One muscle is made of thousands of muscle cells (fibers), which are specialized for contraction. When a muscle contracts, it shortens and pulls on a bone. Each muscle fiber receives its own motor nerve ending, and the numbers of fibers that contract depend on the job the muscle has to do. Muscles are anchored to bones by tendons, which are made of fibrous connective tissue. A muscle usually has at least two tendons, each attached to a different bone. The more stationary muscle attachment is called its origin; the more movable attachment is the insertion. The muscle itself crosses the joint formed by the two bones to which it is attached, and when the muscle contracts, it pulls on the insertion and moves the bone in a specific direction. The muscle causing this particular action is termed the agonist.

The approximately 700 muscles in the body are arranged to bring about a variety of movements (Fig. 45.4). The general types of arrangements are the agonist with opposing antagonists and the cooperative synergists.

Antagonistic muscles have opposite functions; such arrangements are necessary because muscles can only pull, not push. If the biceps brachii, for example, flexes the forearm, an antagonist, the triceps brachii, is needed to extend the forearm. Other examples of antagonists are the quadriceps femoris and hamstring groups, the pectoralis major and the latissimus dorsi, and the tibialis anterior and gastrocnemius.

Synergistic muscles have similar functions or work together to perform a particular function. The brachioradialis is a synergist to the biceps brachii for flexion of the forearm; the sartorius is a synergist to the quadriceps group for

FIGURE 45.4 Major muscles. (A) Anterior view. (B) Posterior view. (Modified from Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed. 5. FA. Davis, Philadelphia, 2007, with permission.)

flexion of the thigh. Synergists are necessary to provide slight differences in angles when joints are moved. Without synergism we would be unable to maintain our balance or have the fine motor control needed to do such movements as writing or talking.

ROLE OF THE NERVOUS SYSTEM

Skeletal muscles are voluntary muscles in that consciously controlled nerve impulses cause contraction. Such nerve impulses originate in the motor areas of the frontal lobes of the cerebral cortex. The coordination of voluntary movement is a function of the cerebellum. Neurons in the CNS (central nervous system) regulate muscle tone, the state of slight contraction usually present in muscles. Good muscle tone is important for posture and for good coordination.

Neuromuscular Junction

Each of the thousands of fibers in a muscle has its own motor nerve ending; the neuromuscular junction is the termination of the motor neuron at the muscle fiber (see Fig. 50.2). The axon terminal is the enlarged distal tip of the motor neuron. It contains vesicles of the neurotransmitter acetylcholine. The membrane of the muscle fiber, called the sarcolemma, contains receptor sites for acetylcholine. The

synaptic cleft is the minute space between the axon terminal and the sarcolemma. The inactivating enzyme acetylcholinesterase is available in the synaptic cleft.

When a nerve impulse arrives at the axon terminal, it causes the release of acetylcholine, which diffuses across the synaptic cleft and bonds to the acetylcholine receptors on the sarcolemma. This makes the sarcolemma permeable to sodium ions, which rush into the cell and generate an electrical impulse (an action potential) along the entire sarcolemma. This electrical change triggers a series of reactions in the internal units of contraction called sarcomeres. Put simply, filaments of the protein actin slide over filaments of another protein called myosin, and the sarcomere shortens. All the thousands of sarcomeres in a muscle fiber shorten, and the entire cell contracts. If a muscle has little work to do, few of its many muscle fibers contract, but if the muscle has more work to do, more of its muscle fibers contract.

AGING AND THE MUSCULOSKELETAL SYSTEM

The amount of calcium in bones depends on several factors (Fig. 45.5). Good nutrition is certainly one factor, but age is another, especially for women. One function of estrogen or

FIGURE 45.5 Aging and the musculoskeletal system. This concept map shows the effects the aging process has on the musculoskeletal system.

testosterone is the maintenance of a strong bone matrix. For women after menopause, bone matrix loses more calcium than is replaced. Calcium loss can lead to weakened bones that may result in bone fractures. Weight-bearing joints are also subject to damage after many years. Often the articular cartilage wears down and becomes rough, leading to pain and stiffness.

Muscle strength declines with age as the process of protein synthesis decreases. Such loss of strength need not be exaggerated because aging muscles benefit from regular exercise, which has been shown to increase strength and reduce falls and accidents (Box 45.1 Gerontological Issues).

NURSING ASSESSMENT OF THE MUSCULOSKELETAL SYSTEM

The initial assessment begins with a history that includes the effects the condition is having on the patient's life. It then proceeds to a physical and psychosocial assessment (Table 45.2). Frequent neurovascular assessments may be needed if there is a risk of circulation impairment, such as if the patient has a fracture or musculoskeletal surgery (Table 45.3).

Subjective Data

History

The patient's history should include the following:

- If there was an injury, how it happened and when it happened
- Occupation and activities, including sports and other physical activities
- Risk factors for musculoskeletal problems and family history of musculoskeletal problems (to detect hereditary problems)

Box 45.1

Gerontological Issues

Age-Related Changes in the Older Adult

Age-related changes can lead to impaired mobility, an increased risk for falls, and pain. Common age-related musculoskeletal changes include the following:

- Muscle mass and strength decline.
- Number of muscle cells decrease and are replaced by fibrous connective tissue.
- Elasticity of ligaments, tendons, and cartilage decrease, resulting in weaker bones.
- Intervertebral spaces decrease from loss of water, causing a loss of height.
- Posture and gait change. (Men develop a wider stance and take smaller steps; women have a narrow stance and walk with a waddling gait.)

- Current health status, including ongoing or chronic medical conditions (such as heart disease, diabetes, lung conditions)
- Diet history (including whether calcium and vitamin D intake are adequate to ensure proper bone and muscle maintenance and repair)
- Information specific to the patient's musculoskeletal problems

Patients with musculoskeletal problems frequently report pain or related stiffness and tenderness as a major concern. The pain may be acute or chronic and may limit the patient in everyday life. Assessment includes previous diagnoses, pain severity, medications, treatments, and procedures the patient uses to alleviate the pain. The WHAT'S UP? model can be used to assess the patient's pain (see Chapter 1.)

Objective Data

Physical Assessment

Three areas of musculoskeletal assessment are important: inspection, palpation, and range of motion (ROM). If the patient is able to walk, inspect the patient's posture and gait, noting poor posture or alterations in movement, such as limping. Note the use of mobility aids, such as a cane or walker. Document other gross deformities, such as unequal limbs, malalignment, or contractures. Spinal deformities are especially significant because they can compromise breathing and balance. Inspect the joints and muscles of the arms, hands, legs, and feet for deformity, redness, swelling, increased temperature, or **crepitation** (grating sound as joint or bone moves). Also note the patient's general nutritional status (e.g., normal, obese, emaciated).

After inspection, gently palpate for warmth, swelling, and tenderness in the areas of swelling, redness, and areas where the patient reported pain (being careful to minimize the pain this may cause). For example, reddened joints

TABLE 45.2 ASSESSMENT OF THE MUSCULOSKELETAL SYSTEM

Category	Questions to Ask During History Assessment	Rationale/Significance
	<i>Subjective Assessment</i>	
Demographic	<ul style="list-style-type: none"> • Age, gender, socioeconomic status • Occupation 	<ul style="list-style-type: none"> • Increased age, being female, and lower socioeconomic status increases risk of musculoskeletal injury/problems. • Enables you to begin planning for discharge teaching if the patient has to alter his or her employment.
Previous Health History	<ul style="list-style-type: none"> • Activities patient participates in • Risk factors for musculoskeletal problems • Family history • Diet history 	<ul style="list-style-type: none"> • Provides information regarding the level of activity the patient had before the concern. • Smoking and a sedentary lifestyle are risk factors for musculoskeletal problems. • Some musculoskeletal conditions have genetic and familial tendencies. • Dietary intake such as calcium and vitamin D influence some musculoskeletal disorders.
History of Injury or Present Concern	<ul style="list-style-type: none"> • Allergies • History of the injury (if there was one) • Pain (Use Pain Assessment Scale [PAS]) 	<ul style="list-style-type: none"> • Prevents exposure to medication or compounds used in diagnostic tests, treatments, and therapies. • Provides information that helps in the diagnosis of the problem, as well as making you aware of possible complications of the injury. • Provides information about severity of the condition and effectiveness of the treatment and therapy.
Psychosocial Assessment	<ul style="list-style-type: none"> • Determine if deformities, changes in body image, self-concept, socialization, or employment are present • Determine coping skills 	<ul style="list-style-type: none"> • The patient may need assistance with strategies to cope with the stress of a possible chronic musculoskeletal condition. • Some musculoskeletal conditions require lifestyle alterations that can cause increased stress and difficulties in coping.
	<i>Objective Assessment</i>	
Physical Assessment	<ul style="list-style-type: none"> • Inspect, palpate, and observe range of motion [ROM] of affected areas • Assess color, warmth, circulation, and movement (CWCM) of affected areas • Palpate all pulses below involved area 	<ul style="list-style-type: none"> • Altered gait, tone, size, shape, posture, contractures, deformities, ROM, pain, and effects on activities of daily living (ADLs) can be determined. • Nerve function, sensation, movement, weakness, and the potential development of compartment syndrome can be determined. • Alterations may indicate altered vascular integrity (and therefore tissue integrity) of affected area or demonstrate developing compartment syndrome.

should be palpated for **synovitis** (swollen synovial tissue within the joint) or the presence of bony nodes. In some cases, joints and muscles may seem healthy but are tender when palpated.

Next, assess joint mobility. Stabilize the body area proximal to the joint being moved. Observe the patient's ROM for performing independent activities of daily living. Pay particular attention to the hands and observe movement in finger joints. For a quick and easy assessment of range of motion in the hands, ask the patient to touch each finger, one by one, to the thumb (known as opposition) and then to make a fist.

Also assess the size, shape, strength, and tone of muscles. Evaluate bilateral muscle strength by asking the patient to grip your hands. This enables you to feel the strength and equality. Pushing an extremity against your hand provides a general indication of muscle strength. More specific evalua-

tion is performed by a physical therapist (PT) or an occupational therapist (OT). Using a scale of 0 to 5 (0 = paralysis and 5 = moving a muscle against resistance), the PT or OT measures the strength of each muscle group and rates it as a

TABLE 45.3 NEUROVASCULAR ASSESSMENT

Assess for	Note and Report
Color	Pallor, cyanosis, redness, or discoloration
Temperature	Unusual coolness or warmth
Pain	Pain that is worse on passive motion, pain that no longer responds to analgesics
Movement	Alterations in movement
Sensation	Alterations in feeling, tingling or paresthesias
Pulses	Diminished or absent distal pulses
Capillary refill	Nailbed that does not blanch in 3–5 seconds

synovitis: synovia—joint + itis—inflammation

fraction. For example, 5/5 means that the patient reached a 5 out of 5 possible on the muscle strength scale.

Psychosocial Assessment

Deformities resulting from arthritis or other musculoskeletal disorders can affect a patient's body image and self-concept (see Chapter 46.) Chronic pain may keep the patient from socializing or from working. Many work days are lost as a result of both acute and chronic musculoskeletal problems. Patients often avoid social events and tend to withdraw from people. Data collection should include questions related to the psychological effects of the musculoskeletal disorder.

Patients may experience a tremendous amount of psychological stress resulting from the pain, loss of income, and withdrawal from friends and family. The nurse assesses the patient's ability to cope, asking what coping strategies have been used in the past for other life stressors. Support systems for the patient need to be identified, especially spiritual and social systems. As needed, consult the appropriate member of the health-care team (social work, clergy, support groups) to ensure that the patient's psychosocial needs are being met.

CRITICAL THINKING

Mr. Smith

■ Mr. Smith, age 80, is brought to the emergency department with a fractured left hip. He is positioned for comfort while you collect data.

1. What information should you obtain in Mr. Smith's history?
2. What should be assessed in Mr. Smith's physical examination?

Suggested answers at end of chapter.

DIAGNOSTIC TESTS

Diagnosis of musculoskeletal problems is assisted by laboratory tests and diagnostic imaging (including x-ray examinations and nonradiological tests). Specific tests for patients with connective tissue diseases are described in Chapter 46.

Laboratory Tests

Serum Calcium and Phosphorus

Bone disorders commonly cause changes in calcium and phosphorus (or phosphate) levels. When a person is healthy, calcium and phosphorus have an inverse relationship. This means that when serum calcium increases, serum phosphorus decreases, and vice versa. Some disorders, however, cause an increase in both values or a decrease in both values. Calcium and phosphorus levels are regulated by calcitonin from the thyroid gland and parathyroid hormone from the parathyroid glands. When these glands are not functioning properly, alterations in calcium and phosphorus levels can occur (Table 45.4)

Serum calcium tends to decrease in patients with osteoporosis or in people who consume inadequate amounts of calcium in their diets. Serum calcium levels increase in patients with bone cancer, particularly those with metastatic disease.

Alkaline Phosphatase

Alkaline phosphatase (ALP) is an enzyme that increases when bone or liver tissue is damaged. In metabolic bone diseases and bone cancer, ALP increases to reflect osteoblast (bone-forming cell) activity.

Myoglobin

Myoglobin is a protein found in striated (skeletal or cardiac) muscle. It is what causes the red color of muscle. When skeletal or cardiac muscle is damaged myoglobin levels rise in the blood.

TABLE 45.4 DIAGNOSTIC LABORATORY TESTS FOR MUSCULOSKELETAL SYSTEM

Test	Normal Value	Significance of Abnormal Findings
<i>Serum Calcium</i>	8.5–10.5 mg/dL	Hypercalcemia—may be related to metastatic bone disease or extended immobilization. Hypocalcemia—may be due to poor dietary intake. Can ultimately lead to rickets in a child or osteomalacia (bone softening) or osteoporosis in the elderly.
<i>Serum Phosphorus</i>	2.6–4.5 mg/dL	Usually evaluated with serum calcium. A number of disorders can be associated with high or low serum phosphorus.
<i>Alkaline Phosphatase (ALP)</i>	45–115 U/L (male) 30–100 U/L (female)	ALP increases may indicate bone abnormality (examples: Paget's disease, metastatic bone cancer). ALP is increased when new bone is formed.
<i>Creatine Kinase (CK)</i>	60–400 U/L (male) 40–150 U/L (female)	IM injections can cause a rise in CK.
<i>Isoenzyme CK3 (MM)</i>	95%–100%	High levels indicate need for further testing for muscle disease. Can be used as a screening test for malignant hyperthermia. Will be increased in rhabdomyolysis.
<i>Myoglobin</i>	50–120 µg/mL	Increased myoglobin can indicate MI or skeletal muscle destruction.

Serum Muscle Enzymes

When muscle tissue is damaged, a number of serum enzymes are released into the bloodstream, including skeletal muscle creatine kinase (CK-MM [CK3]), aldolase (ALD), aspartate aminotransferase (AST), and lactate dehydrogenase (LDH). These enzymes increase in certain muscle diseases such as muscular dystrophy, polymyositis, and dermatomyositis.

LEARNING TIP

Rhabdomyolysis is a very serious and potentially fatal condition associated with muscle destruction due to such things as injury (especially crushing), high fever, convulsions, or prolonged muscle compression (such as from lying in a coma) can have CK levels greater than five times normal. If the patient suffered muscle destruction, look at the patient's CK, myoglobin, and serum potassium levels to assess for rhabdomyolysis. The three laboratory values will be elevated.

Radiographic Tests

SAFETY TIP

For any radiographic test requiring injection or instillation of a medication or contrast solution, it is important for the nurse to assess for allergies or untoward responses resulting from previous examinations or exposures. Many of the contrast mediums used have alternate substances available in case of allergies. If the patient is unable to do so, then it is the nurse's responsibility to inform the technologist of the allergies or previous adverse responses experienced by the patient.

Standard X-Rays

An x-ray examination can determine bone density, texture, changes in alignment and bone relationship, erosion, swelling, and intactness. In addition, x-ray examinations can be useful in identifying certain soft tissue damage (e.g., ligaments and tendons) because of alterations in bone position and spacing.

Although there is no special nursing care associated with x-ray examinations, you should inform patients that they will have to lie still during the examination and that the x-ray table will be cold and hard (Table 45.5).

Computed Tomography

Tomograms are radiographs that focus on a particular slice of bone or soft tissue, such as ligaments and tendons. Com-

FIGURE 45.6 Computed tomography scan of fifth cervical vertebra showing a burst fracture of the vertebral body (top arrow) and both laminae (bottom arrows). (From McKinnis, LN: *Fundamentals of Musculoskeletal Imaging*, ed. 2. FA. Davis, Philadelphia, 2005, p 164, with permission.)

puted tomography (CT) is especially helpful for diagnosing problems of the joints or vertebral column (Fig. 45.6). It may be used with or without a contrast medium (similar to a dye), which is given orally or intravenously.

Inform patients that they must lie completely still during the test and that they will be surrounded by the scanner during the test. Headphones are worn for communication with the technician and to listen to soothing music of the patient's choice. Reports of claustrophobia and annoying clicking sounds made by the scanner while it is rotating are common. (See Table 45.5.)

Arthrography

An x-ray examination of any synovial joint can be performed for patients with suspected joint trauma. The most common joints tested are the knee and shoulder (see Table 45.5).

Myelogram

During a myelogram, a contrast medium is injected into the subarachnoid space so that the spine and spinal cord can be visualized. Inform patients that they may be positioned head down for a short period to allow the contrast medium to flow up to the level of the neck. This test is not performed as frequently as it used to be. It is usually reserved for those patients unable to have a CT or MRI or for complicated spinal surgery revisions (see Table 45.5).

Other Diagnostic Tests

Magnetic Resonance Imaging

Magnetic resonance imaging (MRI), with or without contrast media, is a commonly performed test to diagnose mus-

TABLE 45.5 DIAGNOSTIC PROCEDURES FOR MUSCULOSKELETAL SYSTEM

Procedure	Definition/Normal Finding (if applicable)	Significance of Abnormal Findings	Nursing Management (if applicable)
<i>Standard X-Rays</i>	Visualization of skeletal abnormality or deformity. Can also be used to visualize dense or inflamed tissues and joints.	Noninvasive Aids in treatment plan and provides additional information for care. Example: broken ribs will necessitate increased attention to respiratory system.	Inform patient of what to expect during ordered procedures.
<i>Computed Tomography</i>	Radiographic “slices” of bone or soft tissue. Provides a better image.		Check for allergies to contrast medium (or if allergic to contrast media or iodine). NPO for 4 hours before test.
<i>Magnetic Resonance Imaging (MRI)</i>	Electromagnets provide a three-dimensional visualization of the area. Produces the best image available.		
<i>Ultrasonography</i>	Visualization of bone or soft tissue using sound waves.		Inform the patient that the jellylike conducting substance will feel cold when applied.
<i>Nerve Conduction Studies</i>	Electromyography (EMG)—the electrical testing of nerves and muscles.	Alterations usually indicate a problem with the nerves or the muscles.	Inform the patient that there may be some discomfort during the nerve and muscle stimulation as well as when the needles are inserted (if needed).
<i>Arthrography</i>	Injection of air or a contrast medium into a synovial joint which is then x-rayed.	Invasive Aids in the diagnosis of joint abnormalities.	Inform patient that the test is uncomfortable during injection. Joint swelling is common after the procedure. Apply ice and elevate limb. Avoid physical activity for 12–24 hours.
<i>Myelogram</i>	Visualization of the spine and spinal cord after injection of a contrast medium.		Assess for headache and nausea post test. Maximum head raise is 45 degrees for at least 3 hours post procedure (or as ordered by physician).
<i>Nuclear Medicine Scans</i>	Injection of a radioisotope to help visualize bone and other soft tissue abnormalities.	Finding a “hot spot” usually indicates metastases or bone infection.	Inform the patient that the test is not dangerous. Inform patient that the test may take up to 90 minutes.
<i>Gallium/Thallium Scans</i>	Injection of radioactive element which migrates to bone, brain, breast, and inflammatory tissue.		Check if the facility you work in recommends that children and pregnant women stay a few feet away from the patient for the first 48 hours.
<i>Arthroscopy</i>	Direct visualization of the joint and its capsule using an instrument inserted into the joint space.		Assess CWCM frequently. Monitor for complications. Apply ice and keep limb elevated to minimize swelling (if ordered by physician).
<i>Arthrocentesis</i>	Withdrawal of synovial fluid from a joint space. Used for analysis of the synovial fluid or for reduction of excess fluid pressure.		Monitor for infection, inflammation or hemarthrosis.
<i>Bone or Muscle Biopsy</i>	Needle aspiration (closed) or surgical extraction (open) of bone or muscle tissue.		Monitor site of biopsy for bleeding. Provide normal wound care for open biopsy. Perform neurovascular assessments prn.

FIGURE 45.7 Magnetic resonance image of a normal cervical spine. (A) Cerebellum. (B) Spinal cord. (C) Marrow of C2 vertebral body. (D) C4-5 intervertebral disk. (From McKinnis, LN: *Fundamentals of Orthopedic Radiology*. F.A. Davis, Philadelphia, 1997, p 26, with permission.)

culoskeletal problems, especially those involving soft tissue (see Table 45.5) (Fig. 45.7). MRI is more accurate than CT for diagnosing many problems of the vertebral column. If the patient has had previous spinal surgery, a contrast medium is used.

The image is produced by interaction of magnetic fields and radio waves. For very large patients or those who are claustrophobic, the open MRI offers a comfortable alternative to the traditional machine (Box 45.2 Patient Perspective).

The use of an electromagnet in the machine necessitates the removal of anything metal or with metal components from the patient's body. Pacemakers, surgical clips, and any other internally implanted metal device or apparatus are contraindications for MRI.

SAFETY TIP

Check with the facility where the MRI will take place for all contraindications for metal implants within a person's body to prevent injury to the patient.

Nuclear Medicine Scans

Several tests are performed using radioactive material to help visualize bone and other tissues. A bone scan allows visualization of the entire skeleton. The patient is injected with a radioisotope 2 to 3 hours before the scan. The radioisotope is attracted to bone and therefore travels to bone tissue.

For an accurate test, the patient must be able to lie still for up to 90 minutes during scanning. Patients who are elderly, restless, agitated, or in pain may therefore find this test uncomfortable. Sedatives or analgesics may have to be administered before or during the procedure. The physician looks for "hot spots," which indicate areas where the radioactive substance is concentrated. These hot spots indicate abnormal bone metabolism, a sign of bone disease (see Table 45.5).

Box 45.2

Patient Perspective

Emily: Undergoing an MRI

I was told that the MRI scanner was small and could cause feelings of claustrophobia. When asked if I was claustrophobic, I said no and so was not offered an anti-anxiety medication before the procedure. I really am not claustrophobic, but I decided to keep my eyes closed during the test to be sure to prevent these feelings. As the table I was lying on moved into the scanner, my heart began beating fast. I shut my eyes and imagined myself walking on the beach, which is a favorite place for me. The cool air that was blowing in the machine I imagined to be the wind blowing. That air really is essential in keeping you cool and the claustrophobic feeling away. I had on headphones through which the music I had brought with me was playing. I focused on the music and sang along to myself as I "walked on the beach." I felt calmer as I did this. Through the headphones the technician kept me informed of how much longer the test would be and when the loud pounding noise would start. This really helped and I did not mind the noise. I knew that I had to be very still for the

test, so I gave myself pep talks. "Okay, only 10 more minutes. Just lie still and this will be over soon."

Then, halfway through the MRI, I accidentally opened my eyes for an instant. "Uh, oh." I quickly shut them again with my heart racing and a feeling of panic rising. The wall of the MRI machine was only inches from my face. I quickly focused on the music again, told myself I could get through this, and focused on calming myself down by "going back to the beach." Before I knew it, the test was over and I was told that because I held so still it was a great test that went more quickly than usual. I sure was glad to hear that! My personal coping techniques really helped me through the MRI. Without them I would have panicked and been unable to complete the test. The information the nurse gave me helped me know what to expect during the procedure so I could prepare myself to cope with the test. Providing information to your patients on what to expect during the test, as well as coping methods to use, can help them successfully complete an MRI.

LEARNING TIP

Hot spots are created because increased circulation occurs in abnormal bone areas, resulting in increased amounts of the radioactive substance being transported to the abnormal area.

Gallium/Thallium Scans

A gallium or thallium scan is similar to a bone scan but is more specific and sensitive as a diagnostic test. Gallium not only migrates to bone but also to brain and breast tissues and is therefore used to diagnose problems in these tissues as well.

Traditionally used for heart problems, thallium is now used for evaluation of bone cancers. Thallium is best for detecting osteosarcoma. Like the bone scan, these scans are not harmful to the patient.

Arthroscopy

An arthroscope allows the surgeon to directly visualize a joint (see Table 45.5). The knee and shoulder are the joints most often evaluated. Because **arthroscopy** is an invasive procedure performed under local or light general anesthesia, the patient is treated as a surgical candidate.

Arthroscopy is done in same-day surgery settings. The surgeon makes several small incisions and distends the joint with injected saline. The scope is inserted and the joint is visualized from different angles. The joint is moved through range of motion, so tears, defects, or other soft tissue damage can be assessed and or repaired through the scope using special instrumentation. Depending on the extent of the procedure, a bulky or small dressing wrapped with an elastic bandage may be applied.

The nurse in the postanesthesia care unit (PACU) assesses the neurovascular status of the surgical limb frequently (see Table 45.3). If the patient had a diagnostic arthroscopy and no surgical repair, the PACU nurse encourages the patient to exercise the leg, including straight-leg raises. A mild analgesic usually relieves pain, and the patient returns to regular activities in 24 to 48 hours. If a surgical repair was performed, the patient may have activity restriction and need a stronger analgesic, such as oxycodone with acetaminophen (Tylox, Percocet).

Although complications are not common, monitor and teach the patient to watch for and report to the physician the following:

- Thrombophlebitis (blood clot and vein inflammation)
- Infection (fever or warmth, pain, redness, swelling at surgical site)
- Increased joint pain

arthroscopy: arthro—joint + scopy—to examine

If a repair was done during the surgery, the patient is seen by the physician in 1 week to check for complications and progress. The patient may need crutches for the first week to limit weight bearing, depending on the surgical procedure performed. Physical or occupational therapy may be ordered (see Home Health Hints).

CRITICAL THINKING

Mrs. Jones

■ Mrs. Jones was walking down the street when, without warning, she suddenly fell to the ground with extreme pain in her left leg. She was taken to the hospital, where it was determined that the greater trochanter of her left femur was fractured.

1. What information should you obtain from Mrs. Jones?
2. What possible condition may be the cause of her fracture?
3. What tests may be performed to identify the condition creating her problem?

Suggested answers at end of chapter.

Bone or Muscle Biopsy

Bone or muscle tissue can be surgically extracted for microscopic examination to confirm cancer, infection (bone biopsy), inflammation, or damage (muscle biopsy). Muscle can also be biopsied to diagnose malignant hyperthermia, a genetic disorder (see Chapter 11). Two techniques are used to retrieve muscle tissue: a needle (closed) biopsy or an incisional (open) biopsy.

A closed biopsy can be performed in the patient's room or special procedures area. After local or general anesthesia, the physician inserts a long needle into the tissue for extraction of a sample.

The open biopsy is performed in the operating suite under general anesthesia. A small incision is made and a section of bone or muscle is removed. A sterile pressure dressing is applied because bone is highly vascular.

The nurse inspects the biopsy site for bleeding, swelling, and hematoma formation. Increased pain that is unresponsive to analgesic medication may indicate bleeding in the soft tissue. The area is not moved for 8 to 12 hours to prevent bleeding. Vital signs and neurovascular assessments are monitored (see Table 45.3).

Ultrasonography

Sound waves are used to detect osteomyelitis (bone infection), soft tissue disorders, traumatic joint injuries, and surgical hardware placement. The technologist applies a jellylike conducting substance over the area to be tested. A transducer is moved over the area while the ultrasound machine records the images (see Table 45.5).

Arthrocentesis

Arthrocentesis is a diagnostic or therapeutic procedure where synovial fluid is aspirated from a joint for analysis or to relieve pressure (pain) from effusion. Analysis of the synovial fluid aids in the diagnosis of noninflammatory conditions, septic arthritis, crystal detection, and **hemarthrosis** (blood in the joint cavity). Using aseptic technique, the physician provides local anesthetic and then uses a needle to aspirate the contents of the joint space. If required, the physician can instill medications such as an anti-inflammatory corticosteroid or antibiotic. The site is covered with a sterile dressing (see Table 45.5).

Nerve Conduction Studies

Electromyography (EMG) measures a muscle's electrical impulses. This aids in the diagnosis of muscle diseases or nerve damage. There are no special nursing actions related to this procedure other than informing the patient what will occur. Occasionally, slight discomfort occurs at the site where the study occurred. Warm compresses or mild analgesics can be offered for pain relief (see Table 45.5).

CRITICAL THINKING

Mr. Allan

■ Mr. Allan, age 45, comes to emergency with extreme pain in his lower back. The pain radiates down his right buttock and down the back of his leg to his knee. He tells you that he hurt his back picking up a box in the warehouse where he works.

1. What other information should you obtain from Mr. Allan?
2. What is a probable cause of Mr. Allan's pain?
3. What tests, procedures, and treatments may be done for Mr. Allan's condition?
4. How might this injury impact Mr. Allan's life?
5. Mr. Allan is to receive morphine 10 mg by intramuscular injection. You have available morphine 15 mg/mL. How many milliliters will you give?

Suggested answers at end of chapter.

Home Health Hints

- Patients are considered homebound if (1) they are bedbound or require the maximum assistance to ambulate while using a walker or to transfer; (2) they can ambulate with only moderate assistance while using a cane to negotiate uneven surfaces; or (3) they can leave home only for periods of relatively short duration or for need of medical treatment.
- When testing strength, extend two or three fingers and ask the patient to squeeze the fingers.
- Observe patients moving around a room or bed. If they are clumsy or have involuntary movement, make efforts during that visit and subsequent visits to protect them from potential injury. Research has shown that pain or fear of falling may prevent a patient from moving and functioning to maximum potential.
- Use sand or cat box filler on icy steps to increase traction, preventing slips and falls.

REVIEW QUESTIONS

1. Which of the following is the function of synovial fluid in joints?
 - a. Exchange nutrients
 - b. Prevent friction
 - c. Absorb water
 - d. Wear away rough surfaces
2. A patient has been diagnosed with a musculoskeletal disease that causes decreased bone density. Which assessment questions are most appropriate by the nurse?
 - a. "Do you have any broken bones?"
 - b. "Has your doctor informed you not to exercise so you will not break a bone?"
 - c. "What forms of physical activity are you able to participate in?"
 - d. "Do any of your spouse's relatives have problems with their bones?"
 - e. "Do you exercise regularly?"
 - f. "What is typically included in your daily diet?"
3. Which of the following assessments is included in neurovascular checks of the lower extremities?
 - a. Radial pulses
 - b. Checking for clubbing
 - c. Biceps reflex
 - d. Femoral pulses

4. A patient is scheduled for an MRI of the pelvis. Which of the following would the nurse do if during data collection the nurse found out that the patient had had a previous surgery for heart problems?
 - a. Ask if there is any metal in the patient's body.
 - b. Order a chest x-ray examination to identify any metal objects in the patient's body.
 - c. Cancel the MRI.
 - d. Inform the physician.
5. A patient has undergone an arthroscopy. Two hours after the procedure the patient's pedal pulses are diminished from the previous assessment. What should the nurse do?
 - a. Take vital signs.
 - b. Notify the physician.
 - c. Perform neurovascular assessment in 30 minutes.
 - d. Change the dressing and rewrap the elastic wrap.

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Mr. Smith*

1. You should determine if Mr. Smith has any allergies, how and when the injury occurred, if he has had any previous surgeries, what medications he takes, his medical history, and any past problems with anesthesia (in Mr. Smith or his family).
2. You should assess his left leg compared with his right leg, including limb length, deformity, pain, loss of range of motion, edema, and ecchymosis, and perform neurovascular checks, including movement, sensation (numbness/tingling), presence of pulses, skin temperature, color, and capillary refill.

■ *Mrs. Jones*

1. You should assess Mrs. Jones's age, her diet (does she have a low-calcium or vitamin D-deficient diet?), what she was doing at the time of the break, whether anything like this has happened before, whether anything similar has happened to any of her relatives, her pain level, when she ate last, her medications, her medical history, whether she smokes, and whether she has any allergies.
2. There is a possibility that Mrs. Jones has osteoporosis and that she has experienced a pathological fracture from decreased bone density. This is a common occurrence in postmenopausal women.
3. X-ray examinations, bone scans, bone density tests,

and laboratory tests such as serum calcium, phosphorus, acid phosphatase, thyroid, and vitamin D levels are tests that might be performed.

■ *Mr. Allan*

1. You should determine what occurred, when it occurred, how it happened, if the pain was immediate, where exactly the pain is, whether anything makes it better or worse, if any kind of treatment was started, what kind of job Mr. Allan has, whether he has had any back problems in the past, what medications he is on, and whether he has any allergies.
2. Mr. Allan may have ruptured a disk in his vertebral column, which is a common occurrence with improper lifting or trying to lift something too heavy.
3. Test might include x-ray examination, myelogram, MRI, bone scan, and CT scan. Conservative treatment will be attempted first but ultimately a discectomy may be necessary.
4. Many back injuries result in lifelong chronic pain. Depending on the severity of the injury and the effectiveness of therapy, Mr. Allan may have to limit his physical and social activities. He may also have to find another type of employment.
5. Unit analysis method:

$$\frac{10 \text{ mg}}{15 \text{ mg}} \left| \frac{1 \text{ mL}}{15} \right. = \frac{10}{15} = 0.67 \text{ mL}$$

QUESTIONS TO GUIDE YOUR READING

1. What are the signs and symptoms and complications of fractures?
2. Which nursing interventions are appropriate when caring for a patient in a cast or traction?
3. What are causes, prevention, and nursing care for osteomyelitis?
4. What are the risk factors for the development of osteoporosis?
5. What signs and symptoms may be seen in patients with Paget's disease?
6. What is the pathophysiology, treatment, and nursing care for gout?
7. Which nursing interventions are appropriate when caring for patients with systemic lupus erythematosus, scleroderma, and polymyositis?
8. How would you differentiate between the care for osteoarthritis and rheumatoid arthritis?
9. What would you include when preparing a plan of care for the patient with a fractured hip or undergoing a total joint replacement?
10. What patient education would be included for a patient with a lower extremity amputation and prosthesis?

BONE AND SOFT TISSUE DISORDERS

The musculoskeletal system is the second largest system in the body. A variety of injuries and diseases can affect bone, soft tissue, or both. Common problems are discussed in this section.

Strains

A strain is a soft tissue injury that occurs when a muscle or tendon is excessively stretched. Causes of strains include falls, excessive exercise, and lifting heavy items without using proper body mechanics. Back and ankle injuries are common. Strains can be mild, moderate, or severe. A mild strain causes minimal inflammation; swelling and tenderness are present. A moderate strain involves partial tearing of the muscle or tendon fibers. Pain and inability to move the affected body part result. The most severe strain occurs when a muscle or tendon is ruptured, with separation of muscle from muscle, tendon from muscle, or tendon from bone. Severe pain and disability result from this injury.

RICE is an acronym for rest, ice, compression, and elevation. These four components are the basis of therapy for strain injuries. Immediately after a strain, ice should be applied to decrease pain, swelling, and inflammation. Applying an elastic bandage (compression) and elevating the affected area (if appropriate) provide support and minimize swelling. Once inflammation subsides, heat application (15 to 30 minutes four times a day) brings increased blood flow to the injured area for healing. Activity is limited (depending on the severity of the injury, casting may even be required for immobilization) until the soft tissue heals, and anti-inflammatory drugs are prescribed. Muscle relaxants may also be used. Exercise may begin as early as 2 to 5 days after the injury (depending on the severity of the injury), but it may take 1 to 3 weeks of immobility before exercise can begin. For more severe strains, surgery to repair the tear or rupture may be needed. These procedures are done on an ambulatory, same-day-surgery basis.

