability and Government Structure

South Africa is the only African country whose contribution to global warming is significant (Chevallier 2010) due to its energy-intensive, fossil-fuel-powered economy. The 2000 estimate was 435 million tons of CO_2 (Letete et al. 2009). A greater warming trend has been observed throughout the continent since the 1960s (IPCC 2007). Even under very conservative emission scenarios, it is predicted that by mid-century the South African coast will warm by around 1–2 °C and the interior by around 2–3 °C (RSA 2011). Declining rainfall patterns and increased frequency of extreme climate events such as droughts and floods are projected (Maponya and Mpandeli 2012; IFRC 2011). These changes will significantly affect human health, agriculture, and other water-intensive economic sectors such as mining and electricity generation. Moreover, a large number of South Africans live in conditions of chronic disaster vulnerability such as fragile ecologies or marginal areas (RSA 2005). The severe June 1994 floods in Cape Town's historically disadvantaged Cape Flats exposed the country's disaster soft underbelly.

South Africa is a federal government comprised of a three-tier devolved system: national, provincial, and local. The president is the head of state and government. The Parliament is made up of the National Assembly and the National Council of Provinces. Each of the nine provincial governments is allowed to make provincial laws and may adopt their own constitution. Three categories of local governments (or municipalities) exist (Pasquini et al. 2013): metropolitan, local municipalities, and district. Many of their responsibilities have important implications for climate change management. The constitution also recognizes the role of traditional leadership. All the three levels of government must observe and adhere to the principles of cooperative government. As is expected, the country's decentralization has its challenges (cf. Koelble and Andrew 2013).

Legislative Framework

South Africa does not have a framework climate change law. The *National Climate Change Response White Paper* (2011) is the key policy document guiding climate change management. It sets mitigation targets that should collectively result in a 34 % and a 42 % deviation below its "business as usual" emission growth trajectory by 2020 and 2025, respectively, conditional on international financial and technological support (RSA 2011). It also outlines the institutional and other planning frameworks. Existing legislations, especially those dealing with disaster risk reduction and general environmental regulation, e.g., the Air Quality Act 2004, are also relevant to adaptation and mitigation efforts. To ensure that climate change is fully mainstreamed into the work of all three spheres of government, all government departments and state-owned enterprises are to regularly review their policies and plans (RSA 2011). The *Disaster Management Act of 2002* definition of "disaster" as a progressive or sudden, widespread or localized, and natural- or human-caused occurrence (RSA 2003) can be interpreted as inclusive of climate change. The White Paper also considers DRR as short-term adaptations to climate change and acknowledges the existence and crucial role played by the Disaster Management Act. Overall, South Africa seems to have no immediate intention of enacting a stand-alone framework climate change law. Implementation of the actions stipulated in the White Paper will, where necessary, be implemented through piecemeal changes to relevant existing legislations and regulations. This is at variance with all the other countries analyzed. Mainstreaming is however at the core of its climate change management efforts.

Institutional Framework

Unlike the Philippines and Mexico, South Africa's climate change institutional framework is fragmented. Several institutions are responsible for various aspects of climate change, many of which overlap, thus creating possibilities of conflict. Most are also not anchored in any law and lack administrative capabilities or budgetary allocation.

Interministerial Committee on Climate Change (IMCCC)

Established in 2009, the IMCCC is to oversee all aspects of the implementation of the climate change policy. In justifying the need for the IMCCC, the White Paper states that "the strategic, multi-faceted and crosscutting nature of climate-resilient development requires a coordination committee at executive (Cabinet) level that will coordinate and align climate change response actions with national policies and legislation" (RSA 2011, p. 36). This illustrates the necessity of a high-level cross-sectoral institution with convening powers as is similarly applied by the countries analyzed so far. However, contrary to the above statement and at variance with the other developing countries, the IMCCC is to be chaired by the minister responsible for the environment rather than the president or Cabinet secretary. Additionally, technical, analytical, and administrative capacity to the IMCCC will be provided by a secretariat based in the sectoral Department of Environmental Affairs (DEA). Though interministerial, the arrangement makes the IMCCC less high level relative to the rest of the countries analyzed. The net effect is a lowering of the profile of climate change in the national agenda and potential challenges in integrating climate change across government. In many governments the world over, ministries of environment are rarely viewed as "powerful" based not only on their perennial paltry annual budgetary allocation but also because of the late entry of environmental issues on the national agenda, many countries having only established environmental ministries after the 1992 Earth Summit in Rio de Janeiro, Brazil. Environmental ministries thus lack the political clout, financial muscle, and convening powers necessary to effectively coordinate and mainstream a crosscutting issue such as climate change across government. Moreover, Giordano et al. (2011) view the IMCCC as merely an information platform which does not include all relevant ministries, especially that of finance.

Forum of South African Directors-General Clusters

Forum of South African Directors-General (FOSAD) was established in 1998 to enhance integration of crosscutting issues within the overall policy and implementation framework and address identified coordination weaknesses such as lack of alignment between different governmental planning cycles and between the central and devolved units (RSA n.d.). Mirroring the main Cabinet committees, they are to provide strategic leadership for the national climate change response actions. However, their structure and functioning has been criticized as potentially inappropriate for the prioritization of climate change issues (Giordano et al. 2011).

Intergovernmental Committee on Climate Change (IGCCC)

Established in 2008, the IGCCC's role is to operationalize cooperative governance in the area of climate change by bringing together the relevant national, provincial, and municipal departments under the principle of cooperative government. It fosters information exchange and consultation. However, lack of representation of the Department of Cooperative Governance and Traditional Affairs (COGTA), inability to provide practical assistance in policy development or implementation, and lack of an administrative budget or structure (Giordano et al. 2011) potentially weaken its effectiveness.

Other Institutions

The National Committee on Climate Change (NCCC), which is to be formalized into an advisory council *with statutory powers* and extended responsibilities beyond the current communication function, is one of two mechanisms set up to coordinate activities and consult with key stakeholders (RSA 2011). Its upgrade could remedy its current lack of legal backing, a secretariat, and regular budget and lack of executive power (Giordano et al. 2011). The second stakeholder coordination mechanism is the National Economic Development and Labour Council (NEDLAC) which brings together the government, business, and labor unions. The environment, including climate change, is a concurrent function between the provincial and national government. Each province is to develop its own climate response strategy, and municipalities are to integrate climate change considerations and constraints into their development plans and programs. To make clear local governments' mandate and assign them specific climate change-related powers, COGTA is to review relevant policies and legislations. Parliament is to review legislation and determine the legal requirements to support the existing or proposed institutional and regulatory arrangements, while line ministries and agencies are to integrate climate change into their policies and programs.

Climate Finance

By necessity, South Africa's climate finance strategy comprises a comprehensive suite of measures, including market-based ones, to create and maintain a long-term funding framework for mitigation and adaptation actions. In the short- and medium-term period, a transitional climate finance system and interim climate finance coordination mechanism are to be established, the nature of which is not outlined. In the long term, however, climate change actions will be integrated into the fiscal budgetary process of all the three tiers of government.

Kenya

Climate Change Vulnerability and Government Structure

Kenya has experienced increasing temperature trends over most parts of the country for the past 60 years (GoK 2010a). The time series of annual and seasonal rainfall for the standard seasons of December–January–February, March–April–May, June–July–August, and September–October–November indicates a neutral to slightly decreasing trends. The effects of the observed climatic changes include a reduction in the glacier on Mt. Kenya, variability in weather patterns, and frequent, prolonged, and severe drought and flood conditions (NEMA 2008). Kenya's natural resource-based economy makes it particularly vulnerable to climate change. Agriculture is mainly rainfed, while tourism largely depends on wildlife and the ecosystem, both highly susceptible to climate change (cf. GoK 2010a; Kameri-Mbote and Odote 2011; NEMA 2008; Mutimba et al. 2010). Some estimates put the future net economic costs of climate change at 2.6 % of GDP per year by 2030 and doubling by 2050 (SEI 2009).

The new (2010) constitution makes Kenya a presidential republic with a two-tier decentralized system of distinct and interdependent central and 47 county governments (GoK 2010b). The president is the head of state and government and together with the deputy president, attorney general, and several Cabinet secretaries form the Cabinet. The bicameral Parliament is made up of the National Assembly and Senate. The Senate represents the interests of the counties, while county assemblies have legislative powers. County governments' functions have a bearing on climate change management and include county planning, controlling air pollution, natural resource and environmental conservation, agriculture, health, transport, and trade.

Legislative Framework

Kenya, like South Africa, is yet to enact a framework climate legislation. However, Kenya has made strong indications of its intention to do so in the near future. The country's climate change governance scope is encompassed in various policy and regulatory frameworks interrelated to its natural resources (Mutimba and Wanyoike 2013). This analysis will focus primarily on the National Climate Change Response Strategy 2010 (NCCRS), National Climate Change Action Plan 2013–2017 (NCCAP), and, briefly, the Climate Change Authority Bill 2012. The NCCRS was developed in 2010 with the aim of achieving a prosperous and climate change-resilient Kenya. It admits that "the integration of climate information into Government policies is important… (but) the same has not been adequately factored into most of the sectors of the country's economy including government development policies and plans" (GoK 2010a, p. 6), an endorsement of mainstreaming. It outlines an enabling policy, legal, and institutional framework. It recommends the development of a comprehensive climate change policy which should be translated into a climate change law by either strengthening existing legislations or developing a new stand-alone law (GoK 2010a). Despite being time-consuming and expensive, the NCCRS prefers an entirely new climate change law.

Launched in March 2013, the NCCAP operationalizes the NCCRS. It covers, among others, low-carbon development strategies; adaptation and mitigation options; climate finance; and an enabling policy, legislative, and institutional framework intended to enhance mainstreaming. The actions are premised on their contribution toward achieving Kenya's long-term development goals in addition to intermediate benefits such as improved livelihoods, attracting international climate finance, as well as demonstrating global leadership (GoK 2013). It further commits all government ministries, departments, and agencies to play a role in mainstreaming climate change across their functions and processes. No emission reduction target is set. Rather, priority low-carbon development areas and options are outlined. In keeping with the NCCRS, the NCCAP recommends development of a coherent stand-alone climate change policy to, among others, provide guidance on (i) the envisaged legislative framework to be established through a climate change law and (ii) the specific sectoral legislative amendments that will enable full implementation of the NCCAP's priorities. It reaffirms "the need to enact a *stand-alone framework climate change law* to facilitate the necessary direction, coordination, policy setting and high-level political prioritization in order to *mainstream* climate change across government functions" (GoK 2013, p. 100). The stand-alone climate law is to be accompanied by a series of sectoral legislative and regulatory amendments through either an omnibus bill or a number of separate legislative amendments in order to bring sectoral legislation in harmony with the framework climate change law.

The Kenya Climate Change Authority Bill, 2012, is a private member's bill presented to the Parliament in April 2012. Some of its proposals are at variance with those of the government which consider it a parallel effort (GoK 2013). Developed mainly by the civil society under the aegis of the Kenya Climate Change Working Group, the Bill seeks to establish a Climate Change Authority and provide a framework for mitigation and adaptation (GoK 2012). A Climate Change Trust Fund is also proposed. The Bill is, however, not comprehensive since beyond the proposed institutional framework, it covers very little else. It is evident from the NCCAP that the government has sidestepped the Bill and is focused on enacting an entirely new stand-alone framework climate change law. It seems that the proposals in the NCCRS and more specifically the NCCAP are the official Government of Kenya position on climate change. Consequently, the proposals in the Bill will not be considered any further.

Institutional Framework

The NCCRS considers a dedicated climate change institution as important in establishing a coordination instrument to ensure that all cross-sectoral activities match the overall vision of a prosperous and climate change-resilient Kenya (GoK 2010a). But its proposed institutional structure gives the sectoral ministry responsible for the environment a dominant role, with all the key institutions placed under it. The potential lack of effectiveness of such a sectoral and non-high-level institutional arrangement is already discussed under section "Institutional Framework" of South Africa. In summary, the National Climate Change Secretariat (NCCS), which was instrumental in developing the NCCAP, was established. In addition, the National Climate Change Steering Committee (NCCSC) was charged with gathering and collating information from various stakeholders, while the existing cross-sectoral National Climate Change Activities Coordination Committee (NCCACC) continued in its advisory capacity. Perhaps recognizing the potential weaknesses of the NCCRS proposal, the NCCAP proposes a radically different institutional framework intended to achieve high-level oversight and policy guidance, mainstream climate change, involve county governments and stakeholders, and enhance technical and scientific analysis capabilities (GoK 2013). The following institutions proposed in the NCCAP will most likely receive the necessary legal backing with the eventual enactment of a stand-alone climate change legislation.

National Climate Change Council (NCCC)

The proposed NCCC will be responsible for policy direction, coordination, and oversight across government. Consistent with similar institutions in the Philippines and Mexico, it will be located in the Office of the President and, therefore, high level. Although initial proposals (in which the author was involved as a consultant) involved making the president of the republic the chairperson of NCCC, the government eventually settled on the secretary to the Cabinet. Reporting annually to the Parliament, it has representatives of both the national and county governments as in the UK's Committee on Climate Change (see section "Institutional Framework" of the UK). Interministerial and interagency, the NCCC represents a wide cross section of stakeholder interests from public, private, academia, research, and civil society. The mandate, location, and composition of the NCCC accord it the necessary political clout, convening, and resource mobilization powers necessary to adequately champion and effectively mainstream climate change across government, both national and devolved. The NCCC will be supported by a technical *National Climate Change Secretariat* located within the sectoral ministry responsible for climate affairs. Its functions will include continuous revision of climate policy, proposal of relevant legislation, and program implementation. It may have decentralized structures at the county level to collect and collate climate change data.

Other Institutions

The ministry in charge of national planning is to spearhead integration of climate change into planning processes. One way will be through installation of climate change desk officers in all line ministries. The National Environment Management Authority (NEMA) remains the Designated National Authority (DNA) on the Clean Development Mechanism (CDM) and the National Implementing Entity (NIE) for the Adaptation Fund. County governments will have climate change functions coordinated and supported by the National Climate Change Secretariat (NCCS). A Climate Change Resource Center hosted by the NCCS is to become the one-stop shop for Kenya's climate change information and knowledge.

Climate Finance

A Kenya Climate Fund (KCF) located within the ministry responsible for finance intended as a vehicle for mobilizing and allocating both international and domestic financial resources toward climate change activities is proposed. The public sector's capacity to efficiently and effectively absorb the expected funding, scaling up access to international carbon markets and possible establishment of a carbon trading platform, as well as improving the "investment climate for climate investment" are some of the proposed climate finance strategies. Climate change funding will also be prioritized in the annual budget by creating climate change line items and coding them for ease of tracking.

The UK

Climate Change Vulnerability and Government Structure

The UK was the first country globally to enact a framework stand-alone climate change legislation in 2008. A developed country, the UK has a long, even intimate, history with GHG emissions based on its role in igniting the industrial revolution and the transition to the current fossil-fuel economy, the "anthropocene" (cf. Crutzen 2000). The warming trend throughout Europe is well established (IPCC 2007). The UK's first Climate Change Risk Assessment indicates both positive and negative impacts of climate change on production systems such as agriculture, forestry, and fisheries and key economic sectors such as tourism and energy (DEFRA 2012). The UK is a parliamentary democracy with a constitutional monarch. While the prime minister is the head of government, the queen is the head of state. The Cabinet is made up of the prime minister and several secretaries of state. Some power is devolved to Scotland, Wales, and Northern Ireland which are in charge of local environment, health, education, and transport.

Legislative Framework

Response to climate change in the UK has been varied (cf. Hulme and Turnpenny 2004). The first attempt to enact legislation aimed at reducing GHG emissions was through the *Climate Change and Sustainable Energy Act 2006* which sought to promote renewable energy and compliance with GHG emission-related building regulations (UK Govt. 2006). The Act was not comprehensive, lacking in areas such as adaptation, emission trading, and enabling institutional structures. A new comprehensive *Climate Change Act 2008* was therefore enacted. It sets a legally binding 2050 emission target of at least 80 % lower than the 1990 baseline, establishes an institutional framework and emission trading schemes, and makes provisions for adaptation (UK Govt. 2008). It also amends and harmonizes relevant existing legislations and regulations. While the legally binding emission reduction target is an obligation under the UNFCCC, the attention given to adaptation illustrates the need to plan for and build adaptive capacity even by developed countries.

Institutional Framework

Committee on Climate Change

The *Committee on Climate Change* is to give *advice* to the government and its agencies, including the devolved units. It is composed of a chairperson and five to eight members jointly appointed by the national authorities, i.e., the secretary of state and Scottish, Welsh, and Northern Ireland ministers responsible for climate change affairs. Cumulatively, the Commission must have experience in or knowledge of a set of expertise or *knowledge areas* crucial to a holistic understanding and management of climate change. The Committee appoints a *chief executive* and may establish several subcommittees, but with a *mandatory* adaptation subcommittee. It makes regular progress reports to the Parliament.

Other Institutions

Implementation of the advice and recommendations of the Committee on Climate Change are entirely left to the central and devolved governments. The Parliament plays its oversight role by receiving regular progress reports, while the Committee is required to involve the public and other stakeholders in carrying out its functions. Unlike the developing countries analyzed, the Climate Change Act 2008 does not provide for any resource mobilization strategy since requisite resources are to be included in the relevant implementing agencies' annual budgets.

Relation to Developing Countries' Frameworks

The UK's enactment of a stand-alone climate change law is in tandem with that of most of the developing countries analyzed. Institutionally, the UK adopts a lean structure. Relative to the developing countries, the composition, appointing authority, and apparent administrative independence give the impression that the Committee is not high level. However, this might not necessarily be the case given the UK's unique system where the executive, just like the Committee, is accountable to the Parliament. That all government agencies must seek and consider its advice further raises its profile and potential buy-in for its recommendations. However, the Committee's role is limited to advice, and its membership is expert led rather than stakeholder based. Such a scientific approach potentially depoliticizes and reduces conflicts within the Committee but can be criticized for ignoring the positive aspects of stakeholder participation. Its success is thus contingent on a high degree of public faith in science for policy.

The direct inclusion of representatives of devolved units in the premier climate change institution is shared by the UK and Kenya. This could be attributed to their unique devolved systems which wield significant powers and autonomy. The arrangement enhances interpretation and smooth implementation of climate change goals at the local levels and is worth emulating. Overall, despite being the pioneer in enacting framework climate change legislation, it is hard to tell to what degree the UK has influenced the legal and institutional structures of the other developing countries.

Synthesis of Emerging Climate Governance Best Practice

Climate change governance frameworks are still evolving. The few but growing number of countries that have proposed legal and institutional structures provide insight which can guide other countries. The foregoing comparative analysis has revealed certain emerging best practice, summarized below, which forms elements of a climate change governance structure developing countries can reproduce, expand, or tailor to their domestic sociopolitical situations.

Enactment of New Stand-Alone Framework Climate Change Legislation

Except South Africa which has no immediate intention of enacting a stand-alone framework climate change law, all the rest either have done so or have unequivocally demonstrated their intention to do so. Two key factors seem to favor such a framework law: (i) the "wicked" nature of climate change requires strategies and policy instruments that go beyond what existing sectoral legislations might have been conceived to deal with, and (ii) the nature and degree of potential amendments to existing sectoral laws are so extensive that they are best captured in a comprehensive stand-alone legislation. The UK's experience of initially opting for the limited *Climate Change and Sustainable Energy Act*, *2006*, before settling on the more comprehensive *Climate Change Act*, *2008*, illustrates this point.

Mainstreaming Is Key to Climate Change Management

Mainstreaming of climate change into policies, legislations, and programs is widely advocated in literature as a more effective approach to tackling climate change. Yet, its uptake and application in laws and institutions are yet to be fully assessed. This comparative analysis provides some empirical evidence that mainstreaming is finding its way into policy and planning instruments from academia. All the countries assessed embrace mainstreaming and commit to integrating climate change through various strategies. This calls for early targeted training on how to mainstream climate change at different levels and constant monitoring and evaluation of applied strategies.

Mitigation Actions Are as Domestically Beneficial as Adaptation

The need to grow their economies in order to lift their growing populations out of poverty has traditionally been used to explain a seeming focus on adaptation at the expense of mitigation by many developing countries. However, empirical evidence from this analysis indicates that most of these countries now view mitigation as a function of adaptation, basing their emission reduction actions on envisaged benefits or "win-win" outcomes. These are generally packaged as low-carbon development strategies or pathways. Apart from the urge to demonstrate global leadership, a possible frustration with international efforts, and jab at the developed countries for perceived lack of commitment, such benefits include job creation and access to new technology and international finance. The distinction between mitigation and adaptation actions is increasingly becoming blurred. Many mitigation actions have adaptation benefits and vice versa.

High-Level Climate Change Institution

The dominant trend across the countries analyzed is the establishment of a *new* high-level cross-sectoral climate change institution with representation from a wide cross section of stakeholders. Charged with overall advice, policy guidance, coordination, and oversight, its high-level status emanates from being chaired by the country's president, or secretary to the Cabinet, and location in the Office of the President (OP) or Cabinet Office, or both. Remember most of the countries are presidential systems. The UK and Kenya go a notch higher by including representatives of the devolved units in this premier climate change institution. Such an arrangement puts climate change high up on the national agenda, enhances political commitment, and promotes mainstreaming. Complementing the climate change institution is an advisory board made up of academia, private sector, civil society, and other special interests. A dedicated secretariat to oversee the technical aspects of the climate change policy and handle day-to-day affairs completes the institutional structure.

Clear Roles, Responsibilities, and Coordination Mechanisms

Clearly defining the roles and responsibilities of institutions with regard to climate change reduces conflicts and leads to effective resource use. However, in doing so, the ability to innovatively interpret such roles and responsibilities should be allowed by not being so prescriptive. For institutions, it is especially important to harmonize their roles and responsibilities if any meaningful results are to be achieved, a situation South Africa currently faces. Clear coordination and communication within and between central government, devolved units, and other governance levels are critical for effective implementation of planned climate change actions. Various mechanisms of doing so are highlighted in the case studies, including oversight, financial and other capacity-building assistance, and regular progress reporting.

Mixed Climate Finance Strategies

The climate finance mobilization and management strategies are mixed. While expected sources of finance include public and private funds from both local and international sources, some countries opt to align climate-related actions to regular budgetary process and/or establish climate change funds along the lines of the UNFCCC's Adaptation Fund. Setting up and/or trading in the carbon market is still popular with many countries. Other proposals include improving the capacity of the public sector to efficiently and effectively absorb the expected climate finances and improving the general investment climate.

Concluding Remarks

Responding to the threat posed by climate change requires establishment of effective and efficient governance structures. For many developing countries, this process is already underway. The comparative analysis of the climate change legislative and institutional frameworks of the four developing and one developed country presented in this chapter reveals several emerging best practices which can constitute elements of a broad governance framework developing countries could reproduce or tailor to their domestic situations.

However, the results also raise broader issues that need closer attention and focus. One such concern is the need to incorporate and actively support the development of national climate change governance structures in discussions leading to the achievement of the outcomes of the Durban Platform for Enhanced Action. The "Durban Platform" is tasked with developing "a protocol, another legal instrument or a legal outcome" under the United Nations Convention on Climate Change (UNFCCC) applicable to all member countries by 2015. Such consideration would ensure synergy between national- and global-level efforts while appreciating the multilevel nature of climate change governance. The lack of an international enforcement body for UNFCCC-related proposed actions should reinforce the need to support national-level actions.

It is hard to tell whether the seeming enthusiasm by the developing countries sampled in this study to prepare national climate change legislations will spread significantly to other countries. However, success in their implementation will more likely inspire confidence in others to follow suit. Yet, such a successful implementation requires a range of other conditions to be met, resources or otherwise. There are many potential challenges which could derail the achievement of the intended outcomes of the so established climate change legal and institutional frameworks. Targeted capacity building in various areas is thus necessary. More important, however, is the need for sharing experiences by the different countries.

The apparent significance which developing countries attach to mitigation represents an important paradigm shift in the way mitigation is viewed. For a long time, mitigation and adaptation have been separated in both the academic and policy fields. The view that mitigation is a function of adaptation and that the two complement rather than antagonize each other, adopted by most of the developing countries analyzed in this study, is the closest to reality. What this reveals is that reducing emissions does not necessarily lead to a reduction in socioeconomic development. Such a revelation should inspire developed countries to cut their emissions not only as a way of slowing and hopefully reversing the current rate of global warming but also as a way of increasing welfare in those very countries and beyond. Genuine efforts at tackling climate change are linked to sustainable consumption and production. Dematerialization, decoupling, degrowth, and such sustainability buzzwords should not be mere rhetoric.

Climate Compatible Physical Infrastructure in Coastal Bangladesh

Mustafa Saroar

Contents

Abstract

Concerns have been raised to make coastal physical infrastructure climate resilient for enhancing the resiliency of the coastal community. However, so far little has been done in this regard. This paper has threefold objectives. The first is to identify the nature of projects that have been implemented in the coastal areas that put higher emphasis on adaptive capacity maximization and ignored the issues of exposure minimization. Second is to unveil how donors' biases toward adaptive capacity building projects have undermined the climate compatible physical infrastructure development projects until recently.

DOI 10.1007/978-3-642-38670-1_45

Third is to present the recent development as regards climate compatible physical infrastructure development with the support of the government as well as the donors.

This study is primarily based on review of data sources presented in the full chapter. It follows a meta-analysis technique for review of published studies on building resilient coastal communities in Bangladesh. Particularly studies and reports have focused on projects for adaptive capacity enhancements and exposure and sensitivity minimization through the establishment of physical measures such as coastal roads and highways, rural growth centers/markets, embankments, polders, sluice gates and cyclone/flood shelters, and afforestation program. While analyzing, the DPSIR (driving forces, pressure, state, impacts, responses) framework was used implicitly.

Although coastal infrastructures are in general vulnerable to both intensive risk and extensive risk posed by various hydrometeorological disasters, infrastructures are mostly vulnerable to cyclonic surges due to their higher 44 exposure. Although disrupted infrastructures seriously undermine the people's efforts toward building a resilient community, yet for decades, donors have neglected the issues of climate compatible infrastructure development; rather, they have pumped millions of dollars for community-wide adaptive capacity enhancement through NGOs. However, lately, it was realized that adaptive capacity enhancement alone can do little to build a resilient coastal community unless adequate attention is given for exposure and sensitivity minimization measures. It has appeared that investing in climate compatible infrastructure development could minimize the exposure and sensitivity of coastal people toward the threats of climatic disasters. Therefore, a new form of investment is underway, which will be discussed in the paper to a greater level of detail.

Keywords
Adaptive capacity • Climate compatible planning • Exposure and sensitivity • Coastal infrastructures • Bangladesh

The Science of Climate Change

Over the last two decades or so, there has been an enormous growth of literature concerning modification of weather, variability in climatic condition, and change in the patterns of climatic (hydrometeorological) disasters. The weather, which is the state of day-to-day atmospheric condition, is believed to become chaotic for quite a long time in many parts of the globe. This chaotic weather pattern has been turning to a regular event of climatic variation. Climatic variation is simply a deviation from normal climate. Climatic variation and weather extreme form the basis for climate change. Changes in pattern of precipitation, temperature, melting of snow and ice, and rising global sea level are all clear manifestation of global climate change (Alley et al. 2005; Nerem et al. 2006). Climate change is attributed to global warming. Global warming depends on the amount of carbon emission. Therefore, human contributions to future climate change largely depend on future emission of greenhouse gases. Then again future emission of carbon depends on the future state of the world (Cazenave and Nerem 2004; Nerem et al. 2006). Assuming various plausible socioeconomic development pathways (i.e., future state of the world) and using various models, scientists have developed various future climate change scenarios (Rajagopalan et al. 2002). Although the outcome of one model differs often markedly with the results of others due to the use of different set of assumptions, yet most models agree in some points. For example, most models acknowledged that temperature and precipitation have been changing and would continue to change.

From a multiplicity of models, this research heavily draws on the climate change scenarios of the IPCC. In fact, IPCC's emission scenarios (Leggett et al. 1992; IPCC 2001a) are extensively used to model climate change impacts (Hinkel 2005). The IPCC publishes every 5 years an assessment report of the global climate. Among its various reports, the second, third, and fourth assessment reports are the most widely referred. The fifth assessment report is due in 2013. Among various outputs of the models the change in temperature and precipitation which would contribute to the accelerated sea level rise and amplification of the devastating capacity of the hydrometeorological disasters have secured global attention (IPCC 2007).

Climate change due to global warming not only increases the air temperature but also increases sea surface temperature (SST) (Manabe and Stouffer 1980). With the increased sea surface temperature, the thermal expansion takes place in addition to melting of glacier and iceberg which leads to sea level rise (SLR). Thus, one of the major consequences of global warming and climate change is the SLR. Constant increase in sea surface temperature would cause thermal expansion which would cause SLR. Again due to the increase in global temperature, the process of melting of continental and polar ice sheets would be accelerated which would contribute to SLR. Both from tide gauge observation for the last 50 years and from the satellite altimetry measurements, a rising trend in sea level is confirmed (Nerem et al. 2006). Sea level rise may accelerate by a factor of 10 over present rates within the next century. It is estimated that global temperature rise due to the greenhouse effect may ultimately cause the sea level to rise as much as 3 m by the year 2100 (Castro-Ortiz 1994). However, the most widely used estimates are the two provided by UNEP (2002) and IPCC (2001a). According to UNEP, the humanity might experience an SLR of 1.5 m, and for the same period, IPCC projected a rise of about 1 m (88 cm). Therefore, acceleration in SLR has posed a formidable challenge for heavily populated coastal nations and small island nations (Adger et al. 2003). In fact, 180 million people would be affected from 22 coast-lying countries. Over 150,000 km^2 of land would be lost, including 62,000 km^2 of coastal wetland (Middleton 1999; Mimura 1999). Bangladesh would be one of the most severely affected countries in terms of number of population affected (Nicholls 1995; IPCC 2007; UNDP 2004).

Vulnerability of Coastal Bangladesh to Climate Change-Induced Events

Bangladesh is a tropical low-lying country. It has a population of nearly 150 million out of which more than 35 million live in the coastal fragile flood plain (Bangladesh Bureau of Statistics [BBS] 2011). Coastal area covers an estimated amount of 36,000 km^2 (Ali Khan et al. 2000). Some 700 km coastline is extended from east to west (Singh 2001). The country has 19 coastal districts in 3 distinct coastal zones. Among these districts, 12 districts have exposed coastline. There coastal zones are western, central, and eastern. In the southwestern part – known as the Ganges tidal plain – the topography is very low and flat. The largest mangrove forest – Sundarbans – is located here. The central region, being most active, experiences continuous processes of accretion and erosion. The eastern region, being covered by hilly areas, is more stable, and it has one of the longest beaches in the world (Figs. 1 and 2).

People in the coastal flood plains earn their livelihood primarily from agriculture, fishing, and similar natural resource-based activities. As the land price is low relative to other parts of the countries, mostly poor and marginalized people from various parts of the country prefer to settle here. Except some parts of the eastern zone, the entire coastal area is hardly 1 m above the mean sea level (MSL). Furthermore one-third of the country's landmass is under tidal excursions (Ali 1999, 2003). As the country receives enormous amount of ice-melted water from the Himalayan catchments and has poor discharge capacity, severe flooding is a regular phenomena (Schmuck 2000). About 20 % of the country experience regular flooding due to upstream water or heavy rainfall during monsoon. The coastal area is the one that experiences regular flooding, cyclone, storm surge, erosion, salinity intrusion, etc. (Islam et al. 1999). In the changing scenario of climate, the coastal area would experience one more disastrous event, i.e., accelerated SLR (Castro-Ortiz 1994; Nicholls et al. 1995; Ali 1999; Huq et al. 1998; Ali Khan et al. 2000; World Bank 2000; IPCC 2001b, 2007; Singh 2001; Cannon 2002; GOB 2006; Department of Environment [DOE] 2007) (Fig. 1).

Many of the above-cited studies projected a rise in sea level within the range of 0.50–1.5 m along Bangladesh coast [Bay of Bengal]. Although IPCC (2001a) indicated about 1 m rise by the end of this century, the United Nations Environmental Programmes [UNEP] (2002) projected a rise of 1.5 m. Although some experts opined that due to the subsidence effect of immature delta, the coastal area of Bangladesh might experience SLR of more than the above-cited figure, others ruled out such prediction. The latter group of experts believes that the coastal area of Bangladesh has been receiving enormous amount of silt from the Himalayan catchments which would help in lowering the level of SLR. Considering all the possibilities related to coastal dynamic of Bangladesh coast, Bangladesh government document accepted the US country study's lower projection of 30 cm and higher projection of 1 m [or 88 cm NAPA] (Government of Bangladesh [GOB] 2005). The National Program of Actions (NAPA) accepted that Bangladesh coast might experience 14, 32 and 88 cm rise by the years 2030, 2050, and 2100.

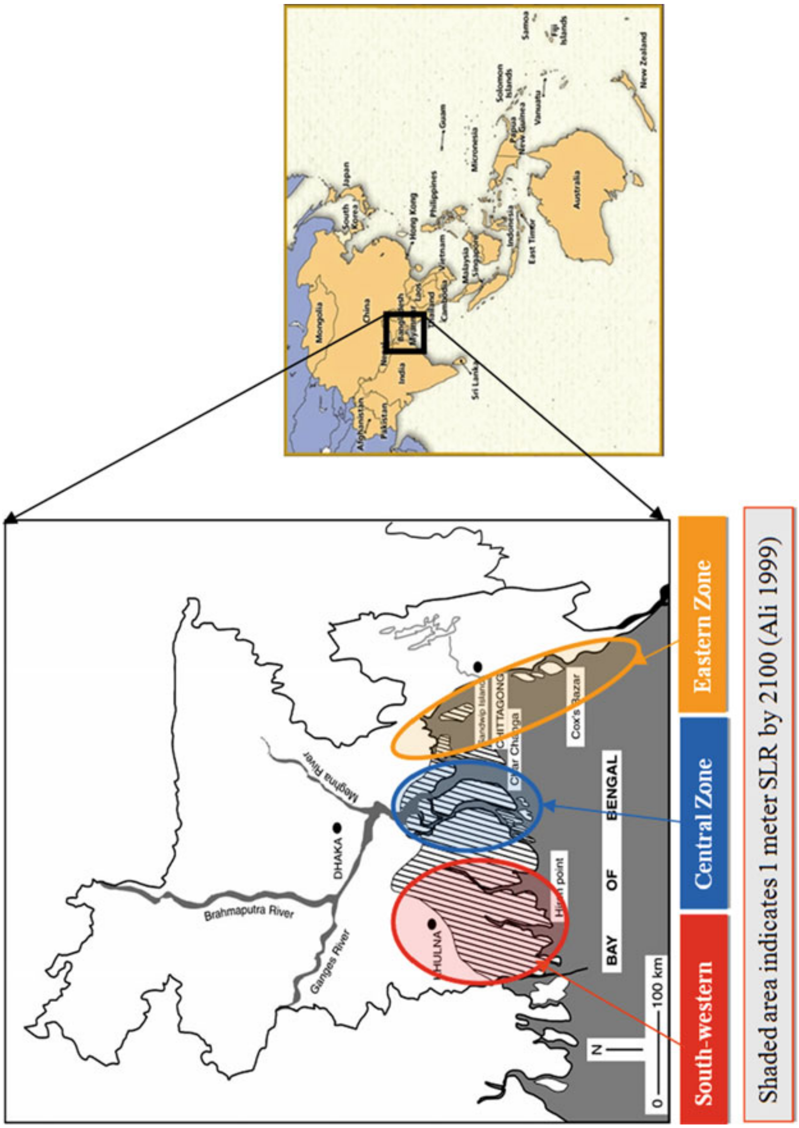

Fig. 1 Bangladesh in relation to countries in the Asia-pacific region (Source: Author)

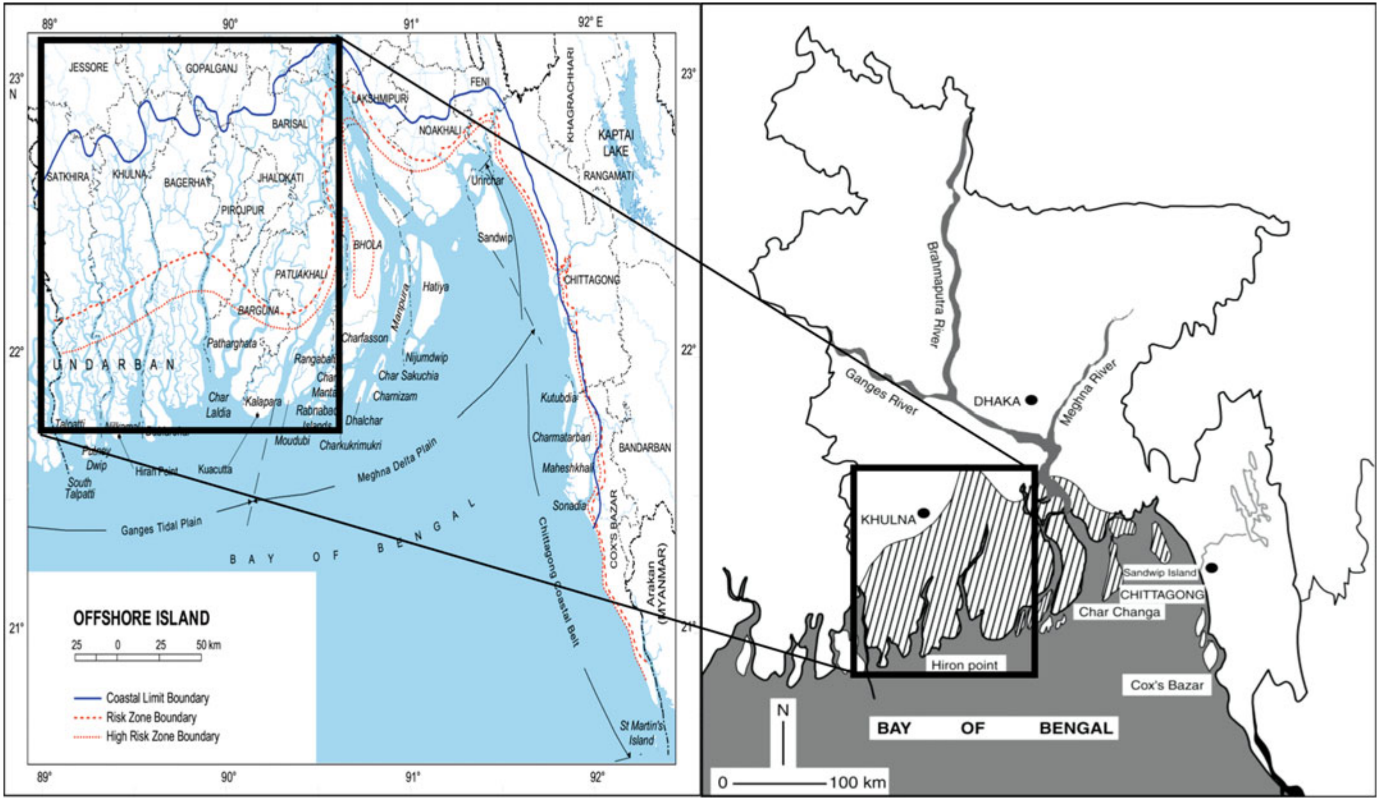

Fig. 2 South-west coastal Khulna region (inside rectangle) in relation to Bangladesh (Source: Author)

The increase of sea level along the Bangladesh coast is likely to enhance the risks of coastal flooding, salinity intrusion, storm surge, and even catastrophic cyclone (Ali Khan et al 2000; CARE 2003; Sing et al. 2001). Each of these would have various effects on coastal topography and morphology which would cause network of impacts on the lives and livelihood of coastal people. Some of the impacts are already visible.

Impacts of SLR and Its Associated Events in the Southwest Coast

The SLR would have a network of impacts on the low-lying parts of coastal areas because of the amplification of the devastating power of some of the already occurring events such as coastal flooding, salinity intrusion, cyclones, and storm surges. Because of tidal influence, some parts of the coastal area especially the southwest coast already have experienced the worst impacts of coastal inundation and saline water intrusion.

Assuming a population of 1995 and no adaptation (Nicholls 1995), Nicholls et al. (1995) estimated that a 1 m rise in sea level would inundate 24 million people and permanently displace as many as 15 million people. In such a case, the estimated amount of loss of land would be 25,000 km^2 (17.5 %). Same study argued that a 1 m rise in sea level and a 15 % increase in precipitation would inundate 71 million people because of massive flooding. Massive flooding may result from drainage congestion and water logging in the delta during high flow periods in the three major river systems in Bangladesh due to SLR-induced backwater flow. Although it is hard to forecast when such massive inundation would take place, it would have severe impacts on agriculture and forestry, food security, human health, transport and infrastructure, and settlement and housing. Therefore, Bangladesh is shown as rank 1 in terms of the number of population likely to be affected by climate change and SLR and its associated events (Nicholls 1995; Nicholls et al. 1995). If the future increase of population is considered, the number of affected people would be even more. An increase of 130 million people over the next 50 years in Bangladesh is projected, among which at least one-fifth would be from the coastal area (GOB 2009). However, another recent estimate by UNEP (2002) puts the number of displaced people at 17 million (15 % of the population) for a rise in sea level of 1.5 m along Bangladesh coast. Therefore, it is reasonable to assume that the projected SLR would generate considerable number of climate refugees

The effect of saline water intrusion in the estuaries and into the groundwater would be enhanced by combined effects of low river flow [during winter], SLR, and subsidence. The adverse effects of saline water intrusion would be significant on coastal agriculture (Ali and Chowdhury 1997; Faruque and Ali 2005; GOB 2006). Agriculture is the key livelihood avenue in the coastal area. Due to SLR perpetual intrusion of salinity in soil, subsoil water table and surface water bodies will have serious impacts on coastal agriculture (Huq, et al. 1998). The presently practiced rice varieties may not be able to withstand against increased salinity (Ahmed 2005). Therefore, food grain production may significantly reduce. IPCC's report (2007) under the title Climate change in Asia "too alarming to contemplate" projected that in Bangladesh, rice production may fall by 10 % and wheat by 30 % by 2050. Already about 830,000 million hectares of arable land is affected by varying degrees of soil salinity. More adverse impacts are projected for the coming decades, particularly for low-lying coastline and floodplain ecosystems (DOE 2007).

Coastal region that has very significant part in Bangladesh is about one-fourth of the country's population, with poor income groups forming about three-fourths of the coastal population. The coastal zone has diverse livelihood activities that are in danger to natural hazards and are also affected by man-made hazards.

Climate change can affect the productivity of coastal agriculture in a variety of ways:

- Changes in heat and rainfall affect the dynamics of ocean currents, the flow of rivers, and the area enclosed by wetlands. This will have effects on ecosystem structure and function and on the distribution and production of agricultural products.
- Increased incidence of extreme events such as floods, droughts, and storms affects the safety and efficiency of cultivation and increases damage and disruption to coastal services and infrastructure.
- Sea level rise, melting of glaciers at the headwaters of major rivers, and other large-scale environmental changes will have unpredictable effects on coastal and wetland environments and livelihoods.
- Complex links between climate change, farming, and other sectors have indirect effects being affected by changing water demands from agriculture, changing prices of and access to aquaculture feedstuffs, and diversion of government and international financial resources.

Another important dimension of SLR is salinity intrusion in mangrove forest Sundarbans. The IPCC Working Group II has indicated in its fourth assessment report that for a 1 m rise in sea level, the Sundarbans mangrove forest would probably be lost. Similar assertion is made by the Organization for Economic Cooperation and Development [OECD] in its study done by Agrawala and his colleagues (2003). Sundarbans mangrove forest not only provides ecological service; its resources provide livelihood opportunity for millions of people. If Sundarbans mangrove forest is affected, the livelihood avenues of dependent population would be severely affected. Furthermore, in the absence of Sundarbans mangrove, approximately 1,000 km^2 of cultivated land and sea product culturing area would be salt marsh. Likewise, SLR-induced salinity by reducing the amount of fresh water fishing area will cause reduction in fish production (Choudhury et al. 2005). Culture fisheries in the coastal area would be affected by intrusion of salt water into ponds, unless embankments are made around them. Shrimp farming in the coastal area is a lucrative business. Increase in salinity would probably jeopardize the shrimp farming as well (CARE 2003). For the last few decades, more and more attention is being given to sea fish and brackish water fisheries. The CC-SLR may arrest this trend.

The inundation of the coastal plains due to floods is common during monsoon (July to September). Because this time, it is often the case that the descending water from Himalayan catchments synchronize with heavy rainfalls and backwater flow from the bay due to tidal influence. As a consequence, floodwater continues to accumulate and bringing more areas under inundation. Backwater effects might aggravate the coastal flooding because of SLR (Ali 1999, 2003).

A direct consequence of SLR would be the intrusion of salinity with tide through the rivers and estuaries (Ericson 2006). According to an estimate of the Master Plan Organization (MPO), about 14,000 km^2 of coastal and offshore areas have saline soils and are susceptible to tidal flooding. A half meter rise of sea level would bring almost similar amount of coastal land under saline zone. Because due to SLR, the salinity front would be pushed further inland. The present interface between freshwater and saline water lies around 120–160 km inward from the shoreline. This would well be pushed further inward due to SLR (ADB 2000). For example, 5 ppt saline front would shift about 40 km inward due to SLR of 88 cm. A big chunk of the freshwater zone would disappear. Therefore, anticipated SLR would increase salinity in soil, subsoil water table, and surface water bodies (Ahmed and Alam 1998; Huq et al. 1998; Ahmed 2005).

Furthermore, SLR would cause shoreline retreat. It means the basin areas would increase along Bangladesh coast. Experts warned that this would allow the cyclone to remain longer in the water and acquire and release more latent heat. As a result, coastal areas may experience cyclones having more energy, intensity, and wind speed. Therefore, with the rise of sea level, the risk of cyclonic impact would be increased as well. For example, storm surge height might increase 13–46 % for SLR of 0.3 m and 1 m (for detail, see Ali 1999, 2003). Surge water that hits the coastline of Bangladesh would travel far inland. It means the risk zone (RZ) and a high-risk area (HRA) would shift inward. Since multipurpose cyclone and flood shelters are located in current risk zone and high-risk area [HRA], these shelters may be less effective as well because those would be standing in newly submerged areas.

From the forging discussion, it could be summarized that the projected SLR along the coastal areas of Bangladesh will be about 88 cm by the year 2100. If this comes true, a majority of the low-lying non-embanked coastal areas may be completely inundated. There will be increasing risk of coastal salinity (both soil and surface water). The mixing zone between fresh (sweet) water and saline water will also shift. Scarcity of saline-free drinking water will be even more pronounced. SLR will have compounding effects on coastal drainage and erosion. Land use suitability, particularly in relation to current agricultural practices, will change. Embanked coastal agricultural areas will be at higher risk of tidal surge and subsequent inundation with saline water. Therefore, the livelihood of coastal people would be severely affected in the coming decades due to SLR and its associated events.

Major Climatic Disasters and Impacted Infrastructures in Southwest Coast

Coastal districts, particularly those which have exposed coast such as Khulna, Bagerhat, Satkhira, Barguna, Patuakhali, Bhola, and Cox's Bazar, are particularly vulnerable to multiplicity of disasters including cyclones, storm surges, coastal inundation, salinity intrusion, etc. To protect the settlements in these areas from the 1960s onward, various infrastructures such as polders, levees, embankments, sluice gate, and cyclone and flood shelters have been constructed, the most notable of which are more than 2,500 cyclone shelters, 6,000 km embankment, 4,700 km drainage channel, and about 125 polders that have been constructed in addition to coastal greenbelt program. Although a significant portion of these exposure minimization infrastructures are in the southwest part of the coast, the sensitivity of this part of the coastal area is very high due to repetitive exposure to cyclonic and storm surges. Moreover, salinity intrusion and erosion causes damage to these infrastructures. Therefore, infrastructure failure is very common during the disastrous events which severely affect the life and livelihood f millions of coastal population. This southwest coastal area is affected by 2–3 cyclonic episodes each year. From 1950 about 50 cyclones hit this region. One devastating cyclone hits this area in every 5–10 years. Most recent cyclonic events that severely ravaged this area are Sidr and Aila. Although the death tolls were only few hundreds to few thousands, the damage of infrastructure and degradation of agricultural field were unprecedented. Almost 1,200 km protection embankment was either wholly or partially destroyed. Almost hundred thousand families were displaced from their settlements for few months to even 2 years due to these two devastating cyclones (GOB 2010a) (Table 1).

It is widely believed that due to change in climate, this kind of devastating cyclones would be even more apparent in the years to come. To minimize the impacts of such events, there is a growing need for anticipatory adaptation planning. Such anticipatory adaptation plan must include the exposure and sensitivity minimization measures and adaptive capacity enhancement measures (Brooks et al. 2005). Exposure and sensitivity could be minimized through building resilient infrastructure, and adaptive capacity could be enhanced through minimizing socio-economic vulnerability (Blaikie 1994). A starting point for building resilient infrastructure to minimize exposure and sensitivity could be detailed a inventory of the condition of all physical infrastructures such as polders, levees, dykes, embankments, roads, bridges, culverts, sluice gates, growth centers, schools, cyclone shelters, river ports and lending stations, hospitals, power stations, etc.

Adaptation to Climatic Disasters: Donors' Bias Toward Adaptive Capacity Building

A good number of initiatives have been taken so far, and some are ongoing as well to address the climate change impacts in various spheres of coastal life and livelihood. Such program covers emergency relief and rehabilitation to health and

Table 1 Major cyclones along coastal Bangladesh and respective surge heights

Cyclonic event	Season	Surge height (meter)
November 1876	Post-monsoon	3.0 ~ 10.0
May 1941	Pre-monsoon	4.0
May 1960	Pre-monsoon	3.2
October 1960 (first event)	Post-monsoon	5.1
October 1960 (second event)	Post-monsoon	6.6
May 1961 (first event)	Pre-monsoon	3.0
May 1961 (second event)	Pre-monsoon	6.0 ~ 8.0
May 1965	Pre-monsoon	7.6
December 1965	Post-monsoon/winter	8.8
October 1967	Post-monsoon	7.6
October 1967	Post-monsoon	7.6
October 1967	Post-monsoon	7.6

sanitation, food security, income generation to even infrastructure building to enhance the resiliency of the affected populations. In this respect, various donors such as European Community, USAID, DFID, and DSCC have been playing very instrumental role. Especially the European Union devotes huge sum of money for various projects under Climate Change Resilience Fund. Various local and international NGOs have been implementing a wide range of programs.

In fact, southwest coastal region being the most affected region in Bangladesh has so far got the highest international attention. A large sum of money already has been committed by various international development agencies to increase the resiliency of the region against climatic disasters and similar environmental stressors. Although for building a resilient community there is a need for package of programs which should include minimization of exposure and sensitivity and enhancement of adaptive capacity, analysis of recent trend shows that nearly all programs are targeted toward mainly adaptive capacity enhancement and, in some cases, sensitivity minimization of poor and marginalized coastal population (Table 3). It is probably because, first, the northern donors often prefer community-wide intervention for livelihood security; second, they intervene by engaging the local community with the help of NGOs. Therefore, exposure minimization – an important component of resilient community building – is always missing in their intervention. Therefore, although the poor and marginalized people enhance their adaptive capacity and minimize their sensitivity toward natural disasters by accumulating new skills and resources over time, these hard-earn gains are destroyed while they are exposed to devastating disastrous events next time. Therefore, greater need is felt by policy planners as well as the community as regards minimization of their exposure to those disastrous events. One way to do this is to invest in exposure minimization measures. Such investments include climate compatible physical infrastructures that relate to transport and physical communication, water supply and sanitation, health and education, marketing and trading establishment, construction of safe shelters, and protective embankments. Among these only some supports are extended by few northern donors (e.g., German Red Cross) for periodic maintenance of safe shelter and coastal embankments.

In Table 2, various programs/projects that have been implemented and also under implementations by such international agencies are presented in brief.

Climate Compatible Physical Infrastructure for Exposure Minimization: Current Status and Ways Forward

Especially after the massive strike of super cyclone Sidr in 2007 and Aila in 2009 which destroyed either fully or partially about 1,200 km protection embankment, the importance of exposure minimization measure for building a resilient coastal community came into the forefront (GOB 2009). Therefore, it was highly felt that coastal physical infrastructures, such as roads, bridges, culverts, embankments, dykes, polders, levees, sluice gates, cyclone shelters, urban drainage systems, schools, and marketplaces, need to be climate compatible. Although it is already late, still it is encouraging that policy makers, planners, government, and the donors have realized that only by enhancing adaptive capacity could a resilient coastal community not be built against the impacts of accelerated pace of climate change. In fact, scientific community warned that adaptation has its limit (Adger et al. 2009); enhanced adaptive capacity gives synergy to build resilient community if bundled with exposure and sensitivity minimization measures. In line with this new understanding, both the government and donors are coming forward to redesign their interventions.

Following the outcome of COP 15 (conference of parties), Bangladesh government expected that the bilateral donors would come up with funding support committed earlier for helping adaptation. However, when the United Kingdom (UK) announced that they would give their part of ODA (Official Development Assistance – earlier) with a new label for financing adaptation instead of establishing a new funding mechanism for helping adaptation, Bangladesh government refused to get that. Later in 2010, Bangladesh government in line with its Bangladesh Climate Change Strategy and Action Plan (BCCSAP) established initially a US$ 100 million fund from its own budget to finance adaptation. In the

Table 2 Review of major programs/projects which have been launched between 2007 and 2013 to enhance adaptive capacity and minimize sensitivity against climatic disasters in coastal Bangladesh

Donors and implementing agencies	Programs/projects name	Brief description	Strategies to reduce vulnerability
The Swiss Agency for Development and Cooperation (SDC) in partnership with local NGOs – Ashroy Foundation and Bangladesh Disaster Preparedness Center (BDPC)	Early Recovery, Cash for Livelihood (CfL) and Community Cyclone Shelter Program for the Cyclone Aila victims	The activities of CfL project were directed to increase the capacity of farmers, fishermen, small enterprise owners, and day laborers whose livelihoods were severely affected by cyclone “Aila” to overcome the loss of income in order to restart their economic activities through a cash contribution and to become independent from relief	Mainly for adaptive capacity enhancement and few measures for sensitivity minimization
		The main project objective was to reduce risk and vulnerability due to cyclones of communities living in high-risk areas in southern Bangladesh	
The UNDP Bangladesh was the lead agency. The project framework is based on broad partnership among government, UN agencies, local and international NGOs, interested donors, the private sector, and other stakeholders that play a critical role in disaster management	The Early Recovery Facility (ERF) project	The ERF project aims at generating sustainable and nationally owned processes for better and more effective post-crisis recovery, by linking post-disaster humanitarian rapid response with longer-term recovery actions that include measures for mitigation of future risks. The ultimate goal is to enable the local population affected by regular natural disasters to recover more timely and in a more sustainable way and ultimately to become more resilient to the regular setbacks caused by natural hazards	Mainly for adaptive capacity enhancement

(*continued*)

Table 2 (continued)

Donors and implementing agencies	Programs/projects name	Brief description	Strategies to reduce vulnerability
European Union	**Sundarbans Environmental and Livelihoods Security (SEALS) project**	The overall objective is to contribute to maintaining or improving ecosystem productivity and the environmental and social integrity of the north coastal lands of the Bay of Bengal	Mainly for sensitivity minimization and few measures for exposure minimization as well
		The purpose of the EU support is sustainable development of the Sundarbans Reserved Forest and the people who currently depend on its resources	
European Union	**Increasing Resilience and Reducing Risk of Coastal Communities to Climate Change and Natural Hazards in the Bay of Bengal**	The objective is to contribute toward poverty alleviation among poor communities in coastal areas of the Bay of Bengal, through reducing their risk to the impacts of hazards and climate change	Mainly for adaptive capacity enhancement
European Union	**Collective Action to Reduce Climate Disaster Risks and Enhancing Resilience of the Vulnerable Coastal Communities around the Sundarbans in Bangladesh and India**	The overall goal of the project is to reduce climatic disaster risks and enhance resilience of the coastal communities around the Sundarbans by building capacity of the vulnerable communities, local actors, and stakeholders through sustainable natural technologies	Mainly for adaptive capacity enhancement

European Union in cooperation with Relief International and local NGO – Uttran	**Social and Economic Security for Traditional Resource Users of the Sundarbans**	The overall objective is to reduce extreme poverty in the target areas through outreach to workers in the informal economy. The specific objectives are (i) to enable informal workers (traditional resource users) in the Sundarbans Impact Zone (SIZ) to attain decent work and break the cycle of extreme poverty and (ii) to empower them to identify, access, and advocate for social protection rights and services	Mainly for adaptive capacity enhancement
European Union in cooperation with Concern Universal and Dhaka Ahsania Mission	**Ensuring Water and Sanitation Facilities towards Disaster Risk Reduction**	The overall objective of the action is to promote people participation for reducing the morbidity and mortality caused by inadequate water and sanitation provisions in selected coastal disaster prone areas of Bangladesh	For sensitivity minimization and adaptive capacity enhancement
European Union in cooperation with CAFOD (UK), Caritas, and local NGOs – Prodipan and Dhaka Ahsania Mission	Improved Food and Livelihood Security in Bagerhat District, Bangladesh in the Context of Increased Disaster Risk and Climate Change (IFLS)	The overall objective of the action is to improve food and livelihoods security in Bagerhat District, Bangladesh, in the context of increased disaster risk and climate change	For adaptive capacity enhancement and sensitivity minimization
European Union in cooperation with BRAC	**Instrument for Stability – Restoring Socio-economic Stability and Strengthening Community Resilience in Areas Affected by Cyclone Aila**	The specific objective of this action is to support the rehabilitation of agriculture-based as well as nonagriculture-based livelihoods in severely cyclone Aila-affected districts of Bangladesh. In addition, the program would indirectly improve the food security situation of the most vulnerable population in the cyclone Aila-affected coastal areas	Mainly for adaptive capacity enhancement and few measures for sensitivity minimization

(*continued*)

Table 2 (continued)

Donors and implementing agencies	Programs/projects name	Brief description	Strategies to reduce vulnerability
European Union in cooperation with BRAC	**Instrument for Stability – Post-SIDR Livelihoods Rehabilitation**	The specific objective of this action was to support the rehabilitation of agriculture as well as nonagriculture-based livelihoods in severely cyclone Sidr-affected districts of Bangladesh. In addition, the program indirectly improved the food security situation of the most vulnerable population in the cyclone Sidr-affected coastal areas	Mainly for adaptive capacity enhancement and few measures for sensitivity minimization
BRAC	Bangladesh Agriculture & Food Security: Crop Intensification	To rehabilitate the victims of cyclone Sidr, BRAC introduced hybrid rice in winter (Boro/Rabi) season in the coastal area for the first time. The farmers cultivated this rice using tidal river water. Additionally, BRAC has implemented high yielding variety (HYV) and hybrid rice cultivation in pre-monsoon (Aus) and monsoon (Aman) seasons in traditional single-crop areas. BRAC introduced maize, sunflower, and other vegetables as new crops in areas with limited nonsaline water as part of the rehabilitation of Sidr victims	Mainly for adaptive capacity enhancement and few measures for sensitivity minimization
USAID in cooperation with Worldfish Center	Integrated Protected Area Co-management (IPAC)	The overall objective is to promote and institutionalize an integrated protected area (PA) comanagement system for sustainable natural resources management and biodiversity conservation that result in responsible, equitable economic growth and good environmental governance. USAID/Bangladesh expects IPAC to have widespread environmental, social and economic impacts	For sensitivity minimization and adaptive capacity enhancement

UK DFID in cooperation with local NGO – Uttran	Stimulation Household Improvements Resulting in Economic Empowerment (SHIREE): The Extreme Poverty Monitor and Information on Shiree's Change Monitoring System (CMS)	The aim of the project was to distribute *khas* (government wasteland) land among extreme poor landless people. The model involves government institutions (the Upazila, subdistrict administration; local government unit, Union Parishads) to effectively transfer *khas* land to the extreme poor. They maintain and share this database to other parties who would take program targeting this vulnerable group	For adaptive capacity enhancement and sensitivity minimization
UK DFID in cooperation with local NGO – Shushilan	SHIREE: Adapting Natural Resource Management to Climate Change and Increasing Salinity	The project is aimed to increase resources and sustain household incomes in ways that are resilient to climate change. Action program include activities that improve access to unused land and water bodies for the extreme poor. Furthermore, it provide need-based skills training and initial inputs and resources to test and develop agro-based microenterprises such as floating gardens, cultivation of rabi crops, mangrove nurseries, and crab fattening	Mainly for adaptive capacity enhancement and few measures for sensitivity minimization

Source: Author's review

next year, more US$ 100 million were added in that fund. Although this "Climate Change Trust Fund" is aimed to support programs/projects that fall broadly under six major themes, infrastructure development, comprehensive disaster management, adaptation knowledge management, capacity building, low carbon development, and food, nutrition, and health security, in reality lion share of the fund is allocated for climate compatible infrastructure development. For instance, in 2010–2011 financial years, about 75 % fund was allocated for projects that could play significant role in minimizing exposure and sensitivity to the impacts of climatic disasters. Therefore, most of this fund was allocated for climate compatible physical infrastructure development-related activities. There are complains about the process of selection of projects from this fund; Khulna region despite being one of most affected regions failed to get due attention. Among the 62 projects approved, Khulna region could benefit from less than 10 projects that address the issue of coastal resiliency. In Table 3, the name of the projects and the broad mechanism to enhance resiliency are presented in brief.

This poor number of projects from where southwest region could benefit in terms of increased resiliency against the climatic impacts gives a very clear signal that while this region is in most need, it is deprived of government fund. Then again most of these projects are implemented by various departments of Bangladesh government, the most notable of which are the Local Government Engineering Department, Water Development Board, and Forest Department. There is common concern about the quality of implementation work and capabilities of many of the organizations implementing these projects.

More recently both the government and donors realized that coastal rural infrastructure is directly vulnerable to the impacts of climate variability and change, as well as indirectly, through changes to the surrounding environment. To ensure its longevity and sustainability, any rural infrastructure investment, especially in coastal districts, must be resilient to climate change-associated extreme events. Inadequate attention to these impacts will increase the long-term costs of infrastructure investments and the likelihood that such investments fail to deliver the benefits for which they were intended (Thomalla et al. 2005). Therefore, the donors came up with a US$ 120 million new funding scheme called "Climate Resilient Fund" to support coastal resiliency. However, this funding scheme is too small when it is compared with the amount of funding required for climate change adaptation in Bangladesh. Revised NAPA prepared in 2009 identified 45 priority projects under six thematic areas which are roughly estimated to cost more than US$ 4 billion to implement. Bangladesh climate change strategies action program (GOB 2009) has roughly estimated the cost of about US$ 500 million (for years 1 and 2) to support programs for immediate actions such as strengthening disaster management, climate proofing of infrastructure, ensuring food and water security, research and knowledge management, capacity building and public awareness programs, and urgent investment in cyclone shelters. The total costs estimated in the BCCSAP for programs commencing in the first 5 years are at $5 billion. According to a recent study by the Institute of Water Modeling (IWM), Bangladesh needs at least $4.17 billion, only

Table 3 Projects funded from climate change trust fund that could enhance resiliency of Khulna region

Project name	Location/ impact area	Increase resiliency
Construction of Cyclone Resistant Houses at Char Area in Aila Affected District of Khulna	Khulna district	Through minimization of exposure
Construction of Cyclone Resistant Houses at Char Area in Aila Affected Districts of Chittagong, Barisal and Khulna	Khulna district	Through minimization of exposure
Dredging of Bolesshor river from Bagmara to Dopara (Via Khontaghata Platoon, kochua bazaar & Adajuri)	Pirojpur district	Through minimization of exposure and sensitivity
Protection and Repair of damage Sea-dyke and others infrastructure of the coastal polder no-63/1 A		
Re-excavation of Drainage Khal (natural canal) of Madaripur Beel Route Channel (MBR) of Gopalganj District	Madaripur/ Gopalganj district	Through minimization of exposure and sensitivity
Re-excavation of drainage Khal (natural canal) in Upazilla Kalkini, under Madaripur District	Madaripur district	Through minimization of exposure and sensitivity
Re-excavation of 24 (twenty four) drainage Khals (natural canal) in Upazila-Rajoir & Madaripur Sadar under Madaripur District	Madaripur district	Through minimization of exposure and sensitivity
Innovation of Sustainable Crop System for Drought Prone and Coastal/saline Area to Face Climate Change Impact	Nationwide	Through minimization of sensitivity and enhancement of adaptive capacity
Innovation of various mutenants Crop System for Drought Prone and Coastal/saline Area to Face Climate Change Impact	Nationwide	Through minimization of sensitivity and enhancement of adaptive capacity
Plantation of BWDB's Embankment in the Coastal Belt and its adjacent Char Areas	Greater Khulna region	Through minimization of exposure and sensitivity
Community Based Adaptation in the Ecologically Critical Areas Through Biodiversity Conservation and Social Protection	Greater Khulna region	Through minimization of exposure and sensitivity, and enhancement of adaptive capacity
Coastal afforestation to combat adverse impact of climate change	Greater Khulna region	Through minimization of exposure and sensitivity

for the construction of polders to save the lives of coastal people from sea level rise and storm surge. A joint assessment carried out by the GOB and Development Partners (DPs) after Cyclone Sidr in 2008 estimated that US$1.4 billion is required in the short term and US$ 4 billion for the long term (15 years) for adaptation and mitigation measures GOB (2010b).

Although this multidonors' fund is very small in amount as compared to the need, it is believed that this fund would help in arresting other funds as well for building coastal resiliency. Bangladesh government has participated in the Strategic Program for Climate Resilience (SPCR) prepared under the Pilot Program for Climate Resilience (PPCR). The PPCR is a program under the Strategic Climate Fund (SCF) within the Climate Investment Funds (CIF), to pilot and demonstrate ways to mainstream new approaches for integration of climate risk and resilience into development projects, policies and planning. The various project proposals under the Bangladesh's Strategic Program for Climate Resilience (SPCR), prepared under the Pilot Program for Climate Resilience (PPCR) package, strongly build on priorities identified by the Government of Bangladesh's executing agencies and are in line with the recommendations in the *Bangladesh Climate Change Strategy and Action Plan.*

With the support from ADB, World Bank, and IFC, several programs are under process. Most notable of which are:

- Investment Project 1: Promoting Climate Resilient Agriculture and Food Security
- Investment Project 2: Coastal Embankments Improvement and Afforestation
- Investment Project 3: Coastal Climate Resilient Water Supply, Sanitation, and Infrastructure Improvement
- Technical Assistance 1: Climate Change Capacity Building and Knowledge Management
- Technical Assistance 2: Feasibility Study for a Pilot Program of Climate Resilient Housing in the Coastal

Among the above programs/projects, the following two are directly related to building climate compatible infrastructure for building resilient coastal community.

Coastal Climate Resilient Water Supply, Sanitation, and Infrastructure Improvement Project

The Coastal Climate Resilient Water Supply, Sanitation, and Infrastructure Improvement project has components that relate to:

- Climate Resilient Water Supply, Sanitation, and Drainage Development: Develop water supply and drainage system in coastal districts which can provide safe drinking water and sanitation even with anticipated climate change impacts.
- Climate Resilient Infrastructure Improvement: Improve connectivity (small roads, bridges, culverts, etc.) within the coastal districts in a sustainable and climate-proof way to enhance the accessibility of the rural people in the coastal districts to social services, such as health and education and economic

opportunities, and to improve earnings for the rural poor including the poor women by widening the all-weather access to markets and livelihood activities.
- Climate Resilient Small-Scale Water Resources Improvement: Enhance agriculture productivity and sustainability and improve rural livelihoods in subproject areas through the sustainable small-scale water resources (SSWR) management, including flood management, drainage improvement, water conservation, and command area development.

In this respect, it should be noted that as a subproject of the above project, the *Coastal Climate Resilient Infrastructure Project* has been under operation from early 2013 with an estimated cost of US$30 million. Similarly another subproject *Coastal Towns Infrastructure Improvement Project* is in the final stage of approval by the donors. Funded by ADB, KfW, and IFAD, the Coastal Climate Resilient Infrastructure Project is launched in 12 coastal districts for the period of 2013–2018. These districts are Satkhira, Khulna, Bagerhat, Pirojpur, Barisal, Jhalokati, Bhola, Patuakhali, Barguna, Madaripur, Gopalganj, and Shariatpur. This project would deliver the following outputs as regards building climate compatible physical infrastructure.

Output 1: Improved Road Connectivity

The project will upgrade 537 km of rural roads, providing year-round connectivity between agricultural production areas and markets and to the other parts of the country. Road upgrading will involve improving existing roads to appropriate climate resilient standards and widening and rising of embankments, with suitable slope protection against erosion and wave action. The road crest level will be 800 millimeters (mm) above the normal annual flood level, with an extra height of 200 mm that will be added for the effective sea level rise to the standard 600 mm freeboard.

Output 2: Improved Market Services

The project will upgrade 274 rural markets with 15 % of space allocated to women. Each market will be connected either to an existing paved road or to one of those to be improved under the project. Infrastructure improvements include paved trading areas, sheds, water supply system, drainage facilities, sanitation facilities, and market offices. Some key elements within the markets, such as new market sheds, will be made climate resilient. These will be raised on concrete plinths to a level above the existing maximum normal monsoon high tide level plus the effective maximum sea level rise with an additional 250 mm freeboard.

Output 3: Enhanced Climate Change Adaptation Capacity

Upgraded Climate Disaster Shelters. The project will construct or extend 15 multipurpose cyclone shelters, improve 10 existing cyclone shelters, upgrade 15 km of cyclone shelter access tracks, and construct 5 *killas* (animal shelters). The designs will take into account climate change effects and strict compliance to relevant building codes with respect to wind loading and floor bearing capacities. Access roads/tracks will be upgraded to the equivalent of village road climate resilience standard.

Enhanced Knowledge Management. Knowledge management for climate change will be enhanced. A framework for expanding institutional learning and knowledge sharing will be developed. This will entail more effective knowledge capture and compilation, storage, and sharing on climate resilience principles for the design, construction, and maintenance of rural infrastructure. The project will strengthen the management information system (MIS) and geographic information system (GIS) of the Local Government Engineering Department (LGED), develop a special web-portal interface for learning and networking with other agencies, and support establishing a community of practice.

Enhanced Capacity. The capability of LGED staff and local government units will be strengthened to better prepare and manage climate resilient rural infrastructure.

Therefore, this project, while enhancing longevity and sustainability of infrastructure, will improve livelihoods in 12 rural coastal districts vulnerable to climate variability and change and have deficient mobility and accessibility. The project aims to provide climate resilience measures that deliver a degree of climate proofing commensurate with both the task that structures have to perform and the level of acceptable risk as well as being sensibly within available budgets. Each of the project components – roads; growth centers and markets; and cyclone shelters – has their specific tasks and levels of acceptable risk to the impacts of sea level rise (SLR), high wind, increasing temperature, and increasing likelihood of severe cyclone events. The underpinning thrust is ensuring that all structures are constructed within a strong framework of enforced appropriate specifications and an as-built quality audit. "Climate-proofing" measures include enhanced resilience to present climate effects plus forecast future climate change impacts.

Coastal Embankments Improvement and Afforestation Program

Similarly the Coastal Embankments Improvement and Afforestation program includes:

- Embankment Stabilization: Climate proofing (rehabilitate and/or raise the height/or realign) of existing polders/embankments to withstand the current and projected estimates of cyclone and tidal surges.
- Internal Polder Water Management: Rehabilitate, build, and/or improve water management-related structures (e.g., sluice gates, flushing inlets, regulators, drainage channels, etc.) within polders for improved drainage, reduced flooding and water logging, and improved agricultural and fish productivity.
- Afforestation: Raise coastal greenbelt along the embankments through afforestation/reforestation measures to counter tidal surges and strong winds and stabilize the embankment, coastal mapping, and research study on viable climate resilient tree species.

The objective of the proposed Coastal Embankments Improvement and Afforestation Project (CEIP) would be to support the first phase of the Government of

Bangladesh's long-range plans to (i) reconstruct and modernize the coastal embankments system to make it climate resilient; (ii) rehabilitate, build, or improve all water management-related structures within the embankments for improved drainage and reduced flooding and water logging and improve agriculture and fish productivity; and (iii) improve the coastal greenbelt along the embankments and reduce the impact of tidal surges and strong winds by implementing a systematic program of afforestation/reforestation measures. This CEIP project has the following components as regards climate compatible infrastructure planning for building a resilient coastal community.

Component 1: Rehabilitate or Build Climate Resilient Embankments to Protect Human Lives and Assets

This component will finance the optimal design, rehabilitation, and improvement of the embankment system in each polder identified for inclusion in phase I with due consideration to projected population density; economic activity of the area; the value of current assets to be protected and forecast projections for the next 20–25 years; return period and frequency of flooding, cyclones, and their probable direction; stability of current embankments; availability of local material for construction and maintenance; minimum and low-cost operations and maintenance; and impact of climate change and sea level rises.

Component 2: Rehabilitate or Build All Water Management-Related Structures Within Polders

This component will finance the design, rehabilitation, and improvement of all water management-related physical infrastructure and systems within the polders. This will include flushing inlets, sluice gates, regulators, drainage channels, etc., and will improve drainage, reduce flooding and water logging, and contribute to the improvement of agricultural and fish productivity and thereby improve food and income security and livelihoods.

Component 3: Coastal Plantation Along the Embankments

Most of the polders developed in Bangladesh do not have significant greenbelt or coastal plantation. It is only in the 1990s that coastal afforestation and plantation along the roadside and embankments became popular. Past climate-induced disasters have shown that mangrove greenbelts or coastal forests improve climate resilience. This component will finance afforestation along the embankments as appropriate. The greenbelts will strengthen the earthen polders and ensure their longevity. Afforestation will also increase general forest cover, reduce vulnerability against storm surge and cyclones, act as a carbon sink which will contribute to greenhouse gas mitigation, improve livelihoods, and provide habitat for wildlife.

The World Bank is currently funding an Emergency Cyclone Rehabilitation and Restoration Project (ECRRP). Under this project, a *Coastal Embankment Improvement Strategy and Phasing Plan* will be developed to modernize and improve the embankment system of about 125 polders in the entire coastal area. The strategy will also indicate a phased investment plan over a period of 10–15 years, as well as a detailed phase 1 investment plan to cover about 25–30 polders. This project is proposed for inclusion in the *Coastal Embankments Improvement and Afforestation Project*. Therefore, it is expected that in the years to come, a balance would be made among projects that target minimization of exposure and sensitivity and enhancement of adaptive capacity to truly build a resilient coastal community in southwest Bangladesh.

Conclusion

All these are targeted to increase the resiliency of the coastal community against the impacts of climate change on their natural resource-based livelihood. While the above programmed initiatives may have obvious advantages, there are challenges to initiate and implement these programs for building resilient infrastructure. First of all, the government machinery has limited staffing pattern and technical expertise to initiate and supervise design and implementation of such mega projects. Second, the donor's interest often shifts which might act as a hindrance to initiate and implement these kinds of programs. Finally, the participation of and coordination with development partners including the NGOs and civil society can make a difference in the implementations of these program.

Abstract
Chicago Wilderness, a multistate alliance of more than 300 organizations dedicated to restoring biodiversity, is leading the effort to bridge the gap between climate science and biodiversity adaptation practices in urban natural areas and green spaces. In 2010, Chicago Wilderness completed the Climate Action Plan for Nature (CAPN), which describes potential climate change impacts within the 221,000 ha of protected areas in the region, and actions managers can take to help species and ecosystems adapt to climate change. The CAPN represents the first Climate Action Plan to address issues of biodiversity conservation in the Great Lakes region and is the only known example of place-based adaptation strategies for urban biodiversity. This chapter depicts the creation of the Chicago Wilderness Climate Action Initiative and the ensuing work to implement the CAPN, highlighting the challenges and importance of creating landscape level conservation approaches that integrate climate science information into best management practices. This collaborative effort can serve as a model for use in other urban centers.

Biodiversity • Urban • Climate change • Adaptation strategies

Introduction

Recognizing the potential for changes in climate to disrupt their social and economic fabric, cities around the world are developing strategies for reducing greenhouse gas emissions, modifying programs to adapt to a warmer future, and engaging civil society in this effort. In addition to individual actions, cities have banded together to collectively advance local climate actions through the C40 Cities Climate Leadership Group, a network of 58 of the world's largest cities, and the World Mayors Council on Climate Change, with more than 80 members (Rosenzweig et al. 2010). In North America, more than 1,000 mayors signed the US Conference of Mayors Climate Protection Agreement (Hamin and Gurran 2009). Because urban areas are responsible for nearly three-quarters of global energy-related carbon emissions (Rosenzweig et al. 2010), the early emphasis of individual cities and these collaborations understandably was on reducing greenhouse emissions (Wheeler 2008). Only recently, as the inevitability of a rapidly changing climate has become apparent, have cities begun to focus on approaches to reduce risks in the face of climate change as being of equal importance (Bulkeley and Betsill 2013). However, urban adaptation efforts focus on protecting values like public health, livelihoods, and infrastructure, with little or no attention paid to protection of urban nature and the benefits nature provides to urban residents.

At the same time, cities and associated metropolitan areas are becoming increasingly important to global biodiversity conservation. Most cities have been founded in places that are biodiverse and functionally valuable to society, such as in floodplains, along coasts, on islands, or near wetlands. Today, urbanization continues to expand into these valuable habitats and into the hinterland where society most often placed its biological reserves (McDonald et al. 2008). Species previously outside city limits may need to migrate through urban areas as they adjust to a changing climate (Hellmann et al. 2010). Some metropolitan areas now contain important populations of rare species (e.g., Blanding's turtle and the prairie white-fringed orchid occur in the greater Chicago region), made more vulnerable to extirpation by their typically small population sizes and fragmented distribution patterns (McDonald 2013). Terrestrial natural areas in urban settings provide critical habitat for resident and migratory native species but tend to be small and isolated remnants of formerly widespread habitats that are increasingly vulnerable to loss and degradation from a host of urban-centric stressors (Kowarik 2011; Cook et al. 2013). Often termed "green" or "natural infrastructure" by urban planners, the ecological functions of these natural areas and other undeveloped or formerly developed spaces provide increasingly important, but highly threatened, benefits to biodiversity and human communities of metropolitan regions (Goddard et al. 2011; Hostetler et al. 2011; Kattwinkel et al. 2011). Likewise, freshwater biodiversity is threatened by both water withdrawal for urban consumption (McDonald et al. 2011) and the addition of pollutants from urban stormwater, industrial, and residential sources (Alberti 2005; Blanco et al. 2011). These biodiversity impacts are all projected to accelerate as global urbanization trends continue to increase (McDonald 2013).

Despite the regional and global importance of urban biodiversity, its conservation has rarely been addressed directly in urban climate change planning. As stated earlier, most of the focus of urban climate planning is on the reduction of greenhouse gases and on protecting public health and safety. If natural areas are addressed in a city-focused plan, it is typically in the context of green infrastructure, such as wetlands or plantings that help absorb stormwater, or as an adaptation strategy for reducing risks to people, for example, by helping to reduce the urban heat island effect (Enarsson 2011; Gill et al. 2007). Urban climate plans have not addressed the adaptation needs of open spaces, remnant natural areas, and populations of native species to help them to become resilient, persist, and continue to contribute to a biodiverse urban ecosystem and provide benefits to the human community.

A considerable gap therefore exists in most municipalities between conservation planning for nature and natural remnants and adaptation of urban environments for people. Hamin and Gurran (2009) point out that uncoordinated planning for biodiversity and ecosystem processes, on the one hand, and the built environment, on the other, can put the two in conflict. Turner and his coauthors go even further: "At present, climate change is seen as one problem for nature and another for people" (Turner et al. 2009, p. 278).

This chapter is a case study in metropolitan Chicago (population 9.5 million) where a conservation alliance is reconciling this dichotomy by taking a comprehensive regional approach to climate planning and action that incorporates the full range of assets, from social capital (human communities and the built environment) to natural capital (native species and ecosystems). The aim of describing this case study is to help advance such efforts in other cities around the world. In the sections that follow, efforts by the Chicago Wilderness alliance to develop climate change planning for urban nature and actions taken to develop and share adaptation strategies for natural areas in Chicago will be presented. It is the hope that lessons learned from the Chicago experience can be applied elsewhere.

Climate Change Planning for Urban Nature

Chicago Wilderness

In the early 1990s, conservation leaders in the Chicago metropolitan area recognized that a unified vision for biodiversity conservation was needed among their organizations in order to achieve sustained results (Ross 1997). The Chicago Wilderness alliance was launched in 1996 and has grown to include over 300 member organizations and corporations working toward common goals to restore nature and improve the quality of life for native biodiversity and human communities (Moskovits et al. 2004; Miller 2005). The Chicago Wilderness area includes parts of four states at the southern end of Lake Michigan (Fig. 1: Chicago Wilderness map; Caption: The Chicago Wilderness region), one of the Laurentian Great Lakes, and encompasses 221,000 ha of protected natural land that harbors rare natural habitats for resident and migratory species, including nearly 200 species threatened with extirpation either regionally or throughout their range (Brawn and Stotz 2001; Wang and Moskovits 2001; Miller 2005).

The Chicago Wilderness alliance accomplishes its work through four interrelated initiatives: (1) protect and restore nature and the ecological health of the region's land and waters; (2) advance a 567,000-ha natural infrastructure network that contributes to the quality of life of all residents; (3) provide places and programs for generations of families to connect with nature; and (4) develop and deploy actions through the alliance in the areas of climate change mitigation, adaptation, and education.

The Chicago Wilderness Climate Change Initiative began in 2007 with establishment of a Climate Change Task Force comprised of individuals from a wide range of organizations, including federal, state and local governments, NGOs, research institutions, zoos, museums, and an aquarium. Its first undertaking was to prepare the alliance for action by reviewing potential climate change impacts to regional biodiversity (Sullivan and Clark 2007; Chicago Wilderness 2008; Riddell 2009). Following this foundational review, the Task Force embarked on two phases that are described in the following sections: climate planning for urban nature, followed by the implementation of planned actions.

During the start-up period for the Chicago Wilderness climate initiative, the City of Chicago was well on its way toward preparing a Climate Action Plan. Released in 2008, it is the first such plan to be based on a thorough climate change impact assessment exploring the implications of a range of future scenarios on city life during the next century (Wuebbles et al. 2010). The City of Evanston, abutting Chicago to the north, also released a Climate Action Plan that year, and other

Fig. 1 Chicago Wilderness map. The Chicago Wilderness region

municipal and university campus plans were being developed in metro Chicago at the same time. As is typical, all these plans have an overwhelming emphasis on mitigation; collectively they propose significant actions that would lower greenhouse gas emissions from metropolitan Chicago. Actions to reduce risks related to climate change through adaptation were addressed only in the Chicago Climate Action Plan and only in relation to human communities, city services, and the built environment (Coffee et al. 2010). While the effect of climate change on ecosystems was part of the science assessment that informed the Chicago plan (Hellmann et al. 2010) and the city has passed ordinances to reduce impacts on natural resources, the Climate Action Plan did not include any actions to reduce risks to native species or ecosystems in its adaptation strategy (City of Chicago 2008).

Following the release of the Chicago Climate Action Plan in 2008, it became clear to both the Chicago Wilderness and the City of Chicago that complementary climate strategies were needed for the natural capital of metropolitan Chicago.

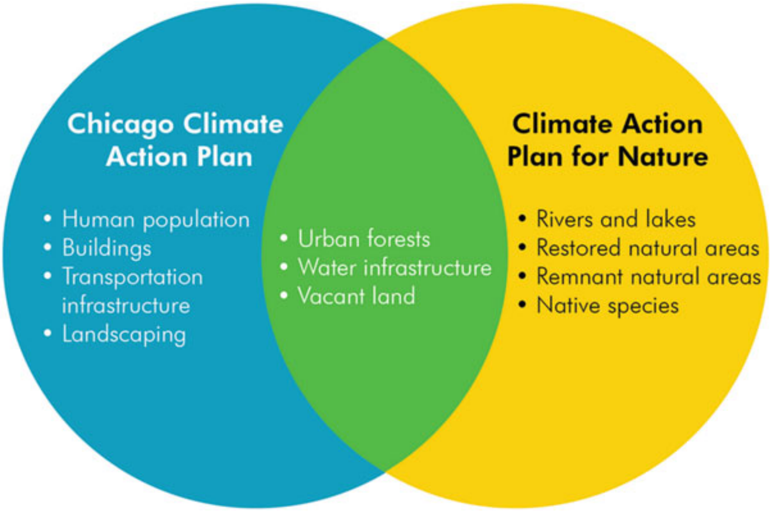

Fig. 2 Chicago Climate Action Plan and Climate Action Plan for Nature. The complementary relationship between the City of Chicago Climate Action Plan and Chicago Wilderness Climate Action Plan for Nature

Goals for such strategies would balance the municipal plans that emphasized mitigation and adaptation for the built environment by focusing on the persistence of native species and ecosystems, provisioning of services to citizens provided by natural infrastructure, as well as the "adaptation services" that open space provides in creating communities more resilient to climate change (Fig. 2: Chicago Climate Action Plan and Climate Action Plan for Nature; Caption: The complementary relationship between the City of Chicago Climate Action Plan and Chicago Wilderness Climate Action Plan for Nature). Chicago Wilderness also recognized that, done in isolation, the human response to climate change could compromise biodiversity, thereby accelerating climate change and reducing the planet's capacity to accommodate climate impacts (Turner et al. 2009). But there were no models for coupled human-nature climate planning in urban settings. Guidance for Climate Action Plans available at the time stressed reduction of greenhouse gas emissions, for example, with model plans for states (US Environmental Protection Agency 2012), cities (ICLEI no date), and even university campuses (Egan et al. 2008). Through a collaborative process, the Climate Change Task Force created a new template that became the Chicago Wilderness Climate Action Plan for Nature (Chicago Wilderness 2010).

Climate Action Plan for Nature

The Climate Action Plan for Nature was completed in 2010 with the primary goal of creating momentum across the diversity of organizations in the Chicago Wilderness alliance. Recognizing the rapidly evolving nature of climate change knowledge and practices, it was also meant to be the first iteration of planning for a dynamic climate action program for urban biodiversity in metropolitan Chicago. The plan includes three major components, engagement, mitigation, and adaptation. All three are tightly linked to the other Chicago Wilderness strategic initiatives mentioned above and mirror the three components of the Chicago Climate Action Plan.

Engagement – The primary engagement objective is for Chicago Wilderness members to become fluent in the vocabulary, concepts, and programs of a new era for urban conservation that includes climate change mitigation and, especially, adaptation. Ultimately, it is envisioned that well-informed members of the alliance will go on to influence decision-makers and their fellow citizens more broadly. Three sets of actions are outlined to achieve this. The first focuses on adaptation by establishing a Climate Clinic program within Chicago Wilderness (described in the next section). The second set of actions build the capacity of informal educators at the region's many environmental education centers to communicate the science and solutions of climate change to the public, especially young audiences and families. The third, more explicitly external, set of actions is to incorporate key climate messages into the general Chicago Wilderness public communications effort.

Adaptation – In this initial version of the Climate Action Plan for Nature, the emphasis is on catching up, that is, taking action to make current conservation strategies "climate informed." While most current protection and management activities in the Chicago region will help make nature more resilient to climate change to some degree, actions in this section of the CAPN focus on evaluating and modifying existing programs that were designed prior to knowledge of climate-induced challenges to enhance the ability of these practices to reduce climate-related risks and help resource managers avoid poor investments. The next sections of this chapter review progress toward meeting these adaptation goals since the 2010 release of the plan.

Mitigation – As a relatively small part of the plan, the CAPN mitigation actions focus on the role that protection and restoration of natural areas play in sequestering atmospheric carbon and the parallel risk of carbon release when habitats are destroyed. The primary mitigation objective is to create recognition of the need for land conservation in climate change decision-making. The plan also recognizes that protected areas play a dual role in climate programs by mitigating emissions as well as increasing the adaptive capacity for biodiversity and human communities.

Climate Change Update to Biodiversity Recovery Plan

The Chicago Wilderness Biodiversity Recovery Plan was collaboratively developed in the late 1990s to be the unifying driver of conservation strategies across the alliance. It was intentionally produced as a living plan that would continue to evolve as new information and new ideas arose. Not surprisingly, the focal biodiversity targets and critical threats that the plan identified 15 years ago were never evaluated with climate change impacts in mind. Since its formation in 2007, the role of the Climate Change Task Force has been to help the Chicago Wilderness alliance incorporate climate change into best management practices for restoring and managing natural communities. Much of what natural resource managers, and certainly restoration ecologists, are already doing to restore the health and functionality of natural areas "counts" as adaptation because it is making these areas more resilient to whatever changes may occur. Thus, the Task Force focused on what, if anything, is needed to be altered, included, or re-prioritized in the context of best management practices given the projected changes and likely impacts both to the region's biodiversity and to the threats species and natural systems were already facing (e.g., pollution, habitat degradation, fragmentation, etc.). This focus guided development of the CAPN, described above, and subsequent activities that include updating the Biodiversity Recovery Plan from a climate change perspective.

Over the past decade, it has become clear that climate change is one of the top threats facing Chicago's environment and its biodiversity (Wuebbles et al. 2010). Projections from climate models suggest that temperatures in the central USA, where Chicago lies, will rise from 2.1 to 2.7 °C by the mid-century compared with the recent past (Pryor and Scavia 2013). Beyond average temperature trends, summer heat waves in the city and extreme precipitation events during winter and spring are expected to increase (Hayhoe et al. 2010; Vavrus and Van Dorn 2010). These changes are predicted to affect human quality of life through public health, flooding, and water security impacts, as well as affecting aquatic and terrestrial biodiversity in myriad ways (Francl et al. 2010; Hellmann et al. 2010; Pryor and Scavia 2013). Many locations in the Chicago region will be climatically and ecologically unrecognizable by historic standards.

In the absence of actions that adapt protection and management practices, climate change has the potential to jeopardize many biodiversity conservation investments made in the Chicago Wilderness region during the past 30 years. Hence, the importance is given to adaptation in the CAPN and, the first priority in its implementation, to prepare a climate change update of the Biodiversity Recovery Plan. With this in mind, the Task Force initiated an in-depth effort to assess how a changing climate may impact the region's natural communities and compound existing threats to their ecological integrity (i.e., fragmentation, pollution, habitat degradation, and invasive species). This process involved translating downscaled climate change projections developed for the Chicago Climate Action Plan (Hayhoe and Wuebbles 2008) into an understanding of how a warmer, drier, and more extreme environment could affect regional biodiversity and, importantly, what management actions could be taken to reduce the impacts.

A great challenge to this endeavor is that understanding the vulnerability of species and systems to climate change is inherently interdisciplinary, requiring integration of information on climate science and modeling, theoretical knowledge of community, behavioral and restoration ecology, and on-the-ground knowledge of best management practices for natural resources in urban landscapes. As observed more broadly among resource managers in the Great Lakes region (Petersen et al. in press), managers within the Chicago Wilderness alliance were found to be often very aware of and interested in planning for climate change but felt they lacked the information and expertise needed to make updates in their management or restoration practices. This challenge of integrating available information to inform adaptation, however, is one Chicago Wilderness has been well

Fig. 3 Chicago Wilderness Climate Clinic. Resource managers and scientists discussing climate impacts to natural resources at the Indiana Dunes National Lakeshore

positioned to address because the alliance can tap into the collective knowledge of a vast intellectual network, ranging from research scientists in many academic fields to natural resource managers.

Between 2009 and 2012, the Task Force deployed Climate Clinics to marshal this knowledge network in beginning the process of ensuring resilient natural areas and open space in metropolitan Chicago. The Climate Clinic approach developed by The Nature Conservancy, whereby climate adaptation strategies are incorporated into ongoing conservation projects through an iterative, peer-learning process (Poiani et al. 2011), served as a model for these clinics. Beyond the important task of informing updates to the Biodiversity Recovery Plan, Climate Clinics also provide peer-to-peer interactions across several sectors of conservation science and practice and are useful for general capacity building of Chicago Wilderness members (Fig. 3: Chicago Wilderness Climate Clinic; Caption: Resource managers and scientists discussing climate impacts to natural resources at the Indiana Dunes National Lakeshore). Along with some individual interviews and topic-focused content reviews, the Task Force was able to solicit relevant expert opinion from over 100 regional conservation researchers and practitioners through two Climate Clinics. The clinics were full-day events that included a mixture of presentations and breakout group discussions, ending with an informal social setting and activity to promote networking and reinforce peer-to-peer learning. Often, simply presenting data and information is not sufficient to encourage dialog about how or whether concepts are meaningful and resonate with people, let alone persuade them to share their opinions based on personal observations of managing the landscape. The clinic format creates a comfortable and relaxed atmosphere, an important element in achieving critical idea sharing.

After two and half years of collaborative work, the Chicago Wilderness Executive Council approved the Biodiversity Recovery Plan Climate Change Update final document in the spring of 2012. This place-based climate change tool for the Chicago region now exists as a web-based resource (climate.chicagowilderness.org), where it continues to be updated as new information becomes available.

Place-Based Actions for Climate Adaptation

The CAPN created momentum for climate action across the Chicago Wilderness alliance, and the Biodiversity Recovery Plan Climate Change Update framed key risks to nature from climate change and linked those to possible adaptation strategies. From these plans, several projects naturally emerged to help the alliance take the next steps of connecting species and systems at risk in particular locations to actions that can be taken to help promote adaptation.

Accelerating the Pace of Adaptation: "Climate Considerations" for Urban Open Space

Building on the development of adaptation strategies for natural areas in the Chicago Wilderness region, the Chicago Department of Environment requested a partnership with The Field Museum, The Nature Conservancy, and University of Notre Dame to create a Climate Considerations Guidebook for natural areas and greens spaces in the urban landscape. The project was originally designed to develop an adaptation "checklist" that would assist City departments in implementing adaptation strategies. However, discussion with stakeholders quickly indicated that a universal checklist for all departments would not provide the kind of specific and useful information that was desired because sites have distinctly different goals and purposes (e.g., forest preserve conservation site versus a multiuse park district site), thus requiring different types of adaptation approaches. Instead, the concept of a guidebook that could help managers identify which of their management decisions may be sensitive to warmer, drier, and more extreme weather and provide resources to help them develop relevant adaptation strategies was the preferred path to follow.

The intended audience of the guidebook is mid-level managers of natural areas and green spaces in a highly urban setting. The first section of the guidebook is intended to convey the relevant information needed to begin the process of developing site-specific adaptation strategies. It begins with an overview of local climate change impacts and an explanation of why adaptation is important, followed by a seven step "workflow" that helps to walk the reader through the process of how to ask the "climate question" of urban natural area and green space projects. The next section poses probing questions in five categories (I. Getting started,

II. Safeguarding species and systems, III. Climate-informed land management decisions, IV. Operations and maintenance, and V. Rethinking goals) to help managers think through which management aspects may be affected by climate change. Following the questions in each category, specific tools and resources are suggested to help managers answer the questions and design their own approaches to reduce the vulnerability of a site to climate change. There are 63 tools and resources available in the guidebook, many of which connect managers to the place-based resources developed by the Chicago Wilderness, such as the Biodiversity Recovery Plan Climate Change Update and the Green Infrastructure Vision, but tools such as Climate Wizard and reports from other urban centers struggling with the same questions (e.g., Climate Change Adaptation Options for Toronto's Urban Forest) are included as well. The last section includes appendices intended to give additional background information (e.g., General adaptation principles, What does adaptation look like?) and an annotated list of all the tools and resources included in the guidebook.

A unique feature of this guidance is that it was developed with the intention of being deployed in an interactive format within the Collaboratory for Adaptation to Climate Change (www.adapt.nd.edu), in addition to being available as a stand-alone document. Funded by the US National Science Foundation and developed at the University of Notre Dame, the Collaboratory is a virtual community that is accessible to the public worldwide and can be used as a collaborative workspace and repository of documents and other information relevant to adaptation planning. The idea behind the Collaboratory is that by promoting more rapid sharing of information and ideas, networks can collectively speed up the pace and effectiveness of adaptation actions. The connection between the Collaboratory and adaptation efforts in the Chicago Wilderness again shows the importance of strong networks: the Collaboratory project leads were attracted to testing out novel technologies with the Chicago Wilderness alliance because of the strong history of collaboration, and several Collaboratory project team members have contributed to the Chicago Wilderness Climate Change Projects, as well as the City of Chicago Climate Action Plan.

Climate Clinics were again used as a mechanism to facilitate the collaborative effort between Chicago City departments and the Field Museum-Nature Conservancy-Notre Dame adaptation team. Participants in the clinics were named "Climate Adaptation Fellows," and their advice was gathered in regular meetings and through a private workgroup on the Collaboratory. Whereas the Biodiversity Recovery Plan Climate Change Update focused mainly on climate impacts to the region's larger natural areas (e.g., wetlands, woodlands, prairies, etc. in the Cook County forest preserves), this project was intended to help facilitate climate-ready decision-making by individuals working on smaller-scale urban natural areas and green spaces (street trees, park districts, boulevards, parkways, university campuses, etc.). This guidebook was crafted from a combination of stakeholder engagement and a literature survey, creating a tool that is both useful and informative.

The guidebook now lives in both a static and interactive format on the Collaboratory for Adaptation to Climate Change (available at, adapt.nd.edu/resources/1019/).

The interactive format, or “workflow,” walks users through the climate clinic process, with links to useful tools and resources. At every step, users are also prompted to contribute to discussions within a public workgroup and to provide feedback on the guidance that will inform updates (The workflow based on the guidance can be accessed at https://adapt.nd.edu/adaptationworkflows.). As of July, 2013, a simple search of “Chicago” in the Collaboratory yields ~50 hits to documents, events, or other resources used or generated in the adaptation planning process, most of which are connected to the Chicago-focused workspace. Over time, the Notre Dame team will study and implement improvements to the workspace and workflow, allowing lessons learned from Chicago to be shared with and benefit the broader adaptation community.

To test the utility of the guidebook, project leaders recruited four undergraduate interns to work with urban natural resource managers to evaluate the recommendations at five Chicago sites during the summer of 2013. Sites were selected based on interest from organizations that were involved in the development of the guidebook as well as a desire to represent a broad range of urban sites (e.g., park district sites with multiuse grounds, museum and university campuses, nature preserves, and natural area restoration sites). Each organization was required to designate one of their natural resource managers to be a mentor to the team of interns who collectively assessed each site. Mentors worked with interns to go through each section of the guidebook and answer as many of the questions as were relevant to a site and provided assistance in developing recommendations for incorporating adaptation into different aspects of their management and planning process. The mentors were also asked to provide feedback on how relevant and/or helpful the guidebook content was to them, including language and concepts used, extent of background information, questions posed, and resources provided. This feedback will be summarized for posting in the collaboratory and used to revise the guidebook in hopes of making it as useful as possible. Additional sites will continue to be piloted in 2014, and a comparative review of all the sites will be completed in order to gain an understanding of the different ways the guidebook can be used and the types of adaptation recommendations urban natural resource managers are developing.

Community Action Strategies

In order to empower and encourage Chicago communities to take action, social scientists from the Field Museum developed a set of Community Action Strategies designed to engage residents of the Chicago region in the goals of the CAPN in their own community through climate-friendly gardens and lawns, water conservation, monitoring, open space stewardship, and climate change education (Climate Action Plan for Nature, Community Action Strategies, www.climatechicago.fieldmuseum.org/sites/default/files/Climate-Action-Plan-for-Nature.pdf). To implement this set of strategies, the Museum led a coalition of over 40 partner organizations in Chicago neighborhoods to develop a bilingual Chicago Community Climate Action Toolkit (climatechicago.fieldmuseum.org). An interdisciplinary team from the Museum facilitated a research-to-action process for involving Chicago communities in implementing city (Chicago Climate Action Plan) and regional (Chicago

Wilderness Climate Action Plan for Nature) strategies for climate action, in ways that simultaneously advance their local agendas for social change. This work built upon previous ethnographic research the Museum conducted to understand socio-cultural viewpoints on climate change in Chicago's diverse neighborhoods (Hirsch et al. 2011). The toolkit comprises 60+ multimedia tools that communities can use to nurture local efforts tailored to their unique cultures that support city and regional climate action strategies.

Chicago Wilderness Green Infrastructure Vision

The Chicago Wilderness Climate Change Task Force was also moving forward during this time to integrate climate change impacts to biodiversity into another Chicago Wilderness effort, the Green Infrastructure Vision project (http://www.chicagowilderness.org/what-we-do/protecting-green-infrastructure/epdd-resources/biodiversity-and-natural-habitats/green-infrastructure-vision/). This project provides a visionary, regional-scale map of the Chicago Wilderness region that reflects both existing green infrastructure – forest preserve holdings, natural area sites, streams, wetlands, prairies, and woodlands – and opportunities for expansion, restoration, and increasing the connectivity of natural areas. The broader goal of this effort is to bring the Chicago Wilderness Biodiversity Recovery Plan to life in a more meaningful, visual, and accessible way for Chicago Wilderness members and outside audiences. In order to bring an explicit climate perspective to the project, the Task Force created a GIS layer to assess the pattern and magnitude of regional carbon storage, information that can be used to help quantify the climate-related co-benefit of keeping natural areas healthy and intact, and to assess where the biggest storage areas were located. This preliminary map, based on aboveground carbon storage associated with habitat types defined from 2006 National Land Cover Data, revealed the region stores more than 77 million tons of carbon, but only 5.4 % occurs on protected land. This illustrates the critical need to engage public and private landowners in conservation management issues.

In addition to assessing the role natural areas and green spaces play in storing carbon, the Task Force initiated a working group to evaluate how well the conceptual corridor models of the Green Infrastructure Vision work in reality for particular species, especially those that are climate-sensitive, at a particular site. As is the case with all Chicago Wilderness working groups, the individuals involved are self-selected and interested in contributing to the collaborative effort because the topic or project is specifically tied to either their own interest or that of their organization; in other words, their involvement helps to forward their own work as well as that of the Chicago Wilderness.

The Green Infrastructure Vision conceptual models for corridors, developed by The Conservation Fund (http://www.conservationfund.org/projects/refinement-of-the-chicago-wilderness-green-infrastructure-vision), were created for individual habitat types (woodlands, wetlands, prairies, etc.) using GIS Terrestrial Movement Analysis software (Norman 2012). This analysis tool uses the average dispersal distance for several habitat-specific species to create minimum movement pathways and corridors between landscape features [e.g., the average dispersal distance for the common muskrat (*Ondatra zibethicus*) and Blanding's turtle (*Emydoidea blandingii*) was used to create the wetland corridor] (CMAP 2012). The Task Force selected the federally endangered Hine's emerald dragonfly (*Somatochlora hineana*) to pilot this work and found corridors generally reflected the real biological conditions of the dragonfly at the site scale (Hasle unpublished data). Work is currently underway to test the model's validity for additional climate-sensitive species, with a goal of helping identify site-scale management implications.

Other related projects that are in progress include working with municipalities on climate-informed stormwater management and developing a regional urban forest adaptation guide. Overall, the Biodiversity Recovery Plan Climate Change Update resource has enabled Chicago Wilderness to effectively integrate both a climate and a biodiversity perspective into work being done at the site, neighborhood, community, and regional scale. These efforts are not only useful for the Chicago Wilderness region but can be scaled up to help inform similar work in other urban centers.

Lessons Learned

As stated earlier in this chapter, there were no models to follow that incorporated biodiversity conservation into urban climate change adaptation programs. Not surprisingly then, important lessons regarding helpful ways to frame the climate conversation and how to respond to challenges and barriers were learned along the way. Below are seven lessons learned, all arising from adaptation planning activities that were pursued in the Chicago region. These might benefit others contemplating similar efforts in their organizations or communities.

Frame the Climate Question in a Local Context

Mid-latitude regions, such as the Midwestern USA, are not yet experiencing the magnitude of temperature change occurring at high latitudes, or highly visible impacts like sea-level rise. While many climate change outreach efforts focus on threats to polar bears or coastal cities, framing this global issue in terms of how climate change is affecting (or expected to affect) species and habitats in the Chicago Wilderness region, as these are what local conservationists really care about was found to be very important. This was a particularly important way to connect with resource managers at Climate Clinics. Thus, Chicago Wilderness Climate Action efforts highlighted strong local impacts and worked with resource managers to connect these impacts to potentially vulnerable species and systems. For example, over the past several decades, the Great Lakes have seen dramatic changes in average ice cover, and the upper Great Lakes (Michigan, Huron, and Superior) have shown rapid increases in summer surface water temperatures, two changes that tend to act in a positive feedback as open water absorbs more heat, and warmer water takes longer to cool and freeze. Specifically, Lake Michigan has shown a 77 % decrease in ice cover (1973–2010; Wang et al. 2012), and summer surface water temperatures in southern Lake Michigan have increased by 1.4 °C, and the rate of increase is about 30 % higher than increases in air temperature during the same time period (1979–2006; Austin and Colman 2007). While it is not clear how these strong changes in local conditions will impact regional biodiversity, focusing on local changes provides both a sense of urgency and a place to start the dialog on how to respond.

There Are No "Experts"

There was a near universal reticence among conservation practitioners, especially resource managers, to participate in climate planning or adaptation clinics because they are not "climate change experts." Apparently there was an expectation that there were climate adaptation experts who already knew what to do and how to do it. These experts do not exist, however, because adapting to such rapid rates of climate change is a new challenge, and as of yet, there are few examples of adaptation implementation and learning from experience. Further, adaptation at the scale of a natural area requires integrating regional changes in climate drivers with information on local ecosystems, management practices, and constraints. Thus, it is always "local," and the most appropriate strategies will vary from site to site such that expertise from one location or habitat will not apply exactly in another. Finally, while many managers look to university partners to find "experts" on relevant topics, experts on adaptation theory do not fully understand the constraints and opportunities of applications in a particular place, as each place has a unique history, set of stakeholders, and priorities. This issue was addressed head-on in Climate Clinics and other engagement actions, telling people that advice about climate change abounds, but that no expert would be able to tell a manager what to do, because they did not know the specific system, decision context, and suite of (often competing) values to be considered. Partners were encouraged to develop their own expertise through helping us to write the Climate Considerations Guidebook and discussing ideas and adaptation options with their peers in the "Climate Fellows" meetings. It is not yet known if this strategy was effective, but there was a sense of increasing confidence among clinic participants that they have the knowledge and institutional capacity to implement adaptation and craft their own climate-informed conservation actions. The Collaboratory for Adaptation to Climate Change has a similar goal in the online universe – to remove institutional, temporal, and geographic barriers to information and knowledge sharing about climate change so that new expertise can grow in diverse places and at a pace that helps us keep up with the changing climate.

Uncertainty Is No Excuse for Inaction

Uncertainty about climate change has been used in political arenas to stall mitigation activities and that the same uncertainty can plague adaptation activities (Morton et al. 2011; Gifford 2011). Uncertainty about the future climate implies uncertainty about the specific stresses that adaptation actions should address.

In some cases, for example, the potential for increases or decreases in future Lake Michigan water levels (Gronewald et al. 2013) in the context of a coastal wetland restoration and adaptation actions designed for one scenario could represent a waste of resources under the alternate scenario. Sometimes these conflicts and trade-offs cannot be avoided, and choices will need to be made. But a better starting point is identifying robust strategies that are likely to be beneficial under a range of possible futures (Hallegatte 2009). For example, designing wetland restoration efforts with a landward buffer that permits inland shifts and with native species that can tolerate drying. The existence of these robust strategies is the best argument for taking adaptation action today and avoiding the uncertainty trap. It also is critical to recognize that inaction is a policy choice as well. Climate change presents a unique challenge because we cannot go back to the way things used to be, and leaving this as is could represent steady erosion in environmental quality and ecosystem services (Schwartz et al. 2009).

Personal Interaction Is Important and Stakeholder Engagement Is Critical

In an era where people increasingly interact via email, listservs, wikis, blogs, webinars, conference calls, and online social networks, the importance of in-person meetings and interactions should be recognized, particularly when a socializing component can be integrated into the experience. Sharing personal opinions and ideas about climate change impacts among professional colleagues, particularly if not everyone is well acquainted, can require a great deal of confidence and/or trust. Important qualitative information (e.g., how extremely low river levels due to changes in precipitation patterns resulted in increased predation on exposed mussel populations) tended to arise organically in an informal conversation. This information is often more forthcoming when personal relationships have been formed to create an atmosphere of trust and confidence for two-way dialog and iterative learning. It is critical to include stakeholder input from the onset so that useful products can be created. Natural resource managers are busy people; providing them with information that they have reason to consult/include is key if their participation is desired.

Adaptation Will Most Likely Occur in Places Where There Is a History of Collaboration

It is perhaps no accident that Chicago Wilderness is in the forefront of advancing ideas on how to design adaptation actions to benefit nature and people. The significant, long-term investment in support for collaboration across organizations to benefit nature is a major factor facilitating integration of information across disciplines and provides a network for sharing observations of climate impacts and critical support for creative problem solving. This bottom-up collaboration also includes the business sector, in addition to the government agencies, research institutions, and

NGOs that typically dominate climate-planning processes in the USA. More than 40 enterprises are members on the Chicago Wilderness Corporate Council, ranging in size from multinational corporations to local businesses. Harnessing strategic partnerships among organizations with differing talents and differing capacity for research and outreach has been found to be very effective. These organizations can come together to develop useful products for adaptation action. Our collaboration between a museum, a university, and a nongovernmental organization is one such example. Most major cities or regions will have each of these institutions.

Consider Multiple Audiences

An important lesson learned as part of the climate clinic process, and in developing the Climate Considerations Guidebook, was that adaptation needs to be defined and illustrated with examples in ways that are accessible to multiple audiences within the resource management sector. Outreach efforts targeted the practitioners, but a message heard repeatedly from this audience was that they needed clear information, and when possible, estimates of likely costs savings, so that these messages could be relayed to higher level managers and policy makers that have the decision-making authority to promote changes in key protocols or practices. Similarly, decisions to participate in collaborative management efforts that extend across ownership boundaries are often not within the control of individual site managers.

Ecosystem Services Have Their Limits, Especially in Urban Settings

A common approach in helping build support for investments in nature conservation under climate change is to highlight nature-based services that can help reduce climate-related risks to people. As we discussed this idea with resource managers, their response was that services, like retention or slowing of stormwater, could come with clear costs in this human-dominated landscape – fragile plants can be uprooted, and wetlands can be contaminated with road salt and other pollutants. Highlighting the service, an idea that we thought would help gain financial support for management and restoration could instead lead to a risk of additional stormwater being diverted to an ecological reserve, reducing its viability. As with other strategies for protecting the nature, all climate adaptation strategies need to be tested with those that know the system, stressors on that system, and the sociopolitical context for management.

Conclusion

Most greenhouse gases emanate from urban areas of the world, and it is critical that cities continue on the path of mitigating their impacts on the global climate by reducing emissions and creating more climatically sustainable energy policies and practices. In terms of recognizing that some level of climate change is inevitable in the coming century, some cities, such as Chicago, have begun implementing robust adaptation programs (Wheeler 2008; Stone et al. 2012). Cities, however, need to look beyond just their built environment to include natural capital in their adaptation efforts. Native species, remnant natural areas, and urban open space, along with a city's built infrastructure, must be included in climate adaptation programs to assure that cities reduce their vulnerability and increase their resilience to rapid climate change. Urban biodiversity is becoming increasingly important globally, and natural assets provide many ecological benefits and climate adaptation services that urban residents count on. There is no assurance that native species and ecosystem services will persist on their own in urbanized landscapes under fast-changing climate regimes.

This chapter has described a regional approach to climate change adaptation for urban biodiversity and ecosystem services that is transferrable to other metropolitan areas. This model complements the current strengths of cities in the climate change arena that primarily focus on mitigation and adaptation for the human community and the built environment. The approach is built around the power and success of the Chicago Wilderness alliance in metropolitan Chicago (Miller 2005), where a long-standing collaborative history was used to marshal a diverse range of resources and knowledge. Our model is best emulated in other areas with collaborative processes that can channel the knowledge of natural resource managers and research scientists into practical place-based adaptation solutions for urban nature.

Acknowledgments We want to acknowledge the generous funding organizations that made this work possible, including Boeing Corporation, Chicago Department of Environment, National Science Foundation, Gaylord and Dorothy Donnelley Foundation, and Kresge Foundation. We would also like to sincerely thank Chris Mulvaney from the Chicago Wilderness for his continued support and assistance in helping to organize the Climate Change Task Force, Doug Stotz from the Field Museum for his leadership of the Climate Change Task Force, and former Deputy Commissioner for Chicago Department of Environment Aaron Durnbaugh for leading the charge to develop the Climate Considerations Guidebook. None of this work would be possible without the participation and support from Chicago Wilderness members and City of Chicago natural resource managers. Finally, we would like to thank Joyce Coffee, Rob McDonald, Laurel Ross, and Doug Stotz for their thoughtful reviews and insightful comments in helping to develop this chapter.

Development and Application of Good Practice Criteria for Evaluating Adaptation Measures

Christian Kind, Andreas Vetter, and Rupert Wronski

Contents

Abstract

Decision-makers on different levels face an information deficit with regard to choosing promising adaptation measures. While the ever present concept of *good practice* may prove helpful in closing this gap, the term is often poorly defined. Therefore, this article attempts to substantiate the concept of *good practice* in climate change adaptation by developing a set of key criteria for evaluating adaptation measures. This potentially leads to sounder decision-making and a better transfer of experiences. By way of an extensive

literature review, a variety of definitions and criteria for *good practice* in adaptation is revealed. Using predefined selection rules like *non-redundancy*, *applicability*, *comprehensibility*, *completeness*, and *measurability*, the identified criteria are condensed and then ranked by experts. This way, the article identifies six key evaluation criteria that should be considered when deciding whether an adaptation measure can be deemed *good practice* example or not. These are *effectiveness*, *robustness*, *sustainability*, *financial feasibility*, *positive side effects*, and *flexibility*. Subsequently, the set of criteria is illustrated by evaluating several *good practice* examples on the local level in Germany. Eventually, limits of the derived *good practice* criteria are discussed.

Keywords

Climate change • Adaptation • Good practice • Set of criteria • Decision support • Adaptation measure

Introduction

For many stakeholders involved, the development and implementation of climate change adaptation measures is a new challenge. It implies, inter alia, the necessity to react to already occurred climatic changes and to yet uncertain future changes (Bedsworth and Hanak 2010). In the face of this uncertainty, public and private stakeholders may find it difficult to develop suitable measures to adapt to climate change impacts or determine which of the potentially available measures are the most appropriate options (Hecht 2009).

Learning from good examples for climate change adaptation is a promising approach to support stakeholders with the planning and implementation of measures. Today, the concept of *good* or *best practice* is already used frequently in the communication of experience gained in the context of climate change adaptation (Land Use Consultants et al. 2006; Islington Government n.d.). However, at the same time, it has to be noted that the use of the concept of *good practice* is often vague and unspecific (Jennings 2007) requiring further research to specify the concept of *good practice* in the context of climate change adaptation (Foster et al. 2011).

For an effective and inspiring communication of a *good adaptation practice*, it seems necessary to substantiate the concept of *good practice*. A transparent approach to this lies in the development of a set of criteria, which can be applied to evaluating adaptation measures to determine whether respective actions constitute a good practice. Thus, the objective of this article is to identify *good practice* criteria for climate change adaptation measures in the context of industrialized countries, such as Germany. Relevant publications and websites are analyzed for that purpose. The research is based on preparatory work on the prioritization of adaptation measures carried out by the Federal Environment Agency (Tröltzsch et al. 2011, 2012; Kind et al. 2011). A consistent and compact set of criteria for *good practice* is derived on the basis of literature research and inputs from an expert survey.

The focus is not so much the analysis of individual examples of *good practice* as such, but rather the highlighting of general criteria of *good practice* that help identify measures as *good practice*. The particular measure and its nature or effects are more at the center of attention than the process of identifying or implementing the measures (as opposed to, e.g., the guiding principles for adaptation by Prutsch et al. 2010). Measures for the application of the set of criteria are primarily spatially and temporally defined activities that directly reduce risks of climate change and often have a more technical or structural nature. Informatory or regulatory measures are, however, not in the focus.

Pervasiveness and Challenges of the Good Practice Concept

Good practice usually describes a procedure that is considered exemplary and worthy of imitation because it has proven to be suitable and extremely successful in certain situations (UNESCAP 2012). The term *practice* refers to a measure, a strategy, a specific procedure, an approach, a methodology, a technique, a system, or a process (UNESCAP 2012). The *good practice concept* is an extenuated form of the *best practice concept* (Krems 2012). The identification and communication of *good* or *best practice* is carried out with the aim of using these initiatives as inspirational guidelines for the decision-making process in similar contexts. Due to the fact that it is often difficult or virtually impossible to determine a solution that is the only and best solution in terms of all objectives and all criteria, the *good practice* concept meets factual restrictions and demands better than the *best practice* concept. Therefore, the following remarks refer to *good practice*.

Although there are a variety of publications such as scientific articles or practical manuals and guidelines for adaptation measures, there are only few approaches for a systematization and evaluation of *good practice* in the context of adaptation measures (Abegg 2008; Laaser et al. 2009; de França Doria et al. 2009; Eriksen et al. 2011). However, in the field of climate change adaptation, it can be useful for decision-makers to review or develop envisaged activities with the help of concise criteria in order to ensure that the plans follow recognized standards *for good adaptation*. The development of a set of criteria to assess *good adaptation practice*s is meant to provide private and public stakeholders with some guidance for climate change adaptation. In the following, *set of criteria* refers to a group of defined criteria, which an adaptation activity should meet in order to be deemed *good practice*, i.e., exemplary and worthy of imitation.

This plan is, however, subject to four key challenges. First, the explicit consideration of climate change in different activities constitutes a very recent practice. For that reason, there is only little data available when it comes to defining successful adaptation and establishing why certain activities taken were particularly successful. Second, *good practice* criteria must ensure a balance between abstractness and concreteness in order to cover as many different areas of activity as possible and provide a sufficient guidance function for the planning or evaluation of measures. Third, experience with successful adaptation gained in other contexts, e.g., agriculture in a developing country, cannot be transferred unconditionally to the aforementioned scope of this article, which concentrates on industrialized countries. Fourth, the good practice criteria should be defined in a way that ensures that their implementation can be verified without an unreasonable effort. At the same time, however, the definitions must be sufficiently specific in order to avert unwarranted and objectively unfounded positive reviews of good practice.

In order to address these challenges, the identification of criteria within this research included manifold sources from industrialized countries. In addition, the subsequent choice of criteria was also based on interviews with experts from different subject areas to ensure a broad thematic validation of the selected criteria. Furthermore, the test application of the criteria toward the end of the article also discusses the risks that transferring *good practice* involves.

Methodology

In general, there are different potential approaches to identify a set of *good practice* criteria. One can roughly distinguish between three general approaches (Jennings 2007): the consideration of expert opinions, the analysis of theoretical literature, and the analysis of empirical evidence. In the first approach, a number of experts in the field of climate change adaptation are asked to name criteria that they think an adaptation measure has to fulfill to be considered a *good practice*. In the second approach, good practice criteria are derived from an analysis of relevant literature and the criteria that are mentioned in these publications. The last approach requires the analysis of successful adaptation measures for deducing common characteristics that were essential for their success.

To make use of the strengths of each of the approaches, the development of a set of *good practice* criteria in this article is based on the combination of an analysis of theoretical literature and the incorporation of judgments of experts from the field of climate change adaptation. The derived criteria set is then applied to a number of implemented measures to test for their applicability. This particular path has been adopted since there are only very few empirical studies concerning the success of adaptation measures.

The derivation of a set of practical criteria for the identification of *good practices* in climate change adaptation is based on seven consecutive steps. A large number of criteria that are deemed to define *good practice* are identified through a comprehensive literature search in relevant journals, monographs, and websites (1). Subsequently, these criteria are divided into thematic categories (2) and preselected according to predefined selection principles (3). The subsequent expert evaluation is used to prioritize and reduce the discussed criteria (4). An argumentative analysis then compiles a draft set of criteria (5). In order to test the applicability of the set, a number of adaptation measures will be evaluated tentatively considering the criteria developed (6). Following this test, the paper will discuss the strengths and weaknesses of the *good practice* approach in general and the set of criteria in particular (7).

Identified Categories and Criteria of Good Practice

As a basis for the identification of *good practice* criteria in the context of adaptation, 48 documents that touch on the characteristics of good adaptation in industrialized countries were identified with the help of a keyword search in a bibliographic database and evaluated subsequently. The majority of the identified sources are research papers or guidelines that have been funded by public bodies with a slight focus on publications stemming from Germany. Table 1 provides an overview of the 31 identified *good practice* criteria for the evaluation of adaptation measures or strategies. Because of duplications in terms of the mentioned criteria, only 21 of the 48 analyzed documents are specified in this table. For reasons of clarity, the table lists only that particular definition which the authors found to provide the most relevant explanation, regardless of the fact that some of the criteria have several descriptions. This overall view reflects the broad scope of the identified *good practice* criteria.

The criteria have been sorted thematically in Table 1. The identified criteria were divided into the following categories: *goals*, *goal achievement*, *costs and incentives*, *dealing with uncertainty*, *consideration of side effects and other objectives*, *consideration of stakeholders*, as well as the collective category *miscellaneous*. This method was chosen in order to structure the variety of criteria used in the literature and thus establish key issues, which can be evaluated subsequently by experts.

Table 1 does not only reflect the large range of potential criteria. It also indicates that these criteria or principles address different stakeholders: some authors refer to practitioners who deal with the implementation of measures, and others address policymakers who shape the strategic framework for adaptation measures. Furthermore, also the analyzed subject matter varies: to some extent, the analyses address rather comprehensive adaptation strategies, while others address more concrete measures. Linguistically, it can be noted that some sources adopt an evaluation perspective ("Was the adaptation strategy developed with the participation of all stakeholders concerned?") or provide practical guidelines ("Adaptation strategies should take concerned stakeholders into account"). Other sources, however, specify particular characteristics ("flexible") or effects of adaptation measures ("effective").

An evaluation of the 48 sources analyzed throughout the project shows that 25 sources (approximately 52 %) do not provide any information as to how the authors actually derived the criteria. In 16 (33 %) of the analyzed publications, the criteria are exclusively derived from literature searches and evaluations. Considering expert consultations (6 cases) or carrying out own investigations or resorting to own experiences with climate impacts and adaptation (2 cases) – however, only played a minor role – in total, this only amounts to approximately 15 % of the analyzed sources.