Sprains

A sprain is excessive stretching of one or more ligaments that usually results from twisting movements during a sports activity, exercise, or fall. Like strains, sprains also vary in severity. A mild sprain involves tearing of just a few ligament fibers and causes tenderness. In a moderate sprain, more fibers are torn but the stability of the joint is not affected. A moderate sprain is uncomfortable, especially with activity. A severe sprain causes instability of the joint and usually requires surgical intervention for tissue repair or grafting. Pain and inflammation prevent mobility.

For mild sprains, RICE is used for several days until swelling and pain diminish. Anti-inflammatory drugs are also used to decrease inflammation and control pain. Moderate sprains may need immobilization with a brace or cast until healing occurs.

Dislocations

Dislocations are a common injury in which the ends of the bones are forced from their normal position. They are usually caused by trauma as in falls or contact sports or a disease such as rheumatoid arthritis. Any joint large or small may become dislocated. Severe pain along with lost range of motion of the joint and joint deformity occurs. Immediate medical treatment is required to preserve function. Splint the extremity as it is found, apply ice, and seek help. Do not move the extremity as blood vessels, muscles, and nerves could be damaged.

NURSING CARE TIP

It is important for those with disease processes that could result in dislocation or fractures to use lift sheets when moving the patient rather than pulling on their arms. Always follow institutional policy for moving patients or you could be found liable for a patient's injury.

Bursitis

Bursae (fluid-filled sacs) cushion tendons during movement to prevent friction between the bone and tendon. Several joints have bursae (shoulder, elbow, hip, knee, ankle, heel). Inflammation of a bursa occurs from repetitive movement, sleeping on the side and compressing the bursa, arthritis, or gout. Prevention is key as it may become harder to cure over time. Muscle stretching and strengthening, move often, avoid repetitive movements for long periods, use cushion seats, and do not lean on your elbows to protect the bursae and prevent compression.

Symptoms of bursitis include achy pain, stiffness, or burning pain over the joint area which worsens with activity. Usually pain decreases in about a week. The condition can become chronic if it lasts more than 6 months. Treatment includes resting the joint, application of ice 20 minutes several times per day until joint warmth is gone, then switching to heat, elevating the joint, ultrasound, massage, foam mattress toppers, nonsteroidal anti-inflammatory drugs (NSAIDs), or physical therapy.

Rotator Cuff Injury

Short tendons that are connected to muscles around the shoulder form the rotator cuff. The cuff covers the top, front, and back of the shoulder. Muscle contraction causes these tendons to tighten and move or rotate the shoulder. Various injuries can occur. The top tendon of the cuff (supraspinatus tendon) and bursa may become impinged in the narrow space under the acromion bone. This causes inflammation when the arm is repeatedly moved forward and pain results. This is known as chronic impingement syndrome. Over time the tendon may finally tear from the bone.

Symptoms of rotator cuff injury include shoulder aching, increased pain with lifting the arm, pain that is

greater at night, weakness, and sometimes limited range of motion. A magnetic resonance image (MRI) can help diagnosis rotator cuff injury. For minor injury, resting the shoulder, NSAIDs, ice, and physical therapy are recommended. For a more severe injury, arthroscopic and or small incision surgery may be needed to relieve the impingement or repair the tear. A sling or special brace is worn after surgery. Physical therapy for rehabilitation after surgery is used.

Carpal Tunnel Syndrome

Pathophysiology

Carpal tunnel syndrome results in the compression of the median nerve within the carpal tunnel when swelling in the tunnel occurs. This swelling can result from edema, trauma, rheumatoid arthritis, or repetitive hand movements (repetitive motion injury) as used in some occupations such as typing or cash register operation.

Signs and Symptoms

Carpal tunnel syndrome usually results in slow-onset finger, hand, and arm pain and numbness. Painful tingling and paresthesias may also be present. Eventually, fine motor deficits and then muscle weakness may develop.

Diagnosis

Diagnosis is based on signs and symptoms, along with the patient's history. A positive Phalen's test (numbness with wrist flexion) is indicative of carpal tunnel syndrome. Electromyography (EMG) can also be used to detect nerve abnormalities.

Therapeutic Interventions

Medical treatment focuses on relieving the inflammation and resting the wrist. A splint is often ordered for the patient to wear. Medications to reduce pain and inflammation are ordered, such as aspirin and NSAIDs. Cortisone may be injected into the carpal tunnel to decrease pain and inflammation.

For some patients, surgery may be necessary. The surgeon may use an open incision or may perform an endoscopy. The median nerve is released from compression during the surgery, thus correcting the problem of the nerve and the surrounding area becoming inflamed. Physiotherapy helps in the recovery of function.

Nursing Management

Educate the patient on methods to prevent carpal tunnel syndrome, such as frequent short breaks during the work day, interspersing ongoing tasks with repetitive movements throughout the day, and using ergonomically appropriate devices to minimize the pressure placed in the area of the wrist.

Provide pain relief as ordered, and if surgery is performed, provide routine preoperative and postoperative care. Postoperatively elevate the patient's hand and use a splint as ordered for up to 2 weeks. Lifting is restricted for several weeks. The patient is taught to report signs and symptoms of neurovascular compromise, such as numbness and tingling, coolness, lack of pulse, pale skin or nailbeds, or limited

movement. The patient may need family assistance with activities of daily living (ADLs).

Fractures

A fracture is a break in a bone and can occur at any age and in any bone. Some fractures are minor and are treated on an ambulatory basis; others are more complex and require surgical intervention with hospitalization and rehabilitation.

Pathophysiology

Bone is a dynamic, changing tissue. When it is broken, the body immediately begins to repair the injury (Fig. 46.1). For an adult, within 48 to 72 hours after the injury a hematoma (blood clot) forms at the fracture site because bone has a rich blood supply. Various cells that begin the healing process are attracted to the damaged bone. In about a week or so, a non-bony union called a callus develops and can be seen on x-ray examination. As healing continues, osteoclasts (bone-destroying cells) resorb any necrotic bone and osteoblasts (bone-building cells) make new bone as a replacement. This process is sometimes referred to as bone remodeling. Young, healthy adult bone completely heals in about 6 weeks; however, it can take up to a year before the whole process of remodeling is complete. An older person takes longer to heal, and children tend to heal more quickly.

Causes and Types

The major reason for a fracture is trauma from either a fall or accident (usually motor vehicle) or some type of crushing injury. Bone disease, such as osteoporosis and metastatic bone cancer, malnutrition, and regular drinking of soda pop (phosphoric acid added to pop may interfere with calcium absorption), can lead to fractures as can various drugs (e.g., certain drugs used to treat human immunodeficiency [HIV] and certain drugs used to treat endometriosis) that as a side effect cause a decrease in bone density. Fractures resulting from any of these diseases are referred to as pathological fractures. One of the most common types of fracture is the hip fracture, which occurs most frequently in middle-aged and older adult women who have osteoporosis (irreversible bone loss).

Fractures can be classified in several ways: by the extent of the fracture, the extent of the associated soft tissue damage, or the configuration of the bone after it breaks. A fracture that is complete, breaking the bone into two separate pieces, is called a displaced fracture. An incomplete fracture does not divide the bone into two pieces; it may also be referred to as a nondisplaced fracture. Complete fractures have the potential to be life threatening because sharp bone fragments can sever blood vessels and nerves.

A fracture may also be classified as open or closed. In an open (or compound) fracture, the bone breaks the skin. A closed fracture does not disrupt the skin. Open fractures are more likely to become infected than closed fractures.

Another way to describe a fracture is by the way that the bone breaks, such as in a spiral or oblique fashion (Fig. 46.2). These fractures may be open or closed, complete or incomplete. Table 46.1 describes the types of fractures.

FIGURE 46.1 Fracture healing phases.

Signs and Symptoms

This section focuses on fractures of upper and lower extremities. If the patient sustains a hairline (microscopic) fracture, the signs and symptoms are not readily observable. The patient may complain of tenderness over the site of the injury or more severe pain when moving the affected part of the body. The patient with a hip fracture usually complains of pain either in the groin area (the hip is a deep joint) or at the back of the knee (referred pain). If the fracture is displaced, the limb is often shortened because of contraction of the muscles pulling on the bone sections.

In addition to pain, patients with more complex fractures experience limb rotation or deformity and shortening of the limb (if a limb bone is broken). Range of motion is decreased. If the affected part is moved, a continuous grating sound (crepitation) caused by bone fragments rubbing on each other may be heard. The extremity should not be moved (to try and reposition the bone alignment) if crepitation is present.

Inspect the skin for intactness. A patient with a closed fracture may have ecchymosis (bruising) over the fractured bone from bleeding into the soft underlying tissue. Ecchy-

TABLE 46.1 TYPES OF FRACTURES

Fracture Type	Description
<i>Avulsion</i>	Piece of bone is torn away from the main bone while still attached to a ligament or tendon.
<i>Comminuted</i>	Bone splintered or shattered into numerous fragments. Often occurs in crushing injuries.
<i>Impacted</i>	Bone is forcibly pushed together, resulting in bone being pushed into bone.
<i>Greenstick</i>	Bone is bent and fractures on the outer arc of the bend. Often seen in children.
<i>Interarticular</i>	Fracture involves bones within a joint.
<i>Displaced</i>	Bone pieces are out of normal alignment. One or both pieces may be out of alignment.
<i>Pathological (also called neoplastic)</i>	Caused by bone's being weakened either by pressure from a tumor or an actual tumor within the bone.
<i>Spiral</i>	Fracture curves around the shaft of the bone.
<i>Longitudinal</i>	Fracture occurs along the length of the bone.
<i>Oblique</i>	Fracture occurs diagonally or at an oblique angle across the bone.
<i>Stress</i>	Results in the bone being fractured across one cortex. This is an incomplete fracture.
<i>Transverse</i>	Bone fractured horizontally.
<i>Depressed</i>	Bone pushed inward. Often seen with skull and facial fractures.

FIGURE 46.2 Types of fractures.

mosis may not develop for several days after the injury. Swelling may also be present and can impair blood flow, causing marked neurovascular compromise. In an open fracture, one or more bone ends pierce the skin, causing a wound, thus increasing the possibility of infection.

Diagnostic Tests

An x-ray examination usually visualizes bone fractures, showing bone malalignment or disruption. Computed tomography may be needed to help detect fractures of complex areas, such as the hip and pelvis. Magnetic resonance imaging is useful in determining the extent of associated soft tissue damage.

For patients experiencing moderate to severe bleeding, a hemoglobin and hematocrit level is obtained. If extensive soft tissue damage is present, the erythrocyte sedimentation rate (ESR) is usually elevated, indicating the expected inflammatory response. The physician may order a serum calcium level to determine baseline values because bone repair requires a sufficient amount of calcium and other minerals.

Emergency Treatment

A patient with a suspected fracture often has injuries elsewhere in the body. Assess the patient for respiratory distress, bleeding, and head or spine injury. If any of these problems occurs, emergency treatment is provided before concern is given to extremity or other fractures.

The treatment of fractures depends on the type and extent of the injury. Emergency treatment is essential to prevent possible life-threatening complications. Box 46.1 Urgent Management of Fractures describes the emergency interventions for the patient with an extremity fracture.

LEARNING TIP

For emergency care of a suspected fracture, do not try to reposition the limb. Remember: Splint it as it lies. Also, ensure that the limb is secured above and below the break to minimize movement and bone grating.

Box 46.1**Urgent Management of Fractures**

1. Immediately immobilize affected limb. If movement is required before splinting, support limb above and below fracture.
2. Unless there is bleeding apply splints and padding (above and below fracture site) directly over the clothing. If bleeding is present visualization may be necessary before pressure can be applied where bleeding is originating. Keep patient covered to preserve body heat.
3. If the fractured extremity is a leg bone, the unaffected extremity can be used as a splint by bandaging both legs together. An arm can be bandaged to the chest or put into a sling to minimize further tissue damage.
4. Assess color, warmth, circulation, and movement (CWCM) of the limb distal to the fracture.
5. Open fractures require the protruding bone be covered with a clean (sterile preferred) dressing.
6. Do not attempt to “straighten” or realign the fractured extremity. Move the affected limb as little as necessary.
7. Transport to an emergency department as soon as possible.

Fracture Management

The goals of fracture management are reduction, or realignment, of bone ends; immobilization of the fractured bone (with bandages, casts, traction, or a fixation device); prevention of deformity or further injury; preservation or restoration of function; promotion of early healing; and pain relief.

CLOSED REDUCTION. Closed reduction is the most common treatment for simple fractures. While manually pulling on the bone (limb), the physician manipulates the bone ends into realignment. Analgesia and/or conscious sedation is typically used before the procedure. An x-ray examination is done to confirm that the bone ends are aligned before the area is immobilized.

BANDAGES AND SPLINTS. For some areas of the body, such as the clavicle or wrist, an elastic or muslin bandage or a splint may be used to immobilize the bone during the healing phase. Splints can be used when the fracture has some associated soft tissue damage that needs care or if there is an expectation of swelling. It is important that the splint be well padded, thereby preventing skin breakdown or unnecessary pressure. Perform neurovascular assessments to ensure adequate blood flow to the area (see Chapter 45).

CASTS. Casts provide a strong support for fractured bones, thereby aiding in early mobility and decreased pain. They are also used to correct deformities and to support weak joints while restricting movement. The type of cast used

depends on the reason the cast is applied. For more extensive fractures or for weight-bearing areas, a more rigid and durable cast is used for immobilization. Once the need for the cast is resolved (e.g., when bone healing is complete), the cast is removed.

Several types of materials are used for casts, including the traditional plaster of Paris (anhydrous calcium sulfate) and a variety of synthetic products such as fiberglass. Plaster is used for large casts and for weight-bearing areas. Because of a chemical reaction that occurs when the plaster is wet, the cast feels hot when applied for about 30 minutes and then feels cool, taking anywhere from 24 to 72 hours to completely dry. The cast is dry when it feels hard and firm, is odorless, and is shiny white. Keep the wet cast open to air and turn the patient about every 2 hours to expose all sides of the cast to the air to aid in drying and prevent mold growth. A wet cast should be handled with the palms of the hand (“palming the cast”) to prevent indentations or a change in the shape of the cast (Fig. 46.3). This prevents the possibility of pressure points forming inside the cast. Unlike plaster of Paris, synthetic material casts such as fiberglass harden quickly and dry in less than 2 hours.

A casted limb is elevated for 24 to 48 hours, and ice can be applied over the injury to reduce swelling. Assess the cast for dryness, tightness, drainage, and odor. A serious complication of a cast being too tight is compartment syndrome (discussed later). If the cast becomes too tight, the physician orders it to be cut (bivalved) with a cast cutter to relieve pressure and prevent pressure necrosis of the underlying skin (Fig. 46.4). If a wound is present or an odor is detected, a window opening into the cast is created to treat the underlying skin problem, often an infected area. The cast window should always be taped in place when wound care is not being provided to prevent the skin from “popping up” through the window and developing pressure points and ischemia. See Box 46.2 Nursing Interventions for a Patient with a Cast.

FIGURE 46.3 A wet plaster cast is moved with the palms of the hand to prevent making indentations in the plaster that could become pressure points.

FIGURE 46.4 Bivalving a cast with a cast saw.

TRACTION. Casts can be worn in or out of a hospital setting, but traction for fracture treatment often requires that the patient be hospitalized. As a general definition, traction is the application of a pulling force to a part of the body to provide fracture reduction (positioning bone fragments in correct alignment), reduce movement, or pain relief. Although still used in certain situations, improvements in surgical techniques and orthopedic devices have greatly decreased the use of traction.

Traction is classified as either continuous or intermittent. Continuous traction is required for fracture management; intermittent traction, although not commonly used, may be applied for patients experiencing muscle spasm. Traction can also be performed manually for short periods of time (e.g., to maintain traction on a leg when removing Buck's traction for skin assessment or skin care). The most common types of traction are either skin or skeletal. Skin traction typically involves the use of a Velcro boot (Buck's traction), sling (Russell's traction or knee sling), belt (pelvic), or halter, which is secured around a part of the body (Fig. 46.5). This type of traction does not promote bone alignment or healing but is used instead for relief of painful muscle spasms that often accompany fractures. Buck's traction is indicated for patients with hip fractures and is frequently applied to prevent further trauma while the patient is waiting for surgery. Occasionally, the patient's physical condition or inflammation surrounding the fracture prohibits early surgical intervention, thus necessitating the application of skin (Buck's) traction. When traction is being applied to the skin, there is a restriction as to the amount of weight that can be applied. The weight applied is usually between 5 and 10 lb (2.2 to 4.5 kg). Skeletal traction, also called balanced suspension, involves the use of pins (Steinmann), screws, wires (Kirschner), or tongs (Gardner-Wells, Crutchfield), which are surgically inserted into the

Box 46.2

Nursing Interventions for a Patient with a Cast

1. Assess color, warmth, circulation, movement (CWCM) every 1 to 2 hours for 24 hours and then qid and prn.
 - a. Assess cast for tightness (ask patient) and for rough or frayed edges of the cast (can interfere with skin integrity).
 - b. Ensure patient can move (wiggle) all digits distal to the cast.
2. With newly applied casts (wet)
 - a. Never grasp a wet cast to hold or move it (and do not place on any surface that can cause an indentation)—only use the palms of the hands (finger pressure on a wet cast can cause pressure points on the inside surface)
 - b. Ensure patient is turned every 1 to 2 hours to prevent “flattening” of cast surface during drying.
 - c. With hip spicas or any cast with an abductor bar, do not use bar to move limb or to help with turns.
 - d. Inform patient that plaster casts give off heat when drying. Ensure cast air dries (may require 24 to 72 hours for complete drying). Do not cover cast or use drying aids such as blow dryers. Place cast on absorbent surfaces not plasticized pillows.
 - e. Protect skin integrity by ensuring rough edges of cast are properly covered.
 - f. Ensure patient knows to keep cast dry during bathing. (Cover with plastic and prevent water seeping into cast ends.)
 - g. Synthetic casts (e.g., fiberglass) can be exposed to water (e.g., for hydrotherapy) as needed but require complete drying afterward.
3. Tissue integrity within the cast.
 - a. When assessing CWCM assess visible skin for signs of impaired integrity.
 - b. Cast edges can be smoothed and covered with stockinette or gauze and tape (ensure there are no tape allergies) to prevent rubbing of cast.
 - c. Monitor for signs and symptoms of infections such as foul odor, heat, redness, and pain.
 - d. Skin products should not be used on affected limb.
 - e. Visible blood on the surface of the cast has to be monitored. (Outline area with a pen to observe for increasing size of area.) Shadowing of blood not quite reaching the surface of the cast is fairly common but also has to be circled and monitored.
 - f. Never place any object inside the cast. Teach patient potential for skin damage if this is done.

FIGURE 46.5 Types of skin traction. (A) Russell's traction. (B) Buck's (boot) traction.

bone for the purpose of alignment while the fracture heals (Fig. 46.6). From 20 to 40 lb (9 to 18 kg) of weight is usually applied for skeletal traction, as ordered.

Balanced suspension maintains the traction while allowing the patient some mobility in bed. A Thomas (or T) splint with Pearson's attachment can be used to provide balanced suspension for the lower extremity. The patient's leg rests on a suspended sheepskin-covered splint (see Fig 46.6). Balanced traction methods require countertraction to ensure the patient does not move toward the pull and therefore minimize the effectiveness of the traction. Usually the patients' weight as well as elevating the foot of the bed provides the countertraction necessary.

Caring for the patient in traction includes frequently monitoring neurovascular status for impaired blood flow,

LEARNING TIP

When applying manual traction, usually done by the physician, it is important to maintain a firm, smooth, continuous "pull" on the extremity and not a jerking or yanking motion. The limb is kept in anatomical position and correct alignment is maintained while providing manual traction.

checking the equipment to ensure proper functioning, and monitoring skin condition for pressure points or irritation from equipment. Traction must be maintained at all times for fractures. All knots, ropes, weights, and pulleys are inspected

FIGURE 46.6 Balanced suspension and skeletal traction for femur fracture.

every 8 to 12 hours for any loosening and intactness. Weights are to hang unobstructed and should never touch the floor or be removed or lifted. The patient's feet should not rest against the end of the bed. It is important that the traction not be inhibited by any form of friction or impedance. Assistance should be obtained to reposition the patient in bed to prevent lifting injuries, especially with heavy weights in use.

For patients in skeletal traction, pin sites are observed for redness, drainage, odor, swelling, and excessive warmth. Clear, odorless drainage is expected. Some agencies or physicians advocate special solutions or ointments for the skin around the pins (pin care). Others recommend no cleaning to maintain skin integrity. Follow agency policy or physician's order for pin care. Depending on the type of pin used, the pin ends may be covered to protect the patient (and health-care workers) from being injured.

Patients who have traction may be immobilized for an extended period and often experience problems associated with immobility. For example, pressure ulcers on heels are common among older adult patients in traction. Unfortunately, loss of bone density is also a complication of immobility, which may create an additional impairment for normal healing. Another common concern is the person's psychosocial health. Ensure that the patient does not become socially isolated because of the need for extended bedrest.

OPEN REDUCTION WITH INTERNAL FIXATION. An open reduction with internal fixation (ORIF) is a treatment reserved for patients who cannot be managed by casts or traction. One of the most common indications for this surgical procedure is fractured hips. Fractures of the hip involve the proximal femur and affect the older adult more than any other age group. ORIF of the hip allows early mobilization while the bone is healing.

As the name implies, the bone ends are realigned (reduced) by direct visualization through a surgical incision (open reduction [OR]). The bone ends are held in place by internal fixation (IF) devices such as metal plates and screws or by a prosthesis with a femoral component similar to that for total joint replacement (Fig. 46.7). For hip surgery, the IF device is not removed after the fracture heals. For ankle or long bone surgery, the hardware may be removed after healing because of loosening or pain (Box 46.3 Nursing Care Plan for the Patient After Open Reduction with Internal Fixation [ORIF] of the Hip).

EXTERNAL FIXATION. An alternative treatment for some fractures is external fixation. External fixation is used when there has been severe bone damage, such as in crushed or splintered fractures, or if there have been numerous fractures along the bone. After the fracture is reduced, the physician surgically inserts pins into the bone; the pins are held in place by an external metal frame to prevent bone movement (Fig. 46.8). External fixation is ideal for the patient who has an open fracture with soft tissue damage that needs to be treated at the same time. Like skeletal traction, the patient with this device is at risk for complications of skeletal pins,

FIGURE 46.7 Internal fixation. (A) Intertrochanteric fracture of the hip with fracture fixation via a side plate and screw combination device. (B) Side plate and screw fixation of radial fracture. (From McKinnis, LN: *Fundamentals of Orthopedic Radiology*. FA Davis, Philadelphia, 1997, with permission.)

CRITICAL THINKING

Mrs. Brown

■ Mrs. Brown, a long-time resident of Happy Hills Care Center, was found lying in the dayroom on her left side, moaning and holding her left leg at 10 a.m. (1/4/07). She cried out with any movement and said she fell and broke her leg. The supervisor notified the paramedics and Dr. Jones. Her vital signs are blood pressure 150/84, pulse 100, respirations 20. Her left leg is noticeably shorter than her right leg. The licensed practical nurse (LPN) remained with Mrs. Brown and instructed her not to move until help arrived. The LPN got blankets and a pillow for her head. The paramedics arrived quickly and took Mrs. Brown to nearby Grace Hospital by ambulance, where she was diagnosed as having a nondisplaced femoral neck (hip) fracture. Dr. Jones ordered 5 lb of Buck's traction. Mrs. Brown is restless and picking at her bedcovers when you assess her at the beginning of your shift.

1. How should the LPN/LVN document the incident of Mrs. Brown's fall at the care center?
2. What is the purpose of Buck's traction for Mrs. Brown?
3. What are your nursing responsibilities while caring for Mrs. Brown?
4. What might explain Mrs. Brown's restlessness?

Suggested answers at end of chapter.

Box 46.3 NURSING CARE PLAN for the Patient After Open Reduction with Internal Fixation (ORIF) of the Hip

Pain related to surgical wound

Patient Outcome Patient states that pain relief is satisfactory.

Evaluation of Outcome Does patient state that pain is absent or at tolerable level (pain rated 0 to 2 on pain assessment scale)?

Intervention

Give pain medication as needed; anticipate need for pain medication.
Give pain medication before activity (e.g., session with physical therapist).
Use nondrug pain relief measures, such as distraction, guided imagery, other relaxation techniques.
Use fracture bedpan.

Rationale

Pain medication relieves pain, especially if given before pain is severe.
Increased activity can cause pain.
Analgesic therapy is enhanced with complementary pain relief measures.
Fracture bedpans are more comfortable and easier to position for patients.

Evaluation

Does patient state pain is relieved?
Is patient restless or agitated during activity?
Does patient report pain relief is enhanced with music or relaxation?
Is patient able to use fracture pan with comfort?

Impaired physical mobility related to hip precautions and surgical pain

Patient Outcome Patient will maintain desired level of activity.

Evaluation of Outcome Does patient maintain activity desired?

Intervention

Reinforce transfer and ambulation techniques.
Place overhead frame and trapeze on bed; teach patient how to use it.
Monitor patient for and take measures to prevent complications of immobility: turn patient every 2 hours and check skin; keep heels off bed; teach patient to deep breathe and cough q2hr; teach use of incentive spirometer.
Apply thigh-high elastic stockings or sequential compression device to unaffected limb as ordered.
Give anticoagulants as ordered.
Get patient out of bed as soon as ordered.
Ambulate patient as early as possible.
Remind patient to practice leg exercises.

Rationale

Activity is restricted due to hip precautions and weight-bearing limitations.
Patient mobility is increased and pain decreased with use of trapeze for movement.
Immobility complications can occur if preventive measures are not used.
Helps prevent blood clots.

Evaluation

Does patient transfer and ambulate as instructed by physical therapist?
Does patient use overhead frame and trapeze for movement in bed with less pain?
Does patient experience complications of immobility?
Is patient free from blood clots?

CRITICAL THINKING

Tommy Martin

■ Tommy, age 18, was in a motor vehicle accident that resulted in a fractured pelvis and femur. He is to be in skeletal traction for several weeks.

1. Identify three nursing diagnoses related to Tommy's physical or emotional well-being.
2. What are some nursing interventions for these diagnoses?

Suggested answers at end of chapter.

which includes pin reaction, compromised circulation, and infection. Pin sites are observed frequently for signs and symptoms of infection. Pin site care varies from facility to facility. The overriding principle is to ensure that strict aseptic technique is always maintained as the pin is a

NURSING CARE TIP

If you have to move an extremity that has an external fixation device, grasp the device and lift, raise, or move the limb as needed. By grasping the device, there is less movement of the healing bone and therefore less trauma to the site of healing and less pain with movement. Care must be taken not to loosen any fasteners holding the pins in place.

FIGURE 46.8 External fixation for complex fractures and wound care.

pathway for microorganisms to directly enter bone tissue and cause osteomyelitis. See Box 46.4 Nursing Care Plan for the Patient with External Fixation of the Lower Extremity.

NONUNION MODALITIES. Although most bones heal properly with the correct treatment, some patients experience malunion (malalignment of healed bone) or nonunion (delayed or no healing). A number of variables influence how a bone heals, including age, nutritional status, and the presence of other diseases that alter the healing process, such as diabetes mellitus.

Several methods for treating nonunion are available, including electrical bone stimulation and bone grafting. For selected patients, bone stimulation may be effective in promoting healing; the exact mechanism of action is not known. Bone grafting involves adding packed bone to the fracture site in an attempt to facilitate healing. Bone-stimulating compounds such as Osteoset, Pro Osteon, or Allomatrix are being used to promote bone growth in patients. These compounds are used during surgical procedures as glue, cement, or filler.

Another fracture healing method is low-intensity pulsed ultrasound (also called Exogen therapy). Ultrasound treatment has provided excellent results for slow-healing fractures, as well as for new fractures. The patient applies the treatment for about 20 minutes each day.

Complications of Fractures

Monitor for possible complications and implement interventions to prevent them. The most common complications include impaired neurovascular status, hemorrhage, infection, and thromboembolic complications. Although they do not occur often, acute compartment syndrome and fat embolism syndrome (more common with fractures of long bones) can be life-threatening complications of fractures.

NEUROVASCULAR. Neurovascular checks are done to detect abnormalities. Decreased or absent pulses, cool skin temperature, and dusky color indicate circulation alterations. Numbness and tingling, decreased sensation, and mobility indicate neurological alterations. These findings should be reported to the physician promptly.

HEMORRHAGE. Bone is highly vascular, and damage to or surgery on bone (particularly the large long bones of the extremities) can cause bleeding. Assess for bleeding and monitor vital signs carefully. Hypovolemic shock may result from severe hemorrhage (see Chapter 8).

INFECTION. Trauma predisposes the body to infection, especially when the skin, the body's first line of defense, is disrupted. Wound infections, pin site infections, drainage tube infections, and osteomyelitis (bone infection) are common. Hospital-acquired infections, such as pneumonia or urinary tract infection, can occur in patients who are immobilized for extensive periods while their fractures heal.

THROMBOEMBOLIC COMPLICATIONS. Deep vein thrombosis or pulmonary embolus (PE) (see Chapter 31)

Box 46.4 NURSING CARE PLAN for the Patient with External Fixation of the Lower Extremity

Risk for infection related to skin integrity impairment

Patient Outcomes Patient does not develop an infection.

Evaluation of Outcome Does patient remain free from infection?

Interventions

Inspect dressings, wounds, pin sites for signs and symptoms of infection.
 Monitor color of and measure wound drainage.
 Change dressings or provide wound and pin care per facility policy using aseptic technique.
 Monitor vital signs frequently.

Rationale

Signs and symptoms of infection could include warmth, redness, heat, swelling, drainage, pain.
 Wound drainage color and amount can indicate severity of infection.
 Use of aseptic technique minimizes chance of infection. Pin wound sites should be free of crusting, which promotes infections because of decreased skin integrity.
 Alterations in vital signs can indicate infection.

Evaluation

Are any wounds infected?
 Does wound have large amount of purulent drainage?
 Are pin sites clean with no crusting?
 Are vital signs within baseline findings?

Impaired physical mobility related to the external fixation (EF) device

Patient Outcomes Patient will maintain desired level of mobility/activity.

Evaluation of Outcome Has patient maintained desired level of mobility and activity?

Interventions

Reinforce transfer and ambulation techniques.
 Place overhead frame and trapeze on bed; teach patient how to use them.
 Teach patient how to move limb using EF device.
 Assess patient for and take measures to prevent complications of immobility. Promote early ambulation to minimize complications.
 Include other disciplines such as the physiotherapist in promoting and teaching about ambulation.

Rationale

Depending on severity of fracture and size of EF device, there may be special needs to transfer and ambulate.
 Patient mobility is increased and pain decreased with use of trapeze for movement.
 Providing patient with instruction on moving the extremity promotes independence and minimizes pain.
 Immobility complications can occur if preventative measures are not used.
 EF devices allow for earlier ambulation. Physiotherapy can provide initial or reinforce the education needed to promote ambulation (e.g., with crutch walking).

Evaluation

Does patient transfer and ambulate as instructed?
 Does patient use overhead frame and trapeze for movement with less pain?
 Does patient move the extremity using EF device?
 Does patient have any complications of immobility?
 Has patient used information learned from other disciplines to aid ambulation?

Disturbed body image related to external fixation device

Patient Outcomes Patient will not experience disturbed body image while EF device is in place.

Evaluation of Outcome Does patient experience disturbed body image resulting from EF device?

Interventions

If possible, explain to patient preoperatively what EF device will look like.

Reinforce the idea that EF device will decrease discomfort and allow for earlier ambulation.

Provide psychological support and an environment of acceptance.

Rationale

Preparing patient for what to expect postoperatively increases likelihood of acceptance and minimizes the unknown.

Promoting early ambulation and increased comfort enhance acceptance.

Accepting your patient and allowing for discussion of concerns promotes a sense of well-being and acceptance of EF device.

Evaluation

Was patient able to verbalize why device is to be used and what device will look like?

Did patient understand benefit of EF device allowing for early ambulation and increased comfort?

Did patient feel comfortable in expressing concerns related to body image?

can develop in patients who are immobile because of trauma or surgery. Thromboembolic complications are the most common problems of lower extremity surgery or trauma and the most fatal complication of musculoskeletal surgery, particularly in the older adult. Leg exercises, early ambulation, and anticoagulant therapy, usually using low molecular weight heparin, such as dalteparin (Fragmin) or enoxaparin (Lovenox), help prevent these problems.

ACUTE COMPARTMENT SYNDROME. Compartments are sheaths of fibrous tissue that support and partition nerves, muscles, and blood vessels, primarily in the extremities (Fig. 46.9). There are several compartments within each extremity. Acute compartment syndrome (ACS) is a serious problem

in which the pressure within one or more extremity compartments increases, causing massive circulation impairment to the area. An external device such as a cast or bulky dressing can increase pressure when there is tissue swelling or compression in the area. The early symptom of ACS is the patient's report of severe, increasing pain that is not relieved with narcotics and occurs more on active movement than passive movement. Decreased sensation follows before ischemia becomes severe. In severe ACS, the patient has the six *Ps*:

- Pain (severe, unrelenting, and increased with passive stretching)
- Paresthesia (painful tingling or burning)
- Paralysis (late symptom)

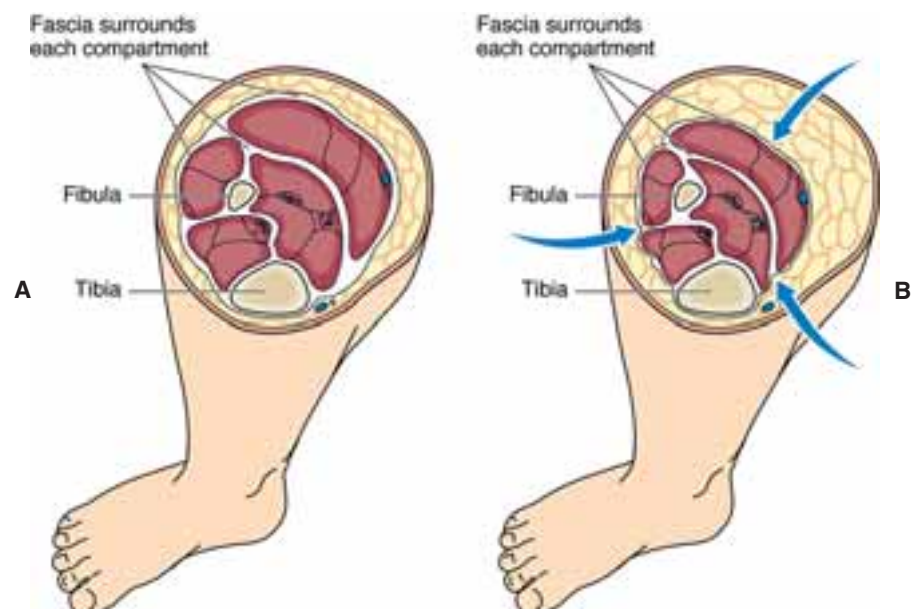

FIGURE 46.9 (A) Lower leg compartments. Each compartment contains muscles, an artery, a vein, and a nerve. (B) Compartment syndrome. Increased pressure in a compartment compresses structures within the compartment.

- Pallor (but there may be warmth or redness over the area)
- Pulselessness (late and ominous sign)
- Poikilothermia (temperature matches environment; i.e., the extremity is cool to touch)

Relief of pressure is the goal. It may be accomplished by removing the source of pressure, such as bivalving a cast, or by performing a **fasciotomy**, which is an incision into the fascia that encloses the compartment. This incision allows the compartment tissue room to expand and relieves the pressure. If more than one compartment has increased pressure, multiple fasciotomies are required. These surgical wounds remain open until the pressure decreases. Then they are closed and may require skin grafting. If this condition continues without pressure relief, tissue necrosis, infection, extremity contracture, or renal failure may result. Renal failure is a potentially fatal complication of ACS.

CRITICAL THINKING

Mr. Andrews

■ Mr. Andrews has suffered a nondisplaced fracture of his right femur. He has a cast on from his groin to the middle of his foot. An hour ago he received 10 mg of morphine intravenously (IV), and he is complaining of continuing and increasing pain.

1. What nursing assessment should now be performed?
2. What might be happening with Mr. Andrews?
3. What interventions may be necessary?

Suggested answers at end of chapter.

FAT EMBOLISM SYNDROME. Fat embolism syndrome (FES) is another serious complication in which small fat globules are released from yellow bone marrow into the bloodstream. The globules then travel to the lung fields, causing respiratory distress. This process most often occurs when long bones (especially the femoral shaft) are fractured or when the patient has multiple fractures. The older adult patient with a fractured hip is also at a high risk for FES. This condition can occur up to 72 hours after the initial injury or procedure.

The earliest manifestation of FES is altered mental status resulting from a low arterial oxygen level. The patient then experiences tachycardia, tachypnea, fever, high blood pressure, and severe respiratory distress (shortness of breath). Most patients also have a measleslike rash, called petechiae, over the upper body. Even when aggressively treated, patients with FES often die from the pulmonary edema that typically develops. Note early FES signs and symptoms and report them to the physician immediately. If a fat embolism is suspected, the following actions should be taken:

fasciotomy: fascia—fibrous tissue + otomy—opening into

- Promote oxygenation by administering oxygen at 2 L per minute via nasal cannula.
- Place patient in high-Fowler's position or raise head of bed as tolerated by patient.
- Maintain bedrest and keep movement of extremity to a minimum.
- Prepare patient for a chest x-ray examination or lung scan.
- Prepare patient for arterial blood gas (ABG) determination.
- Administer intravenous fluids as ordered.
- Administer corticosteroids as ordered.
- Provide emotional support and calm environment.

Nursing Process for the Patient with a Fracture

Caring for the patient with a fracture requires coordinated care with other health team members.

ASSESSMENT/DATA COLLECTION. The most important aspect of monitoring the patient with a fracture is frequent checking of neurovascular status (circulation, sensation, mobility) distal to the fracture site (Chapter 45). As mentioned earlier, acute compartment syndrome is a potentially limb- or life-threatening complication that results when blood flow is impaired.

Pain is managed by both medications and complementary therapies. Bone pain can be excruciating and must be treated aggressively. For the patient who cannot report pain, such as a cognitively impaired or comatose patient, ensure that pain relief is maintained by regularly scheduled analgesic administration.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Determination of the appropriate nursing diagnosis depends on the type of fracture. See Box 46.3 Nursing Care Plan for the Patient After Open Reduction with Internal Fixation [ORIF] of the Hip.

Acute pain related to fractured bone

EXPECTED OUTCOME: Patient will report relief from pain using pain assessment scale.

- Provide analgesics and anti-inflammatories as ordered *to relieve pain and swelling.*
- Ensure proper positioning and alignment *to minimize discomfort and promote pain relief.*
- Assess for compartment syndrome if patient has a cast in place *to prevent neurovascular complications.*
- Apply ice as ordered *to decrease swelling and pain.*
- Teach alternative measure of pain relief *to maximize means to relieve pain.*

Impaired physical mobility related to bone fracture

EXPECTED OUTCOME: Patient will demonstrate increased mobility.

- Encourage independence *to promote mobility.*
- Utilize other disciplines such as occupational and physiotherapy *to encourage and promote patient mobility.*

- Provide equipment and resources such as crutches and wheelchairs *to improve mobility*.

Risk for peripheral neurovascular dysfunction related to increased tissue volume or restrictive envelope

EXPECTED OUTCOME: Patient will maintain peripheral pulses, warm skin, sensation, and ability to move extremity.

- Assess and monitor frequently for compartment syndrome.
- Assess for swelling of affected limb (especially if patient has a cast or tight dressing).
- Keep limb elevated above heart *to minimize edema*.
- Administer anti-inflammatory agents as ordered.
- Monitor for increasing pain even after analgesic administration.

NURSING CARE TIP

A confused or comatose patient may not be able to report pain, the most reliable indicator of pain. Nonverbal indicators (e.g., grimacing, restlessness, elevated blood pressure and heart rate) are not reliable for pain assessment and should not be used to determine pain absence. You need to prevent the patient's pain by anticipating it and treating it in advance. You can do this by recognizing causes of pain and understanding that the effects of mild but repetitive pain (as in turning several times a day) can adversely affect the patient (such as by leading to exhaustion). Causes of pain include conditions or diseases (such as fractures, surgery, trauma, or cancer), procedures (such as turning or wound care), and biomedical devices (such as orthopedic fixation devices, wound drains, urinary catheters, nasogastric tubes, and chest tubes).

With few patients being medicated before painful procedures, some of which may be done several times a day (turning), confused or comatose patients are at greater risk for lack of pain relief. Provide analgesics as ordered before painful procedures and on a regular basis when pain is assumed to be present to keep your patients comfortable. For anticipated pain, the acronym APP (assume pain present) can be used.

Use pain assessment tools designed for those who are cognitively impaired to ensure that their pain is adequately relieved. The **Pain Assessment IN Advanced Dementia (PAINAD)** is a tool that was developed for this purpose. Search the web to view it or visit <http://www.amda.com/caring/may2004/painad.htm>. Share pain research findings with administrators in your institution to establish policies that support proactive pain management for all patients.

EVALUATION. The outcome is met if the patient reports or demonstrates pain is within tolerable levels on a pain assessment scale, demonstrates increased physical mobility, and maintains peripheral pulses, warm skin, sensation, and ability to move extremity.

PATIENT EDUCATION. If the patient has a cast, review the appropriate instructions for cast care (see Box 46.2 Nursing Interventions for a Patient with a Cast). Health teaching is also important for care of the extremity after cast removal (Box 46.5 Extremity Care Following Cast Removal). If the patient has a wound, teach the patient and caregiver how to assess and dress the wound (and provide pin care if needed), and when to report changes such as signs and symptoms of infection.

Teach the importance of adequate protein, calories, vitamins, and minerals for healing to occur. Unless otherwise contraindicated, milkshakes and instant breakfast preparations are good sources of additional protein and calories, as well as a source of calcium.

Osteomyelitis

Osteomyelitis is an infection of bone that can be either acute or chronic. A bone infection lasting less than 4 weeks is considered acute; one that lasts more than 4 weeks is chronic.

Pathophysiology

Regardless of the type of osteomyelitis, the infection results from invasion of bacteria into bone and surrounding soft tissues. Inflammation occurs, followed by ischemia (decreased blood flow) (Fig. 46.10). Bone tissue then becomes necrotic (dies), which retards healing and causes more infection, often as a bone abscess.

Pathogens enter bone in several ways. Direct inoculation means that an injury to the body allows the offending microbes direct access to bone tissue. An open fracture is an example of that process. Contiguous spread occurs when surrounding soft tissue becomes infected. An example is the patient with cellulitis whose infection then spreads to underlying bone. In hematogenous spread, an infection beginning in another part of the body migrates to bone. For instance, a

Box 46.5

Extremity Care Following Cast Removal

- Ensure skin properly cleansed. Soak rather than rub skin to remove dry scales.
- The extremity likely will be weak with decreased ROM—move it gently and provide analgesics prn.
- When extremity is not in use, provide support with pillows or orthotic device until strength and movement return.
- Ensure active and passive ROMs are performed as per PT and patient tolerance will allow.
- Lower extremity swelling can be prevented with elastic support stockings.

FIGURE 46.10 Sequence of osteomyelitis development. (A) Infection begins. (B) Blood flow is blocked in the area of infection. An abscess with pus forms. (C) Bone dies within the infection site, and pus formation continues.

patient with a total hip replacement may acquire osteomyelitis from a urinary tract infection.

Causes and Types

Penetrating trauma leads to acute osteomyelitis by direct inoculation. The most common pathogens causing osteomyelitis are *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Proteus*. The leading cause of contiguous spread is a slow-healing foot ulcer in the patient who has diabetes mellitus or peripheral vascular disease. Multiple organisms may be present in the wound and subsequently the bone. Hematogenous spread results from bacteremia (infection of the blood), underlying disease, or nonpenetrating trauma. Long-term intravenous catheters are primary sources of infection.

Signs and Symptoms

The patient with acute osteomyelitis has fever, as well as local signs of inflammation, such as tenderness, redness, heat, pain, and swelling. Pain (particularly over the area of infection), may be the only apparent complaint. Ulceration, drainage, and localized pain are typical signs and symptoms of chronic osteomyelitis.

Diagnostic Tests

The patient with osteomyelitis typically has an elevated leukocyte (white blood cell) count, an elevated erythrocyte sedimentation rate, and positive bone biopsy for infection. Some patients also have a positive blood culture. MRIs, x-ray examinations, and CT scans can show areas of infection.

Therapeutic Interventions

Long-term antibiotic therapy is the treatment of choice for patients with bone infection. Infection in bone tissue is difficult to resolve and may require weeks to months of medication. Antibiotic therapy alone may not resolve the infection. Patients with chronic osteomyelitis may require surgery to remove necrotic bone tissue or replace it with

healthy bone tissue. Amputations are reserved for patients who have massive infections that have not responded to one or more of the conventional treatments.

Nursing Management

Patients often administer their intravenous antibiotics at home rather than have a costly stay in a hospital. Teach the patient and caregiver about the side effects, toxicity, interactions, and precautions for antibiotic therapy. A home care nurse may be needed to assist the patient.

If a soft tissue wound is present, ensure that sterile technique is used for dressing changes. The home health nurse may teach the patient and family how to perform dressing changes, the importance of hand washing prior to dressing changes, and how to avoid the spread of pathogens.

Osteoporosis

Osteoporosis is a common metabolic disorder in which the bone loses its density, resulting in fragile bones and possibly fractures. The wrist, hip, and vertebral column are most commonly involved. Over 10 million people have osteoporosis, and 18 million more have low bone mass according to the National Osteoporosis Foundation. Both women and men develop osteoporosis, although it is often thought that only women are affected. Women are at greatest risk because their bones are smaller than men's bones. To protect against osteoporosis, good health habits through age 30 are important. They include adequate calcium and vitamin D intake (ages 11 to 25: 1200 to 1500 mg/day), weight-bearing exercise, avoiding alcohol, and not smoking.

Pathophysiology

Bone is living tissue that is resorbing (breaking down) old tissue (osteoclast cells) and constantly building new tissue (osteoblast cells). Bone density (mass) peaks between 30 and 35 years of age. After these peak years, the rate of bone breakdown exceeds the rate of bone building as we age.

Trabecular (cancellous) bone is lost first, followed by a loss of cortical (compact) bone. The result is irreversible bone loss that makes the inside of bones porous and weaker. As a result, over 1,000,000 fractures occur annually, and 700,000 of these are vertebral fractures. Hip fractures are the second most common, accounting for more than 300,000 per year. The mortality rate for hip fractures is about 50% during the first year after the fracture. For postmenopausal women, decreased estrogen appears to slow down the absorption of calcium, resulting in an increased bone loss.

Cause and Types

Osteoporosis is either primary or secondary. Primary osteoporosis is the most common and is not associated with another disease or health problem. Risk factors for primary osteoporosis include the following:

- Caucasian or Asian heritage, postmenopausal, female (less estrogen available to protect bone)
- Sedentary lifestyle
- Decreased calcium intake
- Lack of vitamin D (to absorb calcium)
- Excessive alcohol consumption
- Cigarette smoking
- Excessive caffeine intake
- Small boned, petite body build

Secondary osteoporosis results from an associated medical condition, such as hyperparathyroidism; having renal dialysis; drug therapy, such as steroids and certain anti-seizure drugs, sleeping medications, hormones for endometriosis, or cancer drugs; and prolonged immobility, such as that seen with patients who have a spinal cord injury.

Signs and Symptoms

Most women do not realize they have osteoporosis until they fracture a bone. During the late middle years, the classic “dowager’s hump,” or kyphosis of the spine, is usually present. The patient’s height decreases and back pain may be present. The patient may be embarrassed by the change in body image and may have curtailed social activities. Some patients have difficulty finding clothes that fit comfortably.

Diagnostic Tests

X-ray examination of the bone is not helpful in diagnosing bone loss in its early stages. Computed tomography and quantitative CT scans detect early spinal changes and measure bone density. Ultrasound can also be used to screen bone mass. Dual-energy x-ray absorptiometry (DXA) is used as a screening tool to measure bone mineral content. This test is noninvasive and is currently the most widely used technique to measure bone density.

Serum calcium and vitamin D levels may be decreased, and serum phosphorus may be increased. With severe bone loss, alkaline phosphatase levels may be elevated, confirming bone damage.

Therapeutic Interventions

The cornerstone of treatment for osteoporosis is medication and avoidance of modifiable risk factors to prevent bone loss.

MEDICATION. Medication may be used for prevention or treatment purposes. The current drugs of choice are calcium supplements, vitamin D, and bisphosphonates, such as alendronate (Fosamax) and risedronate (Actonel).

Calcium is also important to prevent bone loss. If serum calcium falls below normal levels, the parathyroid glands stimulate the bone to release calcium into the bloodstream. The result is demineralized bone. Therefore, calcium supplements are an important aspect of treatment. Teach the patient to drink plenty of fluids to prevent calcium-based urinary stones. Vitamin D supplementation, to aid calcium absorption, may also be necessary for patients who have inadequate sunlight exposure (institutionalized people) or who cannot metabolize vitamin D.

Alendronate and risedronate are used to prevent or slow the progress of osteoporosis. They suppress osteoclast activity to prevent the breakdown of bone. Although side effects are not common, serious cases of esophagitis and esophageal ulcers have been reported. Therefore, teach the patient to take the drug early in the morning and follow it with a full glass of water. The patient should not lie down for at least 1 hour after taking the drug.

A newer drug class for osteoporosis is the selective estrogen receptor modulator (SERM). Raloxifene (Evista) increases bone mass 2% to 3% each year. SERM drugs are designed to mimic estrogen in some parts of the body while blocking its effects elsewhere. Recently approved for use is the newest drug class for osteoporosis, recombinant human parathyroid hormone. Teriparatide (Forteo) is used for men and women at a great risk for fracture. Teriparatide increases bone mass by increasing the action and number of osteoblasts. It is considered a bone formation agent.

Other drugs that may be used include testosterone (the male hormone that helps build bone), calcitonin (nasal spray, injection), and sodium fluoride. All these medications have major disadvantages and are consequently not commonly given. Any drug used to prevent or control osteoporosis must be administered under the supervision of a physician, including supplements.

DIET. Increasing calcium and fluids are the main dietary considerations for women. Calcium intake should be 1000 mg/day for those age 25 to 65 and 1500 mg for those over age 65. Teach patients what foods are high in calcium, such as dairy products and dark green, leafy vegetables. If the patient consumes excessive caffeine or alcohol, teach about the need to avoid these substances. For more information, visit the National Osteoporosis Foundation at www.nof.org.

Exercise

Weight-bearing exercise, especially walking, stimulates bone building. The patient should wear well-supporting, nonskid shoes at all times and avoid uneven surfaces that could contribute to falls. Resistance exercise such as weight training or the use of some of the equipment available at fitness centers is also beneficial.

FALL PREVENTION. Osteoporotic bone may cause a pathological fracture in which the hip breaks before the fall.

For other patients, a fall can cause a hip or other fracture. Therefore, fall prevention programs in hospitals and nursing homes are important.

In collaboration with the physical or occupational therapist, case manager, or discharge planner, assess the patient's home environment. The patient and family are taught how to create a hazard-free environment, such as avoiding scatter rugs and slippery floors. Walking paths in the home must be kept free of clutter to prevent falls. If needed, a walker or cane provides additional support.

Paget's Disease

Paget's disease, also called osteitis deformans, is a metabolic bone disease in which increased bone loss results in large, disorganized bone deposits throughout the body. It is primarily a disease of the older adult.

Pathophysiology

Three phases of the disorder have been described: active, mixed, and inactive. A prolific increase in osteoclasts (cells that break down bone) causes massive bone deformity and destruction. Osteoblasts (bone-building cells) then react to form new bone. However, the result is disorganized in structure. Finally, when osteoblastic activity exceeds the osteoclastic activity, the inactive phase occurs. The newly formed bone becomes sclerotic with increased vascularity.

Paget's disease can affect one or multiple bones. The most common areas involved are the femur, skull, vertebrae, and pelvis.

Causes and Types

The exact cause of this disease is not known, but it tends to run in families. Paget's disease may be the result of a latent viral infection contracted in young adulthood. It is more common in Europe than in the United States.

Signs and Symptoms

Most patients with Paget's disease have no obvious symptoms, particularly when the disorder is confined to one bone. Pain is a major symptom in many. For patients with more severe disease, signs and symptoms are varied and potentially fatal.

Diagnostic Tests

Diagnosis may be made solely on x-ray findings. Radiographs of pagetic bone show punched-out areas indicating increased bone resorption. The overall mass of bone may be enlarged, depending on the phase of the disorder. Deformities, fractures, and arthritic changes are not uncommon. Bone scans can also be used to help in the diagnosis.

The primary laboratory findings are an increased alkaline phosphatase (ALP) and an increase in urinary hydroxyproline. Ppyrilinks and Osteomark are urine tests that can be used in place of the urinary hydroxyproline test. ALP reflects bone damage. Urinary hydroxyproline indicates an increase in bone turnover. The higher the level, the more severe the disease. Calcium levels in both blood and urine are elevated as damaged bone releases calcium into the bloodstream.

Therapeutic Interventions and Nursing Management

Nonsurgical management is employed to relieve pain and promote a reasonable quality of life for the patient. For mild disease, nonsteroidal anti-inflammatory drugs (NSAIDs) are given.

MEDICATION. The purpose of drug therapy for the patient with Paget's disease is to relieve pain and decrease bone loss. Calcitonin (Calcimar) is a thyroid hormone that is often effective in initiating a remission of the disease. It appears to decrease bone loss while also decreasing pain. If effective, the ALP level decreases. The usual duration of therapy is 6 months, followed by 6 months of etidronate disodium (Didronel) or another bisphosphonate drug. Its action is similar to that of calcitonin, and it must be taken on an empty stomach. Alendronate is a bone resorption inhibitor and calcium regulator. Intravenous dosing for 5 days may initiate a disease remission.

Plicamycin (Mithramycin, Mithracin) is a potent anti-cancer drug and antibiotic that is reserved for patients with severe hypercalcemia or severe disease with neurological involvement. This drug suppresses both osteoclastic and osteoblastic activity within days, but it has serious adverse effects. As with all drugs, observe for toxic effects such as liver and kidney failure. The platelet count is monitored because the drug can decrease platelet production. When liver enzymes become too high, the drug is temporarily discontinued until they return to baseline.

Nursing management for Paget's disease focuses on pain relief and support for symptoms. Teaching about the disease, medications, and other therapies is done.

Bone Cancer

Bone tumors may be benign or malignant. Malignant tumors may be either primary (originating in the bone) or metastatic, originating from another location and migrating to bone. Primary bone tumors tend to develop in people under 30 years of age and account for only a small percentage of bone cancers. Metastatic lesions are much more common and most often affect the older adult. The pathophysiology depends on the type of bone cancer. The cause of bone cancer is not known.

Primary Malignant Tumors

Osteosarcoma, or osteogenic sarcoma, is the most common primary malignant bone tumor as well as being the most fatal bone tumor. It is a fairly large tumor that typically metastasizes to the lung within 2 years of diagnosis and treatment. Osteosarcoma most frequently affects the arms and legs (particularly around the knees), but can be found in other bones. This type of cancer usually affects young people between the ages of 10 and 25, and boys are twice as likely to develop the disease. Long bones of the legs and arms are most often the sites of origin. More than 50% of osteosarcomas occur in the distal femur in young men.

osteosarcoma: osteo—bone + sarc—flesh + oma—tumor

The disease itself is relatively rare, with an occurrence rate of approximately two per million people. Pain and swelling in an arm or leg that worsens with exercise or at night are some of the manifestations of osteosarcoma. A lump in the area or an unexplained limp may also be cause for further investigation. X-rays, bone biopsy, CT scan, bone scan, and MRI are some of the diagnostic tests that can be performed to help in the diagnosis of the malignancy. Older patients with Paget's disease may also develop these lesions. Chemotherapy and surgical excision of the affected bone with bone grafting or amputation of the affected limb are the treatments most commonly used for osteosarcomas.

Ewing's sarcoma is the most malignant bone tumor. In addition to local pain and swelling, systemic signs and symptoms, including low-grade fever, leukocytosis, and anemia, are common. The pelvis and lower extremity are most often affected in children and young men.

Patients with a *chondrosarcoma* (cancer of cartilaginous cells) have a better prognosis than those with the previously described types of bone cancer. This type of cancer occurs in middle-aged and older people.

METASTATIC BONE DISEASE. Primary malignant tumors that occur in the prostate, breast, lung, and thyroid gland are called bone-seeking cancers because they migrate to bone more than any other primary cancer. Once cancer has metastasized, multiple bone sites are typically seen. Pathological fractures and severe pain are major concerns in managing metastatic disease. See Chapter 10 regarding caring for patients with cancer.

Signs and Symptoms

Primary tumors cause local swelling and pain at the site. A tender, palpable mass is often present. Metastatic disease is not as visible, but the patient complains of diffuse severe pain, eventually leading to marked disability.

Diagnostic Tests

Diagnosis of bone cancer is made by x-ray examination, computed tomography, bone scan, bone biopsy, or MRI. Chapter 45 discusses these tests in detail.

The patient with metastatic disease has an elevated ALP level and possibly an elevated erythrocyte sedimentation rate, indicating secondary tissue inflammation.

Therapeutic Interventions

Management of bone cancer depends on the type and extent of the tumor. The treatment of primary bone tumors is usually surgery, often combined with chemotherapy or radiation. The surgeon attempts to salvage the limb and performs a resection of the tumor. For patients with Ewing's sarcoma or early osteosarcoma, external radiation may be the treatment of choice to reduce tumor size and pain.

Care of the postoperative patient is similar to that for any patient undergoing musculoskeletal surgery. Monitoring neurovascular status of the operative limb to be operated on is a vital nursing intervention (see Chapter 45). Other general postoperative care is discussed in Chapter 11.

For metastatic bone disease, surgery is not appropriate. External radiation is given primarily for palliation. The radiation is directed toward the most painful sites in an attempt to shrink them and provide more comfort for the patient.

Nursing Management

Nursing care for the patient with bone cancer is not unlike that for patients with any other type of cancer. Help the patient adjust to the diagnosis and refer the patient to resources such as the American Cancer Society and its various support groups. Chapter 10 describes the nursing care associated with chemotherapy and radiation therapy. For more information, visit the American Cancer Society at www.cancer.org.

CONNECTIVE TISSUE DISORDERS

Connective tissue disorders comprise a group of more than 100 diseases in which the major signs and symptoms result from joint involvement. Some connective tissue diseases affect only one part of the body; others affect many body organs and systems. Several disorders are discussed here, including gout, systemic lupus erythematosus, progressive systemic sclerosis, **osteogenesis imperfecta**, **polymyositis**, osteoarthritis, and rheumatoid arthritis.

Gout

Gout is an easily treated systemic connective tissue disorder. Men, especially those middle aged and older, are affected more than women. Patients with gout are seldom hospitalized for their disease.

Pathophysiology

Uric acid is a waste product resulting from the breakdown of proteins (purines) in the body. Urate crystals, formed because of excessive uric acid (**hyperuricemia**) build up and are deposited in joints and other connective tissues, causing severe inflammation. When an "attack" of gout occurs, the patient has severe pain and inflammation in one or more small joints, usually the great toe. The inflammation may resolve in several days with or without treatment. Months or years may pass between attacks, and the patient may have no signs or symptoms of joint inflammation between episodes. Urate deposits may appear under the skin (tophi) (Fig. 46.11) or in the kidneys or urinary system, causing stone (calculi) formation (see Chapter 37).

Causes and Types

The causes and types of gout are well known. Primary gout is the most common and is caused by an inherited problem with purine metabolism. Uric acid production is greater than the kidneys' ability to excrete it. Therefore, the amount of

polymyositis: poly—many + myo—muscle + itis—inflammation
arthritis: arthr(on)—joint + itis—inflammation
hyperuricemia: hyper—excessive + uric—uric acid + emia—in blood

FIGURE 46.11 Gout: subcutaneous nontender lesions near joints. (From Goldsmith, LA, Lazarus, GS, Tharp MD, et al: *Adult and Pediatric Dermatology*. F.A. Davis, Philadelphia, 1997, p 405, with permission.)

uric acid in the blood increases. About 25% of patients have a family history of primary gout. Acute attacks of gout may be triggered by stress, alcohol, illness, trauma, dieting, or certain medications.

Patients with secondary gout also experience hyperuricemia, but the increase is the result of another health problem, such as renal insufficiency, or medications, such as diuretic therapy and certain chemotherapeutic agents.

Signs and Symptoms

ACUTE GOUT. Patients with acute gout have one or more severely inflamed joints due to the uric acid crystals, usually small joints, often in the joint of the great toe. The joint is swollen, red, hot, and usually too painful to be touched.

CHRONIC GOUT. Patients with chronic gout may not have obvious signs and symptoms. Tophi are not commonly seen today because management of patients with gout has improved. If they are present, they tend to appear most often in the outer ear. Renal stones develop in about 20% of patients with gout. Various diagnostic tests may be needed to determine stone formation.

Diagnostic Tests

Diagnosis of gout is based on an elevated serum uric acid level. Joint fluid aspiration analysis can identify uric acid crystals in the synovial fluid, further confirming the diagnosis of gout.

Therapeutic Interventions

MEDICATION. The treatment of secondary gout is management or removal of the underlying cause. Drug therapy is the first-line treatment for primary gout. When the patient has an acute gout episode, the physician usually prescribes either colchicine or an NSAID to reduce the inflammatory response to urate crystals. The patient usually takes these medications until joint inflammation subsides.

Uricosuric agents (medications used to decrease uric acid) are the drug of choice when trying to decrease serum levels. Allopurinol (Zyloprim) is the preferred drug for chronic gout. Allopurinol decreases uric acid production,

necessitating several weeks of therapy before the medication becomes effective. The patient must take it every day to keep the uric acid level within the normal range. Probenecid (Benemid) may also be used temporarily to increase renal excretion of uric acid. The patient's serum uric acid level is monitored periodically.

DIET. For patients with gout, certain foods should be avoided or consumed in moderation (Box 46.6 Health Promotion for Patients with Gout). The patient should avoid all forms of aspirin and diuretics because they can trigger an attack. Increasing daily fluid intake is also important to help prevent kidney stones. The patient should also avoid alcohol (especially beer) as this too can provoke an attack.

Systemic Lupus Erythematosus

The word *lupus* comes from the Latin word for wolf, and was originally associated with leg ulcers. However, it became associated with facial ulcers, and the butterfly facial rash that patients with lupus may develop is one of the most defining characteristics of lupus. The rash is red, and thus the word *erythematosus*, meaning reddened, was added to describe the disease.

Most patients with lupus have the systemic type, but a small percentage have the type that affects only the skin, a condition called discoid lupus erythematosus. Discoid lupus is not life threatening; systemic lupus erythematosus (SLE) can be life threatening because it is a progressive, systemic inflammatory disease that can cause major body organ and system failure. Although this definition seems similar to the definition of rheumatoid arthritis (RA), one distinct difference exists. Patients with SLE typically have more body organ involvement earlier in their disease than patients with RA.

Pathophysiology

SLE is an autoimmune disease characterized by spontaneous remissions and exacerbations. The body's immune system normally produces antibodies to fight invaders such as bacteria, viruses, and other materials foreign to the body. In SLE, the body does not recognize itself and begins to produce antibodies directed at the foreign "self." These anti-

Box 46.6

Health Promotion for Patients with Gout

- Avoid high-purine (protein) foods, such as organ meats, shellfish, and oily fish (e.g., sardines).
- Avoid alcohol.
- Drink plenty of fluids, especially water.
- Avoid all forms of aspirin and drugs containing aspirin.
- Avoid diuretics.
- Avoid excessive physical or emotional stress.

bodies attack the self antigens and form immune complexes. Production of abnormal antibodies (antinuclear antibodies [ANAs]), immune complex formation, and complement system activation results in autoimmune effects on the patient's healthy connective tissue. Many of the manifestations result from recurring injuries to the patient's vascular system. The immune complexes that result lodge in the blood and organs, leading to inflammation, damage, and possibly death.

The cause of SLE is unknown, but the disorder tends to occur in families. Identified chromosomal markers indicate a genetic link. There is evidence that environmental factors also play a critical role in the development of SLE. Infections, high stress levels, various hormones and drugs (especially antibiotics such as sulfa and penicillin), and ultraviolet (UV) light have all been linked to triggering SLE. Exacerbation of symptoms often occurs prior to the start of menstruation and during pregnancy, demonstrating the link hormones have in triggering SLE.

African Americans, Hispanics, Native Americans, and Asians are two to three times more likely to develop SLE than others. Lupus most often affects women between ages 15 and 40 and at a rate 10 to 15 times more often than for men. Women represent 90% of all cases of SLE.

With improved therapy, the mortality rate for patients with the disease has improved greatly over the past 30 years. The leading causes of death are kidney failure, heart failure, and central nervous system involvement.

Signs and Symptoms

Unfortunately, there is no classic description of patients with SLE. Some patients have a very mild form of the disease in which only the skin and joints are affected. Others have devastating effects when the disease affects multiple body systems at the same time.

The classic feature of lupus is the characteristic raised, reddened butterfly rash found over the bridge of the nose that extends to both cheeks, although only half of patients develop it (Fig. 46.12). The rash is usually dry and may itch. It commonly is photosensitive, tends to worsen during an exacerbation, and can be triggered by exposure to ultraviolet light or by physical stressors, such as pregnancy or infection. Instead of the butterfly rash, some patients have discoid (coinlike) skin lesions on other parts of the body. During flare-ups, a fever develops which can rise to more than 100° F (38° C). Fatigue, arthralgia or arthritis, myalgia, malaise, weight loss, mucosal ulcers, and alopecia are other possible signs and symptoms of SLE. Table 46.2 lists other possible signs and symptoms of SLE.

Diagnostic Tests

Skin lesions can be biopsied and examined microscopically for signs of inflammation. Patients with suspected SLE are evaluated using the same immunologically based laboratory tests that are used to assess patients with rheumatoid arthritis. These tests include ESR (to detect systemic inflammation) and ANA titers (to detect the presence of abnormal antibodies). There are also two subtypes of ANA: anti-DNA and anti-sm antibodies, which are only found in patients

FIGURE 46.12 Lupus erythematosus: red papules and plaques in butterfly pattern on face. (From Goldsmith, LA, Lazarus, GS, Tharp, MD, et al: *Adult and Pediatric Dermatology*. FA. Davis, Philadelphia, 1997, p 230, with permission.)

with SLE and can be useful when the physician is attempting to confirm a diagnosis of SLE. A new blood test has been developed that aids in the diagnosis of SLE. Systemic lupus erythematosus patients make antibodies against serine/arginine-rich (SR) proteins (which are important in cell division). Seventy percent of SLE patients react positively to the SR proteins. This new diagnostic tool should help in identifying those SLE patients who do not produce some of the other antibodies looked for in the diagnosis of SLE. Although no laboratory test confirms a diagnosis of lupus, the results of the immunological tests may support the diagnosis.

Therapeutic Interventions

Treatment of SLE focuses on decreasing inflammation and preventing life-threatening organ damage. At present, the therapy of choice includes medications to treat the symptoms or the body systems affected. Research is ongoing regarding the possible cause of SLE. Researchers have found the general location of a gene that is believed to predispose a person to lupus. Identifying the genetic cause of lupus will enable researchers to develop new methods of therapy, including gene therapy. Prevention of exacerbations (flares) is important, and therefore taking preventative measures is suggested. Minimizing exposure to the sun and wearing sunscreens helps those patients who are photosensitive. Regular exercise and keeping immunizations up to date are also helpful.

MEDICATION. Medications are prescribed according to the patient's needs. NSAIDs, acetaminophen, corticosteroids, antimalarials (chloroquine [Aralen], hydroxychloroquine

TABLE 46.2 CHARACTERISTICS OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Manifestations

Central Nervous System

- Headache, epilepsy, psychoses
- Peripheral or sensory neuropathies
- Personality changes, mild alterations in cognition

Cardiovascular

- Inflammation of pericardium (pericarditis)
- Alteration in circulation, particularly to digits (Raynaud's phenomenon)

Pulmonary

- Pleural effusions

Renal

- Inflammation of Kidney Glomerulonephritis

Gastrointestinal

- Peritonitis

Musculoskeletal

- Arthralgias (due to inflammation), especially of the hands, wrists, and knees
- Myalgias

Skin

- Butterfly rash across bridge of nose
- Rash is reddened and raised

Constitutional Signs and Symptoms

- Increased temperature
- Malaise, tiredness
- Weight loss

[Plaquenil]), immunomodulating drugs, and anticoagulants may all be part of the medication regimen. Topical cortisone preparations may help reduce skin inflammation and promote fading of skin lesions.

Patients who experience joint inflammation are usually placed on an NSAID. Patients with organ or major body system involvement are given more potent drugs that suppress the immune process, including oral steroids such as prednisone or immunomodulating agents such as azathioprine (Imuran) or cyclophosphamide (Cytoxan). These drugs have serious side effects, and patients receiving them are monitored very carefully. In addition to monitoring for a variety of side effects, patients must be taught to avoid people with infections because they are immunocompromised while taking any of these medications.

Nursing Process for the Patient with Systemic Lupus Erythematosus

ASSESSMENT/DATA COLLECTION. Determine the extent and severity of signs and symptoms, such as pain, fatigue, skin lesions, and fever. Individualize the plan of care as every patient with SLE is unique.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. See nursing process sections on osteoarthritis and rheumatoid arthritis for:

- Acute pain related to joint swelling
- Chronic sorrow related to loss of health, role changes, and having a chronic disease

- Fatigue related to chronic disease process
- Disturbed body image related to alterations in skin integrity
- Self-care deficits

Ineffective coping related to chronic disease condition and alteration in body integrity

EXPECTED OUTCOME: Patient will make appropriate decisions related to personal life and condition.

- Assess patient's coping pattern and ability to have a baseline.
- Provide support and reassurance to patient to let patient know someone is there for them.
- Assist in problem solving without taking over to help when needed but improving self-confidence.
- Encourage inclusion of support systems and resources to utilize all avenues available to help.
- Include input from other disciplines such as social work and clergy to ensure all alternatives are considered.

Risk for impaired skin integrity related to disease condition and increased susceptibility to UV light

EXPECTED OUTCOME: Patient will maintain skin integrity.