Overall, the analysis shows that in spite of several guidelines and brochures found throughout the research, practical experiences or expert interviews are only scarcely used for the purpose of establishing evaluation criteria for *good practice* in

Table 1 Evaluation criteria for good practice of climate change adaptation

Criterion	Description
GOALS	
Clear objectives	Develop and communicate verifiable goals for the adaptation project (UBA 2010)
Verifiable indicators	Qualitative or quantitative evaluation of the different adaptation options is available (Fünfgeld and Mc Evoy 2011)
GOAL ACHIEVEMENT	
Effectiveness	The degree of goal achievement or the likelihood that goals are achieved (UNECE 2009)
Feasibility	The measure is practical, i.e., the adaptation is not limited significantly by institutional, social, cultural, financial, or technological barriers (Smit and Pilifosova 2001)
Strategic importance	The course of action especially addresses seriously affected and endangered regions or areas of activity; the option has a reliable and long-term, goal-oriented effect (risk reduction); the option averts irreversible and dramatic damages (Vetter and Schauser 2013)
COSTS AND INCENTIVES	
Efficiency	Do the benefits of the adaptation's effects outweigh the costs and the expenditures of the measure (UBA 2010)?
Dynamic incentive	Does the measure entail a dynamic incentive toward a better adaptability or does it merely have a one-time effect (Tröltzsch et al. 2011)?
UNCERTAINTIES	
Flexibility	The measure can be modified or further developed; in case of a change of circumstances, the measure can be reversed (Vetter and Schauser 2013)
Dealing with uncertainties	The scope of potential future climate changes is taken into account (UBA 2010)
Reversibility	The measure can be reversed without causing unreasonable costs (definition following Prutsch et al. 2010)
No regret measures	The implementation of the measure is recommendable, irrespective of the climatic developments (De Bruin et al. 2009)
Robustness	The measure is effective not only in the context of one scenario but also under the different future climatic conditions (Hallegatte 2009)
Resilience	Measures that broaden the possibilities to prevent climate change and recover from its impacts (Land Use Consultants, Oxford Brookes University, CAG Consultants, Gardiner and Theobald 2006)
SIDE EFFECTS AND INTEGRATION	
Sustainability	Risks and measures are assessed by taking into account the interactions between economic capacity, social responsibility, and environmental protection; actions are aligned accordingly (following Bundesregierung 2011)
Positive side effects	The measure supports or does not conflict with goals of other federal strategies (sustainability, biodiversity, climate protection, etc.); it has positive side effects in different areas of action (Vetter and Schauser 2013)

(*continued*)

Table 1 (continued)

Criterion	Description
Win-win effects	Apart from their immediate effects, adaptation measures can entail further benefits also in other areas (Smit and Pilifosova 2001); win-win effects are often mentioned in the context of adaptation and climate protection measures (IFOK 2009)
Avoiding negative side effects	Adaptation measures can have unintentional negative effects on humans and the environment; these should be avoided by following sustainable adaptation strategies and measures (Eriksen et al. 2011)
Integration	If possible, measures should be integrated into an adaptation strategy and a multi-sectoral policy (Doswald and Osti 2011)
Mainstreaming	Integration of climate change adaptation into all relevant planning processes and development strategies (IFOK 2009)
PARTICIPATION	
Participation	Systematic involvement of all relevant stakeholders (IFOK 2009)
Cooperation	The capacity to establish good relations with other stakeholders; capacity to cooperate; capacity to deal with and resolve conflicts (Grothmann and Siebenhüner 2012)
Informative supervision	Develop an understanding and knowledge of climate changes, define climate risks and critical thresholds (UBA 2010)
Political and cultural acceptability	Social acceptance: to what extent do the affected social spheres accept the respective measure? Political acceptance: which degree of support can the measure expect at the political level? In that context, it has to be taken into consideration that the political acceptance is often closely linked to the social acceptance (Tröltzsch et al. 2012)
Equity	The effect (regarding costs and benefits) the adaptation activity has on various sectors, socioeconomic groups, and countries/regions and its temporal dimension should be taken into account (Feenstra et al. 1998)
MISCELLANEOUS	
Innovativeness	Climate adaptation measures are particularly effective when they are innovative – technologically as well as institutionally (Rodima-Taylor et al. 2012)
Priorities	Measures should address particularly important climate risks and chances (UKCIP 2005)
Long-term perspective	Continuity in terms of planning and implementation and regular goal verification (following IFOK 2009)
Evidence-based adaptation	Use of the most recent research results, data, and practical experience in order to guarantee well-founded and informed decisions (DEFRA 2010)
Transferability	The measure can be applied also to other regions (cp. Prutsch et al. 2010)
Subsidiarity	Required adaptation measures have to consider regional differences; in accordance with the principle of subsidiarity, they should be adopted and implemented at the most appropriate decision-making level. Strengthening the individual responsibility is an important guiding principle. Precautionary measures taken by other adaptation stakeholders ought to be promoted (Bundesregierung 2011)
Urgency	Urgency of the options refers to the need implementing the adaptation option immediately or whether it is possible to defer action to a later point in time (van Ierland et al. 2007, p. 258)

the area of adaptation. In many sources, the plausibility and thus the validity of the results is relatively small due to the lack of information on the methodology of deriving the criteria. Although the limited experience with climate change adaptation measures justifies such an approach to some extent, it does not explain why expert assessments are not increasingly taken into account. Against this background, expert opinions on the criteria of *good practice* seem to be of particular importance.

Applying Selection Principles

All of the seven established categories (*goals*, *goal achievement*, *costs and incentives*, *dealing with uncertainty*, *consideration of side effects and other objectives*, *consideration of stakeholders*, and the collective category *miscellaneous*) can be considered of relevance for the identification of *good practice* because each category covers several criteria mentioned a number of times in the literature. However, within the respective categories, there are considerable overlaps between some of the criteria.

Some of the 31 identified criteria are rather different in nature. Due to their variety and scope, they would hardly have a useful guiding effect when compiled as a set. Such an effect can only emerge if duplications are reduced, inapplicable criteria are sorted out, and definitions are specified. In order to identify particularly central criteria of *good practice*, selection principles will be used in the following to determine which criterion from one category can be deemed the most relevant. In three of seven cases, several criteria from the same category will be chosen (within the categories *dealing with uncertainty*, *consideration of side effects and further objectives*, and *miscellaneous*), since their respective content differs sufficiently from the other criteria's content (e.g., *flexibility* and *robustness*, *sustainability*, *positive side effects* and *integrated approach/integration* or *innovativeness*, and *evidence-based adaptation*). In the remaining four cases (the categories *goals*, *goal achievement*, *costs and incentives*, and *consideration of stakeholders*), it was possible to identify just one criterion that is representative of the other criteria of that respective category.

In line with Abegg (2008), selection criteria for a preselection are:

- *Applicability/feasibility* – the criterion can be applied to as many measures as possible.
- *Clarity/comprehensibility* – the criterion's intention is clear and distinct.
- *Assessability/measurability* – the quality and quantitative scope of the measure's effect can be verified.
- *Non-redundancy* – no criterion overlaps with other criteria so that duplications and overvaluations of individual aspects are avoided.
- *Completeness* – the set of criteria covers all important aspects; at the same time, it is concise and manageable.

The arguments for and against each of the criteria can be found in Table 2. To begin with, a large number of criteria were sorted out due to a violation of the requirement of non-redundancy in favor of other, superior, or broader criteria. In fact, 12 of the 20 criteria were sorted out because of a violation of this principle. The most important categories within which it was possible to integrate and thereby sort out several of the identified criteria are the following: *dealing with uncertainty* (4 criteria), *consideration of side effects and other objectives* (3 criteria), and *consideration of stakeholders* (3 criteria). In the abovementioned cases, the contents of the different criteria are so closely related (e.g., *dealing with uncertainties*, *reversibility*, *no regret measures*, and *resilience*) that it seemed reasonable to integrate them into the most comprehensive concept (which in this case was *flexibility*). The same applies to the category *consideration of side effects and other objectives* within which different criteria (*win-win effects*, *negative side effects*, *mainstreaming*) were summarized in the category either *positive side effects* or *sustainability*. The criteria *cooperation*, *informative supervision*, and *political and cultural acceptability* were summarized within the category *consideration of stakeholders* (covered by the criterion of *participation*). Furthermore, two criteria (*verifiable indicators and strategic importance*) were sorted out within the categories *goals* and *goal achievement*.

Additionally, several other criteria were sorted out due to a violation of the selection principle *applicability/feasibility*. Thus, five of the 20 criteria were sorted out because of a violation of this principle: within the category *miscellaneous*, the criteria *subsidiarity* and *urgency* were discarded. Furthermore, the criteria *feasibility*, *dynamic incentives*, and *equity* were sorted out from different categories. The remaining three criteria that were sorted out entailed violations of the following selection criteria: *assessability/measurability* (the criteria *priorities* and *transferability*) and *clarity/comprehensibility* (the criterion of *long-term perspective*).

The 31 identified criteria have already been assigned to seven categories (*goals*, *goal achievement*, *costs and incentives*, *dealing with uncertainties*, *consideration of side effects and other objectives*, *consideration of stakeholders*, *miscellaneous*). The number of identified criteria was reduced from 31 to 11 with the help of the selection criteria. Table 2 summarizes the selection process for the reduction of the identified criteria which were then presented to adaptation experts for further evaluation.

Results

A compact set of criteria is developed on the basis of the preselection of good practice criteria in the previous section and under consideration of experts from different scientific and practical fields. The expert opinions were determined with the help of questionnaires. For that purpose, eight climate change experts from German-speaking regions and with different professional backgrounds were asked to assess the preselection of eleven criteria in view of the following specifications:

Table 2 Overview of the selection process to select a reduced set of criteria

Criterion	Compatibility with selection principles	Conclusions
GOALS		
Clear objectives	Yes	Adoption for expert consultation
Verifiable indicators for goal achievement	No: (1) non-redundancy principle is not met; significant overlaps with the criterion "clear objectives"	Sort out in favor of the criterion "clear objectives" because that criterion has a better applicability
GOAL ACHIEVEMENT		
Effectiveness	Yes	Adoption for expert consultation
Feasibility	No: (1) applicability/feasibility (unnecessary in the context of evaluating already implemented measures); (2) clarity/comprehensibility (before the actual implementation, it is slightly unclear under which circumstances a measure can be held to be realizable); (3) non-redundancy (feasibility and transferability are closely connected)	Sort out because several selection criteria are not met
Strategic importance	No: (1) applicability/feasibility (the criterion focuses on a prioritization of measures rather than an identification of good practice)	Sort out because the selection criterion applicability/feasibility is not met
COSTS AND INCENTIVES		
Efficiency	Yes	Adoption for expert consultation
Dynamic incentive	No: (1) applicability/feasibility (suitable for comprehensive policy instruments but not for implementation measures)	Sort out in favor of the criterion "efficiency" because the latter is more exhaustive and comprehensive
UNCERTAINTIES		
Flexibility	Yes	Adoption for expert consultation
Dealing with uncertainties	No: (1) non-redundancy (content overlaps with the criteria "flexibility," "reversibility," "no regret measures," "robustness," and "resilience"); (2) clarity/comprehensibility (very general, procedural criterion)	Sort out in favor of the criterion "flexibility" because that criterion is more precise and descriptive
Reversibility	No: (1) non-redundancy (content overlaps significantly with the criteria "flexibility," "no regret measures," "robustness," and "resilience")	Sort out in favor of the criterion "flexibility" because that criterion is comprehensive and also covers reversibility
No regret measures	No: (1) non-redundancy (content overlaps significantly with the criteria "flexibility," "dealing with uncertainties," "positive side effects," and "robustness"); (2) applicability/feasibility (not a criterion but rather a type of measure)	Sort out in favor of the criteria "flexibility" and "positive side effects" because both can be held to constitute features of measures, whereas no regret refers to a number of measures

(*continued*)

Table 2 (continued)

Criterion	Compatibility with selection principles	Conclusions
Robustness	Yes	Adoption for expert consultation
Resilience	No: (1) clarity/comprehensibility or (2) non-redundancy (difficult to distinguish from the criterion "robustness"); (3) assessability/measurability (does not actually describe a feature of adaptation measures but rather a complex and specific effect)	Sort out in favor of the criterion "robustness"
SIDE EFFECTS AND INTEGRATION		
Sustainability	Yes, even though the measurability is questionable	Adoption for expert consultation
Positive side effects	Yes	Adoption for expert consultation
Win-win effects	No: (1) non-redundancy (content overlaps significantly with the criteria "positive side effects" and "robustness"); (2) applicability/feasibility (not a criterion but rather a type of measure)	Sort out in favor of the criterion "positive side effects"
Avoiding negative side effects	No: (1) non-redundancy (overlaps with the criteria "positive side effects" and "sustainability")	Sort out in favor of the criteria "sustainability" and "positive side effects"
Integration	Yes	Adoption for expert consultation
Mainstreaming	No: (1) non-redundancy; clarity/comprehensibility (overlaps significantly with the criterion "integration")	Sort out in favor of the criterion "integration"
PARTICIPATION		
Participation	Yes	Adoption for expert consultation
Cooperation	No: (1) non-redundancy (overlaps with the criterion "participation")	Sort out in favor of the criterion "participation"
Informative supervision	No: (1) applicability/feasibility (not relevant for every measure)	Sort out in favor of the criterion "participation"
Political and cultural acceptability	No: (1) non-redundancy (overlaps with the criterion "participation"); (2) applicability/feasibility ("good practice" should be evaluated regardless of the political will for implementation)	Sort out in favor of the criterion "participation"
Equity	No: (1) non-redundancy (overlaps with the criterion "participation")	Sort out in favor of the criterion "participation"
MISCELLANEOUS		
Innovativeness	Yes	Adoption for expert consultation

(*continued*)

Table 2 (continued)

Criterion	Compatibility with selection principles	Conclusions
Priorities	No: (1) assessability/measurability (much contextual knowledge is required in order to be able to assess the fulfillment of the criterion – which regions? which temporal scope?); (2) applicability/feasibility (more suitable for a prioritization of measures); (3) non-redundancy (closely linked to the criterion "evidence-based adaptation")	Sort out because the criterion focuses on a prioritization of measures rather than an identification of good practice
Long-term perspective	No: (1) clarity/comprehensibility (criterion is unclear)	Sort out due to the fact that it is unclear whether the criterion refers to (a) the longevity of a measure or (b) the long-term effects of climate change
Evidence-based adaptation	Yes	Adoption for expert consultation
Transferability	No: (1) assessability/measurability (much contextual knowledge is required in order to be able to assess the fulfillment of the criterion – applicable to whom? with what effort?); (2) clarity/comprehensibility	Sort out due to the fact that too much contextual knowledge regarding the circumstances to which the criterion should be transferred is required
Subsidiarity	No: (1) applicability/feasibility (the criterion is irrelevant for local/regional measures); (2) non-redundancy (participation)	Sort out because it is irrelevant for local/regional measures and is closely linked to participation
Urgency	No: (1) applicability/feasibility (the criterion focuses on a prioritization of measures rather than an identification of good practice); (2) assessability/measurability (much contextual knowledge is required in order to be able to assess the fulfillment of the criterion)	Sort out because the criterion focuses on a prioritization of measures rather than an identification of good practice

1 point = less important (*an adaptation measure can be deemed to be exemplary without meeting this criterion*), *2 points = important* (*meeting this criterion is important for the measure's exemplary nature*), *3 points = of crucial importance* (*a measure does not have an exemplary nature unless it meets this criterion*), *and further option* (*I do not understand this criterion*). In addition to evaluating the criteria, the experts were also asked to answer a few questions. The objective was to establish the appropriate scope of the set of criteria, optimize the comprehensibility of the respective criteria, and examine whether important criteria are missing and whether the content of individual criteria overlaps.

Table 3 Results of the expert consultations, sorted according to the arithmetic mean

Criterion	Evaluation			
	Average	Median	Mode	Standard deviation
Effectiveness	2.63	3	3	0.74
Robustness	2.50	3	3	0.76
Sustainability	2.50	2.5*	2.5*	0.53
Clear objectives	2.25	2.5*	3	0.89
Positive side effects	2.25	2	2	0.71
Efficiency	2.13	2	2	0.64
Participation	2.09	2	2	0.59
Flexibility	2.00	2	2	0.76
Integration	1.66	1.65**	1	0.72
Innovative-ness	1.54	1.5*	1.5*	0.58
Evidence-based adaptation	1.50	2	2	0.76

* These evaluations indicate decimal places because it was impossible to determine a distinct value if, for example, the number of times the ratings "2" and "3" were given is the same ("Most frequent rating" therefore "2.5").

** This rating came up because an expert extended the given scale and used decimal places himself/herself.

Table 3 shows how the experts rated the individual criteria. The criteria are ranked according to their average rating. The differently colored sections reflect the evaluations of the expert consultations. Because there were differing evaluations of some criteria, the table also indicates the standard deviation: the closer the figure is to the number 1, the stronger the expert assessments varied. However, if the figure is zero, there was a consensus among the experts. Additionally, the table indicates also the median and mode in order to meet the frequently rather high standard deviation. Especially where the results are particularly scattered, these parameters have a greater significance than the arithmetic mean.

Table 3 is divided into four areas differentiated by color: (1) Out of the eleven criteria the experts evaluated, the three criteria *marked in red* received the lowest ratings. The respective criteria are *integration*, *innovativeness*, and *evidence-based adaptation*. Their average rating is much lower than the medium answer category awarding two points. In all three cases, also the median and the mode were awarded with less than or exactly two points. (2) The four following categories *marked in orange* received an average, median, and mode close to two points. These criteria are *positive side effects*, *efficiency*, *participation*, and *flexibility*. (3) The criterion *clear objectives* that is *marked in yellow* approximates the leading group. While its average is in the upper middle range, its median and mode are already in the leading group. However, the standard deviation is relatively high. (4) The leading group is *marked in green*. It includes the criteria *effectiveness*, *robustness*, and *sustainability*. These criteria received positive ratings for the categories average, median, and mode.

In addition to the evaluation of the criteria, the results of the expert consultations also provided information on the designation and definition of some criteria. Against this background, some of the criteria were renamed and provided with amended definitions. For the further identification of the set of criteria, the following criteria were renamed:

- *Evidence-based adaptation = > climate knowledge-based adaptation*
- *Participation = > legitimacy*
- *Efficiency = > financial feasibility*

To ensure a transparent renaming, the criteria are referred to both with their previous and with their new denotation (e.g., "efficiency/financial feasibility").

In view of the definition of flexibility, it was noted by an expert that the definition's focus on costs is too narrow because transaction and opportunity costs should be taken into account, too (e.g., the period of time required to agree on the readjustment of a measure). The definition of sustainability was partially held to be linked too closely to the economic development. Therefore, the definition was broadened accordingly. The notion of efficiency/financial feasibility should also be accentuated differently because two elements of the original definition were repeatedly addressed: firstly, it was noted that it is usually not easy to determine the relationship between costs and benefits due to insufficient data, and secondly, those who implement a measure may find that the costs and benefits relation is often less relevant than the absolute costs and the related question of whether it is affordable at all. Therefore, a stronger focus on the overall financial viability and the benefits of financially comparable measures seems appropriate. In view of the criterion positive side effects, it was noted that its narrow focus neglects positive effects on the environment. Accordingly, the definition has been broadened. The definition of effectiveness was amended so as to focus less on the terminology "probability"; the aspect of entailed opportunities has been explicitly included in order to contribute to a broader understanding of the criterion. Furthermore, the experts were asked about what number of criteria for the set of criteria they assume to be manageable (Table 4).

The values given range between three and ten criteria; the two smallest and the two highest values appear only once. Only the numbers five to eight were mentioned more than once. The most frequently mentioned value is five. The average of

Table 4 Expert answers concerning the optimal number of criteria

Number of criteria	3	4	5	6	7	8	9	10
Number of times mentioned	1	1	5	3	4	2	1	1

all answers is 6.28, and the median that amounted to six criteria has a similar dimension. Based on this survey, six criteria seem like a reasonable size for the set. Due to the relatively unanimous below-average rating of the criteria in the red group (*integration*, *innovativeness*, and *evidence-based adaptation*), they were excluded from the final set of criteria immediately. Therefore, eight potential candidates for the final set of criteria remain.

Final Set of Criteria

Based on the expert survey, it was possible to define the criteria and the scope of the criteria set. The evaluation of each criterion enabled the rejection of three other criteria. Proceeding from here, a simple definition of the set of criteria based on the mean values of the evaluations does not seem sensible due to the relatively small number of consulted experts, the proximity of the evaluations, and the continued overlapping of contents. In order to ensure the objective of establishing a compact set of criteria, it is necessary to further reduce the number of criteria. In that regard, it is reasonable to consider the number of times the criteria were mentioned in the initial search and the standard deviations of the ratings.

Although the *clear objectives* criterion has received an above-average rating, it also has the highest standard deviation, i.e., the consulted experts held differing views in that regard. Furthermore, it is noteworthy that the *distinct (or clear) objectives* criterion was mentioned less often in the analyzed sources than the other eight criteria. For these two reasons, the *clear objectives* criterion seems the least relevant and will therefore not be included in the final set of criteria.

The experts gave the criterion *participation/legitimacy* an average rating. Also, the number of times it was mentioned in the sources was average. The category *consideration of stakeholders* covers a relatively large number of criteria, which suggests that it generally constitutes a much-discussed aspect with great importance for the model nature of measures. Feedback given within the course of the expert survey emphasized, however, that participation is not an end in itself but rather a means to achieve legitimacy. Provided that legitimacy is ensured by other means, participation is therefore not always crucial for the model character of a measure. Thus, in comparison with the other criteria, this criterion appears to be less significant because it can be assumed that the majority of actions have sufficient legitimacy. Accordingly, the criterion participation/legitimacy will not be included in the final set of criteria.

Therefore, the remaining six criteria are included in the set of criteria for good practice in the field of adaptation (Table 5).

Table 5 Final set of criteria for good practice in the field of adaptation

Criterion	Definition	Example
Effectiveness	The measure reduces the risks of climate change and contributes to the permanent use of opportunities.	A logistics warehouse in a region that is highly prone to floods is moved to a higher location in the context of a restructuring of the company.
Robustness	The measure has positive effects under different climate scenarios.	A chemical company that uses cooling water from a watercourse sets up an alternative cooling process, which does not require water and can replace the water cooling system if necessary. This measure can ensure a smooth operation also in high summer, regardless of how the summer water levels are affected by climate change.
Sustainability	The measure is well suited in terms of meeting all interests (economy, environment, society) and enables an environmentally and socially equitable development of society.	On the occasion of renewing the road surface, an administrative district chooses heat-resistant asphalt with vegetable oil in the bitumen content. Although it is slightly more expensive, its production and overall longevity is more environmentally friendly than conventional asphalt.
Financial feasibility	The adaptation measure is affordable for those who implement it, and alternative measures that cost the same do not yield higher benefits.	The installation of percolation basins in a development area as a precautionary measure to avert the effects of heavy precipitation was easily financed due to low investment costs and hardly any maintenance costs. Comparatively low-priced measures could not be identified.
Positive side effects	In addition to the adaptation to climate change, the measure has further positive effects on the environment, the society, or the implementing organization and the achievement of its objectives. These take effect even without occurring climatic changes.	When selecting new suppliers, a tool manufacturer decides to choose companies that are closer to the production location than before. The shorter delivery routes reduce the risk of damages to the supply chain occurring due to extreme events. The lower absolute fuel consumption also contributes to climate protection.
Flexibility	The measure can be modified with relatively low costs.	An organization that has been increasingly affected by extreme weather events in recent years insures itself against natural hazards. The selected insurance package can be terminated, reduced, or expanded annually.

Thus, the criteria in the set represent four of the seven categories of criteria – the categories *goals*, *consideration of stakeholders*, and *miscellaneous* are not taken into account. The categories *dealing with uncertainties* and *consideration of side effects and other objectives* are represented by two criteria. Although their respective contents contain some overlap, it seems reasonable in the light of the challenges of adapting to climate change to emphasize these two categories. At this stage, it still remains open how the set of criteria should be applied, i.e., whether a measure should, for example, meet all criteria or only a minimum number of criteria in order to be considered good practice. Furthermore, it was not investigated whether particular criteria have greater significance than others in terms of evaluating good practice for individual sectors or measures.

Application of Set of Criteria

In 2010, the German Federal Environment Agency established a database for measures to adapt to climate change in Germany. By now, this database has about 110 entries. It documents measures whose implementation phase has begun or been completed already. To select the best examples among the entries, the Federal Environment Agency started a competition in 2011. The selection of the award-worthy measures was based on the criteria *effectiveness and cost-benefit ratio*, *further benefits*, *participation and acceptance*, *feasibility*, *and transferability*. It had, however, not yet been systematically investigated whether this set of criteria suffices when it comes to identifying a *good practice* in climate change adaptation. Based on the expanded, consolidated set of criteria outlined above, the adaptation measures in the database were then evaluated to test the applicability of these criteria.

The specific conditions of the Federal Environment Agency’s database have to be taken into consideration. Adaptation measures included by external actors are the starting point for the evaluation. The entry of a measure follows a data entry form which has been provided by the Federal Environment Agency and addresses, for example, the following aspects: title, goal, and description of the measure, addressed climate impacts and fields of action, trade-offs and obstacles to implementation, participation, and financing.

The evaluation had to deal with the following practical challenges:

- The data entry form was not drafted in line with the subsequently identified set of criteria.
- It does not require that all entry fields are filled in.
- There are no requirements in terms of how detailed the description of the measure has to be, i.e., there is no guidance as to how to answer the individual questions of the form.
- The type of measures vary; often, there are conceptual preparatory works or strategic inventory analyses which in fact only prepare the actual implementation of the measure.

- Different stakeholders fill in the form.
- The self-portrayal by the measure's guarantor implicates that positive aspects are emphasized, while adverse effects may not be mentioned at all.

After screening the database entries, 25 measures were found to be suitable for an application of the criteria set. Furthermore, the screening found that 27 measures could be evaluated by the good practice criteria at least to some extent. In general, the application of the criteria shows that they are primarily suited for spatial and structural implementation measures, i.e., approaches for adapting so-called "gray" and "green" infrastructure. This includes, for example, flood polders and renaturation of water meadows for preventive flood protection, climate-adapted forest conversion, urban fresh air corridors, and adaptation measures in buildings. In contrast, the application of the criteria to regulatory, informational, communicative, and decision support measures is not useful.

While applying the criteria, the following aspects became apparent:

- The criteria *effectiveness*, *positive side effects*, and *flexibility* could overall be evaluated reliably.
- In many cases, it was not possible to apply *robustness* usefully; other cases only allowed for very general evaluations; however, in exceptional cases, the criterion was very relevant, for example, in the context of cooling through evaporation (cisterns) if potentially decreasing precipitation is not considered.
- Often, it was not possible to evaluate the *financial feasibility* because the total costs of the project were unclear or not communicated; in addition, it was difficult and time-consuming to determine the respective benefit and to compare the benefit with the benefit of other measures.
- The *sustainability* of several measures could not be portrayed in detail due to the fact that the term rather comprehensive and because its definition is relatively broad.
- Overlaps between *sustainability* and *positive side effects* were identified.

The main challenges when applying the criteria uncover the obvious methodological uncertainties. In view of several criteria, it is still unclear with which methodology they should be assessed. To this end, further research is required.

Considering all criteria, a *good practice* measure was identified when all criteria were rated positively. In some cases, however, a practice can also be held to be good although individual criteria were not met. *Robustness*, for example, is an important criterion when it comes to long-term, costly infrastructure decisions. However, if a measure is flexible and its implementation is cost-efficient, its implementation may remain useful even if the measure cannot meet all potentially possible climate developments.

In general, the set of criteria is suitable for the purpose of identifying good practice measures within the database of the Federal Environment Agency and to substantiate the preparation of the selection process. It contributes to the transparency of the evaluation process and covers important aspects that a suitable adaptation measure should fulfill. In order to provide an overall judgment on the basis of the individual evaluations of the criteria, a further consultation of experts considering the respective field of action seems appropriate to further consolidate the results.

Conclusion

In addition to suggesting a set of criteria, the derivation of *good practice* criteria entailed further conclusions. The research of criteria used in the literature in view of *good* adaptation has shown that the sources only very rarely relied on practical observations or opinions of other experts in order to justify the adopted criteria. So far, very limited experience with the effect of adaptation measures can be deemed to constitute a reason for the limited consideration of empirical data. Another reason can be seen in the fact that the majority of the criteria are very general in nature and are important for the selection and implementation of appropriate measures also in other topical areas (e.g., *efficiency*, *effectiveness*, and *participation*). Their general desirability then might not call for elaborate definitions and justification in the literature on climate change adaptation.

The challenge that arises when deriving a compact and easily applicable set of criteria is to justify which combination of the fewest number of criteria has the greatest relevance for the identification of *good practice*. The approach adopted here is based on a thematic grouping of the criteria followed by a selection of certain criteria on the basis of selection principles, which, for example, ruled out redundancies. Subsequently, experts evaluated the preselected criteria. In all three steps (grouping, preselection, and especially the evaluation by experts), the tension between the comprehensiveness of the respective definition and the comprehensibility of the criterion became apparent: the shorter and more abstract the description, the more difficult the evaluation within the preselection and the more frequent the different interpretations by the experts. It was not possible to dispel this tension in the final set of criteria.

The application of the set of criteria to adaptation measures from the database of the German Federal Environment Agency has shown that the problem with briefly formulated criteria can often not be resolved and the ratings thus forfeit their objectivity. In many cases, it was, for example, not possible to verify in detail the fulfillment of the rather abstract criterion "sustainability." This is due to both the lack of detailed information about the measure and the less concrete definition of the criterion itself. The problem with criteria which do not have a sufficiently precise formulation or for which there is no transparent methodology to examine their implementation entails the risk of window dressing, i.e., the whitewashing of suboptimal adaptation measures by decorating them with the criteria. If, however, one would reformulate the criteria in terms of maximum precision, the original purpose of this set of criteria – practical assessment of *good practice* – could no longer be met. Due to the existing uncertainties, the set of criteria cannot provide final judgments in terms of the evaluation of good adaptation practice. It can, however, prepare the according decisions through the structure of the criteria. The set of criteria achieves this with its special focus on the two issues that play a significant role in the context of adaptation: dealing with uncertainties and consideration of side effects.

Gender and Health Adaptation Measures to Climate Change in the Pacific: A Case Study of Papua New Guinea

Sabrina Regmi

Contents

Abstract

This chapter examines the relationship of climate change, health, and gender in the Pacific region; identifies gaps in research, capacity, and support; and proposes a framework illustrating the practical adaptation measures to be applied in strengthening the Papua New Guinea's (PNG) public health sector capacity and policy. Using literature review as the research method, the study found that although other countries in the pacific are mostly affected by the climate change impacts, PNG remains highly affected by the climate-induced health impacts. Hence, a case study on Papua New Guinea was prepared. The chapter provides a practical understanding and knowledge on emerging health threats, gender issues, and adaptation measures to strengthen the Pacific and PNG's public health system. The framework presented in this chapter could be highly beneficial not only for PNG but also for the whole Pacific region.

Keywords
Climate change • Health • Gender • Adaptation measures • Pacific • PNG

Introduction

Although there has been a historical trend of health impacts of climate change at local level, the global attention of health issue in the climate change debate is a late comer in parallel with gender issue. It started getting attention during the 1990s when the World Health Organization (WHO) and the Intergovernmental Panel on Climate Change (IPCC) raised importance of health problems along with gender as the alarming issue in climate change regime (WHO 1990; IPCC 1990).

Both IPCC and WHO reports forecast that extreme climate events as well as changes in weather patterns and climate variability such as temperature and precipitation are expected to bring changes in the environment which may disrupt the socioeconomic lives of people, mostly living in the rural areas. Potential health impacts are expected to occur from the following climate change indicators: increases in extreme events, increases in temperature, decreases in rainfall, and increases in sea level (IPCC 2007). These indicators cause the disruption of the physical and ecological environment and the biological system which eventually threatens the socioeconomic system that functions within the physical, ecological, and biological system. Environmental threats such as contamination of potable water due to flooding leads to health risks such as those transmitted from infectious disease. Similarly, decrease in rainfall results in water shortage (rainwater) that leads to drought and shortage of potable water which consequently leads to food insecurity and poor sanitation and consequently affects nutrition and hygiene (Costello et al. 2009). Similarly, health-related problems may also arise from destruction of socioeconomic systems such as infrastructure that may consist of water sources, sanitation, and drainage and public health center itself (Ebi et al. 2008). Post-disaster impacts such as mental health conditions (depression and anxiety) may occur due to disruption of the social system, loss of livelihood, displacement, and migration (Costello et al. 2009).

Changes in climatic conditions affect directly (through changing extreme weather patterns) and indirectly (through changes in air, water, food quality, and infectious disease transmission and reproduction). Most of the studies in the developing countries show projected impacts that show similar health concerns arising from various climatic factors (for details see, McMichael 1997; Kovats et al. 2006; WHO 2011).

So far sectors such as water and agriculture have been cited in many global and national reports as well as studies as the important sectors for adaptation to climate change impacts, and thus, the measures are recommended and designed from the perspective of these sectors (Lovell 2011; ADB 2011). In the Pacific region, health sector itself has not been included fully and response from the sector has been few (Lovell 2011). Public health planners and policy makers have also been excluded from discussions, debate, and policy making which often takes place within the climate, environment, and agricultural sector, among the professionals in these fields (Lovell 2011).

The study aims to review the past assessments, adaptation measures, and role of public health sector and their response. The study aims to fill this gap in the Pacific regional context and particularly in Papua New Guinea (PNG). The purpose of this chapter is to examine the relationship of climate change, health, and gender in the Pacific region; identify gaps in research, capacity, and support; and propose a framework illustrating the practical adaptation measures to be applied in strengthening the Papua New Guinea's (PNG) public health sector capacity and policy.

Theoretical and Empirical Perspective

There are more predictions of the climate change impacts on health as compared to observed ones. The IPCC assessment (IPCC 2007) provides the evidence of these predictions to be based on scientific means, and most of these are from the developed countries (such as Europe). Hence, health impacts also have been mostly observed in developed countries, such as the extreme heat-related deaths in Europe, changes in vector-borne disease also in Europe, and increases in seasonal production of allergenic pollen in Northern Hemisphere's high and mid-latitudes (IPCC 2007).

Most of the studies looking into the climate change-induced health impacts have projected the likeliness of future health risks, and there are very less contributions to the knowledge on current vulnerability, risks, effects, and adaptation. Efforts have been put toward modeling of future health impacts of weather events such as heat waves, excessive rainfall, patterns of diseases, and food production (Kovats et al. 2005; McMichael et al. 2005, 2008; Lieshout et al. 2004) based on scientific indicators. Very few studies have looked into the risks from the social perspective such as health and gender. For instance, a quantitative study by Kolstad and Johanssan (2011) at a global level computed the projections of future climate change-induced increase in diarrhea which shows that it would increase up to 4 °C over land in the tropics and subtropics by the end of this century.

Nonetheless, IPCC (2001, 2007), WHO (2003, 2010), and IIED (2011) reports state the most vulnerable will be the small island states (located mostly in the Pacific region) and coastal areas in the developing world. Climate change can be a real threat to health of the population living in the Pacific, and their chances of survival and capacity to adapt to could be at stake, as larger population in this region depend on the sea/coastal, agricultural, and fisheries resources for their livelihood that are often damaged by the changes in climate variables and disasters. Hence, they face higher risk of suffering from different kinds of health-related problems such as malnutrition. For example, costal reefs are highly vulnerable to climate change impacts such as sea-level rise. Moreover, reefs are considered the major source of food and the main source of protein in Pacific people's food intake, with over 100 k of fish consumed per person per year (WHO 2003).

Climate change-related health risk from a wide range of diseases and injuries can be easily quantified (e.g., deaths due to storms) but sometimes it is difficult to determine through quantification (the health consequences of food insecurity). Studies show that whether the potential for climate-related disease is translated into actual occurrence of death and illness depends on both how quickly and how successfully humans adapt to new conditions.

In the Pacific context, a study by Patz (2002) using time series analysis of historic cholera in 1893 examined the effect of stationary interannual variability associated with climate change which showed that warming trends over the last century are affecting human disease. Similarly, Singh et al. (2001) studied the impacts in the 18 regions in the Pacific which show some observed (evidence based) outcomes through time series analysis. Based on data between 1970 and 1995, the study shows positive association of dengue with the Southern Oscillation Index (SOI), denoting El Niño condition. It further shows positive association of diarrhea cases between 1978 and 1986 with average temperature and negative association with water availability. Moreover, in Fiji (1978–1992), diarrhea cases were found to be positively associated with the changes in monthly temperature and with extreme rainfall. Another study by Ebi et al. (2006) in small island countries that also includes some of the Pacific countries examined the potential added risk posed by global climate change on dengue transmission using computer-based simulation analysis. The study showed that change in frequent and severe weather may change the range and prevalence of climate-sensitive diseases such as malaria, dengue fever, and diarrhea.

Similarly, assessments on health impacts of climate change are also few. McMichael et al. (2002, 2003) conducted an assessment on health impacts in Oceana that showed consequent increase in heat- and flood-related deaths and injuries and increase in food-borne and waterborne disease in the past years. Another assessment on the health impacts on Canadians in Canada showed increase in waterborne and vector-borne disease with increase in climate variability (Health Canada 2008). On the other hand, a review of historical practices in water-related infectious disease research in developing country's context shows lack of data, limited relevant indicators, and inadequate understanding of factors that cause water-related infectious disease due to climate change (Batterman et al. 2009).

Few assessments have looked into the health impacts on gender. One such assessment is WHO's climate-induced gender health risk assessment that shows indirect impacts such as women's caregiving work, health hazards associated with women traveling long distance for water collection, as well as mental health problems for both men and women (WHO 2010).

Most of these studies have not looked into the potential adaptation measurements for health impacts of climate change. Mostly adaptation measures have been anticipated and proposed within the sectors such as water, agriculture, infrastructure, and engineering (ADB 2011). Moreover, study recommendations for interventions and adaptation are more focused on developing the scientific or economic strategies and less focused on the possibility and kind of contribution the public health sector could provide such as delivery of health services.

Nonetheless, these studies and assessments have provided a good foundation for designing a potential framework and scenario for future studies and assessments that would look into empirical facts to understand whether the projections for the developing countries have any significant impacts or not and the appropriate adaptation measurements for the same. However, it is also important to note that human health impacts of climate change may not be easily detected due to adaptation and non-climatic factors that often determine the level of impact especially in high-income, developed countries where adaptation measurements are well developed. Based on data from 34 stations in the Pacific, a study shows increase in surface air temperatures by 0.3–0.8° C during the twentieth century (Nurse et al. 2001). Some of the observed changes include increased coastal erosion, more saline soils, shifting fishing grounds, and more droughts and water shortages. Models also project the greater climate variability (such as more extreme high temperature and precipitation events). El Niño events are also supposed to strengthen short-term and interannual variations.

The "already overextended" health system and the existing health impacts from noncommunicable diseases are expected to further deteriorate with the climate change-induced health impact that increases the incidence of communicable diseases. Infectious diseases such as malaria, dengue, and diarrhea are regarded as the major health impacts of climate change in the Pacific (Comrie 2007). Moreover, over 20 % of deaths due to unsafe water and poor and inadequate sanitation hygiene are also caused by the climate change impacts such as flooding and drought. This has also strained the majority of the Pacific's public health system (SOPAC 2008).

El Niño events in 1997–1998 caused various health impacts in some countries of the Pacific region. They included health problems such as diarrhea and nutrition deficiency caused by decrease in water availability and agricultural production. Gender-related health impacts were also found. Pregnant women suffered from micronutrient deficiencies in places in Fiji where there was extreme drought (Ebi et al. 2006).

The Pacific region lies in tropical and subtropical zones with weather that is susceptible to the transmission of communicable disease such as malaria which can become worse with the change in climatic condition, inadequate infrastructure, poor waste management practices, and poor public health practices (WHO 2002). In addition, weather and climatic factors coupled with social aspects such as culture and traditions also contribute to disease prevalence.

There was an outbreak of dengue fever in Fiji coinciding with the El Niño event where 24,000 out of the 856,000 population were affected with 13 deaths. Although dengue is frequent in Fiji, the large outbreak was caused by the El Niño event that facilitated mosquito growth and caused extreme health impacts, also affecting the neighboring nations in the Pacific (Ebi et al. 2006).

Other related issues may hamper the overall health in times of climate change impacts such as the vulnerability and access to health services in times of climate change events.

The definition and understanding of the concept "vulnerability" also varies. For example, in the studies of climate change impacts and infectious diseases, vulnerability may be understood as a state of increase of adverse potential outcome on the health, according to direct exposure of certain climatic disasters or the indirect and gradual influence of extreme weather-related environmental hazards on particular diseases that affect health (Woodward et al. 2001).

Discussions of health-related vulnerability in a developing country such as those in the Pacific could be more understood by the concept of "poverty and inequality" that is often associated with the vulnerability concept in low-income countries (Brooks 2003). It is understood as the lack of access to resources and a status of dependency and disadvantage.

Although vulnerable populations have been identified in some studies in the Pacific region, the consequent impacts on specific population group have been left unexplored. Health outcomes such as nutrition deficiency due to food shortage (drought or heavy rainfall) could affect group of people in different ways according to their gender, age, economic status, ethnicity, and geographical location (WHO 2010). In some Pacific countries, women often eat last and the least and are suffering from poor nutrition and anemia. In times of food shortage, they may suffer from severe malnutrition and anemia, which has been found in some South Asian countries, like Nepal (Regmi 2007, 2009). Moreover, women in many rural societies in the Pacific are the providers of water and food to their family and are responsible for providing care to the sick, elderly, and children in the household (Brody et al. 2008). Thus, climate change impacts such as water and food shortage and increases in vector- and waterborne diseases not only affect women's health in general but affect their physical and mental well-being as the burden of diseases, caregiving responsibilities, and work increase. Women and girls often walk miles in search of water sources in the forest areas which could be hazardous for health and could be physically burdensome. Pregnant and nursing mothers as well as infants and children could be at high risk at such times (Regmi 2007).

IPCC defines adaptation as "the adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects." Health adaptation measurements could be designed and undertaken in certain context and situation by certain group of people depending on their capacity and ability, often determined by not only the environmental but also socioeconomic, demographic, and individual factors (WHO 2003). In addition to this, the geographical location and its physical as well as socioeconomic environment also determine the relationship between certain diseases and climate change indicators and the degree of their prevalence. For example, low-income or less developed countries and those in low-lying coastal areas such as the Pacific island countries are understood to be affected by vulnerable diseases such as malaria, dengue, and diarrhea, while health impacts such as heat waves and air pollution are supposed to be high in large cities such as those in developed countries (WHO 2003).

In health terms, adaptation is a measure of what could be designed to minimize the negative health impacts of climate change that may arise in the future and maximize any positives that may occur. An assessment of historical and current vulnerability and adaptive capacity is necessary to plan not only future but current measures. The assessment will provide a thorough understanding of what adaptive measures are needed for the management of potential health effects of climate change Pittock (2003).

Seasonal forecasts have been often used to increase adaptation to climate variability, including weather disasters in some of the states of the Pacific. For example, the Pacific ENSO Application Center (PEAC) warned governments, when a strong El Niño was developing in 1997/1998, that severe droughts could occur and that some islands were at unusually high risk of tropical cyclones (Hamnett 1998). The projects, such as public education and awareness campaigns, were effective in reducing the risk of diarrheal and vector-borne diseases. For example, despite the water shortage in Pohnpei, fewer children were admitted to the hospital with severe diarrheal disease than normal because of frequent public health messages about water safety. However, this did not contribute to the reduction of all negative health impacts, such as micronutrient deficiencies in pregnant women in Fiji.

Research Method and Limitation

The findings of the study are based mainly on literature review. Initially, the study was supposed to analyze the association of climate change and its impact on health using secondary data analysis, but due to lack of access to data, as well as the limitation of time to collect data, the study chose to make a case study instead. The study analyzes the case study of Papua New Guinea (PNG) through information gathered from literature review and secondary data.

Results and Discussions: PNG Case Study

Although various reports (IPCC 2007; WHO 2003) show that climate change impacts could be severe in other Pacific countries, the health-related indicators show that related health impact could be more severe in PNG (see Tables 1 and 2). Hence, the study focuses on PNG as a special case to understand the impacts. It will focus on the climate change-induced health-related vulnerability issues in PNG, types of climate change impacts on health on PNG population, and the adaptation measures undertaken so far.

Climate Change-Induced Health Vulnerability in PNG

Located in the Pacific Ocean, Papua New Guinea (PNG) is one of the least developed countries (LDC) with low economic and human development indicators that often affect the health of the major population (UNDP 2009). The health sector has deteriorated since the 1980s due to neglect of the health system, especially in rural areas, where 87 % of the population live. An estimated 40 % of rural health facilities have closed or are not fully functioning (ADB 2011). The country has

Table 1 Environmental burden of disease in the Pacific

Country	Improved water	Improved sanitation	Diarrhea deaths per year	Diarrhea DALYs/ 1,000 capita/ year	Main malaria vector transmission	Main other vector transmissions	Malaria deaths/ year	Environmental burden on diarrhea (lowest, 0.2; highest, 114)	Environmental burden on malaria (lowest, 0.0; highest, 32)	% malnutrition

widespread poverty and weak health indicators, particularly for maternal and child health. Asian Development Bank's (ADB) report shows the infant mortality rate to be 47 per 1,000 live births and the maternal mortality rate to be 250 per 100,000 live births. The main health problems continue to be communicable diseases.

PNG is also home to several environmental disasters and climate change impact that threaten its fragile coastal and forest areas which often serve as a means of livelihood to the poor rural population. The socioeconomic vulnerability coupled with the geographical vulnerability has made climate change threat a serious problem in PNG, especially for the rural population which depends on natural/forest resources (fisheries, mangroves) and subsistence agriculture for their livelihood. When these resources are threatened, food insecurity increases and ultimately affects the health (nutrition) and well-being. Moreover, the interannual variability in climate change such as changes in temperature, precipitation, and humidity also leads to the contribution of various vector-borne, waterborne, and food-borne diseases that multiply with water shortage as well as poor water management and sanitation.

Increase in the prevalent infectious disease such as malaria further affects the already overburdened health system of PNG that is suffering from poor access and delivery issues. A survey conducted by Papua New Guinea Institute of Medical Research (PNGIMR) predicts the rise of population prone to malaria risk from 65 % to 95 % by 2100. Aside from three countries, namely, PNG, Solomon Islands, and Vanuatu, the other Pacific nations are assumed to be free of malaria. However, the 2006 White Paper on aid in the Pacific and Southeast Asia shows malaria cases to be highest in PNG as compared to Solomon Islands and Vanuatu (see Fig. 1)

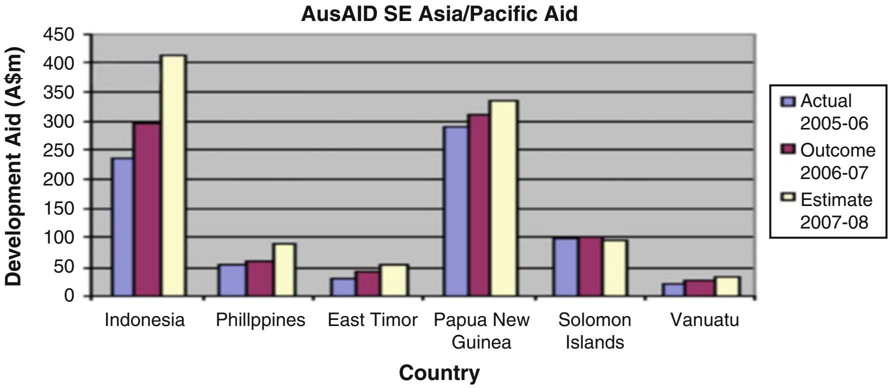

Fig. 1 Malaria cases in AusAID-funded countries in SEA and the Pacific (Potter 2008) (Source: 2007–2008 Foreign Affairs and Trade (AugAID) Budget, "Appendix – AusAID Country and Global Program")

(Potter 2008). While the major prevalence of effects of malaria is expected to be mostly in coastal provinces, the PNGIMR survey warns that climate change puts even other locations such as highland at risk of contracting the disease. WHO has recorded 4,986 malaria cases in the Western Highlands province of PNG in 2005, compared with 638 cases in 2000. The malaria epidemic of 1997–1998 in the highlands which was predominated by *P. falciparum* is consistent with a response to anomalous warming and precipitation, suggesting that malaria trends in PNG may follow similar trends to those of the East African highlands (Githeko 2009). The burden of malaria is likely to increase in PNG with climate change. Malaria has been diagnosed as the major indicator of mortality rates in Papua New Guinea, with around 1.7 million cases in 2003 and 700 mortality cases in 2007. WHO reports that since many cases in remote/rural areas are not recorded properly, the number of cases could be even higher.

However, there is a gap in the understanding of the socioeconomic and demographic differences in the risks to the climate-induced disease that has important implication for understanding the health benefits of the vulnerable population as well as the challenging role and responsibilities of public health sector in meeting the needs and interests of the vulnerable. Similarly, freshwater fisheries, mangroves, and subsistence agriculture which are often threatened by climate change impacts provide food to many people living in coastal communities in PNG, which may consequently affect their nutrition level with unavailability of adequate and nutritious food.

Although there are no major droughts in PNG, in 1997/1998 there was a major drought that took place in many Pacific nations including PNG. Moreover, some minor droughts also occurred in 1914 and in 1941, 1965, 1972, 1982, and 1987 associated with the El Niño event which has been increasing since 1914. About 40 % of PNG's rural population faced food insecurity and water shortages in the 1997/1998 drought associated with the El Niño event. However, there was a low death toll due to the coping strategies followed by the people through initiatives such as foraging in the forest, trading, and activating extended family networks. Although there were few deaths, it increased in the rural part where people had to live longer without enough food and safe water. Few people suffered from diarrhea and mostly from severe malaria.

There is a lack of proper knowledge on the climate change-induced health impacts such as those from drought and the responding mechanism to such impacts. Additionally, considering the nature of health impacts of such causes to be arising through indirect pathways, it is difficult to model the impacts and anticipate and prepare appropriate public health measures. Most of the identified adaptation measures fall under the agricultural sector which is insufficient toward meeting certain needs and interests of the vulnerable populations.

PNG also lacks sex disaggregated data as well as qualitative, demographic, and geographical knowledge on gender-related health impacts given the evidence that the higher prevalence of climate-sensitive disease such as malaria and malnutrition is found more among pregnant women. Maternal and child mortality often has been cited as the result of these diseases.

The emerging threats to the health of the vulnerable groups from factors other than disease such as physical access to health-care services in the rural, coastal, and agricultural part of PNG where the major population lives are crucial to understand and overcome. The increases in the prevalence of malaria and malnutrition are some of the outcomes of the increase in temperature and rainfall and the El Niño-influenced drought events in PNG. This has also increased the vulnerability of people with less capacity and physical access to seek health care and adapt to as well as those with less immunity to fight the transmission of diseases, such as women and children.

Identifying Vulnerable Population, Location, and Key Indicators for PNG

In developing countries such as PNG, vulnerability is often associated with poverty and inequality. PNG holds large population (6.8 million) as compared to other Pacific nations and covers around 83 % of the total Pacific region. It also ranks lowest in the Human Development Index as compared to other Pacific countries (UNDP 2009). High mortality rate and lower literacy rate have also been the key indicators of vulnerability in PNG.

PNG has a total population of approximately 6.8 million, and the majority of these (87 %) live in rural areas where access to markets, services, and income-generating opportunities is limited. Agriculture, fishing, community forestry, and mangroves are the main sources of livelihood in the rural areas (World Bank 2012).

Over 50 % of the rural population lives below the poverty line. Not only the insufficient awareness or adaptation of climate change impacts but also other socioeconomic indicators such as poverty, limited and expensive access to inputs and markets, poor infrastructure, ineffective extension services, and limited access to credit, all contribute to the vulnerability of the PNG's rural population.

Climate variability and change are set to accelerate the occurrence of landslides, soil erosion, deforestation, and loss of biodiversity, as well as increase occurrence of recurrent floods and droughts. However, little is known on the health impacts of climate change in PNG. There has been concern and expectation that malaria may spread from coastal areas to highlands as isotherms (climate particular) are expected to rise doubling the effect of CO_2, the main emitter of GHG and major contributor to climate change impacts (McGregor 1990). However, PNG remains incapacitated to adaptation as it lacks a good public health infrastructure and delivery service, a good community involvement and practice of control measures, and a good disease surveillance system (Lifson 1996).

Few studies in PNG have mapped climate, environment, and nutritional health outcomes at national or local level. Temporal studies can also reveal vulnerability to interannual climate variability or the effect of the El Niño Southern Oscillation. Study in Papua New Guinea has shown that women living in poorer-quality environments produce less food, suffered chronic malnutrition, and had children with lower birth weight (Allen 2002).

The continuous occurrence of El Niño has been associated with high shortages of food. In the year 2002, a technical assessment on the impact of El Niño conducted by the National Agricultural Research Institute (NARI), Australian Aid (AusAID), Australian National University (ANU), and National Disaster Management Office (NDMO) reported not only rural and coastal areas but also highland areas to be highly prone to El Niño-related health impacts. The El Niño weather pattern that runs from June to September in PNG is an important source of drought and eventual shortage of food supplies. The people in rural and highland areas are particularly affected by the impacts of drought as their traditional subsistence agriculture does not cater for such extreme weather patterns.

Framework on Health Impacts and Vulnerability for PNG

Based on the literature review and information gathered, the study has come up with a framework on health impacts and vulnerability for PNG (Fig. 2). The framework shows that PNG's major climate change scenarios are drought and increase in rainfall/temperature. One pathway driving the impacts on health includes food insecurity through drought that leads to malnutrition. Another is transmission and reproduction of disease vectors caused by increase in rainfall in normally dry areas and temperature that leads to malaria sickness. These health problems may decrease with the development of adaptive capacity and appropriate adaptation measures. Similarly, there are three levels of vulnerability that could affect the PNG population. At the individual (micro) level, vulnerability is caused by individual, socioeconomic, and geographical indicators such as less nutrition and care, low income, disability, and living in poor condition. At the community (meso) level, vulnerability is associated with the group of people having less access to social support, lack of community health posts, and less community awareness and education programs. At the national (macro) level, vulnerability is defined by the strength and weakness of

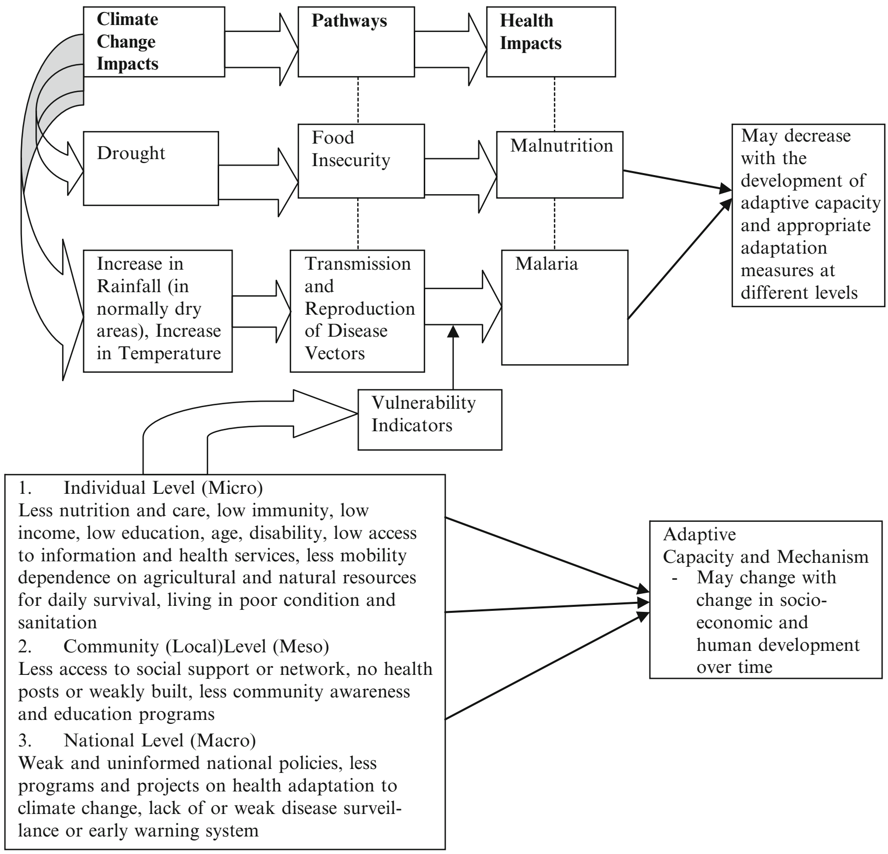

Fig. 2 Health impacts and vulnerability in PNG (Source: Author's Work)

government/state such as weak and uninformed policies and less programs and projects on health adaptation to climate change. The adaptive capacity of these vulnerable individuals, communities, and states may change with change in socio-economic and human development over time.

Adaptation Measure for PNG at Different Levels

The different levels of vulnerability cause different types of impacts (Fig. 3). Hence, the adaptation measures should also be developed with understanding to these levels. At the individual level, a cheaper adaptation measure could be undertaken such as during malaria breakouts, one can use mosquito nets or mosquito spray to protect oneself. At the community level, the measure could be a little expensive as it will include meso-level programs such as vector control, vaccine, and educational

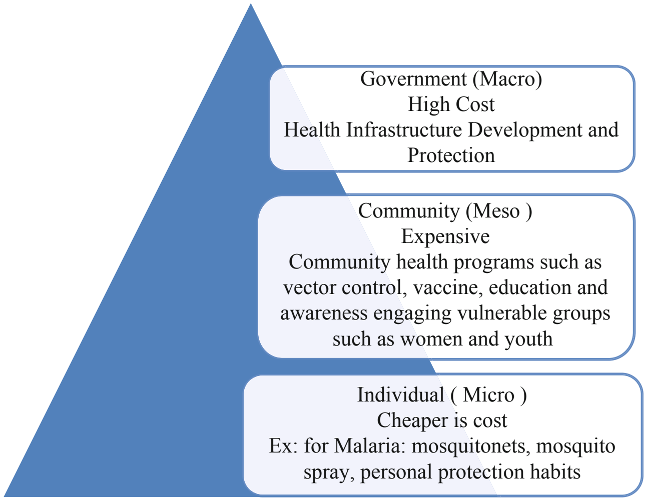

Fig. 3 Levels of adaptation (Source: Adapted from Department of Health Western Australia 2008)

programs. At the governmental level, the macro issues such as infrastructure development protection affect the vulnerability; the cost of adaptation measure is also high and thus needs enough fund and support.

Limitation and Future Research

Human health-related risks have been recently diagnosed under the climate change vulnerability and adaptation issues in developing countries, but there are very few studies especially in the Pacific region and particularly in Papua New Guinea (PNG) where the vulnerability is very high.

Few efforts have been made to understand the observed differences in vulnerability of different socioeconomic and demographic groups in the Pacific, particularly in PNG given the fact that PNG covers the highest population in the Pacific that differs in socioeconomic, geographic, and political order. This has important implications for developing public health adaptation measures, policy making, and planning. Similarly, most of the support has concentrated on the technological and scientific measures for adaptations to other affected sectors such as agriculture and water sources with very few supporting the social sector, such as health. Existing studies/assessments are based on projections, and very little is known on the current impacts with very few successful adaptation measurements undertaken so far.

The study points out the following limitations and gaps in research and support:

- Health issues in the Pacific and particularly in PNG are less informed but critical for the growing population especially the youth and women considering the past, current, and future prospects of climate change impacts.

- Less resources to understand the link and pathways to health impacts of climate change due to lack of research and information sharing on the ground.
- Health sector and its role and responsibilities have not been identified properly.
- Less support has been provided to the health sector, due to importance given to other socioeconomic issues such as poverty, water crisis, and food insecurity.

The study concludes that the Pacific region and particularly PNG lack existing datasets and knowledge to build the association of climate change and health impacts that is based on historical and current knowledge and information. Hence, vulnerability assessment would be the first step to understand certain impacts in certain contexts which will build the foundation of empirical knowledge that could be obtained through either qualitative assessment based on primary data or quantitative analysis using secondary data. Based on the results, certain scenarios then could be developed to make future predictions and anticipate and design adaptation measures. Overall, the study came up with the following recommendations for research and policy:

- Enhance and improve capacity and knowledge of the population and particularly the vulnerable groups by providing education, training, and vocational programs.
- Development and improvement of information sources through collection of socioeconomic (e.g., age, gender, income) and geographic data/indicators.
- Strengthening of public health sector's roles by encouraging participation of health clinicians.
- More support to public health sector on designing adaptation measures to climate change-induced health impacts.
- Physical access to health-care services during climate change impacts such as loss of infrastructure and transportation needs to be improved.

Acknowledgments The author would like to deeply acknowledge the support and guidance of her supervisor Sakiko Tanaka during her internship at Asian Development Bank and without whose supervision, the study would not have been possible. The author would also like to thank the ADB's secretariat, all the staffs of the Pacific department as well as ADB's professionals and experts in Health, Climate Change and Gender who have provided their support during the study in various ways. Lastly, the author is grateful to Dr. Abul Quasem Al-Amin for his valuable comments and suggestions during the write-up of this chapter.

Abstract

Global climate change will have significant impacts on natural systems and human societies throughout the world. Therefore, climate adaptation strategies need to be developed at multiple scales. The Interreg IVB project "Climate Proof Areas" (CPA) has focused on climate adaptation at a regional scale in twelve pilot areas across four North Sea countries. It showed that the regional scale provides challenging opportunities of cross-sectoral climate adaptation. This paper gives an overview of experiences from the CPA pilot studies and embeds these in a generic approach for regional climate adaptation. Attention is paid to typical issues of coastal regions: water management, coastal protection, freshwater supply, land

use, and spatial planning. Based on typical challenges of climate adaptation such as low sense of urgency, high degree of uncertainty regarding future development, and decision-making on a long term, a number of illustrative components are discussed which can contribute to the guidance of regional climate adaptation. These components cover different themes including communication issues, physical solutions, knowledge, and process-oriented approaches and result in a so-called adaptation toolkit. Finally we draw conclusions and derive recommendations about how certain approaches and policies at different levels can contribute to successful regional climate adaptation in coastal areas.

Keywords
Climate change adaptation • Regional scale • Pilot studies • Adaptation toolkit • Policy recommendations

Introduction

Climate change is one of the key challenges in recent environmental and societal research and studies on sustainable development. The Intergovernmental Panel on Climate Change (IPCC) has stated that global warming has accelerated significantly in the second half of the twentieth century and that humans have caused the dominant part of global warming (IPCC 2013). The envelopes of reasonable climate scenarios project further global warming until the end of the twenty-first century. Even if greenhouse gas concentrations will not increase from the level reached in year 2000, global mean temperature will continue to rise by approximately 0.1 °C per decade during the twenty-first century due to delayed response of slow components in the climate system (van den Hurk and Jacob 2009). For the North Sea region, in addition to rising temperatures and sea levels, an increasing rainfall variability is expected which is likely to cause droughts as well as flood events in the future (IPCC 2013; Verhofstede et al. 2011). Therefore proactive strategies are required to react to future climate change.

Based on these commonly accepted facts, science and society are debating on how to react to climate change. Two main complementary strategies are basically agreed on: (1) to mitigate future climate change, e.g., by reducing the emission of greenhouse gases and (2) to adapt to those changes which cannot be mitigated. While mitigation needs to be implemented on a global scale, adaptation to climate change is a local to regional scale issue (Füssel 2007). Independently of the effectiveness of future mitigation, adaptation to climate change is necessary if such climate change exceeds current climate variability. Adaptation to climate change, therefore, has raised public interest in recent years, mainly driven by climate-related disasters (Füssel 2007; Krysanova et al. 2010). As a consequence, preliminary national frameworks have been established towards the development of national adaptation strategies (e.g., for Germany: Bundesregierung 2008).

Due to the increasing relevance of adaptation to climate change, the scientific community as well as the government has paid more attention to this issue in recent years. General concepts and approaches for adaptive planning were introduced (e.g., Füssel 2007) and analyzed with regard to regional possibilities for and limitations of climate change adaptation (e.g., Kabat et al. 2005; de Bruin et al. 2009). Adaptation strategies were compared among different regions and river basins (e.g., Krysanova et al. 2010) as well as their recent status in adaptation planning (e.g., Huntjens et al. 2010). Most studies agreed that adaptation needs to be at a regional scale (e.g., Wesselink et al. 2009) and consider different issues (de Bruin et al. 2009; Veraart et al. 2010) such as nature protection, agriculture, economic development, and water management. Water management is of particular importance in coastal environments (Woltjer and Al 2007; Wesselink et al. 2009; Veraart et al. 2010).

Nevertheless the question remains still open how to organize such an adaptation process at the regional scale. Considering the importance of water management in coastal environments, climate adaptation is required to be in accordance with the European Water Framework Directive (EC 2000), an Integrated Coastal Zone Management (EC 2002, 2013), and the European Flood Risk Management Directive (EC 2007). These EC documents emphasize an intense involvement of stakeholders in terms of participation and collaborative planning of management plans. Guiding principles are required to efficiently organize the regional adaptation process based on practical experience. At present, a gap between the mostly well-figured out adaptation plans at a national level and the implementation in the regional and local development plans can be observed in the North Sea countries. In addition, current regional and local development plans often do not consider the effectiveness of planned measures with respect to climate change (adaptation). Such experiences have been collected in the framework of the Interreg IVB North Sea Region Program project "Climate Proof Areas" (CPA) which focused on climate adaptation on a regional level in a number of pilot areas in four North Sea countries (Germany, the Netherlands, Sweden, the UK). Based on the experiences from twelve pilot studies, an *adaptation toolkit* has been developed as well as a collection of *recommendations* and *guiding principles* for regional adaptation, based on good practice examples. Such guiding principles consider typical challenges of climate adaptation such as low sense of urgency, high degree of uncertainty regarding future development, and decision-making on a long term.

While it is not feasible to develop a "cookbook" for regional climate change adaptation, the *adaptation toolkit*, *recommendations*, and *guiding principles* consider the limiting factors of adaptation processes and aim at achieving consensus of as many actors as possible on the basis of the best available knowledge and experience.

This chapter is structured in order to (1) briefly introduce the pilot studies, (2) characterize regional climate adaptation along coastlines, (3) highlight some adaptation-specific lessons learned from the pilot studies, (4) introduce the main elements of the adaptation toolkit, and (5) finally derive recommendations and draw conclusions about how certain approaches and policies at different levels can contribute to successful climate adaptation in coastal regions.

Pilot Studies

Within the CPA project a number of pilot studies provided information and experience relevant for regional climate adaptation (Adriaanse et al. 2011). The case areas were located in four countries: Germany, the Netherlands, Sweden, and the UK (Fig. 1).

Case Area in Germany

The German case area within the CPA project was the Wesermarsch County in the north of the country, near the North Sea. A regional analysis of climate change-induced hydrological impacts served as basis for participatory problem analysis and the development of adaptation options (Bormann et al. 2009, 2012). Pilot studies and activities within this area concentrated on both rural and urban areas. Within the rural areas, attention was paid to climate change issues concerning the water management system, salt intrusion, and the drainage function for the low-lying hinterland, taking into account the consequences for agriculture, safety against flooding, and nature protection. Another important issue was coastal defense, because of the long dikes which surround the area and the possible consequences of sea level rise and higher flooding of the Weser River. For the urban areas of the county, different focus issues were identified. There, the connection was made with spatial planning solutions and possible investments in waterworks. Solutions for increasing water storage in urban areas were identified as well as interactions between the urban areas and rural hinterlands (Ahlhorn et al. 2011). Regarding both urban and rural areas, attention was also paid to the possible consequences of higher precipitation in the future and possible technical and planning solutions for increasing water storage capacity.

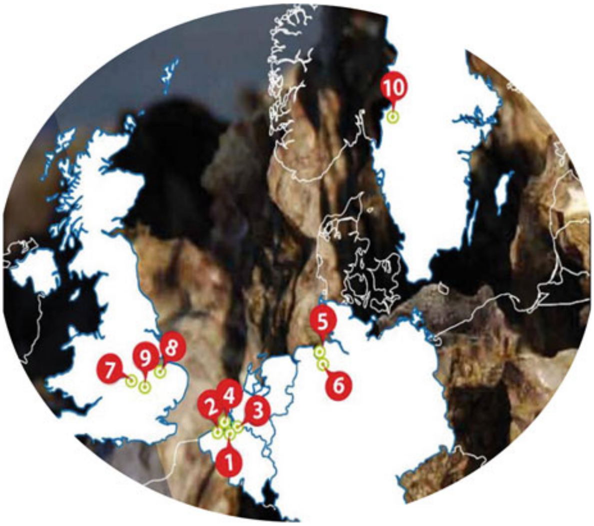

Fig. 1 Location of the pilot areas across the North Sea region

Case Areas in the Netherlands

Schouwen-Duiveland: The island of Schouwen-Duiveland is completely surrounded by dikes and dunes and connected to some of the main Dutch Deltaworks. It was used to study and demonstrate different potential solutions for climate adaptation in practice. A broad regional climate impact analysis provided the basis for a number of follow-up studies and projects within the area. Particular attention was paid to the adaptation of local agriculture to saltwater intrusion and changing freshwater supplies, new approaches for spatial planning and flood safety management, and new combinations of coastal defense, urban development, and cultural heritage.

Oosterschelde (Eastern Scheldt): Since the creation of the Oosterschelde storm surge barrier for coastal defense purpose, the ecological balance of most of the inhabited areas surrounding the estuary has been disturbed. Due to the altered tidal characteristics, the current area of sand flats within the estuary is becoming gradually smaller year by year. Climate change will accelerate this process due to sea level rise. As a result the unique ecological features of the Oosterschelde estuary will disappear until the end of the twenty-first century. To impede this process a number of experiments and pilot projects were executed within the area, such as sand nourishment and the creation of shellfish reefs.

Case Area in Sweden

The Swedish case area within the CPA project was located in the municipality of Arvika, located near Lake Glasfjorden. The area and its surroundings have been identified as an area particularly at risk to flooding as a result of climate change. The water level adjacent to Arvika is partly dependent on the water level of the lake and the water flow of the river Byälven. In Arvika there have been damaging floods (e.g., year 2000). Scenario-based impact studies revealed that climate change will have an impact on the long-term behavior of inflow patterns into the lake, impacting flood risk. Climate change is expected to result in more frequent and severe events, unless proactive steps are taken. The CPA project has analyzed the possible impacts of climate change and identified the consequences for the local infrastructure and storm water drainage systems (Olsson et al. 2013). To cope with future events, a number of physical adaptation solutions have been designed, and implementation has been guided within the CPA project.

Case Areas in the UK

Wicken Fen: Wicken Fen is one of the most important low-lying wetlands in Europe. Below sea level, it is also one of only a few surviving unimproved wetland fens in the East of England. The CPA project has contributed to create a vital green lung and a recreational resource for the nearby highly urbanized growth area of Cambridge. The innovative activities at Wicken Fen not only prepare this vitally important natural site for climate change, but it also makes the area more attractive for tourism and recreation. CPA activities contributed to four major challenges: creating new wetland mosaic habitats, developing water management plans, gaining a clear understanding of the potential of topography and re-wetting peat soils to reduce carbon loss from soil oxidation.

Titchwell Marsh: This pilot project dealt with raising awareness of the need for innovative forms of flood defense as part of adaptation to the impacts of climate change. By raising public awareness and understanding of the issues surrounding climate change and its impacts on coastlines, the CPA project supported the Titchwell Marsh Coastal Change Project. CPA has contributed to educate the public and stakeholders about the necessity of innovative flood management techniques. The main focus has been on communication issues and the construction of an innovative visitor hide, providing a fantastic opportunity for the reserves 80,000 visitors a year to see a managed realignment scheme at first hand and experience how the habitat develops over time. The Coastal Change Project plans to move parts of the present sea defenses, improving it in other areas, allowing the sea to reclaim some land, while protecting the freshwater habitats.

Great Fen: This project created an opportunity to reconnect and buffer two National Nature Reserves, providing a solution to flood risk problems to protect surrounding farmland and property, stop the loss of carbon to the atmosphere, and sequester carbon from it. With regard to these issues, this project anticipated effects of climate change and ensures that the wider area as a whole is climate proof on the long term. The pilot studies and activities concentrated on understanding flood risks, sustainable water resource management, and conservation of the heritage and natural resources. Attention was also paid to a planning framework that supports tourism and the economy.

More detailed information on the pilot projects with CPA is available at www.climateproofareas.eu.

Characteristics of Regional Climate Adaptation

The CPA project was connected to a cross section of a wide variety of projects, initiatives, studies, and stakeholder processes aiming at climate adaptation in a region or area (Adriaanse et al. 2011). Based on the outcomes and experiences of these activities, a number of specific issues can be summarized that are characteristic for regional climate adaptation in general and specific for coastal environments.

"Typical" Climate Impacts in Coastal Regions

In coastal regions the most relevant impacts of climate change are related to the following issues:

- Coastal defense and flood safety structures are primary elements to protect coastal areas against floods, in particular with regard to built-up and inhabited areas, but also rural. Increasing flood risks caused by climate change is related to the expected sea level rise, higher precipitation, higher river discharges, and in some areas ground subsidence. Already today waterlogging is a big problem in built-up and rural areas due to increasing precipitation, heavy peak showers, and groundwater flow, making enhanced drainage infrastructure necessary.
- Natural areas and ecological balance of coastal areas are of high value. Large protected areas have been established, aiming at the conservation of wetlands, tidal areas, and estuaries. A complexity of changes within climate, water management, and land use will cause increasing hazards for nature conservation areas and valuable ecological systems.
- Smart water management is essential for agriculture. Coastal soils are very productive at tidal coasts; therefore, agriculture is of high societal importance. Due to climate change and current water management, there is an increasing probability of droughts and ongoing salt intrusion in regional surface and groundwater systems. Increased effort will be required to maintain freshwater supplies for agriculture and, in some cases, drinking water as well (Faneca Sanchez et al. 2012).
- From the perspective of the tourism industry, coastal regions are highly attractive. Climate change will bring threats and opportunities for leisure and tourism. Expected rising temperatures and changing precipitation patterns will influence leisure and tourism. Investment programs in coastal defenses and improvement of nature reserves can offer new opportunities.

Although climate change studies often refer also to increasing heat stress in cities, this has not been identified as a relevant issue within the CPA case areas, probably because of the absence of larger towns within these cases and the proximity of nearby "cooling" seashores.

Many climate change impacts deal with water issues that have an influence on local and regional land use (e.g., Woltjer and Al 2007; Veraart et al. 2010). Therefore, in most coastal regions climate change has serious consequences for current water management strategies and spatial planning on a local and regional scale. Combinations of land use and water management, or multiple land use options, require additional attention, e.g., combinations of coastal defense with urban development or water storage in combination with improving ecological balance, nature conservation, and supporting tourism.

Decision-Making on a (Very) Long Term

Climate change will happen very gradually during the twenty-first century. As a result, climate proofing is a process that will continue in the long term. This must be remembered when taking measures for current problems at hand. It is vital that decisions made in the short term do not reduce adaptive capacity in the long term.

Interaction Between Different Scales

Climate adaptation must accommodate interactions between local, regional, national, and international scales. First of all, climate change is a worldwide challenge, but the impacts (and how these are perceived) are different for different countries, regions, or local areas (Verhofstede et al. 2011). It is also perceived that the coordination of climate (change) adaptation strategies between different policy levels is often inadequate, including a lack of bottom-up and upscaling mechanisms. Measures, solutions, and regulations on the international and national scales may affect the regional scale and vice versa. Additionally, measures taken in one area can affect another area. Therefore, more detailed site-specific information and data is required than what is actually available on global and national scale.

Uncertainties Due to (the Sum of) Incremental Deviations

An almost inherent aspect of climate adaptation is the uncertainty that comes with the predictions and scenarios for the future. This is not only the case for climate scenarios but also for the socioeconomic development and the (un)foreseeable changes in the views of the involved parties. *What may be a problem today, doesn't necessarily have to be a problem in 2050 or even 2100*. Especially on the regional and local scale, there is often a lack of relevant scenarios regarding climate change impacts as well as future socioeconomic development.

In order to be able to deal with the uncertainties on the long term, the Dutch Delta program has introduced the principle of adaptive delta management. Key elements in adaptive delta management are (http://deltacommissaris.nl/english/topics/adaptive_deltamanagement):

- Linking short-term decisions to long-term issues in the fields of water safety and the freshwater supply
- Adopting a flexible approach in the possible solutions
- Working with several strategies and allowing for switches (adaptation tracks)
- Interlinking various investment agendas

Weak Commitment and Low Sense of Urgency

Climate change is a slow process. Therefore in many cases the sense of urgency is still low, especially at the regional and local level. Consequently, climate adaptation is often perceived as an abstract challenge resulting in little commitment from parties to actively participate in the process of climate proofing. The initially unstructured, multilevel, and multi-sectoral character of climate adaptation makes it difficult to identify which parties or stakeholders should be committed or responsible and to set widely agreed deadlines on decision-making. The necessity to develop and maintain consistent strategies

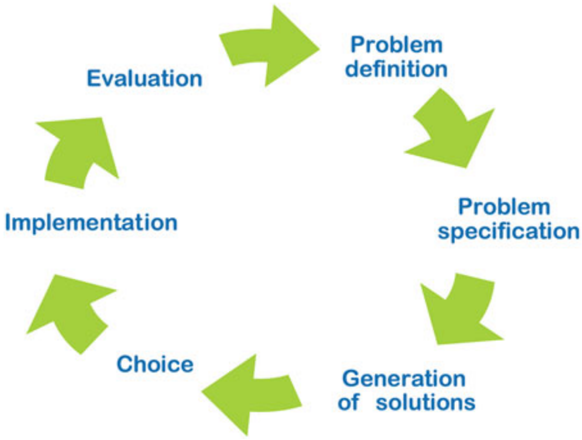

Fig. 2 Elements of the problem-solving cycle (Changed after Bots 1997; Simon 1977)

and to implement disputable measures also requires commitment from decision makers on higher levels within organizations.

Process Rather than a Number of Projects

Climate adaptation policy has to cover the gap between long-term effects and short-term decision-making. Therefore, and because of the often unstructured, multi-sectoral, and multilevel character and the possible involvement of many different stakeholders, climate proofing has to be considered as a process rather than a sequence of projects. In most cases the different phases of this climate proofing process are aligned with a "traditional" problem-solving cycle (problem definition, problem specification, generation of solutions, choice, implementation, evaluation, and back again to problem definition; Fig. 2) that is often referred to form the perspective of policy processes. While climate proofing does not tend to follow straight paths through the different phases of this cycle, the distinct phases can very well serve as a framework to describe the process and practices connected to it.

Lessons Learned from Pilot Studies

Emerging from the pilot cases and studies within the CPA project (Adriaanse et al. 2011), a number of practices and measures were identified as being potentially successful in contributing to regional climate adaptation. These can be tools, methods, physical measures, or any kind of practices that deal with one or more of the characteristics of regional climate proofing as part of the problem-solving cycle. They served as good practice examples for the development of the "adaptation toolkit for the North Sea Region in a changing climate" (van Oostrom et al. 2011) developed in the framework of CPA.

Physical Measures and (Physical) Planning Solutions

The CPA project paid attention to a large variety of possible concrete physical and planning solutions, connected to the "typical" climate impacts as presented in the previous section. Although not every solution is already implemented, the following examples illustrate the character of the different contributions to climate change adaptation. They are structured with regard to some of the main climate adaptation-related challenges on coastal regions: (1) coastal defense and flood safety, (2) water management, (3) nature protection, (4) agriculture, and (5) tourism.

With regard to *coastal defense and flood safety*, the different pilot studies suggested a wide spectrum of measures including removable storm surge barriers (Arvika); realignments of coastal defenses connected to habitat development (Titchwell Marsh); sand nourishment; creation of shellfish reefs and "hanging beaches," also connected to habitat development (Oosterschelde former estuary); multifunctional sea defenses combining flood safety with urban reconstruction, cultural heritage, and nature conservation (Schouwen-Duiveland); regional strategies for so-called multilayer safety where land use characteristics and infrastructure become part of regional flood safety and related emergency facilities (Schouwen-Duiveland); and strengthening of the existing canal system and secondary embankments near and within urban areas (Wesermarsch). Some of these measures follow the current code of practice, but some are innovative and contribute to several targets of regional development.

With regard to water retention and management, suggested measures were to promote "green" roofs for temporary water storage in urban areas (Wesermarsch), temporary water storage in areas characterized by low damage potential in urban areas (e.g., ponds, parking areas, public parks) and polders in the rural surroundings (Wesermarsch), and the climate proof development of public sewage and drainage systems as well as private pipelines (Arvika).

With regard to *ecological balance and nature conservation*, a number of measures were suggested in combination with structures designed for coastal defense and flood safety (Oosterschelde; see above). Alternative solutions were creating new wetland mosaic habitats, developing water management plans, and re-wetting peat soils to reduce carbon loss from soil oxidation (Wicken Fen, Great Fen).

With regard to a*griculture and water supply*, measures included adapting agricultural land use to changing hydrological conditions and water management targets (Wesermarsch). Additionally, a study was conducted to adapt crops to increasing salinity, e.g., salt-tolerant potatoes (Schouwen-Duiveland). Two pilot studies aimed to improve water management by enlarging freshwater lenses above saline groundwater (Schouwen-Duiveland, Wesermarsch) and one by the exchange of water supplies between individual farms and areas with different water system characteristics (Schouwen-Duiveland).

Selected pilots suggested measures with regard to *leisure and tourism*. Synergies of nature protection and nature watching could be generated by the construction of recreational resources and a unique visitors' hide near attractive natural sites that are prepared for climate adaptation (Wicken Fen, Titchwell Marsh, Great Fen). In Schouwen-Duiveland, designs for sea defenses, in combination with urban redevelopment, new leisure zones and the reconstruction of cultural heritage were developed.

Knowledge-Oriented Practices

The measures mentioned above serve as good practice examples but cannot be implemented adequately without regional scale information on climate change impacts. Therefore, every CPA pilot area undertook a regional climate impact analysis, consisting of the following components:

- Translation of existing international or national climate scenarios to *regional climate scenarios* by dynamic or statistical downscaling techniques
- Model- and fact-based quantitative analyses of *climate change impacts* on physical (e.g., hydrology) and biological processes (e.g., ecology)
- Translation of expected regional *climate change impacts* on different economic sectors and land uses

For a more realistic assessment of the possible impacts of long-term climate change, analyses should also consider views on long-term socioeconomic development. Since such information often is not available on regional scale, available information from international (e.g., European Union) or national scenarios can be downscaled to the regional level. Another approach is to use the regional climate impact assessment as a starting point for developing regional long-term visions. These visions can partly be guided by conditioning national and European programs, policies, and regulations. Relevant examples are the Dutch national Delta Program (regarding flood safety and water supply), the EU Water Framework Directive, EU Floods Directive, and EU Bird and Habitat Directives.

In order to boost the regional climate adaptation process, an inventory of relevant national and European programs, policies, and regulations is recommended.

Process-Oriented Practices and Approaches

For a proper implementation of adaptation measures, in addition to physical- and knowledge-oriented practices, process-oriented practices and approaches are required. Such measures aim to involve communities and relevant stakeholders from the region. Practices and approaches are required in order to organize the adaptation process and to maximize the acceptance of the measures among those affected.

Participation is one of the main issues for successful climate adaptation. Involving different stakeholders such as decision makers, entrepreneurs, and the public is necessary to raise awareness, to achieve consensus, and to retrieve information to accelerate the implementation as well as to increase the acceptance of solutions. Based on the experience of the CPA pilots, the following good practice activities can be recommended in the field of process organization:

- A *communications plan* should be developed early on in order to inform all relevant participants. Within the Titchwell Marsh and Schouwen-Duiveland cases, communication strategies were established and successfully implemented. A communication plan provides for a structured process, ensuring that all relevant stakeholders have the opportunity to engage with the project. It clarifies key messages for each audience. This involves, for example, newsletters, press contacts, participation in events, targeted meetings, posters, brochures, maps, reports, and even museum expositions.
- *Organizing stakeholder involvement* is essential for the development of a joint vision and raising acceptance of the adaptation process. This was achieved in the CPA pilot projects through a variety of forms, e.g., regional fora and focus groups (Wesermarsch), public drop-in sessions (UK), and bilateral and multilateral meetings, workshops, and events. Special attention should be dedicated to the involvement of the private sector to better utilize local and regional knowledge and their innovative capacity for the climate adaptation process.
- *School projects* can help increase awareness of climate change issues. The involvement of scholars and students in the development of adaptation options in the Schouwen-Duiveland pilot project proved to be successful for creating awareness. Scholars themselves are future stakeholders in their region, and they spread awareness through their networks and parents as well as other stakeholders involved. As part of the pilot project, they developed innovative solution based on new and unexpected views.
- A tool which can contribute to active participation of stakeholders is a *matrix-based decision support* tool. Such a tool has been developed in Sweden and provides a checklist for monitoring complex integrated processes and a methodology to stimulate discussion among stakeholders about crucial items (Andersson-Sköld et al. 2011). It facilitates the identification of potential measures and land use consequences from short- as well as long-term perspectives. It contributes to a more transparent decision-making process, allowing different stakeholders to give weights to various consequences and actions. Alternatively, a *participatory integrative assessment* can be applied following Ahlhorn (2009).
- As mentioned above, climate adaptation can be characterized by a long-term perspective and a low sense of urgency. To overcome this obstacle and accelerate the process, climate adaptation can be *connected to local problems and initiatives*. One of the strongest approaches to achieve commitment for climate adaptation proved to be the connection to current regional problems, projects, and initiatives in which stakeholders are already involved. Examples are flood mitigation programs, initiatives on urban (re-)development, or ecological habitat improvement programs. Beyond this, currently experienced climate impacts (e.g., within the agricultural sector) can function as a good starting point for climate proofing activities.
- Often, regions or countries are known for their expertise in a specific field of action (e.g., Dutch water and dike boards for their innovative sea defense and water management systems). *Cross-national exchange* between climate adaptation projects can transfer knowledge and experiences to other regions.

During the CPA project there have been several exchanges of experience between the different project areas. Project members from different countries acted as so-called Community of Practice, exchanging experiences and information by means of excursions, project meetings, and mutual presentations. These have been valuable in contributing to the solution of pilot project-related problems and served as a catalyst for successful progress.
- Finally, specific attention can be paid to more *strategic local and regional policy making*, which has been accomplished, for example, in Schouwen-Duiveland by getting connected to the municipal strategic vision for 2040.

Adaptation Toolkit: Towards Regional Climate Adaptation

Analyzing the experiences from the CPA project in terms of successfully applied practices and approaches, it appears meaningful to structure the good practice examples in terms of assigning them to the different phases of the *problem-solving cycle*. Thus, a more generic approach for regional climate adaptation in coastal areas can be outlined, as realized as part of the *Adaptation toolkit towards regional climate adaptation* developed with the CPA project (van Oostrom et al. 2011). This will be illustrated by a number of recommendations and specific issues attached to different phases of the problem-solving cycle.

Problem Definition

First of all, regions should be encouraged to undertake regional climate adaptation initiatives. Climate change is an important issue worldwide, and the regional level provides challenging opportunities to link this issue to different sectors and regional land use planning from an integrative perspective. Assuming there is enough awareness among stakeholders, they are able to form a regional alliance (see, e.g., Goltemann and Marengwa 2012) and initiate a climate proofing process. Stakeholders need to be integrated in the climate proofing process from the beginning.

Problem Specification

In most cases it is recommended to undertake a regional climate impact analysis, including the items as listed in the previous section. This analysis should have regard to the abovementioned climate impacts issues that are particular for coastal regions. Stakeholders representing different sectors have to be involved in the regional analysis. Modeling and the development of (long-term) scenarios is needed to understand the range of possible effects, especially at local and regional scales. Therefore, more detailed site-specific information and data is required than what is actually available on global and national scale. Timescales need to be adjusted to planning periods in order to facilitate the development of no-regret (or at least low-regret) adaptation options.

Generation of Solutions

The CPA project showed that pilot projects can generate a large number of possible options to adapt to the identified climate impacts. In order to raise acceptance (in subsequent phases), it is recommended to involve stakeholders also in this phase of the process. CPA itself was a valuable knowledge base for climate proofing activities in other regions. It is recommended that accessible and clustered information platforms on regional, national, and EU levels are created in order to share experience.

It is a challenge to create consistent and comprehensive regional adaptation strategies, especially those involving both physical and socioeconomic actions. Regional and local knowledge and the innovative capacity of the private sector should be harnessed at the earliest opportunity to better ensure the success of solutions chosen.

Choice of the Best Solution

Regional and local administrations must embed climate adaptation within decision-making processes with regard to any plans, policies, and land use programs that might affect the ability of a region to adapt to climate change in the future. It is therefore essential to integrate climate impact assessment into formal processes such as the environmental impact assessment (EIA).

Whether chosen solutions are successful or not depends on the future development of a region. Therefore, before choosing adaptation solutions, decision makers should agree on a common vision for the region, having involved stakeholders and the public. Adaptation solutions that match the vision should have broader acceptance and accelerate the implementation process.

Finally, adaptation strategies should aim to add value. Socioeconomic and environmental benefits should be identified and considered together in order to generate no-regret solutions and should aim for win-win outcomes.

Implementation of the Selected Solution

Climate adaptation can be accelerated by creating so-called windows of opportunity. Thus, climate adaptation should be delivered through ongoing plans and projects in different sectors. Climate adaptation should make use of the climate and weather impacts already experienced by stakeholders. Awareness of today’s climate variability can be very valuable when linking the assessment of possible impacts of climate change in the future to more strategic local and regional policy making. Current weather impacts can be used during the problem specification phase to contribute to analysis and solutions generation.

Evaluation of the Adaptation Process

Climate proofing projects and processes can play an important role in "learning by doing." The results and experiences should be monitored and evaluated and contribute to new projects and initiatives. In this respect it is particularly important to inform the public on experiences and successes. Adaptation is a continuous process, and successful implementation does not mean the future is secure. When further action is needed, at least one stakeholder should take the coordinating role and restart the process.

Recommendations for Regional Scale Climate Adaptation

Some general recommendations can be given in order to optimize the regional climate adaptation process.

- While climate proofing has to be considered as a process rather than a project, a clear *process management* (and process manager) is required, including a *process plan*. The role, position, and responsibilities of different stakeholders, often from different sectors or administration levels, have to be clear and agreed.
- Through all stages of the process, *participation of stakeholders* is a major issue. There are different ways available to facilitate this. Several examples are mentioned in the previous sections (e.g., regional fora, workshops, exhibitions).
- From the beginning of the climate proofing process, *communication and awareness raising* is crucial, especially because climate change is often still perceived as an abstract problem. A communication strategy is a necessity.
- Organization of *cross-regional and cross-national exchange* between climate proofing areas and projects is recommended. This can be very valuable to achieve progress and to improve the quality of analyses, methodologies, solutions, knowledge, and information sharing.

Although most climate adaptation activities are – or will be – undertaken at national, regional, or local level, these can be supported and strengthened by an integrated and coordinated approach at EU level (Com 2009). This is one of the main reasons why the CPA project has been executed under the umbrella of the EU Interreg IVB North Sea Region Program. In connection with the experiences and results from the CPA project, we conclude with a couple of perspectives on European support for regional climate adaptation in coastal areas.

Research

The complexity of climate proofing processes and climate impact analyses requires coordinated and continued research on a number of subjects that are relevant for all regions involved. The CPA project did not generate a research agenda but identified the following issues as illustrative:

- Water and groundwater management under a changing climate must be linked to the framework of national and EU regulations (e.g., Water Framework Directive, Groundwater Directive, Flood Directive, proposed Soil Framework Directive). Although climate change is already implicitly considered, a more explicit consideration is required.
- Management of freshwater supply and (innovative) food production must take care of changing climate conditions. Droughts, waterlogging, and salt intrusion may have severe impacts which might be compensated by innovative drainage systems, fish and seaweed farms, or salt-tolerant agricultural crops (e.g., potatoes).
- Flood risk management has to cope with climate change. The EU Flood Directive has to be connected with climate impacts.
- Climate and socioeconomic scenario development, alignment, and application are necessary to understand and illustrate the potential impacts of climate change. Uncertainties in the science, long-term developments, and working at different temporal and spatial scales make scenario development challenging.
- Governance issues should be applied to regional climate adaptation processes. Stakeholder involvement, cross-sectoral and cross-level cooperation, institutional and planning frameworks, as well as cooperation with the private sector and communication are relevant issues in this respect.

Exchange of Knowledge and Information

Cross-national and cross-regional exchanges between climate proofing pilot areas and projects proved to be very valuable and stimulating in terms of regional climate adaptation. The North Sea Region (NSR) and EU can support these exchanges in many ways, e.g., by the connection to research programs, conferences, and communities of practice and the creation or strengthening of dedicated platforms (e.g., climate-adapt.eea.europa.eu). In addition, the ongoing improvement of information and expert databases or web portals at EU level will contribute to these exchanges (e.g., www.wiser.eu). In this respect it is important that these facilities are promoted, easily accessible, and harmonized as far as necessary. The EU and regional stakeholders should cooperate more to connect regional climate proofing programs to enduring national and international climate research programs.

Policy and Regulations

An important recommendation from the CPA project is that a new systematic tool should be developed which can help “insert” climate adaptation into decision-making. Therefore, a so-called Climate Adaptation Pre-Assessment (CAPrA) should be developed. This should focus on the development and application of climate adaptation criteria within relevant plans and decision-making processes, according to and based on the spirit of a *Strategic Environmental Assessment* (SEA). This is in line with the EU Impact Assessment Guidelines, stating that for any relevant planning option, it should be identified if it affects our ability to adapt to climate change.

European regulations and their translation into national policy frameworks play an important role defining roles and boundaries for climate adaptation at the regional scale. It is therefore important to incorporate climate adaptation strategies in relevant European policies and regulations and to align them with different administration levels in countries and regions. The CPA project has focused less on this issue. Within the different pilots, projects, and analyses, the following relevant directives and policies have been referred to Bird and Habitat Directives (and Natura 2000), Water Framework Directive (and the related Groundwater Directive), EU Flood Directive, Soil Framework Directive (proposed), and the Common Agricultural Policy. Connected with the previously mentioned characteristic climate impacts in coastal areas, in most cases these policies and regulations should be taken into account in climate proofing projects.

Investment Programs

Most of the presented supportive activities can be connected to ongoing EU investment programs regarding research, regional and economic development, or infrastructure. On the other hand, regional authorities and stakeholders should continuously and in a coordinated way specify their needs and present promising strategies in order for relevant EU programs and networks to take them into account.

Finally, a number of specific remarks can be added regarding European support for regional climate adaptation:

- The EU and the NSR play an important role in raising awareness on climate change and climate adaptation. Keeping adaptation on the agenda, creating easy access to information and knowledge and connecting this to all relevant EU-programs will contribute to continued awareness on different stakeholder levels.
- (Inter-)National cooperation between regions can address how to handle differences in regional or local vulnerability to climate change and how to learn from experiences.
- For relevant programs and activities, closer connections with the mitigation domain (regarding CO_2 policy and regulations, renewable energy programs) can possibly strengthen the achievements in the adaptation domain, especially because of the extensive involvement of the EU in mitigation.

Conclusion

Since climate change will affect coastal regions, it is necessary to foster climate (change) adaptation at different spatiotemporal scales. This should mutually be done from an integrated perspective and be embedded in current projects, initiatives, and policies. The regional level is a very appropriate scale in which to link climate adaptation with different sectors and land use planning. The CPA project provided various ideas and experiences to deal with “typical” climate impacts in coastal regions such as higher flood risk, waterlogging, droughts, salinization, ecological disturbance, and freshwater supply for agriculture. Furthermore, the project suggested a more generic approach to guide regional climate adaptation in coastal areas. However, regional climate adaptation is not yet common practice. It is a long and continuous process that requires close coordination between regional, national, and international levels. At EU level, this can be supported by an integrated and coordinated approach regarding research, exchange of knowledge and information, and mainstreaming of policies and regulations and investment programs. At national level, financial and organizational boundary conditions for climate adaptation are set. But at regional level, tailor-made solutions need to be developed and implemented. The tools and approaches presented in this chapter cannot guarantee a successful climate adaptation. Decisions must be made under uncertainty (e.g., with regard to scenario projections), and decisions are made by people often thinking in timescales of elections, investments, or life span of measures rather than of decadal or centennial visions. No-regret solutions and win-win outcomes will not be available in every case. However, the presented tools and approaches can significantly contribute to a successful adaptation process at regional scale since they aim at increasing integration and acceptance of climate change adaptation measures by identifying joint targets and by involving people. In accordance with Integrated Water Resources Management and Integrative Coastal Zone Management, feedback loops will increase the efficiency of adaptation through learning from successes and mistakes and considering information and knowledge gathered meanwhile.

Acknowledgment The authors thank the European Union for their partial funding of the “Climate Proof Areas” project in the framework of the Interreg IV B North Sea Region program.

Abstract

In the latter half of the twentieth century, an increase in the rate of retreat has been observed in Himalayan glaciers since the advent of industrialization. This chapter attempts to present a critical review and understanding of the recent changes in retreat of selected Himalayan glaciers from climate change and implications for adaptation. The chapter is of great significance to local and regional adaptation planners and local decision makers for communities, ecosystem, and sustainable energy planning. The study discusses the different methods of monitoring changes in Himalayan glaciers; explores scientific evidence and analysis of available data from the glaciers in the Himalayas, from a climate change perspective; and suggests an action plan for future freshwater resource needs downstream.

The data represent fluctuations and varied responses of glaciers of Indian Himalayas towards changes being encountered globally. The longest data series of mass balance available for Shaune Garang glacier does not indicate any generalized trend of mass balance in the region. The analysis of snout retreat in comparison to area of the glacier does not give any information about any relationship between snout fluctuations and area of a glacier. The snout retreat analyzed on regional basis also lack of showing any clear trend of retreat/advance for a particular region. Thus to understand this kind of interrelationship, the influence of microclimatic parameters is required for which there is a lack of data availability. Future efforts in building the resilience of the local community and the ecosystems should take into account a concerted and integrated approach.

Keywords

Himalayan glaciers • Climate change • Water resources • Communities • Power sector • Snout retreat • Glacier mass balance

Introduction

Over the last few decades, changes in climate and local weather conditions have impacted the world's glaciers both in terms of structure and characteristics, reflected in the form of advancement or retreat of glaciers (IPCC 2007; UNEP 2007). The changes in the length, width, area, volume, and mass balance of the glaciers are among the most directly visible signals of global warming, and these changes are the primary reasons for utilizing the glacial observations in climate system monitoring for many years (Haeberli 1990; Wood 1990). These information are useful in areas where time series data on climate (mainly temperature and precipitation) is difficult to get and climate change signals are not yet clear (Yadav et al. 2004; Roy and Balling 2005). Thirty reference glaciers that have been studied in detail since 1975 show an average annual mass loss of 0.58 meters (m) water equivalent in the past decade, which is four times the rate for the period 1976–1985 (UNEP 2007). Hence these unnatural rates of glacial melting can have serious implications on the hydrology of the associated river systems and consequently on the livelihoods of millions of people who are dependent on these rivers and their ecosystems (Stern 2007). Over exploitation of water resources and changes in hydrological cycle could be vital to future developmental strategies of the fertile belt of northern India where agricultural productivity, irrigation, drinking water, and water for industrial use are to a large extent dependent on availability of freshwater resources.

The changing climate is resulting into extremes of temperature and precipitation which impacts negatively by decreasing the seasonal and perennial snow and ice extent (Karl and Trenberth 2003) that further leads to the glacier retreat. Glaciers are retreating in almost every part of the world including in the Alps, Himalayas, Andes, Rockies, Alaska, Africa, and Antarctica (Venteris 1999; Maisch 2000; Barnett et al. 2005; Kaser et al. 2010; Mernild et al. 2011; Venkataraman et al. 2012).

The Himalayas have the highest number of glaciers and snowfields after polar regions (Radic et al. 2013) and is also called as third pole. Most of this snow cover melts away by the end of May (Kulkarni 2010) providing water in their respective catchments. The recent observations through satellite imagery analysis suggest that Himalayan range has about 15,000 glaciers with glacier and ice-covered area of 33,340 km^2 and a total ice reserve of 3,735 km^3 (Bajracharya et al. 2007). In line with the global trends, the Himalayan glaciers and snow cover have also been thinning since the end of the nineteenth century. With significant snout fluctuations, most of the glaciers in the Himalayan mountain ranges have been retreating at accelerated rates in the last three decades, and their rate of retreat is much faster than that of the glaciers in other parts of the world (Parry et al. 2007). In various research studies, it has been found that Himalayan glaciers are retreating in general (Barry 1990; Stone 1992; Shrestha et al. 1999; Barnett et al. 2005; Schmidt and Nüsser 2012) with few exceptions (Bolch et al. 2012). Some more studies are also indicating higher retreating rate of glaciers in the Himalayas (Kulkarni et al. 2005; Kulkarni and Karyakarte 2014) that certainly impacts the future water availability in the associated region. An overall 13 % of glaciated area is lost in the Himalayas in the last 4–5 decades (Kulkarni and Karyakarte 2014). Glaciers of the Himalayas may lose more mass in the coming decades (Chaturvedi et al. 2014). This may affect the streamflow of rivers originating from these glaciers. Ten of the largest rivers in Asia originate from these vast mountain ranges of Hindu Kush Himalayas, flowing trans-boundary to the freshwater demands of more than a billion people living downstream (Kumar et al. 2009). Most of these rivers are perennial due to runoff from glaciers and snow significantly contributing to the flow of these rivers (Immerzeel et al. 2009). Further knowledge of future water availability through the modeling approach is of great help for the policy and planning in the region. Snow and glacier melt model has been used in different parts of the Himalayas using different modeling approach (Kulkarni et al. 2002; Singh and Jain 2003; Singh et al. 2009; Immerzeel et al. 2009; Arora et al. 2010; Ahluwalia et al. 2013).

Snow and glacier melts are one of the most important hydrological processes at these heights and even the minute changes in patterns of precipitation and temperature will seriously affect these hydrological processes. Hence, in comparison to others, these ecosystems are considered as most sensitive towards any likely changes in the climate. The impact on the riverine water system of the Himalayas is manyfold as it supports the requirement for domestic and industrial utilities, irrigation, hydropower generation, and wildlife habitat. Potential of the flow to generate hydropower especially in winter plays a key role in the continuous electricity supply. Also the additional runoff may result in flooding and soil erosion. So a precise estimation for snowmelt runoff in real time is helpful in the planning and execution of mini and micro hydel schemes (Singh et al. 2009).

Several studies, discussed above, are showing negative impact of changing climate on glaciers and snowmelt, which will ultimately affect the water storage capacity and supply in the concerned region. It is interesting to note that some of the studies have reported mass gain in glaciers from different parts of the Himalayan region including Lahaul and Spiti (Vincent et al. 2013) and Karakoram (Hewitt 2005; Bhambri et al. 2012) that raises questions on the understanding of the response of glaciers. A growing body of scientific knowledge solidly indicates that carbon concentrations are changing the global climate and that there would still be significant changes to the global climate even if emissions would drastically reduce. So effects of emissions need to be understood and added onto ongoing glaciological research for having deeper understanding of the climate impacts on critical indicators such as glaciers. This would help in developing regional climate projection models which are more accurate in providing information on future impacts.

The right approach, thus, in addressing these impacts is to have a better scientific understanding through long-term observations and analysis of the interactions of the different components of the mountain ecosystems with their climate, and then utilize this information to formulate effective adaptation and management strategies. There is also a pressing need for disaster management and rehabilitation policies in areas affected by the glacial retreat, particularly focusing on agriculture, meadows, and other livelihood support structures of the local people. The different technologies for the monitoring of snow and glaciers are discussed in next section.

Methods of Monitoring Glaciers

The glacier monitoring is being done with the different objectives, and several techniques are being used as per the requirement and feasibility of the scientific expeditions looking into harsh condition in terms of approach as well as the weather of the Himalayan terrain. Most of the glaciers were monitored at snout to know the recession/advancement in terms of their length and to understand the impact on the discharge patterns. The advent of the remote sensing tool has simplified the glacier monitoring processes for understanding the areal and length changes at larger scale and for longer duration. The only concern is the ground validation of the remotely sensed data and the resolution of the data, which has improved a lot in recent time. With the advancement of the remote sensing technologies, the accuracy became much better and intense monitoring and analysis are being done at a larger scale by different agencies/organizations. The remote sensing imageries have helped in preparing glacier inventory at different interval of time by several agencies.

These studies are still not enough for completely addressing the snow and glacier meltwater in the channels as well as the potential of the freshwater resources in the frozen form. To address the discharge, volume estimation of the snow glacier melt has to be carried out. The volume estimation of glacier melt and accumulation is being done through glacier mass balance for which several technologies are available. Different technologies are being implemented as per the expertise and suitability/feasibility in the glaciated system. The different methods for monitoring of glacier mass balance are listed below.

- Glaciological method
- Hydrological method
- Geodetic method
- Remote sensing method

Glaciological Method

The most common and effective method to assess glacier mass balance is in situ measurement of glacier for ablation and accumulation, known as glaciological method. Mass balance is defined as "the change in the mass of a glacier, or a part of it, over a period of time." The time period for which mass balance is measured is generally as per the hydrological cycle, i.e., end of two consecutive September months. Further, detailed study of accumulation and ablation measurement is done through seasonal measure of glacier mass. The mass balance is mainly influenced by the temperature variation in summer as well as the amount and timing of solid precipitation especially in winter. The mass balance of a glacier in a period of time (t) is calculated by integrating accumulation (c) and ablation (a) over total glacier surface (S).

$$B = \int b\, dS$$

$$b = c + a = \int_{t_0}^{t_i} b\, dt$$

where, $c = \int_{t_0}^{t_i} c\, dt$

$$a = \int_{t_0}^{t_i} a\, dt$$

B = mass balance; S = glacier surface; c = accumulation; a = ablation; t_0 = start of time period; t_i = end of time period; and b = cumulative mass balance over the time period t_0-t_i at a specific point on the glacier.

In situ measurement and direct glaciological methods are synonyms in this measurement process. It involves measurement of ablation and accumulation at the glacier surface by generally using bamboo stakes in ablation area and snow pits and snow probing in accumulation area. The measurements are made at various points and integrated over the entire glacier surface. The possible error in this method is mainly due to network of stakes and pits, the density assumed, as well as the date of measurements and period considered.

Geodetic Method

Cartographic method and topographic method are synonymous to geodetic method. This method refers to determination of glacier mass balance by repeated mapping of glacier surface to estimate the volumetric balance. To convert the measurements of volume change to mass change, information of density of mass loss or gain or assumption on time variation in density is required. The change in elevation with time is generally measured using repeated altimetry, photometry, or ground surveys. The major source of error is assumptions about density of firn and ice required to convert mass change to volume change.

Hydrological Method

This method refers to calculating the mass balance indirectly by solving the water balance equation and calculating the change in water storage in a glacier basin.

$$\mathrm{B} = \mathrm{P} - \mathrm{Q} - \mathrm{E} \pm \Delta\mathrm{S}$$

where B is annual hydrological mass balance, P is precipitation, Q is discharge, E is evaporation or sublimation, and ΔS is variation of storage elements of the catchment area other than glaciers such as groundwater or interception.

This method is comparatively easier but gives information about the whole basin rather the spatial distribution or gradients.

Remote Sensing Method

All earlier methods require presence in field with varying intensities of stay and approach to the glaciers. This becomes difficult in such a harsh terrain and especially if the weather condition is more inclement than the normal. Under the ruthless terrain and weather, earlier methods are difficult to be implemented on many glaciers and especially on larger glaciers. To simplify this process and increase the applicability to a large extent on many glaciers, remote sensing data and tools are being exploited. Based on the field mass balance data on a few glaciers, Kulkarni (1992) was able to introduce an interesting relationship between equilibrium line altitude (ELA), accumulation area ratio (AAR), and mass balance of a glacier. Accumulation area for each glacier usually varies from year to year and mainly depends on the snow line at the end of ablation season. The snow line monitoring has to be done on a weekly basis in the ablation season as per the availability and quality of the remotely sensed data. The WiFS and AWiFS data are being used for snow line monitoring in the Himalaya due to its receptivity of 5 days.

Studies Carried Out in Indian Himalayas

Meltwater Discharge at Different Glaciers of Indian Himalayas

Meltwater discharge is an indirect indicator of glacier health and mass balance. It is also one of the factors needed to calculate the hydrological mass balance of a glacier. It also gives information of fluctuations of glacial meltwater contribution. Apart from knowing the glacier mass balance, the discharge measurements further help modeling the future discharge. The summer (June–September) discharge data available in some part of the Indian Himalayas are presented through Fig. 1.

It is clearly evident from Fig. 1 that the glacial discharge of some of the glaciers in Indian Himalayas are recorded during the melt season (June–September). Long-term monitoring records of discharge contribution are not available to generalize in terms of changes being observed. The discharge data in the graph gives the mixed pattern in different years.

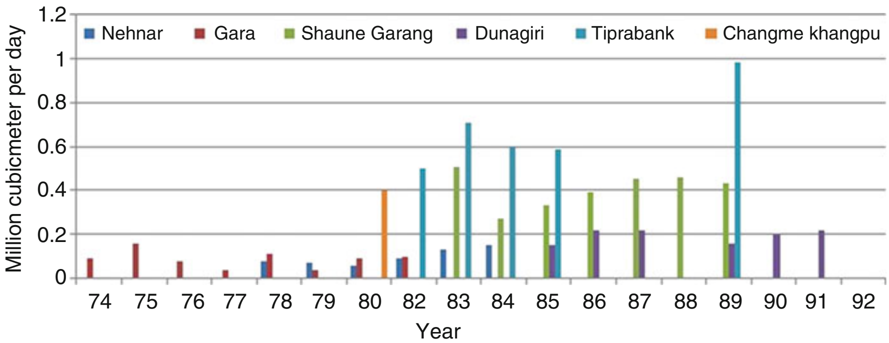

Fig. 1 Average meltwater discharge of some of the glaciers in Indian Himalayas recorded during June–September (Raina 2009)

Mass Balance Studies in Indian Himalayas

The mass balance studies in India dates back to 1974 when Geological Survey of India (GSI) started monitoring of Gara glacier for mass balance over a decade. After that, GSI and other organizations (institutions and universities) took up many more glaciers for mass balance studies. Mass balance studies are carried out using stakes (Wagnon et al. 2007; Dobhal et al. 2008), equilibrium line altitude (ELA), and accumulation area ratio (AAR) methods (Kulkarni 1992; Kulkarni et al. 2004) by satellite laser altimetry (Kääb et al. 2012) or through digital elevation model (DEM) (Berthier et al. 2007). Himalayan glaciers are showing high-mass loss except in Lahaul and Spiti (Vincent et al. 2013) and Karakoram (Hewitt 2005; Bhambri et al. 2012; Kääb et al. 2012). A summary of some of the work in Indian Himalayas carried out on mass balance is presented through Fig. 2 to understand the trend of the mass balance in this part.

The graph shows that in almost three decades of observation of different glaciers in Indian Himalayas, Gara glacier has shown positive mass balance three times and Shaune Garang and Gor Garang glaciers have shown positive mass balance twice. Apart from these few exceptions, all others have shown negative mass balance.

Studies on Glacier Length Changes

Many observations are available in the Indian Himalaya on the changes of position of glacier snout (terminus) since last several decades. It gives information of changes in glacier length but does not give much idea about overall health

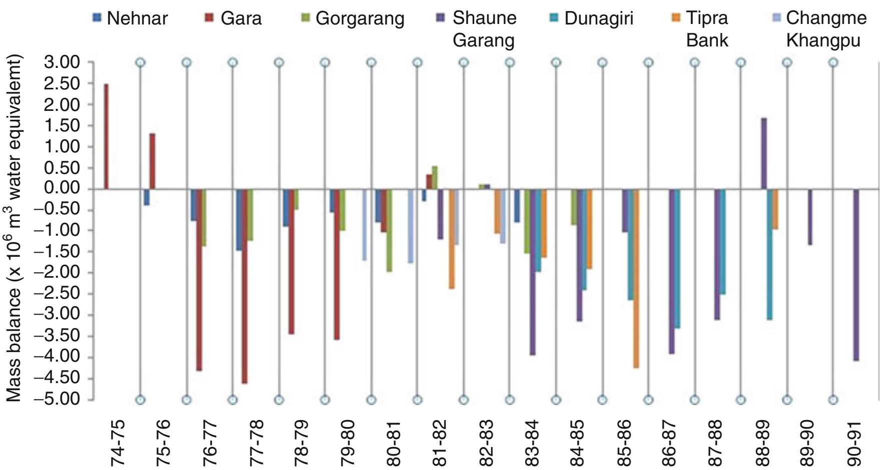

Fig. 2 Mass balance (in million cubic meters water equivalent) of glaciers of Indian Himalayas (Raina 2009)

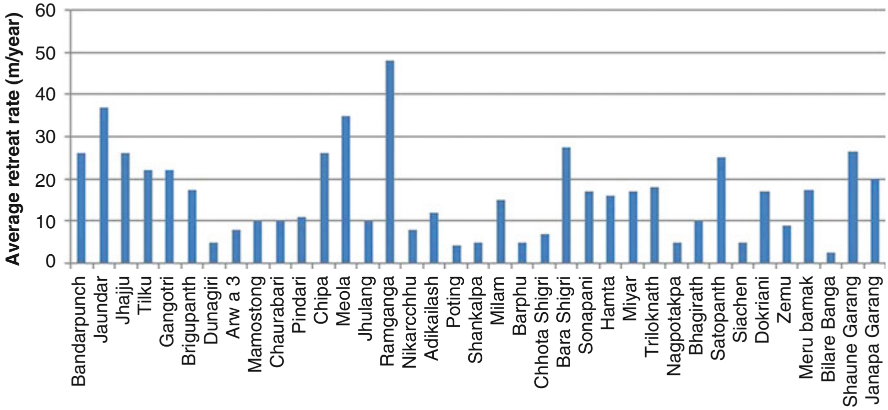

Fig. 3 Average retreat rate of glaciers in Indian Himalayas for which data for more than 20 years were used (Raina 2009; Kulkarni et al. 2005; Kumar et al. 2009; Berthier et al. 2007)

of the glaciers. Some indications of changing climate can be drawn by knowing the change in rate of retreat of the glacier's snout. The response time of glacier to react in form of snout retreat/advance depends on many factors like size of the glacier, temperature variations, and snow precipitation in the region, but the higher retreat rate in the last few decades may be related with the warming trend in the same period. Some of the results of snout retreat from the different publications are shown through Fig. 3. The observations of snout fluctuations for more than 20 years were included to calculate the average retreat/advance of the glaciers. The graph shows that almost all the glaciers are experiencing a retreat more than 5 m per year. Ramganga glacier, Uttarakhand, has been observed to have the highest retreat rate of around 45 m per year.

Issues in Sectoral Adaptation

The threat of glacial melt is likely to have serious implications on several sectors of society and livelihoods exacerbating the stress from existing developmental activities. Sectors which are likely to be affected include water, agriculture, power, and biodiversity.

Water

The supply of freshwater resources is likely to increase as perennial snow and ice volume decrease. Glacial melt runoff in Himalayan glaciers has been highest in the summer months (May–August). The changes in agriculture environments and related water resources may affect crop yields of important crops like wheat and rice in the fertile belt of the Indo-Gangetic Plains. The increased threat of extreme events – floods and droughts leading to glacial lake outburst flood (GLOF) events could threaten mountain communities as well as infrastructure projects downstream.

Agriculture

Changes in freshwater supply in the perennial rivers will affect agriculture productivity. Increases in temperature and water stress are expected to lead to decline in crop yields up to 30 % according to some studies. Changes in phenology and timing of growth due to increased surface temperatures may have a deleterious effect on local vegetation composition. This can have implications for food production and increased competition for land resources.

Biodiversity

The riparian ecosystems in the Himalayan belt comprising deciduous temperate forests are likely to be affected (including shifts in forest boundaries) due to changes in water flows under changing glacial melt. As a result of the rise in average surface temperature, the upward movement of tree line could result in changes in species composition and vegetation types. This will have direct consequences on the range and distribution of high-altitude faunal species including endemic species, some of which occur in a very narrow distributional range. Such species in alpine ecosystems are projected to shift to higher reaches, further shrinking available habitat for their survival.

Power

The perennial rivers of the Himalayan region are an important source for hydropower generation in India. The total hydropower potential of the country has been assessed at about 84,000 MW at 60 % load factor. Of these the Ganga basin has nearly 10,700 MW of hydropower potential. In the past decade, there has been renewed emphasis on exploiting the hydropower potential of such mountain river systems through development of various types of dams for hydro projects. These include run-of-the river hydropower plants which are considered as environmentally friendly by many. However changes in meltwater flows could impact energy security through lack of enough water to run a hydropower plant at full potential. The rapid development of such dams could also cause other indirect effects like environmental impacts of fragile forest ecosystems as well as a livelihood issues like rehabilitation.

Conclusion

There are several methods of monitoring changes in Himalayan glaciers in response to changing climate. Measurement of mass balance is one of the most appropriate methods to have information on overall glacier health and fluctuations. The data represented above clearly shows the fluctuations and varied responses of glaciers of Indian Himalayas towards changes being encountered globally. The short-term increase in discharge contributed by glacier melt and long-term decline in the same are predicted in studies conducted using various models, but the same cannot be concluded from the data discussed. The longest data series of mass balance available for Shaune Garang glacier does not indicate any generalized trend of mass balance in the region.

The analysis of glacial snout and its retreat in comparison to total area of the glacier does not give any information about any relationship between them indicating that there is no any specific impact of size of a glacier on snout retreat. This probably is in agreement with the glacier response time which cannot be concluded on short-term records on glaciers. Distributing the results of snout retreat on regional basis may not show any clear trend of retreat/advance for a particular region. The micro-climate may be playing an important role on the glacier health fluctuation and needs intense study and long data series not only of the hydrological parameters but also of the meteorological parameters to conclude some of the trend very precisely. Hence, one can depict on the basis of these interpretations that despite the area and region, the microclimate of these glaciers is playing the crucial role in determining the changes either in length or mass of glaciers.

Glacial retreat could pose the most far-reaching challenges in the Himalayan region. The importance of Himalayan glaciers for sectoral adaptation efforts in power generation, agriculture, irrigation, food security, biodiversity conservation, river valley ecosystems, etc. has been at the center stage of attention of public and governments as well as the scientists and researchers. For the researchers, the lack of long series data and prevailing uncertainties is of major concern for understanding water resources under the several varying projections of future climate. The dynamics of the monsoon are influenced by Himalayan systems which act as a reservoir to sustaining agriculture, providing freshwater and groundwater recharge, and are home to a unique ecosystem with many endemic species. Adaptation to climate change, therefore, requires not just local action but also trans-boundary cooperative arrangements.

A poor understanding of the glacio-hydrological processes combined with the diversity in topographical relief and climatic conditions within the region makes the hydrological projections speculative about the future water availability, seasonality of runoff patterns, and their impacts on irrigation, hydropower, and hazards.

Future efforts in building the resilience of the local community and the ecosystems should take into account a concerted and integrated approach. There is an urgent need by communities, scientists, and policymakers to take a closer look at the linkages between local impacts, scientific research, policy interventions, and the larger understanding of using resource conservation technologies and practices for promoting societal benefits.

Abstract

Nowadays no other region on earth is more threatened by natural hazards than coastal areas. However the increasing risk in this area is not just a climate extreme events' result. Coasts are the places with highest concentration of people and values, thus impacts continue to increase as the values of coastal infrastructures continue to grow. Climate change aggravates chronic social vulnerabilities since social groups may be affected differently both by climate change as well as by risk management actions. Relationships between these groups are often characterized by inequality, with different perceptions, response, or adaptation modes to climate hazards. Misperception of these differences often leads to policies that deepen inequities and increase the vulnerability of the weakest groups. Population affected by climatic extreme events increases dramatically resulting in urgent adaptation intervention. We address the interdependence of risk perception and vulnerability of coastal communities and the relevance of ecosystem services for adaptation. We developed a methodology where risk analysis and communities' risk perception are linked through key actions at strategic points of risk assessment: (i) initial interviews with qualified local informants to complete an inventory of ecosystem services, (ii) a social valuation of ecosystem services by local people, and (iii) assessment of stakeholders' social vulnerability. This approach allows a truly socially weighted risk assessment to be validated in three sites: Valle de Itajai (Brazil), Estuary of Lagoa dos Patos (Brazil), and Laguna de Rocha (Uruguay). In this novel approach, risk assessment is forced by social perceptions, thus risk treatment can better contribute to realistic adaptation arrangements to cope with climate forces. Public policies could be improved, recognizing healthy functioning ecosystems as key factor for coastal resilience and well-being.

Keywords

Ecosystem services • Risk assessment • Social perception • Extreme climatic events • Coastal areas

Introduction

In the next decades, the global population affected by coastal flooding and other extreme climatic events will increase dramatically, resulting in a growing need for adaptive interventions (Adger et al. 2005). The increasing impact of climate change is exacerbated because the speed of change is uncertain. The implementation of appropriate actions by the various levels of government is difficult because of the uncertainty of timing and magnitude of climate change and also because of the small window of time of the administrative mandate of governments compared to the time required for the climate change to be perceived. There is a need to implement actions to assist in the development of robust and adaptive management to address uncertain future conditions (IPCC 2007).

Studies have shown that socio-ecological systems do not generally respond to changes, such as those induced by climate change, in a linear manner. Tipping points, described as the achievement of critical thresholds in the system, manifest themselves only after cumulative effects are reached, thereby producing dramatic fast changes (Westley et al. 2011). The capacity of socio-ecological systems to adapt to external disturbances (e.g., flooding) without shifting to different states is known as resilience (i.e., less vulnerable to external forces) and depends on factors such as biological, institutional, and knowledge diversity.

Biodiversity and ecosystem services, especially those associated with wetlands (Boyd and Banzhaf 2007), are natural benefits that people obtain from natural processes (e.g., availability of food and freshwater, protection from erosion, disease regulation, and landscape values) and can be classified as provisional, regulation, support, and cultural services. Ecosystem services are tied to human health, well-being, and ecosystem health and integrity (WHO 2010). The recognition of the key role played by ecosystem services in reducing the effects of climate change is growing worldwide (MEA 2005), although the interdependence is complex and sometimes hidden.