- Teach importance of protecting self from UV light (decrease sun exposure, wear sunscreen and appropriate clothing) to minimize flare-ups.
- Ensure good hygiene to help minimize infections and promote skin integrity.
- Apply topical creams and ointments as ordered to help with inflammation and discomfort.

EVALUATION. The outcome is met if patient makes appropriate decisions related to personal life and condition and skin integrity is maintained.

CRITICAL THINKING

Mr. Wolf

- Mr. Wolf is experiencing a relapse of SLE and requires administration of prednisone. The doctor's order states: prednisone 55 mg PO in two equal doses. Prednisone is available as 1-mg, 2.5-mg, and 5-mg tablets. Which of the following combinations of drug would be most appropriate to administer for each dose?
 1. Administer four 5-mg tablets in the morning and five 5-mg tablets in the evening.
 2. Administer five 5-mg tablets in the morning and four 5-mg tablets in the evening.
 3. Administer two and one half 1-mg tablets and five 5-mg tablets in the morning and evening.
 4. Administer one 2.5-mg tablet and five 5-mg tablets in the morning and evening.

Suggested answers at end of chapter.

PATIENT EDUCATION. Teach the patient about skin care and ways to prevent disease exacerbations. Skin care includes use of a mild soap, patting the skin dry, using lotion, avoiding drying agents, protecting from sunlight with sun block of SPF 30, cover with clothing and hats, and avoid tanning beds. Exercise can prevent muscle weakness and fatigue. The patient should be encouraged to be immunized against specific infections. Methods of stress reduction should be identified and utilized.

The Arthritis Foundation and the Lupus Foundation are national organizations that can provide information, assistance, and community support groups for patients diagnosed with lupus. For more information, visit the Lupus Foundation of America at www.lupus.org.

Scleroderma

The term **scleroderma** is Greek in origin meaning “hard skin.” It is similar to SLE in that it can affect multiple organs and other connective tissues. Scleroderma is not as common as SLE but has a higher mortality rate. There are two types of scleroderma: localized and systemic. As the name implies, systemic scleroderma can affect any part of the body. Among other names for systemic scleroderma are diffuse and progressive systemic scleroderma; however, since scleroderma is not necessarily progressive, this term is not encouraged. What is more frequently seen is the term *systemic sclerosis* (SSc).

Pathophysiology

Scleroderma is characterized by inflammation that ultimately develops into fibrosis (scarring) and then sclerosis (hardening) of tissues. The disease is an autoimmune response to the body’s normal tissues. Like some of the other systemic connective tissue diseases, abnormal antibodies damage healthy tissue, resulting in inflammation, which then triggers overproduction of collagen, which is deposited in the skin. The collagen produced is insoluble and when deposited in the skin causes inflammation. Edema in the skin ultimately results in loss of elasticity and tissue function. The same process can occur internally, affecting blood vessels and organs.

SSc is relatively rare in that it affects approximately 300,000 Americans. It affects women three to four times more often than men. It can occur at any age but usually develops between ages 25 and 55. The disease tends to progress rapidly and does not respond well to treatment. Spontaneous remissions and exacerbations can occur. There is a relationship between scleroderma and Raynaud’s syndrome; approximately 95% of patients with scleroderma have Raynaud’s phenomenon.

Signs and Symptoms

Although arthritis and fatigue are commonly seen, the most obvious sign of SSc is manifested at first by pitting edema, starting in the upper extremities. The skin is taut, shiny, and without wrinkles. The swelling is replaced by tightening,

hardening, and thickening of skin tissue. The skin then loses its elasticity, range of motion is decreased, and skin ulcers may appear. As the disease progresses, the patient loses range of motion and the affected area becomes contracted.

The same pathophysiological process affects certain body systems, especially the kidneys, lungs, heart, and gastrointestinal tract. If any of these systems are affected, the corresponding signs and symptoms are present. For example, gastrointestinal tract involvement usually manifests as esophagitis, dysphagia (difficulty swallowing), and decreased intestinal peristalsis caused by decreased smooth muscle elasticity.

The prognosis is thought to be worse when the patient has CREST syndrome, a group of signs and symptoms occurring at the same time:

- Calcinosis (calcium deposits)

- Raynaud’s phenomenon (severe vasospasms of the small vessels in the hands and feet)

- Esophageal dysmotility (decreased activity)

- Sclerodactyly (scleroderma of the finger digits)

- Telangiectasia (spiderlike skin lesions)

Diagnosis

The patient’s clinical history and physical manifestations (particularly the sclerotic changes that occur in the skin) aid in the diagnosis of scleroderma. Biopsies of the skin, laboratory tests (ANA, and most recently anti-Scl-70 antibodies and anticentromere antibodies [ACA]), pulmonary function tests, and electrocardiographic (ECG) or x-ray examinations (including esophageal studies) are used to determine the severity of organ involvement or if other diagnostic testing is not helpful in diagnosing this condition.

Therapeutic Interventions

The goal of medical management is to slow the progression of the disease. Systemic steroids, such as prednisone, and immunosuppressant drugs are used in large doses and in combination during a flare-up of SSc.

Other care approaches are directed toward symptom management. Skin-protective measures can help minimize the chance of ulcerations or irritation. For example, teach the patient to use mild soaps and lotions to moisturize the skin.

If the patient has esophageal involvement, small, frequent, bland meals are better tolerated than large, spicy ones. Difficulty swallowing may necessitate cutting the food into smaller, more manageable portions or by providing food that is pureed (thicker liquids are easier to swallow than thin liquids). Medications to treat esophageal reflux, such as antacids and histamine blockers, may be prescribed.

Patients who have Raynaud’s phenomenon or other types of **vasculitis** usually experience severe pain when small blood vessels constrict. Joints may also be painful. Pain management is a priority in the care of patients with SSc. A bed cradle or footboard keeps bed covers away from skin. Socks and gloves may keep the fingers and toes warm, thus diminishing pain. Minimizing exposure to cold and

avoiding stressful situations, stopping smoking, and taking certain medications, such as calcium channel blockers, anti-adrenergic agents, and angiotensin-converting enzyme (ACE) inhibitors, can all help promote circulation or minimize the likelihood of an attack. Research has suggested that antioxidant therapy may provide another approach to treating SSc.

Rehabilitative therapy may be needed to help the patient be as independent as possible with activities of daily living and mobility. Collaborate with other members of the interdisciplinary team to individualize care.

Osteogenesis Imperfecta

Osteogenesis imperfecta (OI) is a rare inheritable disease that is also called fragilitas ossium or brittle bones disease. It is a congenital abnormality characterized by skeletal bone fragility. The fragility predisposes the person to pathological fractures and bone deformities. In addition, there is connective tissue involvement which can cause changes or abnormalities in the eyes, ears, joints, skin, and teeth.

Pathophysiology

In OI, osteoblasts and fibroblasts synthesize collagen abnormally, resulting in fragile bones, multiple fractures (especially of the long bones), bone deformities (resulting from improper healing and weak callus formation along with thinner, smaller, and shorter bones), fragile and discolored teeth, loose joints, and thin, easily damaged skin. There are four types of OI classified according to severity and characteristics, with type I being the most common and least severe form of the condition.

Signs and Symptoms

There is much variation in the signs and symptoms for a person with OI. Some of the symptoms common to all types of OI include:

- Fragile bones (easily broken or bent)
- Triangular-shaped face
- Potential hearing loss
- Scoliosis (spine curvature) which may create respiratory problems
- Loose joints
- Alterations in muscle tone or development
- Blue, purple, or gray tint to sclerae
- Brittle or discolored teeth
- Smooth, thin skin

OI types II, III, and IV symptoms also include:

- Decreased height (may only grow to 3 feet tall)
- Barrel-shaped rib cage

Diagnosis

The diagnosis of OI may be based on clinical features of the patient. Most frequently, the diagnosis is made because of the frequency of fractures the patient (usually an infant or child) experiences without an apparent cause. Most OI patients can have 40 to 100 fractures by the time they reach puberty depending on the type of OI they have. It is also not

uncommon for type II OI babies to be born with fractures and to either be born dead or die shortly after birth. The only test currently available is a biopsy of the skin assessing the collagen fibers. The test can take weeks to get results and is not definitive.

Therapeutic Interventions and Nursing Care

There is no treatment for OI. Therapy consists of treating the fractures and trying to minimize the bone deformities that result from the disease. Splints, casts, and braces are utilized to aid in healing the fractures and maintaining structure and function. Medications such as pamidronate (Aredia), a bone resorption inhibitor, are being trialed to see if bone density can be increased with the hope of decreasing fractures and improving mobility while decreasing the associated pain. Gene therapy is also being suggested as a means to treat OI; however, this form of therapy will not be soon available. Nursing care requires careful handling of the patients with the understanding that no matter how careful you may be, fractures will still occur. It is important to teach the family and for the nurse to understand that it is not necessarily something that they did that causes the fractures, rather it is the pathological process causing the breaks. The Osteogenesis Imperfecta Foundation (www.oif.org) is an excellent resource for patients, family, and the health-care team.

Polymyositis

Polymyositis is a disease with an unknown cause that results in diffuse inflammation of skeletal muscle, leading to weakness, atrophy, and degeneration. When a rash is present with muscle inflammation, the disease is called dermatomyositis. The disease is progressive; however, remissions and exacerbations are common. Women are affected more than men, especially in their middle-aged years.

The shoulder and pelvic girdle muscles (proximal muscles) are most commonly affected. The patient may have associated conditions such as arthritis, fatigue, and possibly Raynaud's phenomenon (spasms and constriction of small vessels in the hands and feet). Patients with dermatomyositis also have the classic heliotrope (lilac) rash and periorbital (around the eyes) swelling. Malignant tumors occur in patients with these diseases more often than in the rest of the population.

Patients are treated symptomatically, using an interdisciplinary approach, to maintain optimum function. The drug of choice is high doses of prednisone. Side effects, such as immunosuppression, can occur with prednisone.

Muscular Dystrophy

Muscular dystrophy (MD) is a group of nine disorders resulting in loss of muscle tissue and progressive muscle weakness. A number of the disorders are diagnosed in childhood (e.g., Duchenne's MD is most common in children); however, other forms of MD, such as myotonic MD, are most common in adults. In addition, individuals with MD

are now living longer into adulthood as a result of advances in treatment.

Pathophysiology and Etiology

Muscular dystrophy has a genetic origin. However, the exact cause is unknown. Skeletal (voluntary) muscle fibers degenerate and atrophy. This loss of muscle tissue results in muscle weakness and wasting. Muscle tissue is replaced by connective tissue. These changes in muscle tissue result in increasing disability and deformity. Life expectancy after diagnosis depends on the type of MD as well as the speed and severity of progression. Involvement of the heart and lungs also influences the life expectancy. In some forms of MD, young adulthood (mid to late 20s) is the average life expectancy.

Signs and Symptoms

Signs and symptoms usually become apparent in childhood. Difficulty walking and muscle weakness in the arms, legs, and trunk are indicators of MD. Individuals with MD may have difficulty raising their arms above their heads or climbing stairs. Other signs and symptoms include frequent falls, developmental delays involving muscle skills, drooping eyelids (ptosis), drooling, intellectual retardation (only in some types of MD), contractures, and skeletal deformities.

Diagnosis

An increase in serum creatinine phosphokinase (CPK) caused by muscle atrophy is present in MD. Electromyography (EMG) and muscle biopsy can be used for diagnosis. Lactic dehydrogenase (LDH) and the isoenzymes, myoglobin (urine or serum), creatinine (urine or serum), CPK isoenzymes, and aspartate aminotransferase (AST) levels may also be altered in patients with MD. There are also tests looking for gene mutations for some of the various types of MD.

Therapeutic Interventions

Goals include supportive care and prevention of complications. Treatment regimens focus on controlling symptoms and maximizing quality of life. Keeping the patient as active as possible is a priority in the planning of care. Exercise programs (e.g., range of motion, physical therapy) help prevent muscle tightness, contractures, and atrophy. Splints and braces provide support during ADL. Surgery may be done to correct deformities. The potential benefit of gene therapy is currently being investigated. Some of the current research indicates that gene therapy could prove effective with some types of MD.

Nursing Process for the Patient with Muscular Dystrophy

ASSESSMENT/DATA COLLECTION. Assess for muscle weakness, noting what areas of the body are affected and the severity of the weakness. Asking the patient and family what activities can be done with and without assistance helps determine the plan of care.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Impaired physical mobility related to muscle weakness

EXPECTED OUTCOME: Patient's mobility will increase or be maintained for as long as possible.

- Provide assistive devices (e.g., braces, splints, wheelchair) to assist with mobility.
- Provide active and passive range-of-motion exercises and other physical therapy to prevent contractures and improve muscle strength.
- Encourage the patient to do as much as possible to increase independence and help maintain muscle function.
- Include disciplines such as physiotherapy and occupational therapy to provide equipment and devices that will help with independence and mobility.

Ineffective breathing pattern related to muscle weakness

EXPECTED OUTCOME: Patient will demonstrate normal respiratory function and normal oxygen saturation.

- Monitor respiratory function (rate and effort) every 4 hours.
- Monitor oxygen saturation and keep above 90%.
- Administer oxygen at 2 L/minute or as ordered if oxygen saturation drops below 90%.
- Position patient to increase respiratory efficiency.
- Teach and prepare patient about lung function studies to evaluate lungs
- Teach patient to minimize chances of infection (e.g., stay away from crowds) and to ensure early attention to respiratory alterations

EVALUATION. The outcome is met if the patient improves or maintains physical mobility and the patient's oxygen saturation is normal.

PATIENT EDUCATION. The patient and family need to understand the importance of physical therapy in maintaining function and preventing complications. National organizations and support groups provide information, resources, and emotional support. Family members need to encourage the patient to have activity and rest periods. As with any neuromuscular condition, the patient needs to avoid exposure to the cold and persons with infections. For more information on muscular dystrophy, visit www.mdausa.org or www.mdac.ca.

Osteoarthritis

Osteoarthritis (OA) is the most common type of connective tissue disorder, affecting more than 20 million people in the United States. The term *arthritis* means inflammation of the joint, but OA is not a primary inflammatory process. Therefore, some health-care providers may refer to this disorder as *degenerative joint disease*. This term better reflects its pathophysiology.

TABLE 46.3 OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS SUMMARY

	Osteoarthritis	Rheumatoid Arthritis
Pathophysiology	Articular cartilage and bone ends deteriorate Joint is inflamed	Inflammatory cells cause synovitis Synovium becomes thick and fluid accumulates, causing swelling and pain Joint becomes deformed
Etiology	Primary (idiopathic): • Cause unknown • Risk factors include age, obesity, activities causing joint stress Secondary: • Causes include trauma, sepsis, congenital abnormalities, metabolic disorders (Paget's disease), rheumatoid arthritis	Autoimmune disease Can occur at any age (including juvenile rheumatoid arthritis) Cause unknown Familial history possible
Signs and Symptoms	Joint pain and stiffness Pain increases with activity and decreases with rest Nodes on joints of fingers (Heberden's nodes, Bouchard's nodes)	Symptoms vary according to disease process Early symptoms: • Bilateral and symmetrical joint inflammation • Redness, warmth, swelling, stiffness, pain • Stiffness after resting (morning stiffness) • Activity decreases pain and stiffness • Low-grade fever, weakness, fatigue, anorexia (mild weight loss) • Organ system involvement Late symptoms: • Joint deformity • Secondary osteoporosis
Therapeutic Interventions	Medication: • NSAIDs • Acetaminophen • Muscle relaxants • Cox-2 inhibitors Balanced rest and exercise Splinting of joint to promote rest Heat and cold Diet for weight loss Complementary therapies Surgery for total joint replacement	Medication: • Salicylates • NSAIDs • Gold treatment • Methotrexate • Prednisone Heat and cold Balanced rest and activity Surgery for total joint replacement
Possible Nursing Diagnoses	Chronic pain Impaired physical mobility Body image disturbance	Chronic pain Self-care deficits Ineffective health maintenance

ADLs = activities of daily living; NSAIDs = nonsteroidal anti-inflammatory drugs.

Pathophysiology

Osteoarthritis occurs when the articular cartilage and bone ends of joints slowly deteriorate (Table 46.3). The joint space narrows, bone spurs develop, and the joint may become somewhat inflamed. The repair process is not able to overcome the rapid loss of cartilage and bone, eventually resulting in joint deformities, pain, and immobility, leading to the patient's functional decline. Weight-bearing joints (hips and knees), hands, and the vertebral column are most often affected (Fig. 46.13).

Causes and Types

The most common type of OA is primary (idiopathic) osteoarthritis. The cause of OA is unknown, but several risk factors have been identified. Aging, obesity, and physical activities that create mechanical stress on joints are major risks. Each of these factors cause prolonged or excessive

“wear and tear” on synovial joints. The majority of people older than 60 years of age have some degree of symptomatic joint degeneration. Native Americans are affected more often than other groups, but the reason for this is unknown.

Patients with secondary osteoarthritis develop joint degeneration as a result of trauma, sepsis, congenital anomalies, certain metabolic diseases (such as Paget's disease), or systemic inflammatory connective tissue disorders such as rheumatoid arthritis.

Signs and Symptoms

The patient usually seeks medical attention when joint pain and stiffness become severe or the patient has problems with everyday activities. One or more joints may be affected, most commonly in the hands, hips, knees, spine, and feet. Joint pain intensifies after physical activity but lessens following rest. If the vertebral column is involved, the patient

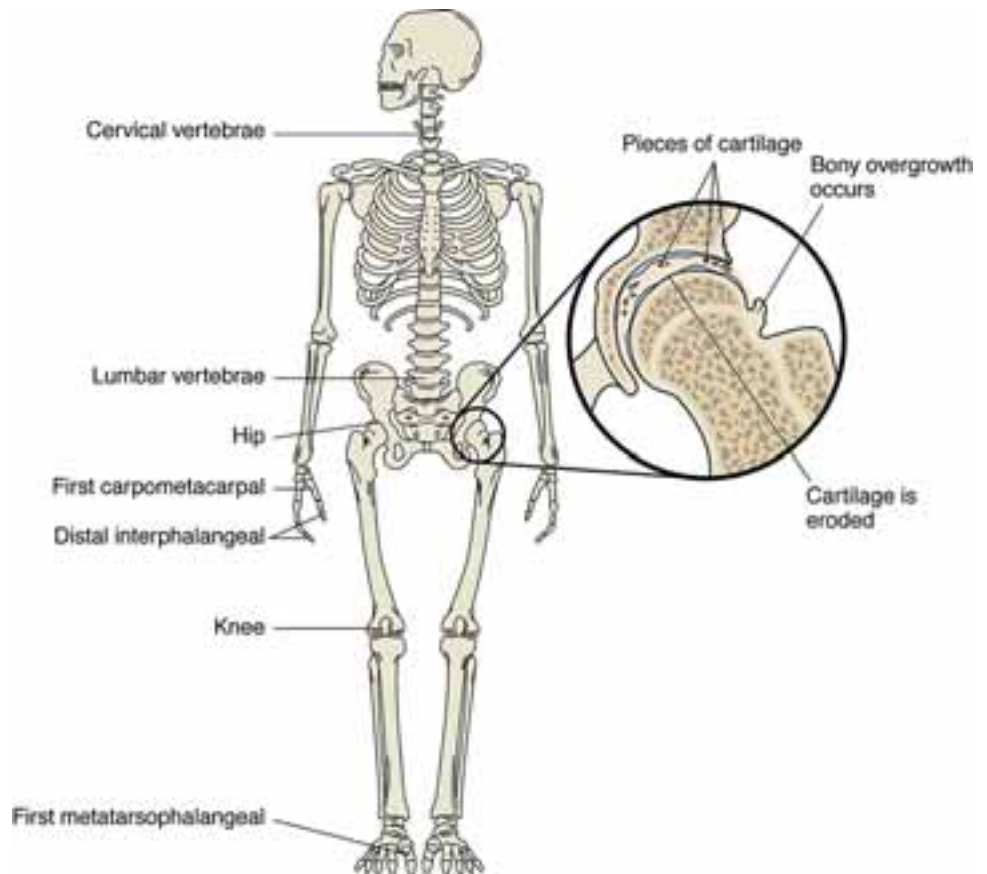

FIGURE 46.13 Common joints affected by osteoarthritis and the changes that result in the joint.

complaints of radiating pain and muscle spasms in the extremity innervated by the area affected.

About half of patients with OA have bony nodes on the joints of their fingers, called Heberden's and Bouchard's nodes. Women tend to have them more often than men, and they may or may not be painful. The nodes have a familial tendency and are often a cosmetic concern to female patients.

Diagnostic Tests

X-ray examinations are useful in outlining joint structure and detecting bone changes. A computed tomographic (CT) scan or magnetic resonance imaging (MRI) may be used to diagnose various joint involvement. Analysis of synovial fluid can aid in the diagnosis of OA while ruling out other pathological conditions of the joint.

Therapeutic Interventions

There is no curative therapy currently available for OA. Management of patients with OA centers on pain control, which is accomplished by drug therapy, other pain relief measures, or ultimately surgery. An interdisciplinary approach is needed to prevent decreased mobility and preserve joint function.

Synvisc is injected directly into osteoarthritic knees and acts like healthy, cushioning synovial fluid. Pain is relieved and flexibility restored when the knee joint is again lubricated and cushioned. For more information about this therapy, visit www.synvisc.com.

CRITICAL THINKING

Mr. Dennis

■ Mr. Dennis is a 59-year-old overweight carpenter who visits his physician with complaints of knee and wrist pain. He has noticed that it is becoming increasingly difficult to climb a ladder or use a hammer. The physician suspects osteoarthritis.

1. What data collection questions should be included in a patient history?
2. What risk factors does he have?
3. What other signs and symptoms might he have?

Suggested answers at end of chapter.

MEDICATION. Drug therapy, often used in combination with other therapies to reduce pain, is commonly used for patients with OA. The most typically used drugs are non-steroidal anti-inflammatory drugs (NSAIDs) (Table 46.4). These drugs have analgesic and anti-inflammatory effects but may cause side effects if not carefully monitored. Common side effects include gastrointestinal (GI) distress; bleeding tendencies, which can be severe; and sodium and fluid retention. Older adult patients receiving NSAIDs on a routine basis should be carefully monitored for congestive heart failure or high blood pressure as a result of fluid reten-

TABLE 46.4 COMMON DRUGS USED TO TREAT CONNECTIVE TISSUE DISEASES: OSTEOARTHRITIS, RHEUMATOID ARTHRITIS, AND OTHERS

Medication Class/Action	Examples	Route	Side Effects	Nursing Implications
Nonsteroidal anti-inflammatory drugs (NSAIDs) Block activity of enzyme cyclooxygenase (COX-1, COX-2), which makes prostaglandins that produce inflammation, fever, pain; support platelets, and protect stomach lining (COX-1 only)	Acetylsalicylic acid (aspirin) Diclofenac sodium (Voltaren) Diflunisal (Dolobid) Etodolac (Lodine; osteoarthritis only) Fenoprofen (Nalfon) Flurbiprofen (Ansaid) Ibuprofen (Motrin) Indomethacin (Indocin) Ketoprofen (Orudis) Naproxen (Aleve, Naprosyn) Oxaprozin (Daypro) Piroxicam (Feldene) Nabumetone (Relafen) Sulindac (Clinoril) Tolmetin (Tolectin)	PO PO PO PO PO PO PO PO PO PO PO PO PO PO PO	Vary with drug: Nausea, vomiting, diarrhea, constipation, anorexia, rash, dizziness, headache, drowsiness, edema, ulcers, bleeding	Teach risk of GI bleeding greatest with COX-1 inhibitors Those with asthma higher risk for allergic reaction. Avoid use in children/teens with chickenpox or influenza to prevent Reye's syndrome
Corticosteroids Reduce inflammation and swelling	Prednisone (Cortan, Deltasone, Orasone)	PO	Weight gain, fat deposits, edema, hypertension, infection, fractures, poor wound healing, GI bleeding, depression, mood swings	Daily weight Monitor I&O. Assess for infection. Give with food/milk Medic Alert ID Not used for osteoarthritis
Disease-modifying antirheumatic drugs (DMARDs) For rheumatoid arthritis, ankylosing spondylitis, lupus. Reduce symptoms, prevent joint damage, and preserve joint function by suppressing immune or inflammatory systems.			Vary with drug: Infection, alopecia, bone marrow suppression, kidney/liver damage.	Slow-acting drugs may take months for effect. Other drugs used to control symptoms until effective. Effect stops when drug stops
Gold Preparations	Auranofin (Ridaura)	PO		
Immunosuppressives	Aurothioglucose (Solganal)	IM		
	Azathioprine (Imuran)	PO		
	Cyclophosphamide (Cytosan)	IV, PO		
	Cyclosporine (Sandimmune, Neoral)	PO		
	Methotrexate (Mexate)	IM also		
	Leflunomide (Arava; rheumatoid arthritis only)	PO		
	d-Penicillamine (Cuprimine, Depen).	PO		
	Sulfasalazine (Azaline, Azulfidine, Sulfzine)	PO		
Antitumor Necrosing Factor	Etanercept (Enbrel)			
Antimalarials	Chloroquine (Aralen)	PO, IM		
	Hydroxychloroquine (Plaquenil)	PO		

tion. Topical creams such as capsaicin (ArthriCare) may also be ordered and applied to the joints. COX-1 and COX-2 inhibitors previously were frequently ordered for OA but ongoing concerns related to adverse cardiac events have resulted in a voluntary recall by the manufacturers, and therefore they are typically not being prescribed for patients with OA.

REST AND EXERCISE. Joint pain from OA tends to decrease with rest; therefore, pain is less severe in the morning. Activities should be scheduled at this time. A severely inflamed joint may be splinted by the occupational or physical therapist to promote rest to a selected joint. However, rest must be balanced with exercise to prevent muscle atrophy from disuse. Exercise has been identified as a means to maintain general health and weight, range of motion, and muscle strength, while decreasing anxiety and depression. To minimize muscle atrophy and to stabilize and protect arthritic joints, patients should be encouraged to perform exercises to strengthen their quadriceps if they have OA of the knee.

Joints should always be placed in their functional position—that is, a position that does not lead to contractures. For example, only a small pillow should be placed under the head when sleeping to prevent excessive neck flexion.

HEAT AND COLD. The patient with OA usually prefers heat therapy unless the joint is acutely inflamed. Hot packs, warm compresses, warm showers, moist heating pads, and paraffin dips provide sources of heat for the patient. Cold therapy minimizes inflammation while altering cutaneous pain receptors, thereby decreasing pain. Cold packs should be applied for no longer than 20 minutes at a time.

Diet

The obese or overweight patient benefits from losing weight to decrease joint stress on weight-bearing joints, thereby reducing pain. If the patient is on medications that can alter fluid volumes (corticosteroids), a diet low in sodium may be appropriate.

COMPLEMENTARY THERAPIES. The popularity of complementary therapies to reduce pain and stress has grown tremendously. Imagery, music therapy, acupressure, acupuncture, and other holistic modalities that foster the mind-body-spirit connection work well for many people. Homeopathic therapies such as glucosamine and chondroitin have been suggested to improve OA. Recent studies have demonstrated that these two therapies are effective in OA therapy; however, further research must be conducted before they become an accepted and recommended therapy for OA.

SURGERY. If the patient's pain is not successfully managed, a total joint replacement (TJR) may be indicated. A TJR is the most common type of **arthroplasty** (see section on musculoskeletal surgery).

arthroplasty: arthro—joint + plasty—creation of

Nursing Process for the Patient with Osteoarthritis

ASSESSMENT/DATA COLLECTION. The patient's complaint of pain is assessed and the joints observed for signs of inflammation or deformity. Also assessed are function, alterations in activities of daily living (ADLs), and mobility (see Chapter 45).

NURSING DIAGNOSIS, PLANNING, IMPLEMENTATION, AND EVALUATION. Chronic pain related to chronic inflammatory disease

EXPECTED OUTCOME: Patient will state pain is within tolerable levels (pain assessment scale 0 to 10).

- Ensure patient is aware that his or her pain is acknowledged by the nurse so that he or she knows the pain is accepted.
- Provide analgesics as ordered *to help alleviate painful sensations*.
- Collaborate with interdisciplinary team such as pain clinic to explore alternative pain relief measures such as surgery.
- Consider alternative methods of therapy such as guided imagery, distraction, acupuncture, and biofeedback to use all possible methods of pain control.

Activity intolerance related to pain

EXPECTED OUTCOME: Patient will participate in ADLs as tolerated.

- Promote as much independence as possible *to promote activity*.
- Assist with ADLs as necessary *to ensure patient does not become exhausted*.
- Provide pain relief measures prior to activity, which will help them increase their activity level.
- Ensure nursing interventions are performed in “groups” *to minimize patient exertion*.
- Collaborate with interdisciplinary team (e.g., occupational therapy, home care physiotherapy) *to utilize their resources and knowledge*.

Chronic sorrow related to altered body image, altered role, pain, and ongoing losses

EXPECTED OUTCOME: Patient will verbalize improvement in feelings of sorrow

- Allow for time to discuss feelings and anticipate trigger events *to ensure the patient is aware of what may increase his or her feelings of sorrow*.
- Encourage use of interdisciplinary team such as social worker, psychologist, clergy, or spiritual advisor *to provide alternate methods of dealing with sorrow*.
- Encourage use of support groups to enable the patient to discuss his or her concern with others experiencing the same problems.

Disturbed body image related to changes in joint function and structure

EXPECTED OUTCOME: Patient will demonstrate acceptance of changes in body image.

- Encourage patient to discuss feelings and concerns *so patient knows nurse understands what patient is experiencing.*
- Provide information and clarify misconceptions *to ensure that the patient is aware of the expected problems and concerns.*
- Encourage socialization *to improve on the person's perceptions of how he or she "looks" to others.*
- Encourage sharing with support groups so that the patient discusses his or her concerns with others experiencing the same problems.

Impaired physical mobility related to altered joint function and pain

EXPECTED OUTCOME: Patient will demonstrate improved physical mobility.

- Administer analgesics and anti-inflammatory agents as ordered *to improve joint function and decrease pain.*
- Encourage active ROM exercises *to prevent or minimize further alteration in joint function*
- Ensure proper positioning and alignment *to promote joint function and decrease pain.*
- Use interdisciplinary team such as physiotherapy and occupational therapy *to utilize resources and knowledge from other sources.*

Self-care deficit related to chronic degenerative joint disease

EXPECTED OUTCOME: Patient will be able to provide own self-care.

- Encourage independence to decrease feelings of despair about being unable to care for self.
- Assist when necessary to minimize frustration when patient unable to perform self-care function.
- Teach patient about assistive devices *to help with ADLs to promote self-care.*
- Collaborate with interdisciplinary team such as home care, occupational therapy, or physiotherapy *to acquire assistive devices and use alternate resources.*

EVALUATION. The outcome is met if patient reports pain is within tolerable levels on pain assessment scale of 0 to 10, verbalizes improvement in feelings of sorrow, demonstrates acceptance of changes in body image, demonstrates improved physical mobility, and is able to provide own self-care.

PATIENT EDUCATION. A vital function of each member of the health-care team is health teaching. The patient with OA is seldom admitted to the hospital for treatment of OA unless surgery is scheduled. However, many patients with OA are admitted for other reasons, and their arthritis needs must also be considered in the comprehensive plan of care.

Most patients residing in nursing homes also have OA, which can affect their participation in recreational activities, as well as their ADLs.

In any setting, including the home, patients can be taught ways to protect their joints and conserve energy. Nurses need to teach patients and their families how to promote health. For information on educational materials and self-help courses, visit the Arthritis Foundation at www.arthritis.org.

Rheumatoid Arthritis

Rheumatoid arthritis (RA) is a chronic, progressive, systemic inflammatory disease that destroys synovial joints and other connective tissues, including major organs. It affects women three times more often than men and Native Americans more often than other ethnic groups. Rheumatoid arthritis can occur at any age; when it occurs in children it is called juvenile RA (JRA). The peak onset of RA is 30 to 60 years of age, and it affects 1% to 3% of the population in the United States. The etiology of RA is still unknown; however, there are indications that genetic predisposition and the environment play a role in triggering its development.

Pathophysiology

Inflammatory cells and chemicals cause **synovitis**, an inflammation of the synovium (the lining of the joint capsule). As the inflammation progresses, the synovium becomes thick and fluid accumulation causes joint swelling and pain. A destructive pannus (new synovial tissue growth infiltrated with inflammatory cells) erodes the joint cartilage and eventually destroys the bone within the joint (Fig. 46.14). Ultimately the pannus is converted to bony tissue, resulting in loss of mobility. Joint deformity and bone loss are common in late RA (see Table 46.3).

Synovial joints are not the only connective tissues involved in RA. Any connective tissue may be affected, including blood vessels, nerves, kidneys, pericardium, lungs, and subcutaneous tissue. The result of body system involvement is malfunction or failure of the organ or system. Death can occur if the disease does not respond to treatment.

FIGURE 46.14 Rheumatoid arthritis.

Many patients experience spontaneous remissions and exacerbations (flare-ups) of RA. The symptoms of the disease may disappear without treatment for months or years. Then the disease may exacerbate just as unpredictably. Exacerbations usually occur when the patient experiences physical or emotional stress, such as surgery or infection.

Etiology

The exact cause of RA is unknown. An autoimmune response occurs that affects the synovial membrane of the joints; it is unknown what triggers the initial response. Antibodies (called rheumatoid factor) are often found in patients with RA. It is suggested that these antibodies join with other antibodies and form antibody complexes. These complexes lodge in synovium and other connective tissues, causing local and systemic inflammation, and may be responsible for the destructive changes of RA in body tissues.

The origin of the rheumatoid factor is not clear, but a genetic predisposition is likely. RA affects people with a family history of the disease two to three times more often than the rest of the population.

Signs and Symptoms

Signs and symptoms vary as the disease progresses differently in patterns and rates from person to person. In general, the signs and symptoms can be divided into early and late manifestations.

The typical pattern of joint inflammation is bilateral and symmetrical. The disease usually begins in the upper extremities and progresses to other joints over many years (Fig. 46.15). Affected joints are slightly reddened, warm, swollen, stiff, and painful. The patient with RA often has morning stiffness lasting for up to an hour, and those with severe disease may complain of stiffness all day. Generally, activity decreases pain and stiffness.

Because of the systemic nature of RA, the patient may have a low-grade fever, malaise, depression, lymphadenopathy, weakness, fatigue, anorexia, and weight loss. As the disease worsens, major organs or body systems are affected. Joint deformities occur as a late symptom, and secondary osteoporosis (bone loss) can lead to fractures.

FIGURE 46.15 Joint abnormalities in hands of patient with rheumatoid arthritis.

Several associated syndromes are seen in some patients with rheumatoid arthritis. For example, Sjögren's syndrome is an inflammation of tear ducts (causing dry eyes) and salivary glands (causing dry mouth). Felty's syndrome is less common and is characterized by an enlarged liver and spleen and leukopenia (decreased white blood cell count).

Diagnosis

No specific diagnostic test confirms RA, but several laboratory tests help support the diagnosis. An increase in white blood cells and platelets is typical, unless the patient has Felty's syndrome. A group of immunologic tests are usually performed, and typical findings for patients with RA include the following:

- Presence of rheumatoid factor (RF) in serum
- Decreased red blood cell (RBC) count
- Decreased C4 complement
- Increased erythrocyte sedimentation rate (ESR)
- Positive antinuclear antibody (ANA) test
- Positive C-reactive protein (CRP) test

RF can indicate the aggressiveness of the disease. However, it is not specific to RA and can also be found in systemic lupus erythematosus, connective tissue disease, and myositis. The ESR is also obtained to evaluate the effectiveness of treatment. If the disease responds to treatment, the ESR decreases. The higher the ESR, the more active the disease process.

LEARNING TIP

ESR is a general screening test for inflammation. It measures the amount of time it takes for RBCs to settle to the bottom of a test tube. In the presence of inflammation, RBCs settle faster in the tube. Therefore, the ESR increases with the presence of inflammation.

X-ray examination and MRI detect joint damage and bone loss, especially in the vertebral column. A bone or joint scan assesses the extent of joint involvement throughout the body. For some patients, an **arthrocentesis** may be performed; the synovial fluid is cloudy, milky, or dark yellow with inflammatory cells present.

Therapeutic Interventions

Like patients with osteoarthritis, patients with RA experience chronic joint pain. Pain can interfere with mobility or the ability to perform ADLs. Drug therapy is often needed to relieve or reduce pain as well as to slow the progression of the disease.

MEDICATION. Treatment for RA includes disease-modifying antirheumatic drugs (DMARDs), which can prevent joint destruction, deformity, and disability with early single or combination drug use; NSAIDs; and corticosteroids. (See Table 46.4.) Newer DMARDs such as leflunomide (Arava) and etanercept (Enbrel) are used to slow the

progression of RA. Leflunomide taken orally has anti-proliferative and anti-inflammatory properties. Etanercept inhibits tumor necrosis factor, which is involved in the inflammatory process, and is given subcutaneously twice a week. Low-dose methotrexate (MTX) or gold therapy is given to induce disease remission. NSAIDs such as aspirin and ibuprofen are prescribed for pain and stiffness, although they do not slow the disease process. Prednisone is a corticosteroid used to induce disease remission. Many of these medications have potentially serious side effects that must be monitored carefully.

Complementary therapies that may help decrease inflammation or pain include capsaicin cream, fish oil, magnetic therapy, and antioxidants such as vitamin C, vitamin E, and beta carotene (see Chapter 4).

HEAT AND COLD. Heat applications or hot showers help decrease joint stiffness and make exercise easier for the patient. For acutely inflamed, or “hot,” joints, cold applications are preferred. As for patients with osteoarthritis, a program that balances rest and exercise later in the day is most beneficial for the patient.

SURGERY. If nonsurgical approaches are not effective in relieving arthritic pain, the patient may have a total joint replacement (discussed later). In general, patients with RA who have surgery are not as successful when compared with patients with osteoarthritis. The presence of a systemic disease predisposes patients with RA to more postoperative complications.

Nursing Process for the Patient with Rheumatoid Arthritis

ASSESSMENT/DATA COLLECTION. A thorough history and physical assessment are needed for the patient with RA because the disease can involve every system of the body. In addition to assessing physical signs and symptoms, assess the patient for psychosocial, functional, and vocational needs.

After having the disease for approximately 15 years, fewer than half of RA patients are totally independent in their ADLs. These limitations may place a burden on family members, who must be included in the care of the patient with RA. Many patients with the disease are young or middle aged. RA can impair their ability to work, depending on the type of job they have. The health-care team assesses the patient’s work skills to determine the need for changes in the workplace or a need to train for a new type of work.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Acute pain related to chronic disease process

EXPECTED OUTCOME: Patient will report relief from pain.

- Provide analgesics as ordered *to relieve pain.*
- Ensure proper positioning and alignment *to minimize discomfort and promote pain relief.*
- Teach alternative measure of pain relief to maximize means *to relieve pain.*
- Encourage maintenance of normal weight *to prevent excess wear and tear of joints.*

Disturbed body image related to changes resulting from disease process

EXPECTED OUTCOME: Patient will come to accept alterations in body.

- Encourage patient to discuss feelings and concerns *to provide the nurse with an understanding of what the patient is experiencing.*
- Provide information and clarify misconceptions *to ensure that the patient is aware of the expected problems and concerns.*
- Encourage socialization *to improve on the person’s perceptions of how they “look” to others.*
- Encourage sharing with support groups *so that the patient discusses their concerns with others experiencing the same problems.*

Fatigue related to chronic pain and suffering and difficulty with mobilization

EXPECTED OUTCOME: Patient will have decreased episodes of fatigue.

- Ensure regular rest periods throughout the day *to not overexert the patient.*
- Assist as required *to minimize the amount of energy the patient needs to use.*
- Teach patient the need to delegate *to ensure they do not overexert.*
- Teach energy conservation techniques *to reduce workload.*

Self-care deficit related to chronic degenerative disease process

EXPECTED OUTCOME: Patient will be able to provide own self-care.

- Encourage independence *to decrease feelings of despair about being unable to care for self.*
- Assist when necessary *to minimize frustration when patient unable to perform self-care function.*
- Teach patient about assistive devices to help with ADL *to promote self-care.*
- Collaborate with interdisciplinary team such as home care, occupational or physiotherapy *to acquire assistive devices and use alternate resources.*

Impaired physical mobility related to chronic inflammation of joints

EXPECTED OUTCOME: Patient will have improved physical mobility.

- Administer analgesics and anti-inflammatory agents *to reduce pain and increase mobility*
- Administer heat and cold therapy *to aid in joint function and movement.*
- Encourage continued mobilization *to minimize complications of immobility.*
- Collaborate with other disciplines *to help with maintaining mobility.*

EVALUATION. The outcome is met if patient reports pain is within acceptable levels on pain assessment scale of

0 to 10, demonstrates acceptance of changes in body image, has decreased episodes of fatigue, is able to provide own self-care, and demonstrates improved physical mobility.

CRITICAL THINKING

Mrs. Summers

■ Mrs. Summers is a 48-year-old nurse who has had upper extremity joint pain and swelling for about 4 years. She was recently diagnosed with rheumatoid arthritis (RA) but has no systemic involvement other than extreme fatigue at this time. She is concerned that she will have to give up providing direct patient care on a busy medical unit in the local hospital.

1. What questions might you ask her at this time about her illness?
2. What should you teach her about pain management?

Suggested answers at end of chapter.

Patient Education

The patient with RA needs extensive patient education regarding the disease process, medication management, and the comprehensive plan of care. Many fads and myths published in popular tabloids are available, and some publicized “cures” can actually be harmful to the patient.

In collaboration with health team members, help the patient plan a daily schedule that balances rest and exercise. Child care responsibilities and other day-to-day activities need to be scheduled. A vocational counselor may be necessary for job training if the patient needs to pursue a different occupation. Patients who are unable to work may be able to qualify for disability benefits through the Social Security program.

Inform the patient about community resources. For example, the local chapter of the Arthritis Foundation provides support groups, information, and other resources for patients with RA and other types of connective tissue disorders. (See Web link in section on osteoarthritis.)

MUSCULOSKELETAL SURGERY

Some health problems cannot be managed conservatively and require surgery. Other disorders are initially treated medically but may need surgery if treatment is unsuccessful. The most common surgeries are discussed here.

Total Joint Replacement

Total joint replacement (TJR) is most often performed for patients who have some type of connective tissue disease in which their joints become severely deteriorated. TJR may also be done for patients on long-term steroid therapy, such as patients with SLE or asthma. Long-term use of steroids, trauma, and complications of joint replacement can cause

avascular necrosis (AVN), a condition in which bone tissue dies (usually the femoral head) as a result of impaired blood supply. Advanced AVN is very painful and usually does not respond to conservative pain relief measures. The primary goal of TJR is to relieve severe chronic pain and improve ability to carry out ADLs when no other treatment is successful.

The most common surgeries are the total hip replacement (THR) and total knee replacement (TKR), although any synovial joint can be replaced. Another term used for joint replacement is *arthroplasty*. The replacement devices, sometimes referred to as prostheses, are made of metal, ceramic, plastic, or a combination of these materials. Some prostheses are held in place by cement. Others are secured by the patient’s bone as it grafts and connects to the prosthesis. Bone substitutes, also called biologics, are being used more often when the amount of available bone is insufficient to provide a good base of support for the replacement devices. Bone glues and fillers such as Osteoset or Pro Osteon and bone stimulants such as Allomatrix help in providing better support for the prosthetics used.

Total Hip Replacement

A THR uses a two-piece device consisting of an acetabular cup that is inserted into the pelvic acetabulum and a femoral component that is inserted into the femur to replace the femoral head and neck (Fig. 46.16). The average life span of a cemented THR is about 10 years. Noncemented prostheses used in younger patients may last longer.

PREOPERATIVE CARE. Total joint surgery is an elective procedure and scheduled far enough in advance to allow ample time for preoperative teaching and screening. A case

FIGURE 46.16 Total hip arthroplasty of arthritic right hip. (From McKinnis, LN: *Fundamentals of Orthopedic Radiology*. F.A. Davis, Philadelphia, 1997, with permission.)

avascular necrosis: a—without + vascular—blood + necrosis—death

manager (registered nurse or social worker) may be assigned to assess the patient's needs and the support systems that are available postoperatively. It is important for the patient to have a caregiver who can assist the patient after surgery.

In addition to the normal preparations for preoperative care (see Chapter 11), the orthopedic patient requires some preoperative baseline assessments. The nurse assesses the neurovascular status (circulation, sensation, mobility) of the extremity to be operated on as well as the patient's level of pain preoperatively. Preoperative mobility can also be assessed to help determine the effectiveness of the surgery postoperatively. The patient may require an IV to be started as the surgeon frequently orders a prophylactic antibiotic preoperatively to minimize the chance of an infection (especially osteomyelitis) developing. The patient is taught about the surgery and what to expect postoperatively. Some patients are scheduled to meet with the physical therapist to learn postoperative exercises and how to ambulate with a walker or crutches. Some institutions have total joint education programs, which are a series of educational sessions designed to make the recovery process smoother and more effective for the patient.

Depending on the amount of blood loss during surgery, some patients receive postoperative blood transfusions. Because total joint surgery is an elective procedure, the physician may order autologous blood donation by the patient. The patient donates blood before surgery per guidelines (e.g., time frames specified, hemoglobin levels normal), which is then available for reinfusion postoperatively as needed. This predeposited blood donation is cost effective and reassures patients who are concerned about receiving blood from other donors.

Patients are often admitted to the hospital the morning of surgery. The patient's length of stay is about 3 to 5 days, depending on the patient's age and progress. Some hospitals have joint camp programs where a group of patients undergoing joint replacements are admitted on the same day, undergo their surgery, and then recover together during activities such as physical therapy with each other for support. Patients have been known to recover more easily in this type of supportive environment and are typically discharged in about 3 days.

POSTOPERATIVE CARE. In addition to providing the general postoperative care that all patients undergoing general or epidural anesthesia require, plan and implement interventions to help prevent the following common complications of THR (see Chapter 11).

Hip Dislocation. The most common postoperative complication for the patient having a THR is subluxation (partial dislocation) or total dislocation. Dislocation occurs when the femoral component becomes dislodged from the acetabular cup. Frequently, if a dislocation occurs, there is an audible "pop" followed by immediate pain in the affected hip. In addition to the pain, the patient experiences shortening of the surgical leg, and possibly rotation of the surgical leg. If any of these signs and symptoms occur, notify the

surgeon immediately and keep the patient in bed. Additional analgesics may be ordered until the patient can be taken to the operating room. Under anesthesia, the surgeon manipulates the hip back into alignment and immobilizes the leg until healing occurs.

Prevention of dislocation is a major nursing responsibility. Correct positioning of the surgical leg is critical. The primary goals are to prevent hip adduction (across the body's midline) and hyperflexion (bending forward more than 90 degrees). To accomplish these goals, place the patient returning from the postanesthetic care unit (PACU) in a supine position with the head slightly elevated. A trapezoid-shaped abduction pillow (sometimes called a triangular pillow), splint, wedge, or regular bed pillows may be used between the legs to prevent adduction (Fig. 46.17). The patient can be turned to either side (even the operative side if the patient is comfortable enough) or to the side specified by the physician, with hip adduction avoided. The patient is turned with the abductor pillow or three regular pillows (one proximal and two distal) in place between the legs. When turning, it is important to turn the hip and legs simultaneously to minimize the chance of dislocation. Support for the leg and abductor pillow is also required when the patient is turned on his or her side to decrease the chance of dislocation.

FIGURE 46.17 Abductor pillow is used to prevent adduction and hip dislocation.

FIGURE 46.18 Hip flexion after total hip replacement should be 90 degrees or less to prevent dislocation.

To prevent hyperflexion, some surgeons initially allow the patient to sit at no more than a 60-degree angle in a reclining chair. The patient's position is progressed to 90 degrees, the maximum allowed to prevent hyperflexion (Fig. 46.18). While the patient is on bedrest, the use of a fracture (also called a slipper) pan when toileting the patient is recommended to minimize discomfort and to prevent the possibility of dislocation.

Skin Breakdown. Because most patients having total joint replacements are older, skin breakdown is a major concern as part of postoperative care. Turning the patient at least every 2 hours (more often if high risk) and keeping the heels off the bed are the key nursing interventions to prevent pressure ulcers. Heels, elbows, and the sacrum are vulnerable and can break down in 24 hours. A reddened area that does not blanch is a stage 1 pressure ulcer and must be treated aggressively to prevent progression to other stages. Prophylactic application of DuoDerm dressings, as well as heel protectors help to decrease the chance of skin breakdown of the heels.

Patients who are incontinent must be kept clean and dry. Toileting the patient every 2 hours and using a protective barrier cream also help prevent skin problems related to incontinence. Adequate diet and hydration are also important to prevent skin breakdown. Box 46.7 (Nursing Interventions Following Total Hip Replacement) describes additional nursing interventions that meet the needs of postoperative patients recovering from THR.

Infection. Orthopedic surgery patients are at an increased risk for infection because of the nature of the surgery and because the patients are often older adults with an already increased risk for postoperative complications. In addition to the preoperative prophylactic intravenous antibiotic, the surgeon can administer antibiotics intraoperatively, and may continue antibiotics for 24 hours postoperatively.

Depending on the institution's policies, the surgeon may or may not remove the initial dressing. Regardless of who removes the dressing, meticulous aseptic care of the surgical wound is important to minimize the chance of infection. Care of the incision, as well as exit sites for drains,

needs to be performed aseptically. When doing dressing changes, observe the incision routinely for signs and symptoms of infection (redness, swelling, warmth, odor, pain, drainage [yellow, green, or brown tinged]). Monitor temperature carefully. An older patient may not experience a fever but may appear confused instead.

Infection may not occur during the patient's hospital stay but can occur 1 or more years later. If this late infection

Box 46.7

Nursing Interventions Following Total Hip Replacement

- Ensure hip that the hip is not allowed to become adducted. Use triangular (abductor) pillow or pillows.
- Turning patient requires abductor pillow to remain in place. Turn patient as a whole, not allowing hip or legs to fall forward or backward. Use pillows to support raised limb.
- Monitor for skin integrity of opposite heel (often used to help mobilize in bed so is prone to friction and pressure sores. Apply protective devices for heels.
- Ensure limb remains in abduction when moving patient out of bed.
- Prevent postoperative pneumonia by encouraging deep breathing and coughing and use of incentive spirometer.
- Pain control is of the utmost importance. Provide regularly scheduled analgesics and ensure breakthrough analgesia is provided prn. Decreased pain allows for earlier mobilization and less complications of immobility.
- Monitor level of consciousness and orientation. Many older patients have alterations in their mental status after surgery due to anaesthetics, analgesics, blood loss, and environmental changes.

does not respond to antibiotics, the prosthesis may be removed and replaced. To prevent infection, antibiotics are often instilled directly into the wound during surgery as beads, as part of the cement mixture, or as an irrigating solution.

CRITICAL THINKING

Mrs. Jacobs

■ Mrs. Jacob's is 78 years old and has had a left THR 3 days ago. When changing her dressing you notice a purulent discharge. Cefaclor (Ceclor) 500 mg PO q8hr is ordered. It is available as a 375-mg/5-mL suspension. How many milliliters should Mrs. Jacobs be given?

Suggested answers at end of chapter.

Bleeding. Like any surgical wound, some bleeding is expected. In joint replacement surgery, up to two-thirds of the blood loss can occur postoperatively. The patient often has at least one surgical drain (e.g., Hemovac or Jackson-Pratt) that is emptied every 8 to 12 hours or as required for the first day or two. Monitor the dressing for signs of bleeding and reinforce the dressing if needed. On the second or third postoperative day, the patient's hemoglobin and hematocrit may decrease to the point that blood transfusion is needed. The patient may receive the preoperatively donated autologous blood or may receive salvaged operative or postoperative blood. Using a cell saver (sometimes called an orthopat, which stands for orthopedic patient autotransfusion) during surgery, about 50% of blood that is lost can be recovered and saved for reinfusion into the same patient. Postoperatively, blood can be replaced by collecting shed blood via suction into a reservoir, then filtering and reinfusing it within 6 hours of collection. Monitoring for blood loss and signs of shock is an important nursing consideration.

Neurovascular Compromise. For any musculoskeletal surgery or injury, frequent neurovascular checks for circulation (color, warmth, pulses), sensation, and movement are performed distal to the surgical procedure or injury (and compared to the unaffected side) when vital signs are checked. The procedure and significance of these assessments are described in Chapter 45.

Pain. Because patients undergoing THR are in chronic pain preoperatively, some patients report that they have less pain postoperatively than they had before surgery. Initially pain is typically managed by epidural analgesia, patient-controlled analgesia (PCA), or injections with analgesics. After the first postoperative day, the patient usually progresses to oral opioid analgesia with a drug (such as Percocet or Tylenol with codeine). Proper positioning also helps minimize surgical discomfort.

Ambulation. Care for the patient having a THR is interdisciplinary. The patient usually gets out of bed and into a chair the night of surgery or early the next day. Ensure that the patient does not adduct or hyperflex the surgical hip during transfer to the chair. The chair should have a straight back and be high enough to prevent excessive flexion. The toilet seat should also be raised for the same purpose. Permitted amounts of weight bearing depend on the type of prosthesis that is used. In general, weight bearing as tolerated or full weight bearing is used for cemented prostheses. If an uncemented device is used, the patient may be restricted to toe-touch, or partial weight bearing, or featherweight bearing.

Early ambulation helps prevent postoperative complications such as atelectasis and deep vein thrombosis (DVT). The physical therapist works with the patient for ambulation with a walker or crutches. Crutches are reserved for young patients. After 4 to 6 weeks, the patient is progressed to a cane. The patient does not need an ambulatory device if there is no limping.

Thromboembolic Complications. Patients having hip surgery are at greatest risk for DVT or pulmonary embolus (PE). Older adult patients are especially at risk because of compromised circulation. Obese patients and those with a history of thromboembolic (TE) problems are also at an exceptionally high risk for potentially fatal problems.

Thigh-high elastic stockings and sequential compression devices (SCDs) may be used while the patient is hospitalized (see Chapter 11). The surgeon orders an anticoagulant medication to help prevent clot formation, including subcutaneous low molecular weight heparin (such as enoxaparin [Lovenox], dalteparin [Fragmin]) or oral warfarin (Coumadin). Occasionally, heparin is still used, and if so, it is important to monitor for heparin-induced thrombocytopenia, which can occur as early as 3 days after the start of heparin therapy. The ordered daily dosage of these drugs is determined by coagulation studies. Partial thromboplastin times are monitored for patients on heparin. International normalized ratio (INR) reported with prothrombin time is monitored when giving warfarin.

NURSING CARE TIP

When giving enoxaparin or dalteparin, follow manufacturer's instructions for administration. The air bubble should not be removed from the pre-filled syringe before administration to ensure the whole dose is given.

Because most DVTs occur in the lower extremities, leg exercises are started in the immediate postoperative period and continued until the patient is fully ambulatory. The physical therapist teaches the patient how to perform foot and ankle exercises such as heel pumping, foot circles, and straight-leg raises (SLRs). The patient also performs quadri-

ceps-setting exercises (quad sets) by straightening the legs and pushing the back of the knees toward the bed. Remind the patient to do several sets of these exercises each day to improve muscle tone and to help prevent blood clots in the leg.

Self-Care. Because of restrictions in hip flexion, patients are instructed not to bend forward to tie shoes or put on pants. The occupational therapist provides adaptive or assistive devices, such as dressing sticks and long-handled shoe horns, to assist the patient in being independent in activities of daily living.

If the patient is medically stable, he or she is discharged home for rehabilitation or to a subacute care unit, rehabilitation unit, or nursing home for short-term rehabilitation, lasting a week or less. The rehabilitation program that began in the hospital continues after discharge until the patient is independent in ambulation and self-care.

Before hospital discharge, the interdisciplinary team provides patient education for home care, including hip precautions that need to be used until the surgeon reevaluates the patient at the 6- to 8-week follow-up visit (Box 46.8 Educating the Patient After Total Hip Replacement and Home Health Hints).

Total Knee Replacement

The knee is the second most commonly replaced joint. It requires three components for replacement: a femoral component, a tibial component, and a patellar button (Fig. 46.19).

Care for the patient with a TKR is similar to that required for a patient with a hip replacement except dislocation and, therefore, preventive positioning are not a concern. Postoperatively, there is usually a bulky dressing along with the normal surgical drain in place. Once again, it is impor-

FIGURE 46.19 Knee joint replacement. (From Richardson, JK, and Iglarsh, ZA: *Clinical Orthopaedic Physical Therapy*. Saunders, Philadelphia, 1994, p 651, with permission.)

tant to monitor for bleeding along with the normal postoperative interventions. Although precautions to prevent dislocation are not applicable for the patient with a knee replacement, other medical complications described for THR, such as deep vein thrombosis, may be seen in the patient undergoing knee replacement (see Box 46.7 Nursing Interventions Following Total Hip Replacement).

Postoperatively, a continuous passive motion machine (CPM) may be used for the operative leg. This motorized machine has a flexible extremity rest (for either the leg or arm) that glides back and forth on a track (Fig. 46.20). The CPM is set at the degree of flexion and speed ordered by the physician and is usually begun in the PACU. The CPM can be applied by a nurse, physical therapist, or technician and is used either intermittently up to 8 to 12 hours a day or continuously while the patient is in bed. The purpose of CPM is to keep the knee joint mobile. Nursing care associated with the use of the machine is summarized in Box 46.9 Application of a Continuous Passive Motion (CPM) Machine. A postoperative knee splint may be worn until straight leg raises (indicating leg strength has returned) can be done by the patient.

Amputation

Simply defined, an amputation is the removal of a body part, which can be as limited as removing part of a finger or as devastating as removing nearly half the body. Amputations may be surgical as a result of disease or traumatic as a result of an accident. Surgical amputations are the most common type and are most often scheduled as elective surgery.

Box 46.8

Educating the Patient After Total Hip Replacement

Safety Measures to Prevent Hip Dislocation

- Keep legs abducted (away from center of body) with pillows.
- Bending at the waist (hip) cannot be greater than 90 degrees.
- Getting up from a sitting position requires pushing straight up off of the chair or bed without leaning forward.
- Walkers can be used to assist walking.
- Physiotherapy and occupational therapy can provide equipment that aids in putting on socks and shoes.
- Sleep with pillows between legs until physician states otherwise.
- Sexual activity can be started when tolerated provided hip safety measures followed.

FIGURE 46.20 A continuous passive motion machine can be used following knee or elbow (as shown here) joint replacement to increase joint mobility and enhance recovery. The CPM machine slowly moves along the track at the set degree of flexion and speed.

SURGICAL AMPUTATIONS. The main indication for surgical amputations is ischemia from peripheral vascular disease in the older adult. The rate of lower extremity amputation is much greater in the diabetic patient than in the nondiabetic patient (see discussion of diabetes in Chapter 40). Surgical amputations may also be done for bone tumors, thermal injuries (frostbite, electric shock), crushing injuries, congenital problems, or infections.

TRAUMATIC AMPUTATIONS. Traumatic amputations occur from accidents, often in young and middle-aged adults.

Box 46.9

Application of a Continuous Passive Motion (CPM) Machine

- Position joint (knee) over flexion point of machine.
- Padding (e.g., sheepskin) is particularly important at proximal end near gluteal fold.
- Ensure speed and angle settings are correct and monitored according to facility policy. A minimum of every shift is required.
- The patient is provided the controls to stop the machine prn unless he or she is mentally incompetent to do so. If unable to self monitor, ensure patient is checked frequently.
- Assess how well patient tolerates the speed and angle of movement.
- Speed and angle adjustments are determined by agency policy, physiotherapist, or the physician.
- Ideal utilization is three times a day for at least 1 hour per session.

Industrial machinery, motor vehicles, lawn mowers, chain saws, and snow blowers are common causes of accidental amputation.

Because in these patients the amputated part is usually healthy, attempts at **replantation** may occur. One of the most common replantations is one or more fingers. The current recommendation for prehospital care of the severed body part is to wrap it in a cool, slightly moist cloth and place it in a sealed plastic bag. The bag may be submerged in cold water until the body part is transported to the hospital.

The surgical procedure is performed by specialists who operate using a microscope. Nerves, vessels, and muscle must be reattached. These procedures are generally performed at large tertiary care centers that have specialty practitioners and equipment for replantation.

LEVELS OF AMPUTATION. The most common surgical amputation is part of the lower extremity. The loss of any or all of the small toes presents little problem. However, the loss of the great toe is more important because balance and gait are affected. Midfoot amputations are preferred over below-the-knee amputations (BKAs) for peripheral vascular disease. For the Syme amputation, the surgeon removes most of the foot but leaves the ankle intact for ambulation and weight bearing.

If the lower leg is amputated, a BKA is preferred over an above-the-knee amputation (AKA) to preserve joint function. The higher the level of amputation, the more energy is required for ambulation. Hip disarticulation (removal through the hip joint) and **hemipelvectomy** (removal through part of the pelvis) are reserved for young patients who have cancer or severe trauma. Rarely, a hemipelvectomy (hemipelvectomy plus a translumbar amputation) is performed as a last resort for young patients with cancer. This radical surgery removes nearly half of the body and requires both bowel and urinary diversion surgeries (ostomies) as well.

Upper extremity amputations are usually more significant than lower extremity amputations and more often result from trauma. The arms and hands are necessary for performing activities of daily living. Early replacement with a prosthesis is crucial for the patient with an upper extremity amputation.

PREOPERATIVE CARE. Patients who are scheduled for elective amputations have the advantage of time for preoperative teaching, prosthesis fitting, and adjustment to the loss of part of their bodies. Preoperative teaching is started in the surgeon's office. Postoperative and rehabilitative care is reviewed with the patient and family or significant other. Those patients experiencing a traumatic amputation have no opportunity to prepare for the significant changes that will result from the accident. Preoperative care will not only involve physical needs being met but also significant psy-

replantation: re—again + plant—to plant + ation—process

hemipelvectomy: hemi—half + pelv—pelvis + ectomy—removal of

chological and emotional concerns will have to be addressed (this will also have to continue postoperatively).

Preoperatively, the patient should be referred to a certified prosthetist-orthotist (CPO) to begin plans for replacing the removed body part with a prosthesis.

Disturbed body image is a common nursing diagnosis for the patient having an amputation. If possible, it is helpful for the preoperative patient to meet with a rehabilitated amputee. Assess the patient's reaction to having an amputation with the expectation that the patient will experience many of the stages of loss and grieving. Support systems and coping mechanisms are identified that can help the patient through the surgery and postoperative period. Ensure that appropriate support is provided by other disciplines such as social work and clergy.

POSTOPERATIVE CARE. In addition to the general postoperative care, plan and implement interventions to help prevent postoperative complications (see Chapter 11).

Hemorrhage. When a patient loses part of the body, either by surgery or trauma, blood vessels are severed or damaged. The patient returns from surgery with a large pressure dressing that is secured with an elastic wrap. Assess the closest proximal pulse between the heart and the amputated body part for strength and compare findings with the nonsurgical extremity. Assess the bulky dressing for bloody drainage. If blood is on the dressing when the patient is admitted to the PACU or the surgical unit, circle, date, and time the area of drainage and closely monitor for enlargement. If bleeding continues, the surgeon is notified immediately. A tourniquet should be readily available in the event that severe hemorrhage occurs.

After the dressing is removed, observe for adequate perfusion to the skin flap at the end of the residual limb, referred to as the stump. The skin should be pink in a light-skinned patient and not discolored (lighter or darker than other skin pigmentation) in a dark-skinned patient. The residual limb should be warm but not hot.

Infection. Infection of the wound can be problematic, especially if the infection enters the bone (**osteomyelitis**). Inspect the wound for intense redness or drainage. Localized infections usually do not cause an increase in body temperature. If temperature is elevated, it could indicate a serious wound infection, a systemic infection, or some other type of infection. Traumatic amputations are at risk for developing infection due to the nature of the injury and the likelihood of exposure to environmental pathogens from the source of the amputation.

Pain. In addition to the usual incisional pain that is expected following a surgical procedure, phantom limb pain occurs in as many as 80% of all amputees (surgical or traumatic). The patient complains of severe pain where the removed body part was located. The pain may be

described as either intense burning, a crushing sensation, or cramping.

Phantom limb pain can be triggered by touching the residual limb, feeling fatigued, or experiencing emotional stress. It is reported that phantom limb pain can also be triggered by pressure or changes in the weather. Although it occurs most often in the immediate postoperative period, phantom limb pain may occur at any time during the first postoperative year or sometimes even years after the amputation. The pain may be mild to severe. The cause is not clear.

Never doubt that the patient is experiencing phantom limb pain. Treat the pain aggressively with medications and complementary therapies. The surgeon prescribes medication based on the type of pain sensation the patient experiences. For example, anticonvulsants, such as phenytoin (Dilantin), are used for knifelike pain. Beta-blocking agents, such as propranolol (Inderal), are appropriate for burning sensations, and gabapentin (Neurontin) or amitriptyline (Elavil) can be used for nerve pain. To complement traditional therapy, a number of therapies may be useful, including biofeedback, massage, imagery, hypnosis, acupuncture, acupressure, and distraction.

Mobility and Ambulation. To reduce surgical swelling, cold application may be ordered. Alternately, the residual limb may be elevated on a pillow for 24 hours or less. Continued use of a pillow for elevation can lead to flexion contractures, especially for patients with a BKA or an AKA. If the hip becomes contracted, using a prosthesis will not be possible because the patient will not be able to walk. Check the limb periodically to ensure that it lies completely flat on the bed. The patient should avoid positions of flexion such as sitting for long periods. If the patient is able, lying prone (on stomach) for 30 minutes four times daily helps prevent contracture.

Postoperative care of the patient experiencing an amputation is interdisciplinary, often requiring an extensive rehabilitation program in a subacute unit, nursing home, or on an ambulatory basis. The physical therapist teaches the patient muscle-strengthening exercises that help with ambulation and transfers and prevent flexion contractures. A trapeze and overhead bed frame aid in strengthening the upper extremities and help the patient move around in the bed.

Prosthesis. The residual limb must be prepared for wearing the prosthesis. A temporary prosthesis may be worn until the swelling subsides.

The residual limb is wrapped at least every 8 hours using an elastic wrap (such as an Ace wrap) in a figure-of-eight fashion (Fig. 46.21). It is important to perform neurovascular checks and assess the residual limb for infection and alterations in tissue integrity at each rewrapping. Begin with the most distal portion and proceed proximally until the bandage is secured to the most proximal joint. The bandage should be tighter at the distal end.

The prosthesis requires special care which the patient should be taught:

osteomyelitis: osteo—bone + myel—bone marrow + itis—
inflammation

FIGURE 46.21 Application of elastic wraps on an above-the-knee amputation helps mold the stump for a prosthesis.

- The prosthesis socket is cleaned with mild soap/water and dried.
- Clean inserts and liners regularly.
- Use garters to keep socks in place.
- Grease parts as instructed.

- Shoes are replaced when worn out with same height and type.

Lifestyle Adaptation. The patient may feel that life will be markedly changed as a result of the amputation. With the technological advances in prostheses, most patients who worked before surgery are able to return to their jobs after surgery. If the discharge planner or case manager thinks it is needed, a job analysis may be conducted by a vocational analyst or specialized case manager. Many patients with amputations are able to bowl, ski, hike, and experience all the recreational hobbies that they were able to do before surgery.

A supportive family or significant other is vital to help the patient adjust to body image change. Consider the need for a sexual counselor or psychologist if indicated. For any patient with an amputation, help the patient set realistic expectations.

For the patient who is not a candidate for a prosthesis, home adaptations for a wheelchair may be needed. The patient must have access to toileting facilities and areas necessary for self-care. Structural changes in the living environment may be necessary before the patient can be discharged from rehabilitation.

A small percentage of amputees return to their nursing home environment without prostheses. These patients need rehabilitation to ensure that they can be as independent as possible.

Home Health Hints

- Instruct the patient with rheumatoid arthritis to rest during acute inflammations and to stop activity if pain develops.
- If equipment or modifications to the home are needed following hospitalization for an orthopedic problem, it is best if they can be arranged or obtained before discharge. Equipment can include raised toilet seats, hand-held reachers, walkers, canes, wheelchairs, and hand rails.
- Physical and occupational therapy are usually ordered for the orthopedic patient discharged from the hospital. They can work with them to help with ambulation, activities of daily living, teaching them how to use assistive devices, and also obtaining the above listed assistive devices.
- Physical and/or occupational therapy can also be ordered to assist the patient regain strength following surgery. The home health nurse can work with the therapist to educate the patient on the prescribed exercises.
- Peak incidents of DVT after hip or knee surgery is highest by the fifth postoperative day and that risk persists for up to 12 weeks. Be alert for signs of DVT: warmth, redness, edema, Homans' sign, and protective behavior of the affected leg.
- Many times the patient is discharged home still requiring Lovenox injections to prevent DVT formation. The nurse needs to educate the patient on how to administer the injection in the abdomen. If the patient cannot do this and no one is available to teach him or her, the home health nurse can make visits in order to administer the injection.
- Home health nurses frequently remove staples and sutures. Always carry several of each type of removal device in your car. Remember staples, scissors, or other items that are "sharp" need to be disposed of in a bio-hazard container.
- Research has shown that pain or fear of falling may prevent a patient from moving and functioning to maximum potential. Encourage patients to wear flat, sturdy, rubber-soled shoes to prevent slipping, tripping, or turning an ankle.
- Encourage the patient to dispose of all throw rugs, unnecessary furniture, or other possible fall hazards in the home.
- Patients who use walkers can get pressure ulcers on their palms. One way to relieve the pressure is to wear padded cycling gloves that leave the fingers free.

- A patient on crutches can use the crutch to prop a casted leg or foot.
- Patients who are having a difficult time putting on antiembolism stockings can be instructed on an easy way of slipping them on. Using a plastic grocery bag,

instruct the patient to tie a knot on the closed end. Slip the bag over the foot, and then put the stocking on over the bag. Once the stocking is on over the heel, the patient or caregiver can pull the bag out using the knot that was tied.