Risk analysis framework is accepted to assist decision-making systematically in doing recommendations as a response to risks and prioritize issues where to focus management efforts (Fig. 1) to address human and natural topics with potential impact (Gimpel et al. 2013), like climate change. The risk analysis approach allows to define links between hazards and ecosystem services (i.e., depicting a pathway effect), which can be used to take the best decision during risk management and risk communication (Lozoya et al. 2011; Cormier et al. 2013). Enormous discrepancies are commonly observed in risk definitions, perceptions, and evaluations, mainly between public opinion and scientific perspectives (Figueiredo 2009).

Understanding social perceptions of climate change risks is critical to motivate public support to promote adequate policies. According to Mastrandrea et al. (2006),

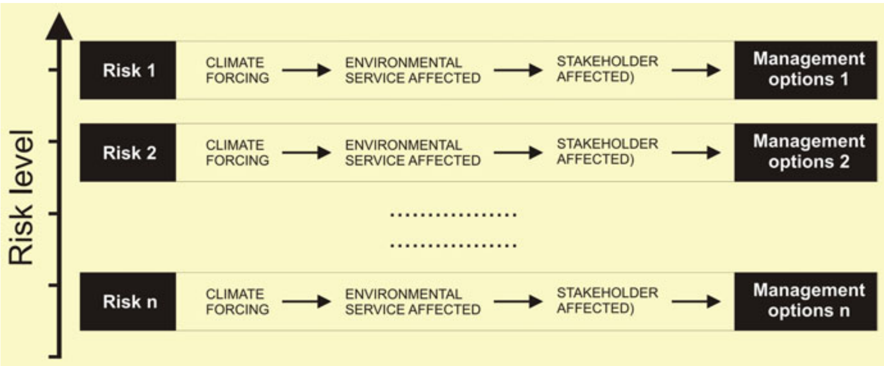

Fig. 1 The role of risk assessment in assisting decision-making to prioritize issues and define management options to cope with climate change. Without a quantitative rank of the risks, the decision where to focus management efforts is unfounded

climate-related risks are commonly perceived by the public as remote, deniable, or manageable, and these misunderstandings must be overcome to motivate support for policy actions (Franck 2009). Risk perception is important because individuals and institutions must be aware and understand climate change as a present threat in order to develop planned adaptation (Burton et al. 2002).

An Interdisciplinary Approach to Risk Assessment

Coastal Areas Within the Anthropocene

The implications of a changing climate are more significant for coastal areas than anywhere else. No other region is more threatened by natural hazards, including winds, storms surges, large waves, hurricanes, and tsunamis (Kron 2013). However, it is not the natural hazard as such that accounts for the consequences of an extreme event. These hazards are natural processes that have always affected the coastal zone. Natural hazards become disasters only if people are killed or injured and/or their possessions damaged or destroyed. Thus, "catastrophes are not only products of chance but also the outcome of the interaction between political, financial, social, technical and natural circumstances" (Kron 2013). Coasts are not just subject to more intense and more frequent natural events, but they are also the places with the highest concentration of people and values. The impacts and associated costs of these natural hazards to humans continue to increase as the amount and values of coastal infrastructures continue to grow (Shepard et al. 2011; Santoro et al. 2013).

Few years ago ca. 3,000 million peoples lived within 200 miles of the sea, which is to say that almost half of our species lives in the coastal zone (i.e., the 10 % of land), bearing densities 2.5 times greater (Tett et al. 2011). This large concentration of population and activities in coastal areas, with its associated effects on the environment, would be part of what a growing number of scientists call a new geological epoch: the *Anthropocene* (Crutzen and Stoermer 2000). Over the past decades, there has been a significant economic growth worldwide. Although uneven and mainly benefiting developed countries, this growth allowed people to access more resources (including natural resources) and thus have more services. While this has contributed to satisfying more needs, current models of growth and development also generated environmental degradation.

This upward trend enhancing general vulnerability makes coastal regions ever riskier. Certainly, the number of natural catastrophes in these areas has been increasing in recent decades (Kron 2013). In this scenario, to achieve a sustainable development (natural, socioeconomic, and cultural) in coastal areas is even more significant. Integrated coastal zone management (ICZM) arises as a strategy that promotes this kind of development, especially after the World Summit on Sustainable Development in 2002, when it incorporates the principles of the ecosystem approach.

Integrated Coastal Zone Management and Risk

ICZM strive for achieving a balance between social, environmental, and economic interest in coastal areas, through an approach based on ecosystem-based management, stakeholders' involvement, and the development of operational tools (Conde et al. 2012). During the last decade, countless countries, governments, and organizations have adopted ICZM as the most suitable policy to effectively address issues and problems in the complex coastal domain. It is seen as the superior course of action to integrate technical, political, and communities' interests and considers the participation by local stakeholder as an elementary component for a successful management (Christie et al. 2005).

As an important component of ICZM planning, the interest in coastal risks analysis and assessment has been growing in the last decade. Risk analysis is internationally recognized as an approach to assist decision-making. It is a systematic way of gathering, evaluating, and disseminating information leading to recommendations in response to an identified risk. It is a tool intended to provide decision makers with an objective, repeatable, and documented assessment of the risks posed by a particular action (Cormier et al. 2013).

Yet risk fields are characterized by a certain lack of clarity on many concepts and principles (Aven 2012). Risk analysis has been broadly defined as including risk assessment, risk characterization, risk communication, risk management, and policy relating to risk (e.g., Society for Risk Analysis). However, to many (e.g., ISO, FLOODsite, UNISDR), risk analysis is part of risk assessment and is defined as "a methodology to determine the risk by combining probabilities and consequences." In turn, risk assessment implies to understand, evaluate, and interpret the perception of risk and societal tolerance and to inform decisions and actions in the risk management process (see Fig. 2).

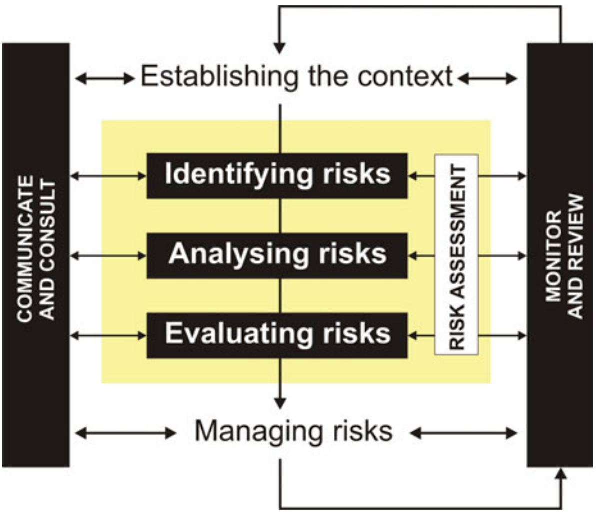

Fig. 2 Key components of the Risk Management Process (Modified from Australian/New Zealand Risk Management Standard)

Given this lack of clarity on many concepts and principles, it is essential, when seeking to carry forward researches on these topics, to establish a priori certain terms and common language in order to be sure of being all talking about the same concepts. This lack of clarity may be even more troubling considering that inter-disciplinary cooperation between physicists, ecologists, economists, and social scientists is essential in risk management processes. Even the use of English is not already a guarantee, since several terms may be interpreted differently in different countries (FLOODsite 2005). Following previous experiences (e.g., FLOODsite 2005; UNISDR 2009; DEFRA 2011), we agreed on a set of key definitions to be used in our project and in this chapter that are presented in the glossary in Table 1.

The set of terms defined in Table 1 present its own particular relationships, which are tentatively depicted in Fig. 3. Key components of the risk assessment method, both addressing the risk on ecosystems and stakeholders derived from climate change hazards, are shown as the central mechanism of an integral risk management process. Ecosystem services are presented as the vital connecting component between end users and ecosystems and human adaptation and ecosystem conservation as the strategies to cope with natural and anthropic hazards.

The Inclusion of Risk Perception in the Integral Analysis of Risk

Risk management calls for integrated processes including all the stakeholders affected (e.g., populations, companies, government, and scientists), joining the main principles of ICZM. Disaster prevention could be truly effective only if all of the stakeholders cooperate in a spirit of partnership (Kron 2013). Communication and consultation are highlighted as relevant at each step of the process (see Fig. 2). However, this dialogue must be bidirectional, stressing consultation and not merely information from managers to stakeholders.

During the last decades, the treatment of public affairs has progressively become more complex. While government agencies maintain significant influence on management, they are just one of multiple actors. In many countries, societies have slowly advanced in the construction of more flexible forms of governance, which are more effective and representative of the interests of diverse social groups. Key factors explaining why new models of governance are emerging include governments' action seeking to implement policies and programs more cost-effective and equitable as well as social demands, which increasingly influence the decision-taking process.

It is extremely important to involve a wide range of stakeholders, particularly scientists with access to detailed knowledge and also those who are most vulnerable and often least consulted. Since climate change affects women and men differently, it is important to consider gender issues such as the unequal power relationships between genders (CEDRA 2012). People's risk perception is based on the expected number of deaths or injuries but also on how well the process is understood, how equitably the danger is distributed, how well individuals can control their exposure, and whether risk is voluntarily assumed. People rank risks based on three major

Table 1 Glossary developed from previous risk management projects (FLOODsite 2005; UNISDR 2009; DEFRA 2011), establishing main key definitions used in this chapter

Concept	Definition
Acceptable risk	The level of potential losses that a society or community considers acceptable given existing social, economic, political, cultural, technical, and environmental conditions
Adaptation	Adjustments in socio-ecological systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities
Consequence	An impact such as economic, social, or environmental damage/ improvement. May be expressed descriptively, by category (e.g., high, medium, low) or quantitatively (e.g., monetary value)
Disaster	Serious disruption of the functioning of a community or a society involving widespread human, material, economic, or environmental losses and impacts, which exceeds the ability of the affected community or society to cope using its own resources
Ecosystem services	The benefits that people and communities obtain from ecosystems
Ecosystem service value	Public's net willingness to pay for an ecosystem service (economic definition); relative value given by stakeholders to ecosystem services in relation to their well-being (social definition)
Engagement	Where the public and/or stakeholders are asked to directly and actively take part in decision processes, but a public agency/authority is still responsible for the decision
Exposure	Quantification of the receptors that may be influenced by a hazard (e.g., number of people and their demographics, number and type of properties, etc.)
Hazard	A physical event, phenomenon, or human activity that may lead to harm or cause adverse effects. A hazard does not necessarily lead to harm. Can be natural or human induced
Impact	The effect that a risk would have if it happens
Inherent risk	Risk arising from a specific hazard before any management action has been taken
Qualitative risk assessment	Describes the probability of an outcome in terms that are by their very nature subjective as the assessment typically assigns relative values to assets, risks, controls, and effects
Quantitative risk assessment	A methodology used to organize and analyze scientific information to estimate the likelihood and severity of an outcome. Objective numerical values are calculated for each component gathered during risk analysis
Residual risk	The exposure arising from a specific risk after action has been taken to manage it (making the assumption that the action is effective)
Resilience	Ability of a system, community, or society exposed to hazards to resist, accommodate, absorb to, and recover from the effects of a hazard in a timely and efficient manner, including the preservation of its essential structures and functions
Response	Provision of emergency services and public assistance during or immediately after a disaster in order to save lives, reduce health impacts, ensure public safety, and meet the basic needs of the people affected

(*continued*)

Table 1 (continued)

Concept	Definition
Risk	The consequence(s) of hazard(s) being realized and their likelihood/probabilities The combination of the probability of an event and its negative consequences A function of probability, exposure, and vulnerability. Exposure could be incorporated in the assessment of consequences; therefore, it can be considered as having two components: the probability that an event will occur and the impact (or consequences) of the event
Risk analysis	Methodology to determine risk by analyzing and combining probabilities and consequences
Risk assessment	A methodology to determine the nature and extent of risk by analyzing potential hazards and evaluating existing conditions of vulnerability that could pose a potential threat or harm to people, property, livelihoods, and the environment on which they depend. Comprise understanding, evaluating, and interpreting the perceptions of risk and societal tolerances of risk to inform decisions and actions in risk management process
Risk management	The complete process of risk analysis, risk assessment, options appraisal, and implementation of risk management measures (i.e., risk treatment)
Risk mitigation	The reduction of the likelihood of harm, by either reduction in the probability of hazard occurring or a reduction in the exposure or vulnerability of the receptors
Risk perception	Subjective appraisal of people (individual or group) on the characteristics and severity of risk, reflecting cultural and personal values, experience, and acquired information
Risk strategy	An organizational approach to risk treatment, well documented and accessible
Risk treatment	Management measures taken to reduce either the probability or the consequences of the hazard or some combination of the two
Stakeholders	Individuals or representatives of groups who are directly or indirectly interested in or affected by an issue or situation
Susceptibility	The propensity of a particular receptor to experience harm. Also a condition that increases the likelihood that an environmental component will be exposed to a particular hazard
Vulnerability	The characteristics and circumstances of a community, system, or asset that make it susceptible to the damaging effects of a hazard. Vulnerability is the result of the whole range of economic, social, cultural, institutional, political, and even psychological factors that shape people's lives and create the environment that they live in
Vulnerable groups	Human groups who are prone to show more adverse responses than other groups, given the same exposure

factors: the degree of dreadfulness of the event (e.g., determined by the scale of its effects and the degree to which it affects innocent bystanders), how well the risk is understood (or accepted as fate), and the number of people exposed (Slovic 2000).

It is therefore highly reasonable to search for methodologies that take into account social differences, since social groups may be affected differently both

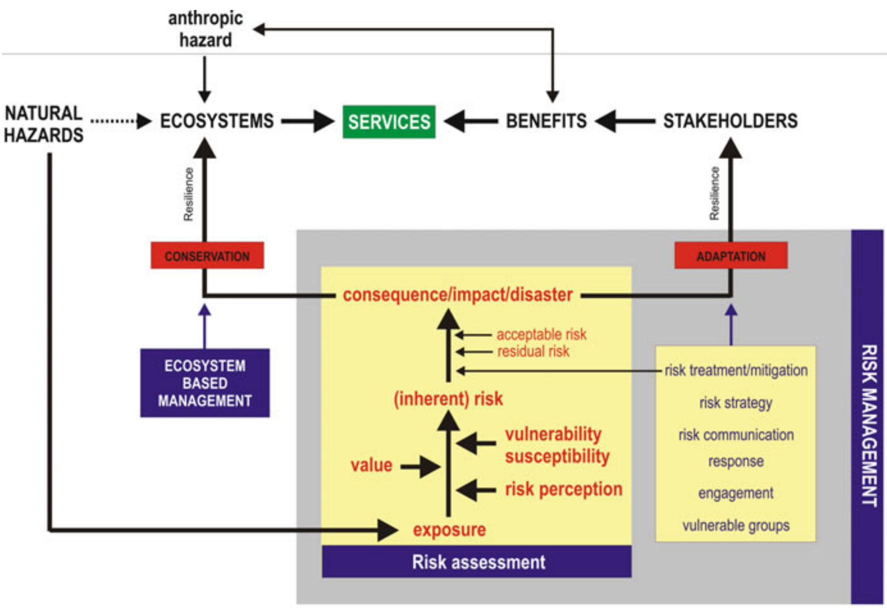

Fig. 3 Flowchart depicting key concepts and terminology related to climate change risk management (and other associated terms), according to the definitions and agreements of the interdisciplinary consortium in charge of this chapter

by climate change and by risk management actions. Identifying different interest groups is relevant because they may also have different perceptions, response, or adaptation modes to climate hazards. Furthermore, the relationships between different social groups are asymmetric and often characterized by inequality. Thus, misperception of these differences often leads to policies and actions that deepen inequities and increase vulnerability of the weakest groups (Fig. 4).

Modified from Shaw et al. (2005), candidate risk perception indicators to these events include, among others, lives threatened during events, impacts on physical and psychological health, and effectiveness of government's and individuals' prevention methods. Although quantification is an essential tool for risk management orientation, the complexity of social/environmental scenarios suggests the necessity integrating the perception of actors and social vulnerability to overcome the merely probabilistic quantification, assuming these are key factors influencing both the final impacts and the adaptive responses.

Ecosystem Services as a Vehicle for Improving an Integral Approach to Risk

During the past two centuries, the dominant paradigm held that natural threats should be managed through better technical protection (Kron 2013). Traditional engineering approaches optimizing for coastal safety are often suboptimal with

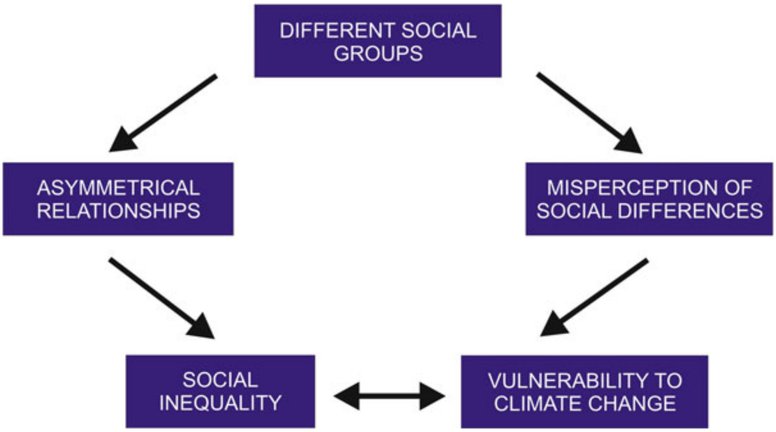

Fig. 4 Asymmetrical relationships among social groups leading to social inequality and how misperception of these differences increases the vulnerability to climate change of the weakest groups, through inadequate policies and actions

respect to other functions and are neither resilient nor sustainable. Historically, coastal protection has been based on hard infrastructures (e.g., walls, jetties, and groins) ignoring and even destroying coastal ecosystems that could provide the necessary protective function.

Natural coastal ecosystems are critical to human societies, providing a diverse range of goods and services that are vital to our well-being, known as ecosystem services (e.g., Costanza et al. 1997; MEA 2005). While scientists and environmentalists have discussed ecosystem services for decades, the UNEP's Millennium Ecosystem Assessment (MEA 2005) marked a major milestone in the historical development of the ecosystem services concept. The MEA distinguished four categories of ecosystem services: provisioning, regulating, cultural, and supporting services, while since then several categorizations have been developed concerning biodiversity conservation, integral environmental assessment, or economic valuation.

The focus on environmental and resources management through the ecosystem services and their link to human well-being proposed by MEA has been pioneering in environmental research. It becomes much clear to identify how changes in ecosystems can affect human welfare. Damage to natural ecosystems will seriously jeopardize their ability to provide these critical goods and services, causing considerable economic and social consequences. One of the most significant contributions of the MEA has been the introduction of ecosystem services in the sustainability's global agenda. The modern concept of ecosystem services has progressed significantly in recent decades, incorporating economic dimensions and providing useful information to decision makers for implementing effective conservation policies which support human well-being and sustainable development (de Groot et al. 2010).

The real importance of coastal services occurred fundamentally after two recent natural disasters: the Indian Ocean tsunami (2004) and hurricane Katrina (2005).

Both scientists and press highlighted the role of marshes as buffers in protecting coastlines, as well as their loss as possible explanation of the disaster. Quickly the protective service eventually provided by coastal marshes against extreme storm surge waves became a contentious issue. Thus the protection of ecosystems and the services they provide can form an important part of climate change mitigation and adaptation strategies (Berry 2013).

Nowadays, ecosystem-based solutions start to be an important component of collaboration between the hazard mitigation and climate change adaptation research communities (Munang et al. 2013). There is a growing interest in identifying where ecosystem-based approaches can fit into the preparation and response to climate change. The importance of ecosystem protection is increasingly recognized (e.g., EU Adaptation Strategy) highlighting the cost-effectiveness and multiple benefits of ecosystem-based strategies that integrating climate and biodiversity policy can help to meet the challenges of a changing climate ensuring the protection of vital ecosystems. However, concerning coastal risk management programs, natural ecosystems and the services they provide to human well-being have just occasionally been considered. The current practice of risk analysis still focuses on damages that can be easily measured in monetary terms. Hence risk assessment mainly deals with damage to assets, while social and environmental consequences are often neglected; this means that risk treatment frequently only manages a part of the total risk (Meyer et al. 2009).

A Regional Approach Linking Social Perception and Risk Analysis to Assess Vulnerability of Coastal Socio-ecological Systems to Climate Change

A Regional Project and Three Pilot Sites

Low-lying coasts in Latin American countries are highly vulnerable to climate variability and extreme climatic events (rain, windstorms and subtropical cyclones, and associated storm surges). The increase of sea level exerts extra vulnerability to low-lying coastal areas already subjected to increasing storm surges and heavy precipitation (Magrin et al. 2007). The coastal area of southern South America is diverse and ecologically stunning, providing a diversity of ecosystems and receiving freshwater from heavily populated watersheds, thus posing substantial risks (Seeliger and Kjerfve 2002). These effects have been shown to cause substantial modifications of the ecosystems' resources, resulting in social impact at diverse scales since communities and institutions have severe difficulties to deal with such changes. These social, economic, and environmental consequences may be synergistically magnified by climate change.

On the Atlantic coast of southern Brazil and eastern Uruguay, low-lying coastal plains formed by sediment accretion, especially during last Holocene period, are susceptible to the effects of flooding and represent a risk to urban areas. Many human groups reveal scarce capacities to cope with further losses of ecosystem services. Although there is an increasing regional recognition of the supporting role played by ecosystem services for human welfare, the perception by communities and managers is still insufficient. Rising sea levels and the increase in frequency and intensity of storms will magnify areas under risk. Coastal vulnerability to climate change has been suggested to generate diverse social and environmental impacts in the region (IPCC 2007).

Impacts at diverse social scales are boosted also because regional communities and institutions still lack capacities and integrated management approaches to deal with climatic long-term changes. Nevertheless, because of the relative homogenous regional culture, opportunities to foster cooperation toward an Atlantic Southern Cone integrated coastal management model are assumed to exist (Menafra et al. 2009). An opportunity to join regional efforts to design and implement management strategies requires identifying lessons learned and sharing previously isolated experiences for strengthening impact mitigation of climate change effects.

To address these topics at a regional, an ongoing research project is specially addressing the interdependence between risk perception and vulnerability of coastal communities to flooding and other extreme events, as well as their perception of the relevance of ecosystem services in reducing the consequences of climate change. This effort is supported by a grant from IDRC-Canada (106,923-001). Universities from Uruguay, Brazil, Canada, and Portugal strengthened an existing consortium addressing integrated coastal management to enable carrying on this research project. The goal of the study is to contribute to develop resilience to climate change in selected coastal wetland ecosystems and communities of the Atlantic Southern Cone of Latin America, especially threatened by extreme climatic events, and to improve recognition of the role of ecosystem services in coping with and adapting to climate change.

Three coastal sites were selected, namely, Valle de Itajai, Santa Catarina; Estuary of Lagoa dos Patos, Rio Grande (in Brazil); and Laguna de Rocha, Rocha (in Uruguay) (Fig. 5). Specific information on relevant socio-ecological features, ecosystem services, and climatic hazards from the three sites are detailed below. Some of the topics now addressed by this consortium have been previously assessed in each of the specific sites, through diverse approaches by coauthors of this chapter. Now, the innovative aim is to develop a regional analysis of these issues, using previous existing information and improving and standardizing the previous experiences, from where to derive lessons learned on a broader scale. Tables 2 and 3 contain comparative listings of major ecosystem services and climatic and anthropic drivers, in the three sites.

Itajai Valley, Santa Catarina (Brazil)

The Itajai Valley is located in the northern portion of Brazil, being drained by the largest river in the state of Santa Catarina, the Itajai River. Floods in the region in the nineteenth century were recognized as a recurring phenomenon. People migration process and occupation on the banks of the rivers turned the situation more complex because of the intense urbanization process. In the last 30 years, countless lives and material losses occurred from major floods (1983, 1984, 2008, and 2011). Society and government efforts with the purpose of seeking,

Fig. 5 Map of the coastal zone of Atlantic South America, showing the three sites where this study was carried out: Valle de Itajai, Santa Catarina; Estuary of Lagoa dos Patos, Rio Grande (in Brazil); and Laguna de Rocha, Rocha (in Uruguay)

diagnosing, planning, and implementing actions and nonstructural actions to mitigate the problems have taken place (e.g., regional economic-ecological zoning strategies, municipal master plans oriented by precautionary principles, National Policy on Climate Change).

In this context lies the city of Itajai, the most important fishing port in Brazil and second largest exporter of containers. The municipality has an area of 289 km^2 and a population of 190,000 inhabitants. It is located in a vast coastal plain in the central portion of the north-central coast of Santa Catarina. Its high urbanization further contributes to economic losses due to flood. The floods of 1983 and 1984 severely affected Itajai, and in 2008 ca. 90 % of the city was flooded. In 2011 the floods affected more than 60 % of the area. To mitigate the existing problems, recent governmental initiatives led to developing models, strategies, and tactics not based on the recognition of local features. There is an urgency of analyzing different low-cost regional planning options, including education, and to propose strategies based on models involving society, governments, and private sector, along a local process of integrated management and governance explicitly recognizing climate change.

Table 2 Listing of ecosystem services in three coastal pilot sites in Brazil and Uruguay

Ecosystem services		
Itajai	Rio Grande	Rocha
Inland artisanal and coastal industrial fisheries	Food supply from industrial and artisanal fisheries and shrimp intense production	Traditional artisanal fisheries and shrimp natural production
Water supply (watershed basins)	Water for domestic, agriculture, and industrial consumption	Water supply for nearby seaside
Riparian services (riparian wetlands taking excess of nutrients and protecting river margins from erosion)	Salt marsh services (taking excess nutrients and protecting the estuarine margins from erosion)	Freshwater marsh and salt marsh services (nursery areas, taking excess nutrients and protecting lagoon margins and coastal front from erosion)
Organic production of the low river and soil formation (supports productive ecosystems like agricultural areas, marshes, and beaches)	Organic production of the estuary and soil formation (supports multiple productive ecosystems like low-energy agricultural areas, marshes, sea grass beds and algal mats, and beaches)	Organic production of the lagoon and soil formation (supports multiple productive ecosystems like extensive cattle grounds, marshes, freshwater macrophyte beds, sea grass beds, and beaches)
Biodiversity (riparian ecosystem and Atlantic rain forest)	Biodiversity (freshwater and brackish wetland and lowlands)	Biodiversity (freshwater and brackish wetland and prairies)
Cultural spiritual and intellectual needs (local people and intensive tourism)	Attractive landscapes suitable for recreation and tourism activities	Astonishing pristine landscape offering recreational, aesthetic, and cultural services

Relevant research done at the Itajai Valley includes contributions on major climatic hazards (Polette et al. 2012), present coastal challenges (Ferreira and Polette 2009), main management tasks (Polette and Vieira 2009), and environmental education (Acauan and Polette 2011).

Estuarine Region of Lagoa dos Patos, Rio Grande (Brazil)

The estuarine region of Lagoa dos Patos, located at the southern Brazilian coast, may be considered as an environmental system with a high ecological, economic, and social importance. Lagoa dos Patos is a coastal system of impressive dimensions. Having an area of 9,913.93 km^2, it is classified as the largest coastal lagoon of the "choked" type (with a restricted connection to the sea) in the globe. The estuarine region, approximately limited by coordinates 52°14′46″ W and 31°41′40″ S and 51°58′24″ W and 32°11′59″ S, encompasses important urban centers of the Brazilian southern shore, such as the cities of Pelotas and Rio Grande, as well as a substantial pool of production, transformation, and business activities. In ecological terms, it may be classified as a typical estuary of a transition system between ocean and continent, thus suffering the influence of processes, sources, and

Table 3 Relevant climatic hazards and anthropic pressures in three coastal pilot sites in Brazil and Uruguay

Climatic hazards and anthropic pressures		
Itajai	Rio Grande	Rocha
El Niño phenomenon (1982/83 and 1997/98) First hurricane ever observed in the South Atlantic demolished over 3,000 houses in southern Brazil	The combination of high tides with the passage of fronts from south can produce meteorological tides that can easily double its heights, producing severe storm surges with strong erosion effects Storm surges can block the large estuary water discharge and produce floods during severe rain periods	Storm surge formation producing coastal impacts Flooding in upstream county city (Rocha city) and coastal villages (La Riviera, Puerto Botes) and cities (La Paloma) Coastal erosion and morphological modification of lagoon's mouth
Unregulated urban growth along the Itajai River, demographic pressure, poverty, and rural migration Low investment in infrastructure and services	Recent population increase due to new port development Lack of adequate urban infrastructure and services A myriad of social and economic activities going on simultaneously	Potential touristic development (in nearby La Paloma city) toward the lagoon's coastal fragile stripe Promotion of urbanization in potentially flooding areas Artificial opening of the lagoon (natural hydrology modification)
Intersectoral uncoordination of leading agencies and stakeholders in the region	Improper integrated management to deal with the complexity of the present situation	Intensive unplanned tourism at the protected area and lagoon Lack of a local management plan and scarce monitoring

controls from both. There is great use, diversity, and density in the water body itself and by the margins of the estuary of Lagoa dos Patos, including urban occupation, port and industrial activities, an important summer resort and tourist activity, as well as environmental protected areas and artisanal and industrial fisheries. These issues are tightly related to impacts by climate change-related events.

Recently, new discoveries of important oil and gas fields concentrated in the exclusive economic zone in the southeast region of Brazil – a deep-ocean, subsalt formation known as pré-sal – have generated a big thrust in the sector related to the exploration, refining, and transportation of those energy sources. Similarly, the new and important phase in Brazilian oil production has significantly stimulated the national shipbuilding sector, with ships for oil and gas exploration and transportation, and the development of port areas to provide logistic support to the endeavor. In the estuarine region of Lagoa dos Patos, where the Port of Rio Grande is located, the installation of an offshore naval construction pool has brought a sizeable enhancement to local economy and may generate considerable environmental impacts on estuarine ecosystems.

Research done at Lagoa dos Patos, relevant for our proposal, includes studies on socio-ecological effects of climate (Janeiro et al. 2008; Leão et al. 2010) and management (Asmus and Tagliani 2009).

Laguna de Rocha, Rocha (Uruguay)

The Atlantic coast of Uruguay, which has recorded the increasing trends in temperature, precipitation, and sea level rise, includes four important coastal lagoons with intermittent connection to the ocean, which belong to one of the largest systems of coastal lagoons on the planet, extending northward to Brazil and southward to Argentina. Most of these coastal lagoons are natural protected areas according to national and international agreements like UNESCO-MaB, the RAMSAR Convention, and others. These highly productive systems sustain important traditional artisanal fisheries, provide relevant ecosystem functions such as reproductive and feeding areas for fish and shrimp of commercial relevance, constitute feeding and resting areas for Nearctic migratory birds, and provide habitat for endemic vertebrate and plants species. Other ecosystem services include hydrological control, soil generation and maintenance, buffering of basin contamination, and aesthetic values for ecotourism.

Laguna de Rocha is the second largest coastal lagoon of Uruguay and presently the most studied aquatic ecosystem in the country. Land use in the basin (which includes the capital city and nearby tourist seaside towns, with ca. 40,000 inhabitants; up to 80,000 in summer) is mainly extensive cattle rising on natural prairies, but forestry with exotic pines and eucalyptus, artificial prairies, and intensive agriculture have increased 5–10 % in the last decade. These towns commonly suffer flooding events. Traditional tourism is increasing around the fragile sandbar area, and environmental impacts, including eutrophication, coastal erosion, and natural habitat degradation, increased threats to endangered species; loss of scenic values, water quality degradation, and alteration of the natural hydrology can be predicted. The sandbar is opened artificially to reduce flooding of adjacent grasslands used for livestock grazing and to permit the entry of important marine larvae, especially commercial shrimp and fishes. Biodiversity and ecosystem services of Laguna de Rocha and its basin are thought to be heavily threatened by climate change.

Relevant research in Laguna de Rocha includes ecosystem services (Nin 2013), effects of climate on ecosystem services (Fanning 2012), and basin management (Rodríguez-Gallego et al. 2012).

Prospective Analysis of Risks

Derived from the information on the most relevant ecosystem services and hazards in each pilot site (Tables 2 and 3), we performed a prospective analysis to tentatively (and nonquantitatively) identify the major risks to climate change (Fig. 6). As seen, in the three sites, the climate hazard that apparently would impose major effects on ecosystem services and stakeholders is flooding, although due to different causes like precipitation, storm surges, and sea level rise, among others. Changes in wind pattern and induced changes in salinity are also indicated as relevant hazards in some of the sites.

LAGUNA DE ROCHA — Risk level ?

	climate stressor	service impacted	stakeholder	adaptation option
$Risk_1$	Changes in wind pattern	Reduction of entrance of fish and shrimp larvae to lagoon Sand bar and hydrology dynamics	Local artisanal fishermen All stakeholders	Sand bar optimal opening according to larval dynamics Zonation and management plan
$Risk_2$	Flooding	Loss of cattle areas	Cattle rangers	Education to show global benefits of flooding frequency
$Risk_3$	Sea level rise and flooding	Loss of areas for urbanization	Tourism sector	Zonation of urbanizable areas according to local scenarios of sea level rise

LAGOA DOS PATOS — Risk level ?

	climate stressor	service impacted	stakeholder	adaptation option
$Risk_1$	Higher frequency of extreme weather events	Navigability of the lagoon channel	Port and industrial sector	Adapt the security por operation protocol
$Risk_2$	Flooding	Safe areas for human occupation	Local communities	Local spatial planning
$Risk_3$	Increase in the precipitation pattern and salinity decrease	Wetland distribution and production	Artisanal fishermen	Adapt fisheries model Marsh construction

VALLE ITAJAI — Risk level ?

	climate stressor	service impacted	stakeholder	adaptation option
$Risk_1$	Flooding	Wetland areas Fisheries Drinking water Recreation and tourism Agriculture &urbanization Harbour areas & industries	Urban population in general Watershed Committee Artisanal/industrial fishermen Tourism sector Harbour sector Industrial sector People living in slums	<u>Structural planning</u> dikes sanitation barriers channels
$Risk_2$	High tide and sea level rise	Loss of cattle areas		<u>Non-structural planning</u> community organization environmental impact assessment indicator system analysis environmental strategic analysis environmental education

Fig. 6 Prospective analysis to identify the most important risks to climate change in three pilot coastal sites along the Southern Cone of Latin America. Without an objective, but socially meaningful, quantification of the risks, the uncertainty of which of them are to be prioritized reduces the effectiveness of the management efforts

Ecosystem services affected include a large and diverse list where the loss of productive areas both for agriculture and fisheries, as well as for urbanization and industrial development, are highlighted, especially in Itajai and Lagoa dos Patos. Only in Laguna de Rocha ecosystem, natural functions are listed as under thread (sandbar dynamics and hydrology) although in Lagoa dos Patos the loss of wetland areas is also emphasized. Stakeholders potentially impacted by these losses are diverse, from traditional fishermen to port industry, including the tourism sector and poor settlements, among others. Optional management practices to be taken include structural and nonstructural actions, as well as coastal zonation, adaptation of fisheries models and operational port protocols, and environmental education.

Nevertheless, this analysis lacks a quantitative approach to enable prioritizing the risks, in order to adequately rank the management options to be adopted. Without objective and socially meaningful risk quantification, the effectiveness of the management efforts is significantly reduced (Dovers et al. 2008). For these reasons and because of the problems arising when risk is analyzed with no support from stakeholders' interests and opinions, the interdisciplinary consortium carrying on the regional project developed a new methodological framework, taking into account these shortcomings, with the aim of adequately linking the approaches of risk analysis and risk perception (see next section).

Methodological Development

The proposed framework consists of several steps, from defining critical ecosystem services to be selected for detailed analysis of risk and perception to finally obtaining a socially prioritized set of risks that can help managers to decide where to focus management efforts for adaptation. For the explanation we will follow the schematic depiction showed in Fig. 7. As seen in the scheme and explained below, there are three entries where social perception feeds the risk

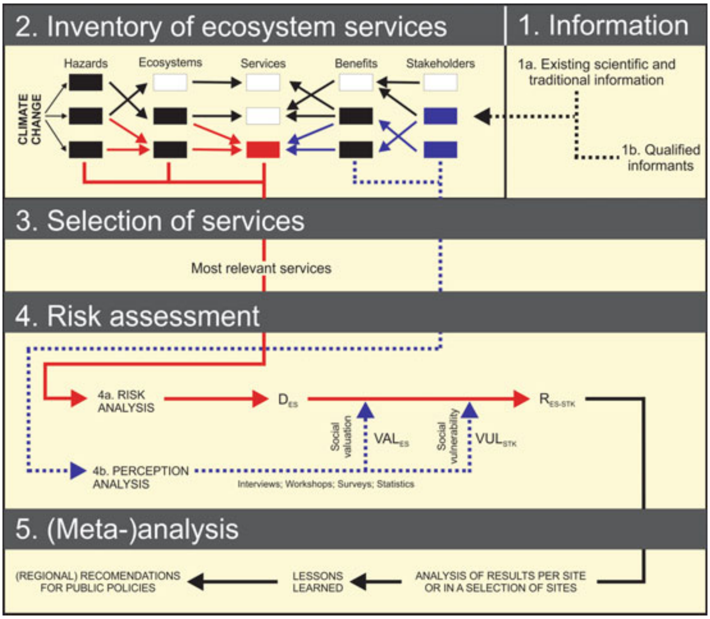

Fig. 7 Methodological proposal for integral risk assessment (*dotted arrows* indicate key points of the framework where social and nonacademic perspectives do feed the risk analysis; *colored boxes* in 2 show an example of how to link one ecosystem service with its climatic hazards, the ecosystems that support that service as well as the related benefits and stakeholders; *red dotted arrows* show the rational pathway from hazards, ecosystems, and services to the risk analysis; *blue dotted arrows* show the rational pathways from stakeholders to the perception analysis) (for abbreviation and other explanations see section "Methodological Development")

analysis: Phase 1 (qualified informants to develop an inventory of ecosystem services), Phases 2–3 (selection of relevant services), and Phase 4 (valuation of services and vulnerability assessment of diverse social groups).

Initially, some agreements must be made on several topics and specific strategies to be followed, by the interdisciplinary consortium. For example, on ecosystem services we decided to follow the classification proposed by Fisher et al. (2009) that differentiates ecosystems (i.e., functions) which provide services, which in turn generate social welfare. To classify ecosystem services, we decided to use a combination of classifications including Fisher et al. (2009), the MEA (2005), and Costanza (2008). Another relevant initial agreement is the definition of the spatial extent of the analysis, which in our case, given we had three different sites, included the provisioning area of the services, as well as the affectation and benefits area. The decision also took into consideration ecological management and operability of the project. These initial definitions are open to any kind of agreement, but it is critical to take place before the further application of the framework.

The first step of the framework consists of the delineation of an inventory of ecosystem services in the working area previously defined (Phase 2 in the scheme of Fig. 8). This must be done as a cooperative effort between scientists and local stakeholders (Phase 1), to obtain the inventory derived from the existing literature (Phase 1b) for the area, as well as from traditional local knowledge. Even if an inventory developed by the academia do already exists for the location under analysis, a series of interviews to qualified informants (Phase 1a) should be carried out to complete it or at least confirm that no relevant information for the local stakeholders is missing. The inventory needs to link climatic forces (hazards) with ecosystems (and ecosystem functions) affected. Then, based on the ecosystem functions, ecosystem services, as well as their associated benefits and stakeholders, can be listed. The potential links between these sequential elements (climate forcing, ecosystems/functions, services, benefits, and stakeholders) can be quantified, especially those critical links between ecosystems/functions and services, using the categorical method proposed by Maynard et al. (2010) based on expert opinion. When the inventory is defined in its wholeness, a decision on which is the critical set of ecosystem services to be addressed in detail can take place (Phase 2 to 3).

It is highly probable that this decision is taken by scientists or managers, but it is relevant that this is done as an artisanal balance taking into consideration not only the scientific opinion by specialized academic staff (e.g., based on climatic scenarios and its potential effect on ecosystems) but also on stakeholders' opinion (i.e., local traditional knowledge), which will obviously prioritize those critical issues that mostly affect their well-being (influenced by their past life experience and the adaption actions they already made, individually or as a community). Seeking for this balance is not an easy task but represents a critical point where a major effort and time must be placed to enable the rest of the framework to be both ecologically and socially relevant. Considering the amount of connections and the number of links between all the sequential elements of the inventory, for the validation of this methodology, one or at least two ecosystem services must be selected, depending on the availability of information and resources at each study site.

* In these examples, all hazards were considered equal respect to their impacts on each ecosystem (i.e. in all cases *k*=1, see general equations).

Fig. 8 Examples of the calculation of the decrease of the ecosystem service provision (D_{ES}) for different hypothetical scenarios (*screen catches* from the supporting information http://www.mcisur.edu.uy/contenidos/riesgo-costero)

After defining these critical ecosystem services potentially affected by climate change, which are also relevant for the local community, the next phase represents the central section of the proposal. Phase 4 corresponds to the risk assessment process, which includes both the risk analysis and the stakeholders' risk perception analysis. Even both analyses have their own methodologies; they are linked through the valuation of the ecosystem services and the inclusion of the stakeholders' vulnerability, as detailed below.

By modifying the methodological development proposed by Lozoya et al. (2011), a risk analysis (Phase 4 in Fig. 7) has to be performed for each ecosystem service and stakeholder (R_{ES-STK}), based on three components: (a) the decrease of the ecosystem service provision (D_{ES}), (b) the value of the service

(VAL_{ES}), and (c) each stakeholder's vulnerability (VUL_{STK}) (see Eq. 1). This calculation gives an estimation of the risk of losing each ecosystem service due to a number of hazards, weighted by the differential vulnerability of each stakeholder associated to the service:

$$R_{ES-STK} = D_{ES} \times VAL_{ES} \times VUL_{STK} \tag{1}$$

It is important to state that some methods included in this phase (e.g., intensity of hazards, valuation, vulnerability, etc.) can be substituted by other specific methods, but it is relevant that these changes are discussed and agreed in advance by the interdisciplinary consortium.

Decrease of Ecosystem Service Provision (D_{ES})

The provision of the ecosystem service of concern will be affected according to the intensities of hazards affecting the ecosystems involved in that provision. Therefore, the decrease of the ecosystem service provision (D_{ES}) is calculated as the summation of the relative contribution of each ecosystem (RC_E) weighted by the intensities of the hazards ($\sum I_H$) affecting each ecosystem (see Eq. 2):

$$D_{ES} = \sum_{E=1}^{E=x} \left(\sum_{H=1}^{H=n} \frac{I_H}{k \times n} \times RC_E \right) \tag{2}$$

where I_H is the intensity of each hazard affecting each ecosystem (E) providing the service, n is the number of hazards affecting each ecosystem, and k is a weighting factor that allows incorporating differences in the relative weights of each hazard, in terms of their effects on each ecosystem.

The relative contribution (RC_E) of each ecosystem to the service provision varies between 0 and 1, being the latter the case where a single ecosystem is responsible for the 100 % of the provided service. RC_E can be estimated based on the methodology proposed by Maynard et al. (2010).

The intensity of each hazard (I_H) affecting the ecosystems can be estimated considering the likelihood of its occurrence (L_H) (e.g., recurrence interval or return period, probability of occurrence, etc.) and its consequences on each ecosystem (CS_E) (e.g., area reduction, functionality reduction, etc.) (see Eq. 3):

$$I_H = L_H \times CS_E \tag{3}$$

Given that several hazards can affect one ecosystem at the same time or space (even producing synergies), their intensities are added in a weighted manner in order to obtain the total intensity affecting each ecosystem (*weighted* I_H).

Finally, if the intensity of hazards increases, the affectation of ecosystem service provision (A_{ES}) will also increase, and therefore the risk of reducing (or even loosing) the ecosystem service will also increase (assuming up to this point that VAL_{ES} and VUL_{STK} are nonzero) (see Eq. 4).

$$R_{ES-STK} = \sum\nolimits_{E=1}^{E=x}\left(\sum\nolimits_{H=1}^{H=n}\frac{I_H}{k \times n} \times RC_E\right) \times VAL_{ES} \times VUL_{STK} \quad (4)$$

In order to illustrate these calculations, two hypothetical cases are presented. Links to the calculations included in each case can be seen and downloaded from http://mcisur.edu.uy/contenidos/Riesgo-Costero/risk-examples.xls. In Case 1, the decrease of the ecosystem service provision (D_{ES}) is calculated for an ecosystem service (ES) that is provided by a single ecosystem (E) (i.e., $RC = 1$) affected by several hazards ($H_1, H_2, \ldots, H_4$). *Weighted* I_H is the total intensity of hazards affecting the ecosystem, and in this case all of them have the same importance (i.e., $k = 1$). In this case the affectation of the ecosystem service provision (A_{ES}) is equal to *weighted IH*, since a single ecosystem is providing the service (i.e., $RC = 1$) (see Fig. 8a below).

In Case 2, the ecosystem service is provided by three ecosystems (E_1, E_2, and E_3), each one of them with different relative contributions (RC_1, RC_2, and RC_3) and affected by different hazards ($H1, H2, \ldots, H5$). As in the first case, for each ecosystem providing the service, the intensities of the hazards affecting were weighted (obtaining the *weighted* I_H, again assuming that all hazards have the same importance, i.e., $k = 1$) and multiplied by the respective relative contribution (see Fig. 8b below). Then, following the main equation presented above, these estimations are added in order to obtain the whole decrease of the ecosystem service provision (D_{ES}) for each scenario (see Fig. 8c below).

Service Valuation (VAL_{ES}) and Stakeholders' Vulnerability (VUL_{STK})
Commonly, an economic valuation of the service is used, based on classical methodology of environmental economics (TEEB 2010; Beaumont et al. 2010). Nevertheless, as part of the methodological development arising from this framework, the interdisciplinary consortium decided to modify this step by replacing the economic valuation by a "social valuation," i.e., based on the relevance of the environmental service for the stakeholders (VAL_{ES}). This will be done through the principles of the analytical hierarchical process (Banai-Kashani 1989), where each interviewed stakeholder (or eventually reaching a consensus in cases of small communities or specific cases of homogeneous opinion) define, on a 1 to 9 scale, how much important are different services, from their viewpoint. Eventually, according to the capacities of the project, an economic valuation can be done in parallel, and results compared or analyzed separately.

A final step in Phase 4 (see Fig. 7) addresses the vulnerability of stakeholders (VUL_{STK}) involved with each service and hazards. It is clear that some groups are to be more vulnerable in losing a specific service by climate drivers. According to Pizarro (2001), the concept of vulnerability seems to be the most appropriate for understanding the transformative impact caused by increased exposure to risks, allowing centering the discussion on social disadvantages, by focusing on the relationships between (i) the physical, financial, human, and social assets available to individuals and groups and (ii) the set of available opportunities delimited by the market, the state, and civil society. Vulnerability analysis emphasizes on quantity, quality, and the diversity of assets (physical, financial, human, and social) that can be mobilized to address environmental dynamics. In this sense, the differential vulnerability among stakeholders will be quantified combining three subindexes that aim to cover all these dimensions:

(a) *Index of unsatisfied basic ne*eds (UBNs): developed by United Nations Economic Commission for Latin America (UNELAC or CEPAL), this index combines population census information on the condition of households (construction material and number of people per room), access to sanitary services, children attending school and education, and economic capacity of household members.
(b) *Index of linkage with the ecosystem service*: based on a set of indicators, this index, developed by this consortium, will measure how connected are actors with the ecosystem service under study, integrating socioeconomic and cultural dimensions (e.g., livelihood, sense of ownership).
(c) *Index of risk perception*: this index, also developed by the consortium, will assess how vulnerable the population perceives itself against the identified hazards. That will be obtained based on indicators providing data on infrastructures, social cohesion, and economic-productive dimensions.

This quantification of the vulnerability will finally allow weighting results of the risk analysis, to be used in the decision process where priorities and issues to be addressed were defined in terms of management, including budget distribution and normative support, among others.

In our case, a further phase (Phase 5 in Fig. 7) of the framework will be pursued, which will allow the regional consortium to derive a series of lessons learned and recommendations based on a meta-analysis of the results from the three cases (Itajai Valley, Lagoa dos Patos estuary, and Laguna de Rocha). These three cases represent a regional gradient which allow for an interesting analysis on how the reduction of wetland areas (i.e., the sequence Itajai → Lagoa dos Patos → Laguna de Rocha) and their associated services, not only due to climate forces but also due to anthropogenic pressures (e.g., urbanization and industrialization), can impact the welfare of local communities and stakeholders and hence reduce their resilience.

Perspectives and Conclusions

The methodology proposed above derives from an interdisciplinary process lasting several months. Experts from several countries, various academic institutions, and a diversity of disciplines developed and adapted a framework that allows prioritizing different risks associated to climate change, according not only to the impacts on ecosystems but also on their services and the human groups that get benefit from them. The framework will now be tested in the three pilot coastal sites along the Southern Cone of Latin America (Laguna de Rocha in Uruguay and Itajai Valley and Lagoa dos Patos estuary in Brazil). Understanding the link between social vulnerability to climate change impacts and the social perception of the risk, as well as of the relevance of coastal ecosystem services, will be valuable to coastal communities, grassroots organizations, governments, and managers at all administrative levels. Regional recommendations, enhancing coastal communities' awareness about the importance of wetland ecosystem services mitigating flooding events, could be derived based on the strength of lessons learned on a regional perspective. This consciousness could lead to the improvement of environmental public policies of the region and involved nations. These local communities affected by climate change will be the major beneficiaries through a better local application of more adequate public policies.

On a more global perspective, in responding to the need for an improved science-policy and science-society interface to manage coastal systems the most sustainable way, the framework presented in this chapter aims to evaluate in a more realistic way the possible effects of climate forces on ecosystems and coastal populations. For it, perception and valuation of local stakeholders are included from the very beginning as a main component of the risks assessment. Community consultation and the need of bottom-up approaches in coastal management have been highlighted since the 1990s as an essential component of the ICZM process. Yet, participation could be seen as more than a democratic right of stakeholders. Cooperation and true engagement is an important condition for successful management, improving equitability and transparency in processes, avoiding the gap between decision makers and affected communities and thereby the failure of planning measures (Jentoft 2000).

This approach is of great importance at present, when climate change aggravates chronic social vulnerabilities, since ecosystem services losses reduce welfare and development opportunities, especially for poorest communities (Malik 2013). On the other hand, considering the relevance of ecosystems and their services to human welfare, as well as its central role in current management and adaptation strategies, it seems essential to place them in the center of the risk management. Thus, this approach may lead to more reliable results in which management decisions can be based on and to improve public policies for better and equitable adaptation strategies, highlighting the central role of healthy ecosystems to cope with climate change.

Local Determinants of Adaptive Capacity Against the Climatic Impacts in Coastal Bangladesh

Mustafa Saroar and Jayant K. Routray

Contents

Abstract

A growing body of literature came up with suggestion to enhance adaptive capacity of poor and marginalized population to build a resilient society against climatic disasters. Although many earlier qualitative works have indicated the factors that should be addressed to enhance such adaptive capacity, however very scanty of them quantitatively assessed the influences of those factors on various dimensions of people's adaptive capacity. This chapter assesses

quantitatively the influences of various demographic and socioeconomic, past adaptive behavioral, climate/weather information/knowledge products, and physical environmental (spatial/locational) factors on the adaptive capacity of coastal people against the livelihood insecurity that are caused by hydrometeorological events.

The empirical part of this research was conducted in three villages of Kalapara Upazila (subdistrict) located close to the shoreline of Bay of Bengal in southwest part of Bangladesh. A total of 285 respondents were randomly interviewed using a semi-structured questionnaire in 2009. Respondents were asked to rate their adaptive capacity against 25 impacts that cause their livelihood insecure. The principal component analysis (PCA) technique was employed to identify the major dimensions of livelihood insecurity. Livelihood insecurities are related to (a) severe constraints in agriculture farming and allied activities; (b) severe damage of physical and socioeconomic infrastructures; (c) severe constraints in fishing (mostly offshore) related activities; and (d) severe crisis in freshwater supply and public health risk. How does adaptive capacity against each of these four dimensions of livelihood insecurity differ due to the influence of various factors is assessed by employing multiple analysis of variance (ANOVAs) technique.

The ANOVAs show that among the demographic and socioeconomic factors, sex, education, occupation, farmland holding, membership status (of social institution), and social capitals have the strongest influence on differential adaptive capacity in general. Similarly, among the past adaptive behavioral factors, except the freshwater crisis all other variables, namely, adaptation against flood, rainfall, and salinity intrusion have strong influence in making difference in adaptive capacity. Likewise, almost all climate/weather information/knowledge products have statistically significant influence on various dimensions of adaptive capacity. The policy implication is that while launching any program to enhance the adaptive capacity of coastal people against the threats of hydrometeorological disastrous events on their livelihood security, the identified factors need to be accounted.

Introduction

This chapter identifies the determinants of adaptive capacity of coastal people in their battle against climate change induced various hydrometeorological events including sea level rise (SLR). Despite considerable uncertainty about the extent and timing of climate change, scientific advances have established a clear link among global warming, climate change, and extreme events (IPCC 2001, 2007). Climate change is basically a gradual change in long-term average conditions, greater variability within the range of normal conditions, and changes in the types of extreme events which are possible or probable (Hare 1991). Common manifestations of climate change is change in global mean temperature, pattern of precipitation, amount of melting of snow and ice, and rising global sea level (Nerem et al. 2006). However, all these have the potential to exacerbate various hydrometeorological disastrous events including cyclonic storms, tidal surges, floods, salinity intrusion, and drought (Wilbanks et al. 2007). The spatial and temporal dimensions of these disastrous events may not be the same across the globe. Therefore, the disastrous events that are more likely for tropics and subtopics may be less likely for arid and semiarid regions and vice versa. Such a variation in climatic events may be felt within a region as well. For example, countries that are located at very lower latitude in the tropics/subtopics may experience noticeably different disastrous events than countries located at more high latitude (IPCC 2001). Although effects of climate change will be felt across the globe, the growing body of literature have warned that small island countries and countries having low-lying deltaic coasts are particularly vulnerable to hydrometeorological disasters (Nicholls et al. 1999; Klein et al. 2001; Karim and Mimura 2008; Tol et al. 2008). Vulnerability will even more increase for countries having low adaptive capacity (Adger et al. 2003; Adger 2006; Stern 2006).

Bangladesh is one of the countries that are susceptible to most of the hydrometeorological disasters, such as floods, cyclones, tidal surges, salinity intrusion, and SLR (Singh et al. 2001; Karim and Mimura 2008; UNDP 2009; GOB 2010; Alvi and Dendir 2011; Pethick and Orford 2013; Ravenscroft et al. 2013; Alam and Rahman 2014; Kulatunga et al. 2014). The vulnerability of this country is attributed to low adaptive capacity and high exposure and sensitivity to these disastrous events (World Bank 2000, Agrawala et al. 2003). It is true that people of Bangladesh have been adapting with natural calamities of various types since time immemorial. They have had accumulated experience of coping and adaptation. However, in the changing context of climate, many of the known hydrometeorological disastrous events may appear very differently than what were earlier. Various climate projection and hydrodynamic models have already warned that Bangladesh may experience more intense cyclonic storms, surges, prolonged flooding, salinity intrusion of perpetual nature, and accelerated SLR (Ali 1999, Singh et al. 2001; Karim and Mimura 2008; GOB 2010; Alvi and Dendir 2011; Pethick and Orford 2013; Ravenscroft et al. 2013; Kulatunga et al. 2014). As Bangladesh is located in a very peculiar geographical setting where the Himalayas is in the north and the Bay of Bengal is in the south, the melting of Himalayan glacier may contribute substantially to exacerbate the flooding situation (Alvi and Dendir 2011; Rahman et al. 2011). In fact, two-third of Bangladesh is located only 5 m above the mean sea level (MSL) and one-fifth of the landmass is within 1 m from the MSL (Islam et al. 1999; Brammer 2014). Past experience shows that decadal developmental gains are ruined by a single episode of massive flood or cyclone (World Bank 2000; GOB 2010). Before reaching the middle of this century, this problem may even get worse primarily because of excessive salinity intrusion in surface, subsurface water table, and in top soil. All these will seriously impact the crop agriculture – the mainstay of the country's economy

(Sarker et al. 2012). Increase in salinity is projected to jeopardize the growth of inland fisheries, horticulture, and forestry as well (Swapan and Gavinb 2011; Islam et al. 2014; Karim et al. 2014). After agriculture, these are the most dominant sources of livelihood in the coastal Bangladesh. Numerous studies already have made strong assertion that if these really happen, a significant number of people with low adaptive capacity will turn out as climate migrants from this fragile coast before the middle of this century (Ali 2006; GOB 2009; Bhuiyan and Dutta 2012; Akter and Mallick 2013; Penning-Rowsell et al. 2013). As any failure to adapt to these impacts of hydrometeorological disasters will cause huge out migration, these massive relocation for a land-scarce country like Bangladesh could only be avoided through enhancing the adaptive capacity of the affected coastal people (Saroar and Routray 2012; Penning-Rowsell et al. 2013).

While enormous literature on adaptive capacity against famine and food vulnerability to natural disasters such as droughts are available in global context, only scanty of literature on adaptive capacity of coastal people against the impacts of hydrometeorological disasters in Bangladesh are found (Adger and Barnett 2009; Adger et al. 2009; Wolf et al. 2010). Often the works of Cannon (2002), Choudhury et al. (2005), Thomalla et al. (2006), Paul and Vogl (2011), Khandker (2012), and Mottaleb et al. (2013) are cited in this regard. While these qualitative studies have unveiled many insightful examples of adaptation against flood, cyclone, drought, even salinity intrusion, those very compelling narratives, however, have the common limitation of analyzing the adaptive capacity qualitatively from a macro perspective. In this regard, notable exception is Saroar and Routray (2012) who have quantitatively assessed the adaptive capacity of coastal people from a micro perspective. However, they have failed to come out from the compartmentalization approach of assessing adaptive capacity. For instance, they have assessed adaptive capacity against major groups of impacts. They have assessed how a person's adaptive capacity differs for different groups of impacts. However, this has little policy significance as it does not empirically tested the causes that make difference in people's adaptive capacity against various hydrometeorological events. Readers may find this chapter as a departure from those qualitative and compartmentalization approaches to identifying the determinants of adaptive capacity at local scale. The practical significance of the finding is that it may help policy makers, planners, and practitioners alike while designing a program of interventions for enhancing people's adaptive capacity.

Adaptive Capacity Against Livelihood Insecurity: Literature Review and the Hypothesis

Livelihood insecurity is often understood as the susceptibility to circumstances of not being able to sustain a livelihood (Alwang et al. 2001; Adger 2006). Therefore, a person's livelihood is considered secure when the person can cope with and recover from stresses and shocks and maintain or enhance capabilities and assets both now and in the future, while not undermining the natural resources base (Scoones 1998). Livelihood security depends on peoples' knowledge and ability to use their assets in such a way that the family can make a living, meet their consumption and economic needs, cope with uncertainties, and respond to new opportunities (de Haan and Zoomers 2005). This means, given the scenarios of changing climate, livelihood security of coastal inhabitants of low-income societies by and large will depend on their ability to adapt to the impacts of climatic disasters as they heavily depend on coastal ecosystem services and agriculture for their livelihood (Wall and Marzall 2006; Allison et al. 2009). Ability to adapt means adaptive capacity which includes some processes or actions, in order to better cope with, manage, or adjust to some changing conditions, stresses, hazards, risks, or opportunities (Fankhauser et al. 1999; Kelly and Adger 2000; Smit and Pilifosova 2001; Brooks et al. 2005; Smit and Wandel 2006). In the changing context of climate, IPCC conceptualizes adaptation as an adjustment in natural or human systems in response to actual or expected climate stimuli or their effects, which moderate harm or exploits beneficial opportunities (McCarthy et al. 2001). Although adaptation is essential, it does not take place automatically. Adaptive capacity largely determines the adaptive potential (Adger et al. 2005; Perry 2007; Norris et al. 2008). Now the question is what motivates individuals to go for anticipatory adaptation against the climatic disasters when there is wide uncertainty?

Although both basic research and empirical studies have identified some of the factors that determine general adaptability of people, none did it quantitatively in the specific context of coastal people. For instance, Kellstedt et al. (2008), and Roser-Renouf and Nisbet (2008) conclude that people adapt when they have the knowledge about the benefit of adaptation and risk of nonadaptive/maladaptive responses (Steel et al. 2005). Their argument is that if the people are well aware about the benefit of adaptive response, they bolster their adaptive capacity. Conversely, people employ their full force to adapt due to fear of loss from no adaptive response. However, other scholars argue that while informedness is necessary but not sufficient. To them, only comprehension of the need for adaptation cannot guarantee any adaptive response in absence of the people's ability to adapt (Smith 1997; Smithers and Smit 1997; Adger et al. 2005). To them, individual's adaptation is largely determined by the material resources that they possess (Blaikie et al. 1994). Drawing on the literature of Maddux and Rogers (1983) personal motivation theory (PMT), some scholars even argue that psychological and behavioral factors also determine people's adaptive capacity. Those who place higher emphasis on disposition of various physical resources argue that a person without these at best can initiate a maladaptive response (Wisner et al. 2004; Pelling and High 2005; Allison et al. 2009). Those who give higher emphasis on psychological matters, they basically point finger to a person's belief about his/her ability to adapt and belief about the effectiveness of such adaptive responses (Maddux and Rogers 1983; Leiserowitz 2006; Semenza et al. 2008; Blennow and Persson, 2009). On the other hand, the proponent of adaptive behavioral factors argues that past experience of adaptive response are invaluable to demonstrate adaptive capacity against a new episode of disastrous event (Patt and Gwata 2002; Grothmann and Patt 2005; Grothmann and Reusswig 2006; Saroar and Routray 2012). The logic here is the utilization of accumulated experience helps them to initiate a new adaptive response. In fact, all arguments have their own merits. Recently, the need for climate information communication appeared as an important determinant of people's adaptive response (Kurita et al. 2006; Collins and Kapucu 2008; Leal Filho 2009; Saroar and Routray 2010). The argument here is timely access to climate/weather information products help people to prepare themselves to adapt. This is vital both for sudden and rapid onset disastrous events such as cyclones, wave surges, tsunamis, and for slow onset or creeping disasters such as desertification or some kinds of floods as well. The bottom line is that timely access to information through various public and private channels help enhancing adaptive capacity. In this respect, another often ignored dimension that some scholars count is the physical environmental or spatial/location factors (Nicholls et al. 1999; Klein et al. 2001; Tol et al. 2008). Some locations due to their geographical/morphological character are more exposed to natural disasters. People who have been living in such marginalized areas are often the disadvantaged groups having very thin adaptive capacity (Adger et al. 2003; Molnar 2010). Although they have very thin physical and financial capital, they often possess solid experience of recurrent adaptation. Apart from these abovementioned factors, various demographic and socioeconomic factors are often counted as cross cutting elements of adaptive capacity (Adger et al. 2003, Moser and Satterthwaite 2009). In fact, adaptive capacity is determined by a bundle of all of the above factors. A right combination of many of these factors can work better in a particular situation, although the same combination may not probe effective while adapting to a very different situation.

The essence derived from various scholarly works cited in the forgoing section leads one to hypothesize that adaptive capacity of coastal people against the threats of various hydrometeorological events on their livelihood security in a multi-hazard-prone area is a function of multiplicity of factors such as demographic and socioeconomic, adaptive behavioral, access to climate/weather information and knowledge products, and physical environmental (spatial/locational) aspects. The general hypothesis is decomposed in the following ways.

Hypothesis 1: Demographic and socioeconomic factors cause differences in adaptive capacity.

Hypothesis 2: Past adaptive behavioral factors cause differences in adaptive capacity.

Hypothesis 3: Access to climate/weather information/knowledge products causes differences in adaptive capacity.

Hypothesis 4: Physical environmental (spatial/locational) factors cause differences in adaptive capacity.

Research Design

Study Area, Survey Procedures, and Respondents

Empirical evidences and many earlier works suggest that “Kalapara Upazila” (subdistrict) of Patuakhali district (an administrative unit below Province/Division) which is roughly above 1 m from the mean sea level (MSL) and located along the Bay of Bengal is worst affected by various hydrometeorological disasters including cyclonic storms, surges, salinity intrusion, tidal floods, and may experience the same in the years to come (Ali 1999; Ali Khan et al. 2000; Singh et al. 2001; Karim and Mimura 2008; Pethick and Orford 2013; Kulatunga et al. 2014). Three villages from three “Union Parishad” (lowest level local government unit) such as Dulasar, Mithaganj, and Nilganj were selected from this subdistrict for the study (See Fig. 1). As a sample unit, individual household was selected. Data and information were collected through administering a semi-structured questionnaire. Randomly selected 285 respondents (usually the head of household) among which 175 males and 110 females were interviewed during January–April, 2009. Although, the original questionnaire was in English, a Bengali version was administered to facilitate the process of data and information collection.

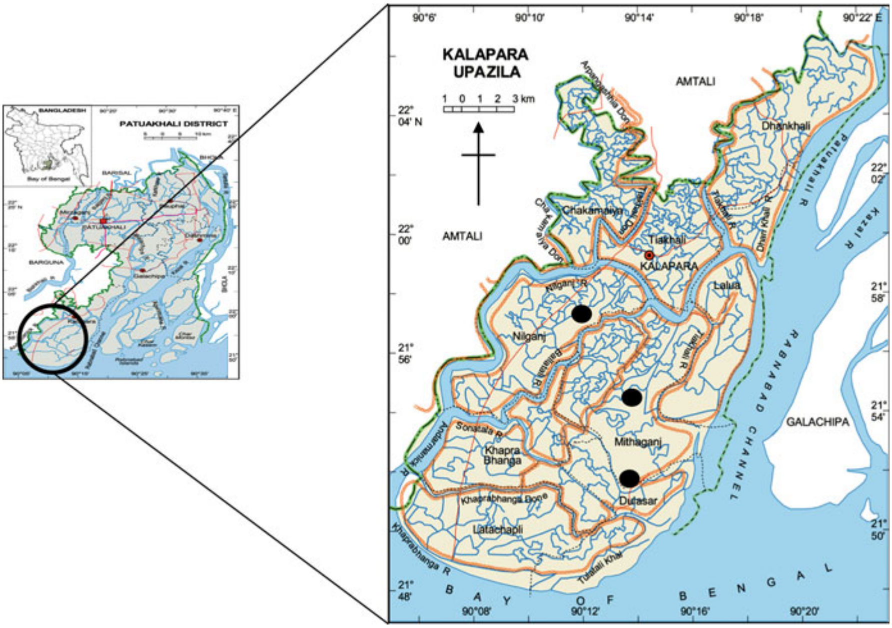

Fig. 1 Study sites (marked with *black circle*) at Dulasar, Mithaganj, and Nilganj *Union Parishad* of Kalapara subdistrict in Bangladesh

The entire study area is crisscrossed by numerous natural cannels/creeks, which are immediately connected to the Bay of Bengal through a network of river system. All the three study sites, which are located roughly within 5–20 km from the shoreline, may experience 10–40 cm inundation due to cyclonic storms, surges, and accelerated SLR before the end of this century (GOB 2005).

The study area is predominantly rural and most land parcels are used for crop agriculture. Cultivation of rice is by far the highest, followed by winter beans, legumes, nuts, and watermelon. Most land parcels are used for wet season rice which is grown during May–November. Peasants and subsistence farmers use family labor, yet agricultural activities generate employment opportunity for a significant number of people during this time. As this time many people go for both freshwater and marine fishing as wel, this brought opportunity for female labors in the farming activities. Usually the day laborers try to earn their maximum during this period to offset the loss of income in unemployed period (winter season). During winter (November to March) people cannot cultivate winter rice because of severe shortage of salt free fresh water. This causes localized seasonal unemployment.

Table 1 shows that the average age of the respondents is 49 years. Nearly half of them belong to senior age group (50 years and above) and almost one-third are in their middle age (35 to below 50). Marginally above 10 % heads of family are within the active age group (below 35 years) who can best utilize their physical labor. Almost 40 % households are comprised of 5 members followed 6-member families (30 %). Almost 60 % of the respondents are illiterate, followed by educational attainment of 5-grade (20 %) and high school graduate (~18 %).

In the traditional society of Bangladesh, the size of landholding determines social position and standing of an individual. Land distribution system is very uneven. Only handful of rich people, locally called *jutders* (landlords) traditionally own most parcels of land. Although one in every four households does not have any cultivable land of their own, some households even have more than 10 acres (~4 hectors) of land. In fact, almost 25 % households do not have any land of their own. Almost half of the households are functionally landless, possessing less than half acre (0.2 hectors) of cultivable land. Yet 8.8 % households possess more than 2.5 acres (~1 hector) of arable land. Even few households possess more than 10 acres of farmland. Therefore, the average farm size is 0.89 acres (0.36 hectors) with a standard deviation of 2.285. This uneven land distribution helps to strengthen a kind of patron–client relationship among the few landlords and the landless/ functionally landless households who cultivate the land of lords accepting often terms and condition unfavorable to them.

The crop agriculture is the most dominant economic activity. Almost one-third of the respondents are engaged in crop agricultural activities. About 20 % families depend on selling labor (day laborer) and almost a similar proportion catch fish (both freshwater and marine) to make a living. Other observed occupations are petty trade, business, transport work, formal job, and various off-farm and on-farm economic activities that combinedly offer livelihood for about 25 % families. However, most of the families possess diversified portfolios of income.

Table 1 Socio-demographic profile of respondents and their families

	Male		Female		Total	
	f	%	f	%	f	%
Age group (year):						
Below 35	19	6.7	12	4.2	31	10.9
35 to below 50	72	25.3	40	14.0	112	29.3
50 and above	84	29.5	58	20.4	142	49.8
Education:						
Nil	101	35.4	70	24.6	171	60.0
Primary level (5th grade)	31	10.9	26	9.1	57	20.
Secondary level (12th grade)	38	13.3	14	4.9	52	18.2
College graduate (14 year plus schooling)	5	1.8	0	0.0	5	1.8
Family size:						
3	16	5.6	8	2.8	24	8.4
4	24	8.4	17	6.0	41	14.4
5	67	23.5	45	15.8	112	39.3
6	52	18.2	30	10.5	82	28.8
7	13	4.6	8	2.8	21	7.4
8	3	1.1	2	0.7	5	1.8
Farmland holding[a]:						
Landless	45	15.8	25	8.8	70	24.6
Functionally landless (<0.50 acre or 0.20 ha)	88	30.9	63	22.1	151	53.0
Peasant farmer (0.50 to <2.5 acres or .20 to 1 ha)	23	8.1	16	5.6	39	13.7
Large farmer (<2.5 acre or 1 ha)	19	6.7	6	2.1	25	8.8

Note: [a]This landholding classification is proposed by BBS (1998) in its Report of the Poverty Monitoring Survey and used to target poor households for poverty-alleviation programs in Bangladesh. It is now widely followed (IFAD 2005).

For most of the occupational groups, flow of income is not smooth throughout the year. The yearly average income of the respondents' families is 141,438 BDT (US$ 2,065; during interview in 2009 the exchange was 68.5 BDT for 1 US$). However, the modal average which is only 65,000 BDT (marginally below US $ 1000) indicates that there are few households who earn much higher than most others.

Selection of Variables and Their Descriptive Statistics

Initially from the review of literature, a total of 23 factors/variables which relate to peoples' adaptive capacity against hydrometeorological disastrous events were selected as explanatory (independent) variables. The dependent variables here are the adaptive capacity of coastal people against various dimensions of livelihood insecurity. Descriptive statistics of these independent variables are presented in Table 2. Following Hardy and Bryman (eds.) (2004), a binary coding procedure is employed for dummy/dichotomous variables. Other variables are measured in their respective SI units. However, as the analysis of variance (ANOVA) technique is

Table 2 Descriptive statistics of explanatory variables used in the research

Original name of the variable and unit of measurement	Variable in abbreviated and dichotomous form	Mean of original variable	Standard deviation
1. Age of the respondent (year)	Age (d): up to 35 is compared with 35 and above	49.34	10.56
2. If sex of the respondent is male? (dummy)	Sex (d): female is compared with male	0.61	0.49
3. Education of the respondent (year of schooling)	Education (d): uneducated is compared with educated	2.86	3.89
4. If agriculture/allied job is the key source of income? (dummy)	Occupation (d): agriculture is compared with non-agriculture	0.76	0.43
5. Total farmland holding (hectare)	Farmland (d): landless is compared with or landholder	0.89	2.29
6. Household's annual income (BDT; 1 BDT = 69.5 US $)	Income (d): up to 60,000 BDT is compared with above 60,000	141438.6	182789.5
7. If member of any social group? (dummy)	Membership (d): no is compared with yes	0.18	0.38
8. Number of times changed settlement since birth due to natural disaster (number)	Change of settlement (number): no is compared with yes	0.20	0.47
9. Distance of settlement from the shoreline (km)	Distance from shoreline (d): up to 10 km is compared with above 10 km	10.00	4.09
10. Distance of safe shelter (e.g., cyclone/flood shelter) (km)	Distance of shelter (d): up to 2 km is compared with or above 2 km	1.73	0.80
11. If safe shelter is easily accessible? (dummy)	Accessibility of shelter (d): no is compared with yes	0.42	0.50
12. If adaptation with flood is recurrent? (dummy)	Flood (d): no is compared with yes	0.75	0.43
13. If adaptation with heavy rainfall is recurrent? (dummy)	Rainfall (d): no is compared with yes	0.63	0.48
14. If adaptation with intrusion of saline water is recurrent? (dummy)	Salinity (d): no is compared with yes	0.53	0.50
15. If adaptation with seasonal scarcity of freshwater or drought is recurrent? (dummy)	Drought (d): no is compared with yes	0.38	0.49
16. If adaptation with cyclone/storm surge is recurrent? (dummy)	Cyclone/surge (d): no is compared with yes	1.00	0.00
17. If always get assistance from relative during income shock? (dummy)	Assistance of relative (d): no is compared with yes	0.42	0.49
18. If always maintain peer network to have weather information? (dummy)	Peer contact (d): no is compared with yes	0.60	0.49

(*continued*)

Table 2 (continued)

Original name of the variable and unit of measurement	Variable in abbreviated and dichotomous form	Mean of original variable	Standard deviation
19. If always use television as a source of weather information? (dummy)	TV (d): no is compared with yes	0.01	0.10
20. If always read newspaper as a source of weather information? (dummy)	Newspaper (d): no is compared with yes	0.04	0.18
21. If always follow radio for weather information? (dummy)	Radio (d): no is compared with yes	0.63	0.48
22. If always adhere weather information? (dummy)	Adherence to information (d): no is compared with yes	0.40	0.49
23. If always maintain contact with officials for assistance? (dummy)	Official contact (d): no is compared with yes	0.20	0.40

intended to use all the independent/explanatory variables (shown in Table 2) are dichotomized based on mean/median values or some logical category as the case applicable. Thus the variable age became younger and elder group; education became uneducated and educated; occupation became agriculture and allied, and others; landholding became landless or landholders; etc. All dichotomized variables are presented alongside the descriptive statistics of original variables in Table 2. However, ultimately the variable – income is not used in the ANOVAs because of the presence of too many outliers (unusually high/low values) at both ends. Likewise, the variable – cyclone is not used because it is appeared as a constant, i.e., 100 % respondents have recurrent exposure to it. Details of the ANOVA procedure are presented later in the respective section.

Result and Discussion

Hydrometeorological Events and Vulnerability of Coastal Livelihood

As the study area is historically exposed to multiple hazards, the respondents are in general familiar with the impacts of cyclones, tidal surges, coastal inundation, salinity intrusion, etc. Although they are not much aware about climate change, global warming or even SLR, they feel that nature has been behaving very differently than what they had seen even one or two decades ago. By and large, respondents have a common perception that recent extreme events are more pronounced than they had been in the past. Furthermore, many of them believe that these extreme events may get even worse in the years to come.

Considering the projected scenario of SLR by the middle of this century, respondents were asked to identify the likely impacts of various hydrometeorological events, including SLR, especially if their farmlands gradually go under half of knee-deep water (20–25 cm) or surge height increases more few meters than they have had in the past. As end-of-the-century projections are large and unstable, so this research has focused on a currently living adult's lifetime as a horizon (for detail arguments, see Allen-Diaz 2009). To facilitate their responses, the respondents were supplied with a list of possible impacts on their livelihood and they were asked to rate their adaptive capacity against each of them in a simple 3-point scale [low to high]. Although the use of 5-point Likert scale is more common, a 3-point simplified scale is preferred to capture the responses of rural illiterate/less educated respondents. Further to assist them, they are suggested to give low adaptive capacity score for impacts that will highly affect their livelihood and vice versa. These simplifications by avoiding complex technical jargons and easing their (ordinary rural people – mostly lay public) understanding of the questions expedited the data collection effort without compromising the quality of data. It is worthy to note that the list of likely impacts of hydrometeorological events on coastal people livelihood security was prepared based on the review of literature having global (see Smith 1997; Middleton 1999; Bosello et al. 2007; Parry et al. 2007; Wilbanks et al. 2007; and Bunce et al. 2010) as well as regional significance with particular reference to the low-lying deltaic coasts of Asia and the Pacific (see Adger et al. 2005; Choudhury et al. 2005; Bi and Parton 2008; GOB 2009).

Table 3 presents the adaptive capacity of people against the impacts of hydro-meteorological events that affect their livelihood security. In more than 50 % cases, the adaptive capacity of people against the impacts of recurrent loss of productive/earning days, freshwater crises, harvest failure and the damage of settlements, food, fuel, and fodder are low. Similarly, a significant proportion of people demonstrate low adaptive capacity against the impacts of low wage rate, limited supply of foodstuffs in the markets, high cost of rebuilding of infrastructure, etc. Although their responses show that about 30 % cases, their adaptive capacity is high against the impacts of risky offshore fishing, increased number of non-fishing days, decreased fish catch per go, and difficulty in fish preservation. These impacts affect the livelihood security of large fishing community (both artisanal and commercial). Therefore, the information directly derived from Table 3 are too broad and do not give any precise grouping of impacts that would affect people's livelihood security by impacting their adaptive capacity.

Livelihood Insecurity and Adaptive Capacity Index

The principal component analysis (PCA) method is employed to bring altogether 25 impact statements under few manageable and distinct categories. Following the Kaiser criterion, the varimax rotation method is used to extract four major groups of impacts against which the coastal people need to have high adaptive capacity to secure their livelihood in the changing context of climate. Although these four groups have explained only 72 % of the variance in people's adaptive capacity against livelihood insecurity, the results are considered statistically valid (i.e., model validity high) because of the following reasons (Field 2005; George and

Table 3 Adaptive capacity of people against the impacts of disastrous events that cause livelihood insecure

	Adaptive capacity[a]		
Impacts of disastrous events	Low % (n)	Medium % (n)	High % (n)
Loss of crop production	48.77 (139)	36.49 (104)	14.74 (42)
Complete harvest failure	51.93 (148)	38.60 (110)	9.47 (27)
Increase cost of agricultural production	44.56 (127)	9.82 (28)	45.61 (130)
Degradation of pastureland	35.44 (101)	16.49 (47)	48.07 (137)
Seasonal shortage of fodder	43.86 (125)	7.37 (21)	48.77 (139)
Difficulty in animal/poultry husbandry	38.95 (111)	30.88 (88)	30.18 (86)
Over bank flow of fishponds/fish farm	3.86 (11)	8.07 (23)	88.07 (251)
Higher risk in offshore fishing	20.00 (57)	14.39 (41)	65.61 (187)
Limited scope of festival and social gathering	35.79 (102)	34.74 (99)	29.47 (84)
Increase in number of non-fishing day	29.12 (83)	5.96 (17)	64.91 (185)
Decrease in fish catch per go	31.93 (91)	3.16 (9)	64.91 (185)

Damage of stock of food, biomass fuel, and fodder	62.11 (177)	10.53 (30)	27.37 (78)
Cost of maintenance and rebuilding of private infrastructure	44.56 (127)	24.21 (69)	31.23 (89)
Damage of road infrastructure	22.46 (64)	43.16 (123)	34.39 (98)
Damage of social physical infrastructure, e.g., market, school, etc.	38.25 (109)	32.28 (92)	29.47 (84)
Difficulty in physical mobility	18.25 (52)	44.56 (127)	37.19 (106)
Difficulty in carrying goods and commodities	32.28 (92)	39.30 (112)	28.42 (81)
Decrease in number of earning/productive day	61.40 (175)	32.28 (92)	6.32 (18)
Fluctuation/decline in wage rate	48.42 (138)	42.46 (121)	9.12 (26)
Limited supply and stock of foodstuff in the market	42.81 (122)	43.86 (125)	13.33 (38)
Spread of contaminated water	28.42 (81)	54.04 (154)	17.54 (50)
Lack of saline free freshwater for drinking	60.70 (173)	20.00 (57)	19.30 (55)
Prevalence of waterborne diseases	26.32 (75)	54.39 (155)	19.30 (55)

Note: [a]Percentage should be read row-wise; the frequency n is in the parenthesis.

Mallery 2006; Hair et al. 2006). First the value of determinant of correlation matrix was found greater than 0; second, the Kaiser–Meyer–Olkin value for sampling adequacy was greater than 0.60 (i.e., 0.85); third, Bartlett's test of sphericity was significant at $p < 0.0001$; and finally the average communality was >0.500. Loading of these 25 variables (load factors <0.300 are not shown) under four major group are presented in Table 4.

In Table 4, the first group of livelihood insecurity against which people may need to have high adaptive capacity could broadly be labeled as "severe constraints in farming-related activities"; this group includes 10 specific impacts and explains 26 % of the variances in people's adaptive capacity against livelihood insecurity. The second group could be termed as "severe damage of physical and

socioeconomic infrastructures," which constitutes seven specific impacts and explains 21.75 % of the variance in people's adaptive capacity against livelihood insecurity. The third group could be named as "severe constraints in fishing (mostly offshore) related activities," which constitutes four specific impacts and explains 15.63 % of the variance. Finally, the fourth group which includes three specific impacts and explains 8.47 % of the variances in people's adaptive capacity against livelihood insecurity is labeled as "freshwater crisis and public health risk."

In general, it was observed that people assigned low adaptive capacity scores against impacts that make them highly vulnerable by heavily affecting their

Table 5 Key statistics of adaptive capacity indices for major four dimensions of livelihood insecurity against the hydrometeorological events

Adaptive capacity index	Min.	Max.	Mean.	SD.	Skewness
Severe constraints in farming-related activities	1.20	2.90	1.91	0.28	−0.43
Severe damage of socioeconomic and physical infrastructures	1.14	2.71	1.88	0.40	0.17

Severe crisis in freshwater supply and public health risk	1.00	3.00	1.80	0.58	0.44

livelihood security. Now following the methodology of Sullivan (2002) and modifying the formula of Wu et al. (2002), the adaptive capacity index (API) of people against each of these four major groups/dimensions of livelihood insecurity is computed. Therefore, ACI is the arithmetic mean of the adaptive capacity scores against respective impacts, which constitute each of the major four groups/dimensions of livelihood insecurity. Mathematically it can be expressed as

$$I_a = \frac{\sum V_i}{n}.$$

Here, I_a is the ACI (adaptive capacity index) of the respondents against each of the major four dimensions of livelihood insecurity; V_i is the absolute value of response that indicates the level of adaptive capacity against a particular impact that causes livelihood insecure; n is the number of impacts that constitute a major group/dimension among the identified four. The key statistics of each of the four adaptive capacity indices are presented in Table 5.

Each of these four adaptive capacity indices is used as dependent variable in ANOVA (analysis of variance) procedure to identify the factors that cause differences in people's adaptive capacity against livelihood insecurity. These are discussed in some details in the respective sections.

Hypotheses Testing to Identify the Determinants of Adaptive Capacity

Earlier from literature review it was hypothesized that in the changing context of climate, the coastal people's adaptive capacity against livelihood insecurity would be largely determined by demographic and socioeconomic aspects, past adaptive behavioral aspects, access to climate/weather information and knowledge products, and physical environmental (i.e., spatial/locational) aspects. How these four groups of factors influence the respondent's adaptive capacities are determined by employing ANOVA (analysis of variance) technique. These four groups of factors are used as independent variable and each of the four adaptive capacity indices is used as dependent variable in ANOVA procedure. Earlier, to make simple and understandable to nonspecialist readers all independent variables were dichotomized either treating the mid value (average/median) as cutoff point or following the binary coding procedure as the case applicable (for details, see Hardy and Bryman eds. 2004). Therefore, ultimately all the independent variables have two levels (dichotomous variable) which are shown in the respective tables (Tables 2, 7, 8, 9, and 10). Normally for variables having two levels, "independent sample *t* test" procedure is followed. However as multiple (four) independent sample t tests would enhance the probability (about 20 %) of occurrence of type I error, multiple ANOVAs or MANOVA (multivariate analysis of variance) is considered a better statistical technique to employ for this analysis (Field 2005). Partial correlation analysis reveals that there exists very limited correlation (all correlation coefficients are $\leq .40$) among the four dependent variables, i.e., adaptive capacity indices. Therefore, multiple ANOVA technique better suits than MANOVA for these hypotheses testing (Field 2005; Hair et al. 2006). Accordingly, four separate ANOVAs are done instead of doing a single MANOVA. In the following couple of sections, these are presented in some details.

Before employing multiple ANOVAs, the normality of data (dependent variables) is checked which is one of the preconditions of ANOVA application. The result shows that skewness for each dependent variable is less than ± 1 which means data are normal for all the dependent variables (see Table 5). Another precondition of ANOVA is homogeneity of variance (Bryman and Cramer 2001). Levene's test of homogeneity of variance shows that the assumption of homogeneity of variance is not violated because $p > .05$ (Table 6). Therefore multiple (four) ANOVAs are done. Finally, to determine the exact nature of differences in dependent variables (adaptive capacity indices) for each independent variable the parameter estimates was computed in each ANOVA. The post hoc test – univariate pair-wise comparison – was avoided as each independent variable ultimately has two levels. Results of each hypothesis test are presented in Tables 7, 8, 9, and 10.

Hypothesis 1: Demographic and Socioeconomic Factors Determine the Adaptive Capacity Against Livelihood Insecurity

Levene's test statistics shows that assumption of homogeneity of equal variance is not violated as all p values are greater than 0.05 (Table 6); therefore, the models are valid. The models show that demographic and socioeconomic factors determine the adaptive capacity against different groups of livelihood insecurity with varying

Table 6 Levene's test statistics in ANOVA for all four dependent variables

Dependent variable (adaptive capacity index)	F value	Df1.	Df2.	Sig.
Severe constraints in agriculture farming and allied activities	1.26	263	21	0.273
Severe damage of physical and socioeconomic infrastructures	0.575	263	21	0.975
Severe constraints in fishing (mostly offshore) related activities	1.37	263	21	0.200
Severe crisis in freshwater supply and public health risk	0.743	263	21	0.854

proportions. For instance adaptive capacity of 37 % ($R^2 = .37$), respondents against livelihood insecurity that results from severe constraints in agriculture farming and allied activities are determined by demographic and socioeconomic factors such as sex of respondents ($p = .005$), possession of farmland holding ($p = .000$), and membership of social group ($p = .09$) (Table 7). For about 46 % ($R^2 = .46$) respondents, adaptive capacity against livelihood insecurity that results from severe damage of physical and social-economic infrastructure are determined by demographic and socioeconomic factors such as education ($p = .057$), membership of social group ($p = .013$), possession of land holding ($p = .000$), and source of income ($p = .000$) (Table 8). Similarly, for 41 % ($R^2 = .41$) respondents, adaptive capacity against livelihood insecurity that results from severe constraint in fishing-related activities are determined by demographic and socioeconomic factors such as membership of social group ($p = .054$), possession of land holding ($p = .000$), and source of income ($p = .000$) (Table 9). Finally for 32 % ($R^2 = .32$) respondents, adaptive capacity against livelihood insecurity that results from severe crisis of freshwater and public health risk are determined by demographic and socioeconomic factors such as membership of social group ($p = .03$) and access to social capital (i.e., assistance from relatives) (Table 10).

Parameter estimates further reveals that severe constraints in agriculture farming and allied activities affect families having own land 0.22 times more ($p = .000$) and families not belonging to any social groups 0.09 times more ($p = .093$). Conversely, female-headed households are affected 0.08 times less ($p = .005$) than male-headed households. This finding is a bit different than most qualitative research where female-headed families are portrayed as having less adaptive capacity (Cannon 2002; CARE 2003). Why female-headed families are more adaptive against severe constraints in agriculture farming and allied activities is unclear to this author; this requires further exploratory research. Similarly, severe damage of physical and socioeconomic infrastructure affects educated families ($p = .057$) and families not belonging to any social groups ($p = .013$) 0.09 and 0.21 times more, respectively. Landless families are 0.23 times more adaptive against the damages of physical and socioeconomic infrastructures ($p = .000$). Severe constraints in fishing-related activities affect 0.51 and 0.32 times more the families belonging to nonagricultural activities (i.e., fishing) ($p = .000$) and belonging to any social groups ($p = .054$), respectively. Similarly, landless families are 0.45 times less adaptive to the severe constraints in fishing-related activities. Families belonging to any social group ($p = .003$) and families having social capital (e.g., get assistance from relatives) ($p = .000$) are 0.38 and 0.54 times less affected by severe crisis of freshwater and public health risk. Therefore, the hypothesis is not rejected.

Hypothesis 2: Past Adaptive Behavior Determines the Adaptive Capacity Against Livelihood Insecurity

The models show that respondent's past adaptive behavioral factors determine the adaptive capacity against different groups of livelihood insecurity with a varying combinations (Tables 7, 8, 9, and 10). For instance, adaptive capacity against

Note: Dependent variable: adaptive capacity against livelihood insecurity that results from severe crisis in freshwater supply and public health risk.
*significant at 0.10; **significant at 0.05; ***significant at 0.01

salinity intrusion ($p = .004$). Respondents who have past experience of recurrent adaptation against flooding, drought, and salinity intrusion are 0.22, 0.17, and 0.28 times more adaptive against livelihood insecurity that results from severe constraints in fishing-related activities (Table 9). However, it is unclear why people having recurrent experience of adaptation against rainfall are less adaptive to severe constraints in fishing-related activities. Finally, adaptive capacity against drought (e.g., freshwater crisis) and public health risk are determined by adaptive behavioral factors such as torrential rainfall ($p = .013$). Respondents having recurrent experience of adapting to torrential rainfall are 0.184 times more impacted by freshwater crisis and public health risk (Table 10). Therefore, the hypothesis is not rejected.

Hypothesis 3: Access to Climate/Weather Information and Knowledge Products Determines Adaptive Capacity Against Livelihood Insecurity

The models show that respondent's use of climate/weather information and knowledge products determines the adaptive capacity against different groups of livelihood insecurity with varying combinations (Tables 7, 8, 9, and 10). For instance, adaptive capacity against livelihood insecurity that results from severe constraints in agriculture farming and allied activities are determined by respondent's use of climate/weather information and knowledge products such as television ($p = .013$) and newspaper ($p = .012$). Respondents who use television and newspaper on a regular basis as a source of climate/weather information and knowledge products are 0.37 and 0.23 times more adaptive against livelihood insecurity that results from severe constraints in agriculture and allied activities (Table 7). Similarly, adaptive capacity against livelihood insecurity that results from severe constraints in fishing-related activities are determined by respondent's adherence to climate/weather information and knowledge products ($p = .086$). For instance, respondents who always try to follow the climate/weather information and knowledge products are 0.16 times more likely to be adaptive to severe constraints in fishing-related activities (Table 9). Finally, adaptive capacity against livelihood insecurity that results from severe crisis of freshwater and public health risk are determined by respondents use of climate/weather information and knowledge products such as newspaper ($p = .072$) and official sources ($p = .070$). Respondents who use newspaper and official sources (by contacting local officials) on a regular basis are 0.35 and 0.21 times more adaptive against livelihood insecurity that results from severe crisis in freshwater and public health risk (Table 10). However, uses of climate/weather information and knowledge products do not significantly influence the respondent's adaptive capacity against livelihood insecurity that results from severe damage of physical and socioeconomic infrastructures (Table 8).

To all surprise, it has been observed that no significant differences in adaptive capacities are observed among frequent radio users and nonusers. This finding does not confirm many other findings such as the ones of Kurita et al. (2006), Collins and Kapucu (2008). This research lacks in sufficient empirical evidences to substantiate this unusual finding. Further exploratory research may bring out the latent causes. Similarly, contrary to general expectation it is found that adherence to climate information make only little differences in adaptive capacity of the respondents. Those who always follow weather information are rather worse off while adapting against loss of employment in offshore activities. It is probably because, those who care about weather information hardly go out for off shore/deep sea fishing; therefore, they loss too many earning days throughout the rainy season (June to October) when most of the gusty wind and cyclonic events take place. Finally it can be argued that despite very casual influence of some of the climate/ weather information sources, by and large access to climate/weather information and knowledge products cause differences in respondents' adaptive capacity against the impacts of hydrometeorological events on their livelihood security. Thus, the hypothesis is not rejected.

Hypothesis 4: Spatial and Locational (i.e., Physical Environmental) Factors Determine the Adaptive Capacity Against Livelihood Insecurity The models show that physical environmental factors determine the adaptive capacity against different groups of livelihood insecurity with varying combinations (Tables 7, 8, 9, and 10). For instance, adaptive capacity against livelihood insecurity that results from severe damage of physical and socioeconomic infrastructures are determined by physical environmental factors, such as distance from the shoreline ($p = .096$) and access to safe shelters ($p = .000$). Respondents who have been living within 10 km from shoreline are .07 times less adaptive to severe damage of physical and socioeconomic infrastructures than people who have been living more than 10 km away from the shoreline. Similarly, respondents who have good accessibility to safe shelters are 0.18 times less likely to be affected by severe damage of physical and socioeconomic infrastructures (Table 8).

Similarly, adaptive capacity against livelihood insecurity that results from severe constraints in fishing-related activities are determined by physical environmental factors such as distance of safe shelters from home ($p = .089$). Respondents who have claimed that the nearest safe shelter is less than 2 km away are 0.19 times more likely to be adaptive to livelihood insecurity that results from severe constraints in fishing-related activities (Table 9). Finally, adaptive capacity against livelihood insecurity that results from severe crisis of freshwater and public health risk are determined by physical environmental factors, such as distance of safe shelters from home ($p = .093$). Respondents who have claimed that the nearest safe shelter is less than 2 km away are 0.14 times more likely to be adaptive to livelihood insecurity that results from severe crisis of freshwater and public health risk (Table 10). It is probably because in most cases construction of safe shelters are accompanied by construction of freshwater ponds for use in emergencies as well as in normal time. However, physical environmental factors do not have statistically significant influence on respondent's adaptive capacity against livelihood insecurity that results from severe constraints in agricultural farming and allied activities. Therefore, the hypothesis is not rejected.

Overall findings suggest that highest number of nine factors determine the adaptive capacity of people against the livelihood insecurity that results from severe constraints in fishing-related activities. Among these nine factors, three are related to demographic and socioeconomic aspects; four factors are related to adaptation behaviors. One factor from each of climate/weather information/ knowledge products and physical environmental category significantly influence the adaptive capacity against the livelihood insecurity results from severe constraints in fishing-related activities. As a whole, adaptive behavioral factors have the highest influence followed by demographic and socioeconomic factors. Livelihood insecurity that results from severe damage in physical and socioeconomic infrastructures is significantly determined by eight factors. Among these eight factors, four factors are related to the demographic and socioeconomic aspects of people. Two factors are related to people's adaptation behaviors. Another two factors are linked to the physical environment where the livelihood of people operates. Highest number of two physical environmental factors determine people's adaptive capacity against the impacts that result from severe damage in physical and socioeconomic infrastructures. Climate/weather information and knowledge products-related factors do not have statistically significant

Note: LISD-1: Livelihood insecurity results from severe constraints in agriculture; LISD-2: Livelihood insecurity results from severe damage in physical and socioeconomic infrastructures; LISD-3: Livelihood insecurity results from severe constraints in fishing related activities; LISD-4: Livelihood insecurity results from severe crisis of freshwater and public health risk.

influence on this group of adaptive capacity. Adaptive capacity against the impacts of livelihood insecurity that results from severe constraints in agriculture and allied activities is primarily determined by three demographic and socioeconomic factors. Physical environmental factors do not have any statistically significant influence on this adaptive capacity. Finally, the adaptive capacity against the livelihood insecurity that results from severe crisis of freshwater and public health risk is determined by six factors. Among these factors, two are related to demography and socioeconomic aspects and another two are related to use of climate/weather information products. Both adaptive behavioral and physical environmental factors have limited influence on this adaptive capacity. In sum, adaptive behavioral factors are the strongest determinants of people's adaptive capacity against the livelihood insecurity that results from severe constraints in fishing-related activities. Conversely, demographic and socioeconomic factors are the strongest determinants of adaptive capacity against the livelihood insecurity that results from severe damage in physical and socioeconomic infrastructures. Physical environmental factors have highest influence on adaptive capacity against the livelihood insecurity that results from severe damage in physical and socioeconomic infrastructures as well (Table 11).

Concluding Remarks

Increasing numbers of literature stress the importance of identification of factors that determine the adaptive capacity of people against the impacts of natural disasters. In the changing context of climate as both the frequency and the magnitude of some of the hydrometeorological events are projected to increase this call for a fresh look at the impacts of these events on livelihood security of the coastal people. This chapter first established the ground of amplification of various hydrometeorological disastrous events in coastal Bangladesh. It then identifies the likely threat of various hydrometeorological events on the livelihood security of natural resource-dependent coastal community in Bangladesh taking Kalapara Upazila (subdistrict) as the case study. Employing the PCA analysis from a long list of sources/causes of livelihood insecurity, four major dimensions of insecurity are identified. Therefore, the livelihood insecurity against which adaptive capacity need to be enhanced are (a) severe constraints in agriculture farming and allied activities; (b) severe damage of physical and socioeconomic infrastructures; (c) severe constraints in fishing (mostly offshore) related activities; and (d) severe crisis in freshwater supply and public health risk. At this point, the question arises how to intervene to enhance these four dimensions of adaptive capacity of peoples. It is highly unlikely that adaptive capacity of every one need to be enhanced in the same way. Hence, it is important to determine the characteristics that are associated with different dimensions of adaptive capacity. The multiple ANOVA techniques were employed to determine the influences of four groups of variables, namely, demographic and socioeconomic, past adaptive behavioral, climate/weather information/knowledge products, and physical environmental (spatial/locational) aspects on four dimensions of adaptive capacity.

The findings are robust. Among the demographic and socioeconomic factors, sex, education, occupation, farmland holding, membership status (of social institution), and assistance from neighbor/relative have the strongest influence on differential adaptive capacity in general. The influence of other demographic and socioeconomic factors is not statistically significant. Similarly, among the past adaptive behavioral factors, except the freshwater crisis, all other variables, namely, flood, rainfall, and salinity intrusion have strong influence in making difference in adaptive capacity. Likewise, among the climate/weather information/knowledge products, almost all have limited influence on various dimensions of adaptive capacity. However, contrary to expectation no statistically significant influence of radio on adaptive capacity is identified. This finding does not follow most literatures on the burgeoning role of information communication media on adaptive capacity. Therefore, this finding has to be triangulated with more in-depth study before making any conclusion about the role of information channels on adaptive capacity. This seems to be a weakness of this research as well. On the positive side, it can be argued that this research opens up a new avenue of further exploratory research. Similarly, all the physical environmental (spatial/locational) factors have limited influence on differential adaptive capacity of coastal people. Finally, it could be argued that while all the four major group of factors are important determinants of adaptive capacity against hydrometeorological disastrous events in coastal Bangladesh, the past adaptive behavior against flood, rainfall, salinity intrusion, and the few others socioeconomic factors, such as occupational engagement, land holding, and educational attainment are the key drivers of peoples adaptive capacity. Considering the heavy influence of most of the adaptive behavioral factors it can be said that the past experience of adaptation probably the cause of the winning the battle of the resource poor coastal people of Bangladesh against the various hydrometeorological disasters throughout the history. This finding stresses the importance of nurturing of local/traditional/indigenous knowledge of adaptation alongside initiation of programs for livelihood vulnerability reduction. Finally, it is concluded that rather than launching very generic program for adaptive capacity building of the coastal inhabitants in general, specific program may be initiated for specific group of natural resource-dependent coastal people whose livelihood are vulnerable to specific impacts of various hydrometeorological disastrous events. This finding can help policy makers and planners alike in identifying people in need of specific adaptive capacity enhancement program.

Acknowledgment The authors acknowledge the research grant provided by the Norwegian Ministry of Foreign Affairs as a part of Scholarship for doing Doctor of Philosophy (PhD) of the first and corresponding author at the Asian Institute of Technology (AIT) in Thailand, supervised by the second author. The authors would like to thank anonymous reviewer (s) for giving constructive comments. Finally, first author is thankful to the field surveyor team led by Papon and Shamim of URP discipline, Khulna University.

Mainstreaming Integrated Climate Change Adaptation and Disaster Risk Reduction in Local Development Plans in the Philippines

Ebinezer R. Florano

Contents

Abstract

This chapter illustrates how the two conceptually distinct climate change adaptation (CCA) and disaster risk reduction (DRR) are mainstreamed in the development plans of local government units in the Philippines using integrated frameworks for vulnerability analysis and the development of climate-resilient local Comprehensive Land Use Plan (CLUP) and Comprehensive Development Plan (CDP) prescribed by the national government. The integration of CCA and DRR in the Philippines came after the failure of the passive disaster management, utilized since 1954, to prepare and response to disasters caused by extreme weather events of climate change. Using the case study approach, this chapter narrates how disaster-prone Sorsogon City was able to incorporate CCA and DRR measures and strategies in its CLUP and CDP.

Mainstreaming • Climate change adaptation • Disaster risk reduction • Vulnerability analysis • Local development planning

Introduction

Climate change adaptation (CCA) and disaster risk reduction (DRR) have always been treated as two distinct epistemic communities in scholarly literature (Mercer 2010; Schipper and Pelling 2006; Tearfund 2008; Thomalla et al. 2006; UNISDR 2008a, b, c). Thus, it is no wonder that even in practice, the two coexist, but they are operationalized independently of one another. In the Philippines, for example, there are two separate laws on climate change (CC) and disaster risk reduction and management (DRRM), namely, the *Climate Change Act of 2009* (Republic Act No. 9729 or RA 9729) and the *Philippine National Disaster Risk Reduction and Management Act of 2010* (Republic Act No. 10121 or RA 10121), respectively. They are implemented by separately funded national government agencies – the Climate Change Commission (CCC) and the National Disaster Risk Reduction and Management Council (NDRRMC). Both laws mandate local government units (LGUs), namely, provinces, cities, municipalities, and *barangays* (villages), to mainstream their local CCA and DRR plans to their local development plans. Is this possible, given the conceptual and operational divide between CCA and DRR? Can the two be reconciled? Can an integrated CCA and DRR be mainstreamed in local development plans? To answer these questions, this study revisits the discourses on the similarities, differences, and signs of convergence between the two communities. It also examines the nexus between the two based on the implementation of the CC and DRRM laws in the Philippines. Finally, using a case study on an LGU, this chapter proves that, indeed, the two can be integrated and mainstreamed in local development plans.

Similarities, Differences, and Points of Convergence Between CCA and DRR

Theoretically speaking, it is inconceivable to integrate CCA and DRR primarily because of their temporal and spatial nuances. According to generally accepted views, CC-induced hazards and disasters are less predictable because they are based on projections of the atmospheric and ocean conditions which are still to happen in the future, while non-CC-related hazards and disasters are studied based on historical records and, hence, are relatively predictable. Second, due to the uncertainties in projecting CC, its impacts are difficult to calculate, while those in DRRM are easily discernible because it relies on records to determine the extent of damages that can be caused by particular hazards in the future. Third, in terms of origin, CC originated from scientific theory, while DRRM evolved out of the need to

Table 1 Summary of similarities, differences, and signs of convergence between CCA and DRR

DRR	CCA	Signs of convergence
Relevant to all hazard types	Relevant to climate-related hazards	Not applicable
Origin and culture in humanitarian assistance following a disaster event	Origin and culture in scientific theory	CCA specialists now being recruited from engineering, agriculture, health and DRR sectors
Most concerned with the present – i.e., addressing existing risks	Most concerned with the future – i.e., addressing uncertainty/new risks	DRR increasingly forward-looking
		Existing climate variability is an entry point for CCA
Historical perspective	Future perspective as above	Same as above
Traditional/indigenous knowledge at community level is a basis for resilience	Traditional/indigenous knowledge at community level may be insufficient for resilience against types and scales of risk yet to be experienced	Examples where integration of scientific knowledge and traditional knowledge for DRR provides learning opportunities
Structural measures designed for safety levels modelled on current and historical evidence	Structural measures designed for safety levels modelled on current and historical evidence and predicted changes	DRR increasingly forward-looking
Traditional focus on vulnerability reduction	Traditional focus on physical exposure	Not applicable
Community-based process stemming from experience	Community-based process stemming from policy agenda	Not applicable
Practical application at local level	Theoretical application at local level	CCA gaining experience through practical local application
Full range of established and developing tools	Limited range of tools under development	None, except increasing recognition that more adaptation tools are needed
Incremental development	New and emerging agenda	Not applicable
Political and widespread recognition often quite weak	Political and widespread recognition increasingly strong	None, except that climate-related disaster events are now more likely to be analyzed and debated with reference to CC
Funding streams ad hoc and insufficient	Funding streams sizeable and increasing	DRR community engaging in CCA funding mechanisms

provide humanitarian assistance to disaster victims (Mercer 2010; ProAct Network 2008; Schipper and Pelling 2006; Tearfund 2008; Thomalla et al. 2006; UNISDR 2008a, b, c). There are many other points of divergence between the two (as can be seen in Table 1), but there are also points of convergence, the most important of which is to reduce risk and enhance resilience.

In the Philippines, it is argued that there are "conceptual" and "operational" divide between CCA and DRR in terms of approach, organization and institutions, strategies, policies, and funding as shown in Table 2.

Initially, "conceptual divide" permeated the debates between CCA and DRR in the Philippines immediately after the laws that created them were passed.

However, not long afterward, it was finally recognized that although the two are distinct fields, they are connected in their objective to reduce risk to CC-induced hazards and disasters. While DRR deals with both man-made and "natural disasters" caused by geophysical and ecological hazards, it is also concerned with climate- and weather-related hazards which fall within the ambits of CC, i.e., gradual changes in climatic parameters (e.g., sea-level rise, rising mean temperature, and changes in precipitation patterns) and extreme weather events with increased frequency and severity. Figure 1 below illustrates the conceptual convergence between the two.

The "operational divide" is believed to be the most persistent issue between the two because the evidences are clear – two distinct laws, two government agencies, separate budgets, and distinct approaches. Although CCA came a year ahead (through the *Climate Change Act of 2009*) of DRR (through the *Philippine National Disaster Risk and Management Act of 2010*) in terms of enactment, the latter has been institutionalized since 1954 with the creation of the National Civil Defense Administration via Republic Act No. 1190 also known as the *Civil Defense Act of 1954*. Seven presidential issuances after that law, the National Disaster Coordinating Council was created through Presidential Decree No. 1566 issued in 1978. Hence, DRR acquired "seniority" over CCA and its operating agency (the NDRRMC) gets more funds, has a larger bureaucracy, has longer track record, and is relatively more technically competent to do its tasks. CCA and its operating agency (the CCC), on the other hand, is still in its infancy stage. Yet, a closer scrutiny of the laws, institutional and operational arrangements reveal points of operational convergence.

First, both laws, even though they use two interventions, i.e., adaptation and disaster mitigation, aim to reduce risks or vulnerabilities from natural hazards.

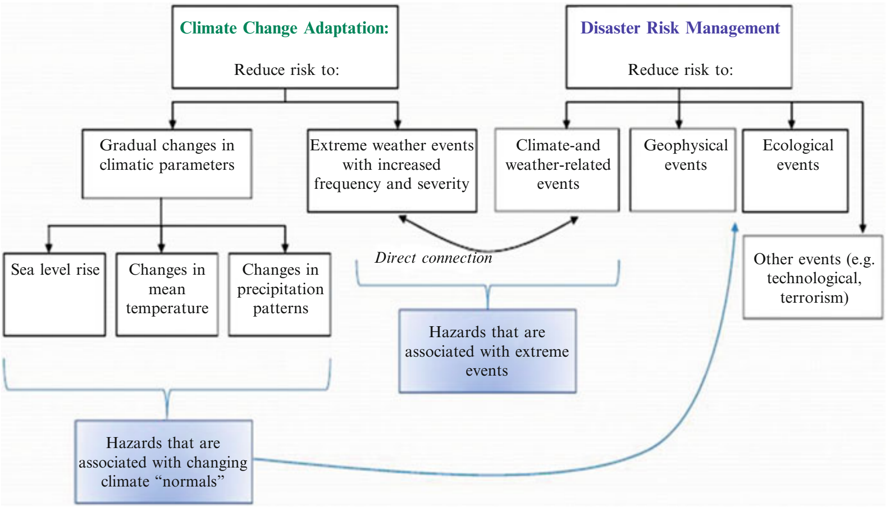

Fig. 1 CCA and DRR: point of conceptual convergence (Source: Gotangco 2012)

- **Section 3n of the *CC Act of 2009*:** Adaptation – "refers to the adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, *which moderates harm or exploits beneficial opportunities*"
- **Section 3 of the *DRRM Act of 2010*:** Disaster mitigation – ". . .Structural and non-structural measures undertaken to limit the adverse impact of natural hazards, environmental degradation and technological hazards and to ensure the ability of at-risk communities *to address vulnerabilities aimed at minimizing the impact of disasters. . .*"

Thus, the visions of the two, as contained in their national plans of action, for a climate-resilient Philippines also converge:

- ***National Climate Change Action Plan (NCCAP)***: "Build the adaptive capacities of women and men in their communities, *increase the resilience of vulnerable sectors and natural ecosystems to climate change* and optimize mitigation opportunities towards gender-responsive and rights-based sustainable development."
- ***National Disaster Risk Reduction and Management Plan (NDRRMP)*:** "Safer, *adaptive and disaster-resilient Filipino communities* toward sustainable development."

Second, both laws recognize the two fields (CCA and DRR) and their interrelationships:

- **Section 2 of the *CC Act of 2009*:** "Further recognizing that climate change and disaster risk reduction are closely interrelated and effective disaster risk reduction will enhance climate change adaptive capacity, *the State shall integrate disaster risk reduction into climate change programs and initiatives*."
- **Section 6 (n) of the *DRRM Act of 2010*:** "*In coordination with the Climate Change Commission, formulate and implement a framework for climate change adaptation* and disaster risk reduction and management from which all policies, programs and projects shall be based. . ."

Third, both laws aim to mainstream CCA and DRR in local development plans. The *CC Act of 2009* mandates all government agencies to draw up their CC action plans which are going to be mainstreamed, in synergy with DRR, in national, sectoral, and local development plans. On the other hand, the *DRRM Act of 2010* orders all local governments to come up with their local DRRM plans which are going to be incorporated in their CLUPs and CDPs.

Fourth, the CCC and NDRRMC are headed by the President of the Philippines as their chairman. Hence, should conflicts arise, they can be resolved under the supervision of one person – the President of the Philippines.

Fifth, heads of both agencies are members in the decision-/policy-making units of the other. The Executive Director of the Climate Change Office (CCC) is a council member of the NDRRMC. On the other hand, the chair of the NDRRMC (i.e., Secretary of National Defense) is a member of the advisory board of the CCC.

Sixth, even though the CCC and the NDRRMC have separate budgets at the national level, local governments are free to use their 5 % Local DRRM Fund and 20 % Local Development Fund for CCA- and DRR-related activities.

Seventh, in a memorandum of understanding for collaboration program on Philippine climate risk reduction signed in April 2011, the NDRRMC and the CCC pledged to work together to harmonize, coordinate, and support the implementation of the local CC action plans and local disaster risk reduction and management plans of LGUs (NDRRMC-CCC 2011).

Last, the most important of all, the operational plans of the CCC's *NCCAP* and the NDRRMC's *NDRRMP* have integrated the activities of both fields. In the *NDRRMP*, all DRR phases (i.e., mitigation and prevention, preparation, rescue and relief, and recovery and rehabilitation) integrate two major priority areas of the CCC's *NCCAP*, namely, "human security agenda" and "ecosystem and environmental stability" (see Table 3). Majority of these integrated CCA and DRR operational activities can be mainstreamed in the local development plans of LGUs.

Mainstreaming CCA and DRR in Local Development Plans

LGUs in the Philippines are mandated to formulate two major local plans which serve as the entry points for CCA and DRR integration. These are the Comprehensive Land Use Plan (CLUP) and the Comprehensive Development Plan (CDP). They are both formulated with guidance from political leaders' visions for their localities and constituencies. Ideally, the CLUP is formulated first to serve as framework for the CDP and other plans (see Fig. 2). However, the planning of both the CLUP and the CDP can proceed simultaneously once the visions of the local leaders are known and have been validated.

Integrating CCA and DRR in the CLUP

The CLUP is the long-term (10–15 years) physical development plan for the management of local territories. It is formulated by the local planning and development office and approved by the local legislative council, i.e., *Sangguniang Panlalawigan* (Provincial Legislative Council) in case of a province, *Sangguniang Panglungsod* (City Legislative Council) in case of a city and *Sangguniang Pangbayan* (Municipal Legislative Council) in case of a municipality.

CLUPs spell out local governments' land use policies in the areas of settlements, infrastructures, production areas, and protected areas. These land policies are aimed to rationally distribute population in the territory, ensure that the population has access to basic social and economic services and opportunities, protect the environment, and promote sustainable development.

CLUPs at the municipal and city levels must be aligned with their higher counterparts, i.e., Provincial Physical Framework Plan, Regional Physical Framework Plan

Table 3 Points of integration of the operational plans of the *NCCAP* and the *NDRRMP*

NCCAP	NDRRMP
Human security agenda	
Conduct of provincial-level vulnerability and risk assessments	Prevention & mitigation
Mainstream and implement local plans based on information from the vulnerability and risk assessment	Prevention & mitigation
Develop and implement knowledge management on CC and disaster risks	
Increase local and community capacities for CCA/DRRM	
Integrate CC and DRR in the training of health personnel and community workers	Crosscutting concerns Strategies Prevention & mitigation Preparedness
Improve system for health emergency preparedness and response for climate and disaster risks	
Improve system for post-disaster health management	
Develop a long term plan for adaptation of highly CC vulnerable population and climate refugees	Prevention & mitigation
Extensive IEC program on CC risks and population management	Strategies Prevention & mitigation Preparedness
Ecosystem and environmental stability	
Conduct a nationwide gendered ecosystem vulnerability and risk assessment	Crosscutting concerns Prevention and mitigation
Derive and implement mitigation and adaptation strategies for key ecosystems	
Implement the National REDD Plus Strategy	Prevention and mitigation
Expand the network of protected areas (PAs) and key biodiversity areas (KBAs)	Prevention and mitigation
Establish ecosystem towns or eco-towns in PAs and KBAs	Prevention and mitigation
Design gender-fair innovative financing mechanisms and a bundle of CC adaptation assistance for eco-towns/communities	Crosscutting concerns
Implement moratorium on polluting and extractive industries in PAs, KBAs, and other environmentally critical areas	Prevention and mitigation
Increase knowledge and capacity for integrated ecosystem-based management at the national, local, and community levels	Strategies Prevention and mitigation Preparedness
Review and revise Philippine Economic-Environmental and Natural Resources Accounting (ENRA)	Prevention and mitigation
Implement training programs on wealth accounting or ENRA for key government agencies	Prevention and mitigation

Source: NDRRMC 2011, p. 65

and National Physical Framework Plan (see Fig. 3). Once approved, the CLUPs are enforced through zoning ordinances (ZOs) and become the basis for the formulation of CDPs (refer again to Fig. 2).

In the preparation of CLUPs, the Housing and Land Use Regulatory Board (HLURB), a national quasi-judicial government agency tasked in planning and regulating housing and land development matters, prescribes the following 12-step

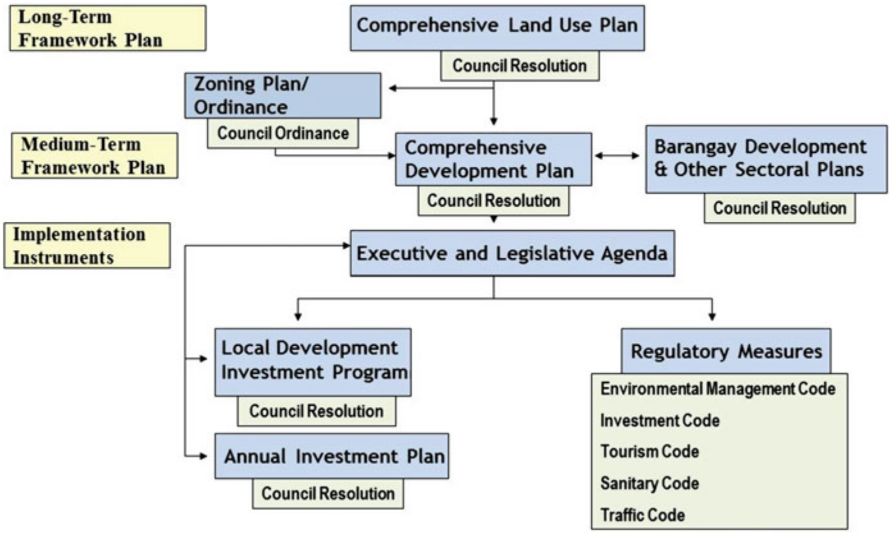

Fig. 2 Level of local development plans (Source: DILG-BLGD 2008, p. 19)

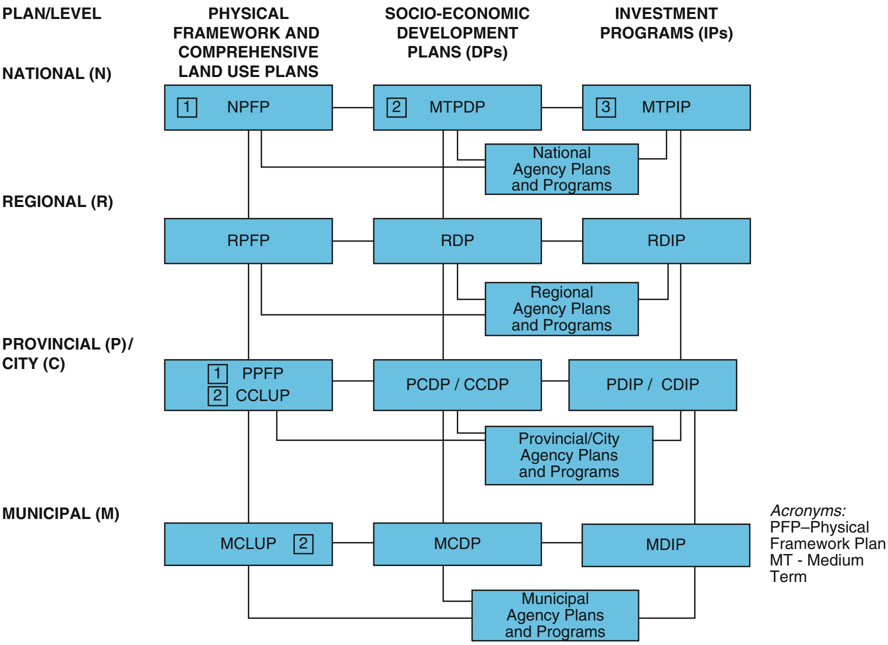

Fig. 3 Hierarchy and linkages of plans (Source: HLURB 2006, p. 4)

process for comprehensive land use planning: (1) getting organized; (2) identifying stakeholders; (3) setting the vision; (4) analyzing the situation; (5) setting the goals and objectives; (6) establishing the development thrust and spatial strategies; (7) preparing the land use plan; (8) drafting the ZO; (9) conducting public hearing on the draft CLUP and ZO; (10) reviewing, adopting, and approving the CLUP and ZO; (11) implementing the CLUP and ZO; and (12) monitoring, reviewing, and evaluating the CLUP and ZO. In 2011, the HLURB, in consultation with CC and DRRM experts, identified the entry points of CCA and DRR in each step of the planning process. The factors considered were funds, CC/DRRM experts/agencies' involvement; inclusion of CC and DRR concepts, measures, strategies, and indicators in each step; etc. For details, see Table 4.

Integrating CCA and DRR in the CDP

The CDP contains the multi-sectoral medium-term (6 years) plans of a local government that promote the general welfare of its inhabitants. It consolidates the goals, objectives, strategies, programs, projects, and legislative measures of the following development sectors: economic, social, environmental, physical/infrastructure, and institutional.

CDPs are crafted by Local Development Councils (LDCs) which are composed of technical experts and political leaders. At the technical side, members include representatives from local special bodies (e.g., local school board), sectoral and functional committees, department heads, local planning and development office, national government agencies and private sector. At the political side, there are representatives from the LDC itself, local legislative council, the congressional representative and civil society organizations. LDCs are chaired by local chief executives.

A CDP's timeframe is coterminous with the term of the elected local chief executive. Once a CDP has been written, it serves as inputs to Executive-Legislative Agenda (ELA) of the local leaders. The development sectors' programs and projects are then incorporated in the Local Development Investment Program (LDIP) which, in turn, is implemented through the Annual Investment Program (AIP) and the Annual Budget (AB). Refer to Fig. 2 above and Table 5 below for the hierarchy and relationship of these major local government plans.

In 2008, the National Economic and Development Authority (NEDA), the central planning agency of the Philippines, published the *Guidelines on Mainstreaming Disaster Risk Reduction in Subnational Development and Land Use/Physical Planning*. It is a tool to improve regional and provincial planning analysis by recognizing risks posed by natural hazards and the vulnerability of the population, economy, and the environment to these hazards.

The guidelines were initially focused on mainstreaming DRR to CLUPs, CDPs, and other local development plans because, as was stated before, the Philippines has a long history with disaster management. Later, CCA was incorporated into the DRR mainstreaming framework.

Table 4 Entry points for CCA/DRR integration into the 12-step planning process for CLUP

Step no.	Process	Entry point for CCA/DRR integration
1	**Getting organized** Getting endorsement/approval from local legislative council Preparation of work program Organization and briefing of planning team	Include budget for DRR/CCA Involve representative from DRR Office in the planning team
2	**Identify stakeholders** Listing of stakeholders Action planning Information dissemination	Involve DRR/CCA stakeholders and collective strengthening on community awareness on natural disasters (CSCAND) agencies
3	**Setting the vision** Conduct of visioning workshops Adoption of vision and informing the public	Include DRR/CCA concepts in the vision (e.g., "safety," "secured," "climate resilient," "climate proof," etc.)
4	**Situation analysis** Data gathering and land use surveys Base map preparation Sectoral studies and physical/land use studies Mapping of results Consultation/validation workshops Need/issues analysis and projections Cross-sectoral analysis and integration	Conduct CCA/disaster risk assessment and vulnerability assessment Conduct adaptive capacity assessment Use results to conduct analysis of climate change/risk impacts to land use and exposed population, socioeconomic conditions, infrastructure system Identify/propose policies/mitigating/adaptation measures
5	**Setting the goals and objectives** Goals and objectives formulation workshops	Identify development issues and their translation to goals, objectives, and targets Include CCA/DRR concepts in the goals, objectives, and targets
6	**Establishing desired development thrust and defining spatial strategies** Development options Preferred development thrust and spatial strategy Structure plan/conceptual framework plan	Consider CCA/DRR strategies and measures to respond to identified CC/DR
7	**Preparing the land use plan** Proposed land and water uses policies Proposed circulation network Major development programs/projects	Involve representative from DRR office in the planning team Ensure land use and zoning policies address identified CC/DR such as disaster risk zoning Identify CCA/DRR projects, plans, and activities (PPAs)
8	**Drafting of zoning ordinance (ZO) and other development controls**	Involve representative from DRR office in the planning team Ensure land use and zoning policies address identified CC/DR such as disaster risk zoning Identify CCA/DRR projects, plans, and activities (PPAs)

(*continued*)

Table 4 (continued)

Step no.	Process	Entry point for CCA/DRR integration
9	**Conduct public hearing** Conduct of public hearings/ consultations Refinement of draft CLUP and ZO	
10	**CLUP review/adoption and approval** Endorsement for review of appropriate body Conduct of review by appropriate body Refinement of CLUP by local government unit Local legislative council adoption of refined CLUP Endorsement to local legislative council/ HLURB for ratification/approval Ratification of local legislative council/ HLURB	Involve representative from DRR office in the regional/provincial land use committee (RLUC/PLUC)
11	**Implementing the CLUP** Required operating bodies/offices Permitting and clearance system CDP-LDIP-AIP-PPP implementation	Ensure strict implementation of CCA/ DRR-enhanced CLUP and ZO
12	**Monitoring, reviewing, and evaluating the CLUP**	Include CCA/DRRM indicators in the monitoring and evaluation system Continually monitor level of disaster risks/CC effects and emerging threats

Source: HLURB 2012

Acronyms: *CDP* Comprehensive Development Plan, *LDIP* Local Development Investment Plan, *AIP* Annual Investment Plan, *PPP* public-private partnership

At first, the guidelines advise LGUs to undertake disaster risk assessment (DRA). Briefly, DRA involves the following: (a) hazard characterization/frequency analysis, (b) consequence analysis, (c) risk estimation, and (d) risk prioritization. Below are the summaries for each of the processes involved in each step of DRA:

Hazard characterization/frequency analysis – the in-depth study and monitoring of hazards to determine their potential, origin (i.e., geologic or hydrometeorologic), geographical extent, and hazard impact characteristics including their magnitude-frequency behavior, historical behavior, and initiating (or triggering) factors

Consequence analysis – determining or defining the elements at risk from a given hazard and defining their vulnerability

Risk estimation –involves the integration of the results of *hazard characterization and frequency analysis* (or *hazard analysis)* with *consequence analysis* to derive an overall measure of risk

Risk prioritization – is undertaken to guide the identification of areas needing urgent attention

Source: NEDA-UNDP-ECHA 2008, pp 35–47

Table 5 Major plans of local government units

Plan	Definition	Main contents	Timeframe
Comprehensive Land Use Plan (CLUP)	Policy guide for the regulation of land uses embracing the LGU's entire territorial jurisdiction	Policies on settlements, protected areas, production areas, and infrastructure	10–15 years
Comprehensive Development Plan (CDP)	Multi-sectoral (economic, social, environmental, physical/infrastructure, institutional) plan to promote the general welfare of the LGU	Sectoral goals, objectives, strategies, programs, projects, and legislative measures	6 years
Executive-Legislative Agenda (ELA)	Term-based counterpart of the CDP	Sectoral goals, objectives, strategies, prioritized programs and projects, and legislative measures	3 years
Local Development Investment Plan (LDIP)	Principal instrument for implementing the CDP and ELA	Prioritized projects, plans and activities (PPAs) and program for planned financing	3 years
Annual Investment Plan (AIP)	One year slice of the LDIP	Prioritized PPAs proposed for inclusion in the annual local budget	1 year

Source: DILG-NEDA-DBM-DOF 2007, p. 9

The results in the DRA are then mainstreamed in development planning through the following primary entry points: (a) analysis of the planning environment; (b) identification of issues and problems; (c) formulation of goals, objectives, and targets; (d) formulation of development strategies, and (e) identification of programs, projects, and activities (PPAs). Refer to Fig. 4.

Issues and problems are based on either existing or potential land use conflicts associated with the risks or their impacts to the developmental objectives of LGUs. From these analyses, goals, objectives, and targets are identified and refined according to the vision of local governments. Once these had been made, the corresponding interventions, in the forms of PPAs, of the local government vis–àvis the disaster risks are formulated and prioritized. These interventions may come in the form of the following measures: (a) risk avoidance or elimination, (b) risk reduction or mitigation, (c) risk sharing or transfer, and (d) risk acceptance or retention.

The secondary entry point for the mainstreaming of the integrated CCA/DRR is in the plan implementation stage. This involves investment programming, budgeting/financing, implementation, and monitoring and evaluation.

In investment programming, the LDIP is drafted. It is a prioritized list of PPAs for 3 years with the corresponding annual expenditures. The LDIP is then sliced into 1-year AIP whose expenditures are to be included in the annual local budget. Funds for the budget come from local development fund, local DRRM fund, local

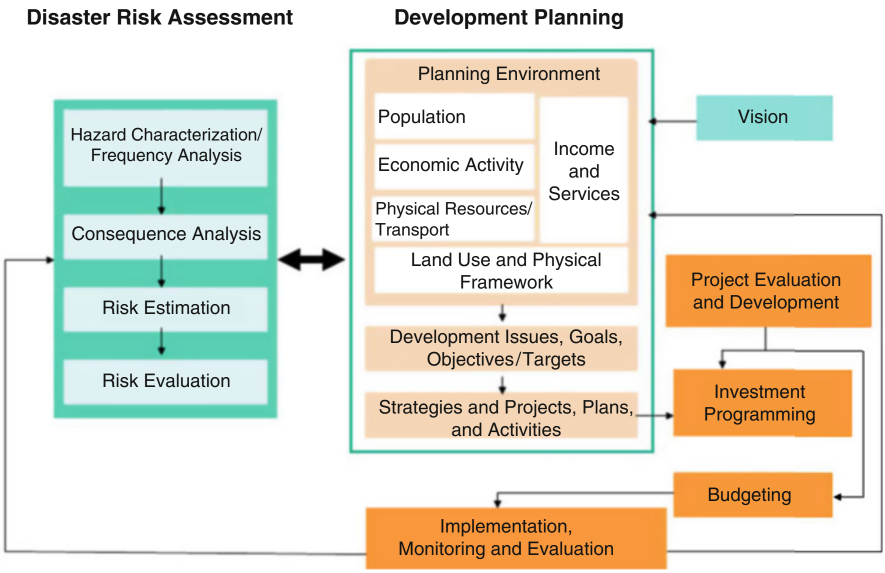

Fig. 4 Framework for mainstreaming DRR in subnational plans (Source: NEDA-UNDP-ECHA 2008, p. 32)

taxes, risk transfer/transfer financing, etc. The implementation of the PPAs are then monitored and evaluated to determine the project outcomes and impacts. Refer again to Table 5 for the details of these plans.

CC was later incorporated into the DRA mainstreaming framework. In the area of risk assessment, climate scenarios based on projected temperature and precipitation data are incorporated in hazard characterization/frequency analysis. Sectoral impacts and their vulnerability are, then, integrated in consequence analysis and risk evaluation, respectively. See Fig. 5.

In the development planning stage of the mainstreaming framework, climate variability, sectoral impacts, and vulnerability analysis are incorporated in the planning environment (refer to Fig. 6). In particular, the effects and impacts of climate variability to population, economic activities, income and services, physical resources, transportation, land use, and physical framework are taken into consideration. The results of vulnerability analysis are, then, factored in the formulation of development issues, goals, objectives/targets, strategies, and PPAs.

Finally, a framework for integrating CCA and DRR into local development planning was conceived (see Fig. 7). The formulation of CCA/DRR-enhanced plans starts with the projection of CC scenarios in the future. Its impacts on various sectors (i.e., coastal areas, health, agriculture, water, forestry, etc.) and on known "natural" hazards (i.e., typhoons, earthquakes, rain- and earthquake-induced landslides) are then assessed using the DRA tool. Integrated CCA/DRR strategies are then identified and prioritized. These can be now included in the CDPs. Demonstration projects are implemented to pilot test the PPAs.

The Integration of CCA and DRR in the Local Development Plans of Sorsogon City

Brief Profile of Sorsogon City

Sorsogon City, a component capital city of Sorsogon Province, was created in August 2000 through a national law (Republic Act 8806). The law combined two municipalities – Bacon and Sorsogon to create the new city. Sorsogon City is bordered in the east by Albay Gulf which opens up to the Pacific Ocean and in the west by Sorsogon Bay which is connected to China Sea, making it a coastal local government. Because of its geographical location, it is a transshipment corridor and gateway for the islands of Visayas and Mindanao (UN Habitat-Philippines n.d., p. 3) (see Fig. 8).

The city is the largest city in the Bicol Region – it measures up to 31,292 hectares (ha.) with 9,930 ha. dedicated to agriculture, 7,612.76 ha covered by forests, and 72 ha. for built-up areas. It is divided into three districts and 64 *barangays* (towns), 37 of which lie along the coastal areas. As of 2010, its population was pegged at 151,454 with an annual growth rate of 1.78 (in 2000–2007). It is the most populous city in the region (UN Habitat-Philippines n.d., p. 3).

The main economic activities in the city are agriculture, fishing, trade, and services. In the Philippine local government classification, the city is classified as second class for having obtained the second to the highest income among its peer

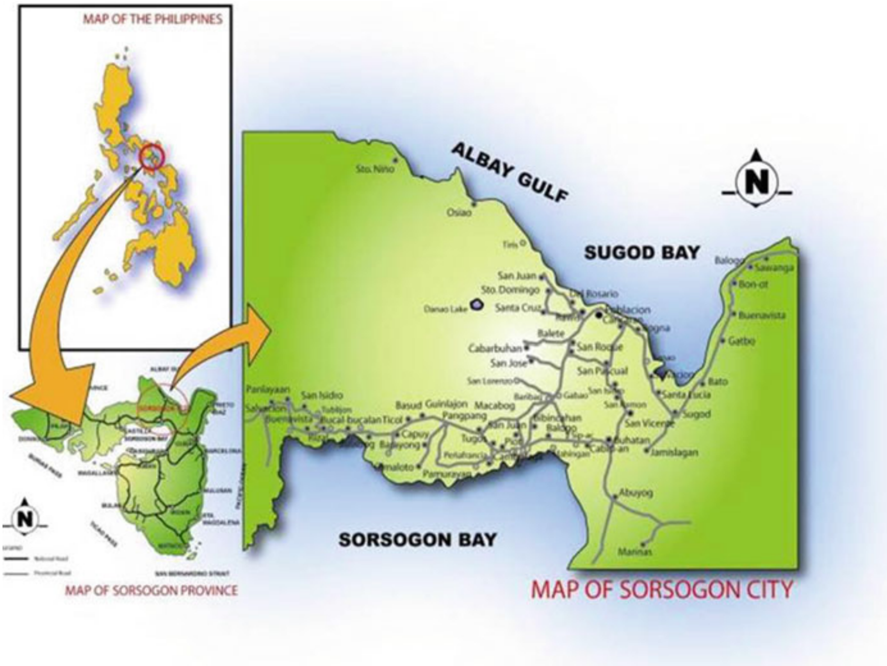

Fig. 8 Locational map of Sorsogon City (Source: UN Habitat-Philippines n.d., p. 3)

cities. As the capital city of Sorsogon Province, it serves as the latter's administrative, commercial, and educational center (UN Habitat-Philippines n.d., p. 3).

Sorsogon City's climate is classified as type II (Modified Coronas Classification System) where there is no dry season but with a pronounced rainfall from November to January. According to local data, rainfall usually starts late September or early October and rainfall ranges from 2,800 to 3,500 mm. Rains usually last 200 days in a year which continue even in the driest months (UN Habitat-Philippines n.d., p. 3).

The city experiences temperate temperature from 21 °C to 32 °C and relative humidity of 82 %. The prevailing winds are the monsoons and Pacific trade winds (which visits the city every April and May). From October to March, the northeast monsoon blows, while the southwest monsoon occurs from June to September. Unfortunately, the city is located at the Philippines' geographical zone 6 where three typhoons/cyclones pass every 2 years (UN Habitat-Philippines n.d., p. 7).

Vulnerability to Climate Change and Natural Disasters

According to the projections of the national government's meteorological agency (i.e., Philippine Atmospheric, Geophysical, and Astronomical Services Administration or

PAGASA), under the A1B scenario (using the PRECIS model of the UK Met Office Hadley Centre for Climate Prediction and Research), the whole province of Sorsogon, which includes the city, will experience 0.8–1.1 °C increase in temperature in 2020 and 1.5–2.1 °C in 2050 (UN Habitat-Philippines n.d., p. 10).

On the other hand, seasonal rainfall in the province and city will decrease by as much as –6.8 % in the March-April-May period and will increase from 5.1 % to 10.8 % in the other periods of the year 2020. By 2050, the decrease in seasonal rainfall in the March-April-May period will be almost double, –11.4 % and substantial increase to 7.4–27.3 % in the other periods of the year (UN Habitat-Philippines n.d., p. 10).

Owing to its geographical location and climatic conditions, it comes as a no surprise that it is always visited by strong tropical cyclones. In 2006 alone, two super tropical cyclones (locally named "Milenyo" in September and "Reming" in November) with more than 200 km per hour sustained maximum wind struck the city leaving more than 10,000 houses (33 % of the city's houses) and PhP208 million (around US$50 million at US$1 = PhP42) worth of damages. The city's poor and informal settlers were the hardest hit sector by the two typhoons which wiped out not only their houses but also their livelihoods. From the vulnerability assessment conducted by the city government, it is estimated that 34 coastal *barangays* out of 64 barangays (or 53 %) are in danger from strong surges brought by tropical cyclones (UN Habitat-Philippines n.d., pp. 10, 13).

Increase in rainfall is another direct CC problem by the city. With torrential rains, the city has experienced floods year in and year out. In 2009, for example, a weak storm (signal no. 1) brought extremely heavy rains to the city which measured 300 mm within a short period of time. It brought massive destruction worth PhP200 million (around US$48 million at US$1 = PhP42) in infrastructure and agricultural products. Again, from the vulnerability assessment of the city government, 20 *barangays* (or 31 % of 64 *barangays*) are prone to floods (UN Habitat-Philippines n.d., p. 15).

The city fears that it would also fall victim to sea-level rise (SLR) just like its neighboring city, Legaspi City, which had experienced seawater rising since 1970 from the Pacific Ocean. According to stories of local residents, SLR must have already taken place in Barangays Poblacion and Cambulaga where about 50 and 15 m of their lands were inundated by seawater since the 1950s. It is estimated by the city government that, again, 34 coastal *barangays* (53 % of 64 *barangays*) are in danger from SLR (UN Habitat-Philippines n.d., pp. 11, 18).

Landslide is another hazard that the city constantly faces. It comes with soil erosion and flashfloods which are triggered by increase in precipitation and volume of rainfall. Eight barangays or 13 % of 64 *barangays* have been identified as vulnerable to landslides (UN Habitat-Philippines n.d., p. 16).

In an assessment conducted by UN Habitat-Philippines in cooperation with the city government, it was found out that the city's adaptive capacity is low due to poor housing structures and infrastructure, climate-sensitive livelihoods, poor state of the environment, high health risks, etc. (for details, see UN Habitat-Philippines n.d., pp. 20–31).

Mainstreaming CCA and DRR into Sorsogon City's CLUP and CDP

The revisions in the CLUP and CDP of Sorsogon City were undertaken through the conduct of vulnerability and adaptation assessment (V&AA) and the integration of the V&AA findings into the CLUP and CDP

Vulnerability and Adaptation Assessment

In April 2009, UN Habitat-Philippines and the City Government of Sorsogon inked an agreement of cooperation which aimed to implement a project that will enhance the CC mitigation and preparedness of the city through the former's *Cities in Climate Change Initiative* (CCCI). The local project is under the *Strengthening Philippine Cities to the Impacts of Climate Change* program funded by the Millennium Development Goals Fund (MDGF)-1656, spearheaded by NEDA, and financially supported by the Spanish Government. Both sides provided financial, technical, and manpower assistance to implement the project.

The V&AA was conducted for the entire city to study the impacts of CC such as storm surges, strong typhoons, sea-level rise, increased precipitation, and higher temperature increase, especially to urban coastal settlements and hotspot areas

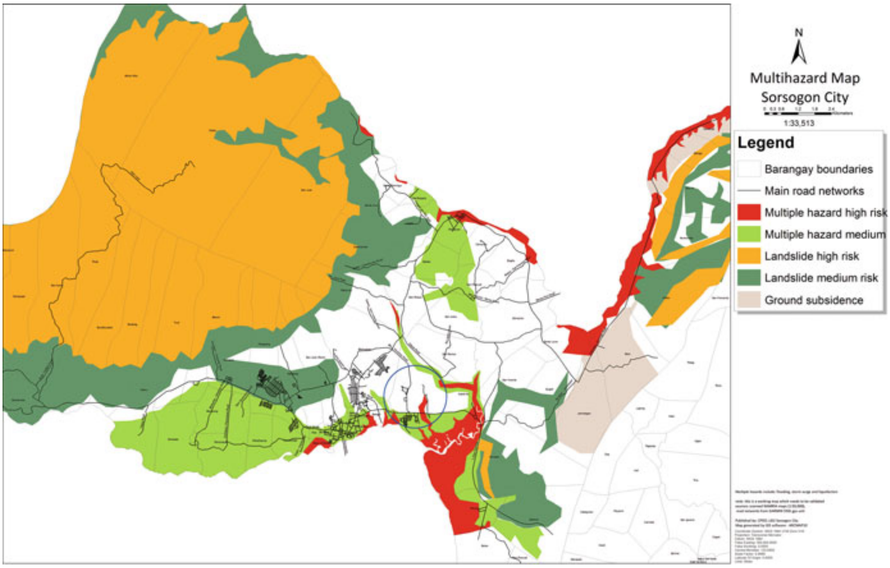

Fig. 9 A multi-hazard map of Sorsogon City (Source: Sorsogon City Government)

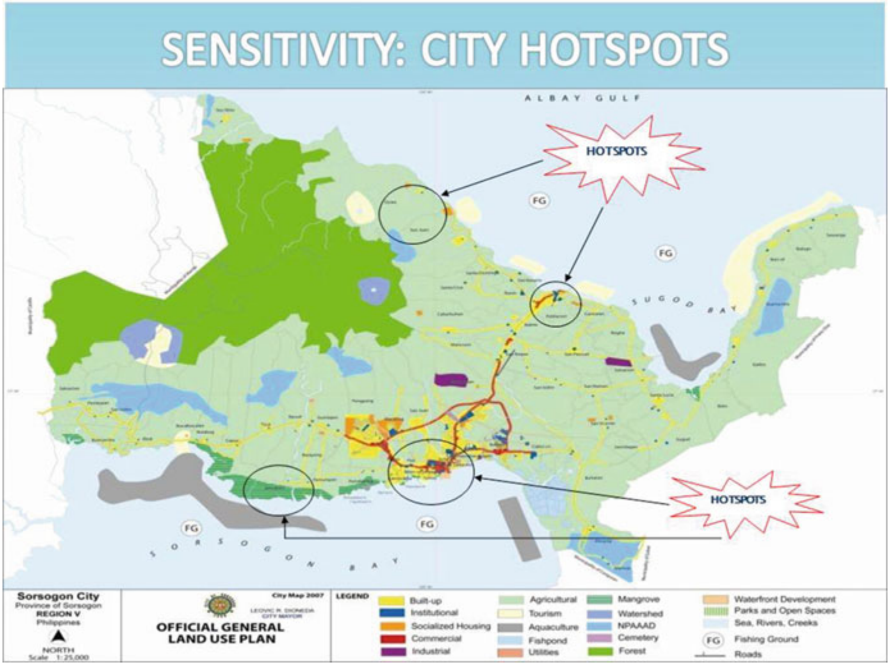

Fig. 10 Hotspot *barangays* (villages) in Sorsogon City (Source: Sorsogon City Government)

which are highly at risk. Briefly, the V&AA was conducted through the following processes:

(a) Collection of data/information on CC scenario (present and future), the socio-economic profile of the city, land use plan, maps, and the capacity of the city to address CC
(b) Analysis of the data to determine the vulnerability of the city by identifying the exposed elements (people, places, sectors, etc.), the sensitivity of the city, and its adaptive capacity
(c) Visualization of the CC hazards and risks through maps

In the visualization process, seven hazard maps were generated. These were for flood, ground subsidence, landslide, liquefaction, sea-level rise, storm surge, and tsunami. All of these were combined in multi-hazard maps, one of which is shown on Fig. 9.

It was found out from the multi-hazard maps that the following coastal *barangays* are vulnerable to the hazards and disasters that could be caused by CC: Cabid-an, Sampaloc, Sirangan, Bitan-o/Dalipay, and Talisay (see Fig. 10). Moreover, it was pointed out that the *barangay* residents have limited knowledge on CC, its impacts, and how to adapt. It was suggested that these *barangays* be made as sites of demonstration projects for CCA and DRR. These findings and

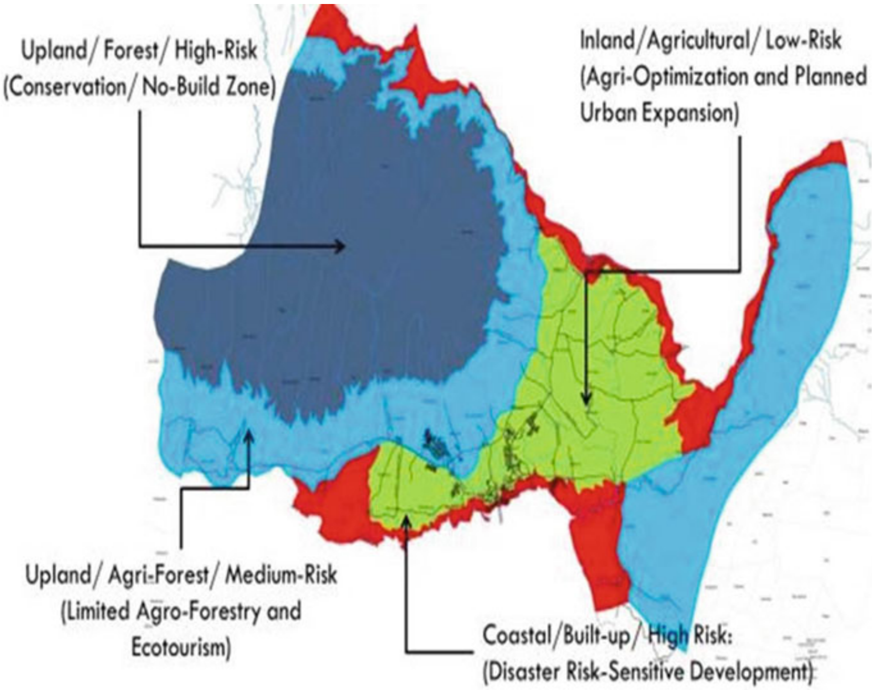

Fig. 11 Four policy zones in Sorsogon City (Source: Sorsogon City Government)

suggestion were validated in a multi-stakeholder consultation conducted in May 2009. In the same consultation, the following sectors were prioritized: housing and urban infrastructure, livelihood, environmental management, and disaster risk management. Workshops were also conducted for these four sectors to identify specific short- and long-term action plans.

Mainstreaming CCA/DRR in the CLUP and CDP

In July 2010, UN Habitat-Philippines and the Sorsogon City Government agreed to make the city the pilot site of mainstreaming the integrated CCA/DRR in its CLUP and CDP. This move received financial and technical support from the Swedish International Development Cooperation Agency (SIDA) and the Department of the Interior and Local Government (DILG).

The mainstreaming processes were composed of the following steps:

1. Assessment and updating of the existing situation
2. Assessment and updating the vision and development goals and objective
3. Assessment and updating of a 15-year CLUP and long-term (15 years) CDP and updating of medium-term (6 years) CDP and 3 years Executive-Legislative Agenda (ELA)

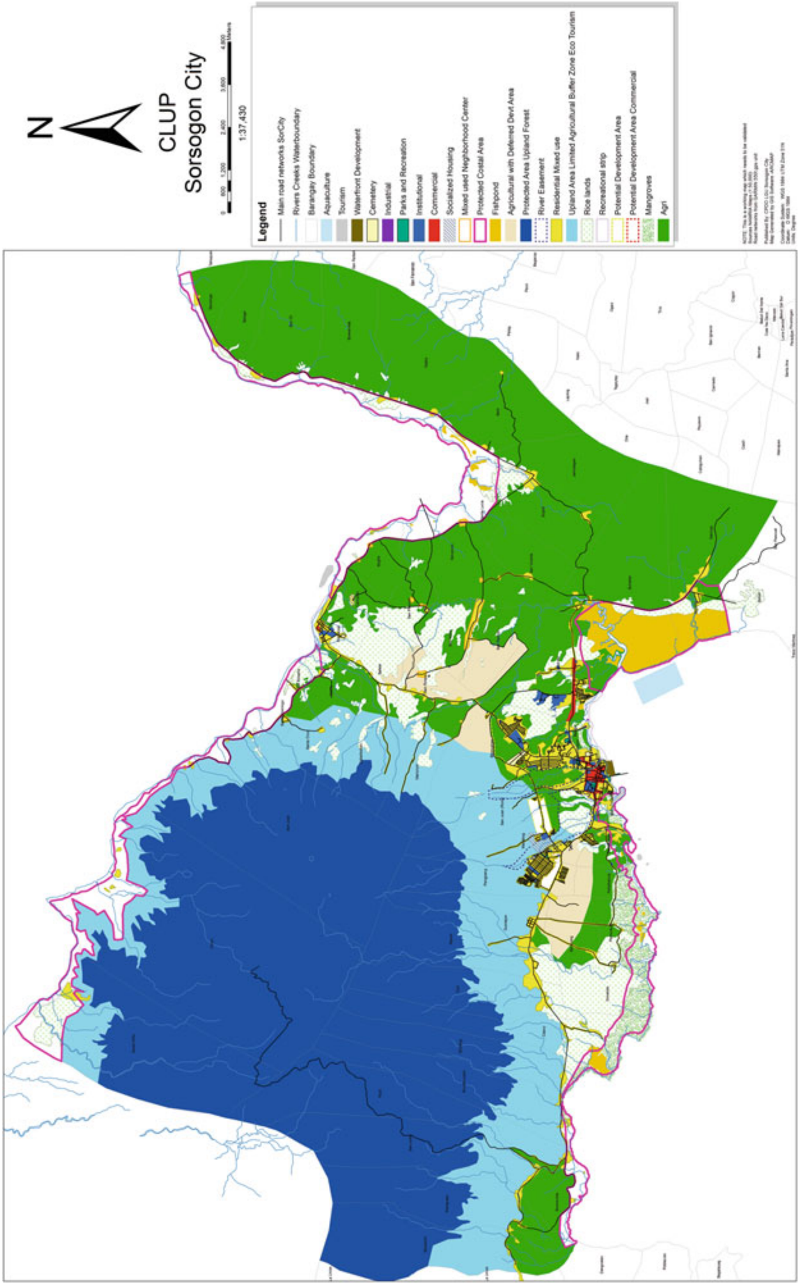

Fig. 12 New CLUP map of Sorsogon City (Source: Sorsogon City Government)

The V&AA hazard maps served as inputs in the review of the existing CLUP and CDP. Workshops among relevant city government officials, technical experts, barangay officials, and representatives from national government agencies and nongovernmental organizations were held to propose revisions in the two major local development plans. Sectoral consultations in the areas of environmental management and livelihood were conducted in November and December 2010 to refine the situational analyses. In addition, members of the local legislative council were briefed in February 2011 on its role in the formulation of the CLUP and CDP.

In a multi-stakeholder workshop on mainstreaming CCA and DRR in CLUP and CDP in March 2011, the participants identified four policy zones – areas which will be regulated and planned by the city for CCA and DRR through the CDP (Fig. 11). These areas, with the corresponding level of risks, are:

1. Coastal/built-up/hazard prone
2. Inland/agricultural/low risk
3. Upland/agri-forest/medium risk
4. Upland/protected forest/high risk

As a result of the formulation of the four policy zones, the city government, with approval from its legislatives council, decided to change the city vision. The new city vision is “A model city in CC and disaster risk resiliency with a contented, empowered and values oriented society that pursues socio-economic developments within the limit of nature thru genuine commitment to good governance.”

Aside from changing the city vision, a new CLUP map was drawn that incorporates findings from 12 socioeconomic maps (agriculture, commercial, built-up, infrastructure, informal settlers and settlement areas, rice, fishing grounds, urban areas, tourism, protected areas, minerals, and road networks) and four geographical feature maps (topographical, elevation, slope, and rivers). Refer to Fig. 12. In November 2011, a new CLUP was written which was submitted to the local legislative council for approval.

Conclusions

Generally, CCA and DRR are treated as conceptually and operationally distinct because of their spatial and temporal nuances. In the Philippines, the passages of two separate laws on CC and DRRM seemed to have sealed these so-called conceptual and operational divide. A closer scrutiny, however, reveals that they complement each other and they converge for the purpose of reducing risks to natural disasters and promote resilience. The national government has already laid down the guidelines for the integration of CCA and DRR in local development planning. Aided by these guidelines, Sorsogon City has shown that, given enough technical and financial assistance, the integrated CCA/DRR can be mainstreamed to local development plans, namely, CLUP and CDP.

Abstract

Climate change adaptation governance is characterized by complexity and uncertainty, requiring harmonization across different sectors and scales as well as flexibility to respond to changing realities. International organizations have been increasingly involved in adaptation activities, particularly targeted at vulnerable populations, under established project management routines. However, to be effective, adaptation must be inherently context specific and dynamic to suit the ecological conditions and socioeconomic aspects of any given locale. This poses a dilemma: how can international organizations translate their often broadly defined global mandates, while simultaneously downscaling those mandates to suit the specific adaptation needs of given populations and ecosystems?

This research takes a case study approach to investigate the climate change adaptation experience of selected United Nations-led programs, investigating their responses to context-specific needs and highlighting the opportunities and challenges found in these experiences. The case study countries comprised of Bosnia and Herzegovina, China, Colombia, Egypt, Ethiopia, Jordan, Mauritania, Mozambique, Peru, and Turkey. Through the use of the 5C+ Protocol theoretical framework, the experiences of these country programs were compared to determine which factors were of greatest influence in successful program implementation.

The research concludes that the most significant challenges were: early inclusion of stakeholders to enable support and ownership of adaptation activities, meaningful participation by people at all levels in the identification of problems and solutions, and proper coordination of activities across affected sectors and governance levels. Paying specific attention to these challenges will allow for greater program effectiveness. However, incorporating such measures into adaptation must also include deliberate learning processes, to allow flexibility in response to potential nonlinearities of climate change.

Keywords

Climate change • Adaptive capacity • Learning • International institutions • 5C+ Protocol

Introduction

The Problem: Downscaling Complexity

Climate change adaptation is an emerging need worldwide because of the imminent threats of new climate regimes and the high levels of vulnerability of many socioeconomic groups and regions (IPCC 2007). In response, numerous international organizations have been planning and implementing climate change adaptation measures. Yet, adaptation to climate change is a complex governance challenge, characterized by uncertainty, long time frames, and nonlinearities. Adaptation normally requires coordination among a range of sectors, agencies, and interests, who traditionally may not have the working culture or framework for such collaboration – making not only the issues addressed but also the response methods novel and unprecedented in their complexity.

To be successful, climate change adaptation measures must take into account processes at multiple spatial and temporal scales and be inherently context specific to suit the ecological conditions, socioeconomic aspects, and institutional framework of any given locale (Cash et al. 2006). This poses a significant obstacle for international organizations. Such organizations usually have broadly defined global mandates, but the complexities of climate change adaptation require those mandates to be downscaled to suit the specific needs of individual populations and ecosystems (Hilde 2012; Wiechselgartner and Marandino 2012). It also raises the question of generality: how can practitioners learn from, generalize, and transfer lessons learned in different contexts in a way that is relevant elsewhere?

With these questions in mind, the aim of this research was to investigate how international organizations, such as the United Nations (UN), might most effectively apply their broadly defined global mandates by addressing specific local adaptation needs. Using a case study approach and a common analytical framework, this chapter first provides an assessment of the programmatic ability to respond to context-specific needs and, second, highlights the opportunities and challenges found within several such experiences. The case study in question focuses on the climate change adaptation experiences of selected Joint Programs (JPs) operating under the UN Millennium Development Goal Achievement Fund (MDGF). The lessons learned from the MDGF are intended for use by international organizations to inform the design of future adaptation-related interventions in the field.

The Case Study and Rationale

The MDGF was established by the UN with funding by the Spanish government to advance international efforts towards the achievement of the Millennium Development Goals (MDGs). All MDGF programming is implemented in the spirit of the UN "Delivering as One" initiative, which aims to improve harmonization of UN efforts in relevant member states (MDGF 2011a). MDGF programming was implemented in eight thematic windows, one for each of the MDGs. Several countries implemented programs in several windows. Within a country activities were implemented through a Joint Program (JP) that drew together UN agencies and national collaborators (MDGF 2011b). The MDGF case study looks in depth at the work of JPs in ten countries, including Bosnia and Herzegovina, China, Colombia, Egypt, Ethiopia, Jordan, Mauritania, Mozambique, Peru, and Turkey, that implemented activities between 2006 and 2012, under the MDGF environment and climate change window, related to MDG 7 to improve environmental sustainability. In each country, a variety of activities were undertaken, ranging from national policy mainstreaming to localized community-based climate change adaptation projects. Examples include a community-based forest management program

Fig. 1 MDGF case study countries (Image Source: Adapted from WikiCommons 2005)

in Mozambique, development of a national climate change and health adaptation strategy in Jordan, conservation and adaptation programs with indigenous populations in Colombia, and partnering with private sector industries in China (Fig. 1).

Data for the case study analysis are drawn directly from the specific experiences of the ten countries. Each JP is part of a global program, yet given the broad geographical scope and range of activities, the comparison among their experiences revealed different approaches to regional differentiation and contextualization. The rich diversity, due to the wide range of programs and experiences from the case study countries, allows the outcomes from our analysis to have generality, making them relevant in other contexts.

These ten MDGF programs were chosen as the basis for analysis for two primary reasons. First, the MDGF operates under the UN, which plays an important role globally in norm-setting and guiding country-level programs (UN 2008). The UN's international influence, particularly its leadership in global environmental governance, puts it at the forefront of emerging activities in the field of climate change. Second, the institutional framework of the MDGF has been set up to complement the UN's current efforts to "Deliver as One" – a direct response to institutional fragmentation and program inefficiency problems and an effort to improve harmonization of cross-sectoral activities (UNSGHLP 2006). The MDGF JPs implemented their activities jointly with several UN agencies, as well as government and community partners at both national and subnational levels. This institutional framework reflects the emerging role of collaborative environmental governance (CEG) and its importance in addressing complex problems such as climate change (Andresen 2001; Gunningham 2009).

Due to its potential for playing a norm-setting role through the UN, and manifestation of CEG, the lessons from the MDGF provide real value for emerging climate change adaptation interventions implemented through other international organizations.

Methodology

The Framework: 5C+ Protocol

An analytical framework, the 5C+ Protocol, was used to investigate how the JPs responded to context-specific needs, both opportunities and challenges faced through implementation. The research relied mostly on the use of a rich database of qualitative information, but quantitative information was also used where available and relevant. The experiences of the JPs were compared to each of several variables in the 5C+ Protocol, and relationships among those variables, to determine which were of greatest significance to the work of the JPs.

The 5C+ Protocol was developed as a modification of an original 5C Protocol framework by Najam (1995) that was based on a synthesis of literature on policy implementation, intended to help analyze and diagnose practical policy implementation measures. Najam identified five common variables – the "5Cs" – which he argued are interlinked explanatory variables essential for reviewing the effectiveness of policy implementation, particularly the "domestication" of international environmental measures (Najam 1995).

The 5C Protocol was modified by adding a sixth variable (thus, 5C + Protocol) to provide a common structure for analyzing the diverse experiences of the MDGF JPs. This framework was deemed appropriate for analysis of the MDGF case studies because it guides the investigation of several factors which influence practical implementation measures. As the 5C Protocol was developed for use in a general policy context, it was assumed that it also applies, with possible fine-tuning, to adaptation-related policies and activities. The framework also emphasizes how different variables, at various levels, interrelate and impact upon one another. The framework therefore has a dynamic element and simultaneously provides structure so the user does not get lost in the complexity of the issues studied. We addressed each of the six variables individually, and in relation to one another, for each of the case study countries (Table 1).

Critically, it is not only the variables themselves but also the relationships among them that provide insight into implementation effectiveness. Najam posited that in the 5C Protocol "the task is to catalog the strength and influence of each variable on specific implementation efforts as well as to identify critical linkages between them on the basis of their strengths and weaknesses, and, most importantly, their potential to enhance the effectiveness of the particular implementation process" (Najam 1995, p. 36).

The variables in the 5C+ Protocol are interlinked with one another (Fig. 2). This framework was used to analyze and compare the MDGF case study countries.

Data Collection and Analysis

Data for the study were collected using a variety of methods, including targeted literature reviews, participation in MDGF meetings and processes, and interviews.

Table 1 Variables and definitions associated with the 5C+ Protocol (Modified after Najam 1995)

Institutional corridor	The institutional environment through which policy and activities must travel, a variable that also provides the boundaries for specific implementation activities
Content	The content of a policy or program is threefold: what it sets out to do (i.e., goals), how it problematizes the issue (i.e., causal theory), and how it aims to solve the perceived problem (i.e., methods)
Commitment	The commitment of those entrusted with carrying out implementation, at various levels
Capacity	The capacity of implementers to carry out the changes desired by the policy, program, or activities; this includes both human and financial resources
Clients and coalitions	The groups or individuals whose interests are enhanced/threatened by the policy and/or program and the actions they take in response to its implementation either in support or opposition
Environmental conditions	The environmental characteristics (i.e., elements, state, dynamics, challenges, and opportunities) of a given geographical location

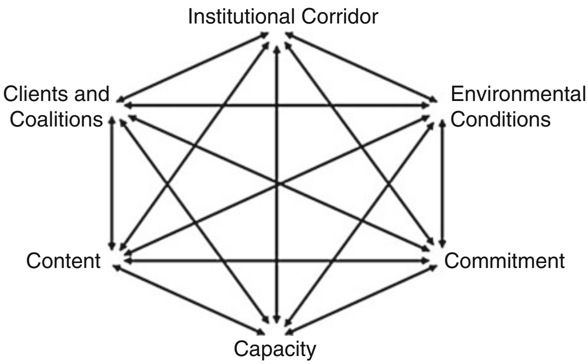

Fig. 2 5C+ protocol

Primary data were collected through in-depth interviews with selected JP representatives. The interviews were guided by the 5C+ Protocol and analyzed according to the variables shown in Fig. 2. The interviews were semi-structured, using open-ended questions, which alluded to each of the variables in tandem. Interviews took place both face-to-face and online. The interviews were transcribed and coded manually using the ATLAS.ti software. All data were coded according to the variables of the 5C+ Protocol then analyzed quantitatively, using total counts and co-occurrences to identify the strength of each variable and relationships to one another.

A second round of interviews was conducted with climate change adaptation experts not involved in MDGF, to validate and cross-check the results and conclusions of the primary interviews. Further, all results were compared to similar relevant findings in the literature and sharpened where warranted to ensure relevance for a wider audience.

Research Results

The primary interviews produced very rich qualitative data on the nature of the JPs and the challenges and opportunities experienced in implementation. The use of the theoretical framework and the coding software allowed these data to be analyzed quantitatively by use of total counts per variable and the co-occurrences (relationships) among the variables. Note that in this section, unless otherwise stated, all quotes come directly from the primary interviews.

Variable Counts

After transcription and coding of the interviews with representatives from the ten case study countries, the total count for each of the six variables in the framework was identified. The range of occurrences was 26–65 (Table 2).

It is clear from the aggregated results that the most commonly discussed variable, among all interviews, was clients and coalitions – the groups or individuals whose interests are enhanced/threatened by the policy and/or program and the actions they take in response to its implementation either in support or in opposition. This is unsurprising due to the crosscutting nature of the climate change field. The clients and coalitions variable was discussed by the JP representatives mostly with regard to the challenges they faced when dealing with competing and/or conflicting interests. The JPs faced various challenges when trying to understand the perspectives of different sectors and integrating these perspectives according to the aims of their various activities. For example, the Jordan JP representative stated that:

> If I say that we have been supported by all partners from all sides from the beginning, I wouldn't be telling the truth. We have different partners who are looking at the JP from different perspectives, so some of them see it as an opportunity to gain out of the JP, and some of them have seen it as an initiative that will make them lose some of their benefits and privileges.

Similar sentiments were repeated by each of the JPs interviewed. In all cases, they faced various camps of support and opposition, which had to be addressed in order to ensure implementation of the JP work.

Another common topic of discussion within the clients and coalitions variable was that of champions, i.e., finding the right individuals or groups who will showcase their support and through their convening power help the JP activities to gain the trust of potential ambivalent or opposition groups. These champions

Table 2 Total counts by variable

Clients and coalitions	65
Content	60
Institutional corridor	52
Commitment	40
Capacity	30
Environmental conditions	26

could be government or nongovernmental officials, the key point being that influential champions play a major role in a successful intervention. For example, the Mauritania JP representative emphasized in the interview how they utilized traditional leaders in their field activities:

> We use [non-state local leaders] as speakers, moderators or organizers. When they ask for a meeting, people will come. And when they speak, also the people listen to them.

From the perspective of the Ethiopia JP, it was a lack of champions that seemed to hinder their work at the national level:

> . . . you have to have champions – and champions mean having one or two key people in the policy process. . . Some of the issues we are dealing with are the allocation of national resources – the more you have a champion, that's why you get better access to the resource. I think that's one area where the JP didn't put in the list of priorities, but it should.

Other countries, for example, Peru, Mozambique, Jordan, China, and Bosnia and Herzegovina also highlighted the important role of champions within the governmental system. On the other hand, in some countries champions were explicitly nongovernmental. In Colombia, for example, tensions between the government and local communities made a local representative a more effective champion. It is clear, therefore, that while important in general, the selection of champions must also be highly sensitive to local opinions and realities.

Another frequently cited variable in the interviews with a total score of 60 was content, i.e., what a program sets out to do (its goals), how it problematizes the issue (causal theory), and how it aims to solve the perceived problem (methods).This variable was referenced during JP interviews most often in regard to the methods used to determine problems and solutions. For example, one of the main aims of the JPs was to ensure high levels of ownership on the part of domestic stakeholders (i.e., government officials at the national level or community members in field-level projects). With this aim in mind, the majority of JPs utilized participatory methods to engage local stakeholders. A parallel aim of such participation was to achieve better contextualization of the problems at hand. For example, the Turkey JP representative emphasized that:

> We tried to be participatory at maximum extent. . . When you talk about climate change adaptation, the national strategies or efforts are too generic. Because even between two villages, 5 km from each other, your adaptation efforts may change when it comes to climate change.

Another important point brought up repeatedly during the interviews with regard to content was the need to include livelihood activities and income generation options in all "solutions." The Mauritania JP representative, for example, stated that the environment had to be seen as "natural capital," so as to engage poor and vulnerable populations in the JP activities. Similar sentiments were described by the Mozambique JP representative:

> [We have] activities designed to help people to adapt to climate change, and also to help them to diversify their livelihoods – you can't really disassociate those two.

Particularly in field-level activities, the JPs were working mostly with vulnerable socioeconomic groups. Even at the national level where the JPs worked largely on mainstreaming climate change into national strategies and programs, there was a clear demand for economic benefits as part of any adaptation work. This need to integrate economic needs with environmental ones was very clearly emphasized throughout all of the JP interviews, showing that climate change adaptation cannot be achieved for environmental benefits alone; it must be seen as integrated with other pressing social and economic realities.

The third most common variable discussed in the interviews with a score of 52 was institutional corridor – the institutional environment through which policy and activities must travel, which also provides the boundaries for specific implementation activities. Related to the clients and coalitions variable discussed above, institutional corridor was most often brought up in relation to the crosscutting nature of the work and the difficulties faced in integrating several parties and interests, both within the UN and between UN and national government agencies. For example, the Turkey JP representative stated:

> It was very challenging putting all of them together in one team, because they have their own working cultures, their own administrative rules, plus no culture of working together.

Similar issues were raised by each of the JPs. Because climate change adaptation work requires the collaboration of several different sectors, it faces challenges not just on the administrative front but also in terms of culture. Many of these forms of behavior have been established over time and resilient to change even by a "joint" program. Often a series of behaviors and methods must be unlearned, and new ones learned to overcome traditional silo mentalities. An observation from the Ethiopia JP representative was:

> My assessment is that we have to do this several times before agencies can work together. The issue is sometimes mandates are overlapping, sometimes there is problems of synchronization... [all] this has an impact on the overall delivery of the program. There definitely needs to synchronize and harmonize a bit more, and if possible talk a little bit more to each other.

Another common thread raised by the JPs was the issue of institutional misfits. For example, several UN agencies were tasked to provide specialized input into the programs. Some of those agencies were nonresident (i.e., did not have permanent presence and staff within a country) and were asked to work alongside resident agencies. In some cases, it was clear only after implementation started that some agencies did not have the capacity or structure to allow them to operate effectively at the field level. For example, as revealed in the interview with the Mozambique JP representative:

> [As a non-resident agency] we're not really geared to delivering at the field, so it's not necessarily that people don't want to support, it's just the rules don't allow the level of flexibility that you need working in the field... I think there's a tension between the field and headquarters within the UN.

That same theme was apparent at more local levels when certain institutions were not capable of carrying out tasks, even if they were mandated to do so. In Mauritania, for example, this problem was apparent with respect to selected civil society organizations:

> . . . we call them ‘ONG cartables’ – it’s the NGO with an empty bag. . . as the country is poor, the civil society is not very strong, so maybe it’s the only NGO you find there and you will be supposed to work with them. There is no way you can work with someone else, but you know from the beginning that there is also a lack of capacity.

In some circumstances therefore, even though there is a need to integrate the expertise of different agencies or sectors, it is clear that there also is a need for realism to ensure the most appropriate partner is tasked with carrying out each activity, and if even the most qualified and appropriate partner lacks capacity, then capacity building must be a significant element of the work. This requires a careful balance between involving different areas of expertise and allowing actual implementation to be carried out by the most appropriate actors.

The other variables within the 5C+ framework were addressed less frequently, but revealed rich information. The commitment variable with a score of 40 was mostly clearly related to the JPs’ need to gather the right agencies and groups early in the process, in order to develop ownership of the activities. A failure to do so was often counterproductive to the work of the JPs. The capacity variable was often related to capacity building as an inbuilt component of the JPs. However, this variable was also referenced in regard to capacity-related realities that JPs faced on the ground, which required them to change their approach or alter certain implementation activities. The variable of environmental conditions occurred least frequently in the interviews with a score of 26. This is likely due to the close relationship between environmental conditions and content (i.e., the circumstances the JP itself was addressing). Notable within discussion of this variable, however, is that whenever environmental conditions were mentioned, the human dimension was always emphasized, as was the need for strengthening people’s adaptive capacities to deal with both rapidly changing and slowly changing environmental conditions.

Variable Relationships

The discussion above reveals that there is a degree of overlap among the variables. For example, the clients and coalitions variable was closely related to institutional corridor, with respect to the crosscutting nature of climate change adaptation work. The content variable and participatory methods was closely related to commitment, as an avenue for trying to encourage ownership of JP activities.

The relationships among variables (i.e., “co-occurrences” between codes) were quantitatively analyzed using ATLAS.ti version 7. Out of all the variables, there were 15 possible relationships. The number of co-occurrences (Table 3 below) helps understand the strength of these relationships.

Table 3 Codes co-occurrences

	Content	Institutional corridor	Commitment	Capacity	Clients and coalitions	Environmental conditions
Content		9	5	4	8	5
Institutional corridor	9		3	4	11	0
Commitment	5	3		3	19	1
Capacity	4	4	3		10	0
Clients and coalitions	8	11	19	10		2
Environmental conditions	5	0	1	0	2	

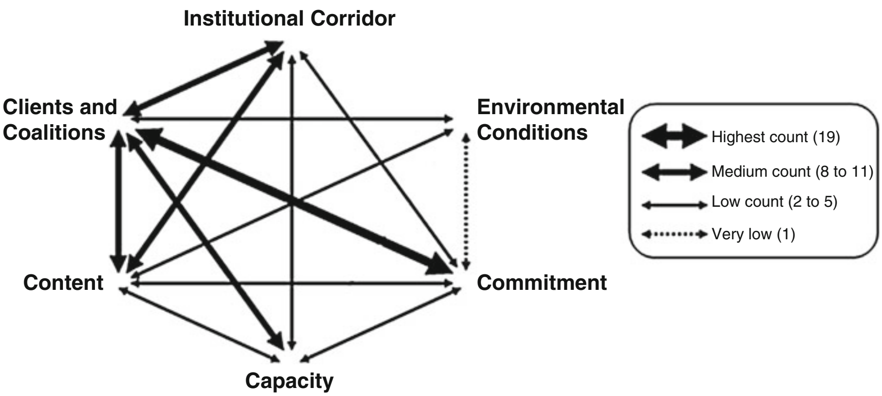

Fig. 3 Strength of factor relationships based on total count of co-occurrences

The co-occurrences can be expressed graphically (Fig. 3).The thickness of the lines indicates the relative strength of the relationship between two variables. The thickest line indicates the highest count (19), the medium-thickness line shows strength of 8–11, the thinnest lines indicate strength of 2–5, and the dotted line indicates the weak relationship of only 1. The absence of a line indicates that there was no mention of a relationship (0 count) between variables.

Based on the raw co-occurrences therefore, it can be seen that the strongest interrelationship is between clients and coalitions and commitment. To see whether this relationship strength remained true for all case study countries, another dimension of analysis was added to show the distribution of the relationships. The combined total variable counts, the level of co-occurrences, as well as the country distribution of the relationships are plotted in Fig. 4. The darkest blue line shows that the relationship occurred in all of the case study countries, while the lighter blue shows a lower level of occurrence in the case study countries. The relationship between clients and coalitions and commitment remains the strongest, in all dimensions of the analysis.

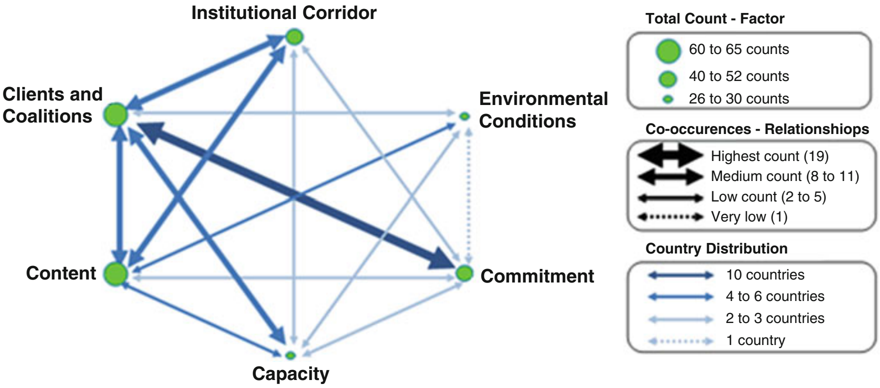

Fig. 4 Combined counts, relationships, and country distribution

The previous section revealed how the variables clients and coalitions and commitment were related strongly to the crosscutting nature of climate change work; it also demonstrated the importance of ownership and champions. Based on the experiences of the MDGF JPs, it is clear that the ability to include clients (i.e., targeted beneficiaries of a program) from the onset is necessary, not only to correctly identify needs and responses but mostly to garner their support for program aims and intentions. Getting the beneficiaries "on board" is also a key avenue through which positive coalitions can be built. Thus, it can be seen that both ownership and sustainability of program interventions are interconnected with the commitment and the clients and coalitions variables. This point was also strongly raised in various arenas outside of the JP interviews, including additional materials and discussions with the MDGF representatives (e.g., progress and evaluation reports, regular online "Weeks in Focus," and meetings in Kenya and Ecuador).

The relationship between commitment and clients and coalitions is also an important consideration when downscaling an intervention from a broad, global mandate to a more specific national or subnational program. If people with more localized responsibilities – both clients and potential coalitions – are not involved early and in a meaningful way, they are only given the possibility to react to a strategy and not have significant influence on design and execution of activities (Deri A. Independent consultant specialized on capacity development, including the role of learning and knowledge systems in resilience and adaptive capacity, "Personal interview," online, 6 May 2012). Similar points were also raised by Swanson et al. (2004) and Mitchell et al. (2006), who argued for the early inclusion of program participants. In fact, stakeholders should be involved in a process of "coproduction of knowledge" (Mitchell et al. 2006, p. 19), and not just be passive recipients, in order to ensure relevance of and commitment to program goals. Without this, it is not surprising if commitment or ownership is weak or nonexistent; as ownership must derive from a process of involvement, it cannot be simply superimposed at a later stage externally. This finding, of course, is not specific to adaptation, but given the highly contextual nature of this work, it is not surprising to find it particularly important.

Champions, on the other hand, are not only important for showcasing commitment but also for gaining support of other groups (i.e., forging partnerships and developing supportive coalitions with those who may have been external to the initial process). An inability to develop a sense of commitment to and identify a champion for a program's cause can be counterproductive by allowing negative coalitions to emerge among those who have an interest in blocking certain processes. There is therefore a cautionary tale to be told in that the relationship between clients and coalitions and commitment must be considered from the outset when planning or designing a program. This is particularly pertinent for issues of climate change adaptation, which are often crosscutting and likely to affect and be affected by various sectors and groups, at multiple levels of influence (Bulkeley and Newell 2010).

This linkage between commitment and clients and coalitions is intuitive and was hypothesized by Najam in his discussion of the clients and coalitions variable: "... with regards to commitment, the linkages are likely to be the strongest" (Najam 1995 p. 54). Thus, it can be seen that these variables have a very strong influence on determining the nature of each other, even outside of the specific experience of the MDGF JPs.

Another striking relationship with the clients and coalitions variable is that of institutional corridor. This relationship is characterized by the identification (either prior to or during the JP implementation) of clients and coalitions within the existing institutional framework, who could either support or actively block the JP processes. For example, at the national level, the ways in which the JP worked through the institutional framework could create blocking coalitions, by either failing to take some parties into account or by not including them in JP processes. On the other hand, actively involving key actors within the existing institutional framework often was deemed positive not only for the duration of the program but also for the sustainability of program interventions. An example of this was provided by the Ethiopia JP. In this case, although the JP had a limited impact on the policy level, it was reported that because all program activities were carried out through the conduit and preexisting framework of the Ministry of Environment, the work begun by the JP would still be carried through beyond the formal life span of the MDGF. Hence, by institutionalizing the aims of the JP within an existing framework, the clients of the program formed a supportive "advocacy" coalition (Sotirov and Memmler 2012).

The relationship between clients and coalitions and institutional corridor further highlights the comparative advantages of different institutional frameworks. In the majority of JPs, for example, particular activities were implemented by those UN and government agencies that had a specialized advantage in the activity (e.g., the Food and Agriculture Organization carried out agricultural activities, while the World Health Organization carried out health-related activities). Looking at external partnerships, however, in a number of instances, nongovernmental organizations (NGOs) or community-based organizations were deemed more appropriate for carrying out specific activities because their institutional framework was a better fit. In some cases, JP representatives commented that they had failed to capitalize on such positive external coalitions.

It is clear that institutional framework can greatly affect the types of activities that can be carried out, as well as their appropriateness to the specific problem at hand. This issue of institutional fit, and matching the correct institutional form with function, has been raised as an important point in the literature on institutional relevance for adequately addressing environmental concerns (Young 2002). In certain circumstances, a conscious choice must be made as to which institutional contexts are the best fit for certain activities. This may require delegation of different roles and responsibilities to external partners of a different institutional form where their form is deemed to be better suited to the task at hand (i.e., coalitions or clients).

The relationship between institutional corridor and clients and coalitions can also extend to include the capacity variable. For example, at the local level, the existing institutional framework and capacity levels of civil society and/or government determined which clients and/or coalitions were brought into the JP work. For example, in Bosnia and Herzegovina, high levels of civil society capacity allowed the JP to select NGOs that could actively carry out the work required and garner the necessary support for the work to go through. In contrast, the communities in which the Mauritania JP worked often had low capacity levels, which could have led to existing NGOs having a monopolistic effect on the selection of JP activities. These examples show a complex relationship in which capacity levels, clients and coalitions, and institutional corridor can impact each other. This is a particularly important point for those UN agencies that do not themselves have strong implementing capacity in a given country. These agencies by definition must rely on partners with reliable capacity to deliver.

A further significant relationship is between capacity and clients and coalitions. This relationship was highlighted by Najam, who stated that "… the linkage [of capacity] with clients and coalitions, although less obvious, is… critical" (Najam 1995, p. 51). In the identification and selection of clients and coalitions, for example, existing capacity levels can be a determining factor. As an example, targeted beneficiaries may be required to have specific capacity levels or a longer track record of relevant experience in order to facilitate program implementation. Moreover, the nature of capacities found among clients and coalitions may affect program delivery as well as support.

In the example of Bosnia and Herzegovina, for instance, local government activities were facilitated largely through select municipalities who already had high capacities and could spread their own work to others through a peer-review process. On the other hand, the Turkish JP experienced differentiated capacity levels. Despite the high capacities of technical staff with respect to climate change science, capacity at the level of political decision makers to understand climate change and impacts was very low. As a result, at the government decision-making level, the JP faced a great deal of opposition to the program in certain sectors. This was only remediated through targeted capacity development measures.

Lastly, a relatively strong relationship was seen between the institutional corridor and content variables. This relationship is based largely on how the different JPs designed their specific activities using the countries' existing institutional framework. For example, at the policy level of environmental mainstreaming, target clients and activities were identified using existing institutional frameworks. At the field level, the JPs often capitalized on existing institutional arrangements or frameworks – such as local government authorities or existing community-based organizations/cooperatives – and used these as channels to identify as well as deliver JP activities. Therefore, the linkage between institutional corridor and content derives mostly from the goal and causal theory levels; by targeting existing institutional arrangements, the JPs designed their activities according to existing gaps or opportunities. As mentioned above, utilization of existing institutional arrangements (both formal and informal), as opposed to investing in creating new institutions, seems a key factor in sustainability of program efforts.

Discussion

All of the analysis, including interviews with JP stakeholders as well as external climate change adaptation experts and cross-checking with the literature, has allowed the validation of the external relevance of the results of this research as well as the applicability of the 5C+ Protocol for analyzing climate change adaptation interventions.

Relevance

The multifaceted relationships described above resonate strongly with other studies. In particular, a study carried out by Cash et al. (2002) investigated key factors in transferring knowledge from environmental assessments into practical action. They highlighted three factors, salience, credibility, and legitimacy, as central to success (Cash et al. 2002):

- Salience – the relevance of information to decision making of various actors
- Credibility – how scientifically plausible an actor views information
- Legitimacy – if the process of knowledge creation is perceived as unbiased

All three of these factors have resonance to the key variables and relationships described above. Salience is linked closely to the capacity levels of actors receiving the information, clients and coalitions through early engagement, the realities of environmental conditions and points of comparison, as well as to the type of institutional frameworks at which these types of information are being directed. Credibility links closely to capacity, as well as the content of an information source (e.g., how an issue has been problematized and the process of this problematization). Legitimacy is linked clearly to content, clients and coalitions, as well as commitment.

The resonance of the interview results, both of isolated variables and their relationships to one another, with external sources, including expert opinion and research papers, highlights the utility of the results.

Utility and Lessons for the 5C+ Protocol

The 5C+ Protocol served as a valuable framework through which to investigate the experience of the JPs' work on climate change adaptation. The relationships among the different variables are complex and multifaceted; yet the lens of the 5C+ Protocol has allowed a systematic and guided analysis of these relationships. The chosen approach utilized both quantitative and qualitative data and analyses. This systematic information gathering and analysis serves as the basis for the conclusions and recommendations.

However, this research also revealed several lessons with regard to the limitations of the use of the 5C+ Protocol: identification of specific climate change adaptation practices and missing elements of time and learning.

The first limitation of the 5C+ Protocol is that, through its focus on institutional or procedural aspects of an intervention, it does not suggest specific climate change adaptation measures. The Protocol cannot be readily used to develop a set of best practices or guidelines related to specific types of climate change vulnerabilities or adaptation activities. Rather, the 5C+ Protocol-based analysis has greater utility in highlighting procedural aspects of climate change adaptation interventions, such as partnerships and participatory implementation. This may have applicability at broader climate change activities, which have to be inherently context specific (Schipper and Burton 2008). While it is often difficult to determine specific transferable activities (outputs) within climate change adaptation, particularly on shorter time scales, focusing on process elements/characteristics arguably has significant utility.

The second limitation of the 5C+ Protocol is that it does not include a built-in element of time and learning, which are critical components for climate change adaptation. An essential element of the management of complex and nonlinear issues such as climate change is the need for time frames that include adaptive management, revision of strategies, and corrective actions taken in response to changing circumstances (Swanson et al. 2004). Deliberately incorporating time as a variable would create the conditions for learning to take place (Siebenhüner 2002). However, this element of time will not automatically lead to learning if it is not a conscious part of an evaluation or assessment process (Siebenhüner and Arnold 2007). By not including a time component, the 5C+ Protocol remains limited in its ability to help facilitate learning processes. As it is, therefore, the 5C+ Protocol cannot be considered as an overall guiding framework for adaptive management in response to climate change. To do so, there must be specific recognition of this limitation.

To help facilitate learning, however, the 5C+ Protocol could be used as a common framework for a series of periodic assessments. The common framework can allow analysis of the current state (characterized by the variables and their relationships) and comparison of these states among different time periods. These comparisons can be used to track progress as well as highlight specific intervention needs. Therefore, organizations such as the UN could use the 5C+ Protocol as a quick analysis tool, prior, during, and after program implementation to identify specific challenges and opportunities related to the different variables, as well as identifying progress made in different areas (Bizikova L. Project Manager at International Institute for Sustainable Development, whose recent work is focused on adaptation to climate change, "Email communication," 22 May 2012). The common framework could also be used as a point of comparison among different, but similar, program implementers, helping to share experiences and methods to overcome procedural challenges.

Recommendations

This chapter shows that the implementation of national and subnational climate change adaptation activities, when derived from a general global mandate, faces specific challenges. A series of synthetic recommendations (Fig. 5) show a broad set of procedural measures that can aid international organizations such as the UN in addressing these challenges and effectively delivering context-specific climate change adaptation interventions.

However, to provide a more practical focus, there is a need to prioritize the most pertinent recommendations, based on the experience of the MDGF JPs and the results of this research. The most significant challenges we found were related to support and ownership of program activities, identification of most relevant problems and solutions, and coordination across sectors and governance levels. These challenges and possible measures to address them are summarized below:

- ***Support and ownership of program activities*** (clients and coalitions/ commitment):

  It is important to involve stakeholders early in the design of adaptation programs. Identifying and allowing for the meaningful participation of relevant stakeholders from an early stage increases commitment and ownership needed to carry out adaptation activities. As a specific element, the engagement of influential champions (individuals or groups) who can serve as program advocates is also important for rallying support from relevant clients and coalitions in the broader society.
- ***Identification of most relevant problems and solutions*** (content):

  This point also relates to the early inclusion of relevant stakeholders. By incorporating the inputs of program beneficiaries or partners early on – including the vulnerability problem identification and adaptation response in the design stage – there is a higher likelihood that problems and targeted activities for the intervention will focus on what really matters. This is particularly important for adaptation measures that are being "downscaled" based on higher-level templates or thinking and thus may not have full contextual information of the specific intervention area. It also raises the

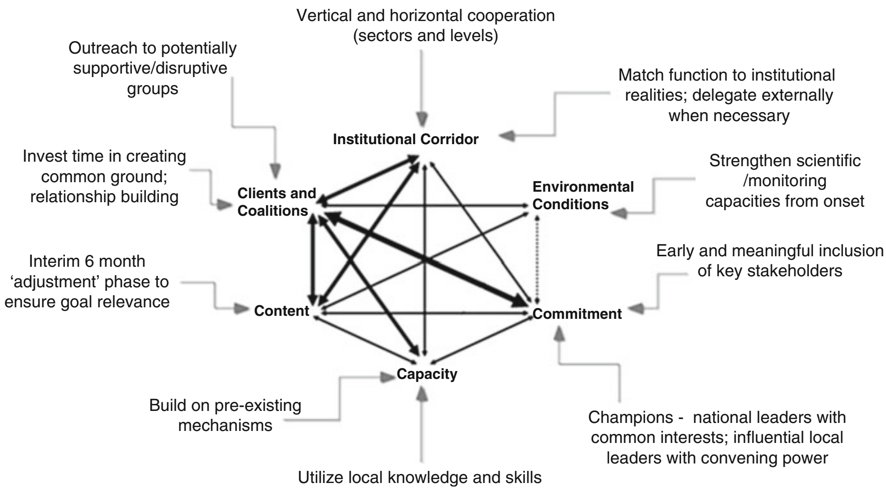

Fig. 5 Summary recommendations based on the 5C+ Protocol and JP experiences

potential for including the results of technical or scientific assessments as well as local knowledge at an early stage in the process. To facilitate this, we suggest incorporating an initial period for substantive stakeholder engagement at when adaptation programs are conceptualized, planned, evaluated, or adjusted. Additionally, later in the implementation stages, the work should have sufficient flexibility to incorporate the perspectives of significant stakeholders that may not have been included in initial stages, and in response to adaptation program results, as a form of institutional learning.

- ***Coordination across sectors and governance levels*** (institutional corridor):
The majority of JPs faced significant challenges in coordinating their work not only across different sectors (e.g., agriculture, water, health) but also between and across different types of governance and levels (e.g., national government ministries, UN agencies, and local communities). Addressing the potential for fragmentation is essential to ensure that competing interests and organizational mandates of diverse institutions do not compromise the program's ability to address adaptation needs. These needs, by definition, often cut across institutional, geographic, and other boundaries. To successfully manage issues as crosscutting as climate change adaptation, there must be a concerted effort to enhance coordination and harmonization and offer truly "joint" implementation of activities.

Remediation of these challenges will increase the probability of greater program effectiveness, building greater adaptive capacities, and ultimately a higher probability of long-term sustainability of climate change adaptation measures. However, to be effective, such adaptation measures must incorporate long-term planning and deliberate learning processes, to respond to the changing circumstances and potential nonlinearities associated with the effects of climate change.

Conclusion

It is notable that the JP operating framework and types of issues being addressed were in many circumstances the first of their kind in the countries where these programs were implemented. Jointly run climate change adaptation interventions are still young for the UN, and significant scope for learning remains. The experiences and lessons from the work of the JPs provide an important step towards improving the governance and management of climate change adaptation measures and enhancing effectiveness as well as building adaptive capacities of the most vulnerable.

However, this learning potential will not be achieved without targeted efforts. To be effective, adaptation measures must incorporate deliberate learning, to respond to the influence of various sectors, scales, and levels, their changing circumstances, and the nonlinearities associated with the effects of climate change (Berkhout et al. 2006). International organizations such as the UN must engage in intentional and effective organizational learning and adaptation processes, both to allow necessary adjustments within a program's life cycle and to ensure that the relevant and valuable lessons from specific program experiences can be accessed and used by others engaged in similar activities (Swanson et al. 2004; Swanson et al. 2010; Walker et al. 2001). Moreover, given that the field of climate change adaptation is young – and the danger of no or maladaptation has severe consequences, particularly for vulnerable populations – efforts towards such learning and information sharing should be enhanced.

Another cautionary point is related to the nature of prioritized adaptation activities. Adaptation to climate change is a long-term process, where building adaptive capacity (to respond to and thus reduce vulnerabilities) in the face of climate change is key. Climate change adaptation may require societies to respond/adapt to often completely new and hard-to-predict extreme events or "surprises" (Patt 1997). In such cases, following the traditional project cycles of development interventions is an ill fit. In part, the issue is that projects are often too short – generally not over 3–4 years and typically much shorter. Building real adaptive capacity often requires deeper structural changes that take more time to conceptualize, establish, and put into practice, whether it involves new measures or integrating new measures into existing mechanisms. Projects by definition also tend to have tightly defined objectives and activities with limited maneuverability during the project life cycle if conditions change. While this is desirable from the project management and accountability point of view, it limits flexibility and learning within the project if new learning emerges or if conditions change. Such project designs and time frames limit the relevance, flexibility, and responsiveness of the work that effective climate change adaptation requires.

If international organizations such as the UN want to implement truly effective climate change adaptation interventions, they must adopt a more long-term view that incorporates flexible project design and budgeting requirements, geared specifically towards building adaptive *capacities* rather than just adaptation activities

(Folke et al. 2002). It may also require mechanisms that allow longer project life cycles, involving dynamic partnerships with other donors and participants from the public and private sector, considering the shifting modality of international development assistance. Having a longer-term view and involving additional partners may also require addressing the reality that adaptation activities cannot be restricted to climate change in a narrow sense of the term. While climate change is a significant new source of vulnerability, it is certainly not the only one. Climate vulnerability is often coupled with vulnerability due to other factors, and thus both for reasons of effectiveness and efficiency, adaptation responses should where possible also be integrated. Moving in this direction will require concerted efforts and time to design and implement adaptation measures based on principles of meaningful joint planning, participation, and thematic integration.

Adaptive, cross-scale and collaborative management approaches are key to ensuring that international organizations are able to address the complexities and urgency associated with climate change vulnerability and adaptation. However, an important challenge faced by international organizations such as the UN is the relevance of downscaling their global initiatives to suit localized needs. By its very nature, climate change adaptation requires a high level of context relevance and specificity. As such, it also requires international organizations to invest time and effort required to build relationships with beneficiaries and/or to forge strong relationships with key counterparts who may be a better fit for delivering such contextualized measures.

Abstract

Changes in climate during this century will have broad impacts on human activities and ecosystems, and the likely consequences are of such a magnitude that the simultaneous need to adapt to the new climate conditions and to reduce the carbon footprint to prevent even further damage will likely become one of the main driving forces for the global community over the coming decades. We attempt to simultaneously address two main questions related to the climate change challenge for Latin America and the Caribbean. First, what are the key physical impacts and consequences of climate change? Second, what are the likely costs to the regional economies derived from these impacts? Results indicate that conservative annual damages are about US$100 billion by 2050 and the overall investment required to adapt is approximately one-fourth to one-sixth of the costs associated with those impacts. Rapid and decisive adaptation actions are urgent to reduce the magnitude of these effects although some irreversible damages would remain as adaptation measures do not generally result in the full restoration of lost natural and cultural capital.

Keywords

Climate change • Adaptation • Economic impacts • Latin America and the Caribbean

Introduction

The global average concentration of carbon dioxide (CO_2) in the atmosphere has increased considerably, rising from approximately 280 parts per million (ppm) in the late eighteenth century to 400 ppm in early 2014 (NOAA 2014). This trend is just below the most pessimistic scenario (A1FI) visualized by the Intergovernmental Panel on Climate Change (IPCC) in 2000 and might trigger climate feedback effects that are not well known (Ackerman and Stanton 2011). Scientific analyses indicate that a CO_2 atmospheric concentration of 450 ppm is consistent with a 2 °C increase in global temperature, relative to preindustrial levels.

The 2 °C threshold has been the basis behind efforts to stabilize climate conditions given that it is linked to the strong likelihood of "dangerous" changes in the climate (Schellnhuber 2009; IPCC 2014). Despite a degree of uncertainty regarding the future "business-as-usual" emission trajectory and climate sensitivity, there is a growing consensus that emissions need to be reduced to a level consistent with this guardrail to avoid further climate destabilization. Even if greenhouse gas (GHG) emissions are effectively reduced, consistent with the 2° guardrail, climate impacts are likely to affect the economies and natural resources of Latin America and the Caribbean (LAC). This is in large part because of the region's substantial but intrinsically fragile natural capital (which includes climate-sensitive ecosystems), geographic location, and vulnerable infrastructure. Adaptation responses to the impacts of a 2 °C temperature rise are therefore necessary and play a critical role in any regional climate strategy.

This chapter attempts to simultaneously address two main questions related to the climate change challenge for the region. First, what are the key physical impacts and consequences? Second, what are the costs to the regional economies derived from these impacts? For this purpose, the impacts of climate change are identified and their economic impact is quantified. Then, an overview of associated cost of adaptation measures is presented. Mitigation activities are also needed to avoid the dire projections of temperature rise above 2 °C; the analysis of these actions – although important – is beyond the scope of this study. For a comprehensive treatment of mitigation pathways in LAC, see Vergara et al. (2013).

Physical Impacts and Consequences

The physical impacts of climate change depend on atmospheric concentrations of GHG emissions and the capacity to adapt to these changes (Wilbanks et al. 2007). Mitigation and adaptation targets are thus interrelated – mitigation attenuates the risks of global climate change, whereas adaptation ameliorates specific impacts in a particular location. Some now consider a midcentury temperature increase of 2 °C over preindustrial levels to be virtually unavoidable (Hansen et al. 2012) unless drastic and immediate actions are undertaken. Climate change of this magnitude will significantly disrupt livelihoods, social conditions, and ecosystems (IPCC 2007). Some of the key physical consequences projected for the region follow.

Agriculture

The impacts of climate change on agriculture are expected to reduce food supply and increase food prices, with potentially negative impacts on income, food security, poverty, and nutrition (Ahmed et al. 2009; Nelson et al. 2009). As temperature, moisture, and rainfall patterns change, so will crop yields and the distribution of agricultural production (Dawson and Spannagle 2009). In the short run, yields of certain crops may increase or decrease in different areas, according to projected rainfall, temperature, and weather variations. For instance, yields might increase because of a CO_2 fertilization effect or more benign weather conditions (Nelson et al. 2010; Magrin et al. 2007; Seo and Mendelsohn 2008a, b, c; Mendelsohn and Dinar 2009). Over the longer term, LAC's agricultural output is anticipated to fall because of combined changes in rainfall patterns and soil conditions (ECLAC 2010; Tubiello et al. 2008; Mendelsohn and Dinar 2009).

Negative effects of climate change on crops in LAC could be significant and are expected to play a major role in the global food supply chain (Fernandes et al. 2012). In this study, the authors report that simple adaptation alternatives (e.g., improved varieties, change of sowing dates, and modest irrigation) are not sufficient to overcome the forecasted impacts of climate change which will account for US$32–54 billion annual reduction of agricultural exports in the region by 2050. These impacts, particularly in the context of a tight global food supply–demand balance, may also trigger other consequences including food market speculation and threats to food security.

Coastal and Marine Zones

LAC is particularly vulnerable to sea-level rise because of its extended coast, geomorphology, prevalence of coastal settlements, and value of coastal economic activities (Nicholls and Tol 2006; Sugiyama 2007). Sea-level rise and an increased frequency and severity of storm events will likely lead to greater coastal flooding and erosion, which may cause substantial property and infrastructure damage, ecosystem losses, and partial land loss (Suarez et al. 2005; Jacob et al. 2007; Williams et al. 2009). Estimated annual costs of a 1 m rise in sea level in the region are approximately US$19 billion (Dasgupta et al. 2007). Accumulated costs associated with this impact are around US$255 billion considering capital and net wetland losses in Latin America (Sugiyama 2007). Moreover, recent data by ECLAC (2012) show that this increase in sea level would affect approximately 6,700 km of roads in the region and at least 40 % of the population living in the coastal areas of Chile and Uruguay.

Sea-level rise is also increasing hydrostatic pressure on coastal freshwater aquifers, some of which play a critical role in water supply. For instance, measurements of conductivity in the San Andrés Islands (INAP 2012) indicate a long-term trend that, if continued, will eventually render the water supply unsuitable for human consumption. There is thus an urgent need for more significant contingency planning and adaptation efforts along coastlines.

Most corals are highly sensitive to changes in the environment; when stressed by rising temperatures, corals lose the symbiotic arrangements needed for photosynthesis, leading to bleaching and eventually death. Temperatures in the Caribbean are anticipated to reach threshold values that would lead to repeated bleaching and a collapse of the coral biome. This is of great importance since significant economic impacts and losses in biodiversity could occur as coral reefs are the most biologically diverse marine ecosystem with more than 25 % of all marine species. For example, annual cost derived from losing half of the coral cover in the Caribbean has been estimated at about US$7 billion (Vergara 2009).

The recent increase in land-falling hurricanes has been associated with a broader increase in average tropical cyclone wind speeds as sea-surface temperature rises (Curry et al. 2009), and hurricanes are intensifying globally (Emanuel 2005; Webster et al. 2005). Expected annual economic impacts associated with intensified hurricane activity by 2050 are in the US$5 billion range (Toba 2009), while damages from tropical cyclones are projected at about US$110 billion–US$149 billion for 2021–2025 (Curry et al. 2009).

Health

Main health threats associated with climate change in Latin America are malaria, dengue, cholera, and heat stress (Githeko and Woodward 2003). Increased temperature and precipitation will expose the region to a higher transmission risk of malaria (Magrin et al. 2007), whereas changes in geographical transmission limits

(Hales et al. 2002) and distribution of vector-borne diseases would favor the incidence of dengue. Moreover, LAC is expected to suffer from a higher prevalence of diarrheal diseases and malnutrition with an associated annual health burden of around US$1.3 billion by 2030 (see Table 1).

Hydrology

Hydrological regimes would be affected by changes in average conditions and increases in the amplitude and frequency of extreme precipitation events. The hydrology of major rivers in the Amazon Basin is projected to become less stable with probabilities of higher peaks and lower nodes (Vergara and Scholz 2011), and intensification of flooding in the Grijalva Basin in Mexico has caused damages valued at 30 % of the region's GDP in 2007 (CONAGUA 2009). Less stable hydrological regimes in major basins will lower firm capacities in hydropower production and result in the need for additional storage to maintain reliability in water supplies. For Brazil, these unstable conditions would reduce the firm-guaranteed minimum capacity of hydropower reservoirs by around 30 % (De Lucena et al. 2010), equivalent to an estimated yearly cost of US$18 billion (Table 1).

Visible impacts of the changes caused by new climate patterns are evident in the Andes: warming temperatures have caused rapid retreat of glaciated areas, and variability and extremes in weather conditions have started to affect Andean ecosystems and human activities. Black carbon emissions within the region from land clearance, biomass burning, and other sources like transportation may also be contributing to glacier retreat (Simões and Evangelista 2012; Vergara and Rios 2013) and are changing the albedo in the Antarctic Peninsula (Pereira et al. 2006). During 1970–2002, the area of tropical glaciers in the Andes decreased by more than 15 % (Kaser and Osmaston 2002). This phenomenon has significant consequences. For example, glacier retreat is estimated to lead to an annual incremental cost between US$212 million and US$1.5 billion for the generation of energy in Peru (Vergara et al. 2007), and the city of Quito would require an additional investment of US$100 million over the next 20 years to guarantee its future water supply (Vergara et al. 2007).

Potential Rainforest Dieback

Current climate trends and human-induced deforestation may be transforming the structure and behavior of the Amazon rainforest (Phillips et al. 2009). Any drastic changes in the ground cover of the Amazon Basin will modify the provision of a variety of ecosystem services such as carbon storage and sequestration, soil fertility, and water supply and affect local and regional climate. The probability of a substantial reduction in Amazon forest biomass due to climate change, or Amazon forest dieback, has been the focus of a growing body of research

Table 1 Estimates of annual damages from some key physical impacts by 2050

Impact	Area	Projected annual costs[a] (2005 billion US$)	Projected cumulative costs	Source
Loss in net export agricultural revenues: wheat, soybean, maize, and rice	LAC	26–44		Fernandes et al. 2012[b]
Sea-level rise (1 m)	LAC	22		Dasgupta et al. 2007[c]
Coral bleaching	Caribbean	8–11		Vergara et al. 2009[d]
Intensification and frequency increase of extreme weather events	CARICOM	5	110–149 for 2021–2025	Toba 2009[e]
	Mexico's Gulf Coast, Central America, and the Caribbean			Curry et al. 2009[f]
Health (increase in incident cases of diarrhea and malnutrition)	LAC	1		Ebi 2008[g]
Amazon dieback	Latin America	4–8		Authors' estimation[h]
Glacier retreat	Peru	1		Vergara et al. 2007[i]
Loss of ecosystem services	Latin America		36	Authors' estimation[j]
Hydropower generation	Brazil	18		Authors' estimation[k]
Estimated total		85–110		
Percent LAC GDP[l]		1.8–2.4		

[a]Estimated total must be considered a conservative range of values with the following caveats: (a) estimations are gathered from different studies with varying methodologies, assumptions, and uncertainties; (b) many costs are only partially presented, and others are difficult to estimate; and (c) nonmonetary costs are excluded. The CPI is used to convert costs to 2005 US dollars (Bureau of Labor Statistics). When information was not available, costs were assumed to be reported in US dollars of the year in which the study was published

[l]2010 GDP measured in 2005 dollars

[b]Projected loss in net export revenues in 2050

[c]Impact on GDP observed when a 1 m rise in sea level is reached

[d]Estimation derived from losing 90 % of coral cover under SRES A1B scenario. Includes lost value of coastal protection, fisheries, tourism, and biochemicals

[e]Considers impacts of "climate disasters" (floods, droughts, and windstorms) on agricultural production, human health, tourism, government, and GDP loss

[f]2007 US dollars. Projected costs correspond to tropical cyclones during 2020–2025, scenario A1 (lower range) and scenario B2 (upper range)

[g]Cost in 2030 under a scenario assuming (i) stabilization of emissions at 550 ppm of CO_2e by 2170 and (ii) annual cases and treatment costs remain constant

[h]Projected cost in 2100 obtained from TEEB (2010). These costs consider ecosystem services in terms of carbon storage and sequestration, agricultural productivity, hydropower generation, sustainable timber harvest, reduced siltation in hydropower reservoirs, commercially viable fish populations, subsistence life styles, and improvements in quality of life. Reduction in rainforest biome obtained from Vergara and Scholz (2011). Note that many of the services provided by the biome are transnational and global services and as such their valuations are not considered

[i]Incremental cost for the power sector based on rationing cost

[j]Economic impact assuming a doubling of CO_2, estimated in 2000 dollars. Authors' elaboration based on data from Leemans (1989)

[k]Value estimated based on the reduction in firm power hydroelectric generation in 2035 under scenario B2 reported by De Lucena et al. (2010), hydropower generation from the Brazilian National System Operator (ONS), and the cost of rationing from Mauerer et al. (2005)

(Malhi and Phillips 2004; Malhi et al. 2006; Phillips et al. 2009; Nepstad et al. 2006; Brando et al. 2008; Saleska et al. 2007; Cox et al. 2004; Sitch et al. 2008). While individual results vary, climate change is expected to have a negative effect on the rainforest biome in the Amazon. In economic terms, a partial estimate of this impact is about US$4–9 billion annually.

Ecosystems and Biodiversity

In addition to impacts affecting human activities and infrastructure, climate change will alter natural ecosystems and species. Climate change is accelerating the natural process of biodiversity modifications affecting vegetation, composition of ecosystems, and distribution and migration of various animal species (IPCC 2001, 2007). Changes in air temperature and the onset of seasonal variations will affect the capacity of species to migrate and the composition of the habitats on which they depend in their well-timed routes (Robinson et al. 2005). Although assigning monetary values to ecosystem functions entails significant methodological difficulties (Arrow et al. 1993; Heal 2000; Spash and Vatn 2006), an attempt employing meta-analysis reports a net annual economic loss of US$36.5 billion as a consequence of climate change impacts in Latin American ecosystems (see Table 1).

Irreversible effects on biodiversity are projected, and climate change may also produce significant feedback effects that cannot at this time be properly valued or understood. The impacts of irreversible harm to biodiversity are more than merely an economic matter; they have significant ethical implications. Many of these effects represent committed changes that will not be easily reversed and will continue over time, even if reductions in the rate of emissions are secured.

Estimate of Damage from Physical Impacts

Based on the information presented in the previous section, the aggregated value of the projected annual economic damages in LAC resulting from some of the major physical impacts associated with this unavoidable 2 °C increase over preindustrial levels is summarized in Table 1. Damages are expected to grow gradually, reaching approximately US$85–110 billion per year by 2050 (measured in 2005 US dollars). Several aspects must be taken into account when assessing the severity of this economic impact including, among others:

– Reported amounts are a conservative estimate of annual damages; these are not comprehensive and include partial estimates in terms of impacts and geographical coverage.
– Impacts whose economic valuation is challenging due to data limitations and/or difficulties in assigning monetary values have been excluded (e.g., damages to biodiversity, change in the stock of natural resources, biome collapse, irretrievable damages in natural capital, and cultural and social services).
– Effects of climate change accumulate over time – damage is already occurring and will intensify as extreme events become more frequent or intense, and gradual changes like temperature increases take effect.
– This is a simplified analysis where adaptation does not take place. People, households, economic entities, and other businesses will adjust in view of climatic changes and continuous losses. But unplanned adaptation and learning from losses is still costly and could be preempted by adaptation programs and measures that increase resilience.

A Four-Degree Anomaly

Costs of physical consequences and estimates of adaptation costs refer generally to a trajectory consistent with a 2 ºC temperature anomaly. However, the actual path of emissions is closer to scenario A1FI, associated with an atmospheric concentration of CO_2 above 800 ppm and a forecasted 4 °C increase in global temperature. Under this trend, the impacts of climate change will escalate and associated adaptation costs would increase. The changes induced in a 4 °C future would likely be long lasting, even if emission patterns could be quickly reversed.

Overall Adaptation Costs

Table 2 presents adaptation costs for LAC reported by UNFCCC (2007), World Bank (2010), and Agrawala et al. (2010). These studies have significant limitations and uncertainties leading to estimates that are difficult to compare because dissimilarities in methodologies, sectors, time spans, and adaptation measures are considered. Nonetheless, regardless of the value considered, adaptation costs are an order of magnitude lower than the costs of physical damages. This finding highlights the importance of deploying efforts to adapt.

Adaptation has the potential not only to reduce the net impact of climate consequences but also to support the overall sustainability of development in LAC. Whereas development needs are immediate, the problems created by climate

Table 2 Adaptation cost estimates (billions of US$)

UNFCCC (2007)		World Bank (2010)			Agrawala et al. (2010) AD-WITCH

change – though substantial – are perceived as gradual, far-off, and (in some cases) uncertain. But a lack of action on adaptation will generate more development needs in the future. Rather than being viewed as separate from development (Leary et al. 2008), adaptation should thus be seen as an integral component of this process. Unless addressed, climate change impacts will represent a heavy burden to development agendas in the region.

Conclusions

LAC is particularly vulnerable to the observed and projected impacts of climate change mainly because of its geographic location, distribution of population, infrastructure, and reliance on fragile natural resources for economic activities and livelihoods. Key impacts include the collapse of a significant portion of the coral biome in the Caribbean, disappearance of most glaciers under 5,000 m in the tropical Andes, reductions in agricultural yields, increased flooding of coastal zones, higher exposure to tropical diseases, destabilization of the hydrological cycle in major basins, and intensification of extreme weather events. Many of these changes are considered to be not only inevitable but also irreversible; climate change will therefore continue to adversely affect the region over the long term.

Economic damages caused by physical impacts associated with the likely rise of 2 °C over preindustrial levels are projected to gradually increase and reach a conservative annual estimate of US$85–110 billion by 2050. These impacts are already taking place and will intensify as temperatures increase. Losses of this extent will undermine the region's prospects for improvements in quality of life, by significantly limiting development options and restricting access to natural resources and ecosystem services. Economic resources, already inadequate to meet competing demands, will be further strained.

On the other hand, overall adaptation requirements represent approximately one-fourth to one-sixth of the expected damages. Rapid and decisive adaptation actions are thus urgent to ameliorate some of the physical and socioeconomic impacts of climate change. Despite the implementation of these measures, however, some irreversible damages would remain as adaptation does not generally result in the restoration of lost natural and cultural capital.

Abstract

This chapter explores climate change impacts on defense forces (militaries) and suggests ways for them to respond. It considers general military capacity to become more involved in climate adaptation, proposes some best practices, and articulates a decision framework for action. We have developed a framework for capture and analysis of the military role within broader climate adaptation. The Strategic Military Geography (SMG) Framework is a decision framework that allows collaborative exploration of the relationship between climate change impacts and military activities. SMG employs systemic action research, which integrates systems thinking, participatory action research, and triple-loop learning to address the complex, interlinked issues relating to global change, including climate change. It was found that defense forces can play a significant role in climate adaptation, in armed conflict situations, and in military operations other than war, such as humanitarian assistance and disaster relief. For example, military personnel are regularly involved as responders to natural disasters and often play a central role in reconstruction. Practical ways that defense forces can build climate adaptiveness include incorporation of projected change and associated uncertainty into preparedness (readiness) planning, improved forecasting, regional and whole-of-government engagement on climate adaptation, and building energy sustainability that reduces carbon emissions. The framework presented supports system-wide long-term planning, fosters greater dialogue between critical stakeholders, and enables transfer of learning between defense forces and other organizations.

Keywords

Defense • Strategic military geography • Climate change • Adaptation • Security • Decision framework

Introduction

This chapter draws on an Australian Defence study of global change impacts and engagement with other defense and national security organizations including military forces. Defense forces have no choice but to take an interest in adaptation to physical environmental and geographical change. The Australian strategic policy, for example, has formally identified climate change as a threat to national security and homeland infrastructure since at least 2008 (Thomas 2013). Regardless of cultural or philosophical views on the role of military organizations, a great many of them will be central players in climate change adaptation and response.

Climate change, and more broadly global change, is often characterized as a complex, evolving problem. To address such problems, holistic and systemic approaches are advocated (Commonwealth of Australia 2007). One way to contextualize climate change impacts into military organizations is via the construct of

Strategic Military Geography (SMG). The SMG Framework draws on systemic methods of inquiry and learning to explore and take action in a large, diverse military organization. SMG provides ways to frame issues in a military context and collaboratively explore the relationships between global change, including climate change adaptation, and military organizations.

Using the SMG framework has facilitated identification of priority issues for the military in four key areas. These are the operating environment, mission profiles (tasking), supporting infrastructure, and business continuity. Business continuity in this context is a holistic management process that identifies potential impacts that threaten an organization and provides a framework for building resilience and the capability for an effective response that safeguards its critical functions. This framing and analysis has aided the Australian Defence Organisation to begin to prepare for and adapt to global change, including climate change.

The Strategic Context of Climate Change

Military organizations have a keen interest in climate change adaptation. The US Navy, in particular, has arguably been at the forefront of raising awareness and responding to climate change implications for defense and national security (US Navy 2010). Other militaries active in climate adaptation include the UK Ministry of Defence, Indonesia, New Zealand, the Maldives, Bangladesh, Papua New Guinea, and NATO members. In 2010, for example, NATO secretary general Anders Fogh Rasmussen wrote: "Climate change presents security challenges of a magnitude and a complexity we have never seen before. We must be prepared for them" (Rasmussen 2010).

A literature review by Thomas (2013) shows that a range of defense and security scholars have explored the implications of climate change for military forces, particularly in terms of their future capabilities, tasking, and ability to support their nations. Serving and retired military personnel have also been active in raising awareness and talking about the implications for defense and national security (Barrie 2013). This has led to some debate more broadly about the "securitization" of climate change and some suspicion of military intentions. The alternative view is "normalization" of the military as an instrument of state in achieving national goals including greenhouse gas reductions and climate change adaptation (Thomas 2013).

In the Australian SMG study, the latter view has been taken, that is, that defense forces or militaries – as large employers, as a key implementer of national security policy, and as significant purchasers, custodians, and users of government assets – can legitimately play a role in climate change adaptation efforts. In Australian security discourse, the strategic risks of climate change have been identified in academic and think-tank literature as well as formal strategic policy since at least 2006 (Thomas 2012).

The First National Security Statement to the Australian Parliament, published in 2008, described climate change as a "new and emerging challenge" and one that represented a "most fundamental national security challenge." This Statement also called for climate change threats to be formally incorporated into Australia's national security policy and analysis process (Rudd 2008).

The 2009 *Defence White Paper: Force 2030* subsequently crystallized two major security implications of climate change. The first was that climate change may exacerbate the severity and frequency of natural disasters, thereby requiring increased military support to humanitarian assistance and disaster relief (HADR) operations. The second described how climate change may exacerbate existing precursors to conflict whereby vulnerable states (with limited capacity to respond) may dissolve into violent conflict, thus triggering military intervention as a "stabilizing" force. Climate change here is seen as a "threat multiplier" rather than a distinct driver of hostilities (Department of Defence 2009).

More recent guidance from the 2013 *National Security Strategy* and the 2013 *Defence White Paper* has reiterated the strategic risks of climate change (Department of Defence 2013). Related literature including from the Australian Strategic Policy Institute and internal analyses have identified a range of other areas in which climate change may affect the Australian Defence Force.

Investigation, Decision, and Action Framework

To identify and understand climate, and other global, change impacts on military forces, a decision support framework called Strategic Military Geography (SMG) has been developed. The SMG framework employs systemic action research as its main methodology. This methodology integrates systems thinking, participatory action research, and triple-loop learning as these conceptual approaches are useful for investigating complex, multifaceted issues where there is limited or incomplete knowledge of all the affecting factors (Bawden 1990).

Implicit in systemic action research is an assumption that people in a given field of activity are attempting to adapt themselves and their environments in the face of change. Burns (2009) describes systemic action research as:

> The Systemic aspect is crucial because any action taken will be affected by underlying patterns and social norms; complex power relationships between a range of stakeholders; activities that may seem peripheral and beyond the immediate operating environment, non-linear effects of multiple linear interactions and different, sometimes contradictory, impacts at different levels of the system under review.

The entry points where possibilities for change can occur, and the "tipping points" which support sustainable phase change, are often invisible in typical research analysis or organizational development practices.

In this methodology, systems are broadly encompassing, affecting the whole of life. That is, systems can be an understanding of the way the world is, a way of thinking about the world, an approach to dealing with problems, a set of methods and techniques, or all of these. A system is defined as a set of elements connected in some way to form an identifiable whole. The properties of this whole emerge as a result of the relationships between the component parts, rather than being the sum of the properties of the parts (Bawden 1990).

Action is fundamental because action learning provides insights and practices not generated by other types of learning. New opportunities and entry points for development or system change become available through action. In systemic action research, there is an explicit presumption that action does not necessarily follow from analysis. Here, action can – and ought to – inform analysis which in turn can generate new action (Burns 2009).

Research is important because evidence is required; thus inquiries need to be documented so as to generate a sufficient and useable evidence base. Evidence enables the building of a case for action, testing of resonance within the system, and consideration of action options including the teasing out of unintended consequences.

The corollary concept, triple-loop learning, draws on a range of theoretical works and is used as a means to critically examine how a military organization "learns" and whether it is "learning" the things that most matter. This leads to three questions: "Is the organization doing things right? Is the organization doing the right things? How does the organization know what is right?" (Argyris and Schön 1996). It is a process that can be used to critically reflect on the military's ability to adapt to complex change and thereby fulfill its task of upholding national security.

Systemic action research, as a whole, has a number of key aspects. It is multistranded. This enables stakeholders and participants to consider issues from a range of different perspectives and so begin to understand the interconnections and influences between issues, for example, via co-learning and joint analysis. It involves multiple stakeholders and interest groups at different but related levels of hierarchy, for example, "on the ground" or in the immediate unit, within the wider local grouping or system, and in organizational or more strategic settings. This allows the range of key players to engage in "learning, dialogue and the co-construction of action; enhancing the chances that solutions will sustainable" (Burns 2009).

Of critical interest, systemic action research links informal inquiry and action with formal decision-making systems and networks of power. It gauges the significance of issues through the use of resonance rather than representativeness. This methodology is highly emergent in its design, thus seeking to mirror the emergence of the phenomena that it is exploring. Lastly, it requires the research convenors and participants to identify underlying patterns; surface and challenge underlying assumptions so as to identify systemic blockages; identify possible entry points, opportunity spaces, and leverage points to generate action and enter these "entry points" to discover where they lead; be bridges between different parts of the wider system; identify and catalyze powerful sources of leadership; and support action in multiple arenas (Burns 2009).

These distinctions and definitions are important because of the way different approaches can shape the problem definition, analysis, and subsequent solution options or recommendations. How a problem is viewed initially – and what the roots of the problem are – is often a judgment call. In this context, judgment is defined as a combination of experience, knowledge, and learning preferences (Bawden 1990).

Strategic Military Geography

Judgment is often required by military personnel, particularly in operations – be they war or non-conflict activities such as HADR. A key support to judgments and decision-making is military geography, which has long been part of defense doctrine and concepts because military activities are inherently geographic in nature (O'Brien 1991). "Military activities occur on landscapes with distinct physical and cultural character. Understanding how the spatial distribution of landscape elements affects the military operating environment at the tactical and operational scales, and how this applies to military concerns are the strategic scale, is the substance of military geography" (Harmon et al. 2004).

Military geography therefore provides an appropriate basis for a conceptual framework to enable analysis of climate change impacts, consider their implications for the military, decide on priorities, and take action. The term Strategic Military Geography (SMG) is derived from "military geography" and also draws upon the characterization of "global change" in the earth sciences, ecology and humanities, and "geopolitics" and "strategic geography" in the security and international relations disciplines. Using these different – and sometimes competing – constructs helps to encourage the multiple perspectives and cross-fertilization of ideas formalized in the systemic action research methodology.

There are four key tenets in the SMG Framework. The first is to think "big picture" and take a holistic or "helicopter" view, to look at the whole set of challenges and potential changes in the military operating environment in its broadest definition. This helps users to get a sense of the range of issues and how they interact and influence each other. The second tenet is to consider the relationships between the issues as well as understanding specific issues, that is, to take a systems view. The third tenet is to take a participatory approach and engage as broadly as possible – within the military, within the government, and within the science and research communities. The fourth tenet is to use a multilevel learning process that maps across tactical, operational, and strategic military domains. SMG employs these different principles concurrently and iteratively to provide a more comprehensive understanding and analysis, with which to generate options for situation adaptation or improvement.

The Multiplicity of Geographies

Traditionally, the two prime aspects of military geography are the physical terrain or landscape and the cultural characteristics or societal makeup of groups in the military operating area. In the SMG framework, the virtual world or cyber geography has been added as a distinct geography.

Thus, in this Framework, global changes in SMG can be analyzed as the nexus between biogeochemical changes in the Earth system (physical geography) and social, economic, and technical responses (cultural or human geography) and intangible technological considerations (virtual geography).

Physical geography encompasses the military geography domains of air, land, maritime, and more recently space (orbital and intra-solar). Physical geography also includes the diversity of the natural sciences and phenomena, such as sea straits, volcanoes, topography, weather, orbital space, terrain, vegetative cover, natural features, flora and fauna, wind and wave patterns, temperature, and rainfall.

Human or cultural geography is the human world and covers society, politics, philosophy, economics, science and technology, culture, and concepts such as the nation state, transnational corporations, international relations, the precautionary principle, and peacekeeping to name a random few. The focus here is on human activity systems, that is, particular and cumulative effects of human activities on groups of people and on their environment.

Human or cultural geography includes allied nations, neighbors, community values, local economies, recruitment, fallout from the global financial crisis, new technologies such as algae-derived biofuels, sustainable chemistry, gas-to-liquid conversion, nanotechnology, and gene therapy. It also encompasses attitudes and behaviors – individually and collectively, for example, toward physical environmental change, conventional power and energy generation, and future human development.

Socio-technical and economic responses fit within human geography and include domestic and international regulation, economic instruments, societal (nongovernment) reactions, and government activity as well as broader human activities, such as changing patterns of settlement, human demography, impacts of technology applications, and regional/global relationships including disasters and conflict.

Virtual geography (also known as cyber geography) is a recent addition to traditional military geography. It covers activities, phenomena, and effects in the virtual world. These include cyber terrain, simulation, satellite data, virtual reconnaissance, planning, and training as well as online gaming, communications such as e-mail and video link, social media, control networks for electricity grids and other applications, massive open online education courses, global research, and other types of collaboration via the Internet plus commerce, entertainment, and crime. More and more is happening in the virtual world, such that cyber security, hacking, and other types of activities designed to disrupt, disable, mislead, or financially disadvantage are becoming constant features of cyber space.

Interfaces and Interactions

All these worlds interact and influence each other, and all are affected by global change, including climate change. For example, the virtual world has physical aspects such as power sources, hardware and equipment, and development, trade, and disposal of hardware and software. Data collection and storage also have physical aspects. Hardware for the virtual world currently requires rare earths and precious metals, many of which occur in limited quantities globally.

The food-energy-water nexus is another example of the interactions between the three geographies. Production of food for human and livestock consumption depends upon water and energy and for much of it arable land as well, thus linking physical and cultural geography. Agricultural commodity and processed food production, trade, and distribution can be researched, modeled, and simulated virtually, thus linking physical and cultural geography to the virtual world. Production systems can be controlled electronically and growing conditions monitored and adjusted, for example, by restricting or releasing water, via the Internet, situating these in the virtual geography domain. Food production and consumption often have social rituals attached to them, as well as financial value and social status.

Competition for energy sources and energy efficiency also has effects in the physical, cultural, and virtual worlds. Physical geography, for example, yields locations of sources, production, distribution, and consumption. Cultural geography encompasses investment finance, pricing, and social attitudes to different types of energy and how much people or organizations are willing to pay. Virtual geography provides for aspects such as exploration imagery and analysis, planning and design of production facilities, calculations of cost-effective shipping routes and tonnages, data collection on things like consumption interests and intentions that can be used to inform extraction or production adjustments, and complex, real-time price calculations of end products.

Analysis of Global Changes in Strategic Military Geography

The implications, particularly for future operating conditions, mission profiles, and energy resilience, of global changes in SMG, including climate change, are of great significance to military organizations, especially for future preparedness and planning. As military forces with a range of responsibilities, as large employers, as key implementers of government policy, as consumers of goods and services, and as stewards of national technological and biophysical assets, military organizations need to be cognizant of the implications of these changes for organizational and capability decisions that need to be taken now that will have impacts over the coming decades.

Reducing greenhouse gases (mitigation) while implementing adaptation measures represents a fundamental two-track climate change risk management strategy. Military planners routinely operate under uncertainty and make decisions based on incomplete information. If a battlefield commander waited until all facts were known about an advancing enemy, they would put their troops at risk (O'Brien 1991). Addressing climate change impacts on defense and national security can be seen in the same way.

Climate Change Effects

Changing geography and climate will have a range of effects on military forces. These can be categorized in three ways to enable understanding, help generate responses, and aid in decision-making:

First-order or direct effects include changes in the physical operating domains of land, sea, air, and space. This covers effects such as changing wind and wave patterns, strength, speed, direction, more turbulent, and variable. Changes in ocean circulation, wind currents, and atmospheric composition will impact on the conduct of operations, the usability and livability of military bases and facilities, and access to civilian infrastructure.

The conduct of operations may be more challenging physically and psychologically for military personnel training and conducting missions in harsher operating conditions and in dealing with civilians in desperate circumstances. Harsher operating conditions and more frequent support to disaster relief will reduce the service life of many military platforms and much equipment and require more maintenance at shorter intervals. This will affect military budgets, planning and acquisition cycles, and training regimes as military hardware is replaced more often. Life cycles of military equipment, particularly major platforms such as ships, planes, and ground vehicles, may be shortened as a consequence of changed conditions, placing increased demand also on maintenance, life-cycle costs, capability replacement, and disposal regimes.

Without remediation, the usability and livability of military bases and facilities may also be degraded. Airfields, ranges, wharves, fuel, and chemical storage facilities, for example, may become subject to flooding and inundation, increase maintenance in hotter drier conditions, or require upgrade or early replacement due to changed building codes or other regulations. There are implications too for the military workforce in terms of work health and safety, which would likely have organizational impacts on duty of care obligations, workforce productivity, and injury compensation arrangements.

These physical effects, particularly more severe weather events, changing rainfall patterns, and increased temperatures, are already causing greater stress on human populations; their infrastructure and support systems including food, water, and other supplies; and their distribution and waste disposal. Primary health impacts for people, plants, and animals include greater heat stress, more injuries, and reduced productivity because of warmer weather, particularly during the night as this affects rest and refreshment.

Operations and training may also be affected by changed access to harbors due to altered wind and ocean currents. On the east coast of Australia, for example, this could be exacerbated by the loss of significant portions of the Great Barrier Reef.

Second-order or indirect effects include changing mission profiles particularly the likelihood of greater demand for military support to civil communities, humanitarian assistance, disaster relief, peacekeeping, and reconstruction activities. A sufficiently large increase in demand for such missions will have impacts on training regimes, mission planning, disposition of forces, acquisitions, strategic planning, and military-military and civil-military cooperation. For example, increased deployment of military forces for reconstruction efforts, certainly in the Australian context, could require greater recruitment and training of people with the required trades and skills.

Another second-order effect is the impact on tasking and range. For example, Antarctica is changing much more quickly than scientists expected. At the same time, international interest is steadily increasing in Antarctica's role in global climate change and in Antarctica's biological and other resources (ASPI 2013).

Changing patterns of diseases, disorders, and pests are already affecting people, commercially valuable and emblematic (or psychologically valuable) animal, and plant species. These include changes in the ranges of vector-borne diseases, increased allergies, and air pollution.

The risks to human health from climate change include: injuries and fatalities related to heat waves and other severe weather events; spread of some infectious diseases from rising temperatures and changes in rainfall; water and food contamination from rising temperatures, changes in rainfall patterns, and extreme events; exacerbated respiratory allergies from increased allergens (pollens and spores) in the air; exacerbated respiratory and heart diseases in response to increases in some air pollutants; mental health problems in those experiencing physical and economic impacts; and the health consequences of population dislocation as some regions become uninhabitable (McMichael and Butler 2009).

A further second-order effect relates to energy – access, reliability, and security of supply and storage, as well as increased cost volatility. Energy sustainment is a major issue for most, if not all, military forces and a key part of building organizational resilience. Military organizations tend to be significant users of liquid fuels and to have some specialized fuel requirements. Given the rising cost of fossil fuels and the declining energy-returned-on-energy-invested surrounding extraction and production of liquid hydrocarbon deposits, energy sustainability is likely to become a critical issue for military organizations. This is particularly so as many military assets, including most of the larger platforms such as ships, planes, and submarines, are optimized for fossil fuel use. An exacerbating factor is that many military assets have specialized requirements that cannot be met by the current suite of alternative fuels.

Thus, there are risks and vulnerabilities in current military energy acquisition and management. In particular, change in energy demand, plus gaps in energy management, research, and reporting, could lead to significant unfunded cost pressures and potential future restrictions on operational capability.

Third-order or distant effects include economic losses which can have flow-on effects to military funding, implications for the military's reputation, ability to recruit and retain staff, and changes in the broader workforce that will impact on the recruitment pool. Feedback loops are important to consider. In terms of individual and population health, tertiary (or systemic multiplier) effects include famine, increased likelihood of conflict, large-scale migration or species decline, and potentially economic collapse (Butler 2014).

More severe weather will not only create social and economic adversity, it will have knock-on effects in terms of greater insurance premiums and more stringent or changed requirements for buildings, energy efficiency, the use of renewable energy, further or new restrictions on access to and use of chemicals harmful to humans, biodiversity, or the climate. This could loop back to restrict access and operational capability of military forces to finance, facilities, and essential resources such as specific chemicals.

Another financial impost may be liability for carbon taxes or carbon emissions – both directly as an organization and indirectly through increased cost transfers from industry to military forces. This may manifest in higher initial costs, increased legal liabilities and higher maintenance, and disposal costs. For example, in 2012/2013 the carbon tax liability of the Australian military was around A$80 million, which was not included in budget estimates and as a consequence was unfunded (Thomas 2012).

Military Implications and Risks

Internal Australian military analysis and broader analysis of available literature reveal four broad risks for the Australian military. These are (1) increased international, regional, national, and human security risks, (2) degraded homeland infrastructure, (3) altered environmental operating conditions, and (4) business continuity risks.

Firstly, climate change is set to have major geostrategic implications that will affect global, regional, national, and human security. The 2014 US Quadrennial Defense Review (USDOD 2014) stated climate change "will devastate homes, land and infrastructure," exacerbate water scarcity, jeopardize food security, increase resource competition, and place stress on economics, societies, and governance institutions around the world. This Review reflected earlier US national security assessments by reiterating that climate change will act as a "threat multiplier," thereby "increasing the frequency, scale and complexity of future [Defense] missions." The IPCC Fifth Assessment Report (AR5 Working Group II 2014) also identified a number of geopolitical and human security risks due to climate change including new contestations over territory on land and sea, threats to territorial integrity, and the very viability of states.

The IPCC report also noted that "there is justifiable common concern that climate change . . . increases the risk of armed conflict in certain circumstances" and that "human security will be progressively threatened as the climate changes." Indeed, climate change is provoking an upsurge in the intensity and frequency of natural disasters including floods, wildfires, cyclones, droughts, and extreme weather events.

Data from the Centre for Research on the Epidemiology of Disasters (CRED) shows an unprecedented growth in natural disasters since 1900 and their attribution to climate-related events (Fig. 1) (CRED 2012). Total global natural disasters in 2011, for example, killed around 31,000 people, generated a further 245 million victims, and resulted in economic losses of US$366 billion (Guha-Sapir et al. 2012). Most of the damage caused by natural disasters consistently occurs

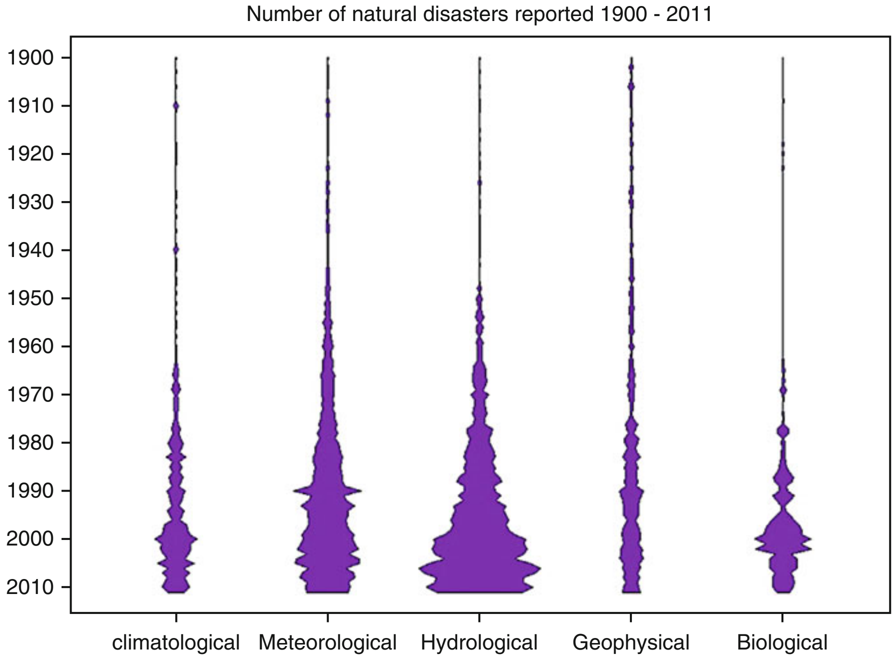

Fig. 1 Number of natural disasters reported by category 1900–2011. Note the increase in climate-related natural disasters (climatological, meteorological, and hydrological) (Source: CRED)

in the Asia-Pacific region. In the same year, Asia accounted for 44 % of global disasters which equated to 86 % of victims and 75 % of the damage (CRED 2012). Civilian authorities (at domestic and international levels) now regularly expect (and demand) military capabilities in order to cope with the increasing scale of natural disaster effects.

Even as a developed nation, Australian people are vulnerable to climate change. Major climate-related events in recent years have seen large-scale deployments of Australian military forces to restore services, repair infrastructure, administer aid and medical provisions, as well as conduct low-level security tasks. Recent Australian military support to the 2009 Victorian bushfires, Queensland floods, and Cyclone Yasi in 2011 saw substantial military contributions to response and recovery.

During the Operation Flood Assist in Queensland, some 1,500 military personnel were deployed to 58 townships across 21 municipalities from Townsville to Toowoomba (Department of Defence 2011). No longer is the summer break considered a "stand-down" period of rest and relaxation – rather it has become part of the Australian defense operational rhythm. In 2011 the Headquarters Joint Operations Command issued a standing order requiring particular defense force units to be ready at short notice over Australian summers in the event of a troika of natural disasters including floods, fires, and cyclones. Almost unwittingly, climate change is now influencing Australian military force generation.

The second implication of climate change on the ADF concerns the degradation of its homeland strategic infrastructure. Rising sea levels, as an example, are set to pose significant risks for a number of military bases located at or near sea level. The damage caused by a combination of sea-level rise, storm surge, and river flooding may, however, extend far beyond maritime infrastructure. Impacts could include degradation of military buildings via inundation, coastal erosion, or direct wave action; degradation of roads on military land via coastal erosion from inundation, restricting base access and capability or damaging road surfaces and foundations; degradation of airstrips via inundation, restricting base access or damaging runway, taxiway, and flight apron surfaces and foundations; and degradation of military pier and marine infrastructure via inundation or wave damage, restricting base access, safe use, or capability.

Other impacts include damage to environmental assets via inundation or wave damage leading to degradation of important flora and fauna habitat, changes to the nature of contaminated land or failure of storage facilities, and environmental pollution; degradation of heritage sites via inundation or wave damage leading to damage to built or cultural sites of significance; degradation of training areas and ranges leading to reduced preparedness; degradation of communications, explosive ordnance testing, logistics, and storage sites; and increased risk of large-scale fires on military training grounds due to lengthening fire seasons and reduced precipitation causing a "drying out" of critical areas.

The costs of relocation or adaptation measures for military bases are not insignificant. A proposed relocation of Fleet Base East from Sydney Harbour 200 km south to Jervis Bay in the 1980s was estimated at over A$2 billion (2011 prices) (Thomas 2012).

Arguably, such risks are already eventuating and being experienced by the Australian military. In October 2013, around 50,000 ha was burnt out and three homes destroyed during the State Mine fires which began during a military training activity at the Marangaroo training area. As noted by the Australian Climate Council in its 2014 report, the Angry Summer, the Australian fire season, is increasing in duration – starting earlier and ending later – with the added threat that "climate change is [now] driving an increase in the risk of bushfires" and is concomitantly "increasing the intensity and frequency of [such] extreme weather events."

The Australian military must adapt to this increased risk, for example, by enforcing stricter risk assessments during training activities. Likewise, the military will need to enhance the resilience of its infrastructure to withstand extreme fire events and perhaps to develop the capability to respond to such events in case civilian fire services are overwhelmed. This latter point raises an important facet of how climate change will have second-order impacts on the Australian military by degrading broader national infrastructure that is crucial to supporting operations and business continuity (Thomas 2014).

A 2011 report Climate Change Risks to Coastal Buildings and Infrastructure (Department of Climate Change and Energy Efficiency 2011) concluded that A $226 billion in commercial, industrial, road, rail, and residential assets are potentially exposed to sea-level rise. Included in this assessment were many facilities and services that support defense activities including 258 police, fire, and ambulance stations, five power stations, 75 hospitals and health services, 41 landfill sites, three water treatment plants, and 11 emergency services facilities. Suffice to say, climate change has second-order impacts on Australian infrastructure that if degraded might significantly disable elements of the Australian military or, as a minimum, its ability to respond to either warlike or natural disaster situations.

The third area of impact on the Australian military is that climate change will alter the fundamental environmental conditions in which the military will raise, train, sustain, and operate. Examples include rising sea levels; increasing ocean acidification; increasing ocean and atmospheric temperatures; changes to rainfall patterns; increasing intensification of extreme weather events; increasing rates of glacial, polar, and permafrost melting; and broader spread of disease.

Arguably, the greatest long-term risk (30–50 years) is the risk of sea-level rise. More immediate, however, is the increased risk of extreme weather and hotter temperatures. Increases in temperature, for example, may change how forces train, particularly as extreme temperatures become the norm rather than the exception. Australia's lead scientific research organization the CSIRO, for example, predicts that under the IPCC business-as-usual scenario, Darwin (home to a significant proportion of Australia's military ground forces and visiting military forces) will experience more than three times the number of extreme temperature days (above 35 °C) by 2030 (Cleugh et al. 2013).

Increases in ocean acidification may also lead to maritime vessels requiring more frequent maintenance regimes. Changes to ocean buoyancy due to lower densities from ice melt may affect submarine operations. Extreme weather events are also likely to see a larger portion of the Australian military's operational duties committed to humanitarian assistance and disaster relief.

Finally, there is the impact that climate change will have on business continuity. This is a broad-ranging concept that includes regulatory impacts, research and development opportunities, personnel, and recruitment.

Military Responses

From this suite of risks, three response or action areas were identified. These are (1) preparing for changes in mission profiles or military tasking; (2) adapting to changes in operating conditions, risks, and costs; and (3) building infrastructure resilience and energy sustainability.

Changes in Mission Profiles

Changes in military tasking are likely in the next 10–30 years as climate and other global change impacts intensify and interact. Military organizations often play a central role in risk mitigation and as responders in the case of natural disasters, pandemics, and humanitarian catastrophes. Militaries also often play central roles in reconstruction activities and may, in extremis, be required to help restore law and order and contribute to stabilization and resource protection activities in the case of national, regional, or global crises.

There is an expectation – and emerging evidence – of greater demand for humanitarian assistance and disaster relief (Campbell 2013). Militaries are also likely to experience greater deployment to peacekeeping missions, support to the civil community, border protection, and support to civil authorities in emergencies.

New roles for the military could well include providing support to research, trials, and deployment of geo-engineering activities as well as protection to civilian geo-engineering actions. Military interdiction of unauthorized geo-engineering activities is equally, if not more, likely. Given military observation capabilities, an even more likely role for military forces will be monitoring geo-engineering research and trials and environmental conditions to ensure that any geo-engineering activities are detected and the impacts recorded for military and civilian analysis. Such monitoring would need to be done in cooperation with other government agencies, research communities, and international organizations.

Military organizations could also be tasked to monitor potential geo-weaponeering developments, including technologies, tactics, trials and simulations, strategy, and planning. A New Zealand Defence Force study also pointed to new or intensified activities such as persistent border surveillance against illegal resource extraction, for example, fishing or mass people movement. This could be done nationally, for and with neighboring countries without the necessary assets, or in a regional partnership (Boxall 2012).

Given that the polar regions are changing far more quickly than scientists expected and much faster than many other regions (IPCC AR5 WGI 2013), there is increasing activity and interest in both the Arctic and the Antarctic, for shipping, biological and other resource extraction, surveying, and research. Parts of Tasmania, New Zealand, the Antarctic, and Southern Ocean provide near-ideal conditions for climate remediation activities such as stratospheric sulfate seeding and ocean iron seeding (Karoly 2012). Construction of research centers in the Antarctic, resource surveying, mapping, and other research are expanding with many countries using their military assets to undertake these operations (ASPI 2013).

More countries are joining the Antarctic Treaty as well. While there is currently a moratorium on the exploration and exploitation of Antarctic mineral resources (the Madrid Protocol 1991), this expires in 2041. In any case, it is currently uneconomic to extract land or seabed-based minerals. This may, however, change in the coming decades if the globe continues to warm and the human world becomes more resource hungry (ASPI 2013). Antarctic Treaty member countries therefore may increasingly deploy military assets to support their strategic, research, and economic interests in the southern polar region.

Similarly, as the Arctic Circle continues to lose ice mass and with projections of a summer ice-free Arctic before 2050 and very likely earlier (Overland and Wang 2013), countries with interests in the Arctic are tasking their militaries with exercises, research, and exploration in the northern polar region. Tensions are surfacing over shipping routes and rights of passage through specific waterways that some countries argue are sovereign and others view as international shipping lanes. There are also increasing interest and activity in Arctic hydrocarbon fields, exacerbating tensions between Arctic Council member countries (Masters 2013).

Expansions in space-based surveillance, communications, and in the future possibly energy generation, industrial manufacturing, and climate remediation are also likely to provide new tasking for military organizations. These kinds of activities are likely to mean military organizations will need to cooperate more and more closely with other government agencies and commercial entities.

Changes in Operating Conditions, Risks, and Costs

This likely increased demand for military operations other than war, including HADR, comes at a time when many governments are reducing spending on military forces (Perlo-Freeman and Solmirano 2014). Increasingly constrained defense budgets means that many military forces will need to rethink how they conduct military operations and how they maintain military capabilities, both human and technological.

Changes in operating conditions, such as severe weather and changing patterns of diseases, are likely to pose greater risks and increase the costs for military forces in terms of damage to infrastructure, bases, and equipment and harm to personnel and their families.

Infrastructure Resilience and Energy Sustainability

Reducing demand, increasing efficiency of energy use, hardening infrastructure, and increasing energy self-sufficiency through the use of alternatives and renewables can enhance national security and military operational effectiveness. It thus makes sense environmentally, operationally, and financially, though there are challenges. Alternatives include synthetic fuels, gas to liquid and coal to liquid and renewable energy derived from solar, wind, biomass, and geothermal energy, waste to energy, hydrokinetic and ocean energy, and fuel cells.

Another way to increase energy sustainability is to take an integrated systems approach, one that encompasses activities and issues across the military rather than leaving energy issues to each service or part of the organization. This could reduce cost pressures by lowering energy demand, enhancing supply chain reliability, and increasing energy efficiency. Military energy requirements, both physical and strategic, could also be situated within broader government and industry energy contexts, enabling systems-level linkages to broader policies and also other military energy strategies. Australian, the US, the UK, and many NATO militaries, for example, have developed or are developing comprehensive energy frameworks or strategies to maximize operational energy effectiveness and minimize demand and energy costs across the board.