REVIEW QUESTIONS

- The nurse is caring for a patient who just had a plaster cast applied. Which action should the nurse take to facilitate cast drying?
 - Cover the cast with blankets to provide extra warmth.
 - Turn the patient every 2 hours.
 - Increase the room temperature.
 - Apply a heating pad.
 - A patient with multiple fractures of the femur returns from surgery for surgical repair with an external fixation device in place. Which of the following nursing interventions would be appropriate to properly care for the pins inserted into the patient's leg?
 - Do not touch the pins.
 - Follow agency protocol for pin care.
 - Cleanse with hydrogen peroxide qid.
 - Loosen the screws holding the pins when cleaning.
- Multiple response item. Select all that apply.
- Which of the following actions can the nurse take to help prevent osteomyelitis for a patient with an open fracture?
 - Wash hands prior to dressing changes.
 - Wear a protective gown.
 - Wear a mask.
 - Wear goggles.
 - Wear sterile gloves to apply new dressing.
 - A patient is postmenopausal, has osteoporosis, has lost 2 inches of height, is thin, and has never exercised regularly. Which of these interventions should be included in the plan of care to prevent further bone loss?
 - Decrease participation in ADLs.
 - Decrease weight-bearing activities.
 - Encourage regular exercise.
 - Encourage weight gain.
 - A priority nursing diagnosis for the patient with Paget's disease includes which of the following?
 - Pain
 - Deficient knowledge
 - Excess fluid volume
 - Deficient fluid volume
 - Which of the following lab values would the nurse expect to be elevated in the patient with gout?
 - WBC
 - RBC
 - Uric acid
 - Ammonia
 - A butterfly rash is a classic symptom of which of the following disorders?
 - Lupus
 - Paget's disease
 - Rheumatoid arthritis
 - Osteosarcoma
 - A patient with osteoarthritis who had a right total knee replacement tells the nurse that her other knee is becoming painful. Which of these is the most appropriate instruction to help the patient preserve function of her left knee?
 - Reduce dietary purines.
 - Maintain ideal body weight.
 - Maintain normal uric acid levels.
 - Begin a jogging program.
 - A patient is scheduled for a right total hip replacement. The nurse should include which of the following postoperative leg positions in the preoperative teaching plan?
 - Maintain legs in adduction.
 - Maintain legs in abduction.
 - Maintain internal leg rotation.
 - Maintain more than 90-degree hip flexion.
 - Following amputation, which of these assessments should the nurse consider a priority to monitor for potential postoperative amputation complications?
 - Sacral edema
 - Level of consciousness
 - Stump dressings
 - Blood sugars
 - Which of the following findings would indicate a complication of a left fibula fracture?
 - The patient has an increased red blood cell count.
 - The patient has a decreased pulse, respiration and BP.
 - The patient has a decreased CD4 lymphocyte count.
 - The patient has an absent left pedal pulse.

12. A patient has a 36-hour-old fractured femur. He had morphine 5 mg intramuscularly 1 hour ago and is reporting severe unrelieved pain. Which nursing action is most appropriate?
- Give pain medication.
 - Adjust the traction.
 - Bivalve the cast.
 - Notify the physician.
13. A patient who had a total knee replacement is to receive Toradol 15 mg intramuscularly every 6 hours as needed for pain. The Toradol comes as 30 mg/mL. How many milliliters should the nurse give?
- _____ mL

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Mrs. Brown*

- When documenting, answer (either explicitly or implicitly by professional knowledge, in narrative or flow sheet format) what, why, when, where, who, and how for completeness.

What? Patient found on the floor lying on her left side, moaning and holding her leg, crying out with any movement.

Why = Fell

When = 10 a.m. on Date

Where = Dayroom

Who = Mrs. Brown (patient)

DATE 1000 Found on floor in dayroom lying on left side, moaning and holding left leg, crying out with any movement. Stated, "I fell. I think my leg is broken." Supervisor immediately notified, and paramedics and Dr. Jones called. Vital signs BP 150/84, P 100, R 20. Left leg shorter than right. Remained with patient and instructed not to move until paramedics arrive. Blankets applied and pillow placed under head for comfort. 1030 taken by ambulance to Grace Hospital. I. Smith, LPN

- The purpose of the traction is to reduce the muscle spasms that often accompany fractures and to increase comfort.
- Nursing responsibilities include the following:
 - Check neurovascular status frequently.
 - Check equipment, including rope, pulleys, knots, and weights at least every shift.
 - Do not allow the weights to rest on the floor.
 - Do not allow the traction to be impeded in any way.
 - Monitor the patient's skin often for areas of potential breakdown.
 - Remove and rewrap the elastic bandages, maintaining the traction, at least every shift. Provide skin care during this time.
 - Monitor area of the fracture for bruising and increased diameter of the limb.
 - Monitor for pain (using pain assessment scale) frequently.
 - Turn and position regularly.

- Her restlessness is most likely the result of pain. She may be unable to state that she is in pain. Evaluate behaviors such as restlessness and other nonverbal cues to evaluate pain management needs. She may also be experiencing shock as a result of blood loss from the fracture. Monitor vital signs, and check the area of the fracture for increased signs of bruising or swelling.

■ *Tommy Martin*

- Possible nursing diagnoses may include:
 - Pain related to injury and immobility
 - Potential for social isolation related to extended need for immobilization
 - Potential complications of inactivity: Constipation, impaired skin integrity related to extended need for traction
 - Deficient diversional activity related to extended need for bedrest
- Nursing interventions may include:
 - Monitor pain level, provide analgesics as ordered, assess pain relief. Assess position for comfort. Provide backrubs prn.
 - To address social isolation, encourage Tommy's friends to come visit; have an occupational therapist assess Tommy's needs; and alternate family visitors.
 - To avoid complications of inactivity, ensure Tommy's diet includes fiber and adequate hydration 1.5 to 2 L/day; give stool softener especially if on opioids as ordered; monitor daily defecation; ensure Tommy does the exercises recommended by occupational and physical therapists; reposition him every 2 to 3 hours; have trapeze set up for Tommy to use; use skin assessment tool to determine risk for skin breakdown; assess for pressure points and signs and symptoms of skin breakdown.
 - To alleviate boredom, encourage Tommy to listen to music; encourage visitors; and ensure access to hobbies, videos, books, magazines, and comics.

■ *Mr. Andrews*

1. Nursing assessments should include the following:
 - a. Perform a neurovascular check.
 - b. Perform a further pain assessment.
 - c. Ask Mr. Andrews to move his limb and see if the pain worsens.
 - d. Take his vital signs.
 - e. Assess for the 6 *Ps* (pulselessness, paresthesia, paralysis, pallor, pain, poikilothermia).
2. He might be experiencing compartment syndrome.
3. Interventions may include the following:
 - a. Bivalving cast
 - b. Possible fasciotomy

■ *Mr. Wolf*

4. Give one 2.5-mg tablet and five 5-mg tablets in the morning and evening. Although response number 3 could have been done, there is an increased chance of administering less than ordered when you have to split a tablet in half (especially if it is not scored). Also there are less pills to administer in response d which also provides a psychological advantage to the patient's thinking. Responses a and b do not follow the doctor's order of giving equal doses.

■ *Mr. Dennis*

1. "What is your typical day on the job like?"
 - a. "Do certain activities increase joint pain?"

- b. "When is your pain worse—after activity or after rest?"
 - c. "How long have you experienced joint pain?"
 - d. "What relieves the joint pain?"
2. Risk factors include that he is overweight, is in late middle age, and has a physically demanding job.
3. Other signs and symptoms may include bony nodules on his fingers (such as Heberden's nodes) and secondary inflammation causing joint swelling.

■ *Mrs. Summers*

1. Ask:
 - a. The nature of her pain
 - b. If it is worse after activity or rest
 - c. If she experiences joint stiffness and, if so, when

Follow the WHAT'S UP? method of pain assessment.

2. Teach her to do the following:
 - a. Balance rest with exercise.
 - b. Use ice for very hot, swollen joints.
 - c. Use heat to decrease stiffness.

■ *Mrs. Jacobs*

Unit Analysis Method:

$$\frac{500 \text{ mg}}{375 \text{ mg}} \left| \frac{5 \text{ mL}}{1} \right. = 6.7 \text{ mL}$$

QUESTIONS TO GUIDE YOUR READING

1. What is the normal anatomy of the nervous system?
2. What is the normal function of the nervous system?
3. What data should you collect when caring for a patient with a disorder of the nervous system?
4. What are the effects of aging on the nervous system?
5. What diagnostic tests are commonly performed to diagnose disorders of the nervous system?
6. What nursing care should you provide for patients undergoing each of the diagnostic tests for disorders of the nervous system?
7. What are common therapeutic measures used for patients with disorders of the nervous system?

REVIEW OF NORMAL ANATOMY AND PHYSIOLOGY

The nervous system is one of the body's control systems; by means of electrochemical impulses, we are able to detect changes and feel sensations, initiate appropriate responses to changes, and organize and store information for future use. Some of this is conscious activity, but much of it is reflexive in nature and happens without our awareness.

The nervous system has two divisions. The central nervous system (CNS) consists of the brain and spinal cord. The peripheral nervous system (PNS) consists of cranial nerves and spinal nerves, which include the nerves of the autonomic nervous system (ANS).

Nerve Tissue

Nerve tissue consists of neurons and specialized supporting cells called neuroglia. There are many kinds of neurons (nerve cells or nerve fibers), but they all have the same gen-

eral structure (Fig. 47.1). The cell body contains the nucleus and is essential for the continued life of the neuron. All neuron cell bodies are found in the brain, spinal cord, or within the trunk of the body; in these locations, most are protected by bone. A neuron may have one or many dendrites, which are extensions that carry impulses toward the cell body. A neuron has one axon that transmits impulses away from the cell body. It is the cell membrane of the dendrites, cell body, and axon that carries the electrical nerve impulse.

In the peripheral nervous system, axons and dendrites are wrapped in specialized neuroglial cells called Schwann cells. The concentric layers of cell membrane of a Schwann cell's plasma membrane form the myelin sheath. Myelin is a phospholipid that electrically insulates neurons from one another. The spaces between adjacent Schwann cells along an axon are called nodes of Ranvier (neurofibril nodes). Only the nodes of the neuron cell membrane depolarize when an electrical impulse is transmitted, which makes impulse conduction rapid. The nuclei and cytoplasm of Schwann cells are outside the myelin sheath and form the neurolemma. If a

TABLE 47.1 NEUROGLIA

Name	Function
<i>Oligodendrocytes</i>	Produce the myelin sheath to electrically insulate neurons of the CNS
<i>Microglia</i>	Capable of movement and phagocytosis of pathogens and damaged tissue
<i>Astrocytes</i>	Contribute to the blood-brain barrier, which prevents potentially toxic waste products in the blood from diffusing out into brain tissue; disadvantage: some useful medications cannot cross it, which becomes important during brain infection, inflammation, or other disease
<i>Ependyma</i>	Line the ventricles of the brain; many of the cells are ciliated; involved in the circulation of cerebrospinal fluid

peripheral nerve is severed and reattached, the individual axons may regrow through the tunnels provided by the neurolemma. In the central nervous system, the myelin sheaths (but not a neurolemma) are formed by oligodendrocytes, another type of neuroglial cell. See Table 47.1 for the names and functions of the other neuroglial cells.

Synapses

When the axon of a neuron must transmit an impulse to the dendrite or cell body of another neuron, the impulse must cross a small gap called a synapse. An electrical impulse is incapable of crossing this microscopic space, so at synapses impulse transmission becomes chemical. The end of the axon (the presynaptic neuron) is called the synaptic end bulb and contains a chemical neurotransmitter that is released into the synapse by the arrival of the electrical impulse. The neurotransmitter diffuses across the synapse and combines with specific receptor sites on the postsynaptic membrane

(Fig. 47.2). At excitatory synapses, the neurotransmitter makes the postsynaptic membrane more permeable to sodium ions, which rush into the cell, initiating an electrical impulse on the membrane of the postsynaptic neuron. The neurotransmitter is then inactivated to prevent continuous impulses. For example, the neurotransmitter acetylcholine is inactivated by the chemical called acetylcholinesterase; each transmitter has its own specific inactivator.

Some synapses are inhibitory synapses in that the neurotransmitter makes the postsynaptic membrane more permeable to potassium ions, which leave the cell and make the membrane resistant to the electrical charge required for an impulse. Thus, the electrical impulse is stopped. Inhibitory synapses are important for things such as slowing the heart rate or balancing the excitatory impulses transmitted to skeletal muscles, which prevents excessive contraction and is important for coordination.

At chemical synapses, impulse transmission is one-way only because the neurotransmitter is released only by the presynaptic neuron; the impulse cannot go backward. This is important for the normal activity of the functional types of neurons. The relative complexity of synapses also makes them a potential target for the actions of medications.

Types of Neurons

A useful classification of neurons according to their function: a neuron is either a sensory neuron, a motor neuron, or an interneuron. Sensory (afferent) neurons transmit impulses from receptors to the central nervous system. Receptors are specialized to detect external or internal changes and then generate electrical impulses. Sensory neurons from receptors in the skin, skeletal muscles, and joints are called somatic; those from receptors in internal organs are called visceral sensory neurons.

Motor (efferent) neurons transmit impulses from the central nervous system to effectors—that is, muscles and

FIGURE 47.2 Structure of a synapse, and the effect of a neurotransmitter such as acetylcholine. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed. 5. FA. Davis, Philadelphia, 2007, with permission.)

glands. Motor neurons to skeletal muscle are called somatic; those to smooth muscle, cardiac muscle, and glands are called visceral. Sensory and motor neurons make up the peripheral nervous system. Visceral motor neurons form the autonomic nervous system, a specialized part of the PNS.

Interneurons are found entirely within the central nervous system. Each is specialized to transmit sensory or motor impulses or to integrate these functions. Such integration is involved in thinking and learning.

LEARNING TIP

To remember the difference between afferent and efferent, try these clues:

- Afferent: A is for affect or sense.
- Efferent: E is for effect (action).
- Or, think of the alphabet—A before E: You have to feel or sense (afferent) a stimulus before you can take action (efferent).

Nerves and Nerve Tracts

A nerve is a group of peripheral axons, dendrites, or both, with blood vessels and connective tissue. Most peripheral nerves are mixed; that is, they contain both sensory and motor neurons. An example of a purely sensory nerve is the optic nerve for vision; the autonomic nerves are purely motor nerves.

A nerve tract is a group of thickly myelinated neurons within the central nervous system; such tracts are often called white matter because the myelin sheaths of the individual neurons are white. A nerve tract within the spinal cord carries either sensory or motor impulses; those within the brain may have sensory, motor, or integrative functions.

Nerve Impulse

A nerve impulse, which may also be called an action potential, is an electrical change brought about by the movement of ions across the neuron cell membrane. When a neuron is not carrying an impulse, it is in a state of polarization with a positive charge outside the membrane and a relatively negative charge inside the membrane. Sodium ions are more abundant outside the cell, and potassium and negative ions are more abundant inside the cell. A stimulus makes the membrane very permeable to sodium ions, which rush into the cell, making the inside positive and the outside relatively negative. This reversal of charges is called depolarization and spreads from the point of the stimulus along the entire neuron membrane.

Immediately following depolarization, the membrane becomes very permeable to potassium ions, which rush out of the cell. This is called repolarization and restores the positive charge outside and the negative charge inside. The sodium and potassium pumps return the sodium ions back outside and the potassium ions inside, and the neuron is polarized again and ready to respond to another stimulus.

A neuron is capable of transmitting hundreds of impulses per second, and at speeds of many meters per second.

Spinal Cord

The spinal cord transmits impulses to and from the brain and is the integrating center for the spinal cord reflexes. The spinal cord is within the vertebral canal formed by the vertebrae and extends from the foramen magnum of the occipital bone to the intervertebral disk between the first and second lumbar vertebrae. The spinal nerves emerge from the intervertebral foramina.

In cross section, the spinal cord is oval shaped; internally it has an H-shaped mass of gray matter surrounded by white matter (Fig. 47.3). The gray matter is where the cell bodies of motor neurons and interneurons are located. The white matter is the myelinated axons. These nerve fibers are arranged in tracts based on their functions; ascending tracts transmit sensory impulses to the brain, and descending tracts transmit motor impulses from the brain to motor neurons. The central canal of the spinal cord is a small tunnel that is continuous with the ventricles of the brain; it contains cerebrospinal fluid (CSF).

Spinal Nerves

There are 31 pairs of spinal nerves, named according to their respective vertebrae: 8 cervical pairs, 12 thoracic pairs, 5 lumbar pairs, 5 sacral pairs, and 1 very small coccygeal pair. These nerves are often referred to by letter and number: the second cervical nerve is C2, the tenth thoracic is T10, and so on.

In general, the cervical nerves supply the back of the head; the neck, shoulders, and arms; and the diaphragm (the phrenic nerves). The first and second thoracic nerves also contribute to peripheral nerves in the arms. The remaining thoracic nerves supply the trunk of the body. The lumbar and sacral nerves supply the hips, pelvic cavity, and legs. The small coccygeal pair (Co1) supplies the area around the coccyx.

Each spinal nerve has two roots, which are neurons entering or leaving the spinal cord. The dorsal root is made of sensory neurons that carry impulses into the spinal cord. The dorsal root ganglion is an enlargement of this root that contains the cell bodies of these sensory neurons. The ventral root is the motor root; it is made of motor neurons that carry impulses from the spinal cord to muscles or glands (their cell bodies are in the gray matter of the spinal cord). When the two roots merge, the nerve thus formed is a mixed nerve.

Spinal Cord Reflexes

A reflex is an involuntary, predictable response to a stimulus, an automatic reaction triggered by a specific change. Spinal cord reflexes are those that do not depend directly on the brain, although the brain may inhibit or enhance them.

REFLEX ARC. A reflex arc is the pathway nerve impulses travel when a reflex is elicited. There are five parts:

FIGURE 47.3 Spinal cord in cross section, with nerve roots and meninges. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed. 4. FA. Davis, Philadelphia, 2003, p 160, with permission.)

1. Receptors detect a change (the stimulus) and generate impulses.
2. Sensory neurons transmit impulses from receptors to the central nervous system (CNS).
3. The CNS contains one or more synapses and the interneurons that may be part of the pathway.
4. Motor neurons transmit impulses from the CNS to an effector.
5. The effector performs its characteristic action.

The spinal cord reflexes include stretch reflexes and flexor reflexes. In a stretch reflex, a muscle that is stretched automatically contracts; an example is the familiar patellar, or knee-jerk, reflex, but all skeletal muscles have such a reflex. The purpose of these reflexes is to keep us upright (because gravity exerts a constant pull on the body) without our having to think about it. They also avoid possible injury from overstretching a muscle. Flexor reflexes may also be called withdrawal reflexes; the stimulus is something painful and the response is to pull away from it. Again, this occurs without the need for conscious thought; the brain is not directly involved.

The clinical testing of certain spinal cord reflexes provides a way to assess the functioning of their reflex arcs. For example, if the patellar reflex were absent, the problem might be in the quadriceps femoris muscle, the femoral nerve, or the spinal cord itself. If the reflex is present, how-

ever, it indicates that all parts of the reflex arc are functioning normally.

Brain

The brain consists of many parts that function as an integrated whole. The major parts are the medulla, pons, and midbrain (the brainstem); the cerebellum; the hypothalamus and thalamus; and the cerebrum (Fig. 47.4).

Ventricles

The ventricles are four cavities within the brain: two lateral ventricles are located within the cerebral hemispheres, the third ventricle lies midline within the thalamus, and the fourth ventricle is midline between the brainstem and cerebellum. Each ventricle contains a capillary network called a choroid plexus, which forms cerebrospinal fluid from blood plasma.

Medulla

The medulla is just above the spinal cord and extends to the pons. It regulates our most vital functions. Within the medulla are cardiac centers that regulate heart rate, respiratory centers that regulate breathing, and vasomotor centers that regulate the diameter of blood vessels and therefore blood pressure. Also in the medulla are reflex centers for coughing, sneezing, swallowing, and vomiting.

FIGURE 47.4 The brain's mid-sagittal section; medial surface of the right cerebral hemisphere. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed. 4. F.A. Davis, Philadelphia, 2003, p 167, with permission.)

Pons

The pons is anterior to the cerebellum and superior to the medulla. Within the pons are two respiratory centers that work with those in the medulla to produce a normal breathing rhythm.

Midbrain

The midbrain extends from the pons to the hypothalamus and encloses the cerebral aqueduct, a tunnel that connects the third and fourth ventricles. Primarily a reflex center, the midbrain regulates visual reflexes (coordinated movement of the eyes), auditory reflexes (turning the ear toward a sound), and righting reflexes that keep the head upright and contribute to balance.

Cerebellum

The cerebellum is posterior to the medulla and pons, separated from them by the fourth ventricle; it is overlapped by the occipital lobes of the cerebrum. The functions of the cerebellum are concerned with the involuntary aspects of voluntary movement: coordination, the appropriate direction and endpoint of movements, and the maintenance of posture and balance or equilibrium. For the maintenance of balance, the cerebellum (and midbrain) uses sensory information provided by the receptors in the inner ear that detect movement and changes in position of the head.

Hypothalamus

The hypothalamus is located above the pituitary gland and below the thalamus. It has many diverse functions:

- Production of antidiuretic hormone (ADH) and oxytocin; these hormones are then stored in the posterior pituitary gland. ADH increases the reabsorption of water by the kidneys and thus helps maintain

blood volume. Oxytocin causes contractions of the myometrium of the uterus to bring about labor and delivery.

- Production of releasing hormones that stimulate secretion of the hormones of the anterior pituitary gland. An example is growth hormone–releasing hormone (GHRH), which stimulates the anterior pituitary to secrete growth hormone.
- Regulation of body temperature by promoting responses such as shivering in a cold environment or sweating in a warm environment.
- Regulation of food and fluid intake; the hypothalamus is believed to respond to changes in blood nutrient levels or chemicals secreted by adipose tissue and bring about feelings of hunger or fullness.
- Integration of the functioning of the autonomic nervous system (discussed in a later section).
- Stimulation of visceral responses in emotional situations, such as an increased heart rate with anger or fear. The neurological basis of emotions is not well understood, but the hypothalamus brings about physiological changes by way of the autonomic nervous system.

Thalamus

The thalamus is above the hypothalamus and below the cerebrum; its functions are primarily concerned with sensation. Sensory pathways to the brain (except olfaction) to the brain converge in the thalamus, which begins to integrate sensations, permitting more rapid interpretation by the cerebrum. The thalamus is also capable of suppressing minor sensations, which permits the cerebrum to concentrate on more important sensations with less distraction.

Cerebrum

The two cerebral hemispheres form the largest part of the human brain. The right and left hemispheres are connected by the corpus callosum, a band of about 300 million nerve fibers that transfer information from one hemisphere to the other.

The cerebral cortex is the surface of the cerebrum; it is gray matter that consists mainly of the cell bodies of neurons. The cerebral cortex is folded extensively into convolutions (or gyri) that permit more surface area for neurons. The grooves between the folds are called fissures (deeper) or sulci (shallower). Interior to the gray matter is white matter, myelinated axons that connect the parts of the cerebral cortex to one another and the cerebrum to other parts of the brain. The cerebral cortex is divided into lobes, whose functions have been extensively mapped.

The frontal lobes contain the motor areas that generate the impulses that bring about voluntary movement. Each motor area controls movement on the opposite side of the body. Also in the frontal lobe, usually only the left lobe, is Broca's motor speech area, which controls the movements involved in speaking.

The parietal lobes contain the general sensory areas for the cutaneous senses, conscious muscle sense (proprioception), and taste (gestation). This is where these sensations are felt and interpreted.

The temporal lobes contain sensory areas for hearing and olfaction (smell). Also in the temporal and parietal lobes, usually only on the left side, are speech areas involved in the thought that precedes speech.

The occipital lobes contain the visual areas that receive impulses from the retinas of the eyes. Perception and interpretation of sight occurs here.

In all lobes of the cerebral cortex are association areas that enable us to learn, remember, and think; they also help form our individual personalities. These are complex behaviors that require integration of several cerebral and lower brain areas.

Deep within the white matter of the cerebral hemispheres are masses of gray matter called the basal ganglia. Their functions are concerned with certain subconscious aspects of voluntary movement: regulation of muscle tone, inhibiting tremor, and use of accessory movements such as arm swinging when walking.

Meninges and Cerebrospinal Fluid

The meninges are the three layers of connective tissue that cover the central nervous system. The outermost is the dura mater, made of thick, fibrous connective tissue. The middle layer is called the arachnoid mater, which has a web-like appearance; the inner layer is the pia mater, a very thin connective tissue on the surface of the brain and spinal cord. Between the arachnoid mater and the pia mater is the **subarachnoid** space, which contains cerebrospinal fluid.

subarachnoid: sub—below + arachnoid—middle layer of the meninges

Each of the four ventricles of the brain contains a choroid plexus, a capillary network that forms cerebrospinal fluid from blood plasma. This is a continuous process, and the cerebrospinal fluid then circulates from the ventricles to the central canal of the spinal cord and to the subarachnoid spaces around the brain and spinal cord. From the cranial subarachnoid space, cerebrospinal fluid is reabsorbed back to the blood through arachnoid villi that project into the cranial venous sinuses between the two layers of the cranial dura mater. The rate of reabsorption usually equals the rate of production.

As the tissue fluid of the CNS, cerebrospinal fluid permits the exchanges of nutrients and wastes between the blood and CNS neurons. It also acts as a cushion or shock absorber for the CNS. The pressure and constituents of cerebrospinal fluid may be determined by means of a lumbar puncture (spinal tap) and may be helpful in the diagnosis of diseases such as meningitis.

Cranial Nerves

The 12 pairs of cranial nerves emerge from the brainstem, with the exception of pair one which originates from the temporal lobe and pair two from the occipital lobe. Some are purely sensory nerves, whereas others are mixed nerves. The impulses for sight, smell, hearing, taste, and equilibrium are all carried by cranial nerves to their respective sensory areas in the brain. Other cranial nerves carry motor impulses to muscles of the face or to glands. Cranial nerves III, VII, IX, and X contain axons of both the somatic and autonomic nervous systems. The functions of all the cranial nerves are summarized in Table 47.2.

LEARNING TIP

The cranial nerves are easier to remember when a mnemonic device is used:

On	Olfactory
Old	Optic
Olympus'	Oculomotor
Towering	Trochlear
Top	Trigeminal
A	Abducens
Finn	Facial
And	Acoustic
German	Glossopharyngeal
Viewed	Vagal
Some	Spinal accessory
Hops	Hypoglossal

Autonomic Nervous System

The ANS is part of the peripheral nervous system in that it consists of the motor portions of some cranial and spinal nerves. These are the visceral motor neurons to visceral effectors—that is, smooth muscle, cardiac muscle, and glands. The ANS has two divisions, sympathetic and

TABLE 47.2 CRANIAL NERVES

Number	Name	Function
I	Olfactory	Sense of smell
II	Optic	Sense of sight
III	Oculomotor	Movement of eyeball; constriction of pupil for bright light or near vision
IV	Trochlear	Movement of eyeball
V	Trigeminal	Sensation in face, scalp, and teeth; contraction of chewing muscles
VI	Abducens	Movement of eyeball
VII	Facial	Sense of taste; contraction of facial muscles; secretion of saliva
VIII	Vestibulocochlear	Sense of hearing; sense of equilibrium
IX	Glossopharyngeal	Sense of taste; secretion of saliva; sensory for cardiac, respiratory, and blood pressure reflexes; contraction of pharynx
X	Vagus	Sensory in cardiac, respiratory, and blood pressure reflexes; sensory and motor to larynx (speaking); decreases heart rate; contraction of alimentary tube (peristalsis); increases digestive secretions
XI	Accessory	Contraction of neck and shoulder muscles; motor to larynx (speaking)
XII	Hypoglossal	Movement of the tongue

parasympathetic; often they function in opposition to each other, and their activity is integrated by the hypothalamus.

An autonomic nerve pathway from the CNS to a visceral effector consists of two motor neurons that synapse in a ganglion outside the CNS (Fig. 47.5). The first neuron is called the preganglionic neuron, from the CNS to the ganglion. The second neuron is called the postganglionic neuron, from the ganglion to the visceral effector. The ganglia are actually cell body collections of the postganglionic neurons.

Sympathetic Division

The cell bodies of the sympathetic preganglionic neurons are in the thoracic and some of the lumbar segments of the spinal cord. The axons of these neurons extend to the sympathetic ganglia, most of which are in two chains just lateral to the spinal column. Within the ganglia are the synapses between the preganglionic and postganglionic neurons; the axons of the postganglionic neurons then go to the visceral effectors. One preganglionic neuron often synapses with many postganglionic neurons to many effectors; this permits widespread responses in many organs.

The sympathetic division is dominant in stressful situations such as fear, anger, anxiety, and exercise, and the responses it brings about involve preparedness for physical activity, whether or not it is actually needed. (Table 47.3 summarizes both ANS divisions.) The heart rate increases, vasodilation in skeletal muscles supplies them with more oxygen, the bronchioles dilate to take in more air, and the liver changes glycogen to glucose to provide energy. Relatively less important activities such as digestion are slowed, and vasoconstriction in the skin and viscera permits greater blood flow to more vital organs such as the brain, heart, and muscles.

The neurotransmitters of the sympathetic division are acetylcholine and norepinephrine. Acetylcholine is released by sympathetic preganglionic neurons; its inactivator is acetylcholinesterase. Norepinephrine is released by most sympathetic postganglionic neurons at the synapses with

the effector cells; its inactivator is catechol-O-methyltransferase.

Parasympathetic Division

The cell bodies of the parasympathetic preganglionic neurons are in the brainstem and the sacral segments of the spinal cord. The axons of these neurons are in cranial nerve pairs III, VII, IX, and X and in some sacral nerves, and they extend to the parasympathetic ganglia. These ganglia are close to or actually in the visceral effector and contain the postganglionic cell bodies, with very short axons to the cells of the visceral effector. One preganglionic neuron synapses with just a few postganglionic neurons to only one effector. This permits localized responses.

The parasympathetic division dominates during relaxed, nonstressful situations to promote normal functioning of several organ systems. Digestion proceeds normally, with increased secretions and peristalsis; defecation and urination may occur, and the heart beats at a normal resting rate (see Table 47.3.)

Acetylcholine is the neurotransmitter at all parasympathetic synapses, both preganglionic and postganglionic; it is inactivated by acetylcholinesterase.

CRITICAL THINKING

Mrs. Stevens

■ Mrs. Stevens receives albuterol treatments for her chronic obstructive pulmonary disease. The medication opens her airways effectively, but after her treatments, she often complains that her heart is racing. What part of the peripheral nervous system do you think this medication affects?

Aging and the Nervous System

With age, the brain loses neurons, but this is only a small percentage of the total and is not the usual cause of mental

FIGURE 47.5 Autonomic nervous system (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed. 4. F.A. Davis, Philadelphia, 2003, p. 180, with permission.)

TABLE 47.3 FUNCTIONS OF THE AUTONOMIC NERVOUS SYSTEM

Organ	Sympathetic Response	Parasympathetic Response
Heart (cardiac muscle)	Increase rate	Decrease rate (to normal)
Bronchioles (smooth muscle)	Dilate	Constrict (to normal)
Iris (smooth muscle)	Pupil dilates	Pupil constricts (to normal)
Salivary glands	Decrease secretion	Increase secretion (to normal)
Stomach and intestines (smooth muscle)	Decrease peristalsis	Increase peristalsis for normal digestion
Stomach and intestines (glands)	Decrease secretion	Increase peristalsis for normal digestion
Internal anal sphincter	Contract to prevent defecation	Relax to permit defecation
Urinary bladder (smooth muscle)	Relax to prevent urination	Contract for normal urination
Internal urethral sphincter	Contract to prevent urination	Relax to permit urination
Liver	Change glycogen to glucose	None
Sweat glands	Increase secretion	None
Blood vessels in skin and viscera (smooth muscle)	Constrict	None
Blood vessels in skeletal muscle (smooth muscle)	Dilate	None
Adrenal glands	Increase secretion of epinephrine and norepinephrine	None

From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed. 5. F.A. Davis, Philadelphia, 2007, p. 191, with permission

LEARNING TIP

Sympathetic—S for STRESS RESPONSE: The autonomic nervous system is a primitive response that affects humans automatically and involuntarily, thus increasing the likelihood of survival. It is often referred to as the fight-or-flight response. When you think of the sympathetic nervous system, think about getting away from a man-eating lion: you need dilated pupils to see the path better; copious production of sweat to lose heat through evaporation; increased rate and force of heartbeat to ensure that enough blood gets to the extremities so you can run faster; dilated bronchioles to get more oxygen to your muscles; decreased digestion so you won't get hungry while you are trying to get away from the lion; decreased urine output so you won't have to stop for the restroom; and increased mental alertness so you are always aware of where the lion is.

Parasympathetic—P for PEACEFUL: The parasympathetic nervous system brings the body back to balance and rest. It is sometimes referred to as the rest-and-digest response. Think, "I just got away from a man-eating lion, now my body can go back to normal and start digesting and urinating again!"

This is a great way to remember the responses, rather than an accurate description of the exact physiology involved.

impairment in the elderly; far more common causes of mental changes include depression, malnutrition, hypotension, and the side effects of medications. Some forgetfulness is to be expected, however, as is a decreased ability for problem solving (Fig. 47.6).

**NURSING ASSESSMENT/
DATA COLLECTION OF THE
NEUROLOGICAL SYSTEM**

The focus of the nursing neurological assessment is to establish the present function of the patient's neurological system and to detect changes from previous assessments. A complete neurological assessment, intended to determine the existence of neurological disease, is typically performed by a physician or nurse practitioner. A baseline neurological assessment should be performed on every patient admission (Table 47.4). In addition to giving valuable information about the current functioning of the patient's neurological system, the assessment provides baseline data for comparison purposes. This is especially important if the patient

FIGURE 47.6 Aging and the neurological system. This concept map shows the effects the aging process has on the neurological system.

has chronic neurological deficits on admission. Consider a patient admitted for placement of a prosthetic hip, who has had a previous **cerebrovascular** accident resulting in **paresis** of the right arm. A complete neurological assessment would document that the right arm is weaker than the left. If during the postoperative course you assess that both arms are equal in strength, you would want to notify the physician so the patient could be further assessed for possible causes of weakening of the left arm.

The results of the baseline assessment are invaluable in planning and implementing safe care. For example, patients who give a history of seizure activity need careful monitor-

TABLE 47.4 BASIC NEUROLOGICAL ASSESSMENT

- 1 Assess level of consciousness (patient's response to verbal or tactile stimulation) and orientation.
- 2 Obtain vital signs (specifically blood pressure, pulse, and respirations).
- 3 Check pupillary response to light.
- 4 Assess strength and equality of hand grip and movement of extremities.
- 5 Determine ability to sense touch or pain in extremities.

cerebrovascular: cerebro—brain + vascular—vessels
paresis: partial paralysis

ing, and all staff members who interact with such patients should be aware of how to respond to a seizure. Patients with **dysphagia** (difficulty swallowing) may need to have restrictions placed on the types of food or fluids they can have. This information must be consistently communicated to all staff involved in the patient's care.

The patient's admitting diagnosis, the presence of any chronic neurological disorders, and the current functioning of the patient's neurological system all influence how often neurological assessments should be done. Orders for neurological assessments may vary from every 15 minutes for an acutely ill or injured patient, to every 8 hours for a patient who is close to being discharged, to every 24 hours for a resident living in long-term care. It is always appropriate to assess a patient more often than ordered, based on observed changes in the patient's condition, and to communicate the findings of those assessments to the primary care provider. The changes noted while assessing the patient may indicate changes in the central nervous system. Rapid detection and intervention may mean the difference between chronic dysfunction and recovery or even between life and death for the patient.

Subjective Data

To understand the patient's neurological status, ask about past and current symptoms, use of prescribed and over-the-counter medications, use of recreational drugs, past surgeries, treatments, and risk factors such as family history, diet, exercise, sedentary lifestyle, caffeine intake, and recent stressors. Assessment of symptoms, as with other

dysphagia: dys—difficult + phagia—eating

body systems, includes asking the WHAT'S UP? questions (Table 47.5).

Health History

The nurse obtains a history of the patient's general health and then focuses on any neurological symptoms. Symptoms of neurological disorders vary in type, location, and intensity. It is important to remember that some neurological disorders can affect the patient's ability to think, remember, speak, or interpret stimuli. It may be necessary to question significant others about duration and severity of symptoms. Some patients may not be able to recognize their own neurological deficits. In these cases, the significant other usually initiates contact with the health-care system and provides the medical and social history. See Table 47.5 for sample questions to ask if the patient has a neurological problem.

In addition to using these questions, the nurse observes the patient during the health history. Is he or she shifting positions and exhibiting signs of discomfort? Is the patient able to change position and move about easily? Is he or she able to carry on a coherent conversation?

Physical Assessment

The physical assessment of the patient begins when you first meet the patient and make an overall evaluation of the patient's mental and physical status. The neurological system is assessed using inspection, palpation, and percussion (with a reflex hammer). When conducting the mental status and cognitive portions of the assessment, be aware that fatigue, illness, or medications can alter findings. When interpreting findings, consider the patient's age, educational background, and cultural orientation.

TABLE 47.5 SUBJECTIVE ASSESSMENT OF THE NEUROLOGICAL SYSTEM

Category	Questions to Ask During History Assessment	Rationale/Significance
Mental Status	<ul style="list-style-type: none"> What is your name? What is the month? Year? Where are you now? 	<ul style="list-style-type: none"> Disorientation is often an initial sign of a neurological disorder.
Intellectual Function	<ul style="list-style-type: none"> Subtract 7 from 100, then 7 from that answer, and so on (serial 7s). 	<ul style="list-style-type: none"> Most people with intact neurological function can complete serial 7s in about 1\12 minutes.
Thought Content	<ul style="list-style-type: none"> What would you do if you smelled smoke? 	<ul style="list-style-type: none"> Assessment of the patient's ability to interpret information and act appropriately is an important safety issue and activity of daily living.
Perception	<ul style="list-style-type: none"> Where would you put milk? Show patient pencil and pen and ask what each is. 	<ul style="list-style-type: none"> Agnosia (inability to interpret or recognize familiar objects) can occur in cerebral vascular accidents and brain lesions.
Language Ability	<ul style="list-style-type: none"> Read the following sentence, ____. 	<ul style="list-style-type: none"> Different types of aphasia can result from injury to different parts of the brain.
Memory	<ul style="list-style-type: none"> Repeat these four or five words____, and repeat them again in five minutes. 	<ul style="list-style-type: none"> Impaired memory can be affected by both delirium and dementia. Delirium can cause impaired immediate and short-term memory, whereas dementia not only affects immediate and short-term memory but also the ability to learn new information. Can also be related to stroke.
Pain	<ul style="list-style-type: none"> On a scale of 1–10 with 0 as no pain and 10 as the worst you have ever had, what is your pain level? 	<ul style="list-style-type: none"> Pain perception may be altered or impaired by spinal injury, medications or alcohol, stress, and level of consciousness. Some spinal injuries may be critical but the patient will not complain of pain.

Level of Consciousness

Level of consciousness exists along a continuum from full wakefulness, alertness, and cooperation to unresponsiveness to any form of external stimuli. A fully conscious patient responds to questions spontaneously. As consciousness becomes impaired, a patient may show irritability, a shortened attention span, or an unwillingness to cooperate. The level of consciousness should be the first thing assessed during a neurological examination because the information obtained can be used to modify the remainder of the examination if necessary. Keep in mind that a decrease in the level of consciousness can be caused by problems such as hypoxia, hypoglycemia, and intoxication, not just dysfunction of the neurological system.

Many health-care institutions use the Glasgow Coma Scale (GCS), which is an international scale used to assess level of consciousness (LOC) and document findings (Table 47.6). The GCS is based on simple and clearly defined parameters of patient responses that provide for consistent assessment data. It is used to evaluate patients who have a potential for rapid deterioration in consciousness. The GCS assesses three parameters of consciousness: eye opening, verbal response, and motor response.

In the first section of the GCS, individuals are numerically scored according to their ability to open their eyes. Spontaneously opening their eyes receives a score of 4, opening with verbal stimulation a 3, with a painful stimulus such as pressure on the nailbeds or trapezius muscle a 2, and no response receives a 1. When initiating a painful stimulus use only enough pressure to elicit a response. Consider the patient's physical ability to respond, taking into consideration trauma, medical condition, and medications. For example, a patient who cannot open his or her eyes because of facial trauma may still have an intact neurological system.

The second section of the GCS addresses the patient's orientation to person, place, and time, often referred to as "oriented times 3." A patient who is fully oriented receives a score of 4. Typical questions include "What is your name? Where are you? What day is it?" (Keep in mind that we all forget the date from time to time!) You can also ask if they

know what season it is (spring, fall, etc.). A resident of a nursing home may consider the facility his or her home and is not necessarily considered disoriented. Be sure your question is appropriate to the patient's living conditions, lifestyle, and medical condition. If the patient is unable to speak because of a stroke (expressive **aphasia**) or being intubated, do not rule out the possibility that the patient is oriented. Give expressively aphasic patients yes-or-no questions such as "Are you in a grocery store? Are you in a bowling alley? Are you in a hospital?" Patients may be able to answer with a shake of the head, or blinks, or hand squeezes as instructed.

Motor response is scored based on following commands or a response to pain. Ask the patient to move the fingers or toes and the raise arms or legs. You will also want to evaluate the equality of strength bilaterally by having the patient squeeze your fingers and show resistance against your hands by raising the arms. Ask the patient to push against your hands with each foot. Localizing pain indicates that the patient has an adequate level of consciousness to recognize where the pain is coming from and to attempt to push it away. An example is the patient who pushes against your hand when pressure is applied to the nailbed. Abnormal flexion posturing, characterized by flexion of the arms at the elbow and bringing the hands up toward the chest with the legs extended (**decorticate** posturing; Fig. 47.7A), indicates significant impairment of the cerebral functioning. A score of 3 is given to patients who exhibit abnormal flexion posturing. Abnormal extension posturing, or **decerebrate** posturing, indicates damage in the area of the brainstem (Fig. 47.7B). In this case, both the upper and lower extremities are extended and the arms are internally rotated. Abnormal extension posturing is scored as a 2.

The total possible score on the GCS ranges from 3 to 15. A score of less than 7 indicates a comatose patient and a score of 15 indicates the patient is fully alert and oriented. When used to score the effects of a head injury, a score of 13 or 14 indicates mild head injury, 9 to 12 indicates moderate injury, and any score of 8 or below indicates severe head injury. For all the categories of the GCS, the type of painful stimuli required to elicit a response should be documented. Deterioration in the patient's condition (i.e., a lowering of the GCS score) should be reported to the physician promptly.

Mental Status

Mental status can be affected not only by the aging process but also can be due to a variety of neurological disorders and injuries. A traumatic brain injury can result in memory impairment, delayed amnesia, affective disorders, and dementia. To assess for cognitive impairment, the Mini-Mental State Examination (MMSE) or Confusion Assessment Method (CAM) can be used. (Find more about these at

TABLE 47.6 GLASGOW COMA SCALE

B. Decerebrate posturing

FIGURE 47.7 Abnormal posturing. (A) Decorticate posturing. (B) Decerebrate posturing

www.GeronurseOnline.org, an excellent collaborative website that provides best practice information related to older adults.) A change in mental status should be taken seriously, especially when the patient is on a variety of medicines or has had a recent medicine alteration. A primary cause of delirium and acute states of confusion is adverse effects from medications.

When you assess cognitive function, you are evaluating the patient's thinking capacity. You want to determine their length of attention span, ability to concentrate, judgment, memory, orientation, perception, problem solving ability, and motor function.

You can learn a great deal about a patient's mental capacities and emotional state by simply interacting with the patient. Behavior, mood, hygiene, grooming, and choice of dress reveal pertinent information about mental status. Mental status examinations can be performed to determine patients' cognitive functioning, thought processes, and perceptions by observing the patient's verbal and nonverbal responses to questions and specific requests. Table 47.5 includes some ways to assess these areas.

Assessment of the Eyes

Assessment of pupillary response is an important part of the neurological assessment and cranial nerve evaluation. The size of the pupils at rest is documented. Many institutions use a millimeter gauge for measuring pupils (Figure 47.8). This allows an objective description of the size. If the patient's pupils are unusually large or small, you should

determine if the patient has had any medications that might affect the size of the pupils. If the patient's pupils are unequal in size (**anisocoria**), without a correlating diagnosis or symptoms, ask the patient or his or her significant others if the patient normally has unequal pupils. Development of unequal pupils in a patient who previously had equal pupils is an emergency and should be reported to the physician immediately. Any deviation from the normal round shape of the pupils is documented.

Once the resting size of the pupils has been noted, the next step is to assess their response to light. In a darkened room, a light source (such as a flashlight) is directed at the pupil from the lateral aspect of the eye. This allows the examiner to see the direct and the consensual response to the light. A consensual response means that when one pupil is exposed to direct light, the other pupil also constricts. Absence of a consensual response may indicate a pathological condition in the area of the optic chiasm. Typically, the speed of the reaction to light is described as brisk, sluggish, or absent. Differences in the speed or size of constriction between the two pupils should be reported to the practitioner. Upon completion of the assessment of the pupils, document PERRL (pupils equal, round, and reactive to light) if no abnormalities are found.

Accommodation is the process of visual focusing from far to near. To evaluate for accommodation the patient

anisocoria: aniso—unequal + coria—pupil

FIGURE 47.8 Assessment of pupil size.

focuses on an object at a distant point and then refocuses on the object at a near point. Pupils should constrict with the adjustment to the near object and the eyes should converge. PERRLA is used to note that pupils are equal, round, and reactive to light and accommodation.

The eyes are evaluated for range of motion and for smoothness and coordination of movements. Eyes that move in the same direction in a coordinated manner are said to have a conjugate gaze. Conversely, a dysconjugate gaze is movement of the eyes in different directions. Some patients may be unable to move one or both eyes in a specific direction; this is called ophthalmoplegia. It is often documented as “limited extraocular movements.” Always document what the limitation is (e.g., “Patient is unable to look laterally with left eye”). This allows colleagues to compare their findings with yours and detect any changes.

Nystagmus is involuntary movement of the eyes. Nystagmus varies in the speed of the movement and the direction. Horizontal nystagmus is the most common. Common causes of nystagmus are phenytoin (Dilantin) toxicity and injury to the brainstem.

Assessment of Muscle Function

Assess muscle groups systematically in the upper extremities and then the lower extremities, comparing right to left. Muscle groups are compared for symmetry of size and strength. The patient’s age and general physical condition should be kept in mind when evaluating muscle strength. One does not expect the same amount of strength from a 75-year-old woman as from a 20-year-old man. If the patient has chronic neurological deficits, ask if the results of the assessment are different from his or her usual level of function.

Many health-care providers use a 5-point scale to document muscle strength. A score of 5 indicates a patient who is able to move the extremity against gravity and the resistance of the examiner, displaying normal muscle strength. If the examiner is able to provide more resistance than the patient can overcome with active movement, the score is 4. If the patient is able to move the extremity only against gravity, but not resistance, the score is 3. If gravity must be eliminated by having the examiner support the extremity to allow the patient to move the extremity, the score is 2. A score of 1 is given if there is no active movement of the extremity, but a minimum muscular contraction can be palpated. If the examiner is unable to detect any muscular function, a score of 0 is given.

To test the deltoid muscles, ask the patient to raise his or her arms at the shoulder. Have the patient resist as you push down on the upper arms. The biceps are tested by having the patient flex the arm at the elbow and bring the palm toward the face, then resist as you attempt to straighten the arm by pulling on the forearm. Tell the patient to “make a muscle.” With the arm similarly flexed, ask the patient to straighten the arm while you resist the movement.

Hand grasps are tested by having the patient squeeze your fingers. Remember to cross your index and middle fingers to prevent the patient from hurting your fingers. If the patient does not release the grasp when told to, it is a reflex

grasp, not a response to command. A reflex palmar grasp may indicate a pathological condition of the frontal lobe.

Assess the patient for arm drift by asking the patient to hold both arms straight in front with the palms upward while keeping the eyes closed. A downward drift of the arm, or rotation so that the palm is down, indicates impairment of the opposite side of the brain. If a pathological condition is present, arm drift may be apparent before differences in muscle strength can be detected.

Assessment of leg muscle strength begins with the iliopsoas muscle. Place your hand on the patient’s thigh and ask the patient to raise the leg, flexing at the hip. Hip adductors are tested by having the patient bring his or her legs together against your hands. The hip abductors and gluteus medius and minimus are tested by having the patient move the legs apart against resistance. Hip extension by the gluteus maximus is tested by placing the hand under the thigh and having the patient push down with the leg. The quadriceps femoris extends the knee and is tested by having the patient attempt to straighten the leg at the knee. The hamstrings are responsible for knee flexion and are evaluated by having the patient attempt to keep the heel of the foot against the bed or chair rung. Dorsiflexion is tested by having the patient pull the toes toward the head. Plantar flexion is tested by having the patient push against the examiner’s hand with the ball of the foot.

Babinski’s reflex is tested by firmly stroking the sole of the foot. Normal response is flexion of the great toe. If the great toe extends and the other toes fan out, neurological dysfunction should be suspected if the patient is more than 6 months old. Deep tendon reflexes are not usually part of a routine nursing assessment. The patient’s gait should be assessed to detect any neurological dysfunction and also to assess ability to ambulate safely. Patients who stagger, weave, or bump into objects may need assistance when out of bed.

Romberg’s test is performed by having the patient stand with feet together and eyes closed. Be sure to stand close to the patient, especially if he or she is an older adult, to prevent falling. A negative Romberg’s test means that the patient experiences minimal swaying for up to 20 seconds. A patient who experiences swaying or who leans to one side is said to have a positive Romberg’s test. A positive Romberg’s test may be seen in cerebellar dysfunction.

SAFETY TIP

A positive Romberg’s test in an older adult is expected as a result of normal aging changes in the cerebellum. Be sure to protect the patient with a positive result from falls.

Assessment of Cranial Nerves

The cranial nerves are usually not examined in depth during routine bedside neurological assessment. Testing requires a patient who is able to cooperate with the examiner. Table

TABLE 47.7 ASSESSMENT OF CRANIAL NERVES

Nerve	Test
Olfactory nerve	Ask patient to identify common scents such as cinnamon and coffee.
Optic nerve	Ask patient to read something; tell how many fingers you are holding up.
Oculomotor nerve	Check pupils for reaction to light and accommodation.
Oculomotor, trochlear, and abducens nerves	Ask patient to follow your finger while it is moved in front of his or her eyes in the positions of a clock: 1, 3, 5, 7, 9, and 11 o'clock.
Trigeminal nerve	Ask patient to identify touch on different parts of the face with eyes closed.
Facial nerve	Ask patient to frown, smile, wrinkle forehead; check for symmetry.
Vestibulocochlear nerve	Have patient identify whisper close to each ear. Observe gait for balance.
Glossopharyngeal and vagus nerves	Watch for uvula and palate to rise when patient says "ahh." Touch back of throat with cotton tipped applicator to elicit gag reflex.
Spinal accessory nerve	Ask the patient to turn head and shrug the shoulders against resistance.
Hypoglossal nerve	Ask the patient to stick out the tongue and move it from side to side.

47.7 provides basic testing techniques that provide a superficial assessment of cranial nerve function.

Assessment Summary

In all cases, the findings of the neurological examination should be correlated with the remainder of the assessment findings. A decreased level of consciousness, coupled with a decreased oxygen saturation on pulse oximetry, point to hypoxia as a cause. Correlation of vital signs with neurological signs is particularly important. Bradycardia, increasing systolic blood pressure, and widening pulse pressure, commonly referred to as Cushing's response, are late indications of increasing intracranial pressure. These findings, in conjunction with a unilateral dilated pupil, may indicate impending herniation of the brain (discussed further in Chapter 48).

CRITICAL THINKING

Tim Thompson

■ You are caring for Tim, a 78-year-old man admitted with heart problems. As you enter his room with his afternoon medications, you find Tim confused. He thinks he is at home, that the year is 1968, and he does not understand who you are or why you are there. He recognizes his wife, who is at his bedside, and knows his own name.

1. How would you describe and document his mental status?
2. What additional data do you need to decide how to proceed?
3. What may have contributed to his confusion?

Suggested answers at end of chapter.

examination, the practitioner may include laboratory tests to look for underlying causes of symptoms: thyroid hormone levels, vitamin B₁₂, complete blood count, electrolytes, creatine kinase and isoenzymes (CK), VDRL, liver function, and renal function. Measurement of erythrocyte sedimentation rate (ESR) and white blood cell (WBC) count may indicate an infection, such as meningitis. Hormone levels, such as prolactin or cortisol, may indicate dysfunction of the pituitary gland related to a brain tumor. Anticholinesterase testing and antibody titers are useful in diagnosing myasthenia gravis (MG).

Lumbar Puncture

Cerebrospinal fluid may be obtained via lumbar puncture and evaluated for glucose and protein levels, presence of bacteria and white blood cells, levels of immunoglobulin, antibodies, and culture and sensitivity. Cerebrospinal fluid samples should be sent to the laboratory immediately following the procedure.

Typically, the lumbar puncture needle is placed at the level of L3–4 or L4–5 in an adult. Because the spinal cord ends at the L1 level, this placement prevents damage to the cord by the needle. If there is any difficulty inserting the needle, this may be done under fluoroscopy to help guide needle placement.

Nursing Care

Assure that informed consent has been obtained prior to the procedure. Assist the patient into a side-lying position with his or her back as close to the edge of the bed nearest the practitioner as possible. Depending on the patient's condition, you may need to help the patient flex his or her knees up to the chest (Fig. 47.9). This position maximizes the space between the vertebrae, which makes it easier for the practitioner to insert the needle. An alternative position is to have the patient sit with the back perpendicular to the edge of the bed. Leaning over a bedside table may help the patient maintain the position. During the procedure, you may be asked to assist the physician with equipment handling.

After the lumbar puncture is completed, instruct the patient to remain on bedrest with the head of the bed flat for 6 to 8 hours, as ordered by the physician, and to increase

DIAGNOSTIC TESTS

Laboratory Tests

Specific diagnostic blood tests do not exist for neurological disorders. However, depending on the history and physical

FIGURE 47.9 Position for lumbar puncture.

oral intake of fluids. Keeping the head flat decreases the likelihood of leakage of cerebrospinal fluid from the puncture site, which can result in a severe headache. Increasing fluid intake promotes replacement of the fluid that was removed. Label and send the specimens to the laboratory as ordered. Check the puncture site for swelling or drainage of cerebrospinal fluid and report any leakage to the health-care provider. Assess the movement and sensation to the lower extremities frequently for the first 4 hours after the procedure. Assess the patient for headache and, if necessary, obtain an order for an analgesic.

NURSING CARE TIP

The idea of a needle being introduced into the spinal canal is frightening to many people. Give simple, clear directions to the patient; help the patient maintain his or her position; and provide emotional support throughout the procedure.

X-Ray Examination

Spinal x-ray examinations are done to determine the status of individual vertebrae and their relationship to one another. If the patient experiences pain with certain movements, he or she may be asked to flex and extend the area of the spine being examined while the radiographs are taken. This allows detection of abnormal movement of the vertebrae. If the patient has possibly sustained trauma to the spine, particularly the cervical spine, radiographs are taken before immobilizing devices are removed. Skull radiographs may be taken to detect skull fractures or foreign bodies. No special nursing care is required.

Computed Tomography

A computed tomographic (CT) scan is used for diagnosing neurological disorders of the brain or the spine. Some of the disorders that can be detected by CT are hemorrhage, ventricle size, cerebral atrophy, tumors, skull fractures, and

abscesses. CT is used when MRI is contraindicated because of metal aneurysm clips or other metal implants. The scan may be performed with or without radiopaque contrast material to enhance the clarity of the images that are recorded. If contrast material is used, a series of images is filmed, and then the contrast material is given intravenously and another series of images is filmed. The patient should be questioned about any allergies to contrast material, iodine, or shellfish. The blood urea nitrogen (BUN) and creatinine levels should be checked before administration of contrast material because it is excreted through the kidneys. Patients with elevated BUN and creatinine or known renal disease may be unable to tolerate the contrast material. Contrast material is most commonly used if a tumor is suspected or following surgery in the area to be scanned. CT scans are commonly used in emergency evaluations because they can be done quickly, an important consideration if the patient is ventilated or unstable.

Nursing Care

During the CT scan, the patient must lie still on a moveable table. Noncontrast scans take approximately 10 minutes; contrast scans take between 20 and 30 minutes. Patients who are receiving dye should be warned that they may feel a sensation of warmth following the injection; warmth in the groin area may make them feel as though they have been incontinent of urine. Nausea, diaphoresis, itching, or difficulty breathing may indicate allergy to the dye and should be reported immediately to the physician or nurse practitioner. Sedation may be required for patients who are agitated or disoriented. Patients who are in pain may require pain medication before the examination.

Magnetic Resonance Imaging

Magnetic resonance imaging (MRI) gives a more detailed picture of soft tissue than a CT scan. It is not as useful when looking for bony abnormalities. MRI is used for diagnosis of degenerative diseases such as multiple sclerosis, arteriovenous malformations, small tumors, hemorrhages, and cerebral and spinal cord edema. An MRI of the mediastinal cavity will determine if the thymus gland is enlarged and facilitate the diagnosis of myasthenia gravis. It is a longer procedure and may be difficult for unstable, disoriented, or ventilated patients. As with a CT scan, the MRI can be done with or without contrast material. Some facilities have the capability to perform magnetic resonance angiograms (MRAs). This test allows visualization of blood vessels and assessment of blood flow without being as invasive as a traditional angiogram.

Nursing Care

Because of the magnetic fields being used, there are restrictions placed on patients undergoing an MRI and the health-care personnel who work within the MRI facility. Individuals with pacemakers or any type of metallic prosthesis are not able to undergo MRI or be in the room when one is performed. This is because the magnetic field is so strong that it could dislodge the prosthesis or pacemaker. Patients

are asked to remove all metal objects, such as jewelry or hair clips, before the procedure. Individuals who may have accidentally acquired metallic foreign bodies (e.g., metal slivers in the eye or shrapnel that was not removed) may need an x-ray examination to determine the presence or absence of such objects. Even permanent make-up and tattoos can cause problems because of the metallic salts in the dyes. Other contraindications include gross obesity, claustrophobia, agitation and inability to cooperate, and inability to lie flat. It may be difficult for the patient to lie in one position for a prolonged period. The patient's need for pain medication should be assessed before the procedure. Use of pillows for positioning may improve comfort. The narrow, tunnel-like structure of the MRI unit causes claustrophobia in some patients; some patients may require use of sedatives or open MRI units. Warn the patient that the procedure involves a noisy “knocking” sound. Encourage the use of deep breathing, guided imagery, and other relaxation techniques.

SAFETY TIP

Educate patients to consider that they may someday need a life-saving MRI before having tattoos or permanent make-up applied!

Angiogram

An angiogram is an x-ray study of blood vessels that is used when an abnormality of cerebral or spinal blood vessels is suspected or to obtain information about blood supply to a tumor. Following injection of a local anesthetic, a catheter is inserted through the femoral artery and advanced until contrast material can be injected into the appropriate vessels. The dye then shows the vessels on the radiograph and provides information about the structure of specific vessels, as well as overall circulation to the area.

Nursing Care

Before an angiogram, the patient receives a clear liquid diet and has an intravenous needle in place. Informed consent must be obtained. BUN and creatinine levels are evaluated because the contrast material is excreted through the kidneys. Potential for bleeding is assessed by prothrombin time and partial thromboplastin time tests because a puncture is being made in a large artery. Typically, the patient receives some type of sedation before being transported to the angiography suite. During the injection of the contrast material, the patient may complain of severe heat sensations and a metallic taste in the mouth. The patient must lie still while the radiographs are being taken, and so should be told about the sensations he or she may experience. Patients who are disoriented or agitated may require sedation to complete the test.

Following the procedure, pressure is maintained on the catheter insertion site and the patient is kept flat in bed for 6 to 8 hours to prevent bleeding from the insertion site. The patient may turn from side to side but must keep the affected

leg straight. In addition to assessing vital signs, evaluate the catheter insertion site and the presence and quality of the popliteal and pedal pulses in the affected leg. Decrease or loss of the pedal pulse may indicate a clot in the femoral artery and should be reported to the physician immediately. Patients should be encouraged to increase oral intake in addition to the intravenous fluids that are administered to aid in the excretion of the contrast material.

Myelogram

A **myelogram** is an x-ray examination of the spinal canal and its contents. Following a lumbar puncture, cerebrospinal fluid is removed and sent for laboratory analysis. Contrast material is then injected into the subarachnoid space. The patient is moved into various positions and radiographs are taken. Compression of nerve roots, herniation of intravertebral disks, and blockage of cerebrospinal fluid circulation may all be detected by myelogram.

Nursing Care

Following the procedure, the patient is kept on bedrest with the head elevated. This lessens the possibility of the contrast material getting into the cerebral cerebrospinal fluid circulation. The contrast material used for myelograms can lower the seizure threshold in some patients. Any patient with a known seizure disorder should have serum levels of anti-convulsants evaluated and be carefully observed for signs of seizures.

Because of their invasive nature, a separate informed consent form may be required for the lumbar puncture and myelogram. The physician performing the test explains the risks, benefits, and possible complications of the examination. Patients who need these diagnostic procedures may have cognitive deficits; therefore, it may be necessary to obtain consent from the legal next of kin.

Electroencephalogram

Evaluation of the electrical activity of the brain is obtained by use of an **electroencephalogram** (EEG). Electrodes are attached to the scalp with an adhesive. Electrical activity is transmitted through the electrodes to a tracing. Analysis of the tracing can identify areas of abnormality, such as a seizure focus or areas of slowed activity.

Nursing Care

Before the test, make sure that the patient's hair is clean and dry. The physician may write orders to withhold sedatives to prevent interference with the EEG, and patients may be weaned from their anticonvulsants if the goal of the test is to identify the seizure focus during a seizure. These patients must be very carefully monitored and protected from harm. Typically, they undergo videotaping while the EEG is performed. Following the procedure, the adhesive must be

myelogram: myelo—referring to the spinal cord + gram—picture

electroencephalogram: electro—electrical activity + encephalo—referring to the brain + gram—picture

washed from the hair. Assist the hospitalized patient to do this as soon as possible, before it becomes hardened and difficult to remove.

THERAPEUTIC MEASURES

Moving and Positioning

Patients who have pain may need help in changing positions and ambulating. Use of heat, cold, or analgesics may allow the patient to be more independent in mobility. Patients with paresis, paralysis, or **paresthesia** may be partially or completely dependent in moving and positioning. Take care to maintain the body in functional positions when routine position changes are made. If the patient experiences sensory loss, ensure that no part of the body is inadvertently compressed (e.g., a hand caught under a hip or the scrotum compressed between the legs). Pressure ulcers are of primary concern with the patient who is unable to move independently. Collaborate with the physical therapist to determine positioning techniques that maximize the chance of useful recovery.

Contractures and footdrop are complications that are often associated with neurological disorders. Contractures are permanent muscle contractions with fibrosis of connective tissue that occur from lack of use of a muscle or muscle group. They cause permanent deformities and prevent normal functioning of the affected part. Footdrop occurs when the feet are not supported in a functional position and become contracted in a position of plantar flexion (Fig. 47.10). Use footboards, high-top tennis shoes, and splints to help prevent footdrop. Splints are commonly used to prevent contractures of the upper and lower extremities and to keep the affected part in a functional position. If splints are used, the patient must be evaluated for discomfort and skin breakdown at the splint site.

Mobilization should be begun as soon as a patient is medically stable. Initially this may involve the use of a cardiac chair if the patient is unable to bear weight. Transfer of

FIGURE 47.10 Contractures, footdrop. (From Hegner, B: *Assisting in Long Term Care*, ed. 3. Delmar Publishers, Albany, NY, 1998, with permission.)

paresthesia: para—beside + asthesia—sensations

the patient to a bedside chair or use of ambulation aids may require a multidisciplinary approach. Be careful to recognize any physical or cognitive deficits that may affect safety and adjust the environment to protect the patient. This includes communicating any safety concerns to unlicensed personnel who interact with the patient.

Activities of Daily Living

The effects of neurological disorders on activities of daily living (ADLs) may range from an inconvenience to complete dependence. Patients may have trouble bending over to put on their shoes and socks, lifting a full cooking pot, or caring for an infant. A high-level quadriplegic may be completely unable to perform ADLs but can be taught to direct his or her own personal care. Patients should be encouraged to use strategies learned in occupational or physical therapy.

Assessment of a hospitalized patient should include a discussion of the strategies the patient normally uses at home to accomplish ADLs. Every attempt should be made to continue to use these strategies. This is particularly true if the patient is admitted to a long-term care facility. Patients who have normal cognitive function should be included in care planning and encouraged to work collaboratively with caregivers. If the strategies the patient uses during ADLs must be changed (e.g., if the patient's transfer technique is unsafe), the rationale for the changes should be explained to the patient and significant others. If patients have impaired cognitive function, try to maintain a specific routine that is as close to their normal environment as possible. Normalizing routines may help patients adapt to a change in environment and maximize their ability to function.

Communication

The communication problems associated with neurological disorders have a variety of etiologies. Some neurological disorders cause difficulty speaking (**dysarthria**). Dysfunction of the lips, tongue, or jaw makes speech difficult or impossible to understand. When dysarthric individuals know what they want to say but cannot be understood, they can become very frustrated. This frustration is compounded if the patients are treated as if they have cognitive deficits merely because they have difficulty communicating.

Patients who have had a stroke can experience different types of aphasia. Expressive aphasia is difficulty or inability to verbally communicate with others. The patient may be able to speak in sentences but inappropriately substitute words, such as "The sky is dish." Word-finding difficulty is another type of expressive aphasia. These patients may tell you "I want a. . ." and then be unable to complete the sentence. In severe cases of aphasia, the patient may make sounds that resemble words or may only utter sounds. For individuals with no intelligible speech or with word-finding difficulty, a picture board with commonly used items may

dysarthria: dys—dysfunctional + arthria—movement of the joints used in speech

facilitate communication. (See an example of a picture board in Chapter 49.) Keep in mind that patients with expressive aphasia may answer yes to all questions rather than just those for which yes is correct. The same is true of answering no. This is one reason why a nurse should never ask a patient, “Are you Mrs. Gonzalez?” An aphasic patient may say yes even if that is not her name. Instead, ask the patient to state her name. If she cannot state her name, check her identification band.

For patients who substitute words, simply correct the substitution and continue the conversation. Patients with expressive aphasia are often very aware of and frustrated by their difficulty communicating. Give them time to try to express themselves. If you cannot understand them, offer possibilities based on the situation. If the patient is sitting in the chair, ask if he or she wants to go back to bed or wants to use the bathroom. If the patient is restless, ask if he or she is in pain.

Some patients use the same word in response to all questions, and for a few patients that word is a profanity. This is very difficult for significant others to deal with, particularly if swearing is not something the patient normally did. Make it clear to the family that you understand that this behavior is part of the patient’s illness.

Receptive aphasia affects the patient’s ability to understand spoken language. Again, the severity of the aphasia varies. Some patients may understand simple directions such as “sit down” or “squeeze my fingers.” In other cases, the nurse may need to pantomime the action the nurse wants the patient to perform, such as showing the patient pills and then mimicking taking the pills and drinking water.

SAFETY TIP

If the patient has receptive aphasia, assume that he or she cannot understand or follow safety instructions, such as “Do not stand up until I get back.” Even going around the corner to get water can give a patient enough time to try to stand up and subsequently fall.

Nutrition

Alterations in the ability to maintain an adequate nutritional intake can have many causes. The level of consciousness may be depressed enough that the patient does not recognize that she or he is hungry or thirsty. Decreased level of consciousness or cranial nerve dysfunction may impair the patient’s ability to swallow safely. Severe weakness may limit the patient’s ability to take in enough food to meet the body’s requirements. These conditions are often compounded by the increased metabolic rate that accompanies neurological injury or illness.

If there is any question of the patient’s ability to swallow, a swallowing evaluation should be performed by a speech therapist. Some institutions use a radiological examination to evaluate the ability to swallow. A small amount of barium is added to food or fluid, and fluoroscopy is used while the patient swallows. This allows visualization of the path of the food or fluid. Patients with swallowing difficulty (dysphagia) may have better success with foods or thick liquids rather than thin fluids. Liquids may be thickened with special thickening agents to allow easier swallowing. All patients should be positioned as upright as possible while eating or drinking, and patients who have difficulty swallowing should be monitored during eating.

If weakness or fatigue is the cause of decreased nutritional intake, several modifications are possible. Serving small portions of food frequently can increase intake. Using high-protein, high-calorie foods and supplements increases the nutritional content of small amounts of foods.

For patients who are unable to swallow or who cannot swallow enough food, enteral tube feedings may be required. If enteral feedings are anticipated to be for a short duration, a nasogastric tube may be used. The disadvantages of nasogastric tubes include impairment of the integrity of nasal skin and the risk of aspiration. The risk of aspiration in neurologically impaired patients who have cognitive impairments is increased because these patients may pull out the nasogastric tube because they do not understand its purpose. If long-term enteral feedings are anticipated, a gastrostomy tube may be placed directly through the abdominal wall into the stomach. This feeding method has the advantage of reducing the risks of aspiration and eliminating nasal skin breakdown.

FAMILY

When working with patients who have a neurological deficit, whether acute or chronic, in the hospital, extended care facility, or at home, the family needs to be included in their care and rehabilitation. Depending on the patient’s diagnosis and prognosis, the family will need support from staff. It is rewarding to see the patient who has had an accident and recovers with rehabilitation, but it is also rewarding to promote quality of life for the patient with Alzheimer’s disease and his or her family. It is important to communicate to the family regarding patient improvements and information about the illness. Include the family in the patient’s care, such as bathing, feeding, and grooming. Suggest that the family participate in physical therapy sessions. Education is of vital importance, especially if the patient is going to be discharged home. Direct the patient and family to support groups and case managers for information regarding financial assistance and community resources during rehabilitation.

REVIEW QUESTIONS

- Which neurons carry impulses from the CNS to effectors?
 - Mixed
 - Motor
 - Afferent
 - Sensory
- Which structure in the CNS regulates body temperature?
 - Hypothalamus
 - Temporal lobe
 - Pons
 - Pituitary
- Which of the following is a symptom of increasing intracranial pressure that should be reported immediately to the primary care provider?
 - Constricted pupils
 - Decreasing level of consciousness
 - Narrowing pulse pressure
 - Bradypnea
- Multiple response item. Select all that apply. What are the normal effects of aging on the CNS?
 - Increased postural stability
 - Reduced blood flow to the brain
 - Impaired short-term memory
 - Sleep disturbances
 - Loss of deep tendon reflexes
- A patient asks what to expect when she has an angiogram. Which response by the nurse is best?
 - “A small needle will be inserted into your spinal column to withdraw fluid for examination.”
 - “You will be in a large machine that uses magnetic energy to create images; it has a noisy knocking sound.”
 - “Electrodes will be placed on your head to monitor electrical activity in your brain.”
 - “A catheter will be placed in your femoral artery, and dye will be injected that will make your vessels show up on x-ray.”
- Which of the following activities should be encouraged when a patient returns from a CT scan using a contrast medium?
 - Ambulation
 - Drinking fluids
 - Turning side to side
 - Coughing and deep breathing
- Which of the following nursing interventions can help prevent footdrop?
 - Position the patient in the left lateral position.
 - Provide daily foot massage.
 - Apply high-top tennis shoes.
 - Maintain the patient in an upright position as much as possible.