Assuming this is the "critical decade" (i.e., that decisions made between now and 2020 will determine the severity of climate change over the next 50–100 years), military forces – like other organizations – need to start making some hard decisions that balance current costs against future well-being. Taking such an approach will also have consequences for future military planning and acquisitions, particularly if it is accepted that the range of technologies available now are the tools to be used for adapting to, and mitigating, climate change.

General Military Capacity to Engage in Climate Adaptation

Militaries generally have much of the capability and competence required to address climate change impacts but can benefit from more collaboration internally and by reaching out to expertise and experience elsewhere – such as gaining insights from other militaries, government agencies, scientists, and other subject matter experts.

There are three broad categories of military capacity that could, in combination, be applied to climate adaptation: institutional, organizational, and individual.

In an institutional sense, governments and military leaders can reorientate military forces and expand their *raison d'être* to include addressing climate change – directly and indirectly – directly via explicit inclusion in military strategic objectives of concepts such as collective environmental security, defense of national critical resources, and carbon-neutral operations and indirectly through a greater focus on military operations other than war, especially resilience building, HADR, and aid to civil authorities. This could be promulgated through strategic planning, implementation of operational guidance, joint exercises, war gaming and simulation, future capability planning, and acquisitions.

Organizationally, military forces can consider how missions are achieved including mobilization, deployment, sustainment, and recovery/return. Focus issues include: How are power and energy thought about and managed? Are there carbon and cost savings to be had by changing practices and attitudes toward liquid fuels and fixed power?

Understanding adaptation approaches, particularly methods for analyzing the likely impacts on military capability, personnel, and budget, can be incorporated into organizational structures and processes, for example, by requiring that military groups and agencies take climate change issues into account in planning and other activities. Military research can also inform other national and local decision-making process. Adaptation responses for military bases often have impacts for local infrastructure such as changed drainage patterns and do not present cost-effective options in isolation requiring planning to be conducted collaboratively.

Another organizational response is the appointment of a high-ranking military officer to be an advocate and focal point for climate change and related issues, including coordination of effort across the military and between the military, government, and broader society. This may require a small, dedicated specialist team to coordinate analyses of change impacts, military operational and estate vulnerability assessments, and strategic response planning across the organization.

Military organizations can also support action at the individual level of defense personnel and their families. Militaries can be viewed as human activity systems, wherein the individuals in the system have some influence over the behavior of the system as a whole. This military system interacts with other systems – or, in this context, communities. The individuals within the military system can choose to change their personal habits and, by demonstration or advocacy, encourage change in others, for example, by taking "green days" and/or by cycling, walking, car-pooling, or taking public transport to work whenever possible. Low-carbon commuting can be encouraged by individuals or units setting up a "green miles" club or competition.

Governments and military organizations can, for example, support cycling schemes through tax rebates, subsidized prices, or providing a pool of bicycles as well as infrastructure such as bike lockers, shower and change facilities, and bicycle paths or lanes on roads and tracks. Support for public transport can include provision of tickets or transport and lobbying governments to provide public transport and bus stops. Car-pooling can be encouraged through privileged parking and reductions in parking fees.

Best Practices

Military organizations are developing best practice approaches to deal with climate change adaptation. These include adopting strategy development principles that support a coherent approach to climate change adaptation.

To achieve best practice adaptation, current military experience shows that there is a need to develop a coherent climate change adaption strategy that is phased by decade and synchronized with capability acquisition; it is necessary to collaborate more internally to enable a coherent and coordinated whole-of-organization approach to climate change adaptation and to increase energy efficiency, reduce demand, and consider alternatives to fossil fuels wherever possible.

This includes the use of reusable rather than disposable equipment, for example, utensils and water bottles; developing public private partnerships, for example, the Carnegie wave energy trial at HMAS Stirling Naval Base in Western Australia; and renewable energy, for example, powering forward bases via energy from waste. These kinds of activities will have the added benefit of reducing the bulk and cost of supply chains and protective details for liquid fuel convoys.

Larger militaries with alliances requiring interoperability can use this need to encourage and support allied militaries to use blended fuels or other lower-carbon alternatives. Militaries of medium to large size can contribute to adaptation by building future resilience into reconstruction, peacekeeping, and disaster relief efforts.

Likewise, military forces can use exercises to practice HADR, cooperate with nongovernment organizations and other government agencies, and enhance the skills and reputation of military forces by delivering aid and support to communities. For example, New Zealand has undertaken a very successful series of exercises, called Operation Twilight, in the South West Pacific along these lines (Boxall 2012).

Further research and investigation by military forces will help to determine, quantify, and cost impacts on them and enable the development of strategies and actions to adapt better to climate change and support their countries to do so as well. Some issues that ought to be considered are:

More research could be conducted on the impacts on service life of hardware and impacts of atmospheric and marine environment changes on observation and communication technologies, optimizing effectiveness and minimizing energy expenditure through a balance of live exercises, training, and simulation. In the same vein, research could be conducted on changing technical specifications, for example, for military-specific fuels, to accommodate new power and energy technologies and alternative fuels. This would include certification of new fuels, oils, and lubricants.

Military organizations could, on their own or in collaboration with commercial providers, conduct trials of alternative energy generation such as wave power and biogas from waste. This would include ensuring that any alternatives meet military specifications for current and future assets. Another key area is energy efficiency research, for example, into reducing surface ship fuel use through design changes and bio-repellent hull coatings and changing the energy generation mix on board to ensure least use and highest benefit from fossil fuels and other high-polluting inputs.

Military assets, such as hydrographic research and mapping facilities, could be used to contribute to data collection and understanding of oceanic and other climate change impacts. These are suggested contributions and support that military forces can make to climate change adaptation and are not meant to be definitive. There would be many other ways in which military forces can demonstrate best practice and support to climate change adaptation.

Conclusion

As demonstrated in this chapter, climate change adaptation is a significant issue for military organizations. They are regularly involved as responders to natural disasters and often play a central role in reconstruction. Climate change impacts on the military include potential changes in mission profiles, increased costs, more humanitarian and disaster relief operations, and changes to their power and energy arrangements for cost, carbon reduction, and operational reasons.

Many military organizations will be pivotal in climate adaptation and response. One way to contextualize climate change impacts into military organizations is via the construct of Strategic Military Geography (SMG). This is a three-dimensional decision framework, underpinned by the systemic action research methodology which integrates systems thinking, participatory action research, and triple-loop learning.

Military issues, especially those with global drivers and connections to other issues – such as climate change and energy – can be teased out through the SMG framework, enabling identification of key implications and how they relate to each other as well as impact on military operations and organizations. This provides a richer picture of issues and their context, which in turn means that organizational impact analysis will be more comprehensive and decision-making can be more keenly focused with better results and fewer unintended consequences now and in the future.

Thus the SMG Framework supports system-wide long-term planning, fosters greater dialogue between critical stakeholders, and enables transfer of learning between militaries and other organizations.

Roles for military organizations in climate change adaptation include building resilience within themselves and their communities, hardening infrastructure to ensure continued operations when required, and providing technological and other leadership in seeking out or developing cost-effective adaptation measures.

project developments consider climate risk and incorporate adaptation measures in their design. This is particularly important in relation to utilities, infrastructure, and the extractives sector (i.e., mining and oil and gas activities). Furthermore, building resilience to climate change and incorporating adaptation measures into project design, as well as impact management programs – such as Environmental and Social Impact Assessments (ESIAs) –, is now being mandated by a growing number of financial institutions, as well as national and state governments.

Climate change also presents a new dimension to the traditional impact assessment conceptual framework in that it implies a dynamic rather than static baseline from which project impacts occur. This means that climate change, occurring irrespective of the project, may have the effect of altering the overall significance or magnitude of project impacts on the human and natural environment.

This chapter outlines these requirements at a high level and discusses integration of climate risk and adaptation into the capital project development life cycle through compliance with lender requirements, Environmental and Social Impact Assessment procedures, and internal risk management processes. It also presents a simple step-by-step approach to streamlining assessment within the project development process.

Keywords

International finance institutions • IFI • Environmental and social impact assessment • ESIA • Climate change • Business risk • Adaptation • Risk management

Introduction

Climate change is already presenting material risks and opportunities to business and industrial sectors. As extreme weather events appear to become more frequent with climate change, these risks and opportunities have grown in prominence and, for a growing number of companies, have become closely aligned with project performance.

Understanding and managing climate risk and adaptation, at a facility or project level, is central to ensuring business continuity and reducing costs. Key to enhancing the resilience of future economic stability and growth is to ensure that new project developments consider climate risk and incorporate adaptation measures in their design. This is particularly important in relation to utilities, infrastructure, and the extractives sector (i.e., mining and oil and gas activities).

Climate resilience and mitigation actions should be firmly on the agenda, particularly for major new infrastructure that can benefit from climate risk, impact, mitigation, and adaptation insights throughout its lifetime.

Furthermore, building resilience to climate change and incorporating adaptation measures into project design, as well as impact management programs – such as Environmental and Social Impact Assessments (ESIAs) – is now being mandated by a growing number of financial institutions, as well as national and state governments. At the forefront of this effort is the International Finance Corporation (IFC) of the

World Bank Group, which revised its *Performance Standards on Environmental and Social Sustainability* in January 2012. The Performance Standards (PS) now recommend the consideration of "relevant risks associated with a changing climate and the adaptation opportunities" associated with these risks (IFC PS1 2012) and identify the need to consider the impact of climate change on community risk and vulnerability as well as on ecosystem services and natural habitats, especially where they play a role in mitigating climate risk. These revised standards have since also been formally adopted by the Equator Principles Association, which provides a risk management framework for financial institutions in relation to determining, assessing, and managing environmental and social risk.

In addition to legislative and lender requirements, companies have internal processes aimed at managing risk through the project development cycle. Engineers routinely factor weather-related meteorological information into project design (e.g., operating envelopes, production schedules), but the extent to which this includes possible variations due to climate change is typically limited.

There are a number of complementary reasons why organizations undertake structured analysis of climate change impacts and adaptation within their capital project development proposals. A climate change risk and adaptation study can:

- **Ensure identification and management of all project impacts, in light of changing baseline vulnerability of the receiving environment**: Climate change not only poses risks to project infrastructure and operations but may also alter the sensitivity profile of both human and natural receptors to project impacts, resulting in potential increased significance and magnitude rankings for some impacts. If these issues are not explicitly evaluated, the project may result in unmitigated and unmanaged impacts to surrounding communities and natural environment, with potential regulatory, operational, and reputational implications for the project developer.
- **Help identify key vulnerabilities of the project to climate impacts and provide opportunities for adaptation/risk mitigation through design/operational measures:** Analysis and review of risks in the early design stages of a project will provide scope to identify risk mitigation (adaptation) actions that are integral to the project rather than "bolt-on," thus potentially reducing both the costs of belated remediation and the probability of costly impacts due to lack of project design resilience.
- **Demonstrate compliance with lender/donor requirements:** As mentioned above, international financing institutions are increasingly extending the scope of their requirements with respect to climate resilience and greenhouse gas mitigation.
- **Demonstrate compliance with emerging national regulatory requirements:** Some national and state governments are starting to formally require that the effects of climate change be considered in project ESIAs and associated studies submitted for regulatory approval. For example, governments in Australia, Canada, and the Netherlands are beginning to implement legal frameworks for incorporation of climate change within the ESIA process (Agrawala et al. 2010).

- **Identify the developer as forward-looking and responsible:** Well-designed and de-risked development solutions make good business sense over the lifetime of the project and create a positive reputation for those responsible.

This chapter outlines these requirements at a high level and discusses integration of climate risk and adaptation into the capital project development life cycle through compliance with lender requirements, Environmental and Social Impact Assessment procedures, and internal risk management processes. It also presents a high-level approach to streamlining assessment within the project development process.

Climate Risk and Adaptation in Project Finance Requirements

International Finance Corporation Performance Standards

The IFC, a member of the World Bank Group, provides financial services and investment in support of development in developing countries. Since many developing countries do not have stringent environmental and social legislation, the IFC has developed policies and standards against which investments are assessed to ensure that projects effectively address environmental and social issues.

The IFC adopted a sustainability framework in 2006 which sets out its strategic commitment to sustainable development and risk management. This was subsequently reviewed and the latest revised version came into effect in January 2012 (IFC 2012).

Included in this framework are eight performance standards (PS) against which a number of environmental and social sustainability risks and impacts of IFC funded projects are assessed. Recognizing the changing global risk landscape associated with climate change, the revised performance standards explicitly include the requirement to consider "relevant risks associated with a changing climate and the adaptation opportunities" associated with these risks (IFC 2012) and identify the need to consider the impact of climate change on community risk and vulnerability as well as on ecosystem services and natural habitats, especially where they play a role in mitigating climate risk.

The specific climate change-related requirements are summarized in Box 1. Note that since PS 3 relates exclusively to mitigating greenhouse gas emissions, the conditions have not been considered further in this chapter.

PS 1 is an overarching standard which mandates the need to consider climate risk within the project development process. The accompanying guidance note emphasizes that "a project's vulnerability to climate change and its potential to increase the vulnerability of ecosystems and communities to climate change should dictate the extent of climate change considerations in the risks and impacts identification process" (IFC 2012). Proportional to that vulnerability profile, the project should "(i) identify potential direct and indirect climate-related adverse effects that may affect the project during its life-cycle, (ii) identify potential direct and indirect climate-related adverse effects that may be exacerbated by the project, and (iii) define monitoring programs and mitigation and adaptation measures, as appropriate" (IFC 2012).

Box 1 (IFC) PS Climate Change Requirements

IFC PS 1

The risks and impact identification process will consider the emissions of greenhouse gases, the relevant risks associated with a changing climate and the adaptation opportunities, and potential trans-boundary effects, such as pollution of air or use or pollution of international waterways (IFC 2012).

IFC PS 3 Requires

- Measures for improving efficiency in consumption of energy, water, as well as other resources and material inputs
- Options to reduce project-related greenhouse gas emissions during the design and operation of the project
- For projects > 25,000tCO_2e/year quantification of direct greenhouse gas emissions within the physical project boundary and indirect emissions associated with off-site production of energy (i.e., purchased electricity)

IFC PS 4 Requires

- Projects must take into account the fact that communities that are already subjected to impacts from climate change may also experience an acceleration and/or intensification of impacts from project activities, since climate change effects may exacerbate their vulnerability.
- Projects must identify and mitigate risks and potential impacts on priority ecosystem services that may be exacerbated by climate change.

IFC PS 6 Requires

Determination of critical habitat should consider sites of demonstrated importance to climate change adaptation for either species or ecosystems.

PS 4 recognizes that project activities, equipment, and infrastructure can increase community exposure to health and safety risks and impacts, particularly for vulnerable groups, and requires that "communities that are already subjected to impacts from climate change may also experience an acceleration and/or intensification of impacts due to project activities" (IFC 2012). The standard further requires identification of "risks and potential impacts on priority ecosystem services that may be exacerbated by climate change" (IFC 2012).

The guidance notes accompanying PS 6 on Biodiversity Conservation and Sustainable Management of Living Natural Resources note that determination of areas of critical habitat should consider "ecosystems of known special significance to endangered or critically endangered species for climate adaptation purposes" (IFC 2012) as well as "sites of demonstrated importance to climate change adaptation for either species or ecosystems" (IFC 2012). Selection of mitigation measures should furthermore take into consideration "existing non-project related threats to biodiversity values," which include, among other threats, climate change (Farell et al. 2013).

Equator Principles

The Equator Principles (EP) represent the best available risk management framework for commercial financing institutions in relation to determining, assessing, and managing environmental and social risk. At the time of writing, 78 financial institutions in 35 countries have signed up to the EP, covering over 70 % of international project finance debt in emerging markets (EP 2013).

Member institutions commit to implementing the principles within their project financing policies and procedures on environmental and social issues. They will not provide project finance or corporate loans (on arrangements exceeding US$10 million) to organizations which are unable to comply with the EP (EP 2013).

For projects in "non-designated countries," i.e., those judged not to have sufficiently robust national environmental impact legislation, the assessment process must be in compliance with the IFC performance standards and environmental, health, and safety guidelines. Of the 31 designated countries, 21 are members of the European Union and the others are all industrialized countries.

The third version of the EP published in June 2013 lists "viability of Project operations in view of reasonably foreseeable changing weather patterns/climatic conditions, together with adaptation opportunities" as a potential issue to be addressed in the ESIA (EP III 2013).

Many of the environmental elements of the PS and EP are considered during the ESIA process and an example of how this is achieved is provided in the section below.

Climate Risk and Adaptation in Environmental and Social Impact Assessments

The International Association for Impact Assessment (IAIA) defines an Environmental [and Social] Impact Assessment as: "The process of identifying, predicting, evaluating and mitigating the biophysical, social, and other relevant effects of development proposals prior to major decisions being taken and commitments made" (IAIA 1999).

The objectives of ESIA are:

- To ensure that environmental considerations are explicitly addressed and incorporated into the development decision making process;
- To anticipate and avoid, minimize or offset the adverse significant biophysical, social and other relevant effects of development proposals;
- To protect the productivity and capacity of natural systems and the ecological processes which maintain their functions; and
- To promote development that is sustainable and optimizes resource use and management opportunities. (IAIA 1999)

Fig. 1 The evolution of integrating climate change adaptation within ESIA (Agrawala et al. 2010)

Since most major capital project developments are required to undertake an ESIA, it makes sense to integrate climate change within this assessment. A 2010 study by the OECD indicates that a number of countries and multilateral organizations had begun working on incorporating climate change within the framework of environmental or Environmental and Social Impact Assessments (EIA/ESIAs) (Agrawala et al. 2010). Interestingly, more developing than developed countries had begun exploring options and developing guidance – predominantly small island developing nations and countries in the Caribbean (see Fig. 1). This is likely to be due to the significant projected impact of climate change on these nations in the future.

In the years since this study, the IFC has produced guidelines as discussed above and the European Union has issued detailed guidance (although not binding) on integrating climate change and biodiversity into EIA pursuant to the 2011 EIA Directive 2011/92/EU (EU 2013).

There are a number of entry points for incorporating climate change in the strategic phase preceding the initiation of the EIA/ESIA to the scoping, detailed assessment, and implementation stages. Figure 2 outlines how a climate risk and adaptation assessment could be included in the ESIA assessment process and asks key questions which can help focus the work.

An example of consideration of climate change during the ESIA process is the case of a proposed mine in the Northern Cape province of South Africa (confidential project). The area is hot and arid with rainfall occurring in infrequent intense thunderstorms. Climate change is likely to lead to hotter weather and less rainfall, exacerbating problems in an already water-stressed area. Specialists conducting studies during the ESIA process were provided with climate change projections in order to include changes in baseline meteorological data in their modeling to understand the impacts on surface water flow and groundwater recharge. This information allowed the design engineers to ensure the site selection and location of key

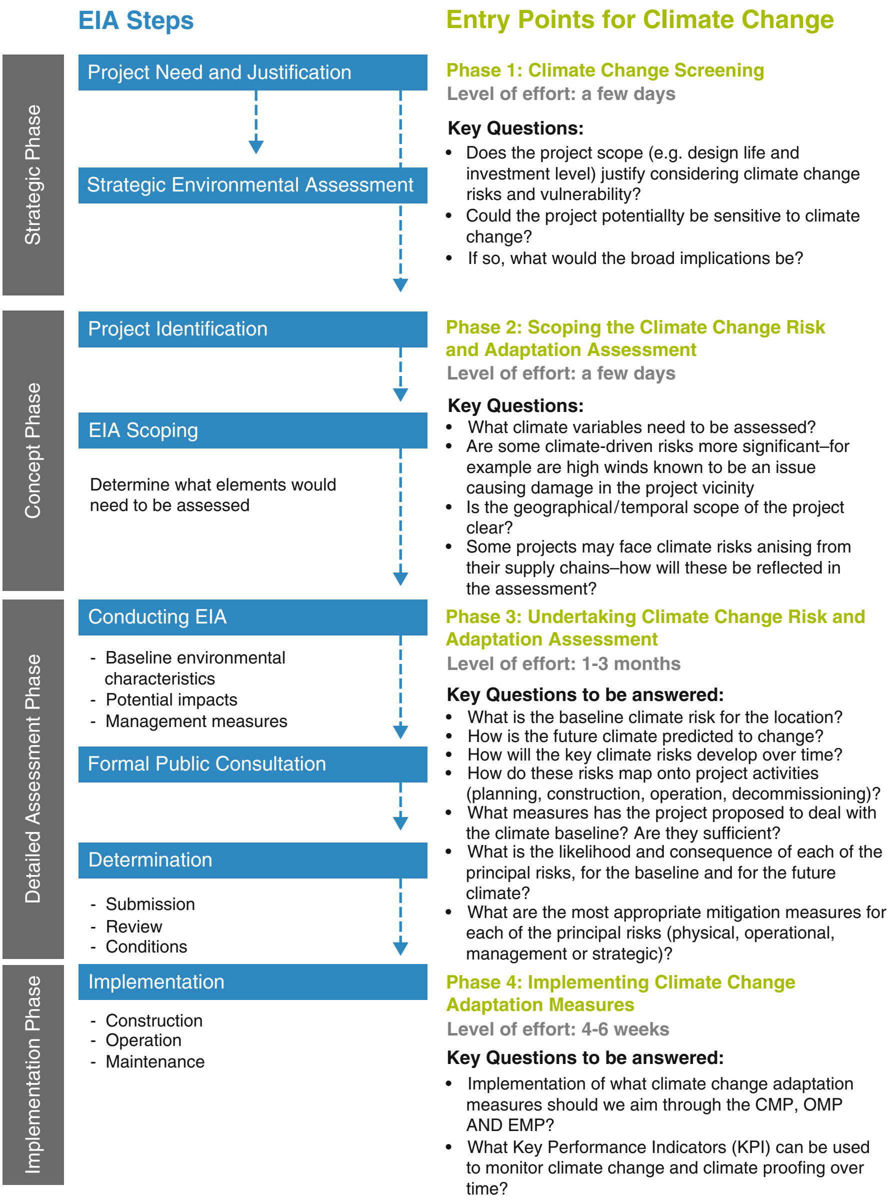

Fig. 2 Entry points for climate change risk and adaptation within the ESIA process (Adapted from Agrawala et al. (2010))

infrastructure was designed to withstand the magnitude of future events rather than only those experienced in the past. The potential impact of reduced water availability on local communities and agricultural activities was also investigated to ensure that the mitigation measures (climate change adaptation measures) identified during the

ESIA process would be relevant in the long term with a changing climate and could help ensure the sustainability of the project and surrounding community.

Integrated Climate Risk Management

Most, if not all, companies have some sort of risk management procedure which allows them to identify, analyze, evaluate, and treat business risks which arise during project development or operation.

The International Standards Organization (ISO) has developed a standard for integrating risk management practices within organizations (ISO 2009). The aim is to provide principles and generic guidelines on risk management to apply the procedures to existing management systems rather than to replace them. The standard provides a framework for integrated risk management and advice for risk identification, analysis, evaluation, and treatment.

Consideration of climate risks within a standard risk management approach can sometimes go a long way to managing the impact of climate change on the organization in a manner which does not require new systems or approaches.

Figure 3 illustrates how assessment of climate change risk and adaptation could be embedded within the integrated risk management framework outlined in ISO 31000. This process is explained in more detail below.

Many organizations will already be managing risks from extreme weather events and assessment of how climate change might amplify these risks simply requires addition of the increase/decrease expected in the future based on climate change projections.

Quantitative assessments focus on assessing risks that arise from an increasing frequency and severity of extreme weather events using likelihood/consequence based on traditional risk management approaches. Baseline or existing risks are assessed according to the method outlined in Fig. 4.

Once the baseline risk has been identified, frequency and severity parameters can be modified based on values that come from climate change projections as illustrated in Fig. 5.

The approach outlined above has been piloted through the development of guidance for integrating analysis of weather and climate risk into the operational risk management procedures of a global mining house (confidential project). By utilizing existing processes, the burden of additional processes/requirements is reduced and the effectiveness of risk management enhanced through ensuring that the amplification of existing risks as a result of climate change is effectively captured in the risk register. For example, fatigue management plans consider the impact of higher temperatures on staff working outside; slope management plans consider the risk of erosion/landslides from more intense rainfall in the future. The result is that the amplification of risks as a result of climate change is automatically considered within the day-to-day management of risks and controls and the likelihood of unanticipated events causing damage or business interruption is reduced.

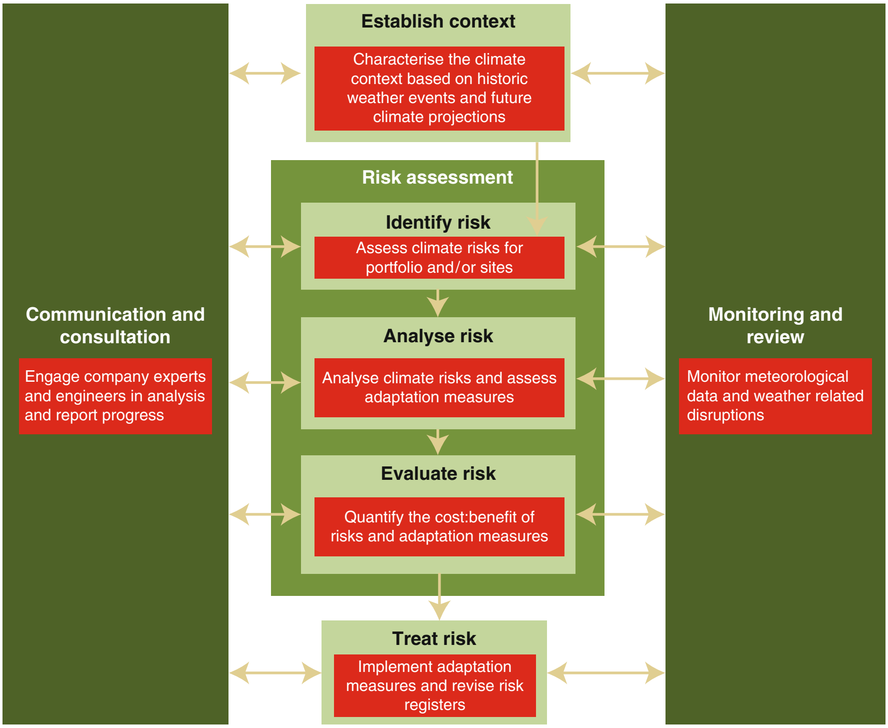

Fig. 3 Embedding climate change assessment within the integrated risk management framework

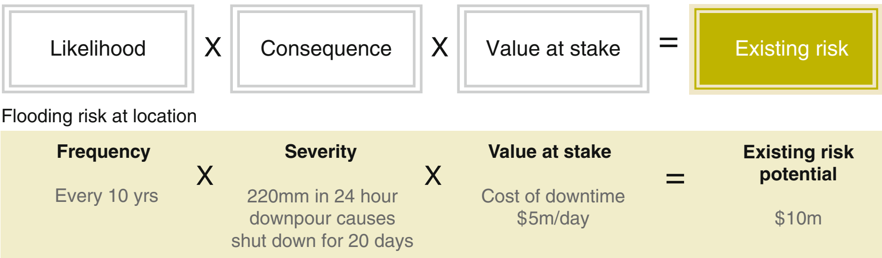

Fig. 4 Assessing baseline risk (Chrysostomidis and Constable 2014)

Streamlining Climate Risk and Adaptation in the Project Development Process

Businesses already have numerous risk management and impact assessment procedures in place, and incorporation of climate change assessment within these processes could help enhance resilience in a more efficient and effective manner than implementing stand-alone procedures in parallel.

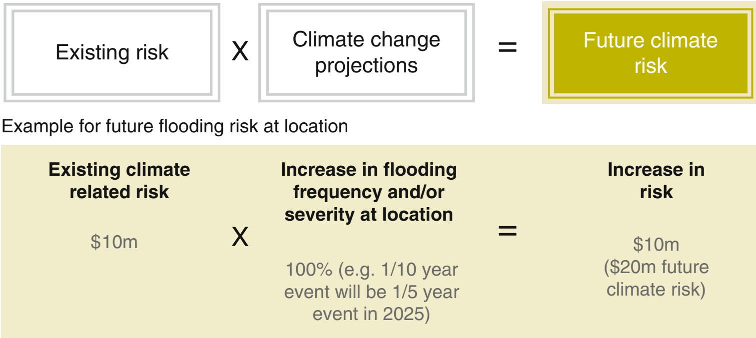

Fig. 5 Estimating future risk (Chrysostomidis and Constable 2014)

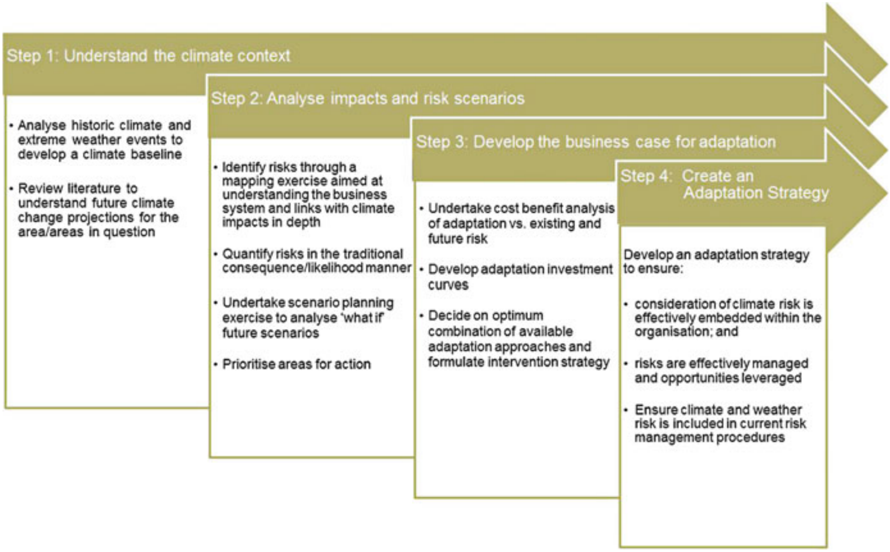

Fig. 6 Overview of climate risk and adaptation assessment process (Chrysostomidis and Constable 2014)

Figure 6 illustrates a simple four-step approach to understanding and managing the risks associated with extreme weather and climate change in a business context. The approach is discussed in detail by Chrysostomidis and Constable (2014) and provides a good starting point, in conjunction with the IFC Performance Standards and associated guidance, for the analysis required to ensure that climate risk is appropriately considered during the capital project development process.

The remainder of this section provides advice on how climate change can be incorporated in the capital project development life cycle through incorporation in ESIA as well as internal project team activities.

Project Team Analysis of Climate Risk and Adaptation in the Project Development Cycle

The approach to assessing climate risks differs depending on the stage of project development. While climate risk and adaptation can be addressed to a certain extent through the ESIA process, it is important that it is also incorporated in the business project approval process (i.e., each decision stage gate in the project development and evaluation process) in order that the risks and opportunities are fully considered through the decision-making stage gates throughout the project life cycle. It is recommended that a designated person act as liaison between the ESIA team and project team to ensure that the necessary information is gathered and incorporated effectively with the project development and evaluation process. This role will be particularly important where climate risks are expected to be the greatest. Figure 7 provides an overview of activities associated with climate risk and adaptation through the project development life cycle, and these are discussed in further detail in the remainder of this section.

Concession, Acquisition

Climate risk should be considered at a high level during due diligence prior to acquisition of a site or concession area. If a company is investigating a range of options in different geographical locations, it may be that the risks from weather at one site, e.g., in an area which is regularly subjected to hurricanes and flooding, outweigh the benefits and that the site (with similar reserves and potential economic return) in a more temperate climate would be preferred.

Exploration

During exploration, the main purpose of considering climate risk is to protect the health and safety of the exploration project team and, if possible, collect baseline climate and weather information.

It is not necessary to undertake a detailed climate risk assessment during the exploration stage, but rather a high-level understanding of where weather events pose risks to activities or people and whether more detailed assessment is warranted.

Phase 1: Identify and Assess Opportunities

During the phase when the technical and economic viability of exploiting the resource is determined, it is important to understand the climate context (current baseline and future projections), within which the proposed project might be developed, and the associated risks for the project. The objective of considering climate risks during this phase is to ensure that climate and weather risks associated with construction, operation, closure, and post closure at that site do not materially impact the viability of the concept. Much of the information required for this assessment could be obtained through the ESIA process.

The activities that could be conducted during this phase include characterizing the climate context for the project, identifying climate risks, identifying key project decisions affected by climate and weather, and identifying further research requirements.

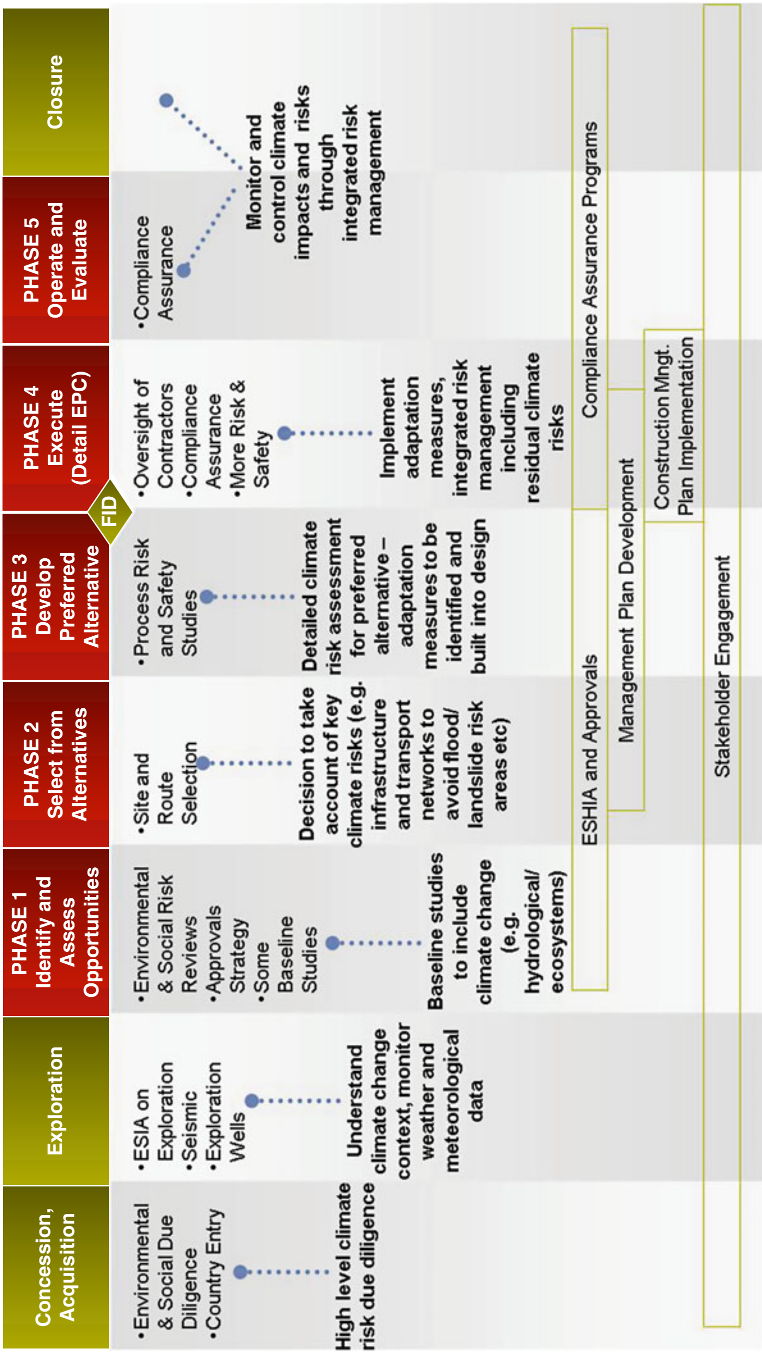

Fig. 7 Overview of climate change activities within the project development cycle

Phase 2: Select from Alternatives

Phase 2 provides the widest scope for the generation, investigation, and elimination of alternatives. At this stage, the purpose of assessing climate risks and adaptation measures is to inform the generation and elimination of project options such that the optimal option (in terms of all technical, commercial, and sustainability aspects, including the climate risk profile) is selected to be put forward for consideration. In addition, adaptation measures to mitigate key risks should be identified for each alternative. Climate risks and opportunities should be assessed at this stage to the greatest possible level of detail for the site as well as the supply chain (based on the information available at that time, much of which could be generated during the ESIA process).

The work undertaken during Phase 1 provides a base upon which to assess risks from extreme weather and climate change in further detail during the option identification and appraisal process in Phase 2.

Phase 3: Develop Preferred Alternative

During Phase 3, the alternatives selected and approved at the end of Phase 2 are refined and finalized to a level of detail and accuracy normally associated with project execution plans.

The purpose of climate risk and adaptation assessment at this stage is to ensure that the "Final Investment Decision" (FID) is based on a design that includes all necessary measures to optimize the climate risk profile of the operation.

Should any new information arise at this stage that raises the climate risk profile of the selected alternative to an unacceptable level, this should be flagged as soon as possible. In this situation, adaptation measures should be identified to bring the climate risk level down to acceptable levels.

Phase 4: Execute and Phase 5: Operate and Evaluate

Once the project design has been finalized and activities turn to construction and operations, the adaptation measures identified need to be implemented and residual risks (i.e., those which cannot be prevented through design such as flooding exceeding thresholds) should be managed through the company's integrated risk management procedures as described above.

It is also important that weather data is monitored on a regular basis and the impact of extreme events tracked in order to feed into risk registers and for additional adaptation measures/controls to be implemented as required during the life of the operations.

Closure

Given the long-term nature of climate change, a company's liability in relation to climate change may continue post closure. For example, in the mining sector an increase in rainfall may threaten the integrity of tailings storage facilities or increase runoff through waste rock leading to contamination of groundwater sources. A hydropower plant may experience generation difficulties during droughts or periods of particularly heavy rainfall.

ESIA Practitioner Guidance for Including Climate Risk and Adaptation in ESIA

Climate change presents a new dimension to the traditional impact assessment conceptual framework in that it implies a dynamic rather than static baseline from which project impacts occur. This means that climate change, occurring irrespective of the project, may have the effect of altering the overall significance or magnitude of project impacts on the human and natural environment. It is critical to capture both elements through the impact assessment and project planning process.

In order to ensure that climate change is effectively incorporated within the capital project impact assessment process, the ESIA project management team should follow the steps below to ensure that the need for and the level of detail required in a climate change risk and adaptation study is carefully considered.

Step 1: Climate Change Vulnerability Screening and Scoping

During the scoping stage, it is important to ascertain the degree to which climate change is a significant consideration in project design and impact assessment. Key questions to answer at this stage are:

- Is the project climate dependent?
- Is the project climate vulnerable?
- Are communities and local ecosystems climate vulnerable?
- Could project impacts exacerbate vulnerabilities?

The project developer, and ESIA team, should consider each of these questions in the context of each phase of the project life cycle, taking into account current climate variability as well as likely future trends in the project's location. "Climate dependency" refers to the degree to which the project requires resources or operating conditions to function which may become more scarce or less predictable because of climate change – for example, reliable freshwater supply (a requirement for most industries), a specific temperature range (such as for agricultural development projects or tourism ventures), a specific sea level (such as for a port), etc. "Climate vulnerability" encompasses the elements of climate dependency but also includes consideration of whether a project's assets or productive capacity may be directly affected by climate related hazards which may become more frequent or intense under future climate scenarios. Such effects may include more frequent or intense floods, hurricane force winds, storm surges, etc.

This will necessarily be a high-level initial assessment but will provide an indication of the potential importance of climate change impacts on the future operations of the project and therefore the level of analysis required during the ESIA process.

The climate change specialist study and ESIA proposal should be drafted based on the findings of these deliberations.

Step 2: Include Climate Change in Specialist Studies

Each project will have its own unique issues relating to the proposed activities, and ESIA specialists are well placed to investigate how climate change might influence the impacts identified during the ESIA process.

While it is possible to conduct a high-level – stand-alone – climate risk and adaptation specialist study, it is recommended that all specialists providing input into the ESIA process are requested to assess the potential impact of climate change on their findings. This will ensure site-specific analysis of the potential impacts to the project, environment, communities, and ecosystem services.

Examples of the types of analysis which could be undertaken include:

- Surface and groundwater hydrology studies to look at how changing precipitation and evaporation might affect stream flow and groundwater recharge
- Biodiversity studies to look at how local ecology and agricultural practices might change with changing temperature and precipitation patterns to feed into decisions on rehabilitation, resettlement, and impacts on local community livelihoods
- Flood risk assessments, including research on the frequency and severity of historical flooding in the area, the influence of topography on flood prone areas within the site, and the projected trends for flood events in light of predicted climate change
- Ecosystem services assessments to consider how the availability and use of services might change in the future and the associated impacts

Where possible, the first phase of the climate risk and adaptation approach outlined in Fig. 8 should be undertaken at the very start of the ESIA in order for the findings to feed into the work of the specialists – i.e., hydrologists will be able to model increase/decrease in precipitation into water balance/stream flow/groundwater assessments.

Step 3: Summarize Climate Change Risks, Vulnerabilities, and Adaptation Measures In Line with IFC Requirements

If the project is required to comply with the IFC Performance Standards or Equator Principles, it is important to ensure that the ESIA covers all of the requirements on climate change risk, impact, and vulnerability included in the 2012 IFC Performance Standards and their accompanying guidance notes.

In this final step, a report should be prepared summarizing the climate change context for the project and collating the information gathered in the specialist

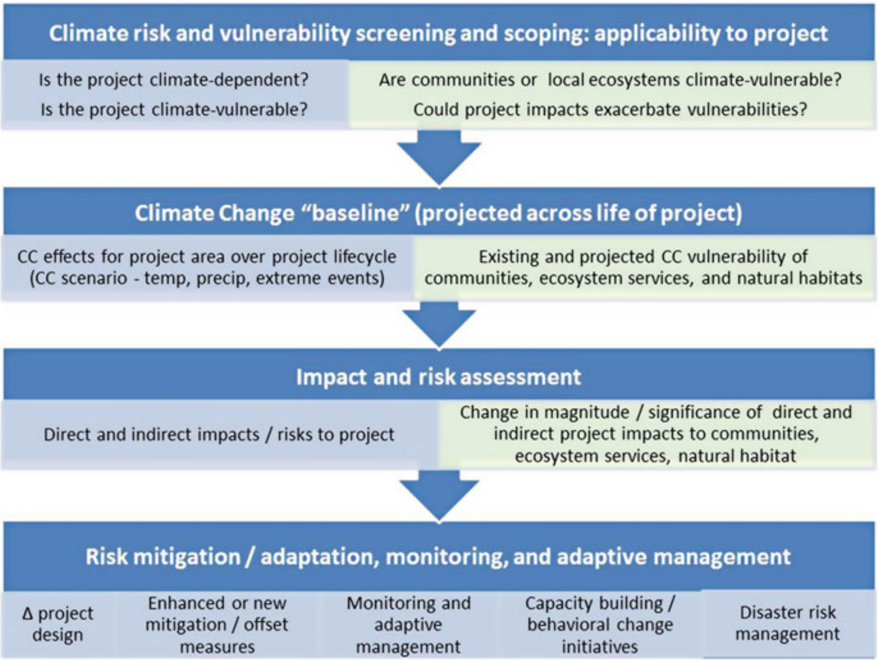

Fig. 8 An approach to incorporating climate risk and adaptation in the ESIA process

studies and any stand-alone analysis required to ensure that the impact of climate change on the project is fully understood and discussed within the ESIA. The report could follow the basic framework outlined in Fig. 8.

Conclusion

As was described in this chapter, understanding and managing climate risk and adaptation, at a facility or project level, is central to ensuring business continuity and reducing costs. This is particularly important in relation to utilities, infrastructure, and the extractives sector (i.e., mining and oil and gas activities). Furthermore, building resilience to climate change and incorporating adaptation measures into project design, as well as impact management programs – such as ESIAs –, is now being mandated by a growing number of financial institutions, as well as national and state governments.

Climate change can also present a new dimension to the traditional impact assessment conceptual framework in that it implies a dynamic rather than static baseline from which project impacts occur. This means that climate change, occurring irrespective of the project, may have the effect of altering the overall significance or magnitude of project impacts on the human and natural environment.

In order to ensure that climate change is effectively incorporated within the capital project impact assessment process, the ESIA management team of the project can follow the steps outlined in this chapter to ensure that the need for and the level of detail required in a climate change risk and adaptation study is carefully considered. Furthermore, incorporation of climate change assessment in the existing risk management and impact assessment procedures could help enhance resilience in a more efficient and effective manner than implementing stand-alone procedures in parallel.

The Role of Climate Services in Adapting to Climate Variability and Change

Paul Bowyer, Guy P. Brasseur, and Daniela Jacob

Contents

Abstract

Adaptation to climate change has risen up the political agenda in recent years, as the realization that we are committed to at least some level of climate change over the next few decades has been acknowledged. It is also the case that a range of different economic sectors, both public and private, increasingly recognize the need for, and importance of, adapting to climate change and the need to manage

their climate risks. Adaptation to climate change is a complex issue, and successful adaptation will depend on the intelligent use and combination of a range of different factors, including scientific, organizational, social, and governance structures. This chapter focuses on the role that climate services can play in helping organizations and societies adapt to climate change and variability. It provides an overview of the key components of climate services and details the essential functions which climate services must develop, in order to fully play their role in supporting adaptation decisions and thus, helping society adapt to climate change.

Keywords

Climate services • Adaptation • Decision support • Risk management • Climate modeling

Introduction

There is an increasing demand from society and governments to have access to information related to weather and climate to assist in the development of adaptation responses to climate risks (Parry et al. 2007; DAS 2008; Cane 2010). This demand places greater importance on the need to support and develop appropriate institutions and resources and has helped spur the development of climate services and climate service centers (Barron et al. 2001; Miles et al. 2006; Visbeck 2008; Tollefson 2010). Climate services may be defined as the provision of timely, decision-relevant, actionable, science-based information, and guidance on climate variability and change, and the associated environmental and social impacts, to assist decision makers (users) in the public and private sector in the development of responses to manage their climate risks. The provision and development of such information represents a considerable challenge, and is one that cannot be met by the resources and capacity of one organization alone, and indeed, in some cases might require international collaboration. To develop actionable climate information that can inform adaptation decision making is a challenge for society in general and climate research and climate services in particular. Recognizing this challenge, various international initiatives have been developed recently to support the provision of climate services, in particular the Global Framework on Climate Services (GFCS) from the World Meteorological Organization (WMO), the Climate Service Partnership (CSP), and the Joint Programming Initiative (JPI). The main aim of the GFCS is to support strong interaction between science and research on the one hand, and communication with stakeholders on the other, to ensure that the climate information is both actionable and usable (Cash et al. 2003; Meinke et al. 2006; Lemos and Rood 2010; Lemos et al. 2012). Additionally, the CSP and JPI go further and advocate for the co-creation of knowledge between users and providers of climate services.

Climate services information comprises a range of products and services, including climate observations, climate model forecasts, predictions and projections of possible future climates at a range of timescales (months, seasons, decadal, and centennial), projected environmental and societal impacts, vulnerability and risk assessments, and decision support tools, among others. As such, climate services can offer an end-to-end analysis and presentation of information relevant to adaptation decisions; they will require strong partnerships and networks between all actors concerned and will support the co-production of knowledge on climate-related issues. The disciplinary breadth required from climate services therefore needs to go far beyond that offered by national meteorological and hydrological services (NMHSs), although clearly these organizations have an extremely important role to play. Climate services should therefore be developed and provided by inter- and transdisciplinary teams including climate, environmental, social, and political scientists, economists, and risk and decision theorists, as well as stakeholders.

Climate information needs to incorporate strong communication channels between decision makers and knowledge providers, to ensure knowledge exchange, facilitate two-way dialogue and shared learning, particularly in relation to understanding user needs and existing knowledge and the limits and capabilities of the science-based information in meeting them.

This chapter provides a discussion of the various elements that are likely to be central to the successful development of climate services, with particular emphasis on the use of climate modeling to support adaptation decision making. The focus is therefore on summarizing key developments, the current state-of-the-art and future prospects for developing seasonal and decadal climate model predictions, and the use of multi-decadal projections of changes in climate. In addition, the need for effective user engagement, and the co-production of knowledge, is argued. Moreover, the institutional challenges including funding of climate services and the role of the public and private sectors in developing climate services are discussed. The chapter finishes with a discussion of the future direction of climate services and conclusions on the current state of climate services and their role in enabling adaptation responses.

Providing Decision-Relevant Climate Information

Climate information can be and has been used in both top-down “scenario led” approaches and bottom-up vulnerability approaches to climate risk assessment (Carter et al. 2007; Wilby and Dessai 2010; Weaver et al. 2013; Stern et al. 2013). The top-down approach has been criticized for not providing decision-relevant information, owing to the fact that the analysis is not structured around valued objectives that a given organization may have and also because the range of uncertainty that can be generated may often overwhelm decision makers (Wilby and Dessai 2010). The discussion presented here is based on the methods that are used in the top-down approach, where global and regional climate models are used in connection with impact models. However, it should be stated that the use of model information in itself does not mean that a top-down approach has been followed, and the limitations of this approach for providing useful information for developing adaptation strategies is acknowledged. Rather, an explicit recommendation for incorporating the use of climate model information into a bottom-up vulnerability or risk-based approach to developing adaptation strategies is made, whereby climate information is used in relation to answering specific questions about system performance. In doing so, a link between the conventional top-down and the bottom-up approaches is made (Mastrandrea et al. 2010; Weaver et al. 2013). This conceptual difference between the top-down and bottom-up approaches is illustrated in Fig. 1.

Uncertainty and Predictability in Model-Based Information

This section reviews the production of model-based climate information at the seasonal to decadal timescales and multi-decadal or centennial projections. The way in which this modeled information can be used in supporting adaptation decision making is discussed in (Bowyer et al. 2014 this volume).

The development of future climate information based on global climate model (GCM) outputs is confronted by three sources of uncertainty related to internal variability, uncertainty in the climate response to radiative forcing (model spread in Fig. 2a), and greenhouse gas scenario or emission uncertainty (scenario spread in Fig. 2a). The relative importance of these different sources of uncertainty varies with the timescale considered. As one moves through time, uncertainty increases (Hawkins and Sutton 2009; Kirtman et al. 2013). This has implications for the kind of methodological approaches that are employed to provide useful future climate information at different timescales and the way in uncertainty in each different source needs to be sampled.

For the development of future climate information at monthly, seasonal, and interannual timescales, internal variability is the main source of uncertainty, while at decadal timescales model spread and internal variability (e.g., dynamical modes such as El Niño) dominate, with scenario uncertainty playing a relatively minor role. At multi-decadal to centennial timescales, scenario spread is the main source of uncertainty. The skill of model predictions and projections is determined in large part by how well the relevant processes can be represented in the models and how well the different sources of predictability in the climate system can be incorporated. These sources of predictability at different timescales, and in the different Earth system components (ocean, land, atmosphere, cryosphere), are summarized in Fig. 3. Because of the relative importance of different sources of uncertainty at the monthly to seasonal and interannual timescales, the nature of the problem is one of initialization (Shukla 1998), whereas at the centennial scale it is the representation of external forcing (scenario spread) and the climate response to this. At the decadal timescale the problem is thought to be one of initialization and external forcing (Meehl et al. 2009). It is important to state that although novel approaches to initializing the climate system may reduce the uncertainty attributable to internal variability, there will always be uncertainty as a result of the chaotic nature of the Earth's climate system.

(**a**) Projections of global mean decadal mean surface air temperature to 2100 together with a quantification of the uncertainty arising from internal variability (*orange*), model spread (*blue*), and RCP scenario spread (*green*). (**b**) Signal-to-uncertainty ratio for various global and regional averages. The signal is defined as the simulated multi-model mean change in surface air temperature relative to the simulated mean surface air temperature in the period 1986–2005, and the uncertainty is defined as the total uncertainty. (**c**–**f**) The fraction of variance explained by each source of uncertainty for global mean decadal and annual mean temperature (**c**), European (30°N to 75°N, 10°W to 40°E) decadal mean boreal winter (December to February) temperature (**d**) and precipitation (**f**), and East Asian (5°N to 45°N, 67.5°E to 130°E) decadal mean boreal summer (June to August) precipitation (**e**) (Source: Kirtman et al. 2013)

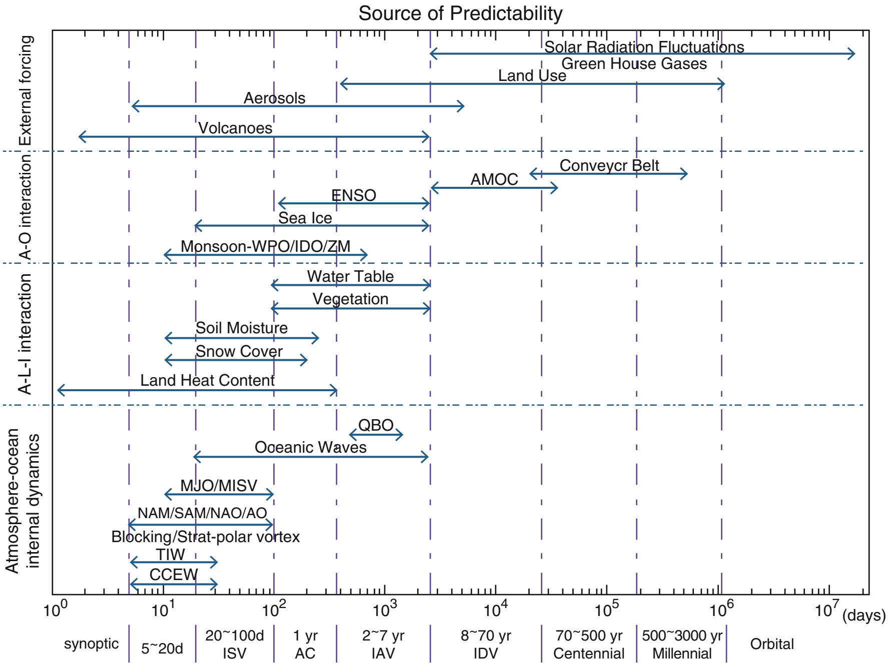

Fig. 3 **Sources of predictability in climate modeling**. Processes that act as sources of ISI climate predictability extend over a wide range of timescales and involve interactions among the atmosphere, ocean, and land. CCEW convectively coupled equatorial waves, TIW tropical instability wave, MJO/MISV Madden–Julian Oscillation/Monsoon intraseasonal variability, NAM Northern Hemisphere annular mode, SAM Southern Hemisphere annular mode, AO Arctic oscillation, NAO North Atlantic oscillation, QBO quasi-biennial oscillation, IOD/ZM Indian Ocean dipole/zonal mode, AMOC Atlantic meridional overturning circulation. For the *y*-axis, “A” indicates “atmosphere,” “L” indicates “land,” “I” indicates “ice,” and “O” indicates “ocean” (Source: Adapted from NRC 2010)

Climate information developed at monthly to seasonal to interannual timescales currently derive their skill from the inclusion of in situ and remotely sensed observations of the initial state of the ocean surface and subsurface and the atmosphere (Goddard et al. 2010; Stockdale et al. 2010). These observations are assimilated into coupled atmosphere–ocean climate models, thus sampling the main source of uncertainty in climate predictions at this timescale (Palmer and Anderson 1994; Stockdale et al. 1998; Palmer et al. 2004; Rodwell and Doblas-Reyes 2006; Weisheimer et al. 2009). The skill of seasonal forecasts varies temporally and spatially, however, which is determined by the persistence and power that an initialization contains for making predictions in different areas of the world. To date, the greatest skill in seasonal forecasting has been demonstrated over tropical regions (Palmer et al. 2008; Lavers et al. 2009; Weisheimer et al. 2009), though this skill also changes with the climate variable concerned and also the time of year. Moreover, this skill is greater for climate variables over the ocean than the land surface, raising questions about the usefulness of such forecasts for informing decision making and underlining the importance of reporting skill scores or measures of reliability with the products.

On the basis that initialization at monthly to seasonal and interannual timescales contains predictability about the climate system, there has been much recent interest in combining the initialization approach with external forcing, to develop model predictions at the decadal timescale (Haines et al. 2009; Meehl et al. 2009; Keenlyside and Ba 2010). This is a timescale for which there is burgeoning demand, owing to the fact that this is often a timescale which is more closely aligned with the planning horizons of a number of adaptation decisions (Cane 2010). Developing decadal prediction systems has duly seen a significant amount of research over the last few years; however, the use and availability of such predictions remains very much in its infancy, and the approach overall is still very much experimental (Meehl et al. 2010; Tollefson 2013). Initializing with observations of the ocean and atmosphere, and using prescribed radiative forcing, has been shown to improve decadal prediction of global surface temperature anomalies (Smith et al. 2007). Work initializing with information on sea surface temperature, and prescribed radiative forcing, has shown improved surface temperature prediction over the North Atlantic (Keenlyside et al. 2008; Pohlmann et al. 2009). These latter two studies did not, however, report increased skill when hindcasting global mean temperature. Other research has shown that initialization contributes little additional predictability compared to changes in external radiative forcing (Troccoli and Palmer 2007; Meehl et al. 2010; Hermanson and Sutton 2010). Furthermore, there is some evidence to suggest that under a warming world, the predictive power of initialization will decrease in decadal temperature and precipitation predictions (Boer 2009).

Multi-decadal or centennial projections of climate change have seen widespread use and application in the adaptation decision-making process, whether this be for the identification of possible climate risks or more detailed studies of what future changes may mean for various economic sectors (Vermeulen et al. 2013). Being able to test or validate multi-decadal projections is clearly very difficult, as one would have to wait for a number of years to be able to test this (Allen et al. 2013). Often what is done to test the various different models is to use hindcasting and use an error statistic to represent how skillfully a given model is able to represent recent and historical climate changes. This is a necessary but not sufficient condition for the use of multi-decadal climate projections in adaptation decision making. This, in addition to the long timescale that is being dealt with, means that there are very large uncertainties associated with the use of these projections. This raises an issue as to how best, or most suitably, to make use of such projections in supporting adaptation decisions (Weaver et al. 2013).

Clearly, much more research is required in monthly, seasonal, interannual, and decadal prediction to establish the reliability of these approaches (Hurrell 2008), such that they may prove suitable for use in informing adaptation decision making. The research community is currently addressing this through such activities as the WCRP/ CLIVAR Working Group on Seasonal to Interannual Prediction (WGSIP). In addition, the pursuit of the seamless prediction system, whereby processes relevant to sources of predictability are represented at all scales, is one that would be of enormous benefit to climate services in making reliable and useful information available to decision makers (Rodwell and Palmer 2007; Lavers et al. 2009). This vision is one that will require enormous effort and resources, both human and financial (Shukla et al. 2010). Similarly, large investments in land-, ocean-, and space-based observing systems need to be maintained and improved through the work of programs like GCOS, GOOS, GMES, and the Group on Earth Observations (GEO). The assimilation of, for example, subsurface ocean heat content from ARGO floats (Roemmich et al. 2009) will likely yield further advances, but this will also require advances in data assimilation schemes, if potential improvements are to be realized.

Downscaling Model-Based Information

Regardless of the timescales and methods used to develop predictions or projections from GCMs (usually at a spatial resolution of 100–300 km), some form of downscaling will be necessary to provide climate information at the regional to local scales (typically less than 50 km), suitable for use with impact models (Wilby and Wigley 1997; Fowler et al. 2007).

Downscaling will be needed for a long time in the future since, even with access to the most powerful computer facilities, it is unlikely that global climate models will soon provide information at a spatial resolution that is sufficiently high to meet the needs of most impact models.

Given the diversity of uses of regional scale information, it seems sensible that both statistical and dynamical downscaling approaches are adopted, as the relative merits of each are better suited to some applications than others (Déqué et al. 2007; Jacob et al. 2007; van der Linden and Mitchell 2009). For example, dynamical downscaling is more suitable in areas with complex topography and where the local observational data are sparse. In contrast, operational applications where the time frame of analysis is relatively short (e.g., seasonal forest fire risk) may dictate that more computationally efficient statistical downscaling is used. Further, it is currently not possible to say conclusively that one method is better than another.

In light of the foregoing discussion, the choice of downscaling method should be guided by the climatic region, local topography, variables of interest, and application to which the results are to be put. However, regardless of which method is used to downscale, all results will ultimately be limited by the accuracy of the driving boundary conditions supplied by the GCM, and as such, research priorities in global modeling are also relevant to the regional models (Schiermeier 2010).

Model Quality Assessment

If users are to apply climate and impact model information to their adaptation decision-making process, they will rightly ask and need to know: are the models any good? Can they be trusted? Which one should I use? Climate service providers need to be able to answer these questions. This issue is related to model skill, and the development of model quality metrics, and is an increasingly important research area (Glecklers et al. 2008; Knutti et al. 2010).

Model skill or performance is typically evaluated with respect to how closely the model simulation corresponds to observations, quantified via some error statistic, e.g., RMSE (Murphy et al. 2004; Reichler and Kim 2008; Flato et al. 2013). This approach is suitable for quantifying the skill of monthly to seasonal forecasts. However, for decadal to centennial timescales, this approach is less suitable, due to a lack of sufficient observations at these timescales. Moreover, it doesn't automatically follow that a model that performs well with respect to past and recent climatology will have future predictive skill. Although there is some evidence that strong relationships do exist between past and future trends (Boer 2009), in the main, this is not the case (Knutti et al. 2010). The evaluation of model performance at decadal (and longer) timescales thus needs to be evaluated against longer timescale data (palaeoclimate data), and how well key climate processes and feedbacks are represented, in addition to observations, if a broader level of evidential support is to be established for the credibility of models at these timescales. Moreover, these evaluations need to be made over a number of different climate variables and for different statistical properties (e.g., mean state, variability amplitude) and at a range of time and space scales.

Having calculated model performance metrics, how are users able to make sense of them in determining model quality? Currently, there is no clear set of metrics which are commonly agreed to serve as useful indicators of overall model quality. Accordingly, it is important when trying to distinguish between different models that more than one metric is used to establish model quality, because a model that simulates one variable well may simulate other variables less well. Therefore, a range of different metrics should be used, and the actual assessment of model quality should be determined on a case-by-case basis, according to the performance of a given model with respect to the key variables and processes that are key to the accurate simulation of the intended application (Wilby and Harris 2006; Flato et al. 2013). This also raises the question of which impacts models are most accurate and thus suited for purpose? This reinforces the importance of quantifying uncertainty along the model chain from GCMs through to the impacts models themselves.

Clearly, there is a long way to go before a commonly agreed set of metrics for evaluation of model quality can be determined and that are application specific. The challenge of communicating these metrics to users, however, will require that the metrics are relatively simple to calculate.

Communication and User Engagement Challenges

For climate services to be useful and usable, i.e., provide decision-relevant information, it is imperative that a sustained two-way dialogue is established between providers and users to support the co-generation of knowledge (Lemos et al. 2012).

The best science in the world may "sit on the shelf" and be irrelevant, if users are not able to make use of the knowledge. There has been research to suggest that there are three essential elements to ensuring "actionable" climate knowledge (Cash et al. 2003; Meinke et al. 2006). These essential elements are *saliency* (the perceived relevance of the information), *credibility* (the perceived technical quality of the information), and *legitimacy* (the perceived objectivity of the process by which the information has been produced). A related issue to the development of actionable knowledge is that the usability of any products developed should integrate smoothly with existing management structure systems (Lemos et al. 2012). This provides a useful framework within which to discuss user engagement in relation to climate services.

To ensure salient climate information is developed, demands that the climate-related problems faced by different economic sectors are well known and explained before product development is embarked upon. This requires the gathering of key people and decision makers from the different economic sectors, together with scientists and other experts, to engage them in a discussion and to learn about their problems. This engagement should be a proper discussion of the issues and possibilities for development of climate products, such that the process is much more than simply asking users what they want. A good example of where such an exchange has taken place is the US Global Change Research Program (USGCRP), whereby a large number of "Listening Sessions" have been held to garner the views of key stakeholders in helping to shape the USGCRP, thus ensuring user-relevant research programs, and user buy-in to subsequent developments. Institutes developing climate services will require to implement these and similar kinds of mechanisms. Furthermore, saliency will relate to the provision of easily accessible and understandable products.

Credibility in the development of climate information and products demands that efforts are made to report and inform on the reliability of different products, both in relation to the methodological approach and the subsequent model results. This underscores the importance of sustained research efforts in the development of model and product quality metrics. Establishing credibility in the products also requires that the institutes and centers that are developing and delivering products are themselves credible. This relates to being open and honest in discussions and genuinely informing and building capacity with users. This will help to build trust, which in turn will aid credibility.

The legitimacy of the process by which climate information and products are developed is related to the way in which the needs of different users have been considered and realized in the final product. This involves having a sustained, mature, constructive, two-way dialogue between users and providers that facilitates the co-production of knowledge, where users can make their needs clear and providers can explain the status of the science to meet these needs, and the implications for possible product development. Only by doing this will users buy into the information and products that are subsequently developed. This issue of legitimacy also relates to the perceived independence of the organizations developing or delivering the climate products and is an issue related to the kind of organizational and institutional framework within which climate services are situated and associated funding models. Ensuring actionable products are delivered will thus demand a large investment of time and effort on the part of both users and providers, and developing this partnership will be critical to the success of climate services.

Another key aspect of user engagement is open and honest discussion of the limitations associated with various climate products and their suitability for, and practical use in, decision making and policy development (Lempert et al. 2004; Lemos and Rood 2010). This discussion of limitations should be accompanied by the provision of advice, training, and genuine knowledge exchange between experts and users with real-world problems. Educating users about limitations, and the appropriate use of observations and climate model information, provides an advisory and consultative function for climate services, which, done well, should reduce the chance of unrealistic expectations on the part of users. Successful user engagement will also depend on the use and development of clear and unambiguous language, so that experts and non-experts alike can understand each other. Accordingly, effective communication is a major task for climate services. Moreover, close collaboration between users and climate services will be essential for the identification of critical thresholds, current coping ranges and vulnerability, and how adaptive measures can help manage current and future climate risks (Jones and Mearns 2005).

Institutional and Organizational Challenges

While a number of developments are underway in developing climate services, there are various challenges that need to be overcome, if climate services are to play their full role in supporting adaptation decision making. To be successful, climate services cannot be isolated from the research community and user needs. The quality of the products to be developed by these services is directly dependent on advances made by the fundamental and applied science. Strong ties between climate services and research institutions are therefore essential.

Climate services make use of information derived from observations and model projections. It is perhaps insufficiently stressed that there is a need to improve access to data and to develop a more integrated monitoring and data management system (Stern et al. 2013). At the same time, the development by the international research community of the next-generation high-resolution Earth system models (Shapiro et al. 2010) and analysis systems requires the development of interdisciplinary teams and dedicated access to state-of-the-art supercomputers. In parallel to these scientific and technical developments, more resources will have to be invested in the analysis of observation and modeling data (to ensure quality control), the development of integrated assessments, risk management and in economic evaluations of adaptation policies.

The provision of suitable infrastructure for running the very high-resolution Earth system models, and handling the very large data sets that will be generated, is an area where the private sector has an important role to play, in ensuring that climate services can be successfully developed. In addition, significant resources will need to be invested in ensuring that these data sets are translated into products and information that are easily accessible and understandable to users. This development will require the close collaboration of scientists and users, and this is a function that will likely best be performed by climate service centers and similar organizations.

The private sector will also need to collaborate as users. The climate risks that an organization may face will vary with the type of business and location. Tourism, energy, agriculture, and water, for example, operate where supply, demand, and price fluctuate considerably with weather conditions. Investments are considerably affected in areas prone to frequent drought, flooding, and other extreme events. In the long term, proactive responses of business to climate-related risks and the early implementation of adaptation measures will likely confer competitive advantage. The information provided by climate services must be objective, legitimate, authoritative, and relevant and thus independent of economically driven pressures. Transparent interactions with the private sector, however, must be established so that decision makers better appreciate climate risks in their business activities and thus their relevance for the success of their business (Ruth 2010).

The financial arrangements in support of climate services must ensure the intellectual, economic, and political independence of the groups generating knowledge and disseminating information. Sustained public funding is therefore a requirement for many of the activities conducted by climate services. The development of constructive interfaces between the services and the users remains, however, a challenge. A possible solution is to create small start-up private companies that work directly with businesses and corporations, regional governments, municipalities, and other local communities (Brooks 2013). These companies would develop joint projects with their customers, address their specific needs, and provide tailored information to facilitate future planning and investments.

Even with such institutional arrangements that clearly separate the respective roles of the public and the private sectors, communicating complex and evolving information in terms that are easily understood remains a challenge. There is a long way to go between the production of scientific knowledge by the research community and, for example, the implementation of adaptation measures by the different economic sectors. The psychological and procedural aspects of the communication process also need to be considered (Pidgeon and Bischhoff 2011). It is therefore crucial to develop efficient and targeted communication channels that highlight the economic benefits for corporations and other entities to immediately prepare themselves for climate change.

Finally, the international dimension of climate services is of crucial importance. Observation infrastructures operate at the local to global scale, and data exchange is of primary importance. Supercomputing facilities may also need to be shared between different research and operational groups from different countries. In addition, in the same way that the national meteorological services from all countries cooperate, it is important that similar institutional partnerships be established to deal with climate information, risk assessments, and adaptation policies. One way in which this could be organized would be to have five or six regional centers distributed around the world, with the dedicated focus of developing research to support climate service activities internationally. International discussions should lead to a better assessment of the demand from society, the need and role of climate services, sustainable funding mechanisms, quality data and information, targeted scientific research and innovation, systematic knowledge exchange, and capacity building.

Conclusion

The development of climate services that play their full role in helping society to respond and adapt to climate variability and change faces many challenges. At the heart of climate services is strong communication between users and providers, ensuring that actionable climate information is delivered. This will only be possible, with a committed and concerted effort on the part of users in the private and public sectors, researchers, government, and society in general. This effort will only be assured when the size and urgency of the adaptation challenge is widely recognized and acted on. This is likely to require some form of legislation, regulation, and incentives to promote a response, e.g., in ensuring that building standards and codes require that possible future climates are considered in the design phase.

For climate services to be successful, they will need to demonstrate that they can meet the needs of users and thus contribute value to adaptation decisions. The use of climate observations and centennial timescale model projections has already demonstrated their value in a number of adaptation responses. For seasonal and decadal timescale model predictions to also provide value to users, however, clearly requires much more research. At present, the state of the science in seasonal, interannual, to decadal predictions is such that it may well be several years and possibly decades before scientifically reliable products can be delivered the world over, at all times of year, and for a wide range of climate variables and spatial scales. Despite this, there are already operational seasonal forecasts generated by, for example, the European Centre for Medium Range Weather Forecasting (ECMWF) and the National Center for Environmental Prediction (NCEP) in the USA, which are applied to a range of activities and from which users derive value.

Regardless of the timescale, deriving value from climate information will need to be patiently constructed and will only be possible through the close collaboration, shared learning, and knowledge exchange between users and providers over a sustained period of time (Brooks 2013).

With respect to downscaling to regional scales, there is much research still to be done in both the global and regional modelling communities. This will likely be achieved through increased resolution and better process representation. In addition, advances in the development of model quality metrics will be needed for a range of different application areas, before users can make a truly informed choice on the types of products they may like to make use of and the range of uncertainty to be expected. Clearly, these issues demand significant investment in fundamental research.

The way in which uncertainty is dealt with is a major issue for making decisions in relation to adaptation. Given the number of different models and the cascade of uncertainty from the global to regional scales through impact models, and the possibility that uncertainty can increase as models become more complex, users need to carefully structure their analyses and assessments based on a careful consideration of the decision context. In addition, advances are needed in the development of dynamically coupled and integrated assessment models, to more realistically simulate the real world, and the interactions between climate, socio-economics, and the environment (Füssel 2010; Nobre et al. 2010). Given the large range of uncertainty from models, together with the fact that there are many uncertainties that are not quantified, necessitates the need for robust adaptation, where decision makers seek flexibility and strategies that perform well across a range of different future climates, rather than striving for optimality (Bowyer et al. 2014 this volume, Weaver et al. 2013).

Climate services offer much potential to help support adaptation to climate variability and change. There is strong institutional support at the global level through the GFCS, CSP, and other initiatives, and this is being accompanied by strong support in a number of countries around the world. Sustaining these activities will require long-term commitment and significant investment in fundamental research, observation platforms, institutions, user engagement, and capacity building, if this potential is to be realized.

Acknowledgments The authors acknowledge Roger Wakimoto, Rick Anthes, and Mel Shapiro for providing helpful comments on a previous version of the manuscript. The Role of Wetlands in Mitigating the Effect of Climate Change in Nigeria

Nasiru Idris Medugu

Contents

Abstract

This chapter reviews the place of wetlands in climate change within the overall frame of environmental resource planning. This is against the background of the importance of wetlands as environmental resources which have been described as the kidneys of the landscape as a result of its hydrological and chemical functions and as atmospheric carbon sinks which stabilize the climate. The study reviewed mitigating and adapting measures in literatures that may be adopted in Nigeria in order to enhance the potentials of wetland resources in the country. The chapter asserts that the declining environmental resource base of the country is mainly due to anthropogenic influences because wetlands in Nigeria are largely exploited for economic gains and are basically used for subsistence living or for physical development. Statistical data from the government shows that 60 % of Nigerian population depend solely on the natural resource base and

are engaged in farming, cattle rearing, and fishing. This chapter provides measures which include restoration programs, reduction of further disturbance on wetlands, and legislative and policy formulations for protecting wetlands which are considered appropriate and can contribute greatly in mitigating climate change when properly harnessed as a way forward toward climate change mitigation and adaptation.

Keywords
Wetlands • Climate change • Resource conservation • Adaptive planning • Developing countries, Nigeria

Introduction

Wetlands are the transitional zones between the aquatic and terrestrial environments. Though there is a controversy over its precise definition because of variety in its types and boundary limits, generally it refers to the intermediary zone between permanently wet and permanently dry environments (Barbier et al. 1997). However, during the Ramsar Convention on Wetlands of International Importance, 100 countries adopted an extremely wide approach and defined wetlands as "areas of marsh, fen, peat land or water, whether natural or artificial, permanently and temporary with water that is static or flowing, fresh, brackish or salt, including areas of marine water, the depth of which at low tide does not exceed six meters" (Barbier et al. 1997). Mitsch and Gosselink (1993) and Barbier et al. (1997) also described wetlands as "the kidneys of the landscape, because of its role in the hydrological and chemical cycles, functioning as "biological supermarkets" and serving as food webs and supporting rich biodiversity." As an interface or the intermediary between land, sea, groundwater, and atmosphere, wetlands are being regarded as one of the most complex regions on earth (Semeniuk 2012).

In relation to climate change, intact wetlands serve as buffers in the hydrological cycle (Bergkamp and Orlando 1999; Junk et al. 2013) and absolve organic carbon from the atmosphere, neutralizing the effects of atmospheric increase in CO_2 (Junk et al. 2013). In fact, the place of wetlands as an environmental resource is monumental, justifying why research is needed to harness its linkage with climate change, especially in developing countries where coping ability is low.

Unfortunately there is paucity of research results that attempt to establish a nexus between wetlands and climate change. This is corroborated by Erwin (2008), who observed that after examining over 250 articles pertaining to wetlands and climate change in peer-reviewed journals and pertinent texts, there was very little discussion of wetland restoration in the climate change literatures, with only an occasional comment in a very small fraction of the documents. Odjugo (2010) is also of the opinion that though the effects of climate change are more pronounced at the regional levels, most data on it are global in scope. This underscores the need for research initiatives to shed light on wetlands within the frame of climate change adaptation at regional levels using Nigeria as case study.

The study therefore aims at assessing wetland resource services in the context of environmental resource planning for climate change adaptation in Nigeria. The specific objectives are as follows:

- To review the impact of industrialization, urbanization, and subsistence living on wetland resource depletion generally but with specific bias to Nigeria
- To review mitigating and adapting measures in literatures that may be adopted in Nigeria in order to enhance the potentials of wetland resources in the country in the light of climate change

Climate Change and the Environment

The environment operates like a giant single, self-regulating, and self-sustaining organism made up of different components that are intricately interdependent. Each and every component has got a vital function for the sustenance of the system. Any dislocation in one generates multiplier effects on other components; thus climate, for example, has an important influence on any environment and can trigger changes, if altered. Climate changes and the impacts of these changes may affect the environment in diverse ways. Warming, for instance, is capable of forcing species to migrate to areas with lower temperatures and more conducive to their survival. Climate change causes irreversible multiplying effects, manifesting in species adapting, migrating, or perishing which ultimately result to losses in local population (Boer 2012). This development can affect environmental services of a particular environmental resource.

Brundtland report on our common future in 1987 stresses the need for counterbalancing the unmet needs of the current generations with the needs of the future generations (Sneddon et al. 2006). They said most scholars and practitioners have come to accept the Brundtland definition of sustainable development as the most appropriate which hinged on environment and development dilemmas. Mohammad (2011) looks at the environment as the composition of the natural, artificial, physical, chemical, and biological elements that make the existence, transformation, and development of living organisms possible. He went further to say that an environment can only be referred to as sustainable when it possesses the ability to continue to function properly and indefinitely. Environmental sustainability therefore aims at reducing environmental degradation, through the process of stopping or reversing any human activities that lead to it.

The United Nations IPCC report established that human activities, especially those associated with consuming energy from fossil fuel, remain the major source for climate change (IPCC 2007). The panel substantiates the above assertion by reporting that between 1970 and 2004, annual CO_2 emission grew by about 80 % due to human activities from fossil fuel burning. Over the years, humanity has solely depended on fossil energy use because of the huge capital and economic benefits. But the global antecedences attached with this source of energy consumption have proved that it is not sustainable.

In search of the earth's vast seemingly unlimited resources, fossil fuels discovery led to a great transition in our societies which became highly dependent on energy use (Agudelo-Vera et al. 2011). Additionally, industrial societies use three to five times as much energy and materials as did agrarian ones (Krausmann et al. 2008). Available statistics shows that resource consumption by the end of the twentieth century already exceeds the productive capacity of critical biophysical systems on every continent and waste production already breaches the assimilative capacity of many ecosystems at every scale (Rees 1999). To add credence to the above assertion, Vitousek et al. (1997) affirm that we are changing earth more rapidly than we can understand it. The rates at which we generate waste exceed the rate at which the earth can assimilate. Though we have made significant progress in reducing industrial pollution and increasing efficiency, globalization is devastating natural habitats, speeding global warming, and increasing air and water pollution (Mohammad 2011). He went further to establish that the yearning for global nature of trade and business has rendered traditional national environment protection techniques less or ineffective.

The reviewed literatures so far are unanimous in supporting the fact that in climate change and sustainability, the environment occupies a central stage. Hossain et al. (2010) affirm that in sustainability studies, the closest element that should be dealt with in climate change is the environment. An unsustainable situation takes place when natural capital (the sum total of nature's resources) is used up faster than it can be replenished. Sustainability requires that human activity only uses nature's resources at a rate at which they can be replenished naturally. Natural vegetation, green spaces, wetlands, waterfronts, etc., can be affected by urbanization and development.

The key manifestations of environmental change are global warming and climate change. In fact, global warming is considered to be one of the most stressing issues that are currently facing humanity (Mezher 2011). However, the Intergovernmental Panel on Climate Change (IPCC) assessment in 2001 has reported that global warming and climate change are receiving a great deal of attention by governments, businesses, consumers, and the mass media due to its publicized impact on human society, biodiversity, water supply, infrastructure, and desertification (Santos 2011). This is in agreement with the European Commission 2005 report on winning the battle against global warming, who also affirmed that there is general awareness in tackling the problem of greenhouse gases (GHG) emission in the light of its damaging effects on the global environment, economy, and international security (Minoia et al. 2009). But this increasing awareness of the impact of GHG and climate change on the environment is still low in the developing countries compared to that in the developed countries. There is general lack of awareness of the role of the natural environment in mitigating climate change in the developing countries. This again underscores the need for research initiatives to shed light on the role of the wetlands as component part of the environment in mitigating climate change at regional levels using Nigeria as case study.

Wetlands and Climate Change

Statistics has shown that 6 % of the land area of the world is occupied by wetlands (Acreman et al. 2007; Erwin 2008). This contains approximately 12 % of the global carbon cycle (Erwin 2008). Earlier statistics however ascribed greater value indicating that nearly 10 % of the earth's surface is wetlands, of which 2 % are lakes, 30 % bogs, 26 % fens, 20 % swamps, and 15 % floodplains (Bergkamp and Orlando 1999). Wetlands are significant carbon stores, and so the role of their conservation also needs to be considered in the development of climate change mitigation strategies. This is in line with what Bergkamp and Orlando (1999) see as the ultimate objective of the United Nations Framework Convention on Climate Change (UNFCCC) which is to reduce GHG emissions.

Wetlands represent a significant storage reservoir of carbon in the global carbon cycle. Statistics shows that of the total storage of carbon in the earth's soils (1,400–2,300 Pg, where 1 Pg = 1,015 g), about 20–30 % is stored in wetlands, much as peat in wetland soils, and that 0.08 Pg/year is stored as peat in wetlands, a small percent of the 6.3 Pg/year that are produced by humans (Cudmore 2011). He also asserts that disturbance of peat deposits can influence global carbon budgets, combustion, and oxidation of peat deposits, and drainage of wetlands also can release carbon back into atmosphere (could be 45–89 % of the carbon being sequestered by wetlands).

Over the years, however, there has been a remarkable loss of wetlands globally though there are no statistics to support this assertion (Barbier et al. 1997). They however reported significant loss in some countries such as the United States put at 87 ha that is 54 % of its original wetlands, Portugal 70 %, and various degrees of loss in European countries. Factors responsible for natural change on the wetlands include issues such as drought, sea-level rise, and infilling with sediment or organic material. Anthropogenic activities on the other hand, such as subsistence agricultural activities, constructions, developments, etc., are human-induced factors that have affected the wetlands over the years. As a temporary feature of the landscape, natural or human phenomenon can introduce change to the fragile landscape, and without some precaution over its usage, it might eventually disappear with time.

Climate change is perhaps the greatest challenge facing wetland management. And wetlands are perhaps the most susceptible to climate change in the aquatic ecosystem. Shallow wetlands that are dependent on precipitation will be the most vulnerable to drying, warming, and changes in water quality. Intermittent and perennial streams, vernal pools, and coastal wetlands and marshes will also be particularly vulnerable to projected changes in temperature, precipitation, and sea-level rise. Wetlands that depend on precipitation for their source of water according to Winter (2000) are the most vulnerable to changes in climate.

The features of the wetlands in developed economy are slightly different from that of the developing countries. Kulkarni and Ramanchadra (2006) established that the environmental challenges confronting the developing countries are considerably different from those facing the industrialized economies. Their assessment shows that in the developing economies, the rural population depends directly in exploiting the natural resources for fishing, rearing livestock, agricultural, fuel, etc., to meet their subsistence needs and gain income. This has escalated land use change in the natural environment causing habitat disappearance and results to loss of the ecological resources and the functions disrupted or loss culminating in climate change.

Although African countries are exonerated from being major contributors to GHG emissions, as the continent's contribution is relatively low compared to other continents, unfortunately climate change does not know regional boundaries and the region is more vulnerable. In recent years, some countries in Africa such as Ethiopia, Eritrea, Botswana, Zimbabwe, Mozambique, South Africa, and Sudan are experiencing increase in severe droughts as a result of climate change (Spence 2005). Increased dependence on firewood has aggravated forest depletion in most African countries. And accelerated forest depletion according to Alaci and Ato (2012) can alter the microclimatic scenario of an area. Some of the forests depleted are actually wetland forests, apart from the fact that what happened to the forests is a bigger picture of what happens to other components of the ecosystem, wetlands inclusive.

Regional evidence shows that some tropical rainforests in western Africa have become drier since 1960 (Malhi and Wright 2004). This according to Velarde et al. (2005) is an indication that shifts in ecosystems or species habitats in Africa due to climate change are expected and are happening already. The continent is most vulnerable to climate change because most African governments may not have the coping abilities to actively react to climate change and global warming (IPCC 2007). Odjugo (2010) also upheld the above assertion, arguing that even though climate change and its impacts are global, the developing countries will experience more of its biting effects most especially in Africa because coping capabilities are low, coupled with the fact that the region is the least equipped to mitigate climate change impacts (Velarde et al. 2005). And more often in Africa, issues of climate change are neither incorporated in policy development matters nor invested in decision making that mitigates it (UNDP 2006).

According to Hossain et al. (2010), striking a balance between climate change and development is essential for identification and implementation of wholesome approaches that will bring more and more management aspects into fore across different sectors in an efficient way. This they said becomes the bedrock of our achievement in development or managing problems, in a sustainable and advanced manner. Hjorth and Bagheri (2006) have however argued that "managing the future is a 'wicked' problem, meaning that it has no definitive formulation and no conclusively 'best' solutions and furthermore, that the problem is constantly shifting."

Wetland Resource Depletion and Climate Change in Nigeria

The landscape of Nigeria is dotted with wetland resources that spread across the northern and southern regions of the country (Ajibola et al. 2011). The wetlands in the country are categorized into two, the freshwater floodplain (FF) wetlands and the saline coastal mangrove swamp (MS) wetlands (Ajibola et al. 2011). *FF* wetland occupies an area of 9,000 km^2 in the coastal states of Akwa Ibom, Cross Rivers, Delta, Edo, Lagos, Ondo, and Rivers (Agbi et al. 1995), while the MS wetland occupies an area of 858 km^2 located in states such as Rivers, Cross Rivers, Imo, and parts of Edo and Lagos (Eregha and Irughe 2009). However, these are not the only locations where wetlands are found in the country as vast wetlands also stretch along the fronts of river Niger and Benue, the two major rivers in the country. Large quantities of wetlands are found therefore in states such as Kogi, Benue, Niger, Taraba, etc., where these rivers and their tributaries navigate.

While the wetlands in the riparian rural communities in the country are being used mainly for farming as the local populations depend on it for their livelihoods, the ones in the urban and suburban communities are being heavily encroached upon by anthropogenic activities such as industrialization, urbanization, recreation, and developments. These encroachments have also been confirmed by the Federal Government of Nigeria who reported that the proportion of land covered by forest has been reducing by 0.28 % on the average in the country (Federal Government of Nigeria 2008). Alaci et al. (2011) and Kodiwo et al. (2012) confirmed that the declining environmental resource base of the country is due mainly to anthropogenic influences. This declining environmental resource includes the wetlands.

Available statistics have shown that the 140 million population in the country is impacting on the country’s land area of 923,000 km^2 through various physical environmental activities (Gbadegesin et al. 2011). In addition they established that 60 % of this population depend solely on the natural resource base of the country and are engaged in farming, cattle rearing, and fishing while the informal sector still largely controls the economic activities in the urban areas and that the wetlands in the country are basically used for subsistence living or for physical development especially in the semi-urban and urban areas. These activities especially physical development are causing a reduction in the wetland resource base of the nation. This is because physical development has the tendency of changing the entire ecosystem of the wetlands. If the human impact on the wetlands in the country continues in this manner, it will reduce the hydrological and atmospheric carbon reduction capacity of the nation’s wetlands. Unfortunately activities on the wetlands are not regulated, although the country has planning authority that is vested with such power. Most of the wetlands in the urban areas are not delineated as planned areas; hence, activities on it are not controlled and the public opinion formed about wetlands is that of free for all properties.

The effect of climate change that has caught up with Nigeria culminated in the flood event of 2012, reckon to be the worst disaster in the history of the country. Lives were lost, thousands of people were displaced, and properties worth millions of dollars were lost. The riparian communities were badly affected, and even communities that were relatively distanced away from the rivers were amazingly taken over by the flood. The destructions that were caused by this flood were monumental, and for many years to come, many people will still live with shock. The wetland floodplains were believed to have played a vital role in absorbing the excess water, without which probably the magnitude of the disaster would have been more. Statistical values have also indicated that rainfall in recent time has consistently decreased for decades in the Sudano-Sahelian Region of Nigeria, reflecting in significant changes in the climate in the form of desertification (Olatunde and Alaci 2012). In crop yields, for instance, Adejuwon (2006) predicted that even though there will be increase in some areas in the country toward the early part of the twenty-first century, toward the end, however, there will be a decrease. Rise in temperature beyond the coping capability of the crops he maintained could cause the decrease in yields. Some parts of the country are experiencing this already.

The Way Forward in Management of Wetland Resource in Nigeria

Alwi et al. (2011) are of the opinion that in order to achieve sustainable development, conservation, appropriate planning, and management of natural resources remain the key elements to be considered. Planning according to Taylor (2010) should not only be concerned with planning the overall physical environment but should encompass the planning and management of the environment in all its aspects including especially the natural environment with its delicate ecology and pattern of habitats. In the forest resource conflict, for instance, Campbell (1996) reported that industrialists must curb their profits increasing tendency to boost timber yields, so as to ensure that enough of the forest remains to "reproduce" itself. He called this practice "sustainable yield," though timber companies and environmentalists disagree about how far the forest can be exploited and still be "sustainable." Although at least this is a sector that has been identified in the environment, methods on how to enhance sustainable practice in the sector can be explored in spite of the debate. This idea can be applied to wetland resource, identifying it as an important sector of the environment in mitigating climate change and controlling its uses as we advance on the debate on the best possible ways in sustaining its usage. Unfortunately these suggested methodologies are nonexistent in Nigeria; if conservation does occur, they are incidental unless were adopted as open space in urban master plan. Destruction of wetlands in attempt for new buildings in urban areas and farming activities is rampant in many rural communities across Nigeria. Deliberate policy guideline on wetland protection is absent, while games harvested from such areas remain choice delicacy among Nigerians.

To ensure that sustainability is achieved both at the global and regional levels, a reduction in resource consumption is particularly relevant. Nature is the common heritage of mankind; to preserve this heritage, mankind must learn the culture of conservation. In spite of the designation of few wetlands as Ramsar sites, Gopal (2013) argues that there are very weak or nonexistent policies concerning wetland conservation globally. This is certainly more obvious in the developing countries, Nigeria inclusive. The idea that has been promoted by both Taylor (2010) and Alwi et al. (2011) as discussed previously remains ideal for the management of wetlands in Nigeria. The frontiers of planning rules and regulations should go beyond the built environment to the fragile component of the landscape like the wetlands since they play a vital role in absorbing excess CO_2 from the atmosphere. Previous studies on wetlands in Nigeria have not adequately related it to climate change and formulation of relevant planning policy that enhance wetland protection.

Although many people are aware that one of the problems facing mankind today is climate change and sustainability, only very few are however conscious of engaging in behaviors that will mitigate climate change (Gifford 2011). Since it is no longer possible to avoid some degree of global warming and climate change, even if efforts to reduce GHG emissions are successful, studies are therefore needed on how to overcome or minimize impact of climate change especially in a developing country like Nigeria. There are two possible strategies, one is mitigation and the other is adaptation. While mitigation is the effort put forth in reducing the accumulation of GHG in the atmosphere, adaptation is all about adjusting to the impact of global warming (Kwok and Rajkovich 2010). This implies that mitigation is attempting to prevent global warming from happening; adaptation is looking for better ways to live with it since it has happened. Adger et al. (2003) look at adaptation to climate change as the adjustment of a system in moderating the impact of climate change by taking advantages of new opportunities or deciding on the best way to cope with the consequences. The IPCC (2007) report said it is the natural or human system adjustment in response to climate stimuli or their effects. Burley et al. (2012) sum it up as exploiting opportunities or moderating harm.

Literature concurs that for adaptation to climate change to be effective, it has to be at the individual finer level of scale such as nature reserve, parks, or watersheds (Mawdsley et al. 2009). Wetland therefore is considered appropriate as one of the finer scales in the environment that can contribute greatly in mitigating climate change when properly harnessed. Wetland users in Nigeria need to seek for fresh environmentally friendly resource utilization of the wetlands by seizing the opportunities that climate change offers or devising conservative measures to cope with its impacts.

There are diverse ways or methods for wetland adaptation to climate change from the literature. But the method to adapt should be a function of prevailing situation because the scope and the nature of the challenge are not the same. According to Mawdsley et al. (2009), no one particular method or strategy is considered optimal over others; hence, the circumstances under review determine which one is more or less appropriate. Others have also concurred asserting that an action that is acceptable by one group, government, or individual may not be acceptable for another and that success should be defined by scale of implementation and the criteria used for evaluation (Adger et al. 2005). Adaptation to climate change however should be ultimately a collective responsibility of the society, while its application may involve individuals, groups, civil society, or the government (Tompkins and Adger 2004; Adger et al. 2005).

Rebecca et al. (2012) have put forward several strategies in coping with climate change. Their strategies are summed up in promoting system *resistance* and *resilience*. The ability to withstand environmental change is what they referred to as resistance, while bouncing back or absorbing environmental change is resilience.

However, some broad-based practical strategies have been recommended in the literatures on the use of wetland resource as mitigating or adapting measures to climate change. Since the assessment of the wetland resource in Nigeria shows lack of regulatory rules on its usage and the country is already experiencing climate change, there is a need to look for ways of reducing or minimizing human impacts on the wetlands.

Among the volumes of the recommended strategies in the literatures, we put forward three for adoption in Nigeria. These strategies are recommended against the background that they are simple to practice as some have been applied in other developing countries like Nigeria. Some of the strategies are not particularly on the wetlands but may be applied. These strategies include issues such as the restoration of wetlands or the entire ecosystem (Erwin 2008; Lawler 2009; Mawdsley et al. 2009), reduction of further disturbance (Erwin 2008; Lawler 2009; Harvey et al. 2012), and legislative and policy formulations (Hartig et al. 1997). The views and principles surrounding these strategies are discussed in the following subsections accordingly.

Wetland Restoration

Erwin (2008) suggested that wetland restoration programs should form part of the restoration projects and policy makers should strategically inculcate wetland restoration into the overall plan as climate change mitigation and adaptation measures. Boer (2012) concurs and is of the views that when wetlands, streams, or riparian zones are restored, it provides buffers that cushion the effects of climate change on the species and the ecosystem at large. Acreman et al. (2007) on the other hand recognize wetland water management as key element in wetland restoration efforts, because hydrology plays a crucial role in wetland maintenance. Created and restored wetlands have the potential to play an important role in carbon sequestration. Rates of 180–190 g C/m^2/year have been reported for created wetlands in Ohio (Cudmore 2011).

Reduction of Further Disturbance on Wetlands

The diminishing ability of the wetlands to respond to climate change among other factors is the issue of intensive use by man in quest for industrialization or subsistence living. Management strategy requires further minimal use of the wetlands. Prevention or reduction of additional stress should be avoided so as to allow the wetlands' response to climate change (Erwin 2008). This stress includes issues such as maintaining hydrology, reducing pollution, controlling exotic vegetation, and protecting wetland biological diversity and integrity. Lawler (2009) on the other hand has confirmed that removal or reduction in the existing environmental stresses and threats to population or species does enhance resilience to climate change in some cases.

Legislative and Policies Formulations for Protecting Wetlands

Hartig et al.'s (1997) review on Eastern Europe's wetlands advanced that the formulation of policies that will protect wetlands will be of assistance to countries that are vulnerable to climate change. They suggested precautionary management measures for sustainable wetland utilization such as establishing buffer zone, advocating for sustainable uses of wetlands, and recapturing of farmed or mined wetland areas. These measures are conspicuously absent in Nigeria as established previously.

In the light of the function of wetlands in mitigating climate change as carbon sink, there is a need for policy makers to establish wetland buffer zones, reclaim wetlands that have been lost to other economic activities, and encourage sustainable use of the wetlands, among others. This will entail that wetland legislative and regulatory laws have to be enacted and enforced. Individuals are not autonomous in decision making in respect to adaptation. There ought to be guiding rules by government institutions that should cover areas such as regulatory structures, property rights and social norms, and associated rules in use (Adger et al. 2005).

Adapting measures that will mitigate climate change has to be multidimensional and not necessary restricted to one component of the environment. Others have also suggested that a multilevel governance approach, by cooperative actions at the different institutional scales, is a step in the right direction toward mitigating and adapting to climate change (Minoia et al. 2009). This they said can be accomplished through delegations of functions from the central government to regional and local governments, so as to support and contribute to the overall effort in reducing GHG through their own policies and actions. GHG emissions can be reduced by the regional or local governments through spatial planning and transport policy, energy-efficient construction, and the renovation of energy-wasting buildings (Minoia et al. 2009) and by promoting renewable sources of energy (Minoia et al. 2009; Mezher 2011). In Nigeria as of the moment, there are no relation between all levels of governance in respect to wetland protection and no regulatory laws, exposing the wetlands to untamed usage. The wetlands for now are synonymous to being an open access. Promulgating laws to protect the wetlands is eminent.

However, policy makers are not only expected to enact laws but ensure that they are enforced. An assessment of the study by Sonak et al. (2011) on Goa wetlands shows that although there were existing legislative rules put in place to protect this particular wetland, implementation was marred by corrupt practices of the officials, leading to policy distortions and weak implementation. Unfortunately, corruption for now is a serious epidemic problem confronting governance in Nigeria at all spheres. Nigerian government therefore has to ensure that laws for protecting the wetlands are not only formulated but implemented. Adopting the above-recommended strategies will not only enhance wetland ecosystem but ensure that it continues to provide its ecological services amidst changing climate.

Conclusions

The management of the natural resources, the natural environment, and the wetlands in particular is therefore crucial to sustainability and climate change mitigation in Nigeria, Africa, and the world at large. Local authorities need to pay attention to the stocks of natural, social, and cultural capital in their communities, since all of these can decline over time in the absence of private and public investment to maintain or increase their value (Saunders and Dalziel 2010). In accordance with Ramsar recommendation, the government and the planning authority in Nigeria can identify wetlands that are of ecological importance and designate their sites for protection at the local levels. This according to Minoia et al. (2009) can be accomplished by the local planners and institutions through evaluation of all the sectors so as to identify the best sectors that needed to be regulated locally and by which planning tool. Research gap exists in information dissemination among researchers, policy makers, and wetland users in respect to human impacts on the wetlands and the resultant effects on global warming and climate change especially in the developing countries. Research findings on wetlands and climate change for now are within the corridors of academicians and researchers. Further studies may therefore focus on reviewing studies on dissemination of research findings on wetlands and climate among the various stakeholders in Nigeria and other developing countries. Erwin (2008) established the need for educating both the public and private sectors so that wetland protection, management, and restoration can be redefined by all in view of climate change.

Understanding and Managing Climate Change Risks and Adaptation Opportunities in a Business Context

Ioannis Chrysostomidis and Lisa Constable

Contents

Abstract

Climate change poses complex challenges for business not only because of uncertainty associated with the timing and magnitude of projected changes but also because of the interconnectedness between risks and impacts in the modern globalized economy. Drawing on the practical experience with forward-thinking companies in the extractives, chemicals, power, transport, and agriculture sectors, this chapter introduces the concept of systems thinking for managing climate risk and developing adaptation strategies and presents four key steps that businesses can take to (1) understand climate context, (2) assess climate

risks and opportunities, (3) develop a business case for managing climate risk and build resilience throughout their value chain, and (4) create a strategy to provide direction and ensure integration within the business. It also presents practical examples of how businesses are addressing these challenges through case studies in a number of business sectors. By providing a means for companies to "see the wood for the trees," the practical actions required to manage climate risk are demystified, and business leaders are provided with tools to help ensure that their companies are proactive in understanding and managing climate risk and adaptation.

Keywords
Climate risk and adaptation • Resilience • Risk management • Systems thinking • Scenario planning and strategy

Introduction

The Earth's atmosphere has always contained greenhouse gases (GHGs), and their ability to trap heat within the atmosphere is responsible for the ambient temperatures under which communities and economies have developed (IPCC 2013). The concentration of GHGs in the atmosphere has always varied naturally as a result of complex cause and effect feedback cycles within the long-term carbon cycle, which is affected by photosynthesis and respiration of plants, weathering of silicates and organic carbon, ocean circulation, and precipitation (IPCC 2013).

Temperature and atmospheric GHGs are intricately linked in this system, and the Earth has already experienced a modest increase in global average temperature of 0.8 °C since preindustrial times (World Bank 2012). Changing mean surface temperatures affect atmospheric circulation, and even small variations in average conditions can have a big influence on weather extremes such as droughts, floods, and hurricanes, as have been witnessed around the world over the last decade (IPCC 2012).

As climate-related risk events become more frequent and climate change continues to modify operating environments, risks and opportunities will grow in importance for business.

Given the complexities of the natural system, the impact of climate change is far reaching and has numerous interconnections with other risks and facets of society as illustrated in Fig. 1 which shows risks linked to failure of climate change adaptation.

A system is a set of interdependent components that through their relationships with each other form a complex integrated whole. Changes in any of the systems components illustrated in Fig. 1 can have domino effect implications for any of the others given the feedbacks integrated within the system. For example, failure of climate change adaptation can exacerbate both the likelihood and impact of other risks, and the bolder the line, the stronger the correlation. Global governance failure, water shortage crises, water supply crises, persistent extreme weather, and

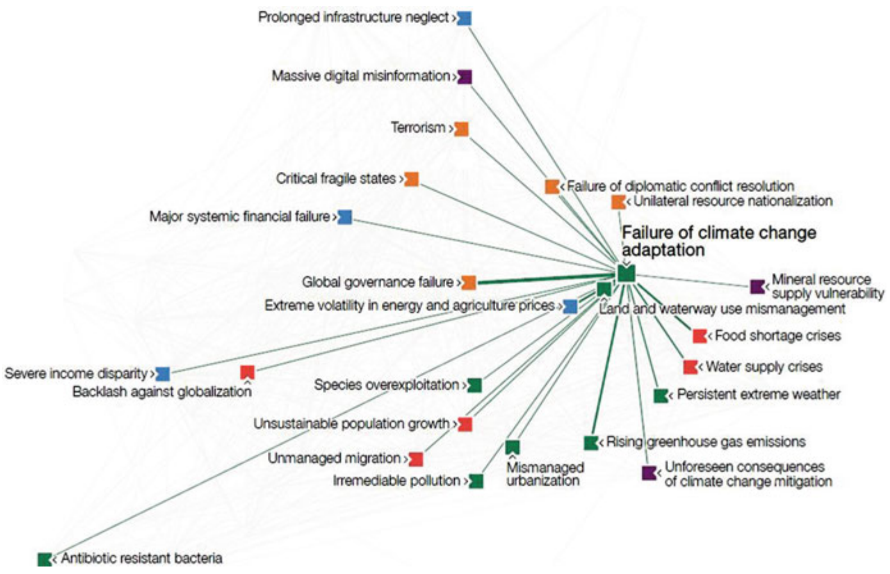

Fig. 1 Systems diagram for risks associated with "failure of climate change adaptation" (WEF 2013)

rising greenhouse gas emissions are the categories most correlated with failing to adapt to climate change (WEF 2013).

A web of interdependencies can give rise to additional risks that are connected within the risk system and once manifested can have knock-on implications within business and societal systems.

Risk Interconnectedness and Domino Effects

Take, for example, the agriculture sector which is being impacted by persistent extreme weather such us flooding and droughts. A failure to adapt to such events could cause food shortage and water supply crises and subsequently increase the risk for other connected events such as unmanaged migration (e.g., millions of people in East Africa as the region suffers its worst drought in half a century) (BBC 2011). It can also cause governance failure and nondiplomatic conflict resolution (e.g., the Darfur conflict in Sudan was fueled by decades of persistent drought) (Humanitarian Exchange Magazine 2008). When risk interconnectedness is "unpacked," it becomes evident that there is a lot more at stake than just what is obvious.

Furthermore, like the complex system which creates the risk, modern business is globalized, interconnected, and interdependent, both vertically (throughout the value chain) and horizontally (companies among same sector), and this can further complicate profiling business risk for a company. A good example is the 2011 floods in Thailand which caused a number of computer hard disk (HD) drive manufacturers to shut down. Aside from businesses like Western Digital and other HD manufacturers who were directly impacted by flooding, the domino effects of this incident resulted in a global shortage of HD drives impacting the sector's *customers* (the computer manufacturer Hewlett Packard lost approximately US$2 billion) and *employees* (NEC slashed 10,000 jobs worldwide amid performance fears of its platform business that was hit due to flooding), all the way down to *consumer* and *business* level (adding $5–10 to the cost of each hard drive and ultimately computers) (Associated Press 2012).

One way to analyze these interconnected risks and opportunities is with *systems thinking*. A systems thinking is a "dynamic thinking" approach which promotes the understanding of risks and their boundaries within a system, how they influence one another, and what patterns emerge and manifest within a value-generating system. It encourages one to "push back" from events and points in time to see the pattern of which they are a part of. The implication is that one will be capable of dealing with a dynamic, rather than only a static, view of reality and thus manage risks better (Barry Richmond 2004).

These interconnected risks and systems are usually beyond a company's capacity to influence or control, but systems thinking combined with approaches like scenario planning offers management a means to entertain possibilities and attempt to both strengthen resilience and reduce the impact cost where this is needed.

This chapter introduces the concept of using systems thinking in conjunction with traditional risk management methodologies to support adaptation and provides a step-by-step guide to understanding and managing climate risk and adaptation – including discussion on scenario planning and how it can be used in a business context to strengthen resilience.

Overview of Climate Risk

Weather varies around long-term climatic averages with some years experiencing above or below average rainfall/temperature producing one-off extreme events such as flooding, heat waves, drought, cyclones, etc. The frequency and severity of events have traditionally been relatively predictable within critical coping thresholds as illustrated on the left-hand side of Fig. 2.

The critical threshold is the point beyond which the consequences are considered unacceptable to the business. Thresholds may be natural, such as the water level at which a river bursts its banks, or a temperature threshold above which machinery cannot operate effectively, or they may be socially constructed based on risk attitude, such as the 1 in 200-year return period for coastal inundation.

The increase in atmospheric GHG concentrations is causing long-term average climate and weather conditions to change. This means that weather vulnerability could increase as the number of extreme events exceeding the critical coping threshold rises over time, as illustrated on the right-hand side of Fig. 2. Basically, climate change loads the dice in favor of more frequent and/or severe extreme

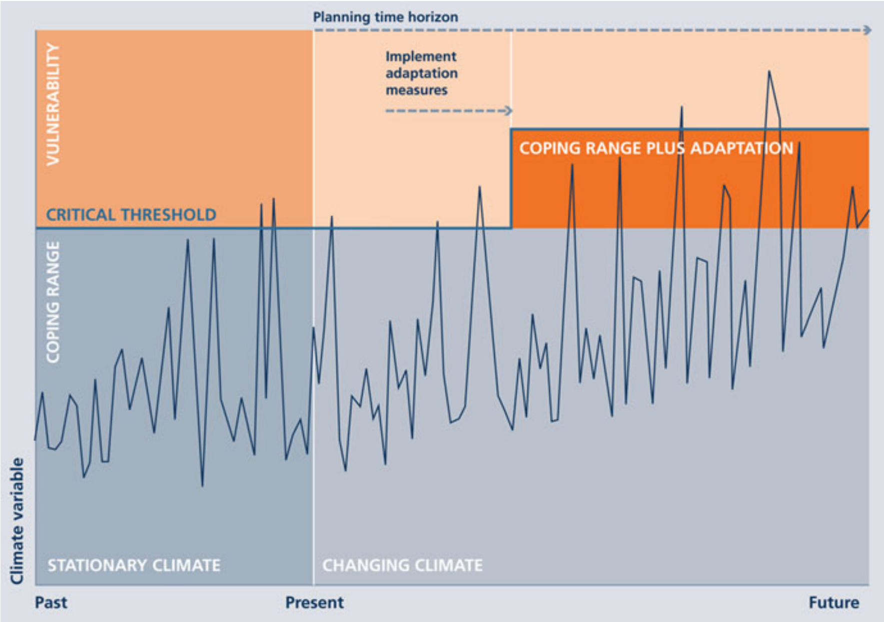

Fig. 2 Climate variability and coping ranges (Willows and Connell 2003)

weather events. Consequently, a critical design threshold (e.g., 200 mm rain in 24 h, 160 km/h wind speed) is expected to be breached more often and/or more severely now, compared to 20 years ago, and in the future compared to now.

The risks and opportunities from long-term climate change are not as easy to identify as those from extreme weather events. There is an anecdote about boiling a frog which is useful in explaining our collective fundamental difficulty in reacting to significant changes that occur gradually. As the explanation goes, if a frog is placed in a pot of boiling water, it will quickly jump out of harm's way. However, if the frog is placed in a pot of water at room temperature and the temperature is slowly turned up over time, the frog will only seek to adjust its own body temperature to match that of the environment, and by the time the temperature becomes deadly, it is too late for the frog to escape. Jumping into boiling water can be compared with experiencing extreme weather events – generally easy to detect and relatively easy to enhance resilience. On the other hand, the impact of incremental changes in temperature are not necessarily easy to identify, and it is important to think about how long-term climate change might affect activities before getting too comfortable in the cooler water and becoming less attuned to the change taking place gradually.

In this context, forward-thinking businesses are beginning to identify their exposure not only to extreme events but also to gradual climate change. They are looking to understand the financial implications, enhance the resilience of their operations, and readjust their core business strategy going forward. Such companies already identify innovative advantage and competitive edge through adopting strategies which provide solutions to real problems posed by climate change, in the same way that digital technology has been the driver for consumer growth in the last decade. For example, companies are already moving to take advantage of significant market opportunities that exist in providing solutions to water scarcity (e.g., desalination, water efficiency, water distribution, manufacture of pipes/pumps, wastewater treatment projects, and irrigation projects) to key industries such as power, steel, paper and pulp, and cement (HSBC 2011).

Traditional risk management techniques can help manage and adapt to the operational risks amplified by the changes in the frequency and severity of extreme weather events.

Long-term climate changes tend to be systemic, i.e., influence many parts of the environmental, business, and societal systems with a wide web of impact connections, and can bring risks and opportunities of a different scale. Resilience to risks or positioning to enhance opportunities can be built by taking a more holistic *systemic* and *scenario planning* approach to managing climate change and enhancing traditional risk management approaches (see Step 2 below).

Managing Extreme Weather

Climate change is transforming primary weather/climatic conditions, which in turn influences the frequency and severity of extreme weather events, resulting in unexpected impacts. Interconnected feedback loops within the broader climate system as well as between the cause and effect illustrated in Fig. 3 could result in numerous difficult-to-predict consequences for business activities, a selection of which are illustrated below.

The feedback loops that exist between events and consequences are important to consider as they can create a web of domino effects between orders of cause and effect with the resultant systemic risks being more complicated to manage than the initial link. *Systemic risk* is a risk that has multiple pressure points and is affecting numerous components within a system. Such risk could potentially influence and impact the entire system, as opposed to risk associated only with any one individual entity, group, or component of a system.

In order to understand the impact of climate change, it is necessary to appreciate both the biophysical impacts of altered weather patterns and the operational, social, and institutional implications of these changes. Climate change impacts are seldom discrete as described in the case study below.

Case Study A mining company operating in water-stressed South America pumps water from a desalination plant at the coast to the mine in the mountains. Changes in precipitation could cause landslides and compromise the integrity of the water pipeline. To secure water supply, the site applies for and secures a temporary

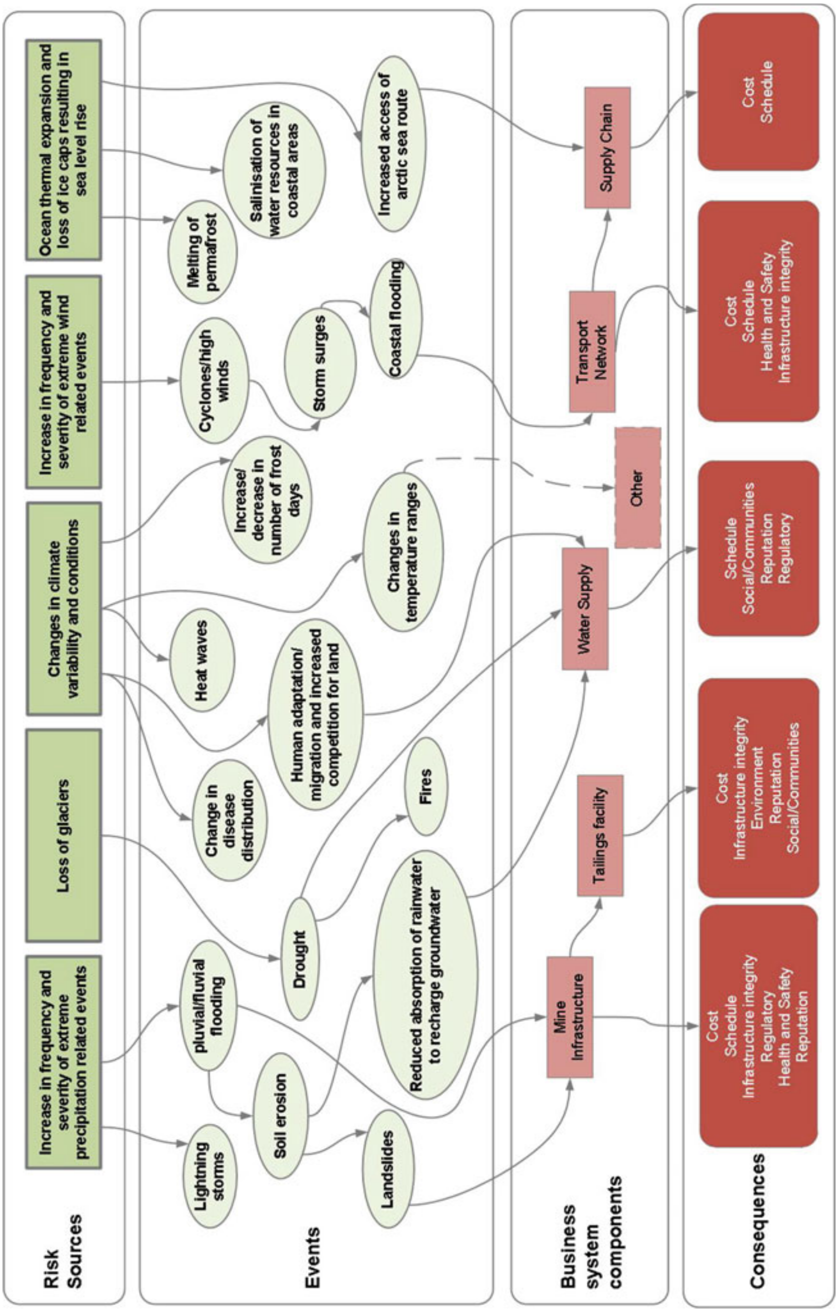

Fig. 3 Climate risk map example for a mining complex

groundwater abstraction license. This source is already under pressure due to historical water stress conditions, and this is exacerbated by reduced groundwater recharge from rainwater due to changing precipitation patterns – the thing causing the problem from the start. Abstraction of groundwater for industrial use at the mine further exacerbates drought in the area and has unintended and unforeseen impacts on local ecosystems and farming activities, erodes local community support, and seriously jeopardizes the project's license to operate.

Business leaders are becoming increasingly more adept at thinking commercially about the system within which they are operating. What this means is framing the systems boundary, identifying the critical interacting elements in the "business system" and how they relate with and affect each other, and keeping the big picture in mind without reducing it down to its component parts in such a way that ignores the interconnectedness. A key aspect to all this is the ability to see relationships between components where once they might have only seen individual parts and to be able to identify the critical relationships that cause the significant positive or negative impacts. It also means being able to look at problem situations and knowing how to resolve them from a variety of points of view and using different *systems* approaches in combination. This approach encourages a kind of creativity to managing a problem.

A certain tolerance to messiness, uncertainty, and ambiguity is needed in order to avoid jumping to solutions too quickly. Spending time in the ambiguity and confusion tends to lead to more elegant, resourceful, and effective responses.

Mapping systems dynamics and identifying and mitigating potential risks early give business leaders the opportunity to refashion their operations, reposition their products and services, and ensure an increasingly sustainable market position.

The remainder of this chapter looks at ways in which climate risk management can be embedded within a systems approach to scenario planning and organizational management aimed at enhancing the resilience and therefore profitability of companies in the face of climate change.

Step-by-Step Guide to Understanding and Managing Climate Change Risks and Opportunities

Understanding the impact of climate change on an organization or site might seem like a daunting task, but focusing the activity in a few simple steps will allow for comprehensive analysis of the business case for undertaking adaptation and the development of a strategy for managing climate risk in the future. The four-step approach summarized in Fig. 4 and discussed in detail in the remainder of this section aims to provide guidance on where to find information and how to interpret it within existing business processes. It draws on the systems approach to ensure that the full range of risks and opportunities are considered and that holistic approaches to managing and leveraging these are identified.

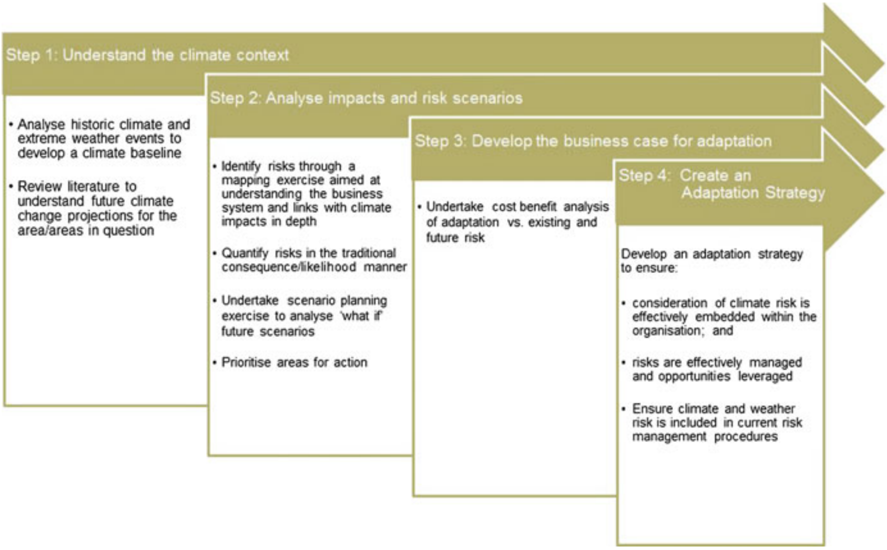

Fig. 4 Overview of step-by-step approach to understanding and managing climate risk and opportunities

Step 1: Understand the Climate Context

The historic climate baseline and projected change in the climate for a project area should be understood so that information on key climate change risks or opportunities can later be identified and ultimately considered in project investment decision making.

Historic Climate Baseline

Information on the climate baseline for an area is important in helping to understand risks associated with current climatic conditions and to provide a reference point from which future climate changes can be assessed as illustrated by the case study below.

Case Study A coal-fired power station in Asia regularly experiences typhoons. Coal storage facilities were originally built to withstand the maximum wind gust speeds experienced at the site in the past 50 years. During typhoons in 2004 and 2005, the domes covering all three storage facilities were torn off resulting in business interruption, reduced efficiency (from wet coal), and high maintenance costs. Analysis of maximum wind speeds in the region around the plant suggests that gusts have reached up to 110 m/s in the past. This figure should form the baseline from which to assess changing typhoon intensity as a result of climate change as it provides an estimate of a possible worst-case scenario in the region.

The following information is useful when compiling the baseline:

- Local weather stations can provide valuable site-specific weather data, including historical temperatures, wind speeds, and precipitation levels. Local environmental/meteorological agencies should be contacted to explore what climate data may be available for an area and how useful it could be in informing the climate baseline.
- National meteorological agencies can provide useful information on "typical" conditions in various regions, such as average temperatures and precipitation levels by month. Information on historical incidences of severe weather events in the region (e.g., floods, droughts, and storms) may also be useful in informing the climate baseline for a site area.
- Global climate datasets (e.g., Climate Research Unit Global Climate Dataset (UAE 2013)) frequently have lower resolution and are therefore less accurate at a site level but can be useful in providing climate data where more local information is lacking.

In addition to establishing an understanding of the physical climatic conditions for the site, information on the social and regulatory climate context for the site should also be gathered.

Climate Change Projections

Having constructed the climate baseline for a site, projections of the estimated change in the regional climate should be analyzed. Climate change projections are typically determined for future scenarios in the middle to the end of the twenty-first century. It is recommended that the climate change horizon selected is in line with the projected lifetime of operations including a period post-closure.

Climate change projections are based on the output of global or regional climate models. These models can be used to obtain climate change projections and data for a particular area. A more textured understanding of projected changes can be achieved through "downscaling" with modeling at regional, provincial, or catchment level. It should be noted that there will be uncertainty in the climate change projections for all climate variables and this needs to be considered in the development of impact scenarios as discussed in Step 2.

Understanding the potential impact to project/operations involves analysis of the climate baseline and projections for the site area in order to understand how current conditions may change in the future. Some example interpretations of climate change projections are provided below:

- Projected increases in precipitation intensity and winter rainfall could mean that in future there is increased flood risk in localized sites in the region that are vulnerable to flooding, for example, sites located at the base of a hill, near to a body of water, or in a relatively flat area with poor drainage capacities.
- Projected increases in average and maximum temperatures could mean that there is increased risk of heat wave events during the hot summer months.

- Projected intensification of tropical storm and cyclone events for a site area located in a tropical cyclone zone could mean that there is increased risk of damage and disruption from storm events in the future.

Step 2: Analyze Impacts and Risk Scenarios

Having understood the impact of climatic events in the past and assessed potential climate change projections in a region of interest, the assessment can now focus on analyzing the impacts and risk scenarios facing the organization.

Risk Mapping

A useful starting point is to generate a *value generation map*. Value generation is the process by which a business creates value from a commodity, e.g., mining activities which create concentrate from ore in the ground; refining raw fossil fuels into other fuels, plastics, etc; and converting crops into luxury products. The value generation process involves a series of inputs, outputs, and associated activities. Figure 5 presents a simple value generation map for a mine and includes the critical *inputs* that need to be sourced (e.g., people, technology, materials, energy, and water) and the *value eroders* associated with mining activities (e.g., mineral and non-mineral waste, landscape/ecosystem alteration, air/GHG emissions, people displacement, etc.). Then follows an identification of a number of *value enablers* and *value protectors* that have to be in place to ensure the uninterrupted flow of inputs (water supply, energy power supply, transport network, etc.) and management of value erosion (e.g., tailing facility, waste rock facility, etc.). It is worth noting that this map is not linear and there are also connections between enablers and connections themselves, e.g., failure of the tailing facility (i.e., a value protector) can jeopardize the presence of a series of value enablers (e.g., community support, license to operate, etc.). Developing such a map will allow for better identification of the critical business components and how they are connected and where the climate risk assessment should focus from an impacts perspective.

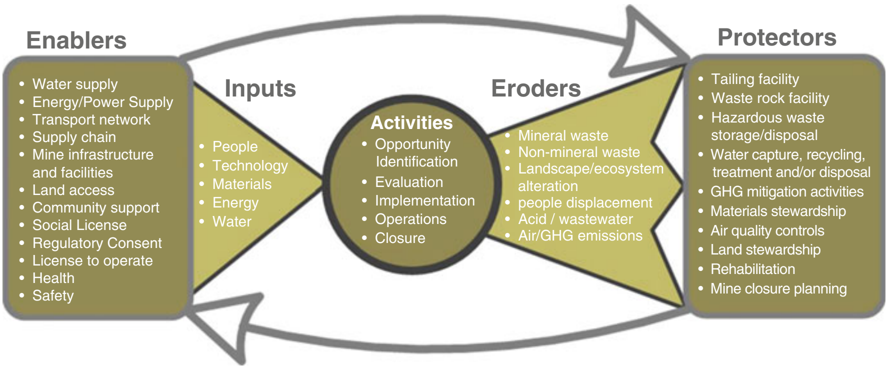

Fig. 5 Mining value generation map

Following the identification of value enablers and protectors, the next task is to develop a *climate risk map* in order to obtain a complete overview of the situation including systemic interconnections. This includes identifying the possible risk sources and associated events, the influence these may have to different components within a business value-generating system, and the likely consequences should the risk materialize. The way climate change interacts with a business system represents complex systems dynamics that would be influenced by long-term climate change (i.e., risk sources) but manifested in distinct events (e.g., risk of flooding, risk of landslides, etc.). A simplified example of this focused only on flooding at a mining complex, and how this might impact value generation protectors and enablers is illustrated in Fig. 6.

Quantifying Risk Using Traditional Methods

Quantitative methods have been developed to help respond to the need to understand and assess the potential impact of extreme weather events and the associated risks. Quantitative assessments focus on assessing risks that arise from an increasing frequency and severity of extreme weather events using likelihood/consequence based on traditional risk management approaches.

Insurance records, underwriters' reports, insurer's catastrophe modeling and operating data, and historical incidence databases along with climate change projections and other data sources can be used in conjunction with sensitivity analysis to quantify relative changes in risk. The purpose is to support judgments about typical business interruption delays or proportion of assets damaged to take account of the specific vulnerability to a given threat. For example, a transport route that has experienced damage or closure due to flooding in the past would be considered highly vulnerable. The key calculation traditionally combines event frequency, severity, financial consequence, and projected climate change to determine the level of risk to a company's operations and assets.

This standard risk assessment process typically involves two steps, with the baseline or existing risk assessed in the first stage as illustrated in Fig. 7.

Once the baseline risk has been identified, frequency and severity parameters can be modified based on values that come either from climate change projections (depending on level of confidence), stress testing or scenario planning (see below), or a combination of these as illustrated in Fig. 8.

Likely impacts to an asset should be considered for the life of the facility including a period following closure and should typically cover the assets, activities, and operations, including the supply chain, as illustrated in the following case studies:

Case Studies *Increased precipitation, flood, and landslide risk* – A regional transport infrastructure development project in Africa looks to ensure that upgrade and new infrastructure projects are resilient to changing risk profiles in 50–100 years by designing bridges, roads, ports, and railways to higher flooding, rainfall, and land stability specifications than has been the case in the past.

More frequent or severe heat wave events – A gas-fired power station in India currently experiences 1.5–3.5 % reduction in generating capacity per year as a result of for each day exceeding 28 °C. As mean temperature in the area is projected

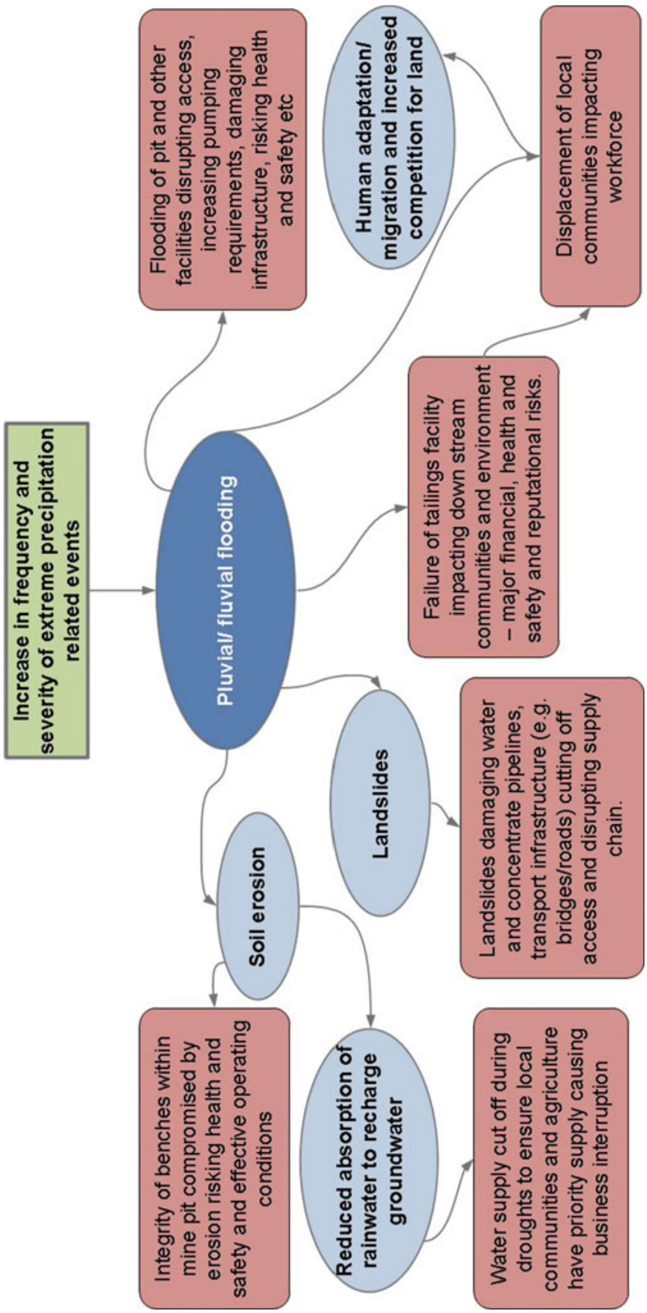

Fig. 6 Flooding risk map for a mining complex

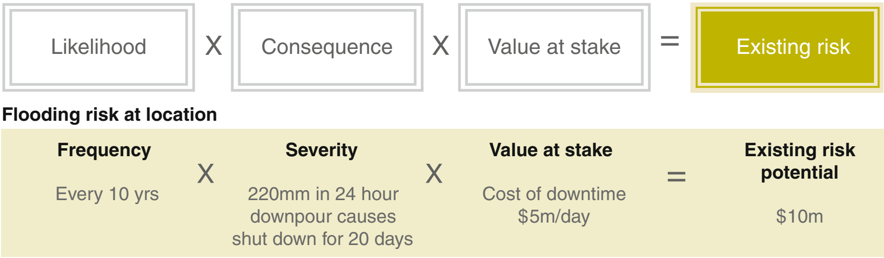

Fig. 7 Assessing baseline (existing) risk (ERM 2012)

Fig. 8 Estimating future risk (ERM 2012)

to increase by 3 °C, the number of days exceeding 28 °C will increase further reducing the generating capacity of the plant. Given that power demand rises during heat waves through increased use of air conditioners, this reduction could risk security of supply and contribute to heat stress in employees and the local population.

More frequent or intense cyclone events – A chemical manufacturing company's facilities in Mozambique and the USA are shut down during cyclones to ensure employee safety and limit the number of people on site in the event that access is restricted. Their facilities in South Africa have experienced supply chain disruption with heavy seas, caused by cyclone/storm activity, preventing feed-stock import.

Changing temperature and precipitation patterns – Recognizing the impact of climate change on biodiversity and ecosystems, a mining company considers how natural vegetation might change in the future in order to ensure that rehabilitation activities and the mine closure plan reflect the potential climate once operations cease in 50 years' time and that sustainable measures are recommended rather than trying to replicate an environment which no longer occurs in the area.

Enhancing Traditional Risk Management Approaches

Risk Amplification

Businesses are constantly undertaking investments on the basis of a set of technical or nontechnical risks that in most cases are considered static and unrelated. For example, social issues in relation to water resources and resettlement may have been identified and are being addressed, but if the effects of climate change are not taken into account, then the sustainability of the solution is not secure and water and social issues may be amplified in the future. Business leaders would be well advised to further consider how climate change and other critical factors might amplify seemingly unrelated risks and their relationships among them or create new opportunities.

Some questions which should be considered during decision-making processes include:

- To what extent will climate change amplify items in the existing risk register?
- How would changes in one set of risks affect other risks in the register or create new risks?
- Proposed resettlement, closure, or environmental/biodiversity management plans will perform differently 30 years from now. How can these plans be modified, and/or what measures can be put in place now to ensure effective performance within and outside the organization in the future?
- How can an operation's supply chain and logistics strategy take advantage of the new transport routes (e.g., arctic passage) or future changes in market conditions?

Stress Testing

In addition to using climate projections, stress testing can be a useful exercise where a "what-if analysis" can be used to assess the resilience of a given operation to hypothetical external shocks. This could assess, for example, what might happen to a project's risk register if future climatic extremes are being underestimated by 20 %. This process can help with uncertainty associated with climate change projections and identify vulnerabilities and opportunities for quick wins.

Scenario Planning

Scenario planning recognizes that many factors may combine in complex ways to create future scenario stories both plausible and surprising. Scenarios take into account climate change and how it might interact with other risk drivers that are not necessarily solely climate-related. For example, scenarios should be developed for social, political, economic, and regulatory issues relating to water scarcity, temperature rise, etc.

The types of indicators used to develop scenarios fall into two broad categories:

1. Those which are relatively *certain* such as demographics, water users in the area, etc.
2. Those which are relatively *uncertain* such as the exact timing and impacts of changes in precipitation, the magnitude of a landslide, etc.

By collecting information about trends and attempting to spot a pattern, trend analysis can be used to inform a series of possible future events. By combining certainty with uncertainty, business leaders can start forming future scenarios beyond the obvious asset impacts. The value of scenarios is that they help companies understand how the various components of their complex and interconnected risk landscape are changed if one or more parameters change. This approach can be used for decisions at a project level, e.g., optimizing economic performance of a manufacturing facility, and for strategic planning at a corporate level as illustrated in the case study below.

Case Study A global agribusiness company informed their medium-/long-term global expansion strategy by using scenario planning to build an understanding of future water scarcity issues and how these will be influenced by climate change among other risks (e.g., regulatory, social, economic, political). The exercise involved undertaking trend analysis for all risk categories and developing scenarios by providing different contexts for each region of expansion so strategic investment decisions can be made with these issues in mind at global level. The process helped to identify "red" and "green" flags in their expansion strategy, ideas, and management options for dealing with risks in existing operations and priority areas that might need additional investment in response to issues as influence by climate change among other interconnected risk sources.

Most corporate risk departments already run scenario planning exercises. There is a need for this process to take into account climate change, climate risk, and broader sustainability aspects as they become material issues for doing businesses. The risk management process can be enhanced by integrating climate change and sustainability issues into company's risk management and strategy and by deepening skills in systemic thinking. Scenario planning, used in this way, can then be seen as a key activity for developing the future leaders, giving them the understanding and skills to help shape the future direction and philosophy of the business.

Step 3: Develop the Business Case for Adaptation

Managing climate risk involves intervening in the system and implementing adaptation measures which alter the flow and feedbacks within the system. A comprehensive understanding of how the system functions is essential to ensure holistic solutions are identified which minimize unintended negative consequences. The value generation and climate risk mapping undertaken in Step 2 will provide valuable input to this process.

Intervening in a system means understanding the critical relationships and focusing interactions with these. It means taking account of the intended and unintended consequences – positive and negative – that result from these interactions and consequences in different interconnected parts of the system; the "problem" may well be a symptom of a problem elsewhere. It means being alert to and able to see and detect patterns that emerge and are unintentional as well as those that are designed and intentional.

The individual risks identified in Step 2 should be considered in relation to the web of impacts, with the aim of increasing the coping threshold increased through identification of adaptation measures to prevent, minimize, and/or mitigate the risk. Key is identifying a small number of measures which address a large number of risks.

The type of intervention selected depends on the site-specific nature of the problem and the extent to which it is connected with other impacts. Figure 9 outlines various types of adaptation approaches, and examples of how these can be used to manage water scarcity.

The potential avoided loss and the capital cost of implementing each option should be quantified and analyzed against the cost of the risk determined in Step 2 in order to create the business case for adaptation.

Once the adaptation options to mitigate climate risks have been identified, realistic costs should be estimated, input to a cost-benefit analysis (CBA), and contrasted against the potential averted losses from impacts analysis in Step 2. The CBA aids the decision-making process by giving monetary values to the risks and opportunities and enables a comparison of like quantities. A CBA can help companies in making decisions on whether previously identified adaptation options are reasonably practicable.

Adaptation options aimed at reducing risk linked to extreme weather events can also be evaluated on the basis of their internal rate of return and make the business case for themselves as with any other type of investment.

An example of a water scarcity adaptation investment curve for a mining complex is provided in Fig. 10. It presents a list of adaptation options by positive or negative return of investment (y-axis) and the cumulative expected averted losses in $million (x-axis).

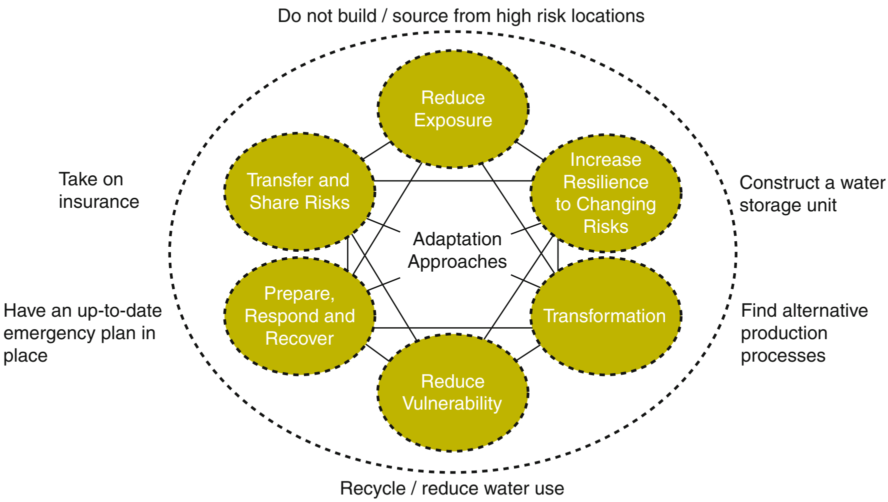

Fig. 9 Types of adaptation approaches with examples relating to drought (ERM 2012; IPCC 2012)

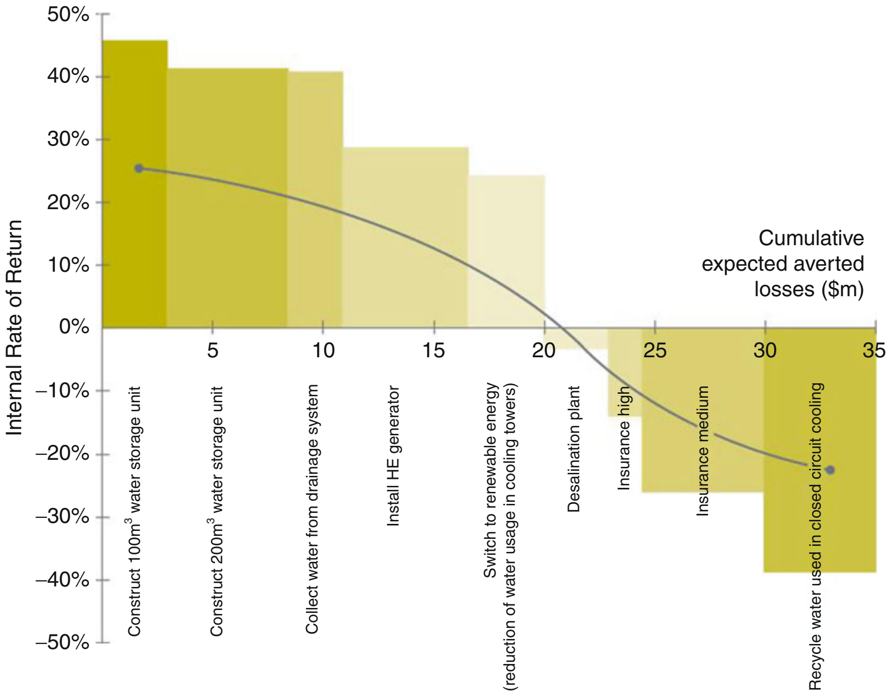

Fig. 10 An example of an adaptation investment curve in relation to water scarcity

Although there is uncertainty associated with the timing of impacts that could represent challenges when calculating the return on investment of adaptation options, companies still find this a useful tool to prioritize and present results to senior management in a clear and concise manner.

Furthermore, sensitivity analysis with regard to the timing of impacts can be undertaken to better describe the uncertainty associated with the investment profile of adaptation options.

It is important to note that financial analysis should not be the only decision-making tool for evaluating adaptation options. In some cases, there will be unquantifiable risks and benefits which need to be considered such as those linked to social and environmental outcomes. It may be that a higher cost option has more unquantifiable benefits than a lower cost option which makes it the preferred course of action as described in the case study below. All the above should be taken into consideration in order to formulate an effective intervention strategy for climate change adaptation.

Case Study Flooding regularly occurs in and around a mining complex in South Africa. The mine is surrounded by local communities housing mine workers and their families and other mining companies. Focusing on managing flooding and storm water discharge within the boundaries of the mine complex misses an opportunity to work with other companies in the area to develop an integrated water management plan and to help reduce the vulnerability of local communities – particularly the informal settlements in the floodplain which are destroyed on an almost annual basis. Collaborative working and a low additional cost could potentially enhance the quality of life for the mine's workforce significantly, in addition to providing a more sustainable solution to water management in a water-stressed area.

Step 4: Create an Adaptation Strategy

The Strategy Development Process

The management of climate risk and adaptation within organizations currently sits somewhere on the continuum illustrated in Fig. 11. The aim of an adaptation strategy is to move toward embedding a systematic approach to climate risk and adaptation into business practices. How an organization chooses to do this depends on the nature of the risks identified, the business case for adaptation, and the company values/ambitions. An adaptation strategy will provide clarity and direction for the steps to address climate risks and opportunities.

Traditional strategy development involves the exploration of the answers to the following questions:

- Where are we as a business today?
- Where are we do we want to be in X years?
- What are the key climate change issues that our business (or project) strategy needs to address now and in the future?
- How can we best position ourselves to take effective action?

The outcomes of steps 1–3 above should provide a wealth of inputs to feed into the standard strategy development process outlined above. Optimization of the outcomes, however, comes with the adoption of a systems approach to strategy creation and organizational leadership.

Fig. 11 Stages of integrating management of adaptation in organizations

In developing a strategy, it is critical to "get the whole system in the room" in order to understand it, engage with it, and see how and where it is relevant for the organization. Rather than seeing strategic planning as the preserve of the "numbers people," collaborative tools for strategy making become essential here in order to bring together all those affected within the system and on the systems boundaries and to engage them in understanding the nature of the situation and its implications. Data and analysis come to the process as inputs, but the key is bringing together different functional disciplines, stakeholders, and generations to interpret the data through multiple lenses and to obtain the deepest insights and uncover solutions to which all players can commit.

The value generation process illustrated in Fig. 5 provides an example of the various connections and interconnections between different elements of the business system. These elements are affected by impacts and adaptation measures and should be considered when developing an adaptation strategy in order to ensure that management of climate risk and the leveraging of opportunities occurs in the most appropriate fora. The strategy that is developed is not only a strategy for the company adapting to climate change but impacts the broader business environment in which the company exists. It recognizes interdependencies between players, climate, and time and puts a value to these.

Finally, the strategy should look to ensure that the organization maximizes opportunities and enhances resilience in the short, medium, and long term depending on the nature of the impacts it is dealing with. This will help ensure that future expenditure and planning take place with an "adaptation lens" and that consideration of climate risk and adaptation is fully integrated within business processes.

The Process and Skills Required

Developing an adaptation strategy this way requires leaders and managers to have a level of fluency in systems thinking or the willingness to acquire this mindset and associated skills. The mindset and skills can be seen as a distinct portfolio of:

- Recognizing systems boundaries
- Perceiving interdependencies in and between systems
- Appreciating the dynamics that underpin complex systems
- Seeking out the points of greatest influence within a system and designing and implementing interventions at these points
- Staying alert to the unintended as well as the intended consequences and responding to these in a way that optimizes outcomes

This portfolio can enlarge the traditional expectations of business leaders around vision and strategy, planning, and execution. It can enable leaders to navigate more effectively through increasingly volatile, uncertain, complex, and ambiguous times and find the right path to address the significant problems that face not only their business but also their broader communities and the Earth.

Using the systems approach as a leadership practice as well as a tool to understand how climate change might influence the relationships within the business system is the key element of the strategy making process and will be what ensure its implementation and sustainability. So a company should ensure that its future managers and leaders participate in the strategy development process, because it is these individuals who need to:

- Own it, be committed to it, and take it forward.
- Understand the climate-related risks and opportunities from a systems perspective, such that this becomes integrated into their way of understanding the business context in which they are operating and that they act from this standpoint.
- Develop and deepen relationships with other stakeholders and build the reservoirs of trust that ensure effectiveness. Trust is the glue that ensures that when unforeseen things happen, stakeholders draw together, rather than pull apart, and find the right path forward together.

Framework for an Adaptation Strategy

The form of a climate change adaptation strategy depends very much on the nature of the business and the values of the company. Ultimately it should become an integral component of corporate strategy development rather than a stand-alone document as this will ensure proper integration with day-to-day activities. To this end, the strategy should build on the company's existing values and policies and focus on priority areas for action. An example of how a strategic implementation framework for adaptation is outlined in Fig. 12.

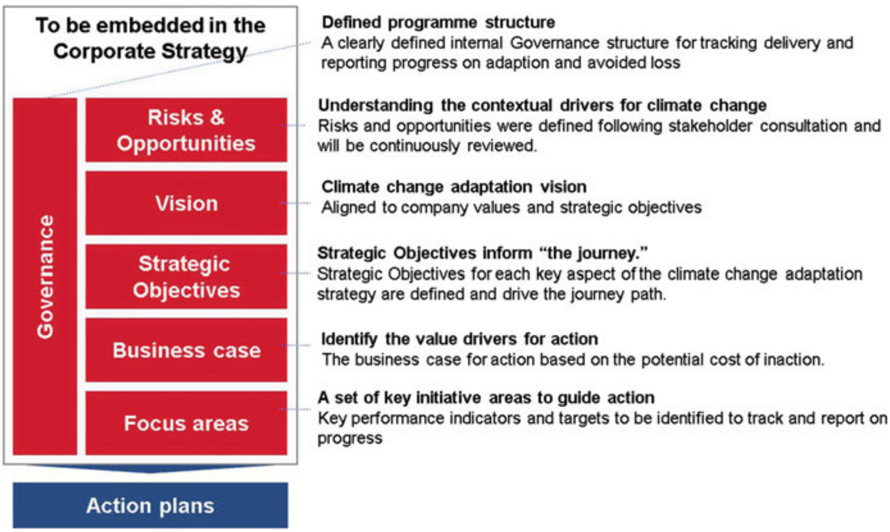

Fig. 12 Example of a strategic implementation framework for adaptation

Conclusion

Climate change poses complex challenges for business not only because of uncertainty associated with the timing and the magnitude of projected changes but also because of the interconnectedness between risks and impacts in the modern globalized economy.

There are traditional approaches for assessing and managing risks and these can be supplemented and further analyzed with *systems thinking*. Traditional risk management techniques can help manage and adapt to the operational risks amplified by the changes in the frequency and severity of extreme weather events. However, understanding of risks and their boundaries within a system and how they influence one another and manifest in impacts within a value-generating system is of paramount importance.

Understanding the impact of climate change on an organization or site might seem like a daunting task, but focusing the activity in a few simple steps will allow for comprehensive analysis of the business case for undertaking adaptation and the development of a strategy for managing climate risk in the future. The four-step approach outlined below aims to provide guidance on where to find information and how to interpret it within existing business processes. It draws on the systems approach to ensure that the full range of risks and opportunities are considered and that holistic approaches to managing and leveraging these are identified:

- Step 1 – Understand the climate change context within which the company is and will be operating through analysis of historic and projected climate data.
- Step 2 – Assess the risks and opportunities that are linked to future scenarios.
- Step 3 – Develop a business case for adaptation through simple economic analysis.
- Step 4 – Create a strategy to ensure consideration of climate risk and adaptation is fully integrated within business activities.

Long-term climate changes tend to be systemic with a wide web of impact connections and can bring risks and opportunities of a different scale. Resilience to risks or positioning to enhance opportunities can be built by taking a more holistic *systemic* and *scenario planning* approach to managing climate change and enhancing traditional risk management approaches. By “seeing the wood for the trees,” managers can identify the practical actions required to manage climate risk, and business leaders are provided with tools to help ensure that their companies are proactive in understanding and managing climate risk and adaptation and leading the companies in the “path of least resistance.” And last but not least, this process is not only about identifying immediate issues and finding solutions but also going through the process itself, building leadership skills, and transforming for organizations and individuals engaged in this process and acquiring a new “systems thinking lens” of the world.

Acknowledgment The authors would like to thank Alison Sayers from ERM for her contribution to the development of the strategy elements of this chapter.

Understanding Impacts of Climate Variation in Varied Socio-ecological Domains: A Prerequisite for Climate Change Adaptation and Management

Nidhi Nagabhatla, Sobhan Kumar Sahu, Armando Gaetaniello, Lijuan Wen, and Wooseop Lee

Contents

Abstract

This chapter examines the impacts of climate variability on selected socio-ecological settings in South Asia. A transdisciplinary conceptual framework is presented that blends multilevel interactions in a social-ecological-climate nexus.

The overarching objective is to draw on empirical experience to build capacity to make use of climate data for societal needs, i.e., to facilitate climate change adaptation planning. The chapter has two modules. The first module, Climate Change Monitoring (CCM), details the operating structure of real-time climate data and its practical use. The second module, Climate Change Assessment (CCA), examines impacts and adaptation options using a case study approach. Focusing on the analytical process, the authors examine three socio-ecological subsystems, i.e., marine fisheries, a rice agroecosystem, and human migration, using a mixed "tool box" of meteorological data, remote sensing images, primary and secondary socioeconomic information, and a variety of software programs. The results indicate that (1) spatial indicators are useful in explaining a decline in marine ecosystem productivity; (2) local-level temperature variability is closely related to agroecosystem transitions; and (3) climatic variability, especially increased frequency of extreme events, triggers human migration. The case studies highlight the need to employ real-time climate data in the design of adaptation strategies and the requirement for a transdisciplinary approach.

Keywords
Climate variability and change • Adaptation • Socio-ecological systems • Transdisciplinary

Introduction

Climate change is acknowledged as a key environmental problem worldwide. Global assessments have classified South Asia as the region that is most vulnerable to the impacts of climate variability and change. To this end, science-based evidence, integrated approaches, and a transdisciplinary mind-set are crucial to ensure that adaptation measures taken are appropriate and effective. The rate of change of climatic processes is such that ecological and socioeconomic systems are shifting toward critical thresholds, a process that in due course will modify the global environmental balance at multiple scales (UNEP 2009). At the same time, the increased frequency of unusual climate events in the recent past has stimulated the scientific community to explore their impact on the stability of earth systems (FAO 2008). Many researchers agree that some climate parameters may well have already crossed critical tipping points, in a process that is irreversible and raises serious concerns for the future of human civilization (Kriegler et al. 2009; Lemoine and Traeger 2011). Climate change is a major overriding environmental issue of our time and particularly a great challenge facing conservation and development managers. It is a mounting crisis in multiple dimensions such as health, economics, and food production/security (quoted, Ban Ki Moon, United Nations Secretary General in his address in 2008).

There is increasing empirical evidence of the impacts of climate change, including abnormal rainfall patterns, increasing surface air temperatures, cyclones, tidal surges, floods, sea level rise, and saline intrusions in coastal areas. These lead to the disruption of environmental and ecological services and loss of livelihoods and thus provoke human mobility. Climate change adaptation measures, including technological aid, financial instruments, and policy, need to factor in the diversity of climate-driven impacts. The gravity of the current situation, the associated uncertainty, the inadequate knowledge, and the manifold impacts of climate change, both anticipated and unanticipated, all point toward the critical need for climate management and adaptation strategies to align with social and economic development agendas (World Bank 2010). To this end, it is important that the socioeconomic consequences of climate change are examined together with other impacts. Integrated transdisciplinary approaches can help deal with the uncertainties associated with climate change assessment and prediction (Nagabhatla et al. 2012).

Global efforts to plan and execute effective climate adaptation measures in accordance with relevant mandates require collaboration between the scientific community, government agencies, and development practitioners, in order to identify and address the principal challenges involved (UNFCCC 2009). A first challenge is to ensure the availability, accessibility, coherence, and accuracy of the relevant data. A second is to foster the necessary expertise and build capacity to analyze data as required for the fulfillment of the defined objectives. A third is to develop the ability to assimilate multiple levels of information, in order to assess the impact of climate change and diagnose the inherent adaptive capacity of the system that is affected (a socio-ecological system in this article). The extent to which one succeeds in addressing these and other challenges will determine the relevance of research and practical initiatives promoting adaptation to climate change (World Bank 2010). Furthermore, downscaling climate information to align with grassroots level research is required to elucidate local-level interactions. This is vital for vulnerability assessment in the framework of climate change adaptation initiatives (Johnston and Williamson 2007). For instance, in order to assess the vulnerability and resilience of a socio-ecological system, information is required on the impact of climate variability on livelihoods (sensitivity), potential risk scenarios at seasonal temporal scales (exposure), and inbuilt coping strategies (adaptive capacity) (Miller et al. 1999). It is essential to take account of climate-related uncertainties in natural resource decision-making and management policies (Banuri et al. 2001). This is a challenging undertaking, since climate dynamics vary at different scales (global, regional, and local) and in different geographical settings; tropical systems in particular are very complex in these respects (Nagabhatla 2012).

Efforts are required to compile and analyze the experiences of initiatives that aim to link modeled and observed information at different spatial scales (Nagabhatla et al. 2012). Scientific research projects and programs involved in testing the competency and compatibility of data models, predictions, and forecasts should widen their objectives to consider not only trends but also patterns of climate irregularities and their potential impacts on natural, social, and economic systems (Hasselmann 1993). To this end, institutions and organizations that produce climate data and develop climate models, such as the Asia Pacific Climate Center (APCC), could act as hubs, fostering partnerships and collaborative initiatives. The APCC aims, through its various new programs, to transfer climate knowledge to a vast set of users. However, experts from the institution point out that packaging climate data in a format that can be applied by experts from different sectors and disciplines is a very challenging task; indeed, it may involve a total recalibration of data and models. The APCC data service system (ADSS) offers a comprehensive set of models and observational climate data for a variety of applications that include monitoring evolving climate events and issuing sub-seasonal to seasonal long-lead forecasts. It also provides a platform for the creation of customized forecasts and analyses of sub-seasonal/seasonal climate variability and predictability (Wang et al. 2009).

The descriptions of case studies in this chapter were produced either in direct collaboration with APCC or by employing their range of real-time climate products. The main datasets employed included satellite-derived earth observation images, climate data, outputs of hindcast and forecast models, and secondary socioeconomic information. It is commonly stated that complex challenges require complex solutions (Ward et al. 2011). With this understanding, the authors employed socio-ecological system as a unit for analysis. The term socio-ecological domain or system is used to refer to a space where natural and social capital interact (Nagabhatla and Kumar 2013). Socio-ecological systems are highly diverse and differ in how they impact or are impacted by climate variability and change (Daw et al. 2009). They are thus appropriate units of analysis for the study and assessment of impacts of climate variability, enabling a contextual understanding of climate-related risk and patterns of extreme climate events. This is a prerequisite for effective climate management, since climate change adaptation measures (interventions, decisions, policy, and governance) must be based on a clear understanding of how natural resource and socioeconomic dynamics interact in their area of application. Analysis of the functional association between climate and the social and economic spheres is as essential as biophysical assessment for effective adaptation to climate change; this applies to local-level initiatives as well as larger-scale programs. The methods discussed here sometimes involve simplifying or deconstructing climate knowledge, as the aim of authors is to highlight how an inter-/transdisciplinary mind-set can prove particularly helpful for their application.

The (Right) Questions

In order to understand the impacts of climate variability in varied socio-ecological domains, it was crucial to ask the relevant questions. A transdisciplinary approach is a prerequisite for planning effective climate change adaptation and management programs. Impressions and perceptions from different stakeholders, both from scientific and nonacademic sectors, are required inputs for the design of a transdisciplinary framework. Based on the above understanding, the following questions were formulated and constitute the overarching focus of this chapter.

1. What kind and type of climate information is important for climate change assessment and monitoring climatic processes?
2. What kinds of approaches and methods show potential to integrate climate-related issues in projects and programs?
3. What kinds of climate processes (abnormal or extreme events) define critical situations, and which climatic parameters are of significance for study of such situations?
4. How can climate data (past trends, current climate dynamics, and future predictions) be used to overcome barriers to adaptation and facilitate effective interventions?

Holistic approaches, as showcased in this chapter, can contribute to improved understanding of multiple layers of knowledge derived from meteorology, satellite data, statistical analysis, and socioeconomic information and, above all, from the interaction of experts from these disciplines working together.

Structural Arrangement of the Study and the Study Area

The first module *Climate Change Monitoring (CCM)* provides a general overview of annual, seasonal, and interannual climate trends at regional and local levels. Hindcast analysis is employed to highlight the variability of two key attributes: rainfall and surface temperature. This module also discusses the potential of forecast information. The APCC's climate information product Multi-Model Ensemble was compared with observation data to assess its usefulness. The second module *Climate Change Assessment (CCA)* adopts a case study approach to explore the impact of climate variability in diverse socio-ecological settings. The selected socio-ecological subsystems are the marine fisheries sector in Bangladesh, a rice agroecosystem in Southern India, and human migration induced by climatic and environmental changes in Bangladesh. The selected systems are very different from each other in many respects; however, food production, livelihoods, and adaptation to climate change are key issues in all three cases. Focusing on these issues, the chapter outlines a conceptual framework for analysis and assessment of climate-led impacts and discusses how up-to-date assessment can facilitate adaptation measures.

Area of Interest: Bangladesh and India

The focal area is South Asia, specifically Bangladesh and India. Consideration of the different socio-ecological circumstances in these two countries highlights the significance of regional and local analysis for climate change monitoring and assessment. Bangladesh is one of the most climatically vulnerable regions of South Asia (Rahman et al. 2007). Agriculture and fisheries are the main sources of natural resource-based livelihoods. About a decade ago (2000–01), marine capture fisheries in Bangladesh, whose territorial waters cover an area of 166,000 km^2, amounted to nearly 22 % of total fish landings in Bangladesh, a proportion that has, however, declined in recent years (Flewwelling 2000). Climate-induced changes, particularly sea level rise, put 12 of 19 districts in the country (>60 % of total land area) at risk, while seasonal flooding represents another big threat to the country's social and economic well-being (Litchfield 2010).

Bangladesh, with its multifaceted challenges, is a prime case of climate-induced threats to human livelihoods. A related concern is the risk of increased climate-induced human migration, both internal (within national borders; those affected are referred to as Internally Displaced People) and external (outside the national borders, generally regarded as refugees). The IPCC's Fourth Assessment Report (2007) reflects on the intensity of human migration that may possibly be triggered as the result of climate-induced changes. For instance, a 1m sea level rise could displace 14.8 million Bangladeshi people, while inundating an area of 29,846 km^2. Recent years have also witnessed an increase in the frequency and intensity of extreme climate events. Many of these exposed a high proportion of the population to coastal and inland floods caused by cyclonic and tidal surges. Growing apprehension for the future of natural resource-dependent livelihoods such as agriculture and fisheries is shared by the development community, resource managers, decision makers, and scientific experts worldwide. However, no clear strategy to address these concerns is yet in place. The country is the focus of attention of global climate experts, both for assessment of the impacts of climate change and to provide guidance on adaptation.

India, with its complex diversity of ecological, social, and economic systems, is also classified as vulnerable to climate-induced changes (Sivakumar and Stefanski 2011). The levels of exposure, impacts, and adaption measures vary among different biophysical and geographical regions. This makes it difficult for experts to arrive at a comprehensive assessment of the impacts of climate change and increase challenge to manage them effectively. As an example of this complexity at local level, described is the rice crop-dominated agroecosystem of Wayanad district in Kerala, South India, an area covering nearly 2,000 km^2. The sociocultural diversity, particularly among the tribal population, is a point of special interest for this region. In recent years, agrarian land use patterns have undergone a notable transformation; with local farmers increasingly opting for cash crop production in preference to the traditional small scale and subsistence rainfed rice cultivation.

Agriculture statistics provide evidence of a steady decline in the area under rice cultivation in Kerala, including Wayanad, since the 1970s. In some areas, this decline is more than 50 % (Nagabhatla and Kumar 2013). Many explanations for such dramatic changes have been put forward by researchers, as well as by local authorities and farmers. In summary, the principal drivers of change may include the development plans that lack holistic insight to balance ecological sustenance and economic stability; the disturbance caused by natural and anthropogenic changes to the environment, climate variability, and change (i.e., fluctuations in onset and amount of rainfall); the relative economic costs of crop production; and the lack of irrigation facilities to meet the growing demand for water. The description in this chapter will focus on climatic variability as the driver of change in agrarian land use.

Module 1: Climate Change Monitoring-CCM

While numerous atmospheric elements influence the environment-human-climate interface, precipitation (rainfall) and atmospheric temperature are considered among the most important dimensions of local-level weather and climate patterns. Real-time climate data is a key resource for the analysis of climate variability. Simulations, predictions, and forecasts provide additional inputs for the interpretation of climate history, typology, and trends, while decision support systems (Crossland et al. 1995) can help translate this scientific knowledge for use in planning practical adaptation interventions (Rizzi et al. 2012). The authors explore this potential with reference to the Indian subcontinent, comparing observed and modeled climate information. The discussion highlights the significance of format, periodicity, spatial, and temporal scale when using real-time data and considers the relevance of predictions and forecasts for adaptation planning.

With regard to forecasting, dynamic seasonal forecasts have potential for use in prediction and monitoring of extreme climate events, including droughts and floods (Luo et al. 2007; Nagabhatla 2012). While prediction and monitoring of climatic trends are demanding processes and the results are subject to a good deal of uncertainty (Hannart et al. 2009), global efforts to understand climate dynamics have benefitted significantly from advances in computerized data analysis, monitoring, and modeling. Wang et al. (2009) describe the initiative by APCC to create a Multi-Model Ensemble (MME), a model-based "output" employed in weather and climate forecasting.

The derivation of MME requires a theoretical analysis of an assembly of deterministic forecasts and typically employs spatial filtering for each variable at each grid point (Wang et al. 2009). In short, appropriate characteristics of several independent models are combined to derive an MME. Tested is hindcast simulation of MME (6 M-1-tier) experimental (downscaled) forecast data based on six coupled models with an annual frequency of 4, i.e., February (MAMJJA, from March to August), May (JJASON, from June to November), August (SONDJF, from September to February), and November (DJFMAM, from December to May), with a resolution of $2.5 \times 2.5°$ at the global domain (144×73 grid) scale, against observation data for Indian region. The hindcast of monthly means for 27 years (1982–2008) was compared with observation values and demonstrated good ability to capture a reasonable portion of rainfall variability on the Indian subcontinent. However, key climate events such as floods were not always captured with high accuracy (Fig. 1a). The level of agreement between the observation data and MME-derived values provides a measure of the capacity of the model ensemble to capture climate phenomenon. Further, the same MME provides inputs for prediction experiments, and the forecast data is available from 2008 onwards (Fig. 1b). Forecast information is a vital component for adaptation planning.

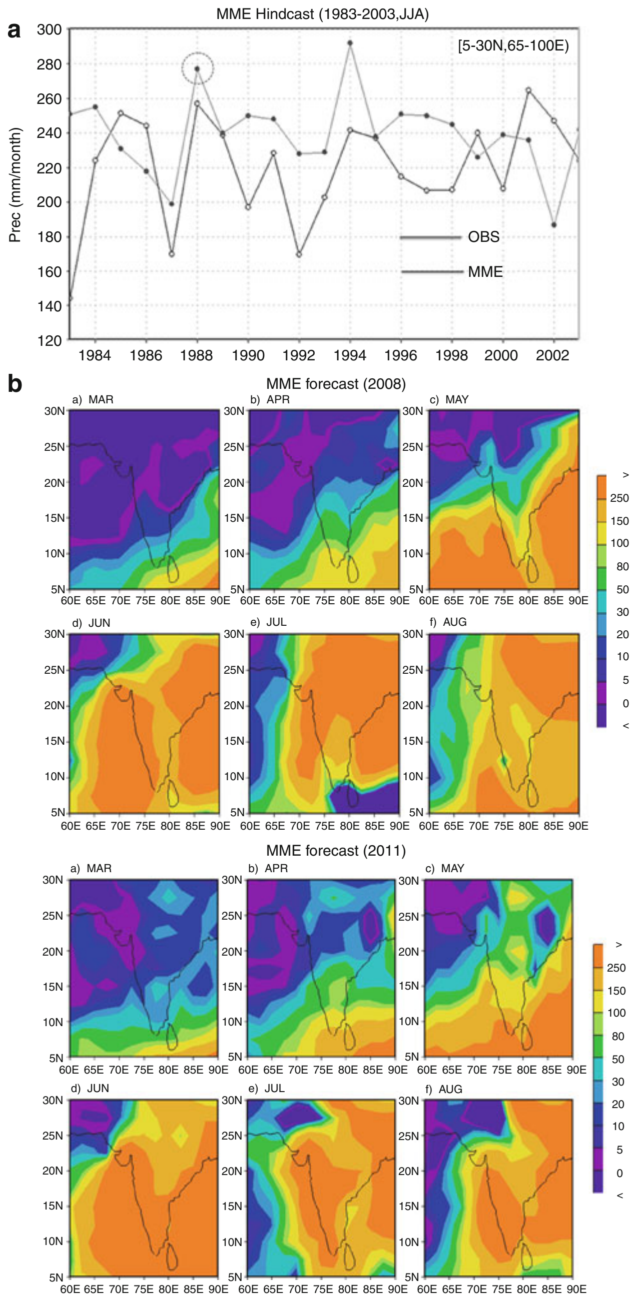

Fig. 1 Multiple dimensions in CCM – part1. (**a**) Modeled data versus observation: MME hindcast tested with rainfall data for India; (**b**) MME forecast for 2008 and 2011 for the Indian region

Currently, only a limited number of the coupled forecasts and ensembles are available for application across different sectors. Improved methods for configuring ensembles are a vital need and remain a long-term goal to enable wider application of climate information across multiple sectors such as agriculture, water management, conservation, and so on (Nagabhatla 2012). The quality of MME depends on the climate models selected to create the ensemble and on whether the selected climate models assimilate the parameters required to capture climate phenomena that are relevant for a particular sector or application. Coupling climate prediction data with resource-specific attributes (ecosystem, socioeconomic, hydrological, etc.) represents a promising way forward to create realistic and practically useful prediction and forecast scenarios. This in turn will help build capacity to cope and respond to change, i.e., contribute to adaptation.

Turning now to the significance of observation data, one may note that climate variability is often expressed as temperature or precipitation fluctuations in a space-time continuum. For up-to-date monitoring of precipitation trends, access to observation rainfall data is necessary. The data is accessed from the web interface of Indian Institute of Tropical Meteorology (http://www.tropmet.res.in). The national-level (for India) data included annual anomaly values for the years 1870–2005 from 316 rain gauges stations and could be conveniently arranged into four seasonal slices (Sontakke et al. 2008): summer (MAM-March, April, and May), monsoon (JJA-June, July, and August), post-monsoon (SON-September, October, and November), and winter (DJF-December, January, and February). Trend analysis is a convenient way to get an impression of shifting or changing climate regimes. The seasonal rainfall trends showed a declining trend in rainfall during the summer monsoon – an observation broadly in agreement with South Asia scenario of Cruz et al. (2007), whereas pre-monsoonal rainfall showed an increasing trend. Correlation analysis of rainfall variation for JJA with frequency of flood and drought events (source: NRAA-2013) provides evidence of increased frequency of droughts and negative rainfall anomalies, especially after the 1960s (Fig. 2a). A research compilation by Mirza (2003) supports the above observation, showing that while many parts of Asia have witnessed both floods and droughts in recent years, the overall trend shows a decline in the number of rainy days and the annual total precipitation.

Similarly, centennial (1901–2001) trends in temperature ($T_{(max)}$ for summer and $T_{(min)}$ for winter) for the east coast of India show increases for all seasons (Fig. 2b shown only for MAM). In the same context, Lal (2003) notes the increasing frequency and intensity of droughts in the region and attributes this trend to the overall temperature increase (especially during summer), as well as to the influence of large-scale climate processes such as ENSO (El Niño-Southern Oscillation). Seasonal prediction of the monsoon phase is crucial for effective application of climate information for adaptation planning and other purposes. Nevertheless, the impacts of climate dynamics vary with sector, scale, and geography and inter-/transdisciplinary collaboration is essential for the adaptation process to be operational and effective. If society is to make use of prediction and forecasting information to design practical adaptation strategies, it is important to understand the multifaceted nature of climate processes (Fraisse et al. 2006).

(**a**) Monsoonal rain (JJA) distribution pattern and anomalies from 1870 to 2005; drought and flood events are highlighted as green and red bars, respectively. (**b**) Centennial trend in summer temperature (anomaly) in east coast India showing a clear increase

Module 2: Climate Change Assessment-CCA

This module explores the impact of climate variability and change on three socio-ecological systems.

Case Study 1: Fisheries, a Sector of Social and Economic Significance

A recent report of the Environmental Justice Foundation (EJF 2012) confirms that Bangladesh is under stress from multiple factors including escalating population, unregulated economic development, transboundary conflicts and, of late, the mounting threat posed by changing climate dynamics. Nagabhatla et al. (2012) describe how annual flooding during the monsoon is becoming more widespread and severe, sometimes submerging nearly one fifth of the country. The impact on communities dependent on natural resources for livelihoods is evident; the direct and indirect impacts of floods on the productivity of marine and freshwater fisheries and the livelihoods of fisher folk are particularly severe (Daw et al. 2009; Nagabhatla et al. 2012). Inland and marine fisheries are a vital sector for the nation's food, livelihood, and economy, making it vital to take steps to mitigate the impact of climate variability on fisheries. To this end, improved knowledge is required on how changing seasonal climate patterns and climate variability affect marine fisheries and specifically their resource-climate-social nexus. This case study explores the potential of real-time climate data to contribute to this understanding.

Technological advancements combined with political and institutional support have helped increase the contribution of the fisheries sector to the gross domestic product of Bangladesh (Deb et al. 2008). However, fisheries resources management has not been able to keep pace with the changing situation brought about by the increased frequency of atypical climate events in Bay of Bengal (BoB) region. Marine fisheries in particular (and the overall functioning of marine ecosystems) have suffered from the atypical behavior of large-scale climate phenomena such as Indian Ocean Dipole and El Niño and their effects on coastal and atmospheric circulations (Ashok et al. 2001). Concern for the future of fish-based livelihoods in Bangladesh is increasingly voiced by the media, development agencies, and national-level authorities (Goswami 2013).

Annual fish production in Bangladesh rose from one to nearly eight million tons in the 50 years to 2010, with sizeable contributions from all sectors: inland, marine, and coastal (Fig. 3a). However, in recent times, the contribution from marine sector has remained static or shrunk. Using secondary data, i.e., records of the Department of Fisheries, Bangladesh, the authors charted the evolution of fisheries landings from 1979 to 2010 in Bangladeshi waters in the BoB region between 5–30°N and 65–100°E. This is the key zone sustaining the majority of the country's marine fisheries (Fig. 3a). The available data covers two historical periods: pre-mechanized (1979–1997) and post-mechanized (1998–2009), i.e., after the introduction of trawlers. The analysis focused on the post-mechanized period. Marine fish productivity was calculated as fish catch per fishing trawl (Fig. 3b).

The remote sensing project SeaWiFS (Sea-Viewing Wide Field-of-View Sensor) is an earth observation mission of NASA (http://www.nasa.gov/) that stores and processes data on global ocean bio-optical properties. Of particular interest for the present study were the data on Chlorophyll (*Chll*-a) concentration, which can be taken as a surrogate of marine biomass. Two other significant attributes that affect the atmospheric and hydrodynamic balance of marine ecosystems areas are sea surface temperature (SST) and sea surface height (SSH). The *Chll*-a data was obtained from SeaWiFS monthly records accessible at the web interface (http://oceanwatch.pifsc.noaa.gov), SST data from NOAA-OISST (National Oceanic and Atmospheric Administration, Optimum Interpolation Sea Surface Temperature), and SSH records from the Archiving, Validation, and Interpretation of Satellite Oceanography (AVISO) data service of the Asia Pacific Data Research Center (APDRC). To evaluate Chll-a, SST and SSH variations over the 12-year period (1998 – 2009) during three 307 seasonal slice, September – November (SON), December – February (DJF), and March – May (MAM), a linear regression-based trend analysis was employed (Fig. 3c).

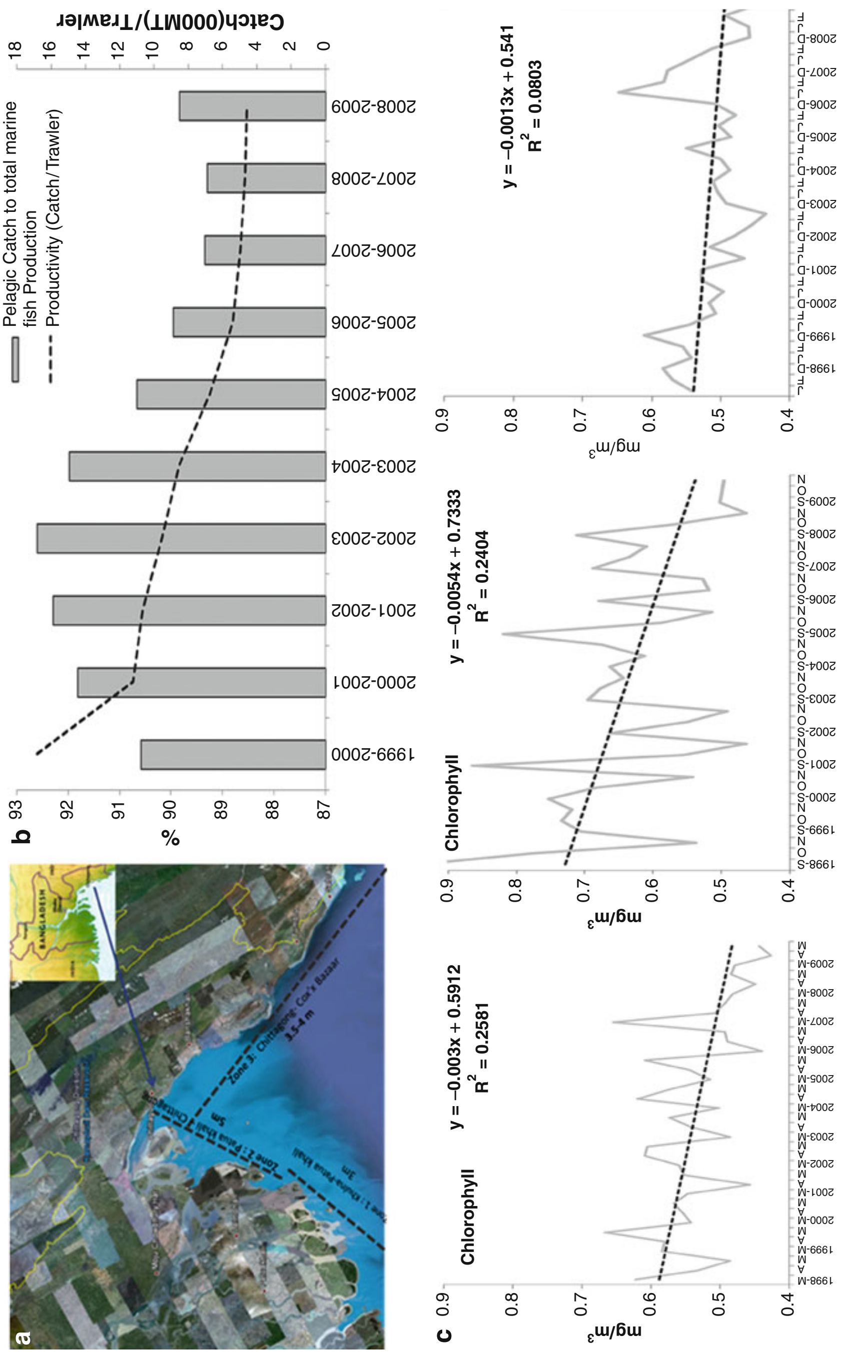

Fig. 3 (continued)

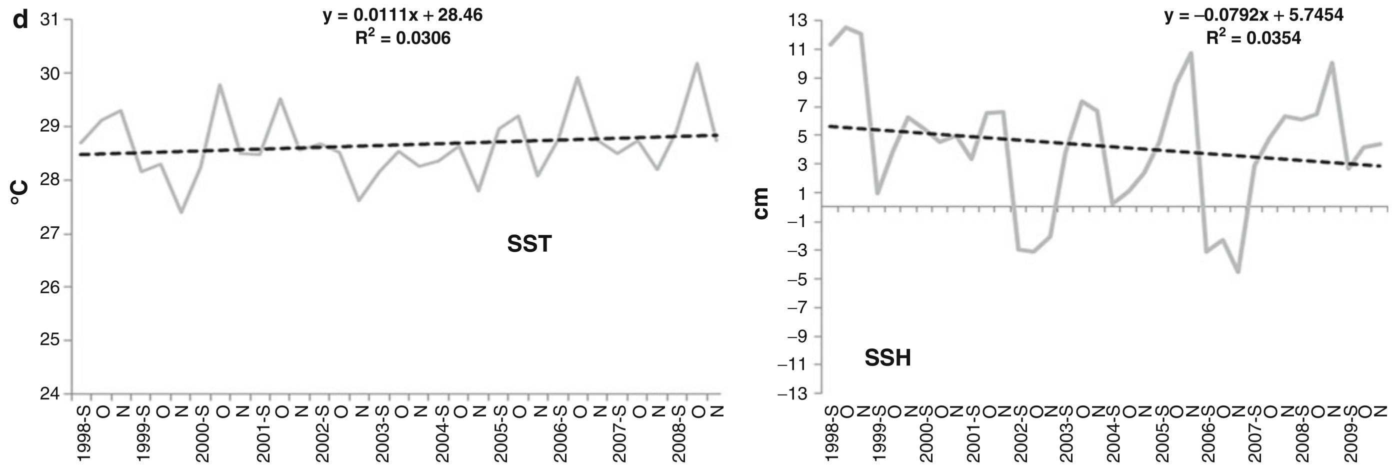

Fig. 3 (**a**) Area of interest – Marine territorial zone of Bangladesh; (**b**) temporal trends in marine fish productivity (1999–2009), measured as catch per trawler; (**c**) distribution of chlorophyll concentration in the BOB region of Bangladesh. Marine fish productivity and chlorophyll concentration both show a declining trend in the temporal slice (1998–2009) under consideration: (**d**) SST and SSH variance in the Bay of Bengal region during SON (inversely related)

The analysis revealed an overall declining trend in marine productivity, shown by a fall in C*hll*-a concentration by almost half, from 0.95 to 0.50 mg/m^3 during SON. However, there was marked variation among seasons, and the decline in *Chll*-a concentration during SON was much greater than in DJF or MAM. In line with the decline in marine productivity, the contribution of marine fish production to total fish production in Bangladesh over the last decade has declined from 20 % to 17.5 %. The decrease in chlorophyll concentration can be explained by the increasing trend of SST, which was of the order of 0.1–0.25 °C during DJF and SON (Fig. 3d, shown only for SON).

These results suggest that the warming climate is disrupting oceanic hydrodynamics and the related marine ecology. The increase in SST can in turn be partially explained by the corresponding trends in SSH, both annual and seasonal (Fig. 3d, shown only for SON). Typically, SST and SSH are inversely related; however, during MAM, there is a direct relationship that could reflect the influence of pre-monsoonal local oceanic circulatory processes and currents, together with the effects of land-sea-atmospheric interactions. These seasonal variations likely affect the marine ecosystem and more specifically fish productivity in the BoB region.

The analysis shows how climate observation time series data derived from satellite remote sensing technology can shed light on the complexity of marine ecosystems. In this case, secondary data on fisheries production complimented the satellite-derived spatial oceanographic information. A large proportion of people in Bangladesh depend on marine fisheries for their livelihood, and the sector involves about 9 % of the labor force (Mazid 2002). The fisheries sector is a prominent socio-ecological system in many regions across the globe, and large numbers of people worldwide are dependent on fisheries for their livelihoods. The fundamental linkages between ecological and socioeconomic dynamics mean that it is essential to address climate-related concerns in a collaborative and interdisciplinary manner and for scientists and policy makers to adopt a holistic approach toward the ecological, economic, and social impacts of climate change. Science-based evidence can contribute to the improved design of adaptation policies for the fisheries sector that strike the right balance between livelihoods security and income generation. State-of-the-art technology such as satellite-based remote sensing has facilitated real-time monitoring of the properties of marine systems and driven advances in marine research; however, further efforts are required to improve the accuracy and precision of analyses of seasonal and annual trends. Data on marine ecosystem productivity in the BoB, i.e., on biomass measured as chlorophyll concentration, reveals a sharp decline within a time span of a decade. Biomass distribution affects the growth of fish, and there is a known relation between them. The next step is to work out how best to make use of this information in the process of discussion and formulation of adaptation measures.

Case Study 2: Multifunctional Agroecosystems and the Climate-Driven Transformation

Many scientists worldwide have attempted to analyze crop responses to weather/climate variability by employing a blend of computer generation simulations and experimental research (Porter and Semenov 1999). The significance of climate variables for agronomic studies is well recognized. For example, the thermal kinetic window for a crop variety is an important attribute of the climate that regulates plant metabolism and physiological activity (Mahan et al. 1987). For rice, there is little temperature effect on leaf carbon dioxide assimilation from 20 °C to 40 °C (Egeh et al. 1994). On the other hand, crop growth simulations show that rice yields decrease by 9 % for each 1 °C increase in seasonal average temperature above a certain threshold value (Kropff et al. 1993). This understanding informs the second case study, which explores the process of agricultural transitions that is associated with a decline in rice production in Wayanad, Kerala, South India. Demonstrated decline in the rice production (harvest in tonnes per unit hectare) shows a considerable degree of correlation to temperature variability and specifically to trends in diurnal temperature range (DTR) anomalies. Diurnal temperature range encapsulates daily temperature fluctuations; this is an interesting dimension of climate variability that apparently has significant effects of crop production (Welch et al. 2010), comparable to those of (more frequently studied) seasonal temperature variation (Jagadish et al. 2010).

Most studies relating crop productivity and climate variability focus on rainfall distribution and variance and its effects on plant growth. Few consider temperature variance, and, among these, only a handful selects fluctuations in temperature as the climate variable for analysis (Easterling et al. 1997). Likewise, scant attention is paid to DTR. Fan et al. (2011) define monthly mean DTR as the difference between the monthly means of maximum and minimum temperature values. There is debate about the nonlinear effects of DTR fluctuation on yields of different crop (Gallo et al. 1996). Nonetheless, most studies conclude that negative effects are sharply accentuated outside the optimal fluctuation range [OFR] for a particular crop type (Lobell et al. 2011). An International Rice Research Institute report examines the temperature sensitivity of the most widely grown (and high-yielding) rice variety in the tropics (IR64): when the daily maximum temperature rises from 28 °C to 37 °C, a 50 % drop in seed set is observed, while a further rise to 39 °C may result in the variety failing to produce any grains at all. In essence, temperature dynamics substantially govern the crop yield (Chen et al. 2004).

Wayanad, unlike the other parts of Kerala, has only two rice growing seasons: summer and winter (other regions also have a third crop, autumn rice, grown post-monsoon) (Fig. 4a). To represent crop production in these two seasons, the temporal trend of rice production is taken as surrogate. The climate data for analysis was procured from archives of the Indian Institute of Tropical Meteorology (IITM). The best available dataset, daily values of T_{max} and T_{min} for the Western region of India (which includes Wayanad), was used in order to calculate the mean monthly values. For analysis DTR anomaly, values for monthly mean T_{max} and T_{min} surface air temperature were analyzed using a linear regression equation. Figure 4b shows centennial (1903–2003) trends in DTR anomaly values [i.e., deviations from the mean] for the Western region of India (including Wayanad), segregated into seasonal trends: MAM (pre-monsoon/summer), JJA (monsoon), SON (post-monsoon), and DJF (winter). The figures also show intra-seasonal DTR variations. How should these trends be interpreted?

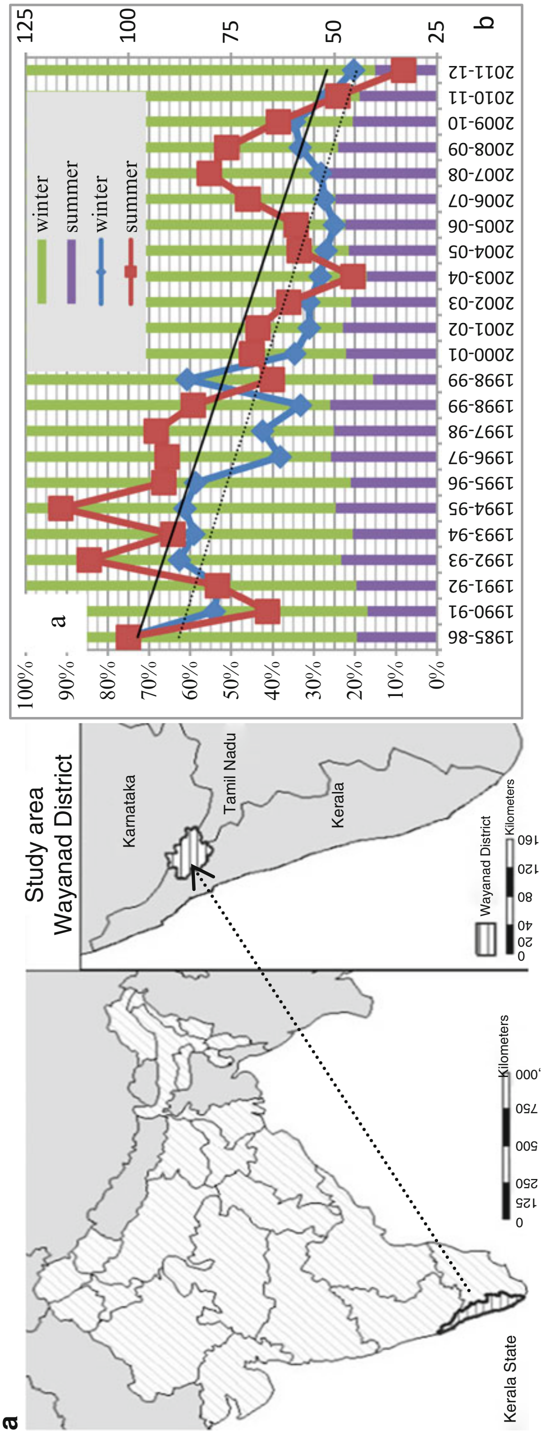

Fig. 4 (continued)

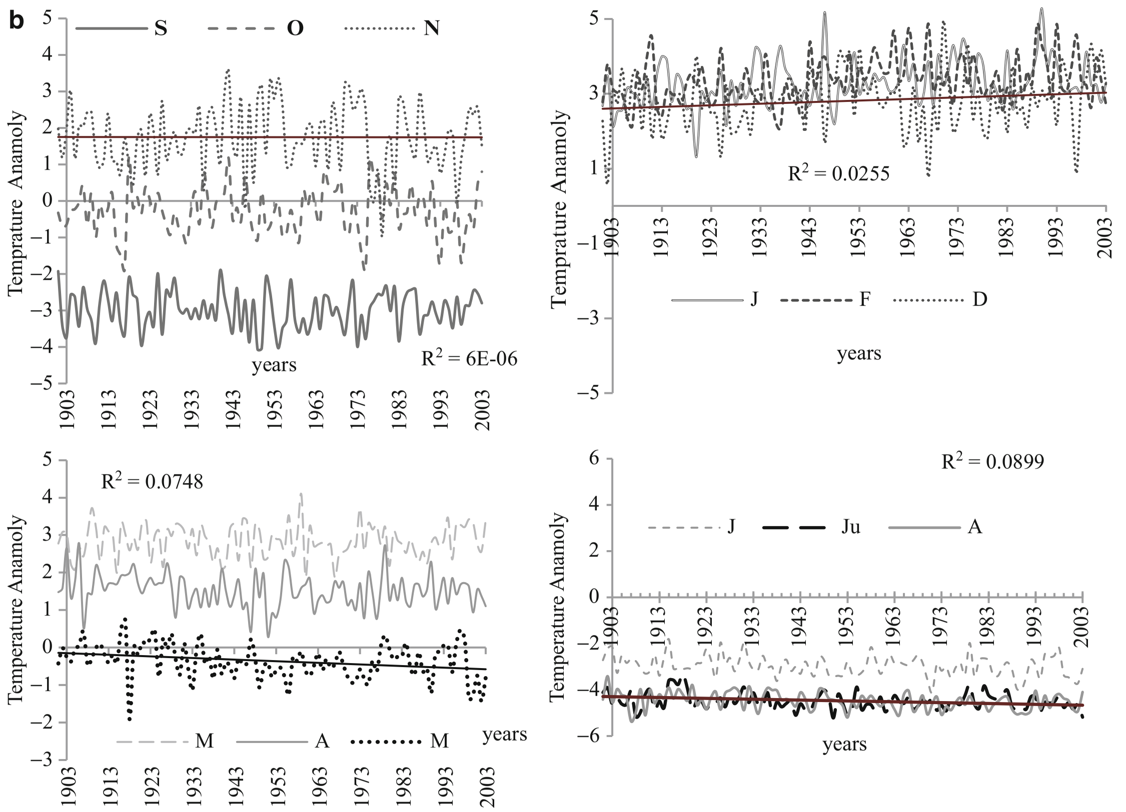

Fig. 4 Location of Wayanad agroecosystem. (**a**) Temporal trend in rice production for two seasons, summer and winter (% on base year 85–86 (*line*), and % on same year (*stacked columns*); (**b**) temporal trend of DTR anomalies for four temporal slices of annual calendar

For DJF, there is a clear positive anomaly, while in May the trend is negative (also in JJA and in early autumn in September). A negative anomaly is a possible indicator of escalating atmospheric warming (if increases in maximum temperature and accompanied by even larger increases in minimum temperatures, reducing the difference between day and nighttime temperatures). For any crop, and especially rice, which is sensitive to difference in day and nighttime temperature, even a small shift away from the optimal temperature range (induced by early warming, increased warming, a change in seasonal maximum temperature range, or reduced difference between day and nighttime temperature) can potentially affect the yield considerably (Jagadish et al. 2010). To examine this possibility, rice production in Wayanad is compared with the DTR trends for the region. Since winter rice is the main contributor to total rice production, a positive temperature anomaly during DJF can be considered to represent favorable conditions for maintaining the yield, while the intra-seasonal variability during MAM can be crucial in determining the harvest. This comparative analysis highlights how comparison of data from different sources can yield new insights, of practical value, into the vulnerability of socio-ecological systems. Specifically, DTR appears to be a useful variable for analysis of the possible influence of climate variability on crop production and its role as a driver of agricultural transformation.

Case Study 3: Climate-Induced Human Migration

This case study examines climate-induced human migration, which is acknowledged as a growing concern worldwide (Reuveny 2007). Regions that are particularly vulnerable to climate change include deltas and catchment areas, low-lying coastal zones, and small islands (Nicholls et al. 2007). Bangladesh is categorized as the region in Asia most vulnerable to climate change and as one of the most vulnerable in the world (IPCC 2007). In addition to classical economic migration (above 3 % of world population migrates annually for work), numerous reports comment on the alarming amount of environmentally induced migration, more recently in connection with climate change. The Stern Report (2006) states that 150–200 million people are likely to be displaced by climate change, while a dossier by Christian Aid (2007) states that the number could be as high as a billion. At a national level, the Internal Displacement Monitoring Center (IDMC) in Bangladesh categorizes one third of the total population as climatically vulnerable, likely to be confronted by the threat of displacement (Yonetani 2011).

The theoretical framework for this study of migration is taken from the Eurostat 2000 report that analyzes migration in terms of the interplay of push and pull factors (Fig. 5a). The concept of Internally Displaced People and Refugees has been adopted for assessing climate-driven migration patterns (Nagabhatla 2012). Drawing on a literature review, discussions with stakeholders and available data (formal and informal, local and national-BBS, 1994), a graphical representation of climate-induced migration in Bangladesh was produced (Fig. 5b). According to Akter (2009), climate-induced human mobility or migration of Bangladesh, driven by natural calamities and extreme events such as floods, droughts, and cyclones, displaces nearly 30 % of the total population each year. Present study, focusing

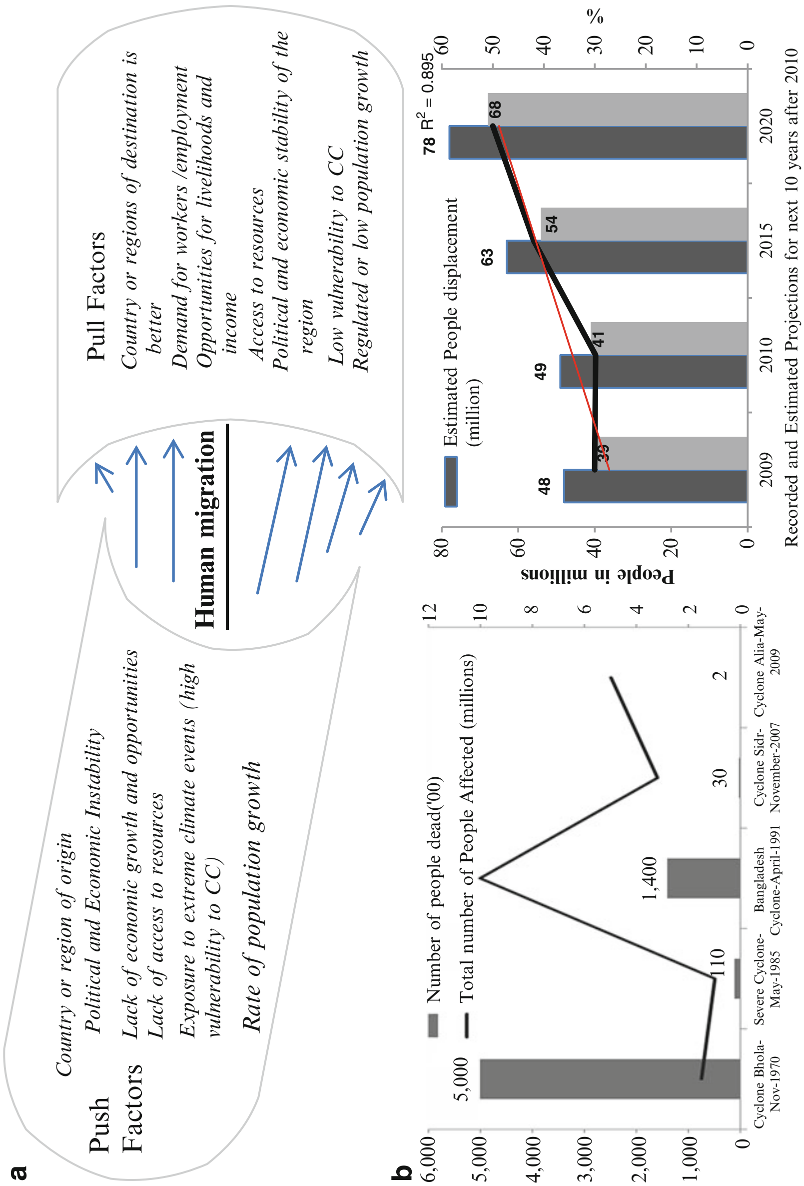

Fig. 5 (continued)

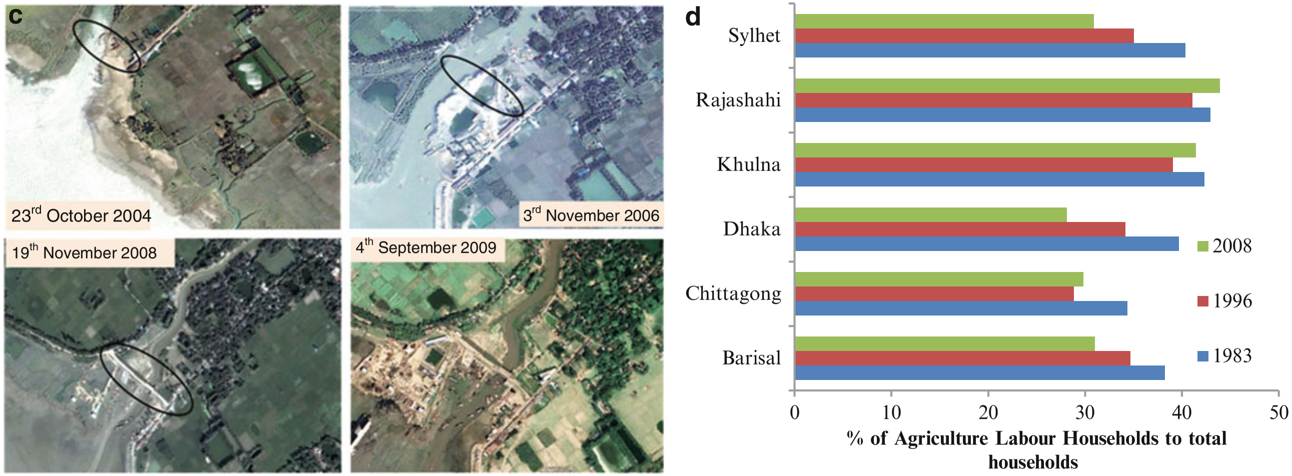

Fig. 5 Climate change vis-a-vis and human migration; (**a**) push and pull factors that are fundamental to drive human migration (Adopted from Eurostat 2000); (**b**) data assimilated from secondary sources for last four decades (1970–2010) and projection for future (refereed from available research) illustrate the intensity of crisis related to human displacement. (**c**) Visual representation of salt water intrusion in coastal Bangladesh that renders croplands unsuitable and pushes locals to migrate for work (Source: Google Earth archives); (**d**) agriculture labor as the selected social indicator at provincial level – an important factor in human migration study

on climate-related determinants of human migration, drew on the secondary data on migration available from various published records, anecdotal information, and the results of surveys by federal agencies. Information aggregation was subject to the common limitation that available data was at different timescales and for different administrative units. This made it difficult to gain an overall view of migration patterns.

At local level, socioeconomic information collected for districts (in Bangladesh, this is the local administrative level below province and state), on attributes such as the total number of households, the proportion of urban versus rural households, and the number of landless households, provided important baseline information for analyzing the impact of climate change and variability on human mobility. In common with most secondary data-based analysis, this synthesis was subject to two main limitations: (a) there were concerns about possible inaccuracies (over- or underestimations) in the data. (b) It was often difficult to separate the required set of information (e.g., for a particular scale of analysis or topic of interest) from the common data pool. For instance, data on human migration recorded by Bangladeshi authorities are national-level records in an aggregate format. So, it is difficult to separate out the human mobility caused by different drivers: economic, environmental, or climatic. A further aspect that was difficult to extract from national records was seasonality, which plays a huge role driving migration, especially climate-related migration.

The statistical analysis of disaster-induced displacement in Bangladesh shows that an average of 2 % of the total population, i.e., about three million people, is possibly affected by cyclones, 25 % (39 million) impacted by floods, 0.1 % (nearly 50,000) by river basin erosion, and about 3 % (5 million) by droughts (ADB 2011, 2005). A total of 26 major cyclonic events affected Bangladesh's costal region from 1970 to 2009; thus in this period, cyclones were almost an annual event. The major cyclones in 1970, 1985, 1991, 2007, and 2009 were the most distressing for human populations and caused the greatest loss of natural capital. Records of human fatalities and loss of assets indicate that the number of people affected is close to the number of people displaced (Fig. 5b). Floods stand out as the type of disaster that displace the largest number of people.

Furthermore, projections in this regard also are very concerning. The country is projected to experience massive environment-driven displacement, affecting in the order of 49, 63, and 78 million people in 2010, 2015, and 2020, respectively (Chowdhury et al. 2009). The alarming estimate that, by 2020, national-level human displacement could affect about half the total population of Bangladesh certainly calls for this issue to be given priority in the national policy agenda. Coastal zones with flat topography and thus maximal exposure to atmospheric and climatic fluctuations are the most vulnerable, as can be appreciated from the estimation that the number of people displaced in these regions will be several fold higher than in inland regions, particularly among the laboring classes. Figure 5c visual represents the condition of salt water intrusion in the coastal zone, the process that by and large impacts the surrounding agriculture landscape. To further explore this phenomenon, a set of socio-ecological indicators of

Table 1 Vulnerability assessment at provincial level in Bangladesh. This process was based on the selected indicators assisted by secondary data

Bangladesh	1(low)–5 (high)	1(low)–5 (high)	1(low)–5 (high)	1(low)–5 (high)
Provincial divisions	Exposure to extreme climate events	Sensitivity (poverty)	Adaptive capacity	Climate vulnerability
Barisal	4	4	2	5
Chittagong	4	3	2	4
Dhaka	2	1	4	2
Khulna	2	3	4	3
Rajshahi	1	5	5	1
Sylhet	5	1	1	4

national-level climate vulnerability was selected. The selected indicators were number of people displaced (taken from official records) as a social indicator (income of agricultural laborers households that are mostly landless is used as a surrogate, as shown in Fig. 5d), poverty as the indicator of the economic situation or economic indicator and the degree of exposure of a resource systems to disasters as an ecological indicator (for details of other indicators, not shown, see Nagabhatla 2012).

Numerical data on above indicators was compared with climatological data at national and district level. Results showed that Rajshahi region had the second highest proportion of landless households (27 %), after Dhaka, the capital city. Nevertheless, evaluation of the whole indicator set at districts level showed that Barisal was the most vulnerable region (Table 1). A study by Chowdhury et al. (2009) is in agreement with current results and also provides information on migration routes. The principal migration flow is from coastal zones to inland areas (up to 200 km inland). In addition, migration from rural to urban zones and from one livelihood sector to another (e.g., from fisheries to industrial labor) is another important dimension. The growth of crowdsourcing in the research and development field opens up opportunities to feed qualitative information and stakeholder perceptions into the integrated decision support systems (Wells 2013). Overall, there is clearly a link between the increase in numbers of internally displaced people and climate dynamics, although more evidence is required on the role of climate change as a driver of long-distance migration, i.e., to show that the term "climate refugees" corresponds to a real phenomenon.

Changes in climate and weather patterns provoke migration not only within a country but also across national borders. This topic has still not received much attention in climate debates and policy. A further difficulty noted by Chellaney (2007) is the lack of clarity on the fundamental nature of human migration, particularly with respect to refugees, including climate refugees. Migration is inherently a transboundary concern and demands a cross-country dialogue and perhaps ratification of migration-specific multilateral agreements. Development interventions, decision-making, and environmental and climate policy on these critical issues and related ones need to be grounded in scientific evidence and ground-level knowledge. Improved accuracy in the forecast and prediction of climate trends and events is a key way the scientific community can contribute to efforts to tackle the issue of migration.

Conclusion

Climate adaption and management is an ambitious task. Data constraints are often mentioned as a factor that hinders integration of climate information in decision-making (Nagabhatla et al. 2012). While the ongoing need to address climate-related uncertainties is apparent, management policies for natural resource governance have not yet been able to satisfactorily factor in the existing and anticipated complexity associated with climate variability and change. For instance, lack of progress in downscaling climate information to fit local requirements is still a matter of concern (Hewitson and Crane 2006), especially since downscaling is crucial for understanding local scale coping strategies and addressing grassroots level problems such as livelihoods and food security. Studies that contribute toward functional knowledge of the complexity that is inherent of climate processes can play an instrumental role in laying the foundations for effective adaptation planning. The two modules of this chapter aim to make a contribution in this regard.

The core of the chapter is the structural weave of the two key modules (CCM and CCA) that (a) elucidates the multilevel interactions within and across different socio-ecological systems, while advocating a transdisciplinary approach; (b) provides an empirical demonstration of the application of real-time climate information covering a range of scales from national to local; and (c) illustrates the multifaceted nature of climate data analysis and its potential to shed light on multiple patterns and trends at inter-seasonal, interannual, annual, decadal, and longer timescales. Clearly these issues – separately and together – are highly relevant for short- and long-term strategic planning for adaptation.

The CCM module highlights how scientifically derived climate information can help to unfold the layers of uncertainty surrounding the impacts of climate change. In fact, scientific observation, monitoring, and modeling have already contributed greatly toward preparation of climate coping strategies (Rozum and Carr 2013). Voices from the scientific community (e.g., FAO 2008), the grass roots (field notes), and the media (Economic Times 2013) coincide in warning that that the long-term impact of climate variability and change may lead to a state of crisis, most likely related to food and water insecurity. Taking heed of these warnings, adaptation planning in multiple sectors, including agriculture, water management, business, development, and conservation, must go hand in hand. Cross-sectoral planning can benefit hugely from application-ready forecast and hindcast climate products, for example, MME. The forecast simulation (using hindcast data) for the Indian region shows a fairly good level of agreement with the observation data, indicating the potential for model-based forecast prediction. MME forecasts captured overall trends of annual and seasonal rainfall; however, events such as floods and extreme anomalies in annual rainfall were not captured with a high degree of confidence. Likewise, tropical monsoon forecasting remains a perplexing task for climate experts (Goswami and Krishnan 2013). In summary, the outputs of climate modeling can be of practical application for adaptation planning if input variables in climate models are set for specific applications (i.e., by customizing application-specific ensembles).

Dialogue on climate change involves experts from varied sectors such as energy, sociology, finance, trade, ecology, economics, and politics, who often ask for projections of possible climate-related impacts on their respective domains of interest. However, it is rare that experts from these different disciplines come together to work on a common domain of interest. Transdisciplinary collaboration has the potential to detect complementarities in adaptation requirements across varied socio-ecological systems. From this perspective, the second module of the chapter provides examples of how climate data can be used as a frame of reference by a range of stakeholders to assist adaptation planning, for example, in the context of case study from Bangladesh, by planning climate smart agriculture that secures livelihoods not just for land owners but also for agriculture laborers, can indirectly mitigate climate-induced human migration.

Additionally, the CCA module highlights the importance of understanding climate interactions in varied social, economic, and environmental contexts and at different scales and for different seasons and regions. The selected case studies demonstrate the application of climate information to three subsystems. The first case study clearly demonstrates the declining productivity of marine fisheries in Bangladesh over the last three decades. One might assume that state-of-the-art technology and fishing gear would have helped alleviate the problems of the marine fish industry and associated livelihoods. However, two factors are crucial: firstly, technology enabled overharvesting of fish resources; secondly, the combined impact of overharvesting and ocean-land-atmosphere dynamics (i.e., local-level climate dynamics) has depressed marine ecosystem productivity. Integration of climate attributes into a reanalysis of the causes of changes in productivity is an example of a synoptic calibration of climate data for sector specific study. This sort of calibration is crucial in order to project long-term impacts on food and livelihood security in the region. In-depth examination of the seasonal and temporal correlation between marine fish productivity and climate variability expressed in terms of changes in chlorophyll, SST, and SSH provides new insights into the problem of declining biomass in marine systems.

The case of agroecosystem in Wayanad in Kerala is a very typical example of local-level analysis. This case study examines how climatological changes alter seasonal temperature patterns that in turn affect crop physiology, potentially disrupting the cycle of regular growth and reducing crop productivity. Productivity is, in turn, a key factor in decision-making on crop selection at the farm level. Transformation in the agroecosystem, specifically a market-driven shift from conventional food crop varieties (in Wayanad, rainfed rice) to more high-value products such as banana, coffee, and areca nut, may have contributed to incomes and the economic stability of landowners. However, the same transformation threatens agrobiodiversity and the livelihoods of agriculture laborers (Nagabhatla and Kumar 2013).

Statistical analysis of temperature variation and rice yield for Wayanad highlights the possible impact of changes in DTR on crop phenology and physiology, as also reported by Wassmann et al. (2009).

The case study of human migration in Bangladesh illustrates the pressing need for appropriate action on climate-driven human mobility. The theory of migration has faced continuous critical review and criticism of the failure to make a clear differentiation between internally displaced people and refugees. A review of literature from Bangladesh indicated that there has been an increase in seasonal migration from 20 % to 45 % and in permanent migration from 2 %to 8 % over the last decade. Much of the increase can be attributed to the more frequent occurrence of extreme climate events, mainly associated with monsoonal anomalies. An early warning system and improved accuracy of forecast information could help address the problem (Nagabhatla 2012). Fisheries and migration is representative of the diversity of socio-ecological systems in the climatically sensitive region of Bangladesh. Empirical experiments similar to those carried out in the present study applied to agriculture, inland fisheries, forestry, and other sectors would be required to provide the overall view necessary to the design integrated approaches for effective adaptation planning.

The CCA module provides further evidence of the need for cross-/ transdisciplinary approaches to assess and address the impact of climate change and in planning adaptation measures for complex socio-ecological systems. While scientific data and models generate strategic knowledge and thus provide key inputs for smart policies for climate change adaptation, a culture of collaboration, partnerships, and exchange of knowledge between the scientific world, local communities, business, and the governance bodies is a prerequisite for adaptation and positive social transformation in response to the challenge of climate change. The analysis presented in this chapter has benefited immensely from collaboration and partnership between the researchers and Asia Pacific Climate Center, an institute with a long-term vision of building capacity for the application of climate information to meet societal needs. The use of climate data for societal well-being will not address all climate-related uncertainties or mitigate all the negative consequences of climate change; nevertheless, it can make a sizeable contribution toward carving a knowledge pathway to respond to and cope with climate change. The key challenge is to set in motion social learning processes that assimilate the multiple dimensions of climate change and its impacts. The analyses and case studies presented in this chapter highlight the potential of climate data, both forecasted and observed, to contribute to social learning. The improved availability, accessibility, and accuracy of data open up new frontiers for transdisciplinary understanding of the uneven impacts of climate change on socio-ecological systems at global, regional, and local scales.

Acknowledgments This chapter is inspired from the talk delivered by the first author titled *Ecological and Socio-economic Vulnerability links closely with climate variation: A study exploring adaptation using this connect* at UNU-WIDER Conference on Climate Change and Development Policy, United Nations University-World Institute for Development Economics Research, Helsinki, Finland, 28–29 September 2012. Abstract

Urbanization has profoundly affected the environment and climate all over the world and has intensified the climate change impacts. The aim of this research is to study of effects of urbanization as the most suspicious factor of climate change in a holistic view applying system dynamics approach. An introduction to urbanization and climate change as an obstacle to sustainable development will be presented in general. Then, in particular, Tehran metropolis is described, since the city is an excellent example of the issue. In this regard, the focus will be on complexity of such dilemma. Then, system dynamics approach (SDA) that can play a key role in solving these kinds of problems will be introduced. Furthermore, the prototypes of the system are recognized. Finally, management practices and solutions of the problem are presented. The effects of urbanization will be reviewed in a new approach which has not been applied in previous studies. The involving mechanisms in this process are recognized. "Fixes that fail," "success to the successful," and "tragedy of commons" are the most prevalent prototypes in the system based on which solutions are presented.

Keywords

Climate change • Urbanization • Tehran • Iran • System dynamics

Introduction

The Intergovernmental Panel on Climate Change (IPCC), the leading international body for the assessment of climate change established by the United Nations Environment Program and the World Meteorological Organization in 1988, indicates that there is "high confidence" in the scientific community that anthropogenic climate change is contributing to sea-level rise and consequent high-risk scenarios for coastal cities without proper infrastructure (IPCC 2007a).

Climate change is undoubtedly a global problem, one that becomes more challenging over time as it continues and more people move to cities. Most affected by climate impacts and climate-induced migration are highly vulnerable cities, notably megacities in developing and, to a lesser degree, emerging market countries where the physical, social, and regulatory infrastructures are typically insufficient to address these emergent stresses (DePaul 2012).

Research on the intersection of climate change and migration and their combined impact on megacities is still in its infancy and hence insufficient in the face of critical policy questions on the subjects of mitigating climate change and building resilience to impacts. Scholars, such as De Sherbinin et al. (2007), Campbell-Lendrum and Corvalan (2007), Khan et al. (2011), and Bambrick et al. (2011), assess the health and social impacts of climate change on cities and megacities, broadly concluding that climate change should be seen as a significant issue for cities, and policies at all levels of government need to be designed to reflect this.

Ahmed (2009), Tacoli (2009), and Ranger et al. (2011) studied migration patterns and climate-induced urbanization in developing and emerging market countries. Their studies suggest that physical and social infrastructure currently cannot cope with mass urbanization. These scholars neglect to consider the stresses that climate change will impose on overpopulated regions. Only Adamo (2010) considers the interrelation of migration, climate change, and cities, though she investigated theoretical implications rather than evaluating specific national and regional policies. Institutions, like the United Nations Population Fund, conduct extensive research on trends in population, climate change, and urban density (Dodman 2009), but the connection to migration is seldom made.

In order to assess the coinciding effects of climate change and climate-induced migration on megacities, DePaul (2012) outlined a typology of climate migrants and refugees by considering the impacts of climate change as multipliers to current push factors of migration. Then, he analyzed the stresses that climate change imposes on megacities, particularly the dual stresses of mass urbanization and increasing climate vulnerability, and he utilized a case-specific analysis of the interconnectedness of developing and emerging market countries such as Bangladesh to illustrate the forces that drive involuntary international and intranational mobility from rural to urban settings and the subsequent stresses megacities experience and will continue to experience in upcoming decades. All in All, the problem at hand is undoubtedly global and so systemic change is necessary. In particular, Tehran metropolis is exposed to chronic situation of pollution as a result of rapid development as well as mismanagement. The study of Tehran City climate change and urbanization and applying system dynamics are the research innovations. The ability of system dynamics has been approved in the other studies in solving such complex issues; the effect of urbanization on climate change will be reviewed in this new approach, and the old approach in managing climate change will be replaced by the new strategies in confronting with climate change.

System Dynamics Approach, an Efficient Tool in Confronting with Such Complex Problems

System dynamics approach (SDA) is a branch of systems thinking which provides a simulation tool to model feedback relations in a system. In this approach, taking care of interactions among the elements, systems are considered as closed systems with feedbacks from outputs to inputs (Bagheri 2006; Hjorth and Bagheri 2006). It is a useful tool to study the trends of changes and their causes, to understand the physical processes and the flow of information, and to design and simulate the consequences of policies in a system. The interactions of system elements make its "structure" which is responsible for the system behavior (Vlachos et al. 2007).

Focusing on controls, feedbacks, and delays, SDA is a modeling approach used for studying and simulating complex systems while emphasizing on policy analysis and design. The relationships between system components as well as feedbacks affecting system regulations are depicted in causal loop diagrams (CLDs). Based on the positive and negative impacts of variables on each other, feedback loops can be reinforcing or balancing (Bazrkar and Eslamian 2013).

Climate change, particularly in an urban watershed like Tehran which is experiencing rapid development, is an excellent example of a system with dynamic complexity. This is a feedback system with many complex parts and vast amounts of data. Thanks to SDA, integrated management of the basin has been studied in many basins and performed well and proved to be an excellent tool to assess and manage water resources in the basin (Madani and Marino 2009; Sanchez-Roman et al. 2009). An excellent source of theoretical and practical evolution of system dynamics is available in Winz et al. (2009). In researches that have been done in the field of global warming, several approaches were applied that most of them neglect or, to some extent, pay low attention to other factors such as social, economic, and cultural impacts. All in all, system dynamics approach (SDA) application for solving such problems has not been applied yet. Furthermore, although the ability of SDA in modeling such complex issues has been proved, it is not applied in climate change adaptation and mitigation. In addition, lack of socioeconomic dimension of the previously used model to generate sustainable strategies throughout the basin is apparent. Therefore, as mentioned above, it is very important to consider socioeconomic aspects of the system in order to model the global warming for achieving a sustainable situation in decision-making. In this chapter, SDA has been applied in order to study climate change process and drivers in a holistic view.

Ten archetypes are generally acknowledged as forming the set of tools that reveal patterns of behavior in systems: limits to growth, shifting the burden, eroding goals, escalation, success to the successful, tragedy of the commons, fixes that fail, growth and underinvestment, accidental adversaries, and attractiveness principle. Each of the archetypes will be illustrated and discussed, along with general guidelines, prescriptive actions, and a set of seven steps that are useful for applying the archetypes for successful managerial interventions.

Dynamic Hypotheses

Observations about system relationships, operations, and patterns that are extracted from observed data are the two bases for the SD method of determining which feedback loops dominate in creating the time patterns. Since the real system usually contains a great number of loops, many of which do not directly create the important patterns; the analyst must eliminate many of the nondominant loops and variables. There is no algorithmic way to do this. It requires informed judgment that arises from long experience in studying systems to conceptualize this

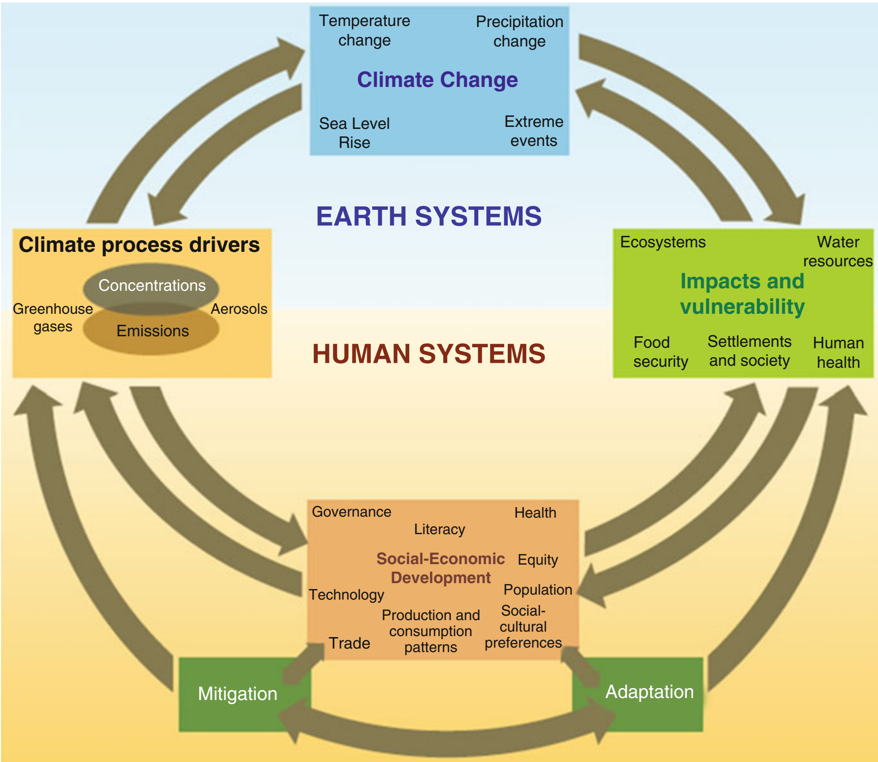

Fig. 1 Schematic framework representing anthropogenic drivers and impacts of and responses to climate change and their linkage (IPCC 2007c)

hypothetical dominant system. Since such judgments are sometimes in error, a procedure has been developed to test the judgment. The analyst's mental model of the dominant loop structure and how it creates the important time patterns is described in detail in writing. This written description is called the Dynamic Hypothesis (Fey et al. 2004). In this chapter, drivers of climate change in the study area will be discussed.

Cities are increasingly vulnerable to climate impacts because of "coastal location, exposure to the urban heat-island effect, high levels of outdoor and indoor pollution, high population density, and poor sanitation" (Campbell-Lendrum and Corvalan 2007). These concurring trends have resulted in unprecedented pressure on megacities (Fig. 1).

Climate Change

Weather and climate have a profound influence on life on Earth. Many consider the prospect of human-induced climate change as a matter of concern. The IPCC

Second Assessment Report (IPCC 1996) (hereafter SAR) presented scientific evidence that human activities may already be influencing the climate. It is necessary to understand the climatic system for assessing and determining human influence on climate led to climate change.

Since the notions "weather" and "climate," in common parlance, are loosely defined, firstly, these two notions will be clearly described.

The "weather," as we experience it, is the fluctuating state of the atmosphere around us, characterized by the temperature, wind, precipitation, clouds, and other weather elements. This weather is the result of rapidly developing and decaying weather systems such as mid-latitude low- and high-pressure systems with their associated frontal zones, showers, and tropical cyclones. Weather has only limited predictability.

"Climate" refers to the average weather in terms of the mean and its variability over a certain time span and a certain area. Classical climatology provides a classification and description of the various climate regimes found on Earth. Climate varies from place to place, depending on latitude, distance to the sea, vegetation, presence or absence of mountains, or other geographical factors.

Statistically significant variations of the mean state of the climate or of its variability, typically persisting for decades or longer, are referred to as "climate change." The Glossary gives definitions of these important and central notions of "climate variability" and "climate change."

Climate variations and change, caused by external forcings, may be partly predictable, particularly on the larger, continental and global, spatial scales. Because human activities, such as the emission of greenhouse gases or land-use change, do result in external forcing, it is believed that the large-scale aspects of human-induced climate change are also partly predictable. However the ability to actually do so is limited because we cannot accurately predict population change, economic change, technological development, and other relevant characteristics of future human activity. In practice, therefore, one has to rely on carefully constructed scenarios of human behavior and determine climate projections on the basis of such scenarios.

The traditional knowledge of weather and climate focuses on those variables that affect daily life most directly: average, maximum and minimum temperature, wind near the surface of the Earth, precipitation in its various forms, humidity, cloud type and amount, and solar radiation. These are the variables observed hourly by a large number of weather stations around the globe. However, this is only part of the reality that determines weather and climate. The growth, movement, and decay of weather systems depend also on the vertical structure of the atmosphere, the influence of the underlying land and sea, and many other factors not directly experienced by human beings. Climate is determined by the atmospheric circulation and by its interactions with the large-scale ocean currents and the land with its features such as albedo, vegetation, and soil moisture. The climate of the Earth as a whole depends on factors that influence the radiative balance, for example, the atmospheric composition, solar radiation, or volcanic eruptions. To understand the climate of our planet Earth and its variations and to understand and possibly predict the changes of the climate brought about by human activities, one cannot ignore any of these many factors and components that determine the climate. We must understand the *climate system*, the complicated system consisting of various components, including the dynamics and composition of the atmosphere, the ocean, the ice and snow cover, the land surface and its features, the many mutual interactions between them, and the large variety of physical, chemical, and biological processes taking place in and among these components. “Climate” in a wider sense refers to the state of the climate system as a whole, including a statistical description of its variations.

Some extreme weather events have changed in frequency and or intensity over the last 50 years.

It is very likely that cold days, cold nights, and frosts have become less frequent over most land areas, while hot days and hot nights have become more frequent. It is likely that heat waves have become more frequent over most land areas. It is likely that the frequency of heavy precipitation events (or proportion of total rainfall from heavy falls) has increased over most areas. It is likely that the incidence of extreme high sea level has increased at a broad range of sites worldwide since 1975.

Temperature Change

Eleven of the last 12 years (1995–2006) rank among the 12 warmest years in the instrumental record of global surface temperature (since 1850). The 100-year linear trend (1906–2005) of 0.74 [0.56–0.92]°C is larger than the corresponding trend of 0.6 [0.4–0.8]°C (1901–2000) given in the average Arctic temperature (TAR). The linear warming trend over the 50 years from 1956 to 2005 (0.13 [0.10–0.16]°C per decade) is nearly twice that for the 100 years from 1906 to 2005.

The temperature increase is widespread over the globe and is greater at higher northern latitudes. Average Arctic temperatures have increased at almost twice the global average rate in the past 100 years. Land regions have warmed faster than the oceans. Observations since 1961 show that the average temperature of the global ocean has increased to depths of at least 3000 m and that the ocean has been taking up over 80 % of the heat being added to the climate system. New analyses of balloon-borne and satellite measurements of lower- and mid-tropospheric temperature show warming rates similar to those observed in surface temperature (IPCC 2007b).

Precipitation Change

Trends from 1900 to 2005 have been observed in precipitation amount in many large regions. Over this period, precipitation increased significantly in eastern parts of North and South America, northern Europe, and northern and central Asia, whereas precipitation declined in the Sahel, the Mediterranean, southern Africa, and parts of southern Asia. Globally, the area affected by drought has likely increased since the 1970s (IPCC 2007b).

Sea-Level Rise

According to IPCC, coastal areas are projected to be “exposed to increasing risks, including coastal erosion, due to climate change and sea level rise. The effect will be exacerbated by increasing human-induced pressures on coastal areas”

(Parry et al. 2007). Estimates for sea-level rise vary from 18 to 59 cm up to the end of the twenty-first century, this along with predicted changes in the frequency and/or intensity of storms, associated surges, and other extremes. Sea-level rise refers to the increase in the mean level of the oceans.

Sea-level rise and its associated impacts will, by the 2080s, affect five times as many coastal residents as they did in 1990. Tropical cyclone sand extratropical storms have been increasing in intensity since the 1970s.

Extreme Events

Ranger et al. (2011) argue that "many of the world's cities are hotspots of risk from extreme weather events and levels of risks in many cities are likely to grow due to a combination of population growth and development and rising intensities of extreme weather events."

Heavy precipitation events are defined as the percentage of days with precipitation that exceeds some fixed or regional threshold compared to an average "reference period of precipitation from 1961 to 1990." On average, observations indicate that heavy 1-day and heavy multiday precipitation events have increased globally throughout the twentieth century, and these trends are very likely to continue throughout the twenty-first century. Deviations from average weather patterns have been observed globally, with an increase in the frequency of heavy precipitation events in most areas of the world.

Flood

Floods are already one of the most frequent natural disasters often overwhelming the physical infrastructure, human resilience, and social organization of Dhaka, Mumbai, Jakarta, Caracas, and many other cities around the world. Some of these disasters are reported in the news and form part of the official statistics generated by national governments and international organizations. Yet for every flood large enough to get noticed internationally, there are hundreds that do not get reported, but kill and seriously injure many people and destroy or damage many people's homes and assets (Satterthwaite et al. 2007).

Floods are among the most costly and damaging disasters posing a critical problem to city planners as they increase in frequency and severity. The frequency and severity of flooding have generally increased during the last decade (compared to 1950–1980 flood data), along with the frequency of floods that exceed levels that only typically occur once every 100 years.

Drought

Drought can be defined as a phenomenon in which precipitation is significantly below normal levels, which leads to hydrological imbalances that negatively affect land resources and production systems.

Droughts have diverse implications for urban water systems and especially for the urban poor: they constrain water availability, and they might result, through complex causal chains, in infectious diseases, respiratory diseases, and other health problems. For instance, the drought affecting the western and central part of the

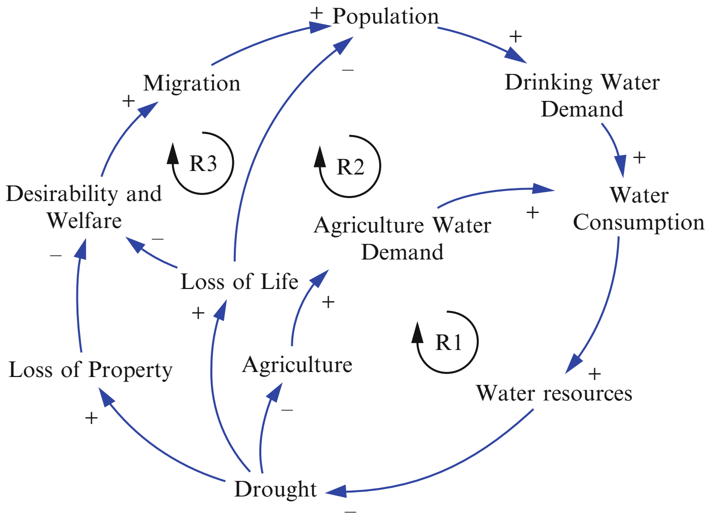

Fig. 2 Three reinforce loops

Amazon region, especially Bolivia, Peru, and Brazil in 2005, resulted in waterborne infections due to low water levels leading to pathogen concentration in surface water. There were also respiratory problems due to heavy smoke from forest fires (Confalonieri and Menne et al. 2007).

The CLDs in Fig. 2 show the interaction between climate drivers on water system. A “+” sign represents that an increase in the variable at arrow tail causes an increase in the arrowhead variable and indicates a reinforcing relationship between two variables. A “–” sign indicates a balancing relationship between two variables at the ends of an arrow and represents one variable that adversely affects the other.

The R sign shows reinforce loop, which means the governing mechanism will continue until the resource will be completely depleted or an inhibitor will stop the governing mechanism.

Climate Process Drivers

Greenhouse Gases

Greenhouse gas (GHG) emissions from commercial and residential buildings are closely associated with emissions from electricity use, space heating and cooling. The type of fuel used for heating and cooling also determines the amount of GHGs emitted. Larger houses consume more energy for heating and cooling.

Globally, 19 % of GHG emissions are associated with industrial activities. Although most cities in North America and Europe emerged and developed as a result of industrial activities, and still require industries to provide jobs and revenue, these same activities generate pollution.

GHG emissions from waste are relatively low in many urban areas in developed countries.

Global urban trends toward suburbanization mean that cities are sprawling and encroaching on land that may previously have been covered with vegetation – thereby reducing its potential to absorb CO_2.

Per capita CO_2 emissions vary from less than 1 t per year for Bangladesh and Burkina Faso to more than 20 t for Canada, the USA, and Australia.

The high concentrations of people and economic activities in urban areas can lead to economies of scale, proximity, and agglomeration – all of which can have a positive impact upon energy use and associated emissions.

The Urban Economy

The types of economic activities that take place within urban areas also influence GHG emissions. Extractive activities (such as mining and lumbering) and energy-intensive manufacturing are obviously associated with higher levels of emissions – especially when the energy for these is supplied from fossil fuels. However, there are fewer of these activities in many cities in developed countries, as lower transportation costs and the lower cost of labor elsewhere have encouraged industries to relocate elsewhere. In London, for example, industrial emissions halved between 1990 and 2006, as industrial activity has relocated to other parts of the UK or overseas (Fig. 3).

Air Pollution and Aerosols

Air pollution practically has the same effects on urban albedo as increased cloud cover. Through increased scattering and absorption in the atmosphere, less short-wave radiation reaches the surface reducing the impact of urban surface albedo. Alpert and Kishcha (2008), for example, show that urban areas (defined as areas with a population density of $\geq$400 people per km^2) received 8 % less solar radiation than rural areas between 1964 and 1989. Also, a little more radiation may be reflected back, slightly increasing the albedo of the Earth-atmosphere system as a whole, and of all the surface albedo values, water has the potentially lowest. Thus, it is not very hard to image, and for most people to remember from personal observations, that surfaces have a lower albedo and appear darker when moist. Although few studies have been done on the relation between albedo and soil moisture content (Wang et al. 2005), those that do seem to agree that moisture reduces the albedo up to at most ~0.08. On a degraded grassland site and a cropland (corn mixed with sunflower) site with sandy soils in northeastern China, Liu et al. (2008) measured the diurnal variability of surface albedo with data from 2003 to 2005. They examined the relation of albedo to soil moisture and solar elevation angle and found a negative exponential relationship. The albedo falls rapidly with the addition of soil moisture measured 5 cm below the surface, up to approximately 0.15–0.2 m^3/m^3 after which it stabilizes at an average albedo reduction of around 0.05–0.08. A case example of a real rainfall event showed a reduction of ~0.02, which may be an indication of a more usual situation.

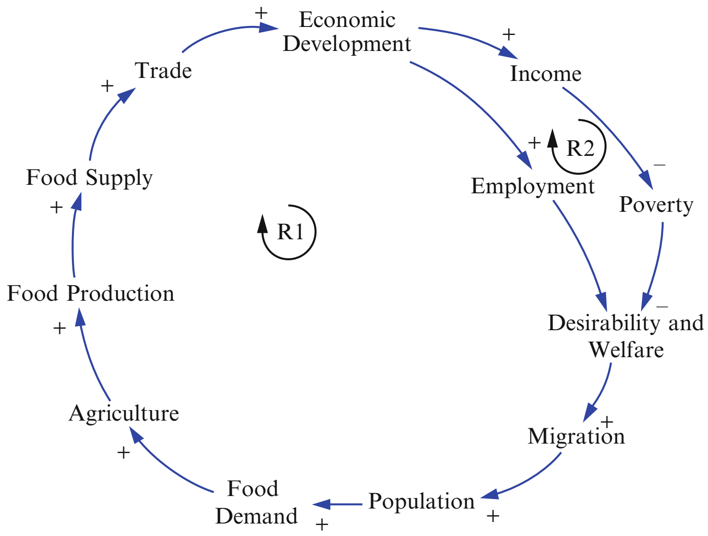

Fig. 3 Urban economy

Wang et al. (2005) also found a negative exponential relationship between surface albedo and soil moisture, with a reduction of more than 0.07 approaching stabilization. While stabilization occurred at a much higher soil moisture content, $>0.6\ m^3/m^3$, this difference may be explained by the more shallow measurement depth of 3 cm or the different soil characteristics of the semidesert to desert area of Gaize on the Tibetan Plateau.

Impact and Vulnerability

Ecosystems

Natural environmental processes provide benefits that are vital to city function and human health. These ecosystem services include oxygen production, carbon storage, natural filtering of toxins and pollutants, and protection of coastal societies from flooding and wind during storms.

The uptake of anthropogenic carbon since 1750 has led to the ocean becoming more acidic, with an average decrease in surface pH of 0.1 unit.

Water Resources

Adamo (2010) discussed an example in northeastern Brazil where "regional rural–urban migration and urban growth have also been related to the negative effects of droughts in agriculture, while growing populations in cities generate a concentrated demand for water that surpasses local availability."

The availability, treatment, and distribution of water could be affected by climate change as temperatures increase and precipitation patterns change.

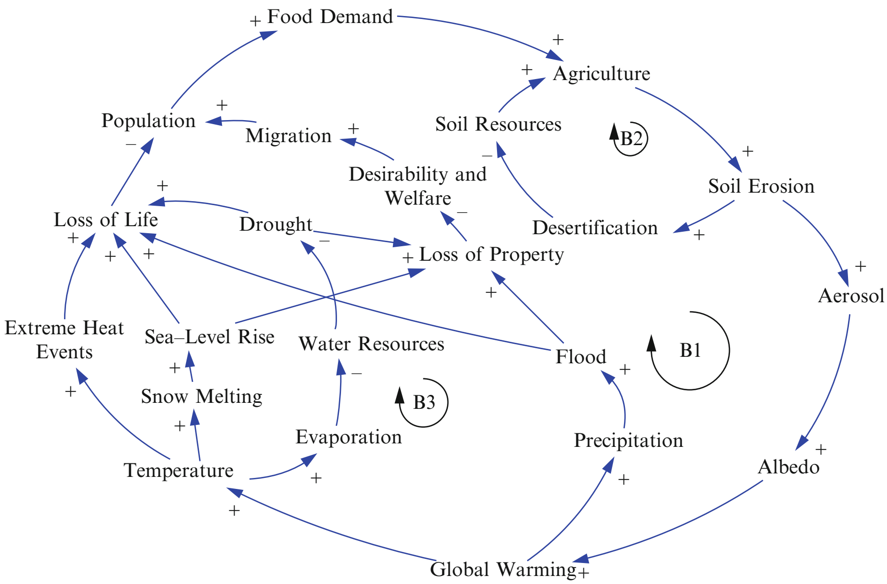

Fig. 4 Food security

According to IPCC (2007b), runoff and water availability are projected to have a regionally differentiated behavior by 2050: increases by 10–20 % at higher latitudes and in some areas in the wet tropics (e.g., populous areas in tropical east and southeast Asia) and decreases by 10–30 % over areas in the mid-latitudes and dry tropics, some of which are presently water-stressed. Increases in the frequency and severity of floods and droughts as well as declines in water quantities stored in glaciers and snow cover are also expected.

Food Security

The most important part of this system, which is affected by climate change, and consequently, water resources decrease, is food. B depicts a balancing loop, which will be balanced by the governing mechanism (Fig. 4).

Settlements and Society

Costs and benefits of climate change for industry, settlement, and society will vary widely by location and scale. In the aggregate, however, net effects will tend to be more negative the larger the change in climate. The most vulnerable industries, settlements, and societies are generally those in coastal and river flood plains, those whose economies are closely linked with climate-sensitive resources, and those in areas prone to extreme weather events, especially where rapid urbanization is occurring (IPCC 2007c).

Human Health

A range of health-related risks is expected to arise from climate change, besides the physical hazards from floods (Confalonieri et al. 2007). It is expected that heat stress and respiratory distress from extreme temperatures will coalesce as air quality decreases. Waterborne and vector-borne diseases will result from changes in temperature, precipitation, and/or humidity. Less direct risks are expected as well as climate change negatively affecting livelihoods, food supplies, or access to water and other natural resources.

Mitigation and Adaptation

Climate change is a global challenge and needs to be addressed with global solutions. Climate change presents unique challenges for urban areas and their growing populations.

Near-term adaptation and mitigation analyses can be matched to conventional planning time scales, can explore opportunities and constraints given institutional and technological inertia, and can play an important role in integrating climate change considerations into other areas of management and policy (IPCC 2007c). Adaptation involves helping their constituents to cope with and adjust to any changes in their climate regime or natural resource base. This might involve targeted poverty reduction, asset building, early warning planning, and disaster response planning. Mitigation involves helping their constituents to reduce their GHG emissions. This might involve forest management or energy conservation interventions

Socioeconomic Development

Transportation Systems

Climate change impacts frequently disrupt transportation systems through weather conditions that have immediate consequences for travel and damage, causing lasting service interruptions.

By their very nature, cities are the center of high demand for energy and related resources. Climate change is likely to affect both energy demand and supply. The combination of urban population growth, changing local weather conditions, urban heat-island impacts, and economic growth has the potential to substantially increase demand for energy.

The increasing frequency and intensity of extreme climatic events and slow-onset changes will increase the vulnerability of urban economic assets and, subsequently, the costs of doing business.

Climate change will affect a broad range of economic activities, including trade, manufacturing, transport, energy supply and demand, mining, construction and related informal production activities, communications, real estate, and business activities.

Nick Mabey (2009) assesses that "these 'worst-case scenarios' are not low probability, but largely inevitable under current momentum of economic behavior."

The use of insurance as a means of spreading and reducing the losses from climate-related events has received increased attention (IPCC 2001; Wilbanks et al. 2007). New insurance mechanisms can be designed to help better distribute losses, for example, expanded property insurance coverage. Insurance can also work as agent of adaptation through incentives for risk reduction strategies, including better building codes and flood prevention schemes.

Substantial damage to residential and commercial structures is expected with the increasing occurrence of climate change-related hazards and disasters. In this regard, flooding is one of the most costly and destructive natural hazards and, as indicated earlier, one that is likely to increase in many regions of the world as precipitation intensity increases.

Health

Extreme climate events can disrupt the ability of individuals and households in urban areas to sustain livelihoods. Climate change-related disasters destroy livelihood assets or the means of production available to individuals, households, or groups.

Climate changes cause local weather conditions including extreme heat and severe weather events – which affect public health in urban areas. Key health issues are impacts related to extreme temperatures, disasters, epidemics, health services, and psychological illnesses. It also considers how poverty acts as a compounding factor, which exacerbates the health impacts of climate change.

Equity

Vulnerability to climate change differs considerably across socioeconomic groups, thus raising important questions about equity (IPCC 2007c). The cardinal climate change inequity is consequently not the potentially unfair allocation of mitigation targets but the inevitably unfair distribution of climate impact burdens. Indeed it indicates that while "equity" is often put on the agenda by developing country experts, the scope of the agenda itself, namely, emission mitigation, has been firmly set by the industrialized world (Muller 2002).

Population

A statistical (time-series) analysis shows that over the past three decades, the proportion of the global population affected by weather-related disasters has doubled in linear trend rising from roughly 2 % in 1975 to 4 % in 2001 (Muller 2002).

Sociocultural Impacts

There is a strong association between rising income and car use in developing countries, meaning that economic growth in developing countries is very likely to result in increased car use and rising traffic congestion. In addition, in many developing countries, the stock of motor vehicles is old and consists largely of secondhand and less efficient vehicles imported from developed countries. At the same time, the conversion of vehicles to use different fuels has the potential to reduce GHG emissions in many cities in developing countries.

The tourism industry is highly dependent upon reliable transportation infrastructure, including airports, ports, and roadways. Climate change has the potential to not only shift regional temperature distributions but also increase the incidence of severe weather events, which would increase transportation delays and cancelations. Since recreational activities and tourism are often major sources of revenue for urban areas, when climate change impacts affect these activities, local urban economies will incur monetary and job losses.

The insurance industry is vulnerable to climate change, particularly extreme climate events that can affect a large area. Storms and flooding can cause significant amounts of damage and are often responsible for a large percentage of total losses.

Climate change could result in increasing demand for insurance while reducing insurability. Insurance industry catastrophe models forecast that annual insured claims and losses are likely to significantly increase over the next century as a result of the increasing intensity and frequency of extreme storm.

Community-based adaptation (CBA) to climate change has recently received more attention, although there is uncertainty about its potential. It is unclear, for example, how it fits in with community-based development and disaster planning among other more established development activities. It is also uncertain how different it is from other forms of adaptation and what particular potentials and limitations it will have when applied to urban areas (Satterthwaite et al 2007).

Social Impacts

The degree to which human settlements are vulnerable to climate change depends not only on the nature and magnitude of physical changes but also on the socioeconomic characteristics of each city.

Poverty

Climate change is considered a distributional phenomenon because it differentially impacts upon individuals and groups based on wealth and access to resources. In general, low-income households in both developed and developing countries are most vulnerable to climate change impacts primarily due to the scale and nature of the assets that they possess or can draw upon.

Gender

In most urban centers, there are significant differences between women and men in terms of their exposure to climate-related hazards and their capacity to avoid, cope with, or adapt to them.

Age

Young children are particularly vulnerable to climate change impacts, in part because of their physiological immaturity.

Ethnic and Other Minorities

Racial and ethnic minorities also exhibit increased vulnerabilities to climate change in both developed and developing countries. Discriminatory practices often segregate groups of minorities into the highest-risk neighborhoods, usually without access to insurance and loans as security against climate change impacts. The majority of flooding victims in Bihar (India) in 2007 were “untouchable” low-caste groups who resided in floodplains and areas prone to landslides.

The most vulnerable low-lying communities in New Orleans (USA) are comprised mostly of African-Americans. This group suffered the relatively most severe losses of life and assets during Hurricane Katrina.

Literacy

The Essential Principles of Climate Science is an interagency guide that provides a framework and essential principles for formal and informal education about climate change. It presents important information for individuals and communities to understand Earth’s climate, impacts of climate change, and approaches for adapting and mitigating change.

Production and Consumption Pattern

Total world energy consumption and CO_2 emissions continue to increase steadily. From 1990 to 2004, world energy consumption increased by about 30 % and CO_2 emissions by 26 %, while world GDP has increased by over 50 %. There have thus been modest improvements in overall energy efficiency (GDP per unit of energy consumed) and carbon intensity (CO_2 emissions per unit energy or GDP), but these improvements in efficiency have been overwhelmed by increasing production and consumption. As a result, the driving forces of human-induced climate change are steadily increasing and Sustainable Consumption and Production (2007) have been on the international agenda since Agenda 21 (1992) identified unsustainable patterns of production and consumption as the major cause of the continued deterioration of the global environment. The climate change impact of patterns and trends and policies and measures by which consumption patterns can be changed to promote sustainable development (United Nations Department 2007).

Governance

In least developed countries, the National Adaptation Programmes of Action to Climate Change (NAPAs) provide a starting point for identifying national priorities for adaptation to climate change. However, they rarely identify the need to work closely with local institutions in implementing priority actions on climate change. In addition, all countries signatory to the United Nations Framework Convention on Climate Change (UNFCCC) produce periodic “National Communications” on

Climate Change, which increasingly draw together both mitigation and adaptation issues, but again are not specific in terms of the role of local authorities. More recently, some countries (particularly middle-income countries) have moved toward the development of comprehensive national climate change strategies with high levels of visibility and political engagement.

Technology

Industrial sectors situated in urban areas or providing urban areas with the commodities. They need to function such as energy supply and demand. Mining and construction are generally thought to be less vulnerable to the impacts of climate change than agriculture, water, and other sectors and services dependent on climate. This is in part because their sensitivity to climatic variability and change is viewed as being comparatively lower and in part because industry is seen as having a high capacity to adapt in response to changes in climate.

Industry and Commerce

Industrial activities can bear potentially high direct and indirect costs from climate change and extreme climate events. Whether industries are located in the heart of urban areas or in adjacent suburban or rural areas, they provide services and resources that are vital to city function. Damage to industries due to climate events thus has direct and indirect impacts upon cities and their residents.

In 2011, there were nearly 1.2 billion passenger vehicles worldwide. By 2050, this figure is projected to reach 2.6 billion – the majority of which will be found in developing countries. The emissions associated with the increase in passenger vehicles can be reduced either through advances in fuel technology or by changes from one mode of transportation to another. The potential for such reductions is particularly strong in urban areas – with the advantage of relatively high densities of people, economic activities, and cultural attractions (Fig. 5).

Urbanization

When investigating urbanization, a need of clear definitions arises. What should be considered urban? There are a myriad of characteristics that can be used, most notably the presence of buildings and structures or people, but regardless of which are chosen, there are still lines to be drawn and assumptions to be made. In the United Nations publication *The State of World Population 2007* (UNFPA 2007), the definition of urban is based on definitions by national statistical agencies. Urbanization, on the other hand, is defined as an increase in the proportion of the population, which live in urban settlements.

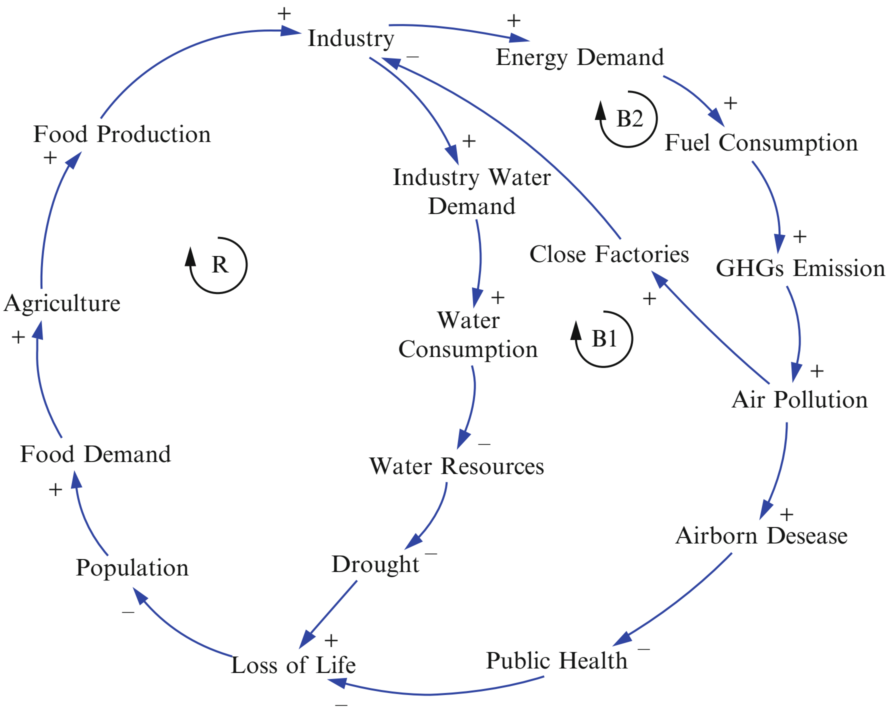

Fig. 5 Socioeconomic impacts

Developed countries and countries that benefit disproportionately from oil and coal industries must accept more responsibility for reducing emissions since they are responsible for the majority of emissions currently in the atmosphere (DePaul 2012).

Viewing the effects of urbanization as negligible on a global scale might be tempting. Urban areas cover only 0.046 % of the Earth's surface according to an estimation given in the Fourth Annual Report (AR4). This estimation, however, originates from global land cover data (Loveland et al. 2000), which for the urban areas used a data layer from the US Defense Mapping Agency's Digital Chart of the World (DCW; Danko 1992). The data layer, in turn, is drawn from map sources made between 1950 and 1979 as also pointed out by Potere et al. (2009). Needless to say, the extent of urban areas has increased dramatically over the last 60 years, rendering the global effects of urbanization progressively less negligible.

Extent of Urban Areas

With the problems previously discussed in finding a suitable definition of urban areas, it is natural that the actual extent of urban areas is still very much unclear. Data from the DCW (Danko 1992) has been widely used for a long time (Potere et al. 2009).

Location and Rate of Urbanization

Most cities are located between 30°N and 65°N (Jin et al. 2005), which, considering this area spans roughly from north Africa to the Arctic circle, is not surprising. Half of the world's population of about 6.4 billion people currently lives in urban areas, compared to less than 15 % in 1900. Many aspects of urban change in recent decades are unprecedented. The world's urban population increased more than tenfold during the twentieth century. The fastest growing cities are mainly concentrated in the world's largest economies (Satterthwaite et al. 2007). But unlike urbanization in the beginning of the twentieth century, mostly confined to countries with the highest levels of per capita income, the most rapid urban change is currently taking place in middle- and low-income countries, which host nearly three quarters of the world's urban population. In regard to climate change, urban areas house a large proportion of the population and the economic activities most at risk from extreme weather events and sea-level rise – and this proportion is increasing.

Why can urban development bring increased vulnerability to climate risks? The concentration in urban centers of people and their homes, as well as of infrastructures, industries, and wastes, has two implications for the urban impacts of climate change and other stresses. On the one hand, urban areas can be dangerous places to live and work; their populations can be very vulnerable to extreme weather events or other hazards with the potential to become disasters. For instance, urban concentration can generate risk when residential and industrial areas lack space for evacuation and emergency vehicle access, when high-income populations are lured by low-lying coastal zones, or when lower-income groups, lacking the means to access safer land, settle on sites at risk from floods or landslides. Urban settlements can increase the risk of concatenated hazards (Lavell cited in Satterthwaite et al. 2007). This means that a primary hazard (heavy storm) leads to secondary hazard (e.g., floods creating water supply contamination). It is possible that the impacts of climate hazards such as heat waves will overlap with pollution events and compound one another making urban disaster risk management even more complex. On the other hand, the same concentration of people, infrastructures, and economic activities in urban centers also means economies of scale or proximity for many of the measures that reduce risks from extreme weather events. Economies manifest themselves in the per capita cost of better watershed management, warning systems, and other measures to prevent and lessen the risks when a disaster threatens or occurs. Furthermore, when provided with policies focused on enhancing sustainability and moving from disaster response to disaster preparedness, urban settlements can increase their effectiveness at coping with climate hazards.

Urban development can relate to increased vulnerability to climate risks for several reasons. First, many cities have developed without consideration of the risks that climate change will carry with it. Most large cities have been built on sites that were originally chosen for trade or military advantage (e.g., Shanghai, New York, Buenos Aires). In the majority of cases, this has meant that they were located on the coasts or near the mouths of major rivers where trade by sea with other coastal cities or by rivers with the interior hinterlands could best be accomplished. These urban centers then became the hubs of trade for their countries and, as such, greatly increased their wealth.

As this wealth continued to build, further development was fueled, and these areas became engines of economic growth for their countries, attracting more capital from private sector investment and labor migration from rural areas and immigration from other countries. The movement to urban centers continues today, and these areas have become magnets of industry and labor without regard to the many environmental risks that are endemic to these areas and the mounting hazards that are predicted to be brought with climate change.

Urbanization is taking place at unprecedented rates, especially in small and medium cities. As migration has accelerated, the abilities of urban centers to accommodate their population have been put under increasing pressure, especially in middle- and low-income countries. Certain urban characteristics have relevance for understanding risks from climate and weather hazards (Satterthwaite et al. 2007).

Why are some sectors of the population more vulnerable? As was emphasized above, not all demographic segments of the urban population are equally affected by the hazards climate change is predicted to aggravate. Wealthy individuals and households have more resources to reduce risks, i.e., safer housing, more stable jobs, safer locations to live, and better means of protecting their wealth (e.g., insurance of assets that are at risk). Wealthier groups often have more influence on public expenditures. In many urban areas, middle- and upper-income groups have been the main beneficiaries of government investment in infrastructure and services. If government does not provide these, higher-income groups have the means to develop their own provisions for water, sanitation, and electricity or to move to private developments, which provide these. Wealthier groups, in short, have higher adaptive capacity.

The populations most at risk from climate change are those living in affected areas who: (a) are very young, already sick, or elderly; (b) lack the capacity to avoid the direct or indirect impacts by having such means as good quality houses and drainage systems that prevent flooding, by moving to places with less risk, or by changing jobs if climate change threatens their livelihoods; and (c) are least able to cope with the illness, injury, premature death, or loss of income, livelihood, or property caused by these hazards (Wilbanks et al. 2007; Satterthwaite et al. 2007). Impacts will also differ according to gender, as gender gaps exist in access to such determinants of adaptive capacity as access to resources, including credit, services, information, and technology, affects adaptive capacity. (Klinenberg (2002) and Cannon (2002) cited in flood plains, unstable slopes, over river basins, and other riskiest areas (Hardoy et al. 2004). Many poor populations face additional risks: they live in informal settlements, work within the informal economy, and are constantly faced with the possibility that governments may forcibly move them off land sites deemed to be vulnerable to weather risks but away from their means of livelihood (Satterthwaite et al. 2007). They may also be moved simply because other actors want the land they occupy for more “profitable” uses.

Furthermore, poorer groups are affected most by the combination of greater exposure to other urban hazards (sanitary conditions, lack of hazard-removing infrastructure). They have less state provision to help them cope and less legal and less insurance protection. Low-income groups also have far fewer possibilities to move to less dangerous sites. This should not lead us to conclude that the poor are passive recipients of all of the risks of climate change and other hazards. They have developed mechanisms to adapt. It only means that structural issues as those referred here pose limits to their coping mechanisms.

What societal and environmental factors underlie the trajectories of emissions by cities? Just as urban centers register different levels and paths of development, cities do not contribute at the same level to global warming. Some scholars point to the fact that urban centers in low-income countries have lower levels of emissions per capita than cities in high-income countries (Wilbanks et al. 2007; Satterthwaite 2008). In fact carbon emissions per capita in cities from high-income countries such as Texas and the District of Columbia are 19- to 20-fold as high compared with those in Sao Paolo, Delhi, and Kolkata. Yet, other wealthy cities such as Stockholm and Barcelona have lower levels of emissions per capita than the four South African cities. Why is this so? Definitive answers to this question cannot be provided, because existing data on emission levels cover very few cities and have not been gathered applying similar or comparable criteria. As a result, it is difficult to apply such statistical tools as regressions or correlations to explore the role of affluence, population dynamics, climate, and other drivers in explaining the levels of carbon emissions by urban centers.

Cities' Responses to Climate Change

It has been recently recognized that urban areas play a key role in addressing the challenges created by climate change in terms of mitigation and adaptation alike (Sanchez-Roman et al. 2009). Different initiatives such as the Cities for Climate Protection, the C40 Cities Climate Leadership Group, and the Majors Alliance for Climate Change Protection in the USA are examples of current responses. A high proportion of these initiatives have been created in large cities of high-income countries and to a lesser extent of middle- and low-income countries.

Urban Infrastructure

Urban infrastructure – in particular, energy (electricity and gas) networks and water and sanitation systems – is critical in shaping the current and future trajectories of GHG emissions. The type of energy supply; the carbon intensity of providing water, sanitation, and waste services; and the release of methane from landfill sites are important, though often hidden, components of GHG emissions at the local level. A dynamic, complex, and strong link exists between economic development, urbanization, and GHG emissions.

Strong evidence exists showing that demographic change is closely associated with greenhouse gas emissions, and future trends in population dynamics will play a key role in attempts to mitigate and adapt to the effects of changes in the climate system. It is clear, in addition to population size, that analyzing the compositional change of populations, specifically the age composition, the distribution of people in urban and rural areas, and household size and composition, is very important for understanding future needs and potential for mitigating carbon emissions and climate change. The analysis presented in this chapter shows that by only including population size as the demographic variable in climate models, the contribution of "population" to climate change has been underestimated. The indications are that the combined influence of climate change and urban growth on the urban flooding situation is significant indeed.

Land-Use Change

The assessment of the contribution of land cover change in the AR4 focuses mainly on deforestation since 1750 and suggests a net cooling effect since croplands, for example, usually have a higher albedo than forest. That is, they reflect a higher portion of the incoming solar radiation. A specific land cover change that could reduce this cooling effect is urbanization. Conversion of high-albedo surfaces such as some croplands into urban surfaces like asphalt or dark walls can lower the albedo considerably. While the AR4 recognizes that urbanization may alter local and regional climates in several ways, potential effects on the global scale are largely overlooked.

The focus on albedo and urban environments requires thorough explanations of the Earth's energy balance, of the definition of albedo itself, and of specific urban climate effects.

Land Use

Feddema et al. (2005) and Roger and Pielke (2005) among others agree that land cover changes need to be included when analyzing global climate change. To fully appreciate the effects of land cover change, urbanization cannot be ignored.

Albedo

The aim of this part is to investigate the climatic effects of urbanization with special focus on albedo and to review the nature and magnitude of urbanization.

A specific climatic effect of urbanization, which has not received as much attention as it might deserve, is the change in the reflective properties of the surface. This section aims to investigate the climatic effects of urbanization, especially albedo (the ratio of incoming to outgoing solar radiation for a given surface).

Urbanization has many effects on surface albedo. It reduces it through the introduction of dark surfaces, through changing the surface geometry to better capture solar radiation, and through reducing snow cover in winter. It can also increase it by increasing the cloud cover and by emitting air pollutants and aerosols. Some effects, such as a modified surface moisture regime or climate changes downwind of cities, can act to both reduce and increase it, with the net effect very dependent on local factors.

The radiative forcing of this albedo reduction is very small. This is mainly because the fraction of Earth's land surface covered by urban areas is only 0.44 % according to the best estimate. While the climatic effects of albedo change due to urbanization are small on a global scale, they are quite distinct on regional to local scales. The small extent of urban areas today is still more than twice as large as the estimate cited in the last assessment report by the IPCC (AR4). With the projected increase in urban populations, the small global effects will become progressively more important and will need to be taken into account in future studies of climate and land-use change.

Urban Climate

Urban areas are among the most altered environments on Earth. From cities to suburbs, the materials composing the surface are determined by their use to humans. The surface geometry is related to human concepts such as construction cost, design, and tradition. What species of plants and animals live here are accepted by human society or deemed too expensive to remove. Changes affect quantifiable climatic variables including temperature, wind patterns, precipitation, evapotranspiration, and even incoming solar radiation (Oke 1987; Collier 2006).

Many studies have shown the potential of urban areas to increase rainfall in and downwind of them (Shepherd et al. 2002; Jauregui and Romales 1996), but there is still a need for more research on the matter, evident by the criticism delivered by Diem et al. (2004) and subsequent replies.

Shepherd et al. (2002) outlined four primary ways in which urban areas change natural precipitation patterns, namely, by:

1. Creating, enhancing, or modifying mesoscale circulations and thus destabilizing the atmosphere
2. Promoting convergence of air near the surface through high surface roughness
3. Increasing the amount of condensation nuclei, for example, from pollution
4. Adding moisture to the air from industrial sources

In their study, rainfall increased on average 5.8 % over the cities examined and 28.4 % over downwind areas, compared to upwind control areas. In another study (Burian and Shepherd 2005), average warm-season rainfall in Houston, Texas, USA, was increased by 25 % between a pre-urban and post-urban period (1940–1958 and 1984–1999). Such an increase in rainfall may correspond to an increased cloud cover, in which case the reflection of incoming short-wave radiation is increased while more long-wave radiation is absorbed and reradiated to the surface. As mentioned, aerosols and other atmospheric constituents act to scatter and absorb radiation, so the addition of pollution to the atmosphere reduces the short-wave radiation reaching the surface (Solomon et al. 2007).

Cities as Drivers of Global Warming

Cities have often been blamed for causing air and water pollution and currently for causing global warming. Yet, do we have any consistent measure of cities' contribution to global GHG emissions? The next sections will address the questions of how much we actually know about how cities generate GHG and impact the atmosphere. We will also look at whether, within our current knowledge, we understand the societal and environmental drivers of the different trajectories of emissions by cities.

How Big is the Contribution of Urban Centers to Global Warming?

To understand how urban centers generate GHG, it is necessary to find a representative measure of carbon emissions (Molina and Molina 2002). Different issues need to be considered here. First, there is a paucity of data limiting the scope of any study exploring how big urban contribution to global emissions is. The second relates to the activities generating those emissions. Most of the total pollution comes from the combustion of fossil fuels (coal, oils, and natural gas) for heating and electricity generation for consumption by commercial and residential buildings, for running motor vehicles, and in industrial processes. Other sources are households consuming fuels in heaters and cookers, or indirectly in air conditioning. It is also usual to find carbon emissions resulting from land-use changes and aggravated by poor land management and many unpaved roads. Landfill sites taking urban wastes are another key source of methane. The manufacturing process used in the production of cement needed for the development of our urban areas can also account for as much as 5 % of global emissions of GHG. Finally, many activities undertaken outside the boundaries of urban centers such as agriculture and cattle, aimed at satisfying urban requirements of food, raw materials, forest products, and construction materials as well as electricity generation in rural areas but largely for urban use, also contribute to carbon emissions.

Second, GHG emissions are formed through different processes and have a residence time before being absorbed by the atmosphere or the oceans ranging from 3–4 years (CO_2) to 8–10 years (Methane) and even 50–100 years (Molina et al. 2002). Third, the impacts of urban emissions range from destruction of ecosystems to photochemical smog and from acidifying emissions to global warming (Molina and Molina 2002; Hardoy et al. 2004). All these impacts impair the health of populations and ecosystems in direct and indirect ways (Molina and Molina 2002).

Last but not least, many scholars, practitioners, and policy makers claim that cities are sources of most of the world's greenhouse gas emissions. Large cities take up only 2 % of the Earth's land mass, but they are responsible for about 75 % of the heat-trapping greenhouse gases that are released into our atmosphere.

Effects on Albedo from Urbanization

In a global perspective, urban albedo change needs to be considered in relation to the albedo of the replaced surface. As a rough example, paving a desert road with an initial albedo of, say, 0.40 with a resulting albedo of 0.10 is a considerable reduction. Paving a road through a coniferous forest after clearing a path might, on the other hand, double the albedo from an already low 0.05. In the same way, albedo changes due to urbanization need to consider previous land cover. Since potential natural vegetation as well as agricultural practices (such as choice of crops) vary with climate, the latitude of a city influences its impact on albedo.

Dark Surfaces

The introduction of dark impervious surfaces is a common and important feature of urbanization.

Many construction materials have lower albedo than nonurban surfaces. Offerle et al. (2003) reported, for example, that roofs and asphalt paving covered 49 % at a site in Chicago and 15 % in a Los Angeles residential area, which has large effects on urban temperatures. Wu and Murray (2003) found impervious surfaces to cover 75 % of a central business district site in Columbus, Ohio, of which a large portion consists of low-albedo surfaces such as asphalt.

Surface Geometry

As mentioned before, the geometry of the urban environment affects albedo in the same way vegetation canopies do, by enabling multiple reflections of the incoming short-wave radiation.

In modeling contexts, the concept of urban canyons is frequently used to describe a generalized situation (Oke 1987).

Increased Cloud Cover

From studying satellite Advanced Very High-Resolution Radiometer (AVHRR) images, Inoue and Kimura (2004) saw a clear increase in low-level cloud cover over urban areas of Tokyo, Japan. The processes responsible were hypothesized to be the higher sensible heat flux leading to an increased height of the mixing layer, so that clouds can form at the top of the enlarged thermals (warm rising air volumes), and also convergence and uplift of air due to local circulation induced by the urban to rural temperature contrast.

Effects from Urbanization Outside of Urban Areas

All modifications of air properties by urban areas, such as the cloud formation and precipitation tendency already discussed or air pollutants, can be transported downwind of its origin in the urban plume (Oke 1987). Thus, the effects of these urban modifications on albedo canal so occur outside of urban areas. Pollutants, for example, which contribute to atmospheric scattering and absorption thereby reducing the incoming short-wave radiation, can act in the same way over downwind rural areas.

Radiative Forcing of Urban Albedo Change

Radiative forcing, as outlined by the National Research Council (NRC 2005), is basically any climate forcing that affects the radiation balance. Pielke et al. (2002)

hypothesized that the radiative forcing of global surface albedo changes due to land cover changes may be comparable to the forcing of solar variability, anthropogenic aerosols, or to some of the greenhouse gases. They also suggested that more regional metrics need to be considered because of the potentially large offsetting regional changes, which would be masked by global averages.

In the latest IPCC report AR4 (Solomon et al. 2007), the radiative forcing of surface albedo change in general was suggested to be between 0 and –0.4 W/m^2, and the level scientific understanding was raised from low to medium-low.

Impacts on Anthropogenic Energy Consumption

In contributing to the UHI effect, urban albedo changes modify human energy needs for cooling or heating buildings. That increasing the albedo of buildings can be an effective measure to reduce energy demand (Akbari and Konopacki 2005). They estimate an annual electricity savings potential of 1294 GWh in Houston, Texas, from the combined use of reflective roofs, tree shading, and urban reforestation.

Climate Change in a Holistic View

See Fig. 6.

Case Study (Tehran Megacity)

If natural disasters, land degradation, and conflict result in sudden mass movements of people, megacities may experience the “urbanization of poverty,” which would send shocks through societies and the global economy as prospects for equitable economic growth deteriorate. While it would be wrong to generalize that these claims apply to all of the world’s 26 megacities, the policy issues at hand could certainly become salient in megacities like São Paolo, New York City, and London, where mass urbanization and climate changes are already major concerns for local governments.

Over 900 million people – more than 70 % of urban populations in developing countries – currently live in slum-like conditions, 151 with this number expected to increase to two billion over the next 30 years (Little and Cocklin 2009). Slum-like conditions are characterized by “low incomes, poor housing and provision of basic services, and no effective regulation of pollution or ecosystem degradation” (Campbell-Lendrum and Corvalan 2007) (Figs. 7 and 8).

Climate Change Scenarios

SRES scenarios (economic-social-population) have been developed by IPCC by which the world situation is evaluated in terms of environmental and economy in

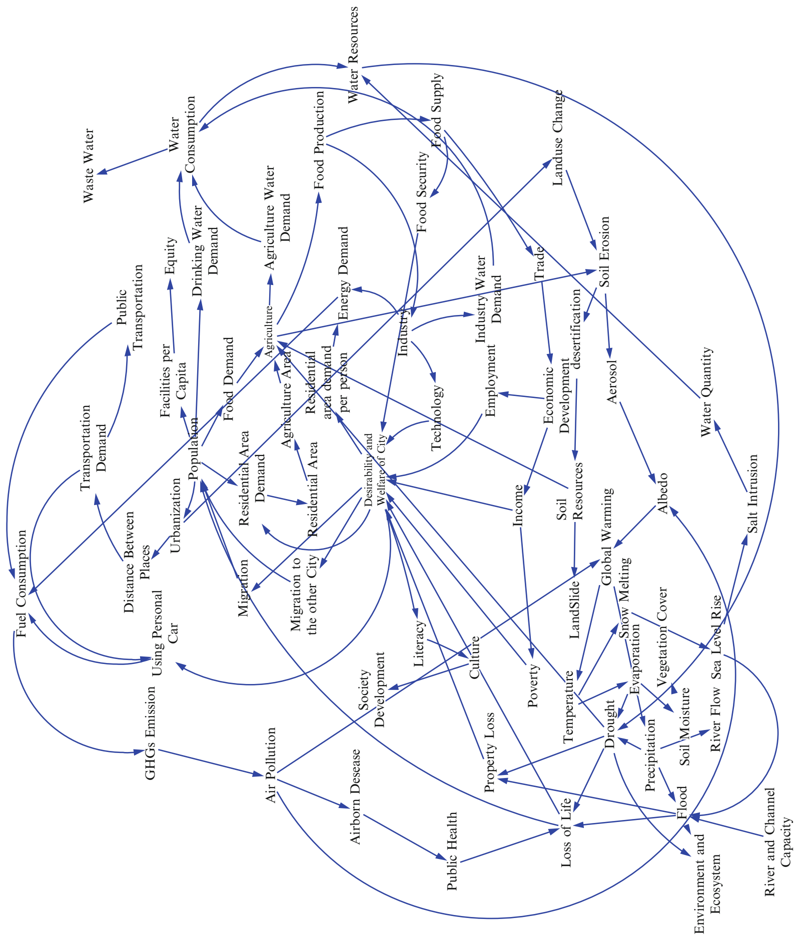

Fig. 6 Climate change drivers and interaction between them

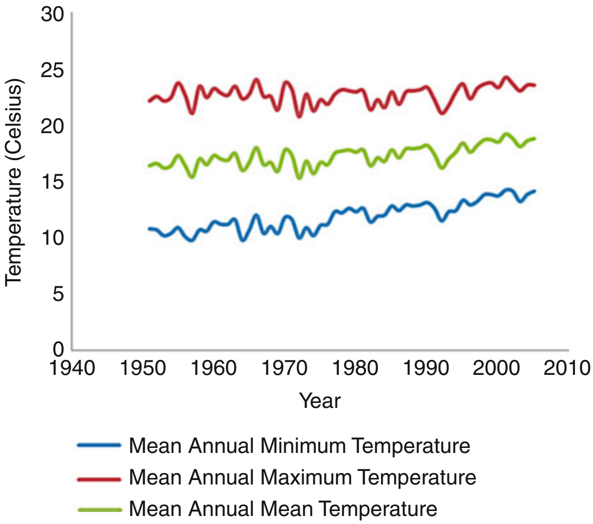
Fig. 7 Temperature increase



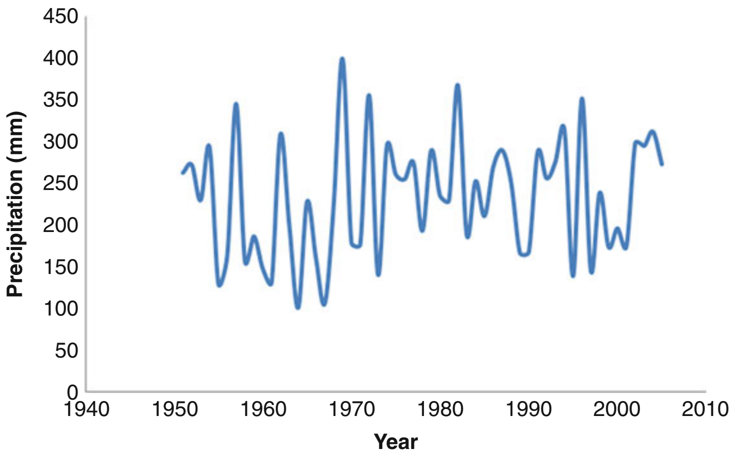


Fig. 8 Precipitation

two scales of global and local-regional. These scenarios are classified into four categories: A1, A2, B1, and B2.

In this research, A2 and B2 have been used for the basic period from 1951 to 2005 and the future period from 2016 to 2070. In addition, Hadcm3 model was applied based on the aforementioned scenarios and the study periods. In this regard, in order to downscale the climate change data, IDW method has been used.

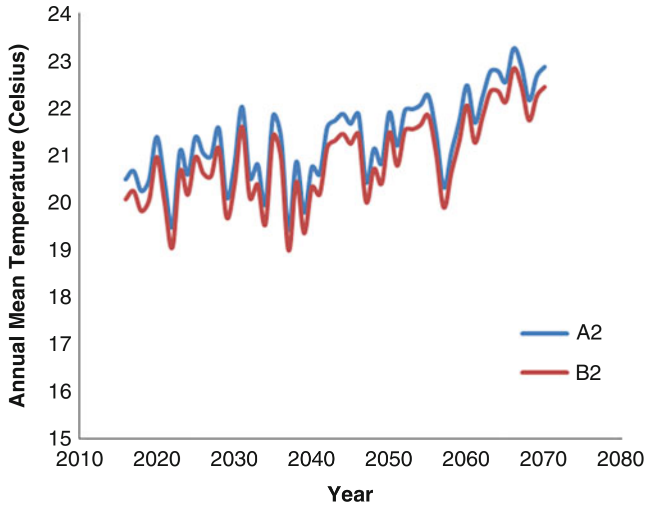

Fig. 9 Mean temperature

The results show an increase in mean monthly temperature in 55 prospective years (2016–2070). The highest mean monthly temperatures were observed in June, July, and August as many as 5 °C, 5.1 °C, and 4.9 °C in A2 and 4.9 °C, 4.9 °C, and 5.4 °C in B2 correspondingly.

In addition, there is an increase in the mean temperature in the prospective period (Fig. 9).

The highest monthly temperatures in the given future period compared to basic period in A2 scenario have been observed in May (5.1 °C), June (5.7 °C), and July (4.98 °C) and in B2 scenario in May (5 °C), June (5.34 °C), and August (5.57 °C) (Fig. 10).

Based on both A2 and B2 scenarios, the minimum temperature in prospective 55 years compared to the basic period has positively increased so that in some months, the minimum temperature has been increased as many as two times. In general, mean temperature, maximum temperature, and minimum temperature of the region will experience an increase (Fig. 11).

Based on the results, it is clear that according to both scenarios the most decrease in precipitation will be observed in May, June, and July. These decreases in A2 scenario are 22.26 %, 27.34 %, and 18.8 % correspondingly and 24.44 %, 22.8 %, and 21.4 % in B2 scenario compared to the observed period. On the other hand, according to A2 scenario, there is an increase in the amount of precipitation in wet seasons and months such as October and November by 1.7 % and 3.6 % correspondingly. Hundred percent of the increase in October is happened through the last 25-year period (2046–2070), and 88 % of this increase in November is occurred through 2046–2070. In addition, based on B2 scenario, 3.8 % and 13.16 % increase

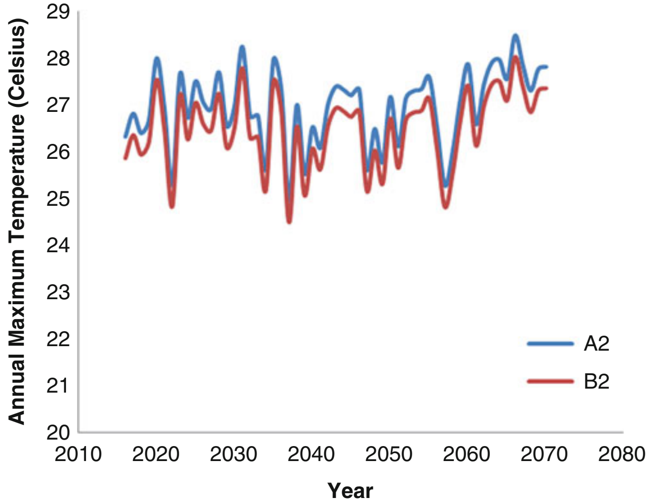

Fig. 10 Maximum temperature

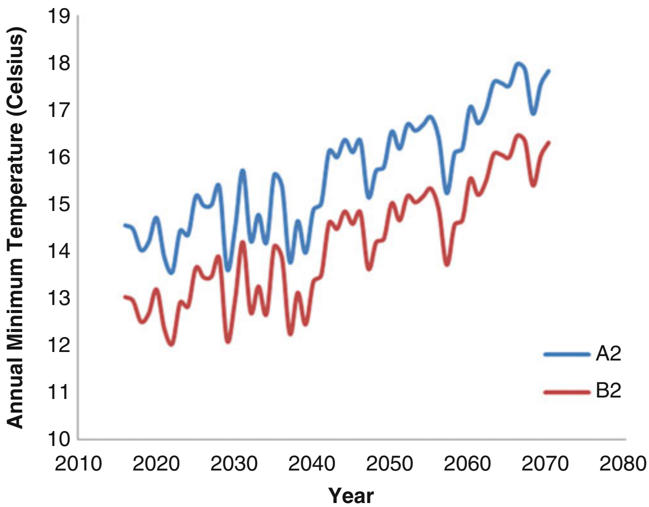

Fig. 11 Minimum temperature

in January and November have been observed correspondingly. Seventy percent of the increase in January is related to the last 25 years of the study period, and the 70 % of the increase in November is occurred in the first 30 years of the period (2016–2045) (Fig. 12).

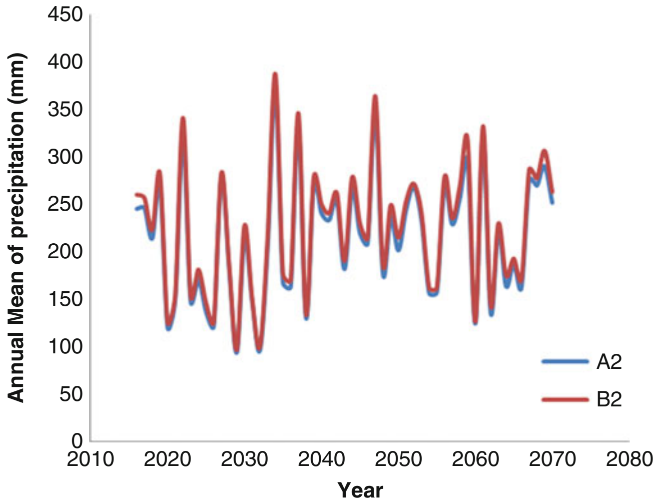

Fig. 12 Precipitation

Conclusions

There are many policy options to choose from. Climate change can be addressed through emission pricing (introducing a carbon tax), emission caps (establishing a cap-and-trade system), voluntary emission reduction targets and incentives for industry, and research funding for and development of new emission-reducing technologies.

The effects of urbanization on Earth's albedo are as diverse and heterogeneous as the urban fabric itself. While some aspects of urbanization tend to reduce the albedo compared to nonurban areas (e.g., dark surfaces, surface geometry, reduced snow cover in winter), some may increase it (e.g., increased cloud cover and air pollution), and some are still too poorly understood to make an assumption (e.g., modified surface moisture regime and downwind effects). It was found from satellite comparison between urban and cropland albedo that urban surfaces have 2–5 % lower.

The extent of urban areas is unclear and depends largely on the definition of urban areas, but the best estimate tends toward 0.44 % of the land surface in 2001, well over twice that cited by the IPCC in the AR4, which bases its estimation on up to 60-year-old data.

Increasing the albedo of all urban areas, globally, by 0.01 is calculated to exert a negative radiative forcing of less than 0.01 W/m^2, or more than 20 times smaller than the negative radiative forcing estimated by the IPCC for all land cover change since preindustrial times. Further expansion of urban areas into high-albedo areas such as croplands or deserts would result in increased warming. However small, this warming reduces the net cooling effect of land cover change.

By comparing the contemporary reality that more people live in cities than rural areas to the fact that only 13 % of the world's population lived in cities during the early twentieth century, it is evident that mass urbanization will impose societal, economic, and cultural pressures on urban centers, since there is currently less space and fewer resources to be shared or distributed (Bhagat and Mohanty 2009). Pressures include new burdens on transit infrastructure, increased competition for jobs, and reduced provision of social services. Instances of xenophobia may increase because some people might make a connection between migration and deteriorating conditions.

According to a publication by the United Nations Population Fund (UNFPA 2007), the size of the world's urban population will have grown to 4.9 billion people by 2030, with most of the growth occurring in the developing world.

Megacities are defined as metropolitan areas with a total population in excess of 10 million people (Rana 2011).

The World Health Organization (2008) reported that a warmer and more volatile climate is expected to increase the already high instances of annual deaths related to natural disasters (60,000), urban air pollution (800,000), diarrhea (1.8 million), and malnutrition (3.5 million).

As Adamo (2010) points out, "a large proportion of urban expansion is taking place in areas exposed to environmental hazards, [for example] low lying plains, coastal zones, stepped slopes and dry lands."

As evidence on the implications of a changing climate builds, migration is becoming a salient consequence of unabated greenhouse gas (GHG) emissions and poor climate risk adaptation (DePaul 2012).

Millions of people move each year, with over five million crossing international borders into developed countries and even greater numbers moving into or within developing countries.

Various strategies of land-use planning have been used in order to limit urban expansion, reduce the need to travel, and increase the energy efficiency of the urban built form.

In developing countries, there are few initiatives to explicitly mitigate climate change through urban design and development. In developed countries, private developers and community groups have led new urban development, brownfield regeneration, and neighborhood renewal projects, which seek to address climate change. Policy approaches for reducing GHG emissions from the built environment have primarily focused on issues of energy efficiency.

Climate change is having real impacts on migration patterns and, in turn, the capabilities of megacities to accommodate influxes of people.

First, sudden-onset climate-related disasters such as floods and hurricanes are push factors that are already resulting in forced migration from disaster areas.

Second, slow-onset climate impacts such as soil erosion and desertification are push factors, which magnify current "interacting physical and social variables, including agricultural and economic decline that ultimately force people from their homelands" (Homer-Dixon 1991).

A third climate-related push factor category marries the first two categories above: slow-onset climate impacts and sudden forced migration. A changing climate's impact on agricultural production and natural resources will lead to what Thomas Homer-Dixon (1991) calls "acute national and international conflict."

Migration patterns will be especially affected by sea-level rise and riverbank erosion, which are already contributing to "impoverishment and marginalization of rural families due to the loss of productive agricultural lands" (Poncelet et al. 2010).

An estimated 20 million Bangladeshis are living illegally in India, a situation that has become "a major source of tension between the two countries" and has generated "a host of destabilizing political, social, economic, ethnic, and communal tensions in many states and union territories of India" (Alam 2004).

Rigorous climate change mitigation and adaptation policies are needed to avoid such scenarios all around the world. Likewise, a normative shift is needed, particularly in climate-sensitive regions and security discourse, to redefine what is threatening. The cases of Bangladesh and India indicate that the real threat is climate change, not migrants. Without addressing the causes and effects of climate change, what many people perceive as threats from migration will never be resolved.

In 1990, the Intergovernmental Panel on Climate Change (IPCC) noted that the greatest single impact of climate change could be on human migration especially to urban centers – with millions of people displaced by shoreline erosion, coastal flooding, and agricultural disruption (IOM 2008). Since then various analysts have tried to put numbers on future flows of what came to be called "climate refugees." Yet it has been difficult to establish a predictive line of causation between climate change and migration (IOM 2008). This is so because finding the primary causes of migration is highly problematic, not least because individual migrants may have multiple motivations, and be displaced by multiple factors (Black 2001). For instance, studies of displacement within Bangladesh, and to neighboring India, have drawn obvious links to increased flood hazard as a result of climate change. However, such migration also needs to be placed in the context of changing economic opportunities in the two countries and in the emerging megacity of Dhaka, the encouragement of migration by some politicians in India, rising aspirations of the rural poor in Bangladesh, and rules on land inheritance and on ongoing process of land alienation in Bangladesh (Abrar and Azad 2004 cited in Wilbanks et al. 2007).

Would Climate Change Affect the Imports of Cereals? The Case of Egypt

Suzanna El Massah and Gehad Omran

Contents

Abstract

Climate change is recognized to be the greatest environmental problem facing the whole world due to its adverse impacts especially on the agricultural production, which is expected to vary across the countries. Within the context of Egypt's dependence on cereal imports to fill its production gap, this chapter shows that the climate change is expected to indirectly affect these cereal

DOI 10.1007/978-3-642-38670-1_61

imports, namely, wheat and maize, through affecting the cereal production in the major exporting countries.

Specifically, the chapter concludes a positive relationship between the Egyptian imports of wheat from the USA and the climate change presented in its impact on wheat production in the USA and on the contrary a neutral and negative relationships for both the Egyptian imports of wheat from Russia and imports of maize from the USA and Argentina.

Accordingly, the chapter recommends diversifying the import markets of cereals to Egypt to prevent the domination of few countries on the imports of such strategic commodities as wheat and maize, in addition to the urgency of enhancing the domestic production through applying the suitable adaptation and mitigation methods to face the expected negative impacts of climate change on cereal production in Egypt.

Keywords

Climate change • Greenhouse gases (GHGs) • Agriculture • Cereal(s) • Wheat • Maize • Imports • Egypt

Introduction

Climate change is one of the overwhelming environmental threats that are defined as a long-term alteration in the global weather patterns, including the temperature, precipitation, soil moisture, sea level, and storm activity. Such climate change is a potential consequence for releasing the greenhouse gases (GHGs) that accumulated in the atmosphere, resulting the global warming.

Climate change is expected to have many adverse impacts on various sectors, yet agriculture is considered to be the most tangible affected sector, as any alteration in the prevailing temperature or precipitation patterns will disturb the agricultural sector as a whole, including the productivity, crop yields, and soil fertility.

However, impacts of climate change on the agricultural production are expected to vary across the world, where some countries are expected to benefit, while others are expected to suffer as the African countries, which are threaten not only by losing their agricultural production, but also by losing their imports from the countries which will be negatively affected from the climate change.

The agricultural sector in Egypt is considered to be one of the vital contributors to the Egyptian economy; it shares by about 20 % in the GDP and employs around 30 % from the total labor force.

The importance of this research is derived from the dependence of Egypt – alike many other developing countries – on importing strategic commodities (cereal and wheat in specific) to fill its production gap; self-sufficiency of Egypt in wheat was only 40.5 % in 2010. However, these imports are threatened by the expected impact of the climate change on the production of cereals in the major exporting countries. Such threat would affect negatively the Egyptian social and economic life of Egypt.

Accordingly, the main goal of this research is to identify how would the cereal imports to Egypt be affected due to expected climate change. Our research is based on the expected production variations of the major exporting countries. The results of this study will help form the necessary actions and adapt the appropriate policies to deal with the expected availability of these strategic commodities in the future.

Consequently, this study tries to answer the following question:

- What is the economic impact of the global climate change (GCC) on Egyptian imports of cereals? Other sub-questions are answered as well:
- How to identify GCC, its causes, and its impact on the agricultural sector?
- What are the major international agreements for the GCC?
- What is the contribution of Egypt in GCC problem, and what is the impact of the GCC on various sectors in Egypt?
- How to measure the impact of the GCC on cereal imports (wheat and maize) to Egypt based on the expected production variations in major exporting countries?

Hypothesis and Methodology

The research is based on assuming an indirect relationship between cereal imports to Egypt and global climate change, through its impact on the production of cereals and hence the exports of the major exporting cereal countries to Egypt. Hence, the focus is solely on the impact of global climate change – through temperature variations – on the Egyptian imports of cereals, while keeping all other variables constant, including the overall domestic and international prices, the competitiveness of the market and/or the product, market competition, political relationships, and any other variable that could affect the Egyptian cereal imports except the global climate change.

The authors use analytical and qualitative methods to achieve the goal of this research. Moreover, the multiple linear regression model is applied to examine the indirect impact of climate change, presented in the production variations in the major exporting countries, on the cereal imports to Egypt using the available annual time series from 1991 till 2011.

The study focuses on the imports of wheat and maize due to their relative production and trade importance for Egypt. Additionally, the USA, Russia, and Argentina are selected as being the major exporters of wheat and maize to Egypt.

Introducing the Global Climate Change

Climate change is one of the greatest challenges facing the whole world, threatening the future development, peace, and prosperity. Climate change is predicted to disturb the global weather conditions including temperature, precipitation, sea level, and frequency of extreme events.

The most common definition for the climate change is that mentioned in the United Nations Framework Convention on Climate Change (UNFCCC), which defines it as the change of climate that is attributed directly or indirectly to the human activity altering the composition of the global atmosphere and that is in addition to natural climate variability observed over comparable time periods (UNFCCC 2007).

It is worth noting the difference between climate change and global warming, in which the first refers to a significant change from one climatic condition to another including changes in temperature, precipitation, wind, and humidity, unlike global warming that shows the average increase in the temperature of the Earth's surface (ICTSD-IPC 2009).

Climate has been obviously changed during the twentieth century, in which the global mean surface temperatures have increased by 0.6 °C and nighttime minimum temperatures have increased at twice the rate of daytime maximum temperatures. Also, sea levels have risen by 10–20 cm and at an average annual rate of 1–2 mm.

Furthermore, although heavy precipitation events have increased over middle and high northern latitudes, the tropical regions especially in Asia and Africa have experienced drier conditions specifically during winter; continental precipitation as well have increased by 5–10 % in the Northern Hemisphere and decreased in other regions as in North Africa. Furthermore, the frequency and intensity of droughts have increased (IPCC 2001). Although the climate is changing naturally throughout its history, the rapid warming seen today and the increased rate of climate change are attributed mainly to human activities (IPCC 2001). The causes of the climate change are classified into natural and anthropogenic ones (Fig. 1).

Although there are natural factors changing the climate, the anthropogenic causes due to human activities are responsible for aggravating such normal changing, through two main factors:

First: Greenhouse gases (GHG), as shown in Table 1, in the form of carbon dioxide, methane, nitrous oxide, and chlorofluorocarbons.

World GHG emissions have increased by about 20 % in only 15 years from 1990 to 2005, as shown in Fig. 2. Despite the existence of several GHGs, the carbon dioxide (CO_2) constitutes the largest share in the total GHG emissions (WRI 2012), indicating the growing use of fossil fuel.

Second: Changing land-use patterns. Various human activities such as the modification in agriculture and irrigation patterns, deforestation, and reforestation have altered the physical and biological properties of the land surface, by affecting the roughness of the absorbed solar radiation, increasing evaporation, and accelerating transpiration rate. Furthermore, it reduces the land's capacity to absorb carbon dioxide and increases the carbon emission from the land by enhancing the biomass decay, causing greater concentrations of GHG and disturbing the global climate (IPCC 2001).

Fig. 1 Cause of GCC

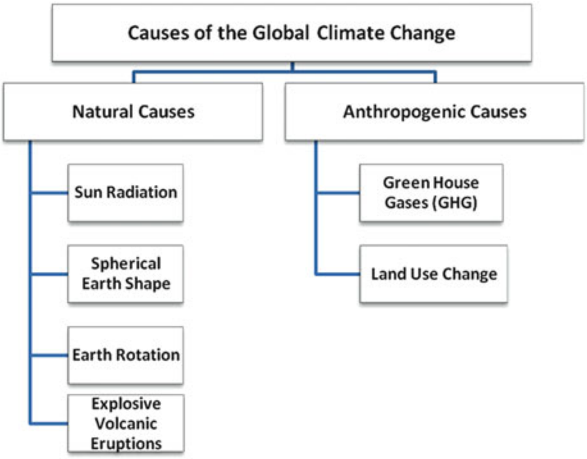

Table 1 Sources of GHGs

GHGs	Principal sources
Carbon dioxide (CO_2)	Burning of fossil fuels
	Electricity, transportation, and the increasingly energy-intensive standard of living
	Oxidation of biomass and the decomposition of the soil resulting from deforestation (burning or cutting of trees for agriculture and cattle ranching) release carbon stored in vegetation and in soil's organic matter into the atmosphere and reduce the number of trees available to absorb carbon dioxide
Methane (CH_4)	Emissions released from agricultural production especially rice paddies and other sources including emissions from landfills, coal mining, natural gas drilling, and leaking gas pipelines
Chlorofluorocarbons (CFCs)	Refrigerants propellants
	Aerosols
	Foaming agents and solvents
Nitrous oxide (N_2O)	It is elevated as result of
	Burning the fossil fuels
	Car emissions
	Expanding the use of nitrogen-based fertilizers

Climate Change and the Agriculture Sector

Agriculture is extremely vulnerable to climate change in that any alteration in the prevailing climate conditions as in temperature or precipitation patterns is expected to affect the agricultural sector as a whole, including the productivity,

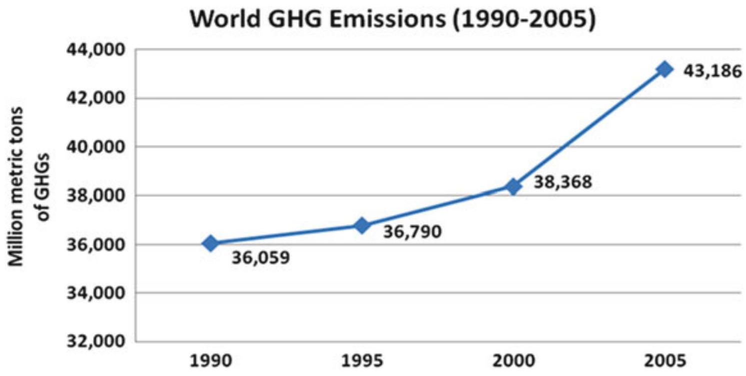

Fig. 2 World GHG emissions (1990–2005)

crop yields, and soil fertility. Yet such changes vary considerably across regions; climate change is expected to change the geographic distribution of the agricultural production, in the favor of higher latitudes and against lower ones which will be negatively affected (IPCC 1996). Latitude specifies the north-south position of a country on the Earth's surface. Higher-latitude countries are those countries lying far from the equator or near the north or south poles and characterized by being colder than the low- and middle-latitude countries due to their location far from the sun rays. Classifications for countries by latitude and world climate map are mentioned in the Annex. This shift in production potential will have to coincide with higher trade flows for agricultural products such as cereals from mid to high latitude to low latitudes, for example, cereal imports to the developing countries are estimated to rise by 10–40 % by 2080 (Huang et al. 2010).

Climate change projections vary; hence different expectations about its effect on agriculture are calculated. Changes in temperature, precipitation, and CO_2 concentrations could result whether in reductions or increases in growth, productivity, and water needs by crops. The direction of such effects depends on several factors such as the crops themselves: some are more sensitive to changes in temperature or CO_2 levels than others; for example, wheat is more sensitive and responsive to the CO_2 increase than maize. The location is another factor; grain crops in northern locations are more likely to benefit from additional heat and increase their yields, while in southern locations, yields are more likely be reduced. Accordingly, the coming analysis will be divided, as shown in Fig. 3, into the effect through temperature and the effect through CO_2.

The Impact of Higher Temperature on Agriculture

The increase in temperature is expected to affect the agricultural process in several ways.

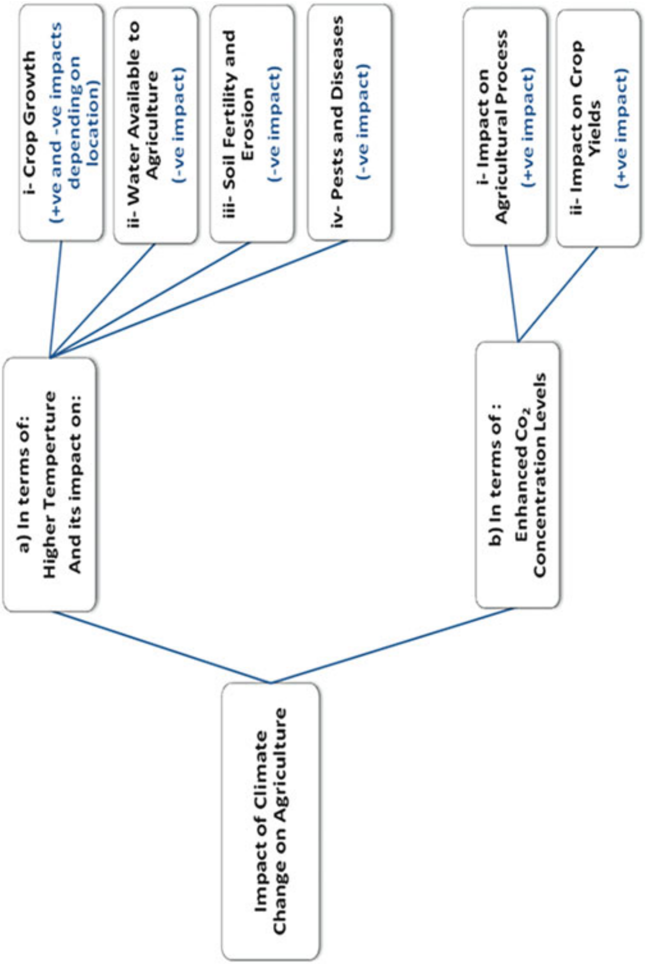

Fig. 3 Impact of climate change on agriculture

The Impact of Higher Temperature on Crop Growth

One of the most important positive effects of the increase in temperature, especially in middle and higher latitudes (e.g., USA, Europe, Australia), is improving the conditions for crop growth through extending the length of the potential growing season, reducing the growing period required by crops for maturation, and thus allowing earlier maturation and harvesting, as well as increasing the possibility of completing two or more cropping cycles during the same season and the likelihood of expanding the crop-producing areas, despite the probability of decreasing the yields in higher latitudes due to the less fertile soils that lie there (Rosenzweig and Daniel 1995):

> So, in middle and high latitudes, increasing temperatures may benefit crop development, which is currently limited by cold temperatures and short growing seasons. However, when temperatures exceed the optimal for biological processes, crops often respond negatively with a steep drop in net growth and yield, as high temperatures accelerate the physiological development, and hence leading to hastened maturation and reduces crop yields by up to half if it coincides with a critical phase in the crop cycle like flowering. (Rosenzweig and Daniel 1995)

On the other hand, increased temperature in warmer/lower-latitude regions is expected to accelerate the respiration rate, at which plants release CO_2 causing less than optimal conditions for net growth (Rosenzweig and Daniel 1995), and increases the evaporation rates therefore reduces the moisture availability which then affects the yields' negatively (Parry 1990). Moreover, higher temperatures during the growing season speeds the development of annual crops, especially in the grain-filling stage, thus allowing less grain to be produced (Downing 1996):

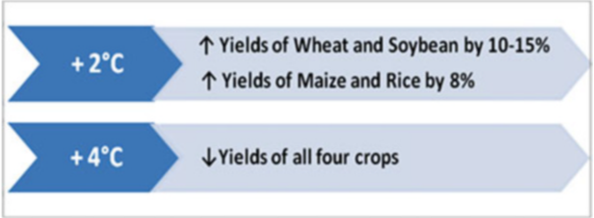
> So crop growth in most of the developed countries (middle and higher latitudes) will benefit from the increase in temperature, comparing to the developing ones (lower latitudes) which will be negatively affected.

Regarding the impact of temperature increase on cereals, which is the concern of this paper, the average crop yield – weighted by national production – shows a positive response to +2 °C warming and negative response to +4 °C, withholding the direct effects of CO_2 and precipitation at current levels, illustrated in Fig. 4. For example, with +2 °C temperature rise, yields of wheat and soybean increase by 10–15 %, and maize and rice increase about 8 %; however, yields of all four crops turn negative at +4 °C (Downing 1996).

The Impact of Higher Temperature on the Water Available to Agriculture

Agriculture is strongly influenced by the availability of water, and climate change is expected to affect the agricultural process by the changes in temperature, seasonal rainfall, and precipitation patterns, in addition to the expected frequency of floods and droughts especially for rain-fed crops and irrigated crops. Also, higher temperatures are expected to enhance the occurrence of moisture stress due to the accelerated transpiration which is harmful to crops, particularly soybeans and wheat, and as a result, there will be a need to develop crop varieties with greater drought tolerance (Rosenzweig and Daniel 1995).

Fig. 4 Impact of temperature increase on cereal yields



Higher temperatures lead to an increase in evaporation rates and therefore faster cycling of water (Huang et al. 2010). Although global warming is likely to increase rainfall, the net impact of higher temperatures on water availability is a race between higher evapotranspiration (the combined effect of soil evaporation and plant transpiration) and higher precipitation; however, that race is typically won by higher evapotranspiration (Cline 2008). The demand on water for irrigation is projected to rise as more water will be required per acre; accordingly, more energy will be needed to pump water, making the practice of irrigation more expensive (Rosenzweig and Daniel 1995).

The Impact of Higher Temperature on Soil Fertility and Erosion

Higher temperatures are expected to affect the soil, as warmer conditions are likely to speed up the natural decomposition of organic matter affecting the soil fertility. However, this negative effect could be balanced by the higher photosynthetic rates (Parry 1990). Also, warmer conditions are likely to accelerate the continual cycling of plant nutrients (carbon, nitrogen, phosphorus, potassium, and sulfur) in the soil-plant-atmosphere system and thus enhancing greenhouse gas emissions (Rosenzweig and Daniel 1995).

Furthermore, warmer conditions and higher CO_2 will increase the process of nitrogen fixation (nitrogen is made available to plants in a biologically usable form through the action of bacteria in the soil), where drier soil conditions will reduce both root growth and decomposition of organic matter and increase vulnerability to wind erosion. And an expected increase in extreme precipitation events will enhance soil erosion (Rosenzweig and Daniel 1995).

Moreover, higher temperature will accelerate the soil evaporation and hence decrease the soil moisture availability (Cline 2008). Finally, higher temperatures will increase the hazard of salt accumulation in the soil due to the intensified evaporation and evapotranspiration.

Generally, changes in soils (e.g., loss of soil organic matter, leaching of soil nutrients, salinization, and erosion) are a likely consequence of climate change. However, cropping practices such as crop rotation, conservation tillage, and improved nutrient management are very effective in combating or adapting such effects (IPCC 1996).

The Impact of Higher Temperature on Pests and Diseases

The warmer conditions are more favorable for the proliferation of insect pests extending their geographic range. Longer growing seasons will enable insects such as grasshoppers to complete a greater number of reproductive cycles during the spring, summer, and autumn (Parry 1990).

Warmer winter temperatures may also allow larvae to grow over in new areas, as it is now limited by the cold temperatures, thus causing greater infestation during the following crop season. Altered wind patterns may change the spread of both wind-borne pests and bacteria and fungi that are the agents of crop disease. Crop-pest interactions may shift as the timing of development stages in both hosts and pests is altered (Parry 1990).

The possible increases in pest infestations may bring about greater use of chemical pesticides to control them, a situation that will require the further development and application of integrated pest management techniques (Rosenzweig and Daniel 1995).

The Impact of the Enhanced CO_2 Levels on Agriculture

The Impact of the Enhanced CO_2 Levels on the Agricultural Process

Crop production depends mainly on the photosynthesis process that allows plants to absorb energy from the sun, carbon dioxide (CO_2) from the air, and water from the soil, converting them into sugar and cellulose/carbohydrates. Accordingly, the impact of an increased CO_2 level on agriculture is summarized in Fig. 5. Any increase in CO_2 concentrations will immediately increase the photosynthetic rate, allowing more CO_2 to be absorbed and converted to carbohydrates. However, such initial strong response is often reduced under long-term exposure to higher CO_2 levels. Increasing in the rate of photosynthesis will increase the leaf area production, hence earlier and complete light interception, which stimulates biomass, thus increasing respiration. So, the difference between photosynthetic gain and loss of carbohydrate as a result of respiration is the net growth (Fisher et al. 2002). Higher levels of atmospheric CO_2 also induce plants to close the small leaf openings known as "stomata" through which CO_2 is absorbed and water vapor is released by transpiration. Thus, under CO_2 enrichment, the transpiration will decrease and crops will use less water even while they produce more carbohydrates. This dual effect will likely improve water-use efficiency, which is the ratio between crop biomass and the amount of water consumed (Rosenzweig and Daniel 1995).

Moreover, an increase in CO_2 level accelerates crop development due to the increase in leaf temperature resulting from the reduced transpiration and leading to an accelerated aging of the leaf tissue, as well as a faster rate of plant development and therefore a considerable increase in leaf area development, especially in the early crop growth stages. However, the overall effects of leaf-temperature increase will depend upon whether or not optimum temperatures for photosynthesis are approached or exceeded. Moreover, at higher CO_2 levels, plant growth damage caused by air pollutants, such as nitrogen oxide (NO_2), sulfur dioxide (SO_2), and ozone (O_3), is at least partly limited because of the reduced stomata opening (Fisher et al. 2002).

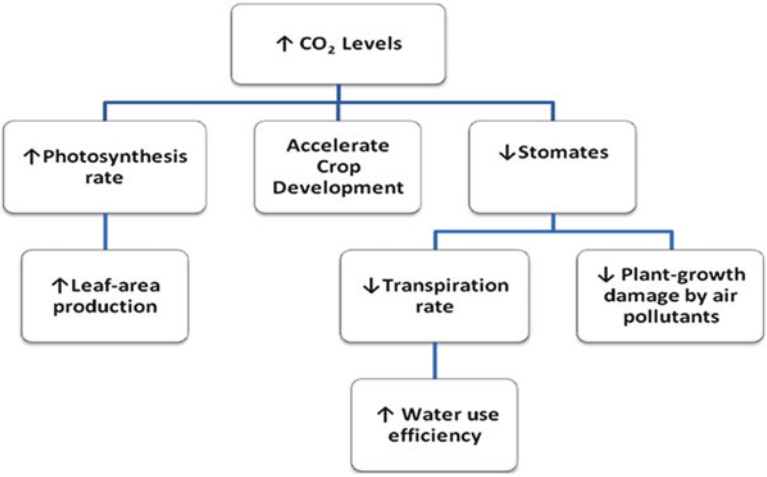


Fig. 5 Impact of enhanced CO_2 levels on agricultural process

Although increased atmospheric concentrations can stimulate photosynthesis and improve the efficiency of water use by plants, the extent to which this happens depends on the type of plant, as crop species vary in their response to CO_2 because of differing photosynthetic mechanisms. CO_2 concentration is known to have more positive effect on C3 crops (C3 crops are so-called because the product of their first biochemical reactions during photosynthesis has three carbon atoms and they belong to a physiological class that responds readily to increased CO_2 levels, e.g., wheat, rice, and soybean) than C4 ones (e.g., corn, maize, millet, sugarcane, and sorghum) that tend to be less responsive to enriched CO_2 concentrations (Stern et al. 2006).

As shown in Fig. 6, C3 plants expected to increase in productivity by about 20–30 % at doubled CO_2 concentrations, while C4 plants show an increase by 5–10 % only which is less pronounced response than that of the C3 crops (Fisher et al. 2002).

The Impact of the Carbon Fertilization Effect on Crop Yields

The impact of climate change on agriculture mainly depends on the size of the "carbon fertilization effect," as carbon dioxide is the basic building block for plant growth. Higher CO_2 concentration is expected to enhance the initial benefits of warming and increase yields through stimulating photosynthesis and decreasing water requirements. Such positive effects was expected to offset the negative ones – as water stress, shorter growing season, and lower yields – raised from increasing the mean temperature (Stern et al. 2006).

Predictions for the carbon fertilization effect suggest that yields of several cereals – wheat and rice in particular – will increase with 2–3 °C temperature

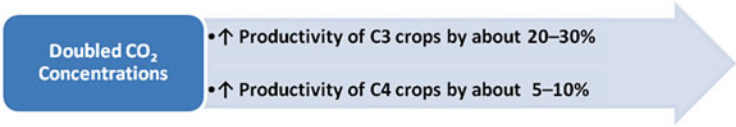

Fig. 6 Impact of doubling CO_2 levels on productivity of cereals

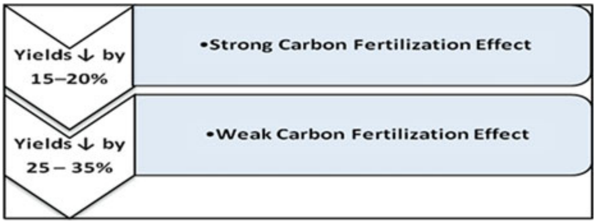

Fig. 7 Percentage yield decrease across Africa and Western Asia (due to temperature increases by 3 or 4 °C)

increase and then starts to fall with greater temperature increases. However, maize shows greater declines in yield with rising temperatures because of its different physiology that makes it less responsive to the direct effects of rising carbon dioxide. And the world cereal production was expected to fall marginally by about 1–2 % only for warming up by 4 °C. Yet, the latest analysis from crops grown in more realistic field conditions suggests that the effect is likely to be more than what previously predicted. That in case of weak carbon fertilization effect, worldwide cereal production is expected to decline by 5 % for a 2 °C rise in temperature and 10 % for a 4 °C rise. By 4 °C, entire regions may be too hot and dry to grow crops. Agricultural collapse across large areas of the world is possible at even higher temperatures (5 or 6 °C); however, clear empirical evidence is still limited. Furthermore, the impact is expected to be strongest across Africa and Western Asia (including the Middle East), illustrated in Fig. 7, where yields could fall by 25–35 % (weak carbon fertilization) or 15–20 % (strong carbon fertilization) once the temperature increases by 3 or 4 °C. Maize-based agriculture in tropical regions – such as parts of Africa and Central America – is expected to be severely declined due to its less responsiveness to carbon effects (Stern et al. 2006).

The carbon fertilization effect becomes obvious when highlighting the expected decrease in the agricultural output capacity, which is predicted to be 3.2 % globally versus 15.9 % if the fertilization effect is not taken into consideration, as mentioned in Fig. 8. Also the developing countries are expected to be highly affected than the industrial ones even if the carbon fertilization effect is taken into consideration (Cline 2007). So the developing countries are expected to be severely affected by the climate change through the reduction in the agricultural yields even if the carbon fertilization effect is considered.

The above impacts of climate change on agriculture indicate that there are interrelated positive and negative impacts for the temperature increase and CO_2 enhancement on agriculture, which could be summarized in Table 2.

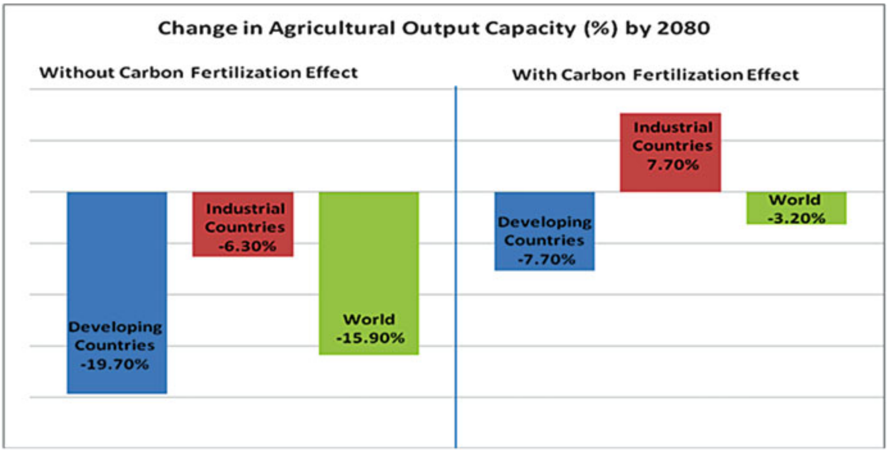

Fig. 8 Expected change in agriculture output by 2080

The above analysis concludes that agriculture is extremely vulnerable to climate change; some tropical low-latitude regions as most of the African and developing countries are projected to be negatively affected by the climate change through the reduction in the available irrigation water, the loss of agriculture land, changes in soil moisture, and increasing pest and disease problems, which would all in all lead to the loss of crops. For example, it is predicted that African countries and some parts in Asia are likely to face 30 % losses in the crop yields by 2080, where the effects of temperature and precipitation changes on crop yields are beyond the inflection point of the beneficial direct effects of CO_2. On the contrary, high-latitude northern countries are expected to benefit from the climate change by extending the growing seasons and decreasing the growing period required for the crop maturation, in addition to augment crop productivity due to the increased photosynthetic activity and improved water-use efficiency as result of the carbon fertilization effect. As well, crop yields in the developed countries are expected to increase as a result of regional increases in precipitation that compensate for the moderate temperature increases and as a result of the direct effects of high concentration of CO_2 (Parry 2004).

The overall effect of moderate climate changes on the world is expected to decrease food production, as reduced production in some areas is balanced by gains in others. Nevertheless, the vulnerability to climate change is greater in developing countries, which in most cases are located in lower warmer latitudes, as cereal grain yields are projected to be negatively affected by the climate change. Hence, agricultural exporters in middle and high latitudes (such as the USA and Canada) stand to gain, as their national production is predicted to expand and particularly if grain supplies are restricted and prices rise. Thus, countries with the lowest income may be the hardest affected (Stern et al. 2006).

Table 2 Positive and negative impacts of climate change on agriculture

Item	Positive impact	Negative impact	Notes/limitations
Impact of enhanced Co_2 concentration levels on agriculture	Increase the photosynthetic rate, and carbon fertilization effect is enhanced	Stimulate biomass	The initial strong response of photosynthetic rate is often reduced under long-term exposure to higher CO_2
	Water-use efficiency will increase as a result of closing stomata	Increase respiration rates	Crop species vary in their response to CO_2 in part due to their photosynthetic mechanisms
	Decrease transpiration rate		CO_2 concentration is known to have more effects on C3 crops than C4 ones
	Accelerate crop development		
	Partly limit the plant growth damage caused by air pollutants		
Impact of higher temperature on agricultural process	Improving the conditions for crop growth as follows:	Accelerates physiological development, leading to hastened maturation and reduced yield	If the temperature exceeds the optimal, crops respond negatively with a great drop in net growth and yield
	Extending the length of the potential growing season	Accelerates the respiration rate	Crop yields respond positively for temperature increases up to 3 °C, after which any further increase will decrease crop yields
	Reducing the growing period required by crops for maturation	Speeds annual crops and allows less grain to be produced	
	Increasing the possibility of completing two or more cropping cycles during the same season	Increases evaporation rates and reduces the moisture availability	
	Crop-producing areas may expand		
Impact of higher temperature on the water available to agriculture	Rainfall increase	Agricultural process; rain-fed and irrigated crops will be affected by the change in the precipitation and rainfall pattern	The evaporation effect of the higher temperature is greater than the rainfall increase
		Causes moisture stress which is harmful to crops	
		Increases evaporation, causing faster water cycling	

Impact of higher temperature on soil fertility and erosion		Speeds the natural decomposition of organic matter affecting soil fertility	Increases in root biomass resulting from higher photosynthesis could offset soil decomposition
		Enhances plant nutrient cycle and increases CO_2 and N_2O gas emissions and leaching of soil nutrients	
		Increases vulnerability of soil erosion, especially with extreme wind and precipitation events	
		Accelerates evapotranspiration rate and decreases soil moisture availability	
		The hazard of salt accumulation in the soil will increase due to intensified evaporation	
Impact of higher temperature on pests and diseases		Increases proliferation of insect pests and hence the greater use of chemical pesticides	
		Extends the geographic range of some insect pests	
		Enables insects to complete a greater number of reproductive cycles	
		Causes greater infestation during the following crop season	
		Altered wind patterns change spread agents of crop disease (wind-borne pests, bacteria, and fungi)	

Correspondingly, given the adverse effects of the climate change on agriculture, the international community and especially the developing countries, which are located in the low warm latitudes and expected to be severely affected by the climate change, should take serious steps toward facing climate effects through mitigation and adaptation methods, in addition to enhancing the international cooperation and activating the related agreements that will be mentioned in the next section.

International Global Climate Change (GCC) Agreements

The overwhelming impacts of climate change raised the call for taking various collective international efforts and agreements as shown in Fig. 9. However, the signature of the United Nations Framework Convention on Climate Change (UNFCCC) in 1992 is considered to be the turning point in addressing the climate problem and providing a new focus for the climate-related activities.

Most of the climate change agreements showed an increasing global awareness for the role of the developed countries in assisting the developing ones, based on the principle of "common but differentiated responsibility" that, for example, only ten developed countries are responsible for releasing almost 70 % from the total world greenhouse gases in 2005 (WRI 2012), yet the whole world countries are suffering from the negative impact of these emissions.

Egypt has realized the importance of international cooperation in dealing with climate change. However, as a non-Annex country, it was not committed to meet any specific emission reduction or limitation targets. Accordingly, Egypt is expected to have a more vital and substantial role in tackling the GCC with special concern toward reducing such increasing emissions by enhancing the active integration in the international GCC activities, not only to be committed to the emission reduction but also to make use from other countries' experience in dealing with GCC through various adaptation and mitigation methods.

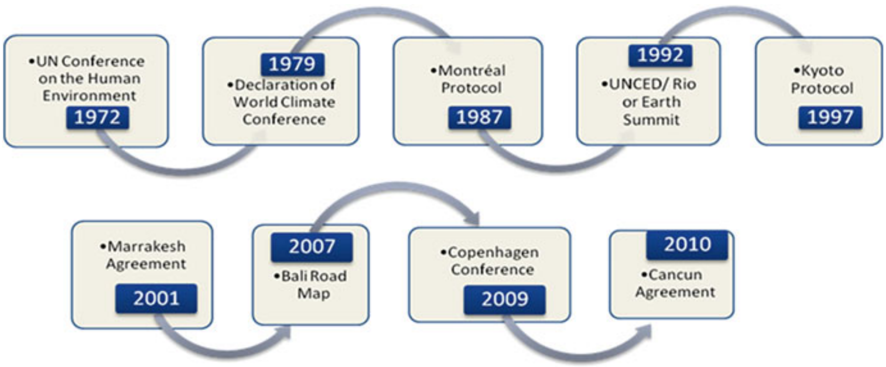

Fig. 9 Major international climate change actions and agreements

The Role of International GCC Agreements

All of GCC international agreement were expected to limit and/or reduce the current levels of the GHG emissions, and hence can be used to measure the impact of these agreements. However, the world GHG emissions have increased by **20 %** during the period from1990 till 2005.

Furthermore, the climate change agreements and especially the UNFCCC and Kyoto Protocol aimed at encouraging the industrialized (Annex I) countries to both reduce their GHG emissions and assist the developing (non-Annex) countries in adapting and mitigating the negative impacts of climate change. However, as shown in Fig. 10, GHG emissions in Annex I countries have been reduced by only 1.5 % from 1990 to 2005, while the emissions of non-Annex countries show an enormous increase of 42 % in 2005 compared to 1990. Moreover, the increasing gap of GHG emissions between Annex I and non-Annex countries indicates the financial and technical capability of Annex I countries to reduce their emissions and use the latest clean and green technologies when compared to non-Annex or developing countries which lack the suitable resources for mitigating the climate change and reducing its emissions.

Accordingly, a special concern should be directed to non-Annex, developing countries that lack technical resources to face the climate change, thus resulting in an enormous increase in their GHG emissions which will expand all over the globe. Therefore, serious international steps should be taken to achieve the objectives of climate change agreements, noting that Annex I countries (i.e. developed countries) should take the lead in combating the climate change by mitigating the climate change, reducing their GHGs emissions, adapting the negative impacts of climate change, and assisting the developing countries to do the same, depending on the principle of common but differentiated responsibilities.

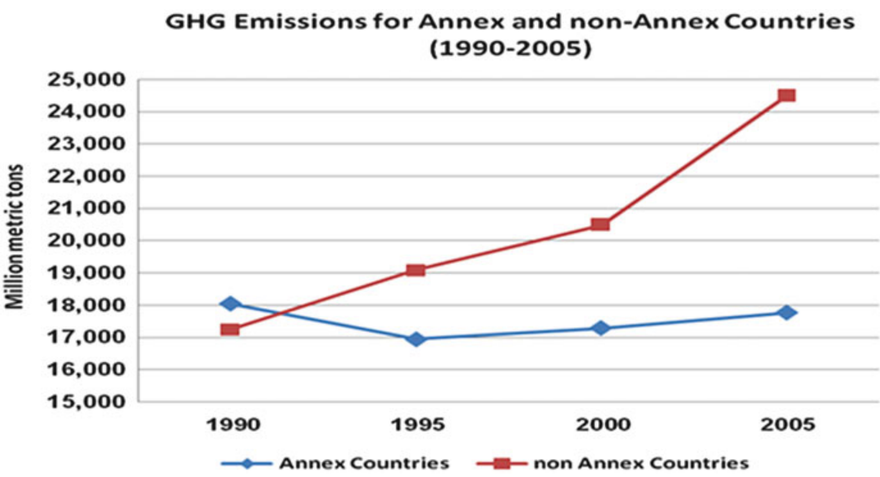

Fig. 10 GHG emissions for Annex and non-Annex countries (1990–2005)

Egyptian Situation Concerning the GCC

Egyptian Contribution in the GCC

Although the total GHG emissions of Egypt are considered minor, representing only 0.53 % of the total world emissions in 2005, these emissions have increased dramatically by around **82 %** in only 15 years as shown in Fig. 11.

Such dramatic increase in the GHG emissions could be explained in the light of several indicators, including the high population growth rates that have also increased by 30.5 % from 1990 till 2005 and the increase in the national energy use by 91.5 % as a result of the expanding consumption of fuel in industry, transportation, and electricity presented in the increase of the energy use per capita during the same duration by 46.5 %.

Figure 12 shows energy sector as the main source of GHG emissions in Egypt by releasing 75 % from the total emissions in 2005 followed by the agricultural sector, industrial process, and waste which release 12 %, 8 %, and 5 % from the total GHG emissions of Egypt in 2005 (WRI 2012).

Accordingly, the agricultural sector is considered to be the second largest emission sector in Egypt. So, mitigation efforts should be directed toward reducing the GHG emissions from this sector parallel with taking the suitable adapting measures toward the climate change consequences in this sector with the highest possible consideration.

Impacts of GCC on Egypt

Egypt is considered to be one of the most vulnerable countries toward the climate change, as its lifeline is concentrated in only 5.5 % from its total area, mainly in the coastal zones and around the Nile, the sole source of freshwater in Egypt. So, any disturbance in the sea level or Nile flow as result of the climate change will

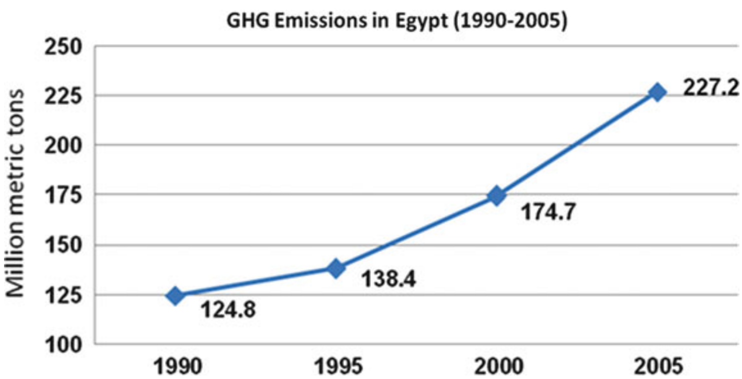

Fig. 11 GHG emissions in Egypt (1990–2005)

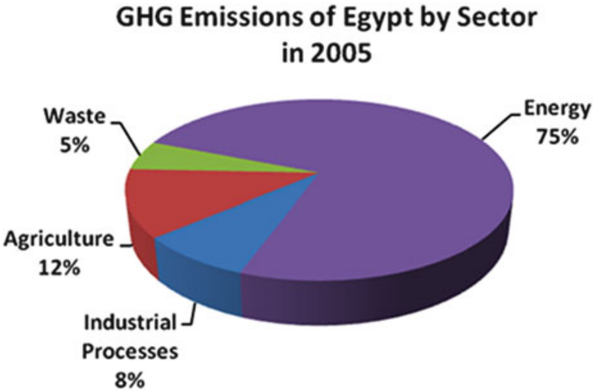

Fig. 12 GHG emissions in Egypt by sector

obviously affect various strategic, economic, and social sectors in Egypt (Saber 2007). One of the most expected sectors to be affected from the climate change is the agricultural sector, which will be affected from both the changes in the temperature and Nile flow, as it consumes 80 % from the total Nile demand and relies mainly on intensive water irrigation (OECD 2004).

Agricultural production is affected in the first place by the overall temperature. Accordingly, temperature increases, disturbances in precipitation, high evaporation rates, elevated CO_2 levels, prevalence of pests and diseases, and other consequences of the climate change will definitely affect the agricultural sector in Egypt. Although Egypt depends currently on importing most of the basic agricultural products to overcome the insufficiency problem of its production against the growing population rates, the problem will be much more complicated when considering that the GCC is expected to increase such insufficiency.

Study by Saber (2007) predicted that the climate change will increase the insufficiency of the agricultural cereal crops by 10–60 % and decrease their productivity by 18 % for wheat and barley, 19 % for maize and sorghum, 28 % for soybean, and 11 % for rice in 2050 which will definitely threaten the food security in Egypt, especially when its related to a strategic crop like wheat. Moreover and based on the expected decline in the productivity, as well as the projected increase in the population rates, the self-sufficiency rates of wheat, maize, and rice are likely to decline by 45.4 %, 80.7 %, and 153 %, respectively, in case of 2–3 °C temperature increase (Noufal 2009). Accordingly, adaptive measures are needed through cultivating different varieties of wheat that can bear high temperatures and show resistance to drought, along with the expansion in cultivating winter crops such as lentils with good distribution of wheat among the geographic areas that are likely to prevent the negative effects of expected or at least reduce the expected negative effects of the climate change (IDSC 2007).

Accordingly, despite the increase that might occur in photosynthetic rates as a result from CO_2 enhancement, climate change is expected to severely affect agricultural sector as whole and from many perspectives as shown in Fig. 13.

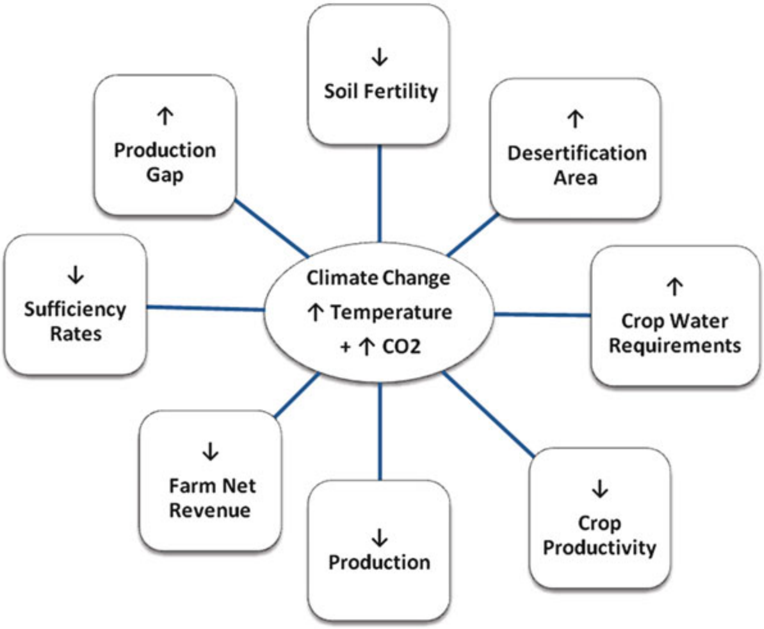

Fig. 13 The impact of GCC on agricultural sector in Egypt

Such consequences will not be limited to the agricultural sector, but it be will be expanded to reach the whole economy, especially when dealing with a strategic sector such as the agricultural one sharing with 17 % from the GDP and 30 % from the total employment in Egypt. Climate change is expected to affect the food availability in general and cereal in specific, affecting both the production in Egypt and in the major exporting countries as well. So, the following section will focus on showing the economic structure of cereals in Egypt to reach a conclusion on how the cereal imports will be affected by the climate change given the expected production decrease of the exporter countries, noting that Egypt is a net importer country for cereals due to its increased insufficiency compared to the increased domestic consumption.

Economic Impact of GCC on Cereal Imports to Egypt

Economic Structure of Cereals in Egypt

Cereals are a strategic agricultural commodity in Egypt as shown in Fig. 14, which have a very special production and trading position. In terms of production, cereals are ranked to be the first agricultural commodity group that shared almost 45 % from the total agricultural cultivated area and 30.8 % from the total agricultural production in 2010. By product, wheat and maize are considered to be the

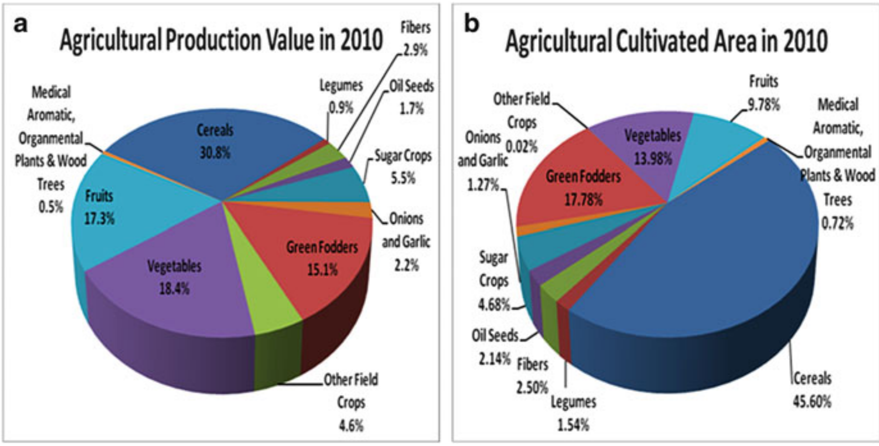

Fig. 14 Agricultural Production and cultivated area in 2010

main cereal crops that shared 78 % from the cultivated area, 73 % from the production value, and 82 % from the average per capita of cereals in 2010, followed by rice, sorghum, and barley, respectively (Ministry of Agriculture and Land Reclamation 2012).

In terms of trade, cereal imports are ranked to be the fifth largest imported products to Egypt, where wheat and maize constituted 63 % and 36 % from the total cereal imports, respectively. Although the cereal imports constitute only 7 % from the total Egyptian imports in 2010, Egypt is considered to be the third largest importing country from cereals generally and the first importing one from wheat specifically (Trade Map 2012).

The trade structure of cereals during the last 15 years has shown that imports were 8 times greater than the exports on average, yet the growth rate of the cereal exports was almost triple the cereal imports during the same period based on Comtrade data, which indicates the continuous active effort of Egypt toward enhancing its trade position by pushing the cereal exports regardless its small share compared to the cereal imports. However, Egypt is considered a net cereal importer country with an increasing trade deficit that jumped by almost 162 % from 1995 till 2010 (Fig. 15). Accordingly, the next section will focus on the cereal imports. It is worth noting that the increase in cereal imports (by $ value) indicates an increase in the cereal import prices rather than the real imported quantity; therefore, this study emphasizes on the cereal import quantities rather than the value ones.

The analysis of the cereal imports per product during the period from 1995 till 2010 shows that wheat and maize constituted the major part and accounted for almost 58 % from the total cereal imports to Egypt, followed by maize with 41 % as shown in Fig. 16.

Accordingly, the remaining sections of this research will focus on wheat and maize, as Egypt is depending on imports to fill its production gap, and hence any decrease in these vital strategic import products, due to climate change, will affect negatively the Egyptian economic and social life.

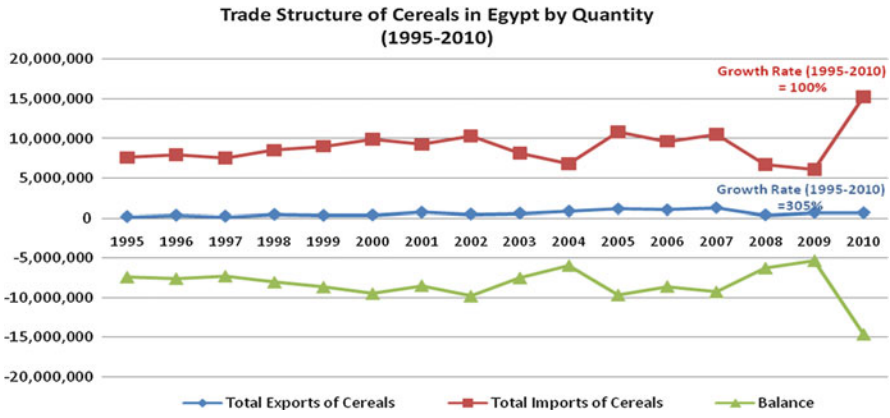

Fig. 15 Trade structure of cereals by quantity (1995–2015)

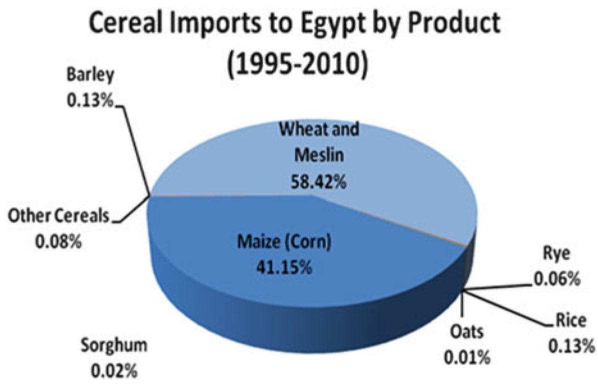

Fig. 16 Cereal imports to Egypt by product

Impact of GCC on Egyptian Imports of Cereals

In order to examine the indirect impact of the GCC on the cereal imports to Egypt, the first step is to identify the direct impact of the GCC on the production of cereals in the major exporting countries to Egypt using a reliable study (Hisas 2011); this will be followed by an econometric model that shows the effect of any production variation in the major exporting countries on the Egyptian imports of cereals and then finally links and shows the impact of the GCC on the cereal imports to Egypt, given the production variations resulted from the GCC.

Accordingly, this section will be divided into the following three subsections:

- Impact of GCC on production of wheat and maize in the major exporting countries
- Impact of production change of wheat and maize in exporting countries on cereal imports to Egypt
- Impact of GCC on Egyptian imports of wheat and maize

Impact of GCC on the Production of Wheat and Maize in the Major Exporting Countries

As mentioned earlier, climate change is expected to amend the geographic distribution of the global agricultural production in favor of higher- and middle-latitude countries (classifications for countries by latitude and world climate map are mentioned in the Annex). A study by Hisas (2011) predicts the impact of the GCC on the food production of different countries for various products in 2020 compared to 2008 based on Parry (2004). In regard to the major wheat exporting countries to Egypt, it indicates that the production of wheat is expected to increase as a result of the GCC in the USA by 10 % and in Russia by 5 % and to decrease in France and Australia by 5 % and 12 %, respectively, while for maize its production is expected to increase in the USA by 10 % and to decrease in Argentina by 5 % and in Ukraine by 10 %. Such expected variation in the production of the largest exporting countries of wheat and maize is likely to disturb the global food security, especially when it is related to a strategic commodity such as wheat. The problem is not limited to these exporting countries but extended to reach those countries which depend mainly on the cereal imports in filling their production gaps like Egypt, as any change in the production is likely to affect international trade as well.

Moreover, the problem is more sophisticated for wheat in specific, as any reduction in this strategic commodity will affect negatively the social and economic life of Egypt, especially when noting that the self-sufficiency of Egypt in wheat was only 40.5 % in 2010, indicating the dependence of Egypt on wheat imports in meeting the growing consumption rates.

Impact of the Production Variations on the Egyptian Cereal Imports

And in order to measure the impact of the production change in exporting countries on Egyptian imports of wheat and maize, a multiple linear regression model (MLRM) is applied for each product and exporting country to Egypt separately with a time series from 1991 till 2011. The four applied models are based and constrained by the availability of data, especially Russia and Argentina which are limited by the unavailability of a complete import data series. The models contain six explanatory variables that affect and shape the Egyptian imports including the production of wheat and maize in the major exporting countries as follows:

$$\begin{aligned}\mathrm{Ln}\left(\mathrm{IMP_{ij}}\right) = \beta 0 + \beta 1\,\mathrm{Ln}\left(\mathrm{C_i}\right) + \beta 2\,\mathrm{Ln}\left(\mathrm{GDP}\right) + \beta 3\,\mathrm{Ln}\left(\mathrm{Prod_{ij}}\right) \\ + \beta 4\,\mathrm{Ln}\left(\mathrm{PR_{ij}}\right) + \beta 5\left(\mathrm{EXCH}\right) + \beta 6\left(\mathrm{FR}\right) + \varepsilon\end{aligned}$$

where

- IMP_{ij} is the Egyptian imports of product i from country j (by quantity)
- C_i is the total consumption of product i in Egypt (by quantity)
- GDP is the real gross domestic product of Egypt
- $Prod_{ij}$ is the total production of product i in country j (by quantity)
- PR_{ij} is the unit import price of product i from country j

Egyptian Imports of Wheat will be affected by:	Production of Wheat in:	The Effect
	USA	+ve
	Russia	neutral
Egyptian Imports of Maize will by affected by:	**Production of Maize in:**	**The Effect**
	USA	-ve
	Argentina	neutral

Fig. 17 Model results by signs

– EXCH is the exchange rate
– FR is the net foreign reserve in Egypt
– ε is the error term

This model has four applications for each crop and country separately. The first is the Egyptian imports of wheat from the USA and then from Russia, followed by another two applications for the Egyptian imports of maize from the USA and then from Argentina, in order to show the impact of the production change in each exporting country on the Egyptian imports of wheat and maize.

By running the model, it shows that the Egyptian imports of wheat are expected to be affected positively by the production change of wheat in the USA and neutral to any production change of wheat in Russia, while, on the other side, the Egyptian imports of maize from the USA are expected to be affected by the production change of maize with a negative relationship and neutral to any production change of maize in Argentina as shown in Fig. 17.

Impact of GCC on Egyptian Cereal Imports (Result Linkages)

By linking the expected impact of the GCC on the production of wheat and maize in the major exporting countries to Egypt that was based on Hisas's study, with the results of the model that analyzed the impact of the production change on the Egyptian imports to Egypt, the impact of the GCC on the Egyptian imports of wheat and maize could be extracted through the expected production variations in the major exporting countries in Fig. 18.

Figure 18 shows that climate change is expected to affect the Egyptian imports of wheat and maize from the USA, while its effect seems to be neutral on the Egyptian imports of wheat from Russia and the imports of maize from Argentina.

Moreover, the effects of the GCC on the Egyptian imports of wheat and maize from the USA are not the same. As though it is positively affecting both wheat and maize production in the USA, it is reflected positively on wheat imports and negatively on the maize imports from the USA to Egypt. This could be recognized in the context of increase in maize consumption in the USA (90 % of its production), compared to the US consumption of wheat (57 % of its production) in 2011 (USDA 2012).

Additionally, despite the expected decrease in the production of maize in Argentina as a result of GCC, no effect was noticed on the Egyptian imports of maize. Perhaps, this is due to its small share in Argentina's total exports. Moreover,

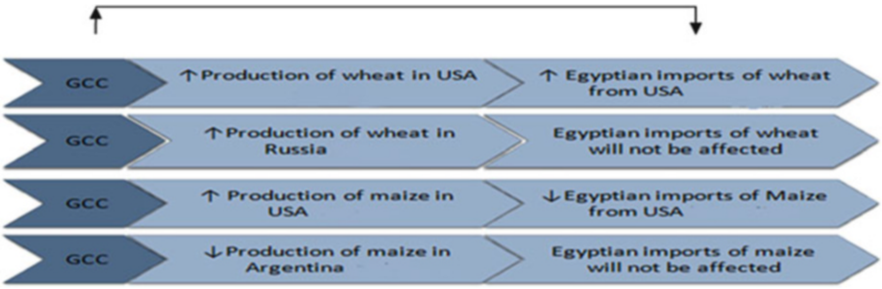

Fig. 18 Results linkages by numbers

no response was observed in the Egyptian imports of wheat from Russia; however, the expected increase in production is due to GCC.

Conclusion

Climate change is one of the greatest environmental problems facing the whole world through its overwhelming adverse impacts across various sectors. Yet, agriculture is expected to be the most affected sector due to its dependency on the overall weather conditions. Impacts of climate change on agriculture vary considerably across different regions, in which the low-latitude countries as most of the African and developing ones are projected to be negatively affected. Agricultural production in general and cereal production in specific are expected to diminish as a result of the increased temperatures and disturbed rain patterns. Egypt, as one of the developing countries, is suffering from a growing insufficiency in cereal production. However, the problem is much more complicated when considering that the climate change is expected to disturb not only the production of cereals in Egypt but also the production of the major exporting countries.

The paper also highlighted the importance of addressing the climate change as a new element in shaping the Egyptian imports. The expected import variations call for the importance of increasing the Egyptian production of wheat and maize by applying the suitable adaptation and mitigation methods, in addition to the import market diversification, in order to prevent the domination of a few countries on the Egyptian imports, especially for strategic commodities such as wheat and maize. This should be applied parallel with taking the impacts of climate change into consideration by targeting the potential countries that are expected to be positively affected from the climate change, such as the USA and Canada.

Finally, this study recommends applying different production methods that aim at mitigating the GCC, in order to reduce GHG emissions, such as efficient usage of energy in transportation, buildings, and industry; switching to zero- or low-carbon energy technologies; improving waste management; reducing deforestation; and improving land and farming management practices. Such mitigation efforts should also be accompanied by adaption ones that aim at diminishing the negative impacts of climate change or to exploit its potential benefits such as using alternative varieties of crops to adapt with the increased temperature, shifting the planting dates, changing fertilizer applications, and building flood controls.

Policy and Climate Change

Adaptation to Climate Change in Cities

Magali Dreyfus

Contents

Abstract

Urbanization and climate change are two current significant trends of the Earth's history. Both influence one another. Given the increasing disastrous impacts of global warming, it is vital to understand their development and interaction.

The concentration of people, infrastructures, and economic activities in urban areas contributes to the global growth of greenhouse gas emissions. But it also makes cities particularly vulnerable to the impacts of climate change. Yet many opportunities lie within the powers held by local governments. In fact, through their sectoral policies (land-use planning, transport, buildings, energy use, waste management, etc.), city governments can develop efficient strategies to mitigate and adapt to the effects of global warming. Adaptation strategies are especially

important as they allow connecting local needs with global concerns. The governance structure of the city and the capacity of the different stakeholders to collaborate in the definition and implementation of adaptation plans are therefore essential to ensure that local actions are efficient.

This chapter presents the implications of climate change in urban environments and the challenges it raises in terms of adaptation policies. It provides illustrations of responses adopted at the city level and points out at the barriers and opportunities faced by local policy-makers.

Keywords
Adaptation • Cities • Climate change • Local governance

Introduction

Urbanization and climate change are two of the few certain global trends for the future. Both raise economic, social, and environmental issues (Moensch et al. 2011). The study of their development and interaction is therefore key for enhancing scientific knowledge and taking action to promote a sustainable future.

Since the mid-2000s, about half of the world population lives in cities, and it is expected that by 2050, this number will raise to 7 out of 10 people (UN 2011; UNHABITAT 2012). One century ago, only 2 people out of 10 were living in urban areas. Moreover, in the past, urbanization went faster in industrialized countries than in developing countries. Nowadays it is the opposite. Today about 70 % of urban residents live in developing countries, which are also hosts to an overwhelming proportion of the world population (82 %). In richer nations, urban population growth is close to stagnant (0.67 % on an annual average basis since 2010). The United States has the highest urbanization rate among these countries (nearly 1 %). But developing countries are projected to have urban growth rates that are roughly the double. Moreover, the number of so-called megacities, which represents urban centers with more than 10 million people, is also increasing. They were 9 in 2008 and they should be 27 in 2025 (UN 2011; Corfee-Morlot et al. 2009). These impressive numbers have an impact on climate change adaptation as well as the well-being of its citizens, in terms of education, housing, and access to services.

Yet there is no standard definition of what a city is, and it may differ largely from one academic discipline to another. For instance, legal scholars and statisticians will often pay attention to the administrative borders of settlements and to the powers held by local governments over these. But a geographer may have a different territorial approach and focus on interconnections that sometimes overtake the formal limits of a settlement. One definition of the city is that it is a geographically limited area, which hosts a high density of population in a densely built environment. It is argued that cities are the results of a surplus in food production. This surplus allowed people to engage in other activities than agriculture and to produce goods as well as services outside of rural areas (Puppim et al. 2012). Thus, cities became key units in the economic welfare of a country.

Some estimates say that urban-based economic activities account for up to 55 % of gross national product (GNP) in low-income countries, 73 % in middle-income countries, and 85 % in high-income countries (Kessides 2000).

Consequently the development of cities has an impact over climate change. Through the concentration of economic activities and production, urban areas are responsible for the consumption of most of the world's energy, and 60–80 % of world energy use emanates from them (IEA 2008; Corfee-Morlot et al. 2009). They are therefore directly as well as indirectly among the largest emitters of CO_2 emissions. On the other way round, climate change impacts may be worsened by the urban settings. This led some commentators to declare that "the fate of the Earth's climate is intrinsically linked to how our cities develop over the coming decades" (Tyndall Centre 2004).

All the more, urban settlements are heavily dependent on what is produced outside their limits, may that be the nearest countryside or the products imported from farther countries. There climate change impacts may have important consequences. It may affect water and land availability, and thus local and global agricultural production, raising the prices of the products. Moreover, rural land in the peripheries is now often dedicated to urban use. As a result a common phenomenon in developed and developing countries is the growth of low-density-based suburbanization (UNHABITAT 2012). Sustainable cities must therefore be thought outside of their administrative and urban borders. This chapter sets aside this complex rural–urban issue and focuses on urban areas, but this is an important issue to bear in mind.

Policy-makers have a direct interest in climate change issues because urban areas are directly and particularly vulnerable to its impacts. In particular adaptation has to be thought locally as it requires taking into account the impacts of climate change on the local territory and the elements of vulnerability (physical, socioeconomic) upon which actions may be taken (Corfee-Morlot et al. 2011). In fact local governments are best placed to provide efficient solutions. Early in 1987, the Brundtland Report on "our common future" included a chapter on cities underlying their importance to design solutions to promote sustainable development (WCED 1987; Betsill and Bulkeley 2006). Then in 1992 during the United Nations Conference on Environment and Development (UNCED) held in Rio, the role of local authorities in meeting global environmental goals was fully recognized and included in Agenda 21, the United Nations (UN) voluntary action plan to promote sustainable development (Bulkeley and Betsill 2003). Lately scholars have slowly turned their attention to them to draw out barriers and opportunities for urban settlements in coping with climate change. They point out that cities concentrate resources and constitute "pools of labour and talent, together with concentration efficiencies for both producers and consumers, and a more fluid exchange of ideas and innovations" (UNHABITAT 2010). The IPCC itself in its fourth Assessment Report acknowledges the role of the cities. In particular, local governments hold responsibilities in sectors, which are relevant to the definition and implementation of mitigation and adaptation strategies. These vary from one state to another and depend on the level of decentralization. They are, for instance, transport, energy, waste, water, land-use planning, and social services. Moreover, local governments are the closest institutional link to the citizens and therefore may be in touch with a wide variety of stakeholders who can help define locally tailored solutions to the climate problem. Finally cities are important economic actors in the national economy, and as such they also have an influence on the definition of national policies and may act as a "role model" for other public authorities.

This chapter first examines the contribution of the cities to global warming (section "Contribution of the Cities to Climate Change") and the impacts of climate change that they bear (section "Impacts of Climate Change and Vulnerability of the Cities"). Then it shows how activities have moved focus from mitigation to adaptation (section "From Mitigation to Adaptation") and examples of some adaptation strategies (section "Urban Adaptation Actions"). Subsequently it dwells on the important questions of urban adaptation's governance (section "Governance of Adaptation in the Cities") and the barriers faced by decision-makers to adopt or implement adaptation strategies (section "Barriers to Cities' Adaptation to Climate Change"). Then in conclusion, three kinds of strategies highlighting potential opportunities for the future are presented.

Contribution of the Cities to Climate Change

The contribution of cities to climate change is highly debated.

Some authors reckon that they have an important share of responsibility, as they are heavy emitters of greenhouse gas (GHG) emissions. Some estimate show that urban activities generate close to 80 % of all carbon dioxide (CO_2) as well as significant amounts of other greenhouse gases. Direct sources of greenhouse gas emissions include energy generation, vehicles, industry, and the burning of fossil fuels and biomass in households. Emissions from vehicles and transport equipment are rising at a rate of 2.5 % each year (UNEP-UN HABITAT 2005). Moreover cities consume two-thirds of total primary energy and produce over 70 % of global energy-related CO_2 emissions. The IEA projects predict that by 2030, as a result of increased urbanization, cities and towns will be responsible for 76 % of global energy-related CO_2 emissions (IEA 2009).

But other studies discuss these findings (Hoornweg et al. 2011; Dodman 2009; Satterthwaite 2008). Some reckon that the actual share of GHG emissions generated in the cities is 40 %. Satterthwaite has described this phenomenon very well. The main source of greenhouse gas emissions in cities is energy use – in industrial production, transport, as well as residential, commercial, and government buildings (heating or cooling, lighting, and appliances). Transport is also an important contributor to greenhouse gas emissions in almost all cities, although its relative contribution varies a lot from one city to another. But the emission profile varies from one city to another depending on their activities as well as on their design and governance. A dense built environment and the use of public transport in a big city may result in lower emissions than in a smaller city where the use of private

Table 1 Greenhouse gas emissions per capita (tons of CO_2 equivalent)

City	GHG emissions per capita (tons of CO_2eq) (year of study in brackets)
Washington, DC (USA)	19,7 (2005)
Glasgow (UK)	8,4 (2004)
Toronto (Canada)	8,2 (2001)
Shanghai (China)	8,1 (1998)
New York City (USA)	7,1 (2005)
Beijing (China)	6,9 (1998)
London (UK)	6,2 (2006)
Tokyo (Japan)	4,8 (1998)
Seoul (Republic of Korea)	3,8 (1998)
Barcelona (Spain)	3,4 (1996)
Rio de Janeiro (Brazil)	2,3 (1998)
Sao Paulo (Brazil)	2,1 (2003)

Source: Dodman 2009

vehicles is more important because of the urban sprawl. For instance, as Table 1 shows, Tokyo's emissions per capita are much lower than in Glasgow, although the latter is smaller in size and population (36,669,000 inhabitants in urban agglomeration in 2010 and 1,170,000, respectively (UNHABITAT 2012)). Even within one urban area, the household's socio-demographic characteristics influence energy use. As a result, a suburban space may have, on average, higher per capita residential energy consumption with respect to central city dwellers (Estiri 2012).

Moreover, places with large coal-fired power stations will be very high greenhouse gas emitters, although most of the electricity they generate may be used elsewhere (Satterthwaite 2008). So a central question is whether greenhouse gas emissions used in producing goods or services are allocated to production or consumption. As a producer of GHG emissions, cities are not necessarily heavy emitters, but if emissions are assigned to the final consumer's home, most emissions from agriculture, deforestation, and industry could be assigned to cities where the goods produced from these sectors are consumed. Moreover, a comparison between energy use in urban and rural areas seems to show that with economic growth, city dwellers tend to consume more and more energy. Krey and others studied urban and rural energy use patterns in China and India functions of three development models that they have defined. On this basis, they show that in most cases, per capita energy use is initially lower in urban areas compared to rural areas, due to higher shares of modern fuels, which are energy efficient. But economic growth shall reverse that trend, and by 2050, urban energy use per capita will have tripled with respect to 2005 (Krey et al. 2012).

This might have important consequences in defining responsibilities for reducing greenhouse gas emissions between nations and within nations between cities and other settlements. Therefore, in the end, an important step to address climate change is to assess the consumption patterns of middle- and upper-income groups within an area (Satterthwaite 2008).

Impacts of Climate Change and Vulnerability of the Cities

Direct impacts of climate change are various, and all of them may affect cities: increased intensity and higher frequency of disasters (storms, rainfall, and typhoons), sea-level rise, and draughts. Indirect impacts will also be born at the local level such as the arrival of refugees fleeing the impacts of climate change or new diseases caused by the apparition of new vectors.

As everywhere, climate change will worsen existing problems as well as creating new ones. But some impacts will be stronger or specific to the urban environment (see Table 2 below).

Then the vulnerability of a city, that is, its ability to withstand direct and indirect impacts, depends on of three factors: its exposure, its sensitivity, and its adaptive capacity.

Table 2 Climate change impacts on urban areas

Change in climate	Possible impact on urban areas
Changes in means	
Temperature	Increase in energy demands for heating/cooling
	Worsening of air quality
	High-temperature impacts exaggerated by urban heat islands in the cities
Precipitation	Increased risks of flooding
	Increased risks of landslides
	Distress migration from rural areas
	Interruption of flood supply networks
Sea-level rise	Coastal flooding
	Reduced income from agriculture and tourism
	Salinization of water sources
Changes in extreme	
Extreme rainfall	Damages to home, businesses, and infrastructures
Tropical cyclone	More intense flooding
	Higher risk of landslides
	Disruption to livelihoods and city economies
Drought	Water shortage
	Higher food prices
	Disruption of hydroelectricity
	Distress migration from rural areas
Heat or cold waves	Short-term increase in energy demands for heating/cooling
	Health impacts on vulnerable populations
Abrupt climate change	Possible significant impacts from rapid and extreme sea-level rise/ temperature change
Changes in exposure	
Population movements	Movements from stressed rural habitats
Biological changes	New disease vectors

Source: Adapted from Bartlett et al. (2009)

In a city, physical elements (infrastructure and ecosystems), agents (people, organizations, and administrative and elected bodies), and institutions (the rule that guide behavior) (Moensch et al. 2011) may be more or less exposed, sensitive, or capable of adapting.

Exposure is the nature and degree to which a system may be directly or indirectly exposed to climate conditions such as temperature changes, rainfall variability, and change in extremes and frequency of other hazards (Moensch et al. 2011). Sensitivity is the degree to which a system is affected, either adversely or beneficially by climate variability (IPCC 2007). Indeed the concentration of people and economic activities make cities more likely to bear greater impacts. And the adaptive capacity is the ability of a system to adjust to climate change to moderate potential damages, to take advantage of opportunities, or to cope with the consequences (IPCC 2007). It can also be described as the ability to shift strategies as conditions change in order to maintain the well-being of populations and ecosystems on which they depend (Moensch et al. 2011).

Typically cities are exposed because they are located in strategic areas such as near the coasts or rivers. Thus, they suffer particularly from sea-level rise and floods. Moreover, cities concentrate a lot of people, and in many countries, the poorest of them live in informal settlements, slums, and townships. This is especially true for developing countries where the urban growth rate is the highest. As it goes faster than the infrastructure capacity, these settlements are very sensitive and their capacity to recover is limited. These are especially vulnerable, as they tend to be built on hazardous sites and to be susceptible to floods, landslides, and other climate-related disasters (IPCC 2007).

Although exposure is strong, the vulnerability of the cities mostly lies on their sensitivity and low adaptive capacity. In particular as seen above, the urban poor are the most vulnerable population to climate change impacts (Corfee-Morlot et al. 2009). Sensitivity is high and adaptive capacity is low among marginalized populations (slum-dwellers, recent migrants, women, etc.) as they are often unable to access or use effectively the services provided in the cities (Moensch et al. 2011).

Moreover, institutions affect vulnerability as they determine how other dimensions are managed (provision of essential services, infrastructure investments, zoning regulations, social assistance, etc.) (Moensch et al. 2011). In least developed countries, these may be weak.

Finally as mentioned in introduction, the vulnerability of the cities cannot be fully detached from its surroundings as climate change may affect food production or transport systems causing an increase in price and thus affecting the lives of citizens.

Urban areas are affected by three kinds of change caused by climate change (Bartlett et al. 2009): changes in means, changes in extreme, and changes in exposure. In the first category lie temperature, precipitation, and sea-level rise. In the second one stand extreme rainfall and tropical cyclone, droughts, heat or cold waves, and abrupt climate changes. Finally the last category refers to migration of population and biological changes.

The impacts of climate change may be exaggerated by the urban setting. A notorious illustration of this phenomenon is the urban heat island (UHI) effect.

It refers to the temperatures of urban centers, which are higher than in the surroundings of the city (about 3–4°C and this can go up to 10°C). The built environment, impervious surface, and lack of vegetation impede the soil to moisture, which would normally use the absorbed sunlight to evaporate water. The UHI in turn affects the level of air pollution as warmer temperatures favor the concentration of conventional air pollutants such as ozone, acid aerosols, emissions of particles, and allergens (Corfee-Morlot et al. 2009). The health of vulnerable populations such as young children and older people is then even more at threat than in a common hot environment.

All these impacts ultimately result in health impacts such as infectious diseases transmitted by mosquitos or tick, water- or food-borne diseases, air pollution, and heat morbidity (Bartlett et al. 2009). In addition the impacts have an economic cost. Some assets and infrastructures may be lost and economic activities may be disrupted. Structures such as underground transport systems may be affected by weather disaster events (Hunt and Watkiss 2010). For instance, during the heat wave that hit Europe in 2003, many French cities suffered from high temperatures. Electricity demand increased with the high heat levels, but electricity production was undermined by the facts that the temperature of rivers rose, reducing the cooling efficiency of thermal power plants (conventional and nuclear), and that flows of rivers were diminished. As a result, six power plants were shut down completely (IPCC 2007), which resulted in economic losses for utility companies and individuals.

From Mitigation to Adaptation

Mitigation policies aim at reducing GHG emissions in order to curb climate change at the global level. Adaptation tends to minimize the effects of climate change by adjusting the systems; it also allows grabbing any opportunity, which may arise. Adaptation activities have a local nature. They are largely determined by local circumstances such as the physical and built infrastructures environment, by the perception of vulnerability and risks by citizens and policy-makers, or even by a long history of dealing with natural hazards and disasters (Satterthwaite 2008; D'Almeida Martins and da Costa Ferreira 2011).

But mostly because cities are considered to be heavy emitters, literature has focused on urban mitigation actions so far.

Moreover, mitigation activities have found important financial support and thus became profit-making actions for local governments. These financial flows originate for instance in the United Nations Framework Convention of Climate Change (UNFCCC) international regime, which binds the most industrialized states to curb their GHG emissions. To do so, they can implement projects such as clean development mechanism (CDM) or emission reduction certifications (CER) in countries which are not bound by any emissions target. Obligations on adaptation are limited to financial and technical assistance from industrialized countries to the lesser-industrialized nations.

In that context, most of the climate city plans focus on mitigation and only a few deals with adaptation (OECD 2009). Many cities have assigned themselves GHG emissions reduction targets (e.g., London, Tokyo, and Paris). Some go even further than the national target. For instance, in the European Union and in France, the targets are 20 % for the reduction of GHG emissions, 20 % less energy consumption, and a 20 % energy consumption coming from renewable energy by 2020. But for the Parisian territory, the local council targets a rate of 25 % (and for the administration itself 30 %). This leads to a general phenomenon of well-developed mitigation project, whereas adaptation policies are still at an early stage of development and hardly implemented (D'Almeida Martins and da Costa Ferreira 2011).

Some authors have criticized this focus on mitigation stating that it is too techno-centric and falls to address the more complex task of defining the nature of vulnerability (Revi 2008). But the difficulty to quantify and monetarize the benefits of adaptation, makes it difficult for decision-makers to justify their choices when they develop adaption strategies. How do you measure the success of an adaptation measure? And how long does it take before you can actually make an assessment? In fact most of the studies assessing adaptation policies options in the cities are qualitative (Hunt and Watkiss 2010).

However, the case for adaptation in the cities in literature is increasing. The importance of this action is recognized. Among the studies, Hunt and Watkiss (2010) have observed that the most addressed risks are sea-level rise, heat, and water resources. Yet to date most of the case studies deal with OECD countries. This is why international agencies now try to promote adaptation through development as a way to incentivize actions in less developed countries (OECD 2009; Sanchez-Rodriguez 2009; UNEP 2011).

The following section turns on some of these initiatives.

Urban Adaptation Actions

Adaptation actions are not always labeled as such nor are they systematically connected to the issue of climate change. This could be the case for instance, for urban environmental projects such as planting trees or the opening of green spaces. However, these actions definitely have an adaptive scope. Moreover, the variety of administrative organization between cities also complicates the possibility to classify actions by sector. They may be overlapping. Therefore, it is difficult to make an exhaustive list of adaptation actions. Before summarizing some of them in a table, here are some more developed examples.

First there are some hard measures meaning that they require some financial and technological investments. For instance, in the building sector, local governments have power to take action.

Isolation of buildings is a key activity for local governments. It allows bringing down temperature and reducing the need for air conditioners. Thus, energy demands and consequently emissions are reduced. This is a much more efficient adaptive measure than the mere spreading of air conditioner appliances which might not be affordable for the poorest and which will be counter-effective in terms of mitigation (OECD 2009).

Harvesting of rainwater can also offset the lack of water in hot summers. In London, a rainwater harvesting system has been incorporated in the design of a community center building. The rainwater is collected from the roof and is stored in an underground tank for future use. This system is supplying water used for toilet flushing and irrigation. It is expected to contribute to save 50 % of water use every year (UKCIP 2007).

Bigger infrastructures may also be necessary. Infrastructures and the built environment in general are mostly affected by extreme events such as floods, storms, and, to a lesser extent, heat waves and drought (Hunt and Watkiss 2010). The construction of flood defense mechanisms, dikes, or break walls is a common response. However, it is a high investment operation, and local governments may not always have the financial resources and technical capacities to undertake these operations.

Softer measures are also efficient to define adaptation strategies. They consist in policy programs. A common measure is to move the location of activities (recreational, farming, and businesses) set in high-risk areas (flood/erosion prone areas) to safer places. To do so, local governments usually use regulatory instruments such as zoning regulations or master plans.

The table below (Table 3) presents some adaptation action functions of the climate challenge they want to tackle. The columns also indicate the sector of intervention and the nature of the corresponding policy instrument. However, this table is only illustrative. Cities are very much different from one place to another in political, economical, social, and physical terms. As a result, the decisions they take vary to adapt to local circumstances. Likewise the sectors and policy instruments are different. As for sectors, the department of a city responsible for a certain matter may differ from one place to another.

There are several kinds of policy instruments, which may support adaptation strategies. They can be combined to ensure a better efficiency. Regulatory tools are binding measures, which fix environmental targets or standards to be reached by some stakeholders. They can also consist in provisions and technical requirements in public procurements. To that regard, local authorities as a major buyer of public works, infrastructures, and constructions may follow a green approach to favor environmentally friendly projects (e.g., climate change may fall within the scope of the environmental, energy, or land use department).

Planning tools are regulatory instruments. Planning is a political process, which organizes the completion of predefined political goals in time. It helps in dealing with uncertainty of future risks relying mainly on data from the past and present and the analysis of trends. It states which policy instruments are going to be used and fix a calendar. Fiscal mechanisms are financial incentives and disincentives to guide behavior towards environmentally responsible activity, and curb undesirable activities, in an effort to reduce damage to the environment. They consist in grants, low-interest loans, loan guarantees, or favorable tax treatment to promote specific activities, technologies, or behaviors of businesses and individuals. For example, in

Table 3 Examples of adaptation actions in cities

Climate challenge	Measure	Sector	Policy instruments
Urban heat island	Increasing tree canopy	Parks, environment	Regulatory
Heat waves	Reforestation		Planning
	Green roofs	Buildings and construction	Regulatory Fiscal Voluntary agreements
	Building regulations (e.g., color of the roofs, standards of energy efficiency)	Buildings and construction	Regulatory
	District cooling through the use of absorption cooling methods (using the heat of other resources, e.g., waste incineration)	Energy	Regulatory Planning
	Heat alert systems	Public health	Informational instruments
	Heat threat educational and awareness program	Education	Informational instruments
Drought Water efficiency	Building regulations (e.g., installation of rainwater collection systems, reservoirs, promote the use of water-efficient technologies and devices)	Building and construction	Regulatory
	Building retrofitting (e.g., shower timers and shower heads)	Water Environment	Informational
	Securing drinking water resources (e.g., designation of drinking water protection areas and well construction)	Water Environment	Regulatory
Biodiversity loss	Biodiversity strategy to protect flora and fauna	Environment Green spaces Tourism and leisure	Regulatory Planning
Floods Sea-level rise	Flood risk mapping	Flood/coastal management Disaster management Urban planning	Regulatory Planning
	Flood alert systems	Flood/coastal management Disaster management	Informational
	Dikes, break waves	Infrastructures Build environment and construction	Regulatory Planning
Crosscutting adaptation issues	Vulnerability assessments and development of blueprints or scenarios to guide local stakeholders	Crosscutting	Planning

Source: Adapted from Ecologic Institute, AEA, ICLEI, REC 2011 mitigation policies, charges are levied on energy sources and fossil fuels. Informational instruments are campaigns or public announcements to inform and communicate with the citizens on risks, to learn to deal with them, and to be resilient. Finally voluntary agreements are measures, which are negotiated between local authorities and industry to achieve environmental targets.

In the end, the table shows that adaptation strategies are based on a mix of soft (policy) and hard (infrastructures and built environment) measures.

Some actions address physical drivers such as dikes and built protection infrastructures, and others address systemic drivers such as laws, urban planning, alert warning systems, or efforts to build capacity to adapt (CorfeeMorlot et al. 2011).

Governance of Adaptation in the Cities

Listing initiatives to adapt to climate change in urban settings is not enough to get a complete picture of the challenge that it represents. In fact sectoral approaches are not enough and a systemic approach is necessary. It means that several administrative departments and stakeholders have to collaborate with one another. Moreover, climate change impacts are not limited to the administrative territory borders, so often collaboration is needed beyond borders, between local governments. Finally upper levels of governments have some adaptation programs and regulations. They may ask local governments to collaborate to implement them. There is therefore a huge governance[1] challenge.

Urban governance processes are actually central to understand the impacts of climate change and to reduce vulnerability. Good governance schemes allow working closely with local stakeholders and understanding how to incorporate climate change impacts in the reform of land use and urban planning instruments. It also gives the possibility to experiment and learn about various responses and the most cost-efficient ones (Corfee-Morlot et al. 2011, D'Almeida Martins and da Costa Ferreira 2011).

Literature has often focused on governance to identify successful factors for adaptation (Tanner et al. 2009; Birkmann et al. 2010; Adger et al. 2005; Amundsen et al. 2010; Dodman and Satterthwaite 2008). They also drew some good governance GG criteria, which enable developing efficient adaptation strategies. GG criteria and adaptive criteria are often redundant. These criteria vary according to authors and often overlap according to their definition. Referring to GG in the framework of enhancing resilience, Moensch et al. (2011) mention decentralization and autonomy, transparency and accountability, and responsiveness and flexibility (Tanner et al. 2009). Other scholars add participation and consensus, effectiveness

[1]Governance refers to "the formation and stewardship of the formal and informal rules that regulate the public realm, the arena in which state as well as economic and societal actors interact to make decisions" (Hyden et al. 2003).

and sustainability, and rule of law, equity, and fairness (Dreyfus 2013). For Adger et al. (2005), adaptation shall rely on effectiveness, efficiency, equity, and legitimacy.

Almost all authors acknowledge participation as a major success criterion. It refers to the degree of involvement of the different stakeholders in decision-making. It is key to understand all the risks, define adaptation objectives, and ensure a good implementation of the measures adopted. The roles of stakeholders are numerous: awareness raising, involvement in understanding the problem, agreeing adaptation objectives, securing financial and human resources, implementation, as well as monitoring and evaluation (Ecologic Institute et al. 2011).

Leadership is another relevant factor at the local level (Ecologic Institute et al. 2011, Schreurs 2008). It is illustrated by the important adaptation strategies developed by some proactive local governments. Being a pioneer can be positive in political terms but also even in economic terms by creating new business opportunities. Sometimes single individuals or "policy entrepreneur" can champion the issue and, this way, adjust the local agenda to include it (Bulkeley 2010).

Moreover, in their analysis, scholars insist on the need to adopt a multilevel governance approach (Betsill and Bulkeley 2006; Corfee-Morlot et al. 2009). This refers to the processes of governance happening across the scales, formally or informally, between state and non-state actors and between public and private actors. Participation is a central process of it. This conceptual approach helps to understand how local governments are embedded in a complex system of actors and how they design and implement policies tackling climate change. Thus, there is a vertical and a horizontal dimension to consider. The vertical dimension focuses on a legal traditional approach where local governments are at the bottom of the state administrative organization and where the central government possesses the supreme authority. Here local governments mostly implement upper level of legislation (international, national, state, or regional). The horizontal dimension focuses on various actors intervening at the city scale: citizens, associations, business actors, and transitional networks of local governments, foreign investors, and experts. In that context, local governments are responsible for defining policies relevant to the local affairs. Relations between them are not necessarily formalized, and they are constantly evolving. Their influence over one another very much depends on the local context (Puppim et al. 2012). This approach allows identifying bottom-up, top-down, and horizontal influences, all of them playing a part in the definition and implementation of adaptation strategies.

Barriers to Cities' Adaptation to Climate Change

There are some conceptual barriers and some practical barriers to adaptation (Ecologic Institute et al. 2011). Conceptual barriers relate to the understanding of the problem. It consists in climate skepticism, uncertainty, and defining what is adaptation. This mostly affects decision-making. It can be overcome by the involvement of external actors such as researchers or international agencies with an interest in the question. Transnational networks of local governments are also helpful, as they allow knowledge and best practice sharing between public authorities.

Practical barriers are more related to organization and resources. They mostly affect the implementation of adaptation strategies.

Adapting to climate change is a long-term process, which as such is not a priority for local governments who have to deal with many other pressing issues, such as the eradication of poverty, public services provision, and development. The uncertainty of climate scenarios and its controversial aspect (some scientists denying its scope) makes it a second rank issue. Uncertainty is also true for socioeconomic trends, which affect the vulnerability of population and activities. Yet this information is as important as climate data. Moreover, analyses of impacts and adaptation options at the city-scale level are at a very early stage and difficult to provide in poorer countries. There is a lack of tools and methodologies to inform decision-makers about risks exposure, which is a main barrier for adaptation decisions in land-use planning (Storch and Downes 2011). Most of the studies are qualitative, and thus, the advance understanding of costs and benefits of local adaptation action is difficult (Hunt and Watkiss 2010; OECD 2009). Yet the making up of climate and urban development combined scenarios could be very profitable. A study on Ho Chi Minh City adaptation strategy shows that the combination of sea-level rise with the planned urban development will increase the exposure and consequently the vulnerability of the city. But it is mostly because of the second factor, which is the land-use plan, that the city will be affected. The decision-makers have not considered exposure and climate risks in the plan (Storch and Downes 2011). Indeed climate change impacts cannot be avoided, but prohibiting constructions on threatened areas can reduce exposure. This will allow avoiding at a later stage the costs of relocation, reconstruction, and disaster relief action. Nevertheless pressed by short public mandate, local governments sometimes focus on policies that can bring more immediate results.

The lack of resources is another major issue. Despite the political will or the adoption of a strategy, the question of financial as well as human resources is a limit. This is therefore sometimes a problem, which precedes issues such as the lack of access to sophisticated datasets or new technologies (Roberts 2010). When there is no support from national authorities, resources may come from external actors. In fact many adaptation programs in developing countries are sponsored from outside, by the World Bank, UN-HABITAT, or UNDP for instence. But then the question is how these initiatives will carry on after the withdrawal of this external funding. There may also be a problem of overlapping competencies and lack of coordination between authorities and policies. As Table 3 shows, initiatives may be shared between various sectors and use different policy instruments. This makes coordination a key step.

Conclusion: Opportunities for Climate Change Adaptation in the Cities

In conclusion, three tracks can provide opportunities for climate change adaptation in the cities.

Adopt a Comprehensive Strategy for the Local Territory

Adopting a comprehensive adaptation strategy will allow defining policy direction for the entire city. It is important because no single measure will allow reducing vulnerability on a long term basis. It is rather a set of different cross-sectoral actions that will allow to improve the current and future situations. A mix of policy measures, technologic, institutional, infrastructure, is necessary. Cities must in fact be thought as a system (Dawson et al. 2007).

It means that cooperation between various administrative departments is essential. Planning is a key process to organize this cooperation.

Creating a specific agency or unit in charge of dealing with adaptation issues may also be useful. It may then identify synergies between sectors. This institution can develop knowledge and expertise between the sectors and lead the policies and organize the cooperation.

So far, only a few general municipal adaptation plans have been adopted. Most of them are in cities of industrialized countries as, for instance, New York or London. But there are some exceptions in developing countries as Durban, Cape Town, Ho Chi Minh, or Quito demonstrate. The motivations behind the adoption of municipal plans lie in the need to assess local impacts carefully and ensure resilience. In Ho Chi Minh, a particular objective is to put in line hard infrastructure responses with a socioeconomic vulnerability assessment of the city (Storch and Downes 2011). In Durban, the need to adapt is perceived in relation with the need to increase the resilience of poorer people by enforcing measures enabling development (Roberts 2010).

Moreover, in compliance with the UNFCCC regime, adaptation in least developed countries is supported financially and technically by industrialized countries as well as by some international agencies. One requirement is to adopt a National Adaptation Programme of Actions (NAPA), which identify priority activities. However, in these programs, little attention has been paid to the local level and urban areas. The adoption of Local Adaptation Programme of Actions (LAPA) and City Adaptation Programme of Actions (CAPA) could be helpful. On the long term, they can underpin and drive innovations in NAPAs (Moser and Satterthwaite 2008).

Use Local Capacities and Share Knowledge

Instead of creating new programs and plans, for which officers may be reluctant to act, it may be worth relying on existing capacities.

A lot of local governments already have experience with planning and environment. For instance, local Agenda 21, which deals with sustainable development, has created an enabling context for environmental issues (Bulkeley 2010; D'Almeida Martins and da Costa Ferreira 2011).

Also synergies between disaster risk management and climate change adaptation can be found. In the more exposed cities, there is often a long and old practice of risk management.

Moreover, using local capacities means enhancing participation of the various urban stakeholders. This enhances knowledge about the local context and the necessary adherence for implementation. There should be therefore a collaborative approach to decision-making when dealing with adaptation (OECD 2009; D'Almeida Martins and da Costa Ferreira 2011).

For instance, in London and New York, the involvement of sectoral stakeholders is deemed to have been key in defining responses to climate change impacts. They created coordinating bodies including sectoral and cross-sectoral representatives who spread in different sector the general policy directions and the results of consultation and studies (Hunt and Watkiss 2010).

In particular the most vulnerable people in the cities need to be heard. As shown in introduction, cities from developing countries are growing very fast. Their population grows more rapidly than their financial, organizational, and infrastructure capacity. Decision-makers are therefore faced with a big number of informal settlements exposed to disasters. Helping the poorest community may therefore increase resilience. It has been observed in developing countries that partnerships between poor communities and local governments focusing on development and tackling risks helped to increase their incomes and thus to reduce health effects of hazards (Satterthwaite et al. 2007). In line with this reasoning, authors promote community-based adaptation (CBA).[2] It is a process which put people at the center of the adaptive strategy. Through learning and development, the poorest appear to increase their resilience and anticipatory capacity.

Sharing knowledge with peers is another good way to highlight potential local capacities. It creates conditions to be inspired and to inspire other local governments who may be faced with the same challenges and constraints. Literature has demonstrated how being part of a network may foster or even be a catalyst in the development of a strategy. Moreover, these networks mobilize also private actors, especially from the business side (e.g., ICLEI's Cites for Climate Protection) (Bulkeley 2010).

Finally, it is important that local governments find support form upper levels of governments which often dictate the norms to implement and the distribution of resources. Central governments should therefore acknowledge the role played by local authorities and consider it the definition of national adaptation strategy. On this basis, they may then provide financial support.

Mainstream Climate Change Adaptation

Mainstreaming climate change adaptation in sectoral policies means considering the impacts of climate change in each sector and providing adapted solutions.

[2]According to CBA, it is "an approach that is putting people in the centre of their own development, by facilitating a learning process that increases resilience and anticipatory capacity. It is not just a response to climate events and shocks, but rather a complex and holistic process that includes personal development and organizational development to ensure an enhanced problem solving capacity, and the capacity to anticipate events and plant so that future shocks are buffered" (Koelle and Annecke 2011).

A general adaptation strategy is important to raise awareness and may be catalyst in considering climate change impacts, but it needs to be trickled down in the sectors.

In Durban, the local government adopted a general adaptation strategy in 2006. But it did not bring any result until some sectors were chosen to further develop an adaptation program, i.e., health, water, and disaster management (Roberts 2010). In fact within local governments, administrative departments are more or well developed, have more or less resources, or even have already undertaken initiatives regarding climate change. On this basis, some departments may be able to adopt more ambitious and efficient strategies.

In that framework, the general adaptation strategy will be an umbrella avoiding contradictory sectoral policy objectives and ensuring coherence. This will also achieve multiple goals (not only mitigation and adaptation targets) (Schreurs 2008).

In particular, mainstreaming climate change adaptation within development programs can prove very efficient. People with higher education level, training, and access to services are less vulnerable. Decision-makers must therefore engage in the development of win-win scenarios, that is, policies, which achieve both adaptation and other development goals.

Decisions taken today will determine the future development path of the city. Yet how cities develop is part of the climate problem but also the solution. Choices regarding long-lived infrastructures (transport networks, buildings, ports, and water systems) are decisive to improve the energy and emission of the built environment as well as to determine their capacity to resist future climate disasters. Also land use and zoning decisions are important to increase or limit the exposure and vulnerability or urban dwellers and activities to climate hazards. It is therefore vital to integrate now climate change impacts and risks in the decision-making process. Combined with socioeconomic data and development policies, it will enable cities to develop in a sustainable manner for the benefit of the local as well as the global environment.

Assessing the Capacity of Law to Facilitate Adaptation to Climate Change

Margot A. Hurlbert

Contents

Abstract

Certainty of law is an important attribute in a democratic society; however, often certainty is synonymous with inflexible, traditional laws, perhaps no longer appropriate in times of rapid social, geographical, and natural system change. Institutional capacity to adapt to climate change has been shown to be a key determinant of adaptive capacity; law is a foundational institution of socio-environmental regimes. Appropriate provisions are required in law in order to ensure that the institution of law can adapt to future variability and extreme climate events of drought and flood. Law must facilitate adaptive governance and reflect principles of adaptive law.

Laws and their mechanisms (regulatory, economic, and suasive instruments) can reduce exposure or vulnerability thereby building capacity to respond to anticipated increasing future variability in extreme climate events. However, there is also the possibility that the opposite impact may occur, and laws impede adaptation. This chapter explores this tension.

DOI 10.1007/978-3-642-38670-1_59

This chapter focuses on an assessment of laws and legal mechanisms to improve adaptive capacity of rural agricultural producers to respond to climate variability and change. Legal instruments in relation to water, specifically the property interest in water, impact rural agricultural producers. A comparative assessment of three legal water tools (market, common property, and public property) impacting vulnerability in relation to extreme events of drought and flood is conducted, and conclusions are made on their ability to assist adaptation.

Keywords
Law • Policy • Adaptation to climate change and extreme climate events • Adaptive law

Introduction

This chapter will focus on institutions in relation to adaptive capacity and more specifically the institution of law in relation to the natural resource of water. This chapter will focus on the market or economic interest – the property interest of water because of the important relationship of the area of water to climate change, adaptation, and vulnerability (UNWATER 2010). A brief discussion of institutions and law and adaptive capacity will be followed by an outline of adaptive governance and adaptive law, a description of the possible tools relating to the property interest of water (market, common property, or public property), and an analysis of how these three possible tools reflect (or do not reflect) the principles of adaptive law and governance. This chapter will conclude with proposals to improve the adaptive capacity of law in relation to the legal instrument, the property interest of water.

Law, Institutions, and Adaptive Capacity

Law is a formal institution (Luhmann 2004, p. 59), a set of rules defining roles and procedures for people determining what is appropriate and proper. As such, law is an important component of the institutional system which contributes to the adaptive capacity of communities. The IPCC argues that nations with "well developed institutional systems are considered to have greater adaptive capacity" and that developed countries have a better "institutional capacity to help deal with risks associated with future climate change" (2001, pp. 896 and 897). Institutions contribute to the management of a community's assets, the community members' interrelationships, and then in turn their relationships with natural resources. Law plays a fundamental role in this regard, especially in relation to defining the relationship of people to one another in respect to access to, caring for, and sharing natural resources. Law establishes the legal rules of property ownership or licensed access to many natural resources such as forests, water, wildlife, and minerals. Law also sets the framework for which organization, levels of government, government departments, or ministries have authority over, establish conflicts in relation to, and protect natural systems and the socioeconomic relationships corresponding to these systems.

This is not to say that law is the only or predominant institution contributing to the adaptive capacity of communities. Vulnerability to climate change impacts is also determined on the basis of the degree of climatic change experienced by a region or community and a combination of the geophysical processes and other existent social conditions (Birkmann 2006; Hilhorst 2004). Other institutions in addition to law contribute to adaptive capacity including formal institutions like government, nonprofit and civil society organizations, and informal institutions such as social norms, values, and contexts which contribute to the relationships of people to each other and natural resources. Further, in addition to these institutions, other determinants of the adaptive capacity of people and communities which determine their ability to respond to, create, and/or shape vulnerability and change (Chapin et al. 2009) exist. These additional determinants of adaptive capacity include the existence of economic resources, infrastructure, and equity, as well as access to technology, information, and skills (including human capital) (IPCC 2001, p. 893).

Studying the institutional context of adaptive capacity can be done through a study of the institutions involved in governance. Governance encompasses laws, regulations, and institutions, as well as governmental policies and actions, domestic activities, and networks of influence, including international market forces, the private sector, and civil society (Demetropoulou et al. 2010, p. 341). Governance entails the interactions among structures, processes, rules, and traditions that determine how people in societies make decisions and share power, exercise responsibility, and ensure accountability (Lebel et al. 2006; Raik and Decker 2007; Cundill and Fabricius 2010, p. 14). Thus, governance involves institutions through which citizens and groups articulate their interests, exercise their legal rights, meet their legal obligations, and mediate their differences (Armitage et al. 2009; Kiparsky et al. 2012). Law is an important institution, operating within the wider institutional context of governance. A rich literature has developed regarding adaptive governance, adaptive water governance, and specifically how the wider institutional context of governance can facilitate adaptation and improve adaptive capacity of communities. As law is an important component of this institutional context (one institution within the institutional context, as it were), this literature is instructive and informative in respect of the consideration of whether law has capacity or whether a better capacity of law can be developed, to facilitate adaptation.

Adaptive Water Governance and Law

How do we recognize a system of water governance as adaptive? Within the adaptive capacity literature, several dimensions have been identified as important characteristics, institutional design principles, or features of governance systems that define an institutional system as adaptive. These include such things as "availability of information," "openness for experimentation," "flexibility," "learning," and others. The discussion in some cases is generic, and it applies to institutions in general (Gupta et al. 2010; Folke et al. 2005; Gunderson and Holling 2002; Olsson et al. 2006) and in some other cases to specific institutional regimes, such as the case of water governance (Moellenkamp and Kastens 2009; Huntjens et al. 2012; Young 2010; Cook et al. 2011; Hill 2012a; Huitema et al. 2009).

The number of dimensions of adaptive institutional capacity tends to vary depending on the author and the institutional context upon which the discussion is focused. They range from a few characteristics, such as the six dimensions listed in the work of Gupta et al. (2010), to a long suite of attributes, as those identified by Cook et al. (2011), who list fifteen attributes. Frohlich and Knieling (2013) in their discussion of climate change governance offer another set of attributes that should also be considered in a discussion of adaptive governance. They refer to a proper understanding of the complexities of the phenomenon of climate change, which include the requirements imposed by boundaries, levels, sectors, and diverse stakeholders, as well as the uncertainties surrounding and long-term time frame of climate change. A table outlining these various dimensions appears below (Table 1).

Adaptive governance entails more flexible, participatory, experimental, collaborative, and learning-based designs and approaches to policy making and governance to increase the adaptive capacity of institutions and sustainability of natural resources (Pahl-Wostl 2010; Pahl-Wostl 2007a, b; Cromwell et al. 2007; Pahl-Wostl 2007a, b, c; Kallis et al. 2006; Tompkins and Adger 2004; Lee and Lawrence 1986; Walters 1986; Walters and Holling 1990). Adaptive governance shifts focus from rule-based, fixed organization to a view of institutions as dynamic, flexible, pluralistic, and adaptive in order to cope with present and future uncertain climatic conditions and the limits of predictability (IISD 2006, p. 5; Carpenter and Gunderson 2001; Levin 1999). Adaptive governance is then a means to the achievement of adaptive capacity (Cook et al. 2011, p. 7) or combating the loss of resiliency (Berkes and Folke 1998, p. 262). An example of adaptive governance is the comanagement of a natural resource such as water in a cooperative fashion by government, community, and stakeholder groups in a cooperative way through local watershed groups, larger basin groups, and regional and national associations.

The last institutional design principle, that of clearly defined boundaries and rules, relates most directly to the institution of law. A primary function of the legal system is accountability, creating rules, and holding people and entities accountable in relation to these rules. Designing the standards and boundaries to which people and entities are held accountable significantly impacts adaptive capacity and vulnerability. The example cited relates to institutional responses in the event of extreme climate events of flood. However, this last design principle is on its face, quite contradictory to many of the other design principles of responsiveness and flexibility, which have been demonstrated as important for the ongoing management of natural resources in the face of climate change and variability. Balancing the institutional design principles to context is key.

Table 1 Institutional design principles of adaptive governance

	Institutional design principle of adaptive governance	Related principles/sub-principles	Explanation	Literature
1	Responsiveness		The ability of governance networks, organizations, and actors to respond appropriately and in a timely manner to climate variability, hazards, and extreme events in a manner that accounts for ecosystem dynamics	Hatfield-Dodds et al. 2007; Kjaer 2004; Dietz et al. 2003
		Robust and flexible process	Institutions and policy processes that continue to work satisfactorily when confronted with social and physical challenges but which at the same time are capable of changing	Huntjens et al. 2012, p. 73; Moellenkamp and Kastens 2009
	Example		An example of responsiveness is the Saskatchewan Farm Ranch Infrastructure Program which was developed by local agricultural producers in South Western Saskatchewan within weeks of a severe drought in order to provide funds for water infrastructure to producers within days of application. The program was amended on an ongoing basis	Hurlbert forthcoming
2	Variety of problem frames		Openness to multiple frames of reference, opinions, and problem definitions offering a diversity of sometimes competing solutions and options to assess a problem as well as resolve conflict	Gupta et al. 2010
		Multilevel – redundancy	A variety of problem frames inherently involve the participation of a variety of different actors, levels of government, and sectors in the governance process and collective choice arrangements, without redundant overlapping costly systems	Huntjens et al. 2012
		Polycentric governance	Different centers of management and control should exist (as opposed to hierarchical systems)	Ostrom 2010
		Sectoral integration	Adaptation requires an integrated sectoral response so institutional arrangements which are similar or related can be adjusted to one another	Moellenkamp and Kastens 2009
	Example		In the 2001 drought in southern Alberta, water users along the South Saskatchewan River Basin were able to respond within days by exchanging water interests allowing a few agricultural irrigators to produce crops and the needs of local communities to be met. This water sharing involved local people and communities, irrigation associations, agricultural producers and provincial personnel, all with various issues and policy frames	Hurlbert 2011

(*continued*)

Table 1 (continued)

	Institutional design principle of adaptive governance	Related principles/sub-principles	Explanation	Literature
3	Learning and institutional memory		Past experiences must be remembered and learned from and routines improved	Huntjens et al. 2012; Gupta et al. 2010; Armitage 2005; Olsson et al. 2004; Pretty 2003; Dietz et al. 2003; Pretty and Ward 2001
		Participation	Participation by non-state actors	Folke et al. 2005
		Collective choice arrangements	To enhance participation of those involved in making decisions about the system in how to adapt	Huntjens et al. 2012
		Monitor and evaluate	Institutional evaluation processes must monitor and evaluate policy experiences	Huntjens et al. 2012
	Example		Wildlife and watershed comanagement allows for learning and institutional memory by involving stakeholders through planning and informational meetings. These stakeholders participate in monitoring programs focusing on aquatic resources by setting priorities, enhancing their own capacity, monitoring the physical resource, sharing information, and local decision making. These methods have been employed in community forestry projects as well	Tidball and Krasny 2007; CCMN 2008; Fernandez-Gimenez et al. 2008
4	Trust		Institutional patterns must exist to promote mutual respect and trust such that participants continue involvement in the process of governance	
		Open to uncertainty/ open to experimentation	Policy experiments allow feedback loops so policy can be changed quickly in response to changed conditions	Moellenkamp and Karstens 2009
		Constructive conflict resolution	Timely response to problems, careful sequencing, transparency	Huntjens et al. 2012
	Example		The incorporation of participatory processes into the management of a dam in the German Dhuenn basin allowed for policy experiments to occur, uncertainties to be handled in a constructive manner, and a level of trust to be built between participants	Moellenkamp et al. 2010

5	Capacity building	Information	The informational, human, and social capital must exist within the governance regime necessary to respond appropriately to climate variability, hazards, and extreme events	Gupta et al. 2010; Olsson et al. 2004
		Leadership	Leadership must exist to act as a catalyst to change	
		Resources	Appropriate resources (financial, political, human) must be available for this change	
		Information	Rigorous up-to-date information, sufficient and reliable	Moellenkamp and Kastens 2009
	Example		A World Wildlife Fund intervention in the Great Ruaha River catchment in Tanzania addressed challenges from natural resource use and climate variability in changing water resource management by applying participatory methods. The project resulted in rural livelihoods becoming more profitable and water sustainable by diversifying livelihood strategies. The leadership and resources provided were a catalyst for capacity building within the community	Kahaigili et al. 2009
6	Equity	Legitimate	The governance regime must be perceived as legitimate and accountable, as well as fair in its process and impact such that there is an equal and fair (re)distribution of risks, benefits, and costs	Gupta et al. 2010; Huntjens et al. 2012; Ostrom 2011
		Accountable		
		Fair		
	Example		An example of an inequitable regime is the water governance regime in Chile that consists of a water market wherein all water is fully allocated, owned privately, and traded. This has resulted in a system completely within the private sphere, outside the purview of government, in which the courts determine disputes and in which many local communities are without access to water	Hurlbert and Diaz 2013
7	Political support		Responding to climate change is a long-term policy challenge which requires solid political support for plans longer than election cycles	Moellenkamp and Kastens 2009
	Example		Often climate change strategies are dependent on political strategy and subject to election cycles. However, long-term planning for mitigation and adaptation to climate change into 2020 and beyond is required	Hurlbert and Diaz 2013
8	Clearly defined boundaries		Clarity over who has rights and who has responsibility, capacities, access to resources, and information in times of climate events	Huntjens et al. 2012
	Example		In times of extreme climate, such as floods, the response of communities, nonprofit organizations, and governments require clarity in roles, tasks, and responsibilities; there must also be access to reliable and up-to-date information about future conditions; lastly, access to resources such as food, clothing, and aid is essential	

Adapted from Hurlbert and Diaz 2013

One of the fundamental pillars of the law is legal certainty (Maxeiner 2008). Internationally recognized as a central requirement for the rule of law, rule-based societies are required in the interest of legal certainty and predictability (Maxeiner 2008). Law is generally regarded in a positivist fashion as a set of rules reflected in the wording of legislation and decisions of judges all forming a code binding on subsequent legal subjects (Luhmann 2004). In system-theoretical terms, law is an operatively closed network of communications which constantly refers to its own decisions, expressly based in turn on legal principles and procedures. This rigidity and certainty of law appears contradictory to the institutional flexibility envisioned in institutional adaptive capacity and adaptive governance. Reform is difficult because of legal principles such as res judicata and collateral estoppel that ensure finality of legal issues (Arnold and Gunderson 2013), organizational bureaucracy resistant to change (Lazarus 2004), and the goal of law to provide stable contexts within which other social systems (banking, health care, etc.) can operate (Ruhl 2012).

A body of literature is emerging, focusing specifically on features that would characterize an "adaptive legal system" or "adaptive law" (Arnold and Gunderson 2013). This literature overlaps with the adaptive governance and adaptive management literature with many of the suggested design principles of an adaptive legal system replicating that of an adaptive governance system. Common principles include those of communication, monitoring and intermediaries, accounting for scale (Garmestani et al. 2013), polycentric systems, iterative feedback loops (Arnold and Gunderson 2013). In fact, often the recommendation is that adaptive governance could be incorporated into formal legal frameworks (Garmestani et al. 2013).

Utilizing examples from the United States, Arnold and Gunderson (2013) illustrate features of the US legal system which are maladaptive. Legal goals are narrow, focusing on the resilience of the legal system itself or economic goals at the expense of ecosystems and other social institutions including local communities, diverse cultures, etc. Further, legal reform giving primacy to ecosystems or biodiversity may produce unintended consequences including non-implementation, under-implementation, or political backlash. Citing numerous examples of this maladaptive conflicts, the authors find that for law to be adaptive, it must build and strengthen the adaptive capacity of multiple institutions just as it builds and strengthens the adaptive capacity of multiple ecosystems including stimulating the valuation of ecosystem services, strong participatory and deliberative governance of local communities adapting to extreme weather events, rising coastlines, and other environmental transformations. Focusing on goals, structures, methods, and processes, Arnold and Gunderson develop a comparison of features of maladaptive law and adaptive law (Table 2):

> Changing the focus of law from uni-central to a polycentric focus by focusing on policies, methods and tools with co-benefits is cited as another requirement of changing laws from being maladaptive to adaptive. This would allow experimentation and innovation in governance and management, by enhancing participation, encouraging democratization, and risk diversification. The polycentric approach is better matched to scales, scope and speed of problems that arise in a socio-environmental context matching decisions to local norms, culture, and politics. Examples of this are cited as large-scale ecosystem restoration projects or interstate river commissions. (Arnold and Gunderson 2013, p. 13)

Table 2 Comparison of features of maladaptive law and adaptive law

Feature	Maladaptive law	Adaptive law
Goals	Legal regimes aim to advance particular stability of single systems. Current regimes focus primarily on political and economic goals. Alternative (reform) regimes focus primarily on ecological goals	Legal regimes aim for multiple forms of resilience: the resilience and adaptive capacity of both social and ecological systems, including constituent subsystems, such as institutions and communities
Structure	Law is monocentric, utilizing fragmented and unimodal responses to problems	Law is polycentric, utilizing multimodal and multiscalar responses to problems that are loosely integrated
Methods	Law controls society through rules, limits on action and authority, demand for certainty, and legal abstractions that resist change	Law facilitates social and ecological resilience through moderate/evolutionary adaptation to changing conditions, context-regarding standards, tolerance for uncertainty, and flexible discretionary decision making
Processes	Law presumes rational, linear decision making and implementation processes by a single authority and the centrality of law to the ordering and management of human affairs	Law recognizes and embraces iterative processes with feedback loops among multiple participants, limits to human and organizational rationality, and the effects of social and ecological forces on the ordering and management of human affairs, and accountability mechanisms for the conservation of capital

Arnold and Gunderson 2013, p. 5

In conflict with established legal norms (predetermined legal pathways consisting of rigid rules and conventional planning requirements; certainty and security in resources and social structures; preference for risk, liability, and mistake avoidance; decision making based on universally applicable legal abstractions), new methods of law are required. These new methods would facilitate adaptive management methods focusing on learning processes and continuous experimentation. To do so, legal institutions will need to allow private property rights to evolve to changing conditions. Existing legal systems favor human development and use of resources, lands even if adversely affected by climate change, and government-funded infrastructure to facilitate development and compensate property owners for losses. Certain aspects of property law are maladaptive as they are antievolutionary and elevate artificial legal constructs and abstractions that are ill matched to the ecological and social realities that law is intended to address. A context-regarding concept of property as a "web of interests" as opposed to a "bundle of rights" would facilitate the interconnected social and ecological conditions in which property issues arise and impacts of various property alternatives for communities, social systems, and ecosystems (Arnold 2002).

Lastly, it is necessary to understand legal processes not as linear conflicts but in a more complex reality of the law, society and nature relationship. Decisions are made by courts or tribunals, which impact the environment and socioeconomic systems, and over time new decisions, new laws, and findings are made. This interrelationship can be tracked over time and thought of as feedback loops allowing evaluation of impacts with are maladaptive or adaptive. In fact the legal system itself could develop and improve its own feedback loops to evaluate the impacts of decisions and actions (Arnold and Gunderson 2013, p. 21). One suggestion is termed reforming administrative law from "front-end" systems to "back-end" systems where agencies would not have to make all decisions at the outset, the issuance of regulations, license, or permit; instead adaptive management practices would allow adjustments to regulation and changes to permits/licenses via deadline extensions, exceptions, waivers, or variances (Garmestani et al. 2013).

How the apparent conflict of clearly defined rules, boundaries and certainty of laws and the ideas of adaptive law, flexibility, and responsiveness are reconciled and balanced will be outlined in relation to a property interest in water. First, the various permutations of the property interest in water will be discussed followed by a discussion of how this legal instrument, which requires certainty, can be made to be more adaptive.

The Property Interest in Water

There are three major alternatives to the property interest of water. Generally these models relate to the bundle of property rights associated with water, i.e., whether it is owned privately (as a saleable interest as in Chile), as public property (freely available to all), or common property (owned by the water users). In Canada, because the Crown owns all water and water rights are allocated by license, this property ownership distinction is not applicable; however, the property distinction is illustrative as parallels can be seen in the characteristics of bundles of water rights received by way of water license. Based on the three models of property rights, the three institutional models are:

- Government agency management, generally associated with water regarded as public property – government defers its authority for the management of water to an agency which assumes authority for directing who does, and does not, receive water rights in accordance with bureaucratic policies and procedures. In Canada, water is owned by the state (or Crown) and interests are allocated by license. Often a first in time, first in right priority scheme applies (Hurlbert 2009b).
- User-based management, generally associated with water regarded as common property – water users, or those with license or rights to water, join together and coordinate their actions in managing water resources. Decision making is collective among users. Irrigation associations are an example of this type of ownership; another example would be comanaged water resources (Plummer 2009).
- Market, generally associated with water owned as private property – water is allocated and reallocated through private transactions. Users can trade water rights through short-term or long-term agreements or temporary or permanent transfers, reallocating rights in response to prices (Bruns and Meinzen-Dick 1995).

Sometimes a combination of these property interests exists. Alberta has led the provinces in Canada in the development of a water market where transfer of water rights is allowed in accordance with an approved water management plan or by Cabinet order in the absence of such a plan. However, water continues to be owned by the Crown, a license granted to property owners in respect of a parcel of land and then transferred with the land. However, it is possible to transfer a water interest. In the South Saskatchewan River Basin in Alberta, for example, there is a South Saskatchewan Basin Water Management plan which allows the Director to consider applications to transfer water allocations within the basin. The market-based management model employed by Alberta is not a true laissez faire market with vendors and purchasers conducting transactions purely based on market rules; a certain amount of oversight is retained in the review of these transactions and, as such, the predictability of a market model reduced somewhat (Hurlbert 2009b).

Chile changed from having water as public property to private property in 1981 by enacting a Water Code that took place in 2005 (Bauer 2004; Carruthers 2001). Water rights were separated from the land, and a new registry was developed allowing trades without land sales. Permanent water rights exist at an expressed volume per time granted within the guaranteed flows of the water body; however, many other water rights also exist. For example, continuous rights allow withdrawal 24 h a day throughout the year; discontinuous rights can only be used during predetermined periods; and eventual rights can be granted if the flow is above a certain average (Articles 12–18 Water Code).

Of the three property interests in water, private, common, and public, which model is the most conducive to facilitating adaptation and building the adaptive capacity of people and communities?

Analysis of the Property Interest in Water: Adaptive or Maladaptive?

The private property interest in water is thought to be a solution to the more efficient allocation and pricing of water. The statutory provisions allowing transfer are touted by some researchers, and the Alberta government, as advancing the goals of efficient allocation of water interests and conservation in encouraging the transfer of surplus interests. This process is also described as creating a non-regulatory method of reducing wasteful use by creating an incentive to save water and transfer its marginal value for compensation (Percy 2004). The Chilean private property interest in water has contributed to the country's economic development and allowed the state ability to finance a number of public services and infrastructural investments relating to water (Hill 2012a). In Alberta, the ability to transfer a water interest has been allowed and irrigators have done so when facing drought. This has allowed the transfer of a water interest for money and resulting assignment of water to higher value crops yet allowing transferors some financial compensation for the reallocation of their water interest (Hurlbert 2009a).

The private property interest in water fulfills the institutional design principle six of adaptive governance in creating clearly defined boundaries and rules; however, the flexibility of managing the water resource would intuitively be compromised as the government would no longer have a role in managing the resource, guarding ecological limits, and resolving conflicts over water (this being now the realm of legal courts). Many would argue the market tool does not capture the community value of water, nor does it facilitate political and ethical considerations in allocation decisions. The risk of the market is that impacts on third parties not party to a market transaction are neglected, and third parties have difficulty enforcing their interests in a court of law. Although the design principle of "certainty of rules" (8) is achieved, the property interest in water operates a maladaptive legal goal aimed at advancing the stability of a particular system, the market.

It is noteworthy that some authors have found the Chilean water market and governance system to have created challenges surrounding lack of data and information on the market and challenges in holding water users to account due to lack of enforcement capacity and informality of the governance approach. Significant barriers also exist in integrating environmental and social considerations into the water governance framework (Hill 2012b, p. 153). NGOs have been weakened because of the predominance of private property (Hill 2012b, p. 202). Further, the predominance of the private property in water has been at the expense of communities and a communal human right to water with very serious impacts on equity (Hurlbert and Diaz 2012), both an institutional design principle of adaptive governance (Huntjens et al. 2012) and a determinant of adaptive capacity (IPCC 2001).

Regarding water as public property owned by the people (via the state, or Crown in the case of Canada) allows for a legislative framework to be established governing the relationships surrounding water. In this sense, water is not left as a true "public property" equally and freely accessible by all. The wealth of literature surrounding water laws and governance systems accounts for the detailed and technical rules governing water's access and use when still owned by the state for the public (Bakker 2007). The public property system can have significant impediments in relation to adaptation including inefficient allocation of water interests and inability to monitor and claw back unused water allocations (Percy 2004). However, it is possible that the government can balance goals on environmental resilience, development, and community rights to water by retaining the overarching ownership of water. Legislative schemes generally provide for minimum flows being retained in river systems to protect the environment, priorities in times of shortages for community drinking water, and conditions on licenses to ensure against over-allocation and changes in the water resource (Hurlbert 2009b).

Some of the most significant impediments to the adaptiveness of public property water regimes as described above relate to the increasing neoliberal agenda of reduced government (in both size and spending) (Hurlbert and Diaz 2012) as well as the difficulty of the government in balancing all of the necessary components in good adaptive water governance. First, there are well-documented difficulties in the policy interface of government with science and specifically climate change science (Choi et al. 2005; Hoppe 1999); second, there are difficulties in incorporating local knowledge into policy (Gagnon and Berteaux 2009). Without the incorporation of local knowledge, people and communities regard the rules surrounding water as imposed by a distant government and may even not be aware of the rules in order to solve conflict (Hurlbert 2009a). Thus a public property interest in water has potential to allow for an adaptive law goal of allowing for multiple forms of resilience through a polycentric structure embracing iterative consultative public input. However, much is dependent on government and the framework of laws structuring the access to water and processes governing these.

The common property interest of water holds much promise of facilitating adaptive law goals (in that all users determine the balancing of environment and development needs in relation to water). It differs from the public property interest in that government does not have the power to determine what is in the public interest; this power is determined by the users. Of course potentially nonusers (future generations or entities such as flora and fauna without legal standing) are sidelined. The common property interest also embodies the "structure" of adaptive law because of participating at multilevels in decisions (local community, provincial, and national) and utilizes "methods" allowing for discretion which respond to change and "processes" that are iterative and continuous. Increasingly examples of successful comanagement of resources are being reported (Armitage et al. 2007), but these of course entail a sharing of power between the government and users; examples of a pure common property management are elusive. In addition, comanagement has barriers to adaptation including not achieving poverty reduction, reinforcing local elite power, and exclusion of marginal stakeholders from decision processes (Berkes 2009).

Conclusion

This chapter focuses on assessment of laws and legal mechanisms, specifically a property interest in water, to improve adaptive capacity of rural agricultural producers to respond to climate variability and change, and specifically drought, in the future. Certainty of law is an important attribute in a democratic society; however, often certainty is synonymous with inflexible, traditional laws, perhaps no longer appropriate in times of rapid social, geographical, and natural system change. Law is one institution that operates within a wider governance context and contributes to the adaptive capacity of a community. Appropriate provisions are required in both public and private law in order to ensure that the institution of law can adapt to future variability and extreme climate events of drought and flood. Principles of adaptive governance (responsiveness, flexibility, etc.) and adaptive law (polycentric responses to conflict with iterative feedback loops) are appropriate.

By comparing the three property interests in water, public, common, and private, an assessment is made of how this legal instrument can facilitate or hinder adaptive capacity. Common property interests in water are most reflective of adaptive law principles. However, significant barriers and difficulties exist in finding a case where water governance is conducted in a common property manner. One example is in an irrigation district context. More research is required in relation to the context and scale in which water could be ascribed with a common property interest.

Private property instrument of water can in certain contexts and applications add features of resiliency. Alberta has had positive experiences with allowing the transfer of a water interest in certain prescribed limited situations. However, the complete adoption in Chile of a market interest in water, or the employment of a private property instrument, has had negative impacts on adaptive capacity. The water market has been plagued by shortages of information, reduced social capital, and disparities in access to water with equity issues (Hurlbert and Diaz 2012).

Public property (if it is accepted that government-administered schemes reflect this) could envision adaptive law and governance principles if orchestrated appropriately. A pejorative review of legislation and policy might be conclusive of the virtues of this ascribed property tool in relation to water representing adaptive governance and law. However, without delving deeper into an institutional analysis of how law actually operates within a socio-environmental system, such a desktop review may be misleading. Further research is required to delve deeper into the lived experience of those with water interests in relation to different public property, or government-administered schemes are required.

Climate Change Adaptation: An Overview on Challenges and Risks in Cities, Regions Affected, Costs and Benefits of Adaptation, and Finance Mechanisms

Manal El-Batran and Mohsen Aboulnaga

Contents

Abstract

Adaptation of climate change (CC) has been defined by many of the world's leading institutions such as IPCC and UNFCCC in various contexts. Many studies, research, and reports on CC mitigation were reported, but less was done on adaptation. Adaptation is strategically needed to lower the impact of CC that is manifesting coupled with serious challenges and risks for cities such as high temperatures, water

availability, floods and droughts, and sea-level rise damage to coastal areas. Adaptation is vital to offset CC impacts on environment challenges such as soils, biodiversity, inland water, and marine environment. By adopting effective measures and early actions for CCA, money and lives can be saved. The EU Climate Action highlighted six areas where adaptation measures should be applied and financed. Strategies for CCA are vital at all levels of government administration whether local, regional, or national to counterbalance CC. Areas with high vulnerability to CC impact and need adaptation actions, policies, and measures; are mainly in Europe, the Mediterranean, Asia-Pacific, North America, and Africa; and have been highlighted. Gaps in the assessment of the full costs of CC compared to that of CC mitigation were discussed. Many researches that have been conducted on CC policy are mainly for mitigation, but less was focusing on the assessment of cost. The EU which allocated 20 % of funding to climate, costs, and benefits of adaptation is recently focusing on the cost inclusion of adaptation in urban policies and projects and the cost of actual adaptation measures. Costs and benefits of adaptation options were reviewed by UNFCCC, mainly methodological issues for estimating the costs and benefits of adaptation options followed by the economics of adaptation in light of the review. Information and guidance for the costing of adaptation options are outlined, including many major methods and techniques for adaptation option appraisal and decision analysis in the climate change adaptation that have been recently reported such as cost-effectiveness analysis (CEA), the cost–benefit analysis (CBA), and the multi-criteria analysis (MCA). It also presents a comparison between these costing and benefits and techniques. This chapter reviews and discusses five main folds: (1) why is climate change adaptation necessary; (2) the importance of climate change adaptation (CCA); (3) what are the methods of CCA; (4) the widening gap between CC impacts and required adaptation measures, including the most affected regions and case studies of CCA in Africa, Asia, Europe, and Latin America; and (5) what is the cost of CCA including how costs of CCA are assessed and financed. It also attempts to review the CCA funding mechanisms with focus on cities and urban areas. It is clear that many actions, measures, and funds have been developed, but the gap is still widening in developing poor countries, and the robust machinery to significantly execute the current funding in productive channels is highly required if facilitating adaptation to CC impacts and minimizes risks.

Keywords

Climate change • Adaptation methods • Adaptation actions and measures • Risk in cities • Cost and benefits • Adaptation and finance mechanism • Vulnerable countries

Introduction

Climate change impact has been widely manifested worldwide in the last 10 years. Climate change (CC) means "global warming" or the "greenhouse effect." This is caused by the emissions of greenhouse gases (GHGs) into the atmosphere through enormous human activities, particularly the burning of fossil fuels. In this part, the challenge of CC, from a development perspective in terms of how can developing countries anticipate and respond to the threats and opportunities brought by CC, is considered.

It is widely recognized that the climate is changing. While local, regional, central, and federal governments continue their efforts to reduce GHG emissions, it is important to prepare for CC impacts that are already underway. This includes more extreme heat and flooding, as well as increased damage to energy, water, and transportation infrastructure from extreme weather events. Also, economic development in many countries remains fundamentally based on fossil fuels. This means societies are going to experience some degree of CC and will have to implement a combination of reactive and anticipatory measures to adapt. There is still much uncertainty about how the climate is likely to change at both regional and national levels. Policy makers and planners often require information about CC at scales which have high levels of uncertainty. Responses to extreme weather and anticipatory planning for CC therefore need to be flexible and resilient to a much wider range of climate conditions than are currently experienced. They must also pursue this on the basis of limited knowledge. For various reasons, more attention in CC research and policy has been given to mitigation than adaptation. Uncertainty about the details of CC whether rainfall will increase or decrease and the timescales over which CC will occur are likely to influence decision-making about funding priorities and target activities. There is, however, close agreement between development agendas and the effects of CC in areas with high climate variability and extremes of weather. It is in these situations that CC will most directly affect vulnerable people, such as those living in small-island states or low-lying coastal areas, subsistence farmers, flood-prone communities, and urban dwellers exposed to extreme temperatures and potential increases in disease transmission. Development work can provide valuable insights into the context-specific and socially mediated links between vulnerability and extremes of weather. Cause and effect between hazard and disaster occurs through human agency, and it is here that development research has much to offer our understanding of climate–society interactions.

This chapter reviews and discusses five main folds: (1) why is climate change adaptation necessary; (2) importance of climate change adaptation (CCA); (3) what are the methods of CCA; (4) widening gap between CC impacts and required adaptation measures, including the most affected regions and case studies of CCA in Africa, Asia, Europe, and Latin America; and (5) what is the cost of CCA including how costs of CCA are assessed and financed. It also attempts to review the CCA funding mechanisms with focus on cities and urban areas.

Why is Climate Change Adaptation Necessary?

Climate change adaptation (CCA) has been defined by many of the world's leading institutions in various contexts. These briefly describe adaptation as action taken, adjustments to a process, strategies, or outcomes. In a different setting, CCA consists of initiatives and measures to reduce the vulnerability of natural and human systems to actual or expected climate change effects. They can be spontaneous or planned responses to actual or expected conditions (Regmi et al. 2010). Adaptation is strategically needed to lower the effect of CC that is happening and poses serious challenges and risks for cities such as high temperatures (heat waves and storms), water availability, floods and droughts, and sea-level rise damage to coastal areas. Sectors that are affected encompass infrastructure and buildings, energy demand and supply for cooling and heating, agriculture production in terms of crop yields, tourism, insurance, and crosscutting business. Also, adaptation is important to offset CC impacts on environment challenges such as soils, biodiversity, inland water, and marine environment. Additionally, social dimension of CC has been manifested by health impact, population employment, and education; hence, adaptation measures are vital to reduce such impacts. By adopting effective measures and early adaptive actions for CCA, money and lives can be saved. Tompkins and Adger (2003) explain the differences between mitigation and adaptation, noting that they share the same underlying factors and are not substitutes for each other but are essentially complementary. They argued that it may be difficult to generalize about how adaptation occurs and how strategies can be exploited. Adaptation may be in response to or in anticipation of events and implemented through the actions of individuals, governments, or other groups.

CCA has been defined by many of the world's leading institutions in various contexts (Gagnon-Lebrun and Agrawala 2007; Harley et al. 2008; UNFCCC 2010a; Brooks et al. 2011; Preston et al. 2011; Poutiainen et al. 2013; Bours et al. 2014). Adaptation refers to the ability of human and ecological systems to manage or cope with a changing climate. Adapting to these impacts must take place at all levels of the government. However, as most impacts will be felt at the local level, municipalities/governorates in particular need to respond to these local challenges. Major challenges also surround the equity issues of CC, particularly between developed and developing countries, in terms of historically unequal emissions of GHGs, constraints on future emissions, and unequal exposure and capacity to adapt to the effects of CC. These are questions to which the developing world and the development community can bring considerable insights (id21 Insights 2004).

International negotiations in Bali, Indonesia (December 2007), failed to achieve consensus on targets for climate change mitigation (CCM), i.e., reducing GHGs' emissions. However, countries have agreed to negotiate mitigation targets for after 2012 by the end of 2009, when the countries meet again in Copenhagen (id21 Insights 2008b). A vital point that had been stressed by the Copenhagen Conference Declaration (CopCD) remains a source of major differences between developed and developing countries: the principle of "common but differentiated" responsibilities. Developing countries insist that developed ones have a historical responsibility and should cut emissions and provide developing countries with finance and technology to do their part. On the other hand, they ask about the growing contribution of developing nations to global warming (Tolba 2011).

If we are to save our planet there must be a real willingness to cooperate, with developing countries accepting part of the responsibility for current and future emissions and developed countries bearing the full responsibility for past emissions. This cannot be achieved without open discussions between both sides. Developing countries must realize that the total 2009 CO_2 emissions by China surpassed those of the USA, the biggest emitter, and that emissions by India are similar to those of Japan or Russia. This indicates that we must immediately begin a series of nonstop informal consultations between the leading countries in both camps with a view to achieving compromises before UNFCCC COP20, 2014. The UN must play the role of a global body concerned about serious global problems. It should also offer a neutral forum but work to produce meaningful compromise formulations that bring together opposing views. Too much is at stake to allow such useless negotiations to continue forever.

The outcomes of the United Nations Climate Change Conference in Cancun, Mexico, December 2010, proved once again that governments are not serious enough about the issue. Nonstop consultations between developed and developing countries must now take place, and they should achieve tangible and effective compromises before the forthcoming UNFCCC COP20 in Lima, Peru, due on December 2014. Efforts are needed to develop more scientific evidence, it is true, but we certainly know enough (Tolba 2011). However, CC has shot to the top of the world agenda in the last 10 years. The first push came from Albert Gore’s 2006 famous film “Inconvenient Truth.” It showed in a dramatic way the ice melting in the North Pole as well as the very strong storms, hurricanes, and floods that swept through various areas of the globe. The second push came, again in the year 2006, from the Chief Economist of the World Bank, Sir Nicholas Stern’s report. When he retired at his home country, Tony Blair, former Prime Minister of the UK, requested him to convene a group of experts to prepare a report on the economics of CC. The British expert group had detailed discussions with experts from all over the globe. The Stern report made three telling points:

(a) Actions today to mitigate climate change cost 1 % the global gross domestic product (GPD) while facing its impacts later will cost the world 5 % of its total GPD.
(b) Any spending in the next 20 years on actions to mitigate climate change will have impact only after 2050 because of the GHGs’ life spans.
(c) Increase of the average global temperature will continue for the next 20 years even if emissions are stopped today, again because of the GHGs’ life spans.

The UN Intergovernmental Panel on Climate Change (IPCC) issued its Fourth Assessment Report in November 2007. In the same year, the IPCC received the Nobel Prize jointly with Al Gore in recognition of their effort to bring the seriousness of the issue of CC to the attention of the world community. The first sentence in the IPCC Synthesis Report of 2007 stated that “Warming of the climate system is unequivocal, as is now evident from observations of increases in global average air and ocean temperatures, widespread melting of snow and ice and rising global average sea level.” They were so categorized far beyond the normal language used by the scientists. The IPCC report further stated that “Most of the observed increase in global average temperatures since the mid of the twentieth century is very likely due to the observed increase in anthropogenic GHG concentrations."

Climate change in Africa is manifested in many forms whether in terms of water, agriculture, aridity, energy demands, or security. The IPCC Report of 2007 also gave the following three disturbing facts about Africa:

(a) "By 2020, between 75 and 250 million people in Africa are projected to be exposed to increased water stress due to climate change."
(b) "By 2020, in some African countries, including North Africa, yields from rain-fed agriculture could be reduced by up to 50 %. By the same date agriculture production, in many African countries is projected to be severely compromised. This would further exacerbate malnutrition."
(c) "An increase of 5–8 % of arid and semi-arid land in Africa is projected by 2080 under a range of climate scenarios."

The IPCC based its emphatic conclusions on global warming on a number of facts which it presented in its 2007 report:

(a) CO_2 atmospheric concentration increased from 280 PPM in 1750–379 in 2005. The average concentration for the last 365,000 years was 300 PPM.
(b) Eleven out of the 12 years (1994–2005) were the hottest years on record.
In the last 50 years, the number of cold days and nights, hot days and nights, and heat waves increased.
(c) Average sea-level rise was 3.1 mm/year between 1993 and 2003, compared to an average of 1.8 mm/year during the period of 1961–2003.
(d) There is up to 97 % confidence within the IPCC that the average global temperature will increase by 2 °C by 2050. This could happen in the year 2035.
(e) The IPCC had more than 50 % confidence that the average global temperature will increase in the next century by 5–6 °C – a situation unfaced before by human beings.

All these disturbing facts were further stressed and accentuated by the UNEP 2007 State of the Environment Report (SOE) and UNDP 2007 Human Development Report; both were devoted entirely to the issue of CC. Additionally, several reports by the World Bank, the European Union (EU), the Organisation for Economic Co-operation for Development (OECD), the US National Science Foundation (NSF), and several others were published in 2008 and 2009 stressing the global negative impacts of CC. The same old very general statements that were adopted in tens of earlier conferences starting from the First International Conference on Climate Change convened in 1988 in Geneva by WMO and UNEP in cooperation with UNESCO, WHO, and FAO. Nevertheless, none of them went beyond stating intentions with no specific details of how and during which period any of these statements will be implemented.

One of the points stressed by the Copenhagen deceleration was that of the principle of common but differentiated responsibilities. This point has been and still a source of huge differences between developed and developing countries. Developing countries insist that developed ones have historical responsibility and should cut emissions and provide developing countries with finances and technology. Developed countries ask and rightly so, what about the current and the future. If we want to move ahead to save our planet, there must be a real willingness to cooperate by the two groups, developing countries accepting part of the responsibility for current and future emissions and developed countries take full responsibility for past emissions. This cannot be achieved without direct and open discussions between the two sides, talking to one another rather than past one another. Developing countries must realize that the total CO_2 emissions by China in 2009 surpassed that of the biggest emitter, the USA, and that emissions by India are similar to those by Japan or Russia.

These disturbing facts were further stressed and accentuated by the United Nations Environmental Programme's State of the Environment Report (SOE), the United Nations Development Programme's Human Development Report and other reports by the World Bank, the European Union (EU), the Organisation for Economic Co-operation for Development (OECD), the US National Science Foundation (NSF), and others. Yet, the outcome of the United Nations Climate Change Conferences at Copenhagen (2009), UNFCCC (2010b, 2011) proved that governments are not serious enough about the issue. If human beings want to survive, nonstop consultations between developed and developing countries must now take place, and they should achieve tangible and effective compromises before the next climate change conference at the end of 2014.

As pointed out by Tolba (2011), "Governments have no option but to halt the dialogue of the deaf and agree on four basic points if Durban is to be a success. These are: agreement on the verification of emission reductions; agreement between developed and developing countries on the principle of common but differentiated responsibilities; specific targets for the GHGs' emissions in developed and developing countries; and finally, developing countries need to be offered a grace period before applying the reductions required by a new treaty. Advanced developing countries (China, India, Brazil, South Korea, Malaysia, etc.) may have a shorter grace period than other developing countries - certainly shorter than those for least developed countries and small-island states. As per the Copenhagen agreements, parties need to define specific figures for financing a climate change adaptation fund, and to establish the details of the technology transfer mechanism. The most affected countries should be supported urgently."

Importance of Climate Change Adaptation

The impacts of climate change are already being observed around the world, from retreating glaciers to changing seasons and rainfall patterns. Climate change (CC) is likely to be evident in the future through more frequent storms, droughts, heat waves, floods, and other extreme events. Amid ineffective local governments that provide inadequate infrastructure and services required to reduce climate change-related risks and vulnerabilities, most of the world's urban populations are living in cities or smaller urban centers that are ill equipped for adaptation. Infrastructure and buildings are considered a key part of adaptation concerns, but much of the urban population in Africa, Asia, and Latin America has no infrastructure to adapt – no all-weather roads and piped water supplies or drains – and lives in poor-quality housing in floodplains or on slopes at risk of landslides (Satterthwaite et al. 2007).

According to El-BATRAN (2010), climate change extreme events, particularly floods and droughts, have severe implications on various sectors and services, including water, energy, livelihoods, transport, and health. In spite of the very low contribution of Egypt in the global GHG's emissions, Egypt is considered as one of five highly vulnerable countries to climate change impacts. The January 2010 floods in North Sinai left 780 homes totally destroyed, 1,076 submerged, and much other damaged. At least 3,500 persons have been affected by the floods or are homeless. The floods were of a surprise as North Sinai had not seen such floods in 30 years as shown in Figs. 1–3. Also in December 2013, the cold spell and heavy snow falls (never happened since 112 years) that totally covered most of Cairo outskirts (Altagamoah, New Cairo) are other manifestations of climate change impact as exhibited in Fig. 4. Also in May 2014, Egypt's eastern part (Taba and Sinai) and Upper Egypt (Aswan) were stormed by torrential rain that had led to floods (Figs. 5 and 6). So, adaptation to climate change is worse in the secondary cities than in capital cities, particularly in case of Figs. 1–6.

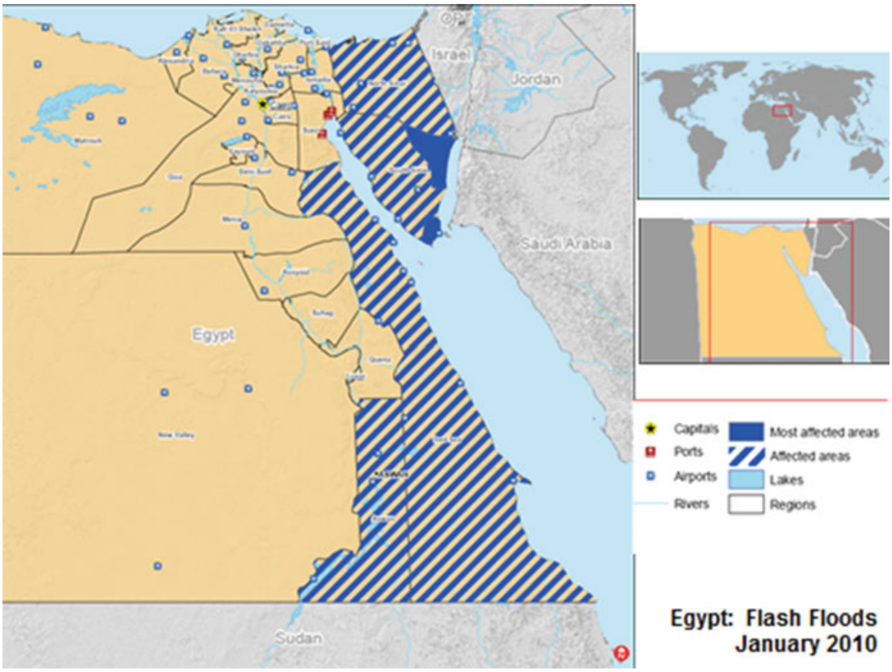

Fig. 1 Egypt's flash flood, January 2010 (Source: Egyptian Red Crescent)

Fig. 6 Torrential rain and floods in Red Sea area and Upper Egypt – May 2014 (Image Credit: http://www.google.com)

Each of these extreme events may affect the security and sustainability of development throughout the world. Developing countries, particularly least developed countries, are likely to be exposed to the greatest impacts. However, CC is caused by current and past emissions from industrialized countries that have more resources to cope with the impacts (id21 insights 2004). Climate-related risks come not only from direct exposure to natural hazards such as floods or droughts but also from the vulnerability of social and economic systems to the effects of these hazards. Responses to these risks should combine two approaches: (a) short-term measures to react to hazards when they occur and (b) structural reforms that enhance the capacities of communities to adapt. Climate change adaptation (CCA) is an adjustment in natural or human systems, which occurs in response to actual or expected climatic changes or their effects (id21 Insights 2008b).

Adapting to CC means adjust and acclimatize to risks from observed or expected changes. Governments, enterprises, and households will all have to adapt. In most urban centers, community organizations and local nongovernmental organizations are also important, especially where they are influential in building homes and communities and providing services within informal or illegal settlements (Satterthwaite et al. 2007).

In human systems, adaptation can reduce harm or exploit opportunities. The disaster risk reduction (DRR) is the development and application of policies and practices that minimize risks to vulnerabilities and disasters. The DRR is an essential part of adaptation – it is the first line of defense against climate change impacts, such as increased flooding or regular droughts. The DRR is now lending its expertise and humanitarian experience to climate change adaptation programs (id21 Insights 2008b).

Mitigation and adaptation are the two responses to CC. Mitigation means reducing emissions of greenhouse gases, the main cause of human-induced climate change, whereas adaptation means adjusting to any new climatic conditions caused by natural and human-induced change. Many parts of the world have had to cope with previous climate variability and have developed strategies to do so. Adaptation can be undertaken in anticipation of impacts or after these have occurred. These can be initiated by individuals through market exchanges and social interactions or through coordinated measures by government or other groups. The mix of anticipatory or reactive adaptation action actually introduced will depend on the existing vulnerabilities of each community or individual, as well as institutional processes, regulatory frameworks, property rights, access to resources, and social conditions. Adaptation is place specific and context specific: there is no single plan for how adaptation should occur.

However, lessons learned from responding to past hazards may be useful for planning for future CC. Investments in adaptation and mitigation are necessary, but these are not substitutes for each other. In fact, the ability of societies to reduce their emissions and to adapt is determined and constrained by the same underlying factors. The resilience of institutions and of resources sensitive to changes in the climate is central to meeting the challenge. These issues are often magnified in developing countries, which are coping with economic globalization and other challenges simultaneously (id21 Insights 2004).

Adaptation is a risk-reduction strategy for ameliorating the adverse effects of CC on human and ecological communities and for capitalizing upon potential opportunities. Adaptation specifically refers to actions, policies, and measures that increase the coping capacity and resilience of systems to climate variability and CC (CSIRO 2006). Also, adaptation can be generally divided into two types of measures: vulnerability reduction and resilience enhancement (Kay and Hay 1993). The term "vulnerability" is used to describe the attributes of a system which will react adversely to the occurrence of external or internal stresses (Nitivattananon et al. 2009). The EU Climate Action highlighted six areas where adaptation measures should be applied and financed as illustrated in Fig. 7 (EEA 2012). The first two measures are highly needed for Africa and mainly Egypt since water and energy shortages are high on the government agenda.

Strategies for CCA are vital at all levels of government administration whether local, regional, or national to counterbalance CC. In addition to other adaptation measures, sustainable urban design, resilient urban management, and improving infrastructure to be green would contribute toward lessening these effects. Given the limitations of impact-driven coastal vulnerability assessments in considering

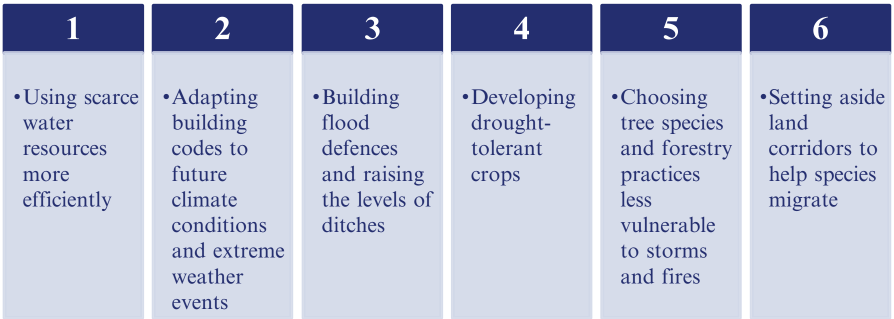

Fig. 7 Adaptation measures (Source: EU Climate Action)

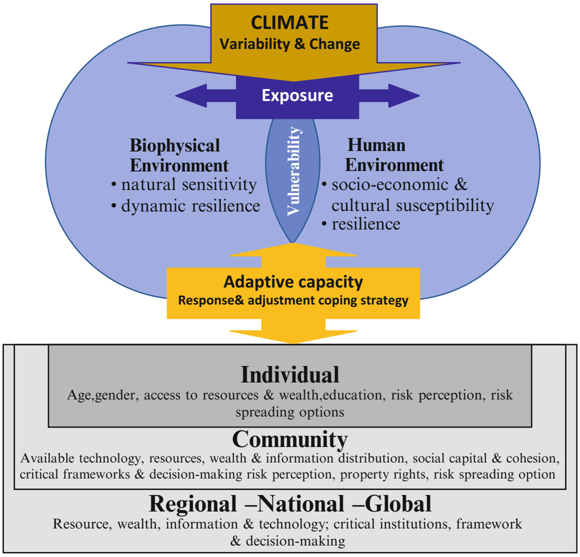

Fig. 8 Integrated vulnerability framework (Source: Modified by Dolan and Walker 2004)

both physical and social aspects of vulnerability and in light of the present need for community-based approaches to adapting to climate change-related risks, Dolan and Walker (2004) proposed an "integrated" framework (Fig. 8).

Such approach considers inherent susceptibilities and resiliencies of both biophysical and social environments as an interrelated and interdependent human environment system. Vulnerability, in this context, can be defined as "the degree to which a system is susceptible to, or unable to cope with, adverse effects of climate change, including climate variability and extremes. Vulnerability is a function of the character, magnitude and rate of climate variation to which a system is exposed, its sensitivity, and its adaptive capacity" (Watson 2001).

Vulnerability to CC is considered to be high in the South due to social, economic, and environmental conditions that amplify susceptibility to negative impacts and contribute to low capacity to cope with and adapt to climate hazards.

Moreover, projected impacts of climate change generally are more adverse for lower latitudes, where most countries in the South are located, than for higher latitudes. Because of the high level of vulnerability, there is an urgent need in the South to understand the threats from climate change, formulate policies that will lessen the risks, and take action (Abou-Hadid 2006). The danger is greatest, where natural systems are severely degraded and human systems are failing and therefore incapable of effective response, specifically in deprived nations.

Furthermore, land degradation and desertification may also be exacerbated in these areas, posing additional threats to human well-being and development, added by intensified human pressures on lands and poor management (Elsharkawy et al. 2009). The agriculture and food resources including livestock and fisheries of the rural poor are threatened by CC with all its impacts, and the vulnerability to adverse health impacts is greater where health-care systems are weak and programs for disease surveillance and prevention are lacking. In addition to multiple factors converging to make the people inhabiting coastal zones and small islands highly endangered from the causes of SLR (Leary and Kulkarni 2007). The coastal Zone and small islands are, therefore, particularly vulnerable to the impact of SLR in addition to impacts on water resources, agricultural productivity and human settlements. But, if no protection action is taken, the agricultural sector will be the most severely impacted, followed by the industrial sector and the tourism sector by a SLR.

The term "resilience" is used in the opposite sense to vulnerability – resilient attributes of a system will typically reduce the impact of internal and external stresses. According to Dolan and Walker (2004), adaptive capacity is reflective of resiliency, such that a resilient system has the capacity to prepare for, avoid, moderate, and recover from climate-related risks and/or change. Nonetheless, Satterthwaite (2008) stated that successful adaptation is about the quality of local knowledge, local capacity, and willingness to act. City governments should have key roles, not only in changing what they do business, but also in the adaptation they encourage and support (Fig. 9).

Development should increase people's ability to act to reduce their vulnerability to climate change – due to improved local knowledge and increased income – and increase poorer groups' ability to influence local governments' action. Insurance can spread risks and reduce the financial hardships linked to extreme events. It can also provide incentives for adaptation and risk reduction, but only a very small proportion of urban households and enterprises have insurance. For low-income groups, supporting the measures they already employ to reduce risk and vulnerability has more relevance – for instance, through community-managed savings groups.

In many countries, groups formed by people in "slums" or informal settlements engage in risk management and risk-reduction initiatives. These include upgrading slums and squatter settlements, developing new housing, and improving water supply, sanitation, and drainage. In some cities, such groups have also developed detailed maps of informal settlements and collected data on who lives there to guide new infrastructure. In Durban, South Africa, adaptation plans demonstrate the important role that local governments can and should play. Adaptation to CC has

1. • Ensuring the availability of an appropriate and widely understood information base about climate change and its local impacts –this does not exist in most cities
2. • Land-use planning that avoids high-risk areas and shifts activities away from them, including ensuring that low-income groups can find affordable land for housing on safe sites.
3. • Revising building and infrastructure standards, in ways that do not impose unaffordable costs.
4. • Planning and public sector investment that considers climate change. For example, much infrastructure needs to be designed to cope with likely changes over 50 to 100 years.

Fig. 9 City government key roles (Source: Satterthwaite (2008))

to be built into the core of all urban planning and management. It is, however, difficult to get local governments to act on adaptation. There are always other priorities that seem more pressing and, at present, the information base on the likely local impacts of CC is weak.

In most cities, planning for adaptation must first overcome an inadequate infrastructure base.

Estimates of adaptation costs have yet to recognize this. Adaptation will need to address this deficit as well as making building improvements, strengthening of lifeline infrastructure, and hazard modification (for instance, repairing and strengthening flood, storm surge, and coastal defenses). All cities need effective disaster risk management plans, both to reduce risks and have in place appropriate responses. Good disaster preparedness is a key part of adaptation. However, adaptation means "better coping," rather than removing risks. It does not remove or even reduce the urgency for mitigation: even for relatively low amounts of warming, there are natural and technical constraints to adaptation. Without strong and early mitigation, the difficulty and costs of adaptation will grow rapidly. While good development and adaptation to CC risks are complementary in important ways, most adaptation does entail opportunity costs (Satterthwaite 2008).

Methods of CCA Assessments and Measures

Many methodologies have been set and used for CCA. These were derived and established by the World Bank, UNEP, and Mainstreaming Adaptation to CC in Agriculture and Natural Resources Management projects. Guidance notes for lessons learned, best practices, recommendations, and useful resources for integrating climate risk management and adaptation to CC in development projects program planners. As highlighted in the "Financing the Resilient City" report

(ICLEI 2011), it provides a bottom-up strategy for building capacity to finance and implement resilience for development. This strategy is centered on the idea of establishing local capacity to plan, finance, execute resilient improvement, and note to raise funds (ICLEI 2011). There is always a challenge in matching the precise enabling finance with local demand for urban resilience. This highlights the importance of the right approach. A number of approaches have been developed to address the issue of mobilizing financial resources.

Widening Gap Between Climate Change Impacts and Required Adaptation Measures

Despite the fact that CC impacts are manifested in many countries, particularly the poor ones, CC adaptation and enacted measures are not yet showing enough to eliminate such risks. This can be seen due to the unavailability of funds to address these impacts; besides, the current local authorities and government are not the institutes for such an adaptation, and they lack the capacity to build and invest, and current urban policies are not addressing CCA.

Climate Change Most Affected Regions

Climate change adaptation (CCA) is bound by population, economic sectors, and social constraints. Areas that are highly vulnerable to climate change (CC) impacts and need adaptation actions, policies, and measures are mainly in Europe, Mediterranean, Asia-Pacific, North America, and Africa. Migration is a key issue of demography that causes stress on the national infrastructure when it comes to climate change impacts (Sheribinin 2013). The diverse linkages between climate change and security, including risks of conflict, national security concerns, critical national infrastructure, geopolitical rivalries, and threats to human security, have been recently highlighted and reviewed by Gemenne et al. (2014). In this study, it has been concluded that much analysis overemphasizes deterministic mechanisms between climate change and security. The importance of mapping these impacts, whether major or minor, is vital in understanding the severity, sectors, and areas. In a study by Sheribinin (2013), regions that are anticipated, based on combinations of high exposure, high sensitivity, and low adaptive capacity, to suffer significant impacts from CC have been highlighted. In the past 5 years, “hotspots” mapping on CC has helped in identifying spots that are affected by the phenomena and that will be impacted in the future. Hotspots mapping efforts underlined a range of issues and sectors such as vulnerable population, humanitarian crisis, conflict, agriculture and food security, and water resources. Many developed climate change “hotspots” have been established by researchers, advocacy groups, and NGOs (Sheribinin 2013).

In Africa, “hotspots” mapping has helped in communicating areas that CC has impacts on and may require adaptation. These areas are (a) Al Wahda Dam, Morocco; (b) Cape Floral Region, South Africa; (c) Etosha National Park, Namibia; (d) Lake Tanganyika, Tanzania; (e) Salonga National Park, D.R. of Congo; (f) Western Highveld, South Africa; and (g) Yirgacheffe, Ethiopia (Union of Concerned Scientists 2011). The top impact and other impacts in these six countries are mainly freshwater (extreme dry), people (water use, food, and coasts), temperature (air and water), and ecosystems (land, lakes, and rivers). Other regions in Asia, Australasia (Australia and New Zealand), Europe, Latin America, North America, polar regions, and small islands can be found in the same reference. This tool (hotspots mapping) can be of significance in identifying the direct and appropriate measures, actions needed, and cost allocation due to these impacts and the required funds and financial mechanism for cities to counterbalance climate change.

Many affected countries will be further impacted by CC across the world based on geographical location and population. Studies carried out by international organizations (UNFCCC and EC) stated that 10 places worldwide that are the highly vulnerable, in addition to Bangladesh, Serbia, Australia, Myanmar, and Sudan, are Uganda, the Alps, Northwest Passage (Arctic), Washington, D.C., Gulf Coast (Florida), Island Nations, the Great Barrier Reef, Northern Europe, Italy, and Nepal (Abou-Hadid 2006). In South Asia, CC is predicted to have drastic consequences, particularly in agriculture, which employs more than 60 % of the region's labor force (Oxfam 2010). Predicted impacts of CC include increased variability in both monsoon and winter rainfall patterns; increase in average temperatures, with warmer winters; increased salinity in coastal areas as a result of rising seas and reduced discharge of major rivers; weakening ecosystems; the recession of glaciers in the Himalayas; and increased frequency and/or severity of extreme weather events (floods, cyclones, and droughts).

Moreover, the recent IPCC report on climate change stated that Egypt is one of the nations that will be heavily affected by the impact of climate change phenomenon. The World Bank study (Dasgupta et al. 2007) stated that Vietnam is among the countries most heavily affected by the consequences of climate change: of the 84 coastal-developing countries investigated in terms of sea-level rise (SLR), Vietnam ranked first in terms of impact on population, GDP, urban extent, and wetland areas and ranked second in terms of impact on land area (behind the Bahamas) and agriculture (behind Egypt). Hence, it requires intermediate planning for adaptation (Waibel 2009). Like Egypt, almost 11 % of Vietnam's population, mostly those people living in the two river deltas, would be impacted by an SLR of just 1 m (Dasgupta et al. 2007).

The Stern Review on the Economics of Climate Change confirms Vietnam's high vulnerability to climate change. Vietnam is ranked fourth behind China, India, and Bangladesh in terms of the absolute number of people living in vulnerable, low-elevation coastal zones (LECZ). This is considered the highest percentage of all countries worldwide (Waibel 2009). It has been concluded that "vulnerable settlements in low-income countries clearly deserve international support to adapt to climate change."

Climate Change Adaptation (CCA): Case Studies

Many countries have taken steps toward climate change adaptation such as Finland, Sweden, Norway, Scotland, and Greenland. The CCA themes were centered on sustainable energy, transport, tourism, and risk management. In these cases, a number of real adaptation activities were carried out by several different communities. These cases were part of the Clim-ATIC project that attempted to identify and understand the issues relevant to stakeholders at a local level in terms of actual development and implementation (Climate Change Adaptation Resources 2014).

This project undertook a number of key activities over a 3-year period, with communities and community sector stakeholders across five regions of the Northern Periphery, to build the necessary knowledge on (a) investigation, collation, and communication of relevant information on potential direct and indirect impacts of climate change to small peripheral rural communities; (b) development of adaptation strategies by these communities to avoid or reduce the negative impacts of climate change, while taking advantage of opportunities; (c) implementation of adaptation demonstration projects with a focus on transnational activities; and (d) establishment of a formal mechanism to disseminate knowledge for community adaptation. Table 1 shows these case studies and related themes.

Nevertheless, when compared with those in poorer countries, little can be noticed; however, cases were reported in the following section about Africa, Asia, Latin America, and Europe.

Africa's Pioneering Countries in Climate Change Adaptation

According to the ICLEI report on their members in Africa which exhibited true commitments on climate change adaptation (CCA) through the C40 group, two key countries have led by tremendous efforts in terms of CCA. These are Cape Town, South Africa, and Dar es Salaam, Tanzania. These cities were involved in the pioneering CCA in Africa program and are pioneering on sustainability and manifesting great leadership through participatory research actions over many years as part of the over 1,000 strong international ICLEI network of local governments and cities. For Cape Town, it is also a leading and founding city of the local action for biodiversity (LAB) program and has been engaged in various aspects of sustainability through the ICLEI network, including advocacy work linked to the UN-CBD, whereas Dar es Salaam participated in a Food–Water–Energy Urban Nexus project that is implemented by ICLEI Africa and funded by GIZ (ICLEI 2014).

Nevertheless, in poor communities, CCA was noticed. In Accra (Ghana), Kampala (Uganda), Lagos (Nigeria), Maputo (Mozambique), and Nairobi (Kenya), a discussion with the residents of poor communities in cities was conducted through a program called ActionAid, including many points of concern (Box 1). Flooding had become more frequent in each of these cities; thus residents suggested that it had become less predictable. Residents emphasized that the lack of adequate drainage and poor management of existing drainage, unplanned and unregulated urban development as well as the lack of attention to the problem by the government, and changes in weather patterns are the main reason for flooding.

Box 1 CCA points of concern – ActionAid in poor communities in some African cities

Table 2 CCA case studies – African poor communities

Country	Case studies	Themes
Nairobi, Kenya	Adaptation strategies include:	Infrastructure (buildings)
	Digging holes around houses before and during floods	
	Building temporary dikes/trenches to divert water away	
	Securing structures with waterproof-recycled materials	
	Relocating to the highest parts of the dwelling that residents think are secure	
	Using sandbags to prevent the ingress of water	
Accra, Ghana	Adaptation strategies include:	
	Using blocks, stones, and furniture to create high places on which to put their most critical valuables during floods	
	Putting goods on top of wardrobes and in the small spaces between ceilings and roofs	
	Sharing high places with others who have no similar safe sites	
Kampala, Uganda	Undertook collective work to open up drainage channels	
	Temporarily moved to lodges and public places like mosques and churches until the water level receded	
	Barriers were built to water entry at the doorsteps and outlets at the rear of their houses to prevent any water from entering their homes and flowed out quickly	
Lagos, Nigeria	Using sand to raise the entire area to a higher level	
	Standard drainage facilities along major streets (within Iwaya/Makoko) would help to solve the flood problem	

Source: Satterthwaite et al. (2007)

Informal settlements in Nairobi that form approximately 50 % of the population specifically responded to the flooding by adaptation strategies. Table 2 exhibits some of these measures of CCA. In contrast, residents in Alajo, Accra, women and children, suffer when the rain and the floods occur which prevent them from moving, and they have to place their children on building roofs, and boats were brought to evacuate them – June and July floods, 2006 (Satterthwaite et al. 2007). In Kampala, similar strategies were adopted by individuals. Some of these measures are highlighted in Table 2.

In Lagos, both those living in informal settlements and representatives of local government believe that clearing the drainage channel running through Iwaya/Makoko would prevent the pooling of water from other parts of the city. The CCA measures in Lagos were also highlighted in Table 2.

As stated in all the cities, residents' responses were typically ad hoc, individual short-term efforts to survive and protect properties and belongings.

Asia's Case Studies: CCA

There are many case studies in Asia that exhibited attempts to climate change adaptation (CCA). The following section highlights some of these case studies mainly in Vietnam and India.

Case Study of Vietnam

In Asia, particularly Vietnam would face losses totaling US$17 billion per year in case of sea-level rise (SLR) of 1.00 m (VNS 2007). This will dramatically increase by 2050, if no adaptation measures are taken (Waibel 2009), but little has been taken due to financial constraints. It has been underlined that the lack of a national and local framework for CCA and coordination among ministries, agencies, and institutions in areas pertaining to CC is among the institutional constraints to implement adaptation planning in Vietnam (Waibel 2009). Limited knowledge on the relationship between CC strategies and the attainment of sustainable development objectives, as well as capacity building on climate change issues among local stakeholders, is also a key obstacle toward adaptation. Based on researches, the potentials and costs of adaptation by industry, settlement planning, and society to climate change are still at an early stage. It was highlighted that Vietnam urgently needs expertise and financial support from the international community (Waible 2008).

Case Study of Indore: India

In Indore, India, flooding is perceived as a natural, seasonal event; hence, many low-income communities and households had taken steps to limit the damage it does as part of CCA. This was mainly applied to households who live on land sites adjacent to small rivers that are also key storm drains and are particularly at risk (Satterthwaite et al. 2007). In this case study, temporary and permanent adaptations to flooding were made by households and small enterprises, including raising plinth levels and paving courtyards, using landfill and materials that resist flooding, choosing furniture that is less likely to be washed away, and ensuring that shelving and electric wiring are placed high up the walls, above expected water levels. Roofing may be unattached to a house, so it can be speedily removed if the structure is in danger of being swept away. Also, flood-prediction and protection systems and contingency plans for evacuating persons and possessions have been developed by residents (Table 3).

In one of the settlements (Shekha Naga), the residents' first response in one of the settlements to the threat of severe floods is an evacuation plan to move the elderly, children, and animals to higher ground followed by (a) electrical goods, (b) other lighter valuables and cooking utensils, and (c) clothes – easily replaced and undamaged by flooding. Additionally, awareness on how to use the state system of compensation for flood damage was aired by residents to enable them to acquire a perverse incentive for them to build houses in the most vulnerable and dangerous areas. All these attempts were made by local residents not the local government (Stephens et al. 1996). Table 2 summarizes the CCA in Indore and other Asian cities.

Latin America's Case Studies: CCA

Many countries in Latin America had taken steps – by several different communities – to CCA, such as El Salvador, Argentina, Peru, Nicaragua, and Colombia. In El Salvador, the difficulties of getting appropriate risk-reduction action for lower-income groups were manifested (Table 4). However, based on interviews and

Table 3 CCA case studies – Asia

Country	Case studies	Themes
Indore, India	Low-income households' adaptation to flooding	Infrastructure (buildings) Risk Management
	Roofing may be unattached to a house, so it can be speedily removed if the structure is in danger of being swept away	
	Raise plinth levels and paving courtyards, using landfill and materials that resist flooding	
	Flood-prediction and protection systems and contingency plans for evacuation	
Baan Mankong, Thailand	Improved housing conditions and infrastructure and services within low-income settlements	
Cavite City, the Philippines	Community-based strategies include:	
	Accommodate sea-level rise by building houses on stilts	
	Strengthening the physical structure of houses	
	Moving to safer places during calamities	
	Placing sandbags along the shorelines	
	Borrowing money from relatives or moneylenders (at very high interest rates)	
	Engaging in alternative income-generating activities locally or in other areas or changing occupation	

Source: Satterthwaite et al. (2007)

discussions with people living in 15 disaster-prone "slum" communities and with local organizations, these difficulties became noticeable. It was recognized by low-income households that most serious risks to their lives and livelihoods were flooding and landslides, lack of job opportunities, and water provision as well as insecurity due to violent juvenile crimes.

Despite that complex range of issues limited their effectiveness such as the individualistic nature of households' investments and the lack of representative community organizations. However, Manizales and Colombia were facing high rates of population growth and environmental degradation. This attempt was part of a larger program that aimed to improve environmental quality and make resource use more sustainable (Satterthwaite et al. 2007). In contrast, Mexico City has given more attention to climate change mitigation through control of air pollution but little toward adaptation to floods.

European's Case Studies: CCA

At the European level, the overall economic impact of water scarcity and droughts in the past 30 years is estimated at EUR100 billion (EC 2007). The average annual impact doubled from 1976 to 1990 to the following 1991–2006, rising to 6.2 per year in the most recent years. Nevertheless, the exceptional drought in 2003 was amounting to the cost of EUR 8.7 (EEA 2010). However, the 2014 IPCC report indicated three key risks from climate change for Europe, but it did not focus on individual countries. These risks are the following:

Table 4 CCA case studies – Latin America

Country	Case studies	Themes
El Salvador	Appropriate risk-reduction action for lower-income groups	Risk Management Infrastructure (water, sanitation, electricity, buildings)
	Households had invested in risk reduction and on average spent 9 % of their incomes pursuing so	
	Measures were taken to lower risks (diversifying their livelihoods or assets that were easily sold, if a disaster occurred)	
	Remittances from family members working abroad were important for many families, especially in providing support for recovery after a disaster	
Manizales, Colombia	Local government acted on:	
	Avoiding rapidly growing low-income populations settling on dangerous sites	
	Households were moved off the most dangerous sites but rehoused nearby, and most of the former housing sites were converted into eco-parks with strong environmental education	
Ilo, Peru	Improvements were made in water supply, sanitation, electricity provision, waste collection, and public space	
Santa Fe, Argentina	Embankments and dikes were created to encounter floods	
Nicaragua	Improving houses in slum and squatters (PRODEL program)	

Source: Satterthwaite et al. (2007)

1. Increased economic losses and more people affected by flooding in river basins and coasts; as urbanization continues, sea levels rise and peak river flows increase.
2. Increased water restrictions. Significant reduction in water availability from river abstraction and from groundwater resources combined with increased water demand (e.g., for irrigation, energy, and industry and domestic use).
3. Increased economic losses and people affected by extreme heat events: impacts on health and well-being, labor productivity, crop production, and air quality.

These findings align well with the UK's own Climate Change Risk Assessment (CCRA) published in 2012, which identified that the biggest challenges in the UK will be flooding and water shortage. Thus, high levels of adaptation can significantly reduce these risks but does not eliminate them.

The Netherlands' Case Study

In the Netherlands, the findings of a project "Climate as Opportunities" that evaluated 100 large infrastructural investment projects related to spatial planning and water management (some in cities) revealed that integrating CC in planned

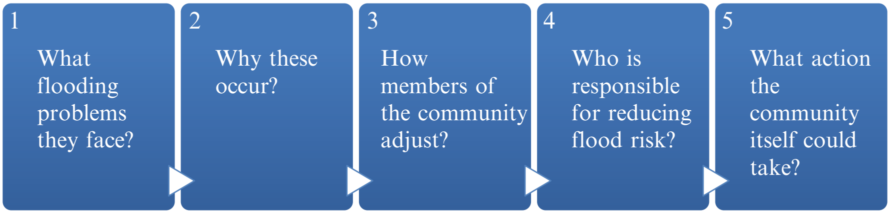

Fig. 10 Adaptation planning in policies (Source: EEA Report 2012)

urban renewal and upgrading projects enhanced sustainability of these projects, hence decreasing the future costs. Figure 10 shows how this was achieved.

Cost of Climate Change Adaptation

Climate change damage is now universally understood that the most significant will be felt in developing countries (Stern 2006), Africa being the continent that causes the most concern. This is mainly due to the reason that their ability to adapt may be limited because of technical, economic, and institutional limitations (Tol et al. 2004). Consequently, economic assessments – integrated assessment analysis – categorize particularly high economic costs from CC in Africa (Downing et al. 2005). As pointed out by van Aalst et al. (2007), conservative estimates are that African economies could be facing losses of at least 1–2 % of GDP or US $10–20 billion annually, though some sectors will be much more exposed.

As highlighted by Watkiss et al. (2010), the potential cost of adapting to climate change in Africa will reach at least US$10 billion but will more likely be in the region of US$30 billion – every year by 2030. Adaptation funding is not a question of aid, it is an international obligation to compensate developing countries for causing damage to their environment, economies, and societies. Developed countries therefore have a responsibility to provide the required adaptation funding immediately through structured financial mechanisms. This finance should be additional to overseas development assistance (ODA).

As indicated in an UNEP study by Watkiss et al. (2010), estimating the costs of adaptation involves a large number of methodological challenges, but perhaps the most significant is the necessity to recognize uncertainty and planning robust strategies to prepare for an uncertain future and not to utilize uncertainty as a reason for inaction. Key findings from the study report the summarized information from the various areas of research from global integrated assessment models (IAMs). These provide aggregated estimates, assessing costs in a single iterative framework. To ensure that this analysis is manageable, they entail simplifications and assumptions but have been the subject of considerable debate. The AdaptCost project commissioned two leading global IAMs, the FUND and PAGE models, to provide results for Africa (Watkiss et al. 2010). Also, it has been stated by Parry et al. (2007) that estimate of the total attributable costs of climate proofing investment to future CC could be a factor of 2–3 higher than the UNFCCC estimates, valued as US$12–28 billion/year by 2030 for Africa. Other studies that count up the additional costs for social protection, to safeguard livelihoods and health related to climate, nevertheless a study by the Grantham Institute (2009) it approximates that an additional US$12–17 billion/year is needed for Africa currently (2015), with this number potentially increasing in future years up to 2030.

From the literature, there are many gaps in the assessment of the full costs of CC compared to that of CC mitigation. Many detailed and comprehensive researches that have been conducted on CC policy are mainly for mitigation, but less was focusing on the assessment of cost. Even with the EU allocating 20 % of funding to climate, the costs and benefits of adaptation are relatively and recently focused on mainly the cost inclusion of adaptation in urban policies, projects, and the cost of actual adaptation measures. Most of the studies such as ClimateCost FP7 and PESETA have looked at the costs in damage terms related to coastal systems, human health, agriculture, tourism, and floods, whereas the cost of heat-related deaths varies according to the methods used (Watkiss 2010; Ciscar et al. 2009). When the "value of statistical life" method is utilized, estimated welfare cost averages will be EUR 30, 102, and 146 billion/year for 2011–2040, 2041–2070, and 2071–2100, respectively (Watkiss 2010). In the USA, the story is similar where little is known about the cost of adaptation.

Studies suggest that adaptation cost could be as high as tens or hundreds of billions of dollars per year by the middle of this century. For Africa, the UNEP has published a report in 2010 estimating the costs of adaptation which involves a large number of methodological challenges, but most essential is the need to recognize uncertainty. It is estimated that due to high uncertainty, the integrated assessment models indicate that the central economic costs of CC could be equivalent to 1.5–3 % of the GDP each year by 2030 and expected to rise over time, with reasonable estimates of around tens of billions of dollars a year by 2030. For example, analysis of sea-level rise in Africa using the DIVA model suggests large impacts and economic costs in coastal zones, but adaptation can reduce these considerably yet has as high benefits when compared to costs; it is estimated at US$1–4 billion/year by 2050. In this respect, low level of investment in some parts of the world led to adaptation shortfall. The Pan African Climate Justice Alliance (PACJA), with the support from Christian Aid, commissioned Practical Action Consulting which developed a report in 2009 with an aim at documenting and analyzing the economic costs of climate change in Africa. It also seeks to contribute to a more detailed understanding of the costs involved for Africa in mitigating and adapting to climate change. Table 5 depicts an outline of possible CC impacts in Africa with adaptation cost ranges (Rebecca, PACJA report 2009).

Costs and benefits of adaptation options were reviewed by UNFCCC, mainly methodological issues for estimating the costs and benefits of adaptation options followed by the economics of adaptation in light of the review. In general, the cost of CC estimates for 2030 which was issued by the UNFCCC has been criticized by Parry et al. (2007). In this study, they looked at the estimates from a range of viewpoints and concluded that key sectors such as ecosystems, energy,

Table 5 Climate change impacts in Africa and adaptation cost ranges

°C rise	1.5	2	4
Cost ranges with adaptation	Minimum US$10 billion a year by 2030 and up to US$30 billion a year, directly in response to climate change		
Cost ranges without adaptation	1.7 % of Africa's total GDP	3.4 % of total GDP	10 % of total GDP

manufacturing, and retailing were not included, yet the additional costs of adaptation have sometimes been calculated as "climate markups" against low levels of assumed investment. Thus, there is a persisting need for detailed appraisals of these costs to care for residual damage. According to the European Climate Adaptation Platform (CLIMATE-ADAPT), the analysis of costs and benefits is vital for assessing feasible adaptation options. A study on the full cost of CC was published by EC-FP7 and coordinated by the Stockholm Environment Institute (2011) highlighted the costs and benefits of CCA.

Planning for urban adaptation is a key approach to reduce the cost of climate change. Improving adaptive capacity is essential in reducing vulnerability of cities to climate-related risk, hence avoids high cost. The IPCC (2007) describes adaptive capacity as "the ability of a system to adjust to climate change (including climate variability and extremes) to moderate potential damages, to take advantages of opportunities, or to cope with the consequence." In brief, it is a set of enabling conditions. Adaptive capacity (AC) can be assessed at various spatial levels from national (Yohe and Toll 2002; Greiving et al. 2011; Haddad 2005; Westerhoff et al. 2011) to local. However, economic resources, capital assets, and financial means are vital components of AC (Smit and Pilifosova 2001). It is essential to mention that wealthy nations are in better position to bear the cost of adaptation and plan yet pay for the measures to uphold and increase their capacity when compared with poor cities. While it seems an obstacle for poor nation, little information on the cost of adaptation is available; nonetheless, a small number of options such as flood defenses were reported (EEA 2012).

Making our cities and their infrastructures resilient would definably reduce the cost of CC but would require actions beyond cities borders to be more effective, including adaptation planning (AP). A number of approaches to AP have been established (Smit et al. 2000; Riberio et al. 2009; CBT 2009). Also, the UK Climate Impact Programme (UKCIP) Adaptation Wizard based on "one-step-at-a-time" approach, which is exploited in six adaptation planning steps by the European Climate Adaptation Platform, CLIMATE-ADAPT (EEA and EC 2012). By adopting these steps, as indicated in Figure 11 at earlier stage, the cost of CCA can be significantly lowered. When adaptation planning (AD) is integrated, as one of the drivers into the development of urban policies, AD does not primarily be costly and time-consuming process. Due to the relative recent focus on adaptation, less information was known on the cost of potential climate damage, the cost of inclusion of adaptation in urban policies and projects, and the cost of actual adaptation measures. According to preliminary studies, it has been indicated that

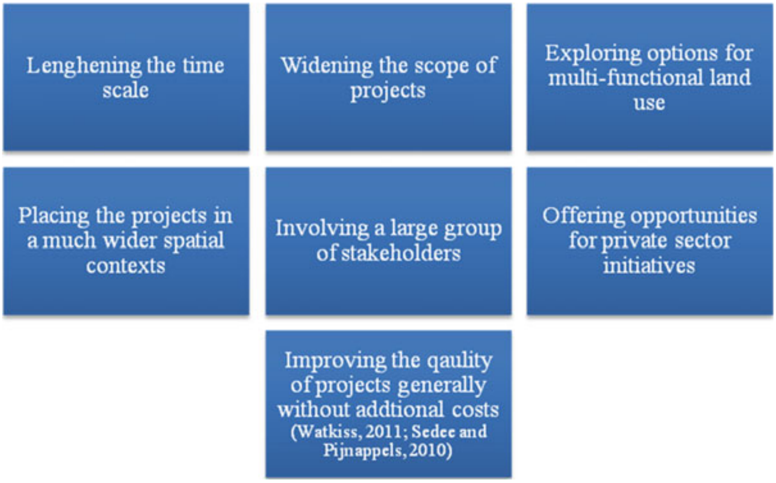

Fig. 11 Adaptation planning steps (Source: European Climate Adaptation Platform (CLIMATE-ADAPT))

benefits often surpass costs. This suggests that if the authorities take advantage of opportunities related to urban renewal, it can result in adaptation benefits surpassing the costs (EEA 2012).

Case Studies of Some European Cities: Affected Regions

To date, most of the studies on adaptation cost have focused on a limited set of easily monetized measures such as floods defenses or other infrastructures. Nonetheless, costing of measures such as greening is more complex. A recent study on green space maintenance and the findings of individual case studies of green roofs in some European cities included in the urban audit database estimated an amount over EUR 7 billion for the first and EUR 100 billion annually for the second, respectively, following a initial investment of about EUR 7 billion (Altvater et al. 2011a, b). The calculations in this study were based around adaptation needs related to current rather than projected climate issues and did not consider the intangible benefits like human well-being, but likewise the estimates for green roofs reflect private and public spending and disregard the savings made. This indicates the importance of taking all costs involved as well as benefits of adaptation options available to estimate their exact economic feasibility.

Mechanism of Financing Climate Change Adaptation

Climate change adaptation funding of actions and measures is essential for development policies in cities and urban areas of vulnerable countries. Most funding in the last decade was mainly directed for CC mitigation. However, financing adaptation to lessen CC impacts varies in developed and least developed countries (LDCs). The latter needs more planning, measures, and funds to adapt to the severity impacts of CC.

Several financial mechanisms exist under the United Nations Framework Convention on Climate Change (UNFCCC) to support adaptation, particularly in low- and middle-income countries.

The UNFCCC Green Climate Fund (GCF) has considered the potential mechanism for mobilizing a share of the proposed international climate financing proposed in the Cancun Agreements and accepted by Parties during the December 2011 conference in Durban, South Africa. The aim of the fund is to support developing countries in their efforts to counterbalance CC via the furnishing of grants and other concessional financing for mitigation and adaptation projects, programs, policies, and activities. Contributions from donor countries and other sources, including both innovative mechanisms and the private sector, will assist in capitalizing such fund (Lattanzio 2013).

The GCF supplements many of the existing multilateral CC funds, e.g., the Global Environment Facility (GEF), the Climate Investment Funds (CIF), and the Adaptation Fund (AF). Nonetheless, the GCF is the official financial mechanism of the UNFCCC; some parties believe that it may eventually replace or subsume the other funds. While many parties expect capitalization and operation of the GCF to begin shortly after the November 2013 conference in Warsaw, Poland, many issues remain to be clarified, and some involve long-standing and contentious debate (Lattanzio 2013).

Also, the UNFCCC listed rich countries with a manifested obligation to assist poor countries to adapt to CC, particularly small-island states and LDCs (id21 Insights 2004). The CCA funds were established as early as 2001 during the UNFCCC Seventh Conference of Parties (Marrakech, Morocco). These funds are shown in Fig. 12.

In terms of effectiveness, the first one (LDCs fund) is the only one that is in operation so far.

Other UNFCCC funds are the "Marrakech Funds" and the Global Environment Facility (GEF) which provides funding for climate change activities (id21 Insights 2004). A special fund of US$50 million for adaptation in developing countries over 3 years has been recently established by GEF. It has been noticed, however, that the GEF rules – they can only be used for the "incremental costs of global benefits" – are considered the barriers to use these funds. Although it is reasonably simple to calculate the costs of global benefits arising from mitigation projects, it is more difficult to do so for adaptation projects (as benefits are usually local rather than global). Nevertheless, the UNFCCC funds are forming a small portion of the financial package that is needed for CCA in the developing nations. In this respect, it is vital to differentiate between adaptation actions and international funding support. The first has to be carried out by vulnerable communities, sectors, and countries themselves, with whatever resources they can provide, whereas the UNFCCC is responsible for international funding support for adaptation in

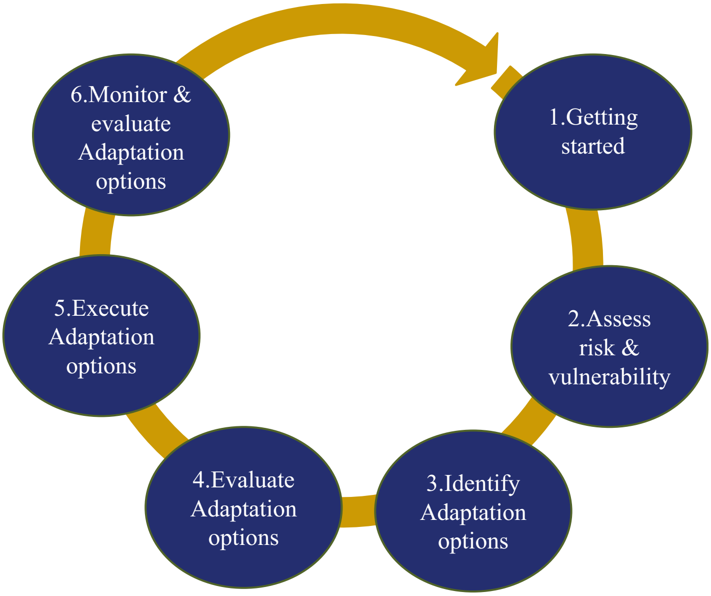

Fig. 12 UNFCCC funds (Source: id21 (www.id21.org))

developing countries. In developing countries, most adaptation will require to be carried out as part of normal development activities. Funding could be secured through bilateral and multilateral funding agencies and through nongovernmental organizations (national and international). These funding mechanisms are shown in Diagram 1. However, it has been stated that a key challenge will be to find ways in which overseas development assistance and UNFCCC funds can be complementary, rather than repeating each other's activities (Huq 2004).

In Asian countries such as Cambodia, Thailand, Lao PDR, and Vietnam, substantial volumes of financing have been noticed. In addition to official development assistance (ODA) and numerous Climate Investment Funds (CIF), such as the Global Environment Facility (GEF) Trust Fund, Special Climate Change Fund (SCCF), and Least Developed Country Fund (LDCF).

Clean Technology Fund (CTF); Strategic Climate Fund (SCF); Asian Development Fund (ADF); the funds from multilateral development and financial institutions such as the Asian Development Bank (ADB), International Fund for Agricultural Development (IFAD), European Commission (EC), and World Bank (WB); bilateral organizations such as the US Agency for International Development (USAID), Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ), Swiss Agency for Development and Cooperation (SDC), Swedish International Development Cooperation Agency (SIDA), Danish International Development Agency (DANIDA), Japan International Cooperation Agency (JICA), and Korea International Cooperation Agency (KOICA); governments of Finland and the Netherlands; the UN; and private sector have been involved in CC adaptation and mitigation efforts. The majority of financing is in the form of grants, technical

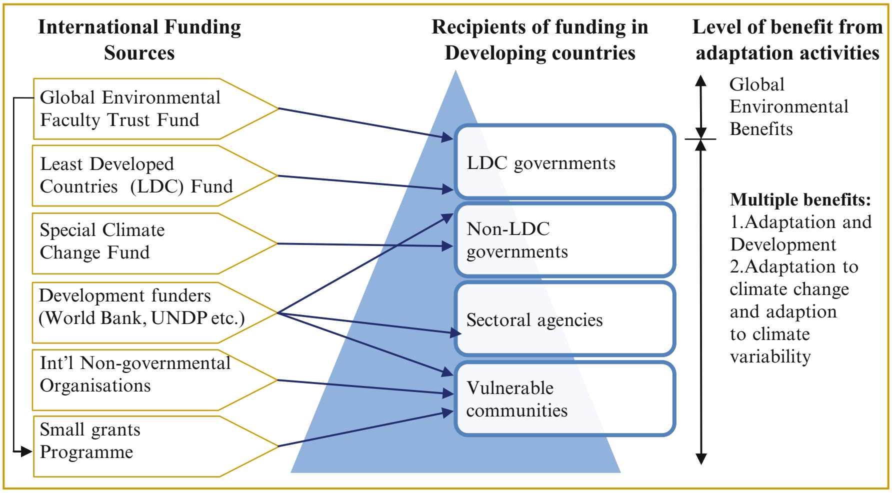

Diagram 1 Entities benefiting from international funding sources for adaptation (Source: Climate Change Programme, International Institute for Environment and Development)

assistance, and then loans. Majority of the initiatives involve two or more financing mechanisms, with a share of country participation, as well. The region will also be targeted with financing from the emerging global Green Fund and other mechanisms as well in the near future (FAO – TCID 2011).

Information and guidance for the costing of adaptation options, including many major methods and techniques, for adaptation option appraisal and decision analysis in the climate change adaptation have been recently reported such as cost-effectiveness analysis (CEA), the cost–benefit analysis (CBA), and the multi-criteria analysis (MCA). It also presents a comparison between these costing and benefits and techniques (2011).

There is a role of financial mechanisms in spreading risks. As pressure increases on traditional risk-sharing strategies so too does the exploitative nature of money-lenders, particularly during disasters. How people access financial institutions for micro-credit, insurance, and financial services requires further research and documentation, including:

- Micro-finance research to better understand how micro-finance can be linked to larger social support systems that strengthen livelihoods and increase disaster risk resilience rather than increase the risk and debt burden for the poor
- Financial incentives research to identify how risk sharing and risk transfers can be promoted through existing institutional mechanisms in terms of CCA

Climate finance is vital for adaptation and it allows nations to adapt to the severe effects of CC and reduce its impacts. The term "climate finance" simply means local, national, or transnational financing, which could be drawn from public, private, and alternative sources of financing. It is essential to handle CC due to

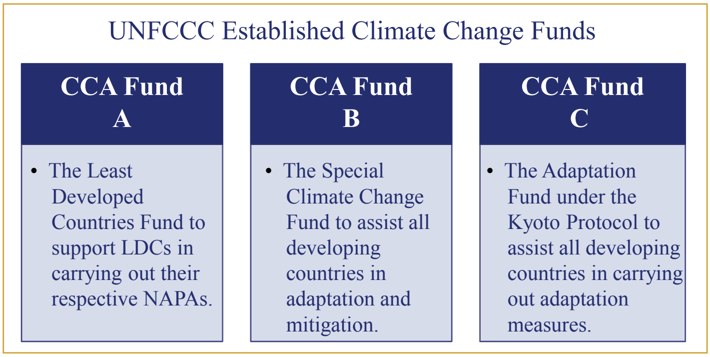

Fig. 13 Programs for financial and technical support (Source: UESPA, GEF, PICCAP)

the fact that large-scale investments are required to significantly reduce emissions, notably in sectors that emit large quantities of GHG. Finance mechanism has been reviewed many times, the latest one was at COP19. This was carried out in accordance with decision 8/COP18, the Standing Committee on Finance (SCF). Expert input was the main focus to the fifth review of the financial mechanism, with a view to review being finalized by COP20. Several initiatives have supported assessments in developing countries. The following programs have provided financial and technical support, with a main focus on capacity building within the scientific and stakeholder communities (Fig. 13).

In the review of the financial mechanism, the objective was to take appropriate measures regarding:

1. Its conformity with the provisions of Article 11 of the Convention and with the guidance of the COP.
2. The effectiveness of the activities it funds in implementing the Convention.
3. Its effectiveness in providing financial resources on a grant or concessional basis, including for the transfer of technology, for the execution of the Convention's objective on the basis of the guidance provided by COP.
4. Its effectiveness in providing resources to developing country Parties under Article 4.3 of the Convention.

A second challenge for those financing adaptations is the need to separate the additional costs of climate change adaptation from "business as usual" development activities. But this is very difficult. In addition, as emphasized above, successful development contributes much to adaptive capacity. Those who want to fund climate change adaptation may want to clarify the difference between risks and vulnerabilities related to climate change and risks and vulnerabilities related to climate variability independent of climate change. From a development perspective, the two need to be integrated. But while the separation may pose many practical challenges, it may be necessary to distinguish between the responsibility (and hence liability) of high-income countries to pay for the damage they have caused (according to the "polluter pays" principle) and funds donated under the banner of philanthropy or charity. For this reason, funding for climate change needs to be in addition to existing aid flows – even if the funding it provides needs to be strongly integrated within development investments. In practice, requirements for detailed additional costs (which are usually virtually impossible to ascertain) are being increasingly waived in favor of approximations.

Another key issue to be resolved is who and what should be prioritized for receiving international funds for supporting adaptation? Should some countries receive priority over others or should some sectors and communities be prioritized? And if so, on what basis? These issues are still under discussion in the UNFCCC and the bilateral funding agencies themselves and have yet to be resolved (Satterthwaite et al. 2007).

Some Remarks on International Fund for Climate Change Adaptation

Most of developing countries, particularly city local governments, ministries, and agencies, have not yet taken climate change adaptation (CCA) seriously within their urban strategies, policies, and investments. Where governments are representative and accountable to poorer segments, they generally have more pressing issues, including large backlogs in provision for infrastructure and services, and much of their population is living in informal settlements where there are little CCA measures. These countries are also under paramount pressure to improve education, health care, and security as well as searching for means of lowering high unemployment rates and eradicate poverty.

Satterthwaite et al. (2007) have argued that unless adaptation to CC is seen to support and enhance the achievement of development goals, it will remain marginal within government plans and investments. Therefore, the need for CCA highlights the importance of strong, locally driven development that delivers for poorer segments and is accountable to them. Similarly, the extreme vulnerability of large sections of the urban population to the many aspects of climate change reveals the deficiencies in "development." He stressed that unless these deficiencies are tackled, there is no real basis for adaptation.

According to the IPCC report in 2014, it is imperative to act immediately. It was stated that actions and choices taken in the early part of this century will shape the risks we face in the latter part of the century. Nevertheless, many of the nations or cities most at risk from climate change lack the political and institutional capacity to address such requirements of adaptation. Even if we can conceive of how this might be addressed, it is difficult to see how existing international institutions, in their current structure, can pursue such tasks. However, early action will allow more time to adapt to impacts, but there are limits to adaptation. Some risks will remain so we cannot rely on adaptation alone. The report also stated that CC will affect all. Poor and rich countries, rural and urban populations alike, must plan for the future and adapt to limit future risks.

Climate change has traditionally received little attention from international donor organizations. A review of 136 projects in Africa funded by the German donor GTZ found no references to climate change (Satterthwaite et al. 2007). International organizations such as the International Monetary Fund and World Trade Organization give little consideration to climate issues in their work. A study by the Organisation for Economic Co-operation and Development revealed the magnitude of development assistance and aid in sectors potentially affected by climate risks (OECD 2003). In Egypt and Bangladesh alone, from 1998 to 2002, between US$1 billion and US$2 billion was directed to sectors affected by climate change and climate variability. As much as 50–65 % of development aid in Nepal was given to climate-sensitive sectors.

Clearly, international donor agencies need to assess the extent to which their investment portfolios in low- and middle-income countries might be at risk due to climate change and take steps to reduce that risk. This is increasingly recognized, and several bilateral and multilateral development agencies and NGOs are starting to take an interest (Agrawala 2004).

At least six development agencies have screened their project portfolios both to ascertain the extent to which existing development projects consider climate risks or address vulnerability to climate variability and change and to identify opportunities for incorporating climate change explicitly into future projects. Donor agencies and NGOs that have started to examine their investment and project portfolios in this way include the World Bank in India; the UK Department for International Development (DFID) in India, China, and Kenya; the Netherlands Department for Development Assistance (DGIS) in Bolivia, Bangladesh, and Ethiopia; the International Institute for Sustainable Development (IISD); and the International Union for Conservation of Nature (IUCN). Most agencies already consider climate change as a real but uncertain threat to future development, but they have given less thought to how different development patterns might affect it.

Conclusions

“A global human-induced climate change has begun, acknowledging the inertia and the next to irreversibility of the climate system, and the likeliness that the response by the global community will not be quick, are strong arguments for concluding that the ongoing change of the climate might be a more serious matter for the future than so far has generally been considered to be the case. Considerably more far-reaching measures during the next commitment period after 2012 than agreed in Kyoto are likely to be necessary in order to avoid serious consequences of a change of climate” (IPCC 2007). Major challenges surround the equity issues of CC, particularly between developed and developing countries, in terms of historically unequal emissions of GHGs, constraints on future emissions, and unequal exposure and capacity to **adapt to the effects of CC**. To address the climate change issue effectively, it must be viewed as an essential part of our efforts to have a sustainable development. Rich countries, partly so, because of their access to valuable resources, must take on a particular responsibility. Also, a more equitable world is necessary and will be to the advantage of everybody, rich and poor, north and south. Otherwise a major irreversible climate change will certainly hit us all.

Climate change is already having an impact on ecosystems and man on all continents and across the oceans. Evidence has grown since the last IPCC report in 2014. As sea levels rise, coastal communities worldwide will experience ever more flooding, coastal erosion, and submergence. Unmitigated climate change poses great risks to human health, global food security, and economic development. Urgent action to reduce emissions is essential to avoid dangerous climate change. The level of adaptation required is dependent on the scale of mitigation. Adaptation is essential to deal with the risks of climate change, but there are limits to what adaptation alone can achieve.

It has been seen that many courtiers are affected and others will be impacted by CC. It is clear that many areas and cities are currently manifesting CC impacts and vulnerable to many risks. But due to poverty, little has been taken for CC adaptation. This left the gap between rich and poor countries widening. Unless real confined measures and policies supported by proper funding (not on paper but materialized) **are enacted on the ground, more risks of CC impacts will be witnessed and manifested; by then, it will be too late to probably act.**

The review shows that climate change adaptation (CCA) is not at the same pace of climate change mitigation (CCM). Thus, more collective efforts are urgently needed at local, regional, and national level. These efforts must be coordinated and successful case studies in similar countries with the same risks and vulnerability should be exchanged.

Despite the fact that there are a bundle of finance mechanism and funding grant to adapt to climate change, more funds are needed mainly in developing countries to lower the gap between the actions, measure, and policies and institutional structure and capacity building.

Reasons for Poor Countries Being Unable to Cope With the Required Adaptation Measures

When considering adaptation, it is easy to get lost in the details of what needs to be done – or in producing “cost–benefit” ratios for nations or regions that do not consider who bears the costs and where they are concentrated. Some examples were noted above of cost–benefit ratios suggesting that certain key cities were unviable – including cities that are central to the current and future development prospects of whole nations.

Discussions of adaptation must also remember the profound unfairness globally between those who cause climate change and those who are most at risk from its effects (Huq et al. 2007). This can be seen in three aspects: first, in regard to people, it is the high-consumption lifestyles of the wealthy (and the production systems that meet their consumption demands) that drive climate change. It is mostly low-income groups in low- and middle-income nations with negligible contributions to climate change who are most at risk from its impacts. Second, in regard to nations, it is within the wealthiest nations that most greenhouse gases have been emitted, but mostly low- and middle-income nations that are bearing and will bear most of the costs. Third, in regard to cities, larger companies and corporations can easily adjust to new patterns of risk induced by climate change and move their offices and production facilities away from cities at risk. But cities cannot move. And all cities have within them the homes, cultural and financial assets, and livelihoods of their inhabitants, much of which cannot be moved (Satterthwaite et al. 2007).

There are figures to show the dramatic differences between nations in average contributions per person to greenhouse gas emissions – for instance, the 80-fold difference between that of the USA and many low-income nations. But these actually understate the scale of these differentials. Greenhouse gas emissions in high-income nations are kept down by the fact that they import many of the energy-intensive goods used or consumed by their citizens and businesses. In addition, a concentration on comparing "averages" for nations obscures just how much the problem is driven by wealthy groups. The differentials in greenhouse gas emissions per person between rich and poor groups can be much larger than the differentials between rich and poor nations. For instance, the greenhouse gas emissions generated as a result of the high-consumption lifestyle of a very wealthy person or household are likely to be hundreds of thousands or even millions of times more than that generated by many low-income households in low-income nations (Hardoy et al. 2001; Hardoy and Pandiella 2007).

The key issue is how to build resilience to the many impacts of climate change in tens of thousands of urban centers in low- and middle-income nations. According to Satterthwaite et al. (2007), such measures should:

- Work with the reduction of risks from other environmental hazards, including disasters (noting the strong complementarities between reducing risk from climate change, non-climate change-related disasters, and most other environmental hazards)
- Be strongly pro-poor (most of those at risk from climate change and from other environmental hazards have low incomes, which limits their autonomous adaptive capacity)
- Build on the knowledge acquired of reducing risk from disasters in urban areas
- Be based on and build a strong local knowledge base of climate variabilities and of the likely local impacts from climate change scenarios
- Encourage and support actions that reduce risks (and vulnerabilities) now, while recognizing the importance of measures taken now to begin the long-term changes needed in urban form and the spatial distribution of urban populations to reduce vulnerability to risks that may become manifest only several decades in the future
- Recognize that the core of the above is building the competence, capacity, and accountability of city and sub-city levels of government and changing their

relationship with those living in informal settlements and working in the informal economy – and the importance within this of supporting civil-society groups, especially representative organizations of the urban poor (this is also to avoid the danger of "adaptation" providing opportunities for powerful groups to evict low-income residents from land they want to develop)

- Acknowledge that government policies must encourage and support the contributions to adaptation of individuals, households, community organizations, and enterprises;
- Recognize the key complementary roles required by higher levels of government and international agencies to support this (and that this requires major changes in policy for most international agencies that have long ignored urban issues and major changes in how adaptation is funded)
- Build resilience and adaptive capacity in rural areas – given the dependence of urban centers on rural production and ecological services and the importance for many urban economies and enterprises of rural demand for (producer and consumer) goods and services
- Build into the above a mitigation framework too (if successful cities in low- and middle-income nations develop without this, global greenhouse gas emissions cannot be reduced)

The very survival of some small-island and some low-income nations (or their main cities) is in doubt as much of their land area is at risk from sea-level rise, yet their contributions to global greenhouse emissions have been very small. There are also tens of millions of people in low- and middle-income nations whose homes and livelihoods are at risk from sea-level rise and storms, although they have made very little contribution to global warming. The economic cost of losing certain cities for which adaptation costs is too high may be relatively small for national economies. But what will happen to international relations as increasing numbers of people lose their homes, assets, livelihoods, and cultural heritages to climate change-related impacts – especially when the main causes of this are strongly associated with the lifestyles of high-income groups in high-income nations – and the reason for their loss is the failure of high-income nations to cut back their emissions? The current Kyoto Protocol requires only industrial countries to cut their greenhouse gas emissions. But, since 1992, governments have been negotiating a new treaty which will ask all countries in the World, industrial and developing countries, to cut their greenhouse gas emissions by 2015.

Adaptation plans must not in any way slow progress toward mitigation. It is obvious that adaptation will be easier and cheaper if greenhouse gas emissions are reduced – so both the amount of adaptation and the rate at which it must be implemented are lessened. Adaptation plans must also bring benefits to the billion urban dwellers currently living in very poor-quality housing, in tenements, cheap boarding houses, and illegal or informal settlements. These billion people include a large part of the population whose homes and livelihoods are most at risk from climate change. A technology-driven, market-led response to climate change does little for them.

Climate Change and Gender: Study of Adaptation Expenditure in Select States of India

Gyana Ranjan Panda, Saumya Shrivastava, and Aditi Kapoor

Contents

Abstract

India is currently executing the National Action Plan on Climate Change (GoI. National Action Plan on Climate Change. Prime Minister's Council on Climate Change, New Delhi, 2008), and subsequently the states have been asked to formulate the state-specific action plans to integrate the national objectives and to implement specific climate change measures. Several questions arise on the impact of mission-mode adaptation policy interventions on enhancing the capacities of women to cope with climate vulnerabilities. Gender is a

crosscutting issue, and it is well established that climate change affects women disproportionately more than men due to inequities in accessing resources and opportunities to enable them to adapt to the inevitable impacts of climate change, as well as due to the roles that they play and the responsibilities that they shoulder. Addressing gender concerns in the context of climate change requires engendering the government-led adaptation strategies, supported by requisite budgetary outlays. So far the gender budgeting framework has not looked into the aspect of climate change impacts on women. In order to fill the research gaps, the paper attempts to bring forth the analytical interlinkage between gender and climate change by analyzing critically the budgets of select states of India – Uttarakhand (UK), Uttar Pradesh (UP), Madhya Pradesh (MP), and West Bengal (WB). The paper attempts to quantify the public expenditure on adaptation to climate change for the select states and the priority accorded to addressing gender concerns in the various sectors within the overall adaptation framework.

Keywords
Climate change • Adaptation expenditure • Gender-responsive budgeting

Introduction

It is now “unequivocally” established through global scientific assessment (IPCC 2007) that climate change is happening and it is happening at a rapid pace. In congruence with the global-level monitoring and assessment, India carried out a country-specific scientific assessment of climate change impacts on India (GoI 2009). The results point to the need for formulating a national level policy to adapt to and mitigate the effects of climate change (GoI 2008). The first ever country-level policy document, National Action Plan on Climate Change, was a result of this process, which maintains categorically that “climate change may alter the distribution and quality of India’s natural resources and adversely affect the livelihood of its people. With an economy closely tied to its natural resources base and climate-sensitive sectors such as agriculture, water and forestry, it may face a major threat.” As India is an agrarian economy with 70 % of its population residing in rural areas and dependent on agriculture and allied activities for livelihood (GoI 2012, p. ii), addressing the impacts of climate change is necessary to ensure food security and viable livelihood options for the vast majority of its population. Also important is to note that women form larger stakeholders in this sector due to increasing feminization of agriculture and their specific needs and vulnerabilities need to be taken into account when formulating the concerned policies.

The degree of climate vulnerability on large segment of society makes a stronger case for “planned adaptation” interventions. It is because reversal of the wheel of carbon accumulation through mitigation measures takes considerable period of time. Adaptation hence is a natural choice of coping with the irreversible changes (Panda 2011). “Adaptation,” as a multidimensional concept (IPCC 2007;

Bosello et al. 2009; Lim Bo and Spanger-Siegfred 2005; Smit and Pilifosova 2001; Smithers and Smit 1997), refers to coping strategies at the national and local levels such as modifications in the behavior and responses of individuals to adapt to changes in their immediate natural and socioeconomic systems induced by climatic variability. As per the IPCC (2007), adaptation is a well-thought-out effective tool to address various impacts resulting from global warming, already unavoidable due to past emissions and future emissions that might go unchecked. Stern Review (2006) further confirmed the proposition that the benefits of strong, early action on climate change outweigh the costs. Effective "planned" adaptation actions are contingent upon the development and optimal utilization of the resources and developmental programs earmarked for building human and adaptive capacities of the poor and marginalized communities, considered as frontline vulnerable groups to the effects of climate change.

Gender in Adaptation Framework

The process of climate change and the policies and programs in place to deal with it have gendered impact. It is widely acknowledged that the process of climate change would affect women more adversely than men. Women suffer more from the potential impacts of climate change due to limited resources that they possess, the differential role that they play, and the responsibilities that they shoulder within the household as well as in the society (IUCN 2007; Terry 2009a). Women are seen as primary caregivers in the society. They are responsible for the provision of basic needs of the family like health; collection of water, firewood, and other natural resources; food provision; subsistence farming; etc. (Rodenberg 2009; Brody et al. 2008; Masika 2002). Since these are inherently linked with the process of climate change and are bound to be adversely affected in the process, they have a direct bearing on the responsibilities carried out by the women.

Moreover, in the wake of climate change-induced hardships, men often migrate to urban areas in search of better livelihood opportunities, leaving women behind to cater to not just the household needs but also to look after farming for livelihood at home (Roy and Venema 2002; Masika 2002; Terry 2009b). Lambrou and Piana (2006) have stressed on the gendered nature of climate change and its impacts. Women bear the burden of caring for the sick, and because increased levels of sickness are expected to result from climate change, women will bear the costs of climate change disproportionately. Kapoor (2011) has also shown that the process of climate change affects women more adversely than men. In a detailed analysis on the potential impacts of climate change on men and women, she has outlined how climate change has a gendered impact, leading to an increase in the hardships faced by women in terms of an increase in their work burden, drudgery, worsening of their nutritional status, increase in the incidence of trafficking and violence against them, a rise in indebtedness, as well as deteriorating their livelihood opportunities. Nellemann et al. (2011) note that "the process of climate change is the most likely to increase the existing inequalities in the society due to socially constructed gender role."

Ahmed and Fajber (2009, p. 35), in the case study of drought-prone villages in Gujarat (India), identified various systems which enable poor women and men to adapt to climate change in autonomous and planned ways like the "social and power relations that facilitate access for different socio-economic groups, men and women, including rights and entitlements to productive resources or assets (land, water, labour, credit), social networks, capacity-building, and the transfer of new knowledge to support livelihood diversification. Governance considerations, such as accountability, transparency, and the informed participation of vulnerable women and men in community decision-making on disaster management, are equally important to ensure that those directly affected can negotiate access to discussions and decisions, and ultimately build their capacity to adapt." In the case study of Andhra Pradesh, Lambrou and Neson (2010) observed that there were changes in key aspects of farming activities over the last past 30 years with the changes in climate variability. Further, the changes had led to increased workloads, but in different areas of work according to gender. The study also found that the climate change has led to an increased pressure on women to provide food, workload at home, health problems, as well as fights or arguments among the family members.

The above analytical framework calls for certain gender-responsive adaptive policy actions. There are only a handful of studies which have focused on the fact that women, with their intrinsic knowledge about the environment, can contribute more to the process of adaptation (Lambrou and Piana 2006; Denton 2004, 2010; Alber 2011). Lambrou and Piana (2006) argue that "focusing solely on vulnerability may be misleading since women often have untapped skills, coping strategies and knowledge that could be used to minimize the impacts of crisis, environmental change and disasters." In reality, "women have a key role in development, and any potential environmental policy should take cognizance of women as key players particularly given their role as natural resource managers."

Brody et al. (2008, p. 13) have highlighted that "women have a great deal of knowledge and experience in coping with the impacts of climate change and understand their own needs and the types of interventions required for ensuring more sustainable agricultural processes in the face of these changes." Citing a participatory research project on the role of women in rural communities in adapting practices in the Ganga river basin in Bangladesh, India, and Nepal to secure their livelihoods in the face of changes in the frequency, intensity, and duration of floods, Brody et al. (p. 13) concluded that the women were not only clear about what they needed in order to adapt better to the floods, crop diversification, and agricultural practices but also about the skills and knowledge training required to learn about flood- and drought-resistant crops and the proper use of manure, pesticides, irrigation, and so on.

Denton (2004, 2010) also observed that there is a need to go beyond highlighting the vulnerability aspect where the women are concerned. There is a need to recognize women as agents of change in adaptation strategies and involve them in the process of planning at all levels. Engendering of the planning process requires recognition of the importance of women in the adaptation and planning and dedication toward incorporating some basic principles of equity in our processes.

Alber (2011) has put forward two arguments as to why gender issues need special attention in the climate policies. To quote him, "Firstly, both women and men need to be equally and meaningfully involved in planning and decision-making. Secondly, gender mainstreaming as a tool to assess the different implications for women and men of planned legislation, policies and programmes is required in all areas and at all levels, including climate policy. Thus working toward gender equity as an issue in its own right needs to be taken into consideration in all policies, and thus also in climate policy."

Mainstreaming "gender" in the climate discourse asks for specific policy efforts to enhance the adaptive capacities of poor and marginalized sections of women to cope with the uncertain climate vulnerabilities. An important policy instrument available with policy planners is gender-responsive budgeting (GRB). Globally GRB has come to light as an important tool in the ongoing struggle to make the government budgets and policies more gender responsive. The current profile of gender budget statement (GBS) in India (see Box 1) is yet to address the effects of climate vulnerabilities on women. Gender budgeting, as being carried out at the level of the Union Government of India as well as certain states which have adopted GRB, remains a limited exercise, whereby it has become an ex post reporting exercise rather than a process of engendered planning (Parvati et al. 2012; Mishra and Sinha 2012; Jhamb et al. 2013; GoI 2007). This does pose serious limitations in using it as an effective tool to address the gender-based challenges in the face of climate change.

Explaining Adaptation Expenditures in Indian Context