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Mrs. Stevens*

Albuterol is an adrenergic agonist (sometimes called a sympathomimetic), which is given to stimulate the sympathetic nervous system, resulting in open airways in patients with respiratory disease. However, it can also stimulate the cardiac system and cause a rapid heart rate and increased blood pressure. Be sure to monitor vital signs in patients receiving medications that affect the autonomic nervous system.

■ *Tim Thompson*

- He is alert but confused, oriented to person only.
- The nurse should ask his wife if this has ever

happened before; check his medical history for any disorders that may contribute to neurological dysfunction; do a quick neurological assessment to determine if any additional deficits exist; check vital signs and pulse oximetry if available; and notify the physician immediately if the symptoms are a new finding.

- Some possible explanations to explore include hypoxemia, stroke, worsening heart problems causing inadequate flow of blood to the brain, hypoglycemia, or even confusion (delirium) related to a sudden transition from home to an unfamiliar environment.

QUESTIONS TO GUIDE YOUR READING

1. What are the causes, risk factors, and pathophysiology of central nervous system infections, including meningitis and encephalitis?
2. What nursing interventions are appropriate for a patient with a central nervous system infection?
3. What are the differences in the varying types of headaches?
4. What education should you provide for the patient experiencing headaches?
5. What are causes and types of seizures?
6. How would you care for someone during a seizure?
7. How would you recognize a patient developing increased intracranial pressure?
8. What nursing interventions can help prevent increased intracranial pressure?
9. What are the causes, risk factors, and pathophysiology of injuries to the brain and spinal cord?
10. What nursing care will you provide for a patient with an injury to the brain or spinal cord?
11. What are the causes, risk factors, and pathophysiology associated with neurodegenerative disorders such as Parkinson's, Huntington's, or Alzheimer's disease?
12. What nursing care will you provide for a patient with a neurodegenerative disorder?
13. What nursing interventions are appropriate for the patient with dementia?

Disorders of the central nervous system (CNS) include problems originating in the brain and spinal cord. Because the CNS is the control center for the entire body, disorders in this system can cause symptoms in any part of the body, ranging from pain to paralysis, confusion, and coma. This chapter presents nursing care of patients with these disorders.

CENTRAL NERVOUS SYSTEM INFECTIONS

Infectious agents can enter the central nervous system via a variety of routes (Table 48.1). Anything that depresses the patient's immune system such as steroid administration, chemotherapy, radiation therapy, or malnutrition can make the patient more vulnerable to infection.

Meningitis

Meningitis is an inflammation of the brain and spinal cord that may be caused by either bacterial or viral infection. Any microorganism that enters the body can result in meningitis. Bacterial meningitis is a serious infection that is spread by direct contact with discharge from the respiratory tract of an infected person. Viral meningitis, also called aseptic meningitis, is more common and rarely serious. It usually presents with flulike symptoms, and patients recover in 1 to 2 weeks.

Pathophysiology and Etiology

The most common bacteria causing meningitis include *Neisseria meningitidis*, *Streptococcus pneumoniae*, and *Haemophilus influenzae* type b (Hib). With current immunization standards in the United States, the *H. influenzae* type b has decreased in recent years. *N. meningitidis*, the cause of meningococcal meningitis, and *S. pneumoniae*, the cause of pneumococcal meningitis, are the major causes of bacterial meningitis. The infection generally begins in another area, such as the upper respiratory tract, enters the blood, and invades the CNS, causing the meninges to become inflamed and intracranial pressure to increase. Vessel occlusion and

TABLE 48.1 ROUTES OF ENTRY FOR CENTRAL NERVOUS SYSTEM INFECTIONS

Route of Entry	Examples
Bloodstream	Insect bite Otitis media
Direct extension	Fracture of frontal or facial bones
Cerebrospinal fluid	Dural tear Poor sterile technique during procedure
Nose or mouth	Meningococcus meningitis
In utero	Contamination of amniotic fluid Rubella Vaginal infection

meningitis: mening—membranous covering of the brain + itis—inflammation

TABLE 48.2 CRANIAL NERVES AFFECTED BY MENINGITIS

Cranial Nerve Affected	Manifestation
III, IV, VI	Ocular palsies Unequal and sluggishly reactive pupils
VII	Facial weakness
VIII	Deafness and vertigo

necrosis of areas in the brain may occur. Cranial nerve function may be transiently or permanently affected by meningitis. Some of the effects are listed in Table 48.2.

Prevention

Vaccines are available against Hib and *S. pneumoniae*. Hib vaccinations are begun during the newborn period, but the vaccine against *S. pneumoniae* is not effective under the age of 2 years and is recommended for those individuals over the age of 65 who have a chronic medical condition. In addition to vaccines, current standards for prevention include early diagnosis and prompt treatment of individuals who have come in contact with diagnosed patients.

Signs and Symptoms

The most common symptom of meningitis is headache, caused by tension on blood vessels and irritation of the pain-sensitive dura mater. A high fever and stiff neck are present and the patient may experience **photophobia**. The patient with meningococcal meningitis usually presents with petechiae on the skin and mucous membranes.

Nuchal rigidity (pain and stiffness when the neck is moved) is caused by spasm of the extensor muscles of the neck. Positive Kernig's and Brudzinski's signs are often seen in patients suffering from meningitis. Both signs are caused by inflammation of the meninges and spinal nerve roots. To elicit Kernig's sign, the examiner flexes the patient's hip to 90 degrees and tries to extend the patient's knee. The sign is positive if the patient experiences pain and spasm of the hamstring. Brudzinski's sign is positive when flexion of the patient's neck causes the hips and knees to flex (Fig. 48.1). Nausea and vomiting associated with meningitis are caused by direct irritation of brain tissue and by increased intracranial pressure (ICP).

Encephalopathy refers to the mental status changes seen in patients with meningitis. These are manifested as short attention span, poor memory, disorientation, difficulty following commands, and a tendency to misinterpret environmental stimuli. Late signs of meningitis include lethargy and seizures.

Complications of Meningitis

Resolution of meningitis depends on how quickly and effectively the disease is treated. Some individuals experience no

photophobia: photo—light + phobia—fear or intolerance
encephalopathy: encephalo—brain + pathy—illness

FIGURE 48.1 (A) Kernig's sign. (B) Brudzinski's sign.

lasting effects, while other patients have permanent neurological deficits. Cranial nerve damage may leave the patient blind or deaf. Seizures may continue to occur even after the acute phase of the illness has passed. Cognitive deficits ranging from memory impairment to profound learning disabilities may occur.

Diagnostic Tests

A lumbar puncture is the most informative diagnostic test for a patient with suspected meningitis (see Chapter 47). Viral meningitis is characterized by clear cerebrospinal fluid with normal glucose level and normal or slightly increased protein level. No bacteria are seen, but the white blood cell count is usually increased. In contrast, the cerebrospinal fluid of an individual with bacterial meningitis is **turbid**, or cloudy, because of the massive number of white blood cells. Bacteria are identified by Gram stain and culture, and a sensitivity test is done to identify the most effective antibiotic. The bacteria utilize the glucose normally found in cerebrospinal fluid (CSF), thereby lowering the glucose level. The amount of protein in the cerebrospinal fluid is elevated. A magnetic resonance image (MRI) or computed tomographic (CT) scan may be done to evaluate for complications.

Therapeutic Interventions

Meningitis can be fatal if not promptly treated. Antibiotics are administered for bacterial meningitis. Symptom management is the same for viral or bacterial meningitis. Antipyretics such as acetaminophen are used to control the fever; a cooling blanket may also be used. Care should be taken to avoid cooling the patient too much because shivering increases the metabolic demand for oxygen and glucose. A quiet, dark environment lessens the stimulation to a patient who has a headache or photophobia (sensitivity to light) and who may be agitated, disoriented, or at risk for seizures.

Analgesics are given to lessen head and neck pain. Corticosteroids and anti-inflammatory agents are given to decrease swelling. Nausea and vomiting are controlled by administering antiemetic medications. The patient with meningococcal meningitis should be placed in isolation because this disease can be transmitted to others.

Patients may become agitated. An important aspect of nursing care focuses on keeping patients from harming themselves. It is very upsetting to families to see a loved one acting agitated or disoriented. Therefore, it is important to teach the family about symptoms and treatment goals for the patient (Box 48.1 Meningitis Summary).

Encephalitis

Pathophysiology

Encephalitis is an inflammation of brain tissue. Nerve cell damage, edema, and necrosis cause neurological findings localized to the specific areas of the brain affected. Hemorrhage may occur in some types of encephalitis. Increased

Box 48.1

Meningitis Summary

Signs and Symptoms	Nuchal rigidity Positive Kernig's and Brudzinski's signs Fever Photophobia Petechial rash on skin and mucous membranes Encephalopathy

CSF = cerebrospinal fluid; C&S = culture and sensitivity; IICP = increased intracranial pressure; r/t = related to.

encephalitis: encephalo—brain + itis—inflammation

intracranial pressure (ICP) may lead to herniation of the brain (see section on increased intracranial pressure).

Etiology

Viruses are the most common cause of encephalitis. They may be specifically related to a particular time of year or geographical location. Some viruses, such as West Nile virus, are carried by ticks or mosquitoes. Others are systemic viral infections, such as infectious mononucleosis or mumps, which spread to the brain. Parasites, toxic substances, bacteria, vaccines, and fungi are other potential causes of encephalitis.

Herpes simplex is the most common noninsectborne virus to cause encephalitis. The majority of individuals harbor herpes simplex virus type 1 in a dormant state. This is the virus responsible for sores on the oral mucous membranes, commonly called cold sores. Infectious diseases, fever, and emotional stress are possible reasons for the virus becoming active, but the exact mechanism is not known.

Signs and Symptoms

As with meningitis, headache and fever are common presenting symptoms. The patient may also complain of nausea, vomiting, and general malaise. These symptoms usually develop over a period of several days. Additional symptoms include nuchal rigidity, confusion, decreased level of consciousness, seizures, sensitivity to light, **ataxia**, abnormal sleep patterns, and tremors. The patient may have **hemiparesis**.

The patient with herpes encephalitis develops edema and necrosis (sometimes associated with hemorrhage), most commonly in the temporal lobes. This significant cerebral edema causes increased ICP and can lead to herniation of the brain. If the patient becomes comatose before treatment is begun, the mortality rate may be as high as 70% to 80%. The first 72 hours, when cerebral edema is worst, is the most likely time for death to occur.

Complications of Encephalitis

Patients who have had encephalitis are often left with cognitive disabilities and personality changes. Ongoing seizures, motor deficits, and blindness may also occur. Deterioration in cognition and personality changes are particularly stressful for significant others. The patient's behavioral control is a major factor in determining discharge plans. Assist significant others to realistically assess the patient's functional level and the family's ability to care for the patient. In-home care, outpatient therapy, and adult day care are options to explore. For some severely impaired individuals, custodial care may be the only feasible and safe discharge option.

Diagnostic Tests

CT scan, MRI, lumbar puncture to obtain cerebrospinal fluid, and electroencephalogram (EEG) are used to diagnose encephalitis. Cerebrospinal fluid analysis typically reveals increased white blood cell count and protein level and nor-

mal glucose levels. Breakdown of blood after cerebral hemorrhage results in yellow-colored CSF.

Therapeutic Interventions

No specific treatment is currently available for insectborne encephalitis. Careful neurological assessment and treatment of symptoms may help prevent complications and improve survival. Anticonvulsants, antipyretics, and analgesics are administered to reduce seizures, fever, and headache. Corticosteroids are used to decrease the swelling from the inflammation. Sedatives may be given for irritability. Antiviral medications such as acyclovir (Zovirax) may also be used, especially for herpes simplex.

INCREASED INTRACRANIAL PRESSURE

Pathophysiology and Monitoring

Any patient with an intracranial pathological condition is potentially at risk for increased intracranial pressure. ICP is the pressure exerted within the cranial cavity by its components (blood, brain, and cerebrospinal fluid). The normal ICP is 0 to 15 mm Hg. This pressure fluctuates with normal physiological changes, such as arterial pulsations, changes in position, and increases in intrathoracic pressure (e.g., coughing or sneezing). Common causes of increased ICP include brain trauma, intracranial hemorrhage, and brain tumors. Prompt detection of changes in neurological status indicating increased intracranial pressure allows intervention aimed at preventing permanent brain damage.

The skull is a rigid compartment containing three components: brain, blood, and cerebrospinal fluid. If an increase in one component is not accompanied by a decrease in one or both of the other components, the result is increased intracranial pressure (IICP) (Fig. 48.2). The consequences of increased ICP depend on the degree of elevation and the speed with which the ICP increases. Patients with slow-growing tumors may have significantly increased intracranial pressure before they develop symptoms. Conversely, patients with a subarachnoid hemorrhage may sustain a sudden sharp increase in intracranial pressure.

The normally functioning body has several methods of compensating for increased intracranial pressure. Cerebrospinal fluid can be shunted into the spinal subarachnoid space. Hyperventilation may trigger constriction of cerebral blood vessels, decreasing the amount of blood within the cranial vault. These compensatory mechanisms are temporary and not particularly effective if the increase in ICP is sudden and severe.

Signs and Symptoms

Initial symptoms of increased ICP include restlessness, irritability, and decreased level of consciousness because cerebral cortex function is impaired. If not intubated, the patient may hyperventilate, causing vasoconstriction as the body attempts to compensate. As the pressure increases, the ocu-

hemiparesis: hemi—one side + paresis—partial paralysis

FIGURE 48.2 Any increase in brain tissue, blood, or cerebrospinal fluid can increase intracranial pressure.

lomotor nerve may be compressed on the side of the impairment. Compression of the outermost fibers of the oculomotor nerve results in diminished reactivity and dilation of the pupil. As the fibers become increasingly compressed, the pupil stops reacting to light. If the compression continues and the brain tissue exerts pressure on the opposite side of the brain from the injury, both pupils become fixed and dilated.

Vital sign changes are a late indication of increasing intracranial pressure. Cushing's response is a classic late sign of increased ICP. Cushing's response (or Cushing's triad) is characterized by bradycardia, bradypnea, and arterial hypertension (increasing systolic blood pressure while diastolic blood pressure remains the same), resulting in widening pulse pressure. By the time these symptoms appear, the intracranial pressure is significantly increased and interventions may not be successful.

Monitoring

ICP monitoring allows for early detection of changes in the pressure on the brain, before changes in symptoms can be seen. The most common method of monitoring ICP in adults

is by placing a catheter in the ventricle of the brain, in the cerebral parenchyma, or in the subdural or subarachnoid space. This can be done at the bedside or in surgery. Each of these methods requires anesthetizing the scalp and drilling a burr hole into the skull.

Placement of a catheter into one of the lateral ventricles is referred to as external ventricular drainage (Fig. 48.3). This method allows for pressure monitoring as well as drainage of cerebrospinal fluid to reduce intracranial pressure. Disadvantages to this method include difficulty in locating the ventricle for insertion of the catheter and clotting of the catheter by blood in the cerebrospinal fluid.

To allow communication with the subarachnoid space, a subarachnoid bolt can be tightly screwed into the burr hole after the dura has been punctured (Fig. 48.4). The advantage of a subarachnoid bolt is ease of placement. Disadvantages include occlusion of the sensor portion of the bolt with brain tissue and inability to drain CSF. An intraparenchymal monitor is placed directly into brain tissue. Some physicians believe that this most accurately reflects the actual situation within the skull. These monitors cannot be used to drain CSF and may become occluded by brain tissue.

FIGURE 48.3 Ventricular drain. A catheter into the ventricle allows ICP monitoring and CSF drainage.

FIGURE 48.4 Subarachnoid bolt monitor:

Patients with ICP monitors are cared for in an intensive care unit (ICU) and require aggressive nursing care to prevent complications. These patients are often mechanically ventilated and may be pharmacologically paralyzed and sedated. In addition to meeting the patient's physiological needs and preventing complications, provide education and emotional support to the significant others.

Nursing Process for the Patient with an Infectious or Inflammatory Neurological Disorder

Assessment/Data Collection

Collaborate with the registered nurse (RN) to obtain a complete history from the patient, if feasible, and from significant others. Particular attention is paid to exposure to risk factors. The physical assessment must include all body systems because neurological impairment affects the entire person. Following the initial assessment, serial neurological assessments continue to be important to detect and report changes promptly. Pupil response, level of consciousness (LOC), and vital signs are monitored for signs of increased intracranial pressure (Box 48.2 Signs and Symptoms of Increased Intracranial Pressure). Headache is monitored on a pain scale. The Glasgow Coma Scale, presented in Chapter 47, is a valuable tool to monitor level of consciousness.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. The patient with increased ICP is usually cared for in an intensive care setting. The LPN/LVN collaborates with the registered nurse in implementing care. For additional interventions for patients with infectious or inflamma-

tory disorders, see Box 48.3 Nursing Care Plan for a Patient with Brain Tumor or Injury.

Pain (headache and nuchal rigidity) related to IICP

EXPECTED OUTCOME: Patient will not exhibit evidence of pain.

- Monitor pain using a 0 to 10 pain scale if the patient is able. *A pain scale is the most accurate way to monitor a patient's pain.*
- If the patient becomes restless, consider pain as a cause. *The patient may not be able to communicate pain sensations.*
- Administer analgesics as ordered. Avoid opioid analgesics. *Opioid analgesics (with the possible*

(Text continued on page 1065)

Box 48.2

Signs and Symptoms of Increased Intracranial Pressure

- Vomiting
- Headache
- Dilated pupil on affected side
- Hemiparesis or hemiplegia
- Decorticate then decerebrate posturing
- Decreasing level of consciousness
- Increasing systolic blood pressure
- Increasing then decreasing pulse rate
- Rising temperature

Box 48.3 NURSING CARE PLAN for a Patient with a Brain Tumor or Injury

Nursing Diagnosis: Disturbed thought processes related to cerebral edema or increased intracranial pressure and cognitive changes with orientation and problem solving

Expected Outcomes Patient will be oriented to person, place, and time, retain memory, and make appropriate decisions to maintain safety.

Evaluation Outcomes Is patient oriented to self, place, and time and able to ask for help appropriately to prevent injury?

Interventions

Assess level of consciousness (LOC) using Glasgow Coma Scale.

Monitor orientation and reorient as necessary.

Observe patient's reaction to simple commands such as "raise your hand."

Monitor patient's capabilities as activities increase.

Rationale

Change in LOC can indicate increased intracranial pressure and should be reported.

Giving correct information to patient will assist in orientation.

This helps distinguish between reflexes and purposeful movement.

Patient may experience dizziness, imbalance, and confusion; the patient will need assistance with mobilization until stable.

Evaluation

Is patient alert and responsive?
Is LOC stable?

Can patient identify who he/she is, location, and month, year, or season?

Is patient able to follow simple commands?

Can patient sit up and ambulate to chair without dizziness?

Nursing Diagnosis: Self-care deficit, bathing/hygiene related to mental status changes and inability to perform ADLs independently

Expected Outcomes The patient maintains as much independence with ADLs as possible.

Evaluation Outcomes Is the patient able to participate in self-care at an appropriate level?

Interventions

Assess what the patient was able to do prior to admission/injury.

Provide all supplies and equipment for hygiene and bath.

Encourage the patient to perform activities at own pace.

Teach and encourage family to participate with care.

Rationale

The patient's potential for participation will depend on what he or she was able to do prior to injury.

Assembling equipment for the patient reserves energy for performing self-care.

The patient may need more time to perform activities.

Including the family in the patient's care promotes support and family interaction.

Evaluation

What was the patient able to do? How does that compare with what he or she can do now?

Is the patient able to perform the majority of bath and hygiene tasks with appropriate set-up?

Does the patient gradually increase performance of self-care in a timely fashion?

Is the family involved? Is the patient accepting of their assistance?

Nursing Diagnosis: Pain related to cerebral edema and headache or other signs of discomfort

Expected Outcomes Patient states pain level is acceptable, or demonstrates a decrease in painful behaviors.

Evaluation Outcomes Does patient state pain level is acceptable? Are pain behaviors reduced?

Interventions

Assess pain using a scale of 0 to 10, or a faces scale (see Chapter 9). If patient is unable to participate, observe for pain behaviors such as restlessness, grimacing, or moaning. Monitor vital signs.

Administer appropriate pain medication as ordered.

Keep head of bed elevated at least 30 degrees.

Provide alternative comfort measures such as dim lights, a quiet environment, and positioning for comfort.

Rationale

The patient's self-report is the best measure of the patient's pain. Pulse and blood pressure may be elevated in acute pain.

Nonnarcotic medications are preferred because they do not alter the level of consciousness. If these are not effective, codeine preparations, which have a minimal effect on LOC, may be prescribed.

Elevating the head of the bed helps prevent increased intracranial pressure, which can increase pain.

Decreasing stimuli in the room by dimming lights and decreasing noise can have a calming effect.

Evaluation

Is the patient able to rate pain? Is there evidence that pain is present?

Does patient state pain has decreased? Is sedation minimized?

Does keeping head of bed elevated help prevent pain?

Is patient resting quietly, with no complaints of pain?

Nursing Diagnosis: Sensory-perceptual disturbance (visual, auditory, or tactile) related to brain injury and cranial nerve involvement as evidenced by alterations in sensations

Expected Outcomes Patient will be kept safe from injury related to reduced sensation.

Evaluation Outcomes Is patient safe? Is skin intact?

Interventions

Monitor patient's ability to perceive stimuli.

Turn patient and assess skin every 2 hours while in bed; provide moisturizer as needed. Protect bony prominences.

Assist the patient out of bed and into a different environment.

Teach the patient to monitor own position and skin, and to direct position changes.

Rationale

Changes in patient's perceptions must be incorporated into the plan of care.

If the patient cannot determine pressure or dryness, the nurse must evaluate and act to prevent skin breakdown.

This can help prevent sensory deprivation and social isolation.

This provides a way for the patient to maintain some control over his body, and to take part in preventing complications.

Evaluation

What can patient feel?

Is skin intact, pink, warm, dry, and without redness?

How does patient respond to being in a chair or wheelchair and taken to sunroom or common area?

Is patient able to direct care activities effectively?

(Continued on following page)

Box 48.3 NURSING CARE PLAN for a Patient with a Brain Tumor or Injury (Continued)

Nursing Diagnosis: Impaired physical mobility related to motor deficits

Expected Outcome Patient will maintain maximum mobility and be free from complications of immobility.

Evaluation of Outcomes Is patient kept mobile without contractures? Is skin intact?

Interventions

Assess degree of mobility limitation.

Turn patient every 1 to 2 hours; if postoperative, avoid positioning on the operative site unless specifically permitted by the surgeon.

Position patient in correct body alignment. High-top tennis shoes, trochanter rolls, and slings can be used to keep the body in alignment.

Perform range-of-motion exercises; consult physical therapy as ordered.

Consult occupational therapist to assist the patient in learning to perform ADLs.

Rationale

A good assessment can help determine how much the patient can actively participate in a plan for mobilization.

Turning helps prevent skin and respiratory complications.

This keeps the patient in functional position in case function is regained in the future.

ROM helps prevent contractures.

The patient may be able to participate in self-care with assistive devices.

Evaluation

How much can patient do independently? Is physical/occupational therapy evaluation indicated?

Is a turning schedule maintained? Is skin free from redness and breakdown?

Are all joints maintained in correct alignment?

If patient unable to perform active range-of-motion (ROM), is passive ROM provided on a regular schedule?

Do assistive devices help patient mobilize and maintain independence?

Nursing Diagnosis: Risk for injury related to seizures

Expected Outcome Patient will remain free of injury during a seizure.

Evaluation of Outcomes Is safety maintained? Is skin intact, without bruising or discoloration?

Interventions

Observe the patient's behavior and time the length of the seizure. When patient is alert following seizure, determine if an aura occurred, and what it was.

If patient should lose consciousness during the seizure, lay patient on his or her side or turn head to the side.

Remove objects from patient's surroundings to prevent injury during a seizure. If the patient must have side rails, pad them with blankets or foam.

See Table 48.5.

Rationale

Observing the seizure can provide clues for teaching the patient to recognize the warning signs of a future seizure and how to maintain safety.

This helps prevent oral secretions from being aspirated.

During a tonic-clonic seizure the patient may be harmed by hitting furniture or other objects.

Evaluation

What did the patient experience? What can be taught to help keep patient safe in the future?

Did patient maintain a patent airway without respiratory distress?

Is patient protected from objects that could cause injury during a seizure?

TABLE 48.3 INTERVENTIONS TO PREVENT INCREASED INTRACRANIAL PRESSURE

Action	Rationale
Keep head of bed elevated 30 degrees unless contraindicated.	Head elevation reduces ICP in some patients.
Avoid flexing the neck; keep head and neck in midline position.	Neck flexion may obstruct venous outflow.
Administer antiemetics and antitussives as necessary to prevent vomiting and cough.	Coughing and vomiting can increase ICP.
Administer stool softeners.	Straining for bowel movement can increase ICP.
Minimize suctioning. If absolutely necessary, oxygenate first and limit suction passes to one or two.	Suctioning can increase ICP.
Avoid hip flexion.	Hip flexion can increase intra-abdominal and thoracic pressure, which can increase ICP.
Prevent unnecessary noise and startling the patient.	Noxious stimuli can increase ICP in some patients.
Space care activities to provide rest between each disturbance.	Clustering care activities may increase ICP.

exception of codeine) are usually avoided because they mask neurological symptoms and make detection of changes difficult.

- Provide a dark, quiet room with few distractions; avoidance of extra stimuli may help reduce headache.
- Implement measures to prevent increased intracranial pressure. See Table 48.3 for measures and rationale.

Hyperthermia related to infectious process

- Monitor temperature. *A high temperature can increase risk for seizures.*
- Administer acetaminophen or aspirin as ordered for fever.
- Provide a cooling mattress or tepid sponge baths as necessary to reduce fever. *Remember these are uncomfortable for the patient. Comfort can be increased and shivering reduced by cooling the patient gradually and wrapping extremities in bath blankets during cooling mattress therapy.*

EVALUATION. Successful nursing management of a patient with an infectious or inflammatory neurological disorder is evidenced by a patient who is comfortable and with no preventable complications such as pressure ulcers or **contractures**. The absence of complications increases the possibility that the patient with a neurological deficit will benefit from rehabilitation and improve his or her level of functioning.

Patient Education

The nature and focus of teaching depend on the patient's level of consciousness and cognitive status. When appropriate, both the patient and significant others should be included in the education process. If the patient is not able to participate, the significant others become the focus of teaching.

Describing the brain as in control of body functions may help significant others to understand some of the symptoms of neurological disorders. The spinal cord can be compared to a telephone cord, with hundreds of tiny individual wires (nerves) making up the cord. The specific wires affected by disease determine the symptoms the patient experiences.

CRITICAL THINKING

Mr. Chung

■ Mr. Chung is an 18-year-old Asian college student. He comes to the emergency department complaining of headache, stiff neck, and fever. On physical assessment you notice a petechial rash on his legs and torso. The physician diagnoses meningococcal meningitis.

1. What tests are likely to be performed?
2. How patient education should be planned for Mr. Chung?
3. What infection control practices should be instituted?
4. What comfort measures might you offer to Mr. Chung?
5. What concerns do you have about how Mr. Chung contracted his illness?

Suggested answers at end of chapter.

HEADACHES

As mentioned throughout this chapter, headache is a common symptom of neurological disorders. However, most headaches are transient events and do not indicate a serious pathological condition. If headaches are recurrent, persistent, or increasing in severity, the patient should undergo a neurological evaluation.

Types of Headaches

Because the causes, signs and symptoms, pathophysiology, and treatment of headaches vary based on the type of headache experienced, these subjects are discussed separately for each type of headache.

Tension or Muscle Contraction Headaches

Persistent contraction of the scalp and facial, cervical, and upper thoracic muscles can cause tension headaches. A cycle of muscle tension, muscle tenderness, and further muscle tension is established. This cycle may or may not be

associated with vasodilation of cerebral arteries. Headaches of this type may be associated with premenstrual syndrome or psychosocial stressors such as anxiety, emotional distress, or depression. Symptoms typically develop gradually. Radiation of pain to the crown of the head and base of the skull, with variations in location and intensity, is common. *Pressure, aching, steady, and tight* are some of the words patients use to describe the pain of tension headaches.

Care must be taken to thoroughly rule out physical causes before attributing the headache to psychosocial origins. Symptom management may include the use of relaxation techniques, massage of the affected muscles, rest, localized heat application, nonnarcotic analgesics, and appropriate counseling.

Migraine Headaches

A migraine headache is believed to be caused by cerebral vasoconstriction followed by vasodilation. The vasoconstriction may be due to a response triggered by the trigeminal nerve, which stimulates release of substance P, a pain transmitter, into the vessels or by the release of amines such as serotonin, norepinephrine, and epinephrine. A migraine may or may not begin with an aura (visual phenomena, such as a flashing light that precedes an attack). The tendency to develop migraine headaches is often hereditary. Commonly used descriptors of migraine pain include *throbbing, boring, viselike, and pounding*. It is usually on one side of the head. Noise and light tend to exacerbate the headache, leading the patient to rest in a dark, quiet environment. Triggers for the headache include specific foods, noise, bright light, alcohol, and stress.

There are two types of migraine headaches: a classic migraine and a common migraine. The classic migraine has a preheadache (**prodromal**) phase in which the patient may experience visual disturbances, difficulty with speaking, and/or numbness or tingling. The headache that follows is often accompanied by nausea and sometimes vomiting, and may last for hours to days. A common migraine does not have the preheadache phase, but the patient experiences an immediate onset of a throbbing headache.

Treatment of migraine may be prophylactic or directed at an acute episode. Prophylactic treatment is usually reserved for those patients experiencing one or more migraine headaches per week. Dietary restrictions may be helpful if precipitating foods or beverages can be identified. Nifedipine (a calcium channel blocker) and propranolol (a beta-adrenergic blocker) are prophylactic treatments that are usually used to control blood pressure. These medications may help prevent the vascular changes that cause the headache. They should be used cautiously because of the potential for lowering blood pressure. Amitriptyline (a tricyclic antidepressant) may also help prevent migraines. Amitriptyline may cause drowsiness, dry mouth, and weight gain. None of these medications should be stopped abruptly after long-term use.

Several types of medications are available to treat the acute migraine headache. Ergot (Cafergot), a vasoconstrictor,

is effective only if taken before the vessel walls become edematous, usually within 30 to 60 minutes of headache onset. Sumatriptan (Imitrex) and zolmitriptan (Zomig) are newer medications available for migraine relief. These drugs work at the serotonin receptor sites and have a vasoconstricting action. Sumatriptan is available in both intramuscular and oral forms. The potentially additive nature of multidrug regimens requires careful monitoring.

Cluster Headaches

Vascular disturbance, stress, anxiety, and emotional distress are all proposed causes of cluster headaches. As indicated by the name, these headaches tend to occur in clusters during a time span of several days to weeks. Months or even years may pass between episodes. Alcohol consumption may worsen the episodes.

The patient may state that the headache begins suddenly, typically at the same time of night. *Throbbing and excruciating* are often the adjectives used by the patient. The headache tends to be unilateral, affecting the nose, eye, and forehead. A bloodshot, teary appearance of the affected eye is common.

Because of the brief nature of cluster headaches, treatment is difficult. A quiet, dark environment and cold compresses may lessen the intensity of the pain. Nonsteroidal anti-inflammatory drugs (NSAIDs) or tricyclic antidepressants may be prescribed.

Diagnosis

Most headaches are diagnosed based on the patient's history and symptoms. Magnetic resonance imaging (MRI), CT, skull x-ray, arteriogram, electroencephalogram, cranial nerve testing, and lumbar puncture to test CSF may be done to rule out other causes for the headaches.

Nursing Process for the Patient with a Headache

Assessment/Data Collection

The WHAT'S UP? mnemonic is particularly useful in helping the patient provide useful information regarding the headache.

- W—Where is the pain? Does it remain in one place or radiate to other areas of the head? Does the headache consistently start in one place?
- H—How does the headache feel? Is it throbbing, steady, dull, bandlike, or does it have other qualities?
- A—Aggravating or alleviating factors should be assessed. Some aggravating factors include red wine, caffeine, chocolate, and foods containing nitrates or monosodium glutamate (MSG). Other factors include particular stages of the menstrual cycle, emotional stress, and tension. Alleviating factors might include lying down in a dark room, cold compresses, and over-the-counter medications.
- T—Timing may be a factor for a patient who experiences headaches just before or during her menstrual

period. For other patients, there may be no predictive timing. Also ask how long the headache lasted.

S—Ask the patient to rate the severity on a scale of 0 to 10. Is the severity consistent or does it vary from headache to headache?

U—Are there associated symptoms, such as nausea, vomiting, or bloodshot eyes?

P—Determine the patient's perception of the headache. Does it interfere with the patient's life? If so, how? Has the patient had a previous evaluation of headaches?

Planning, Implementation, and Evaluation

Acute pain (headache) related to lack of knowledge of pain prevention and control techniques

- Assist the patient to identify and reduce or eliminate aggravating factors. This can be accomplished by keeping a headache diary for a time, recording the time of day the headache occurs, foods eaten or other aggravating factors, description of the pain, identification of associated symptoms such as nausea or visual disturbances, and other factors related to headache symptoms. *Identification of triggers can help the patient lessen the frequency and intensity of attacks.*
- Encourage the patient to use alleviating techniques such as biofeedback or stress reduction. *This helps the patient participate in the treatment of the headache and provides a sense of control over his or her illness.*
- Teach the patient to use relaxation exercises and warm, moist compresses. *These interventions may be helpful for tension headaches.*
- Provide a dark room and rest to reduce stimulation during a migraine headache.
- Teach the patient about medications, appropriate dosage, expected action, side effects, and consequences of misuse. *The patient will need to understand medication administration for appropriate use at home.*

Evaluation

If interventions have been effective, the patient will understand self-care to prevent and treat headaches, and be able to report a reduction in headache occurrences.

SEIZURE DISORDERS

Seizures/Epilepsy

A seizure is defined as “sudden, abnormal, and excessive electrical discharges from the brain that can change motor or autonomic function, consciousness, or sensation. Seizures can develop at any time during a person's life, and they can occur at any time.”¹ A seizure may be a symptom of epilepsy or of other neurological disorders such as a brain tumor or meningitis. Epilepsy is a chronic neurological disorder characterized by recurrent seizure activity.

Pathophysiology

The normal stability of the neuron cell membrane is impaired in individuals with epilepsy. This instability allows for abnormal electrical discharges to occur. These discharges cause the characteristic symptoms seen during a seizure.

Seizures can be classified as partial or generalized. Partial seizures begin on one side of the cerebral cortex. In some cases, the electrical discharge spreads to the other hemisphere and the seizure becomes generalized. Generalized seizures are characterized by involvement of both cerebral hemispheres.

Etiology

Epilepsy may be acquired or idiopathic (unknown cause). Causes of acquired epilepsy include traumatic brain injury and anoxic events. No cause has been identified for idiopathic epilepsy. The most common time for idiopathic epilepsy to begin is before age 20. New-onset seizures after this age are most commonly caused by an underlying neurological disorder.

Signs and Symptoms

Symptoms of seizure activity correlate with the area of the brain where the seizure begins. Some patients experience an aura or sensation that warns the patient that a seizure is about to occur. An aura may be a visual distortion, a noxious odor, or an unusual sound. Patients who experience an aura may have enough time to sit or lie down before the seizure starts, thereby minimizing the chance of injury.

PARTIAL SEIZURES. Repetitive, purposeless behaviors, called automatisms, are the classic symptom of partial seizures. The patient appears to be in a dreamlike state while picking at his or her clothing, chewing, or smacking his or her lips. Patients may be labeled as mentally ill, particularly if automatisms include unacceptable social behaviors such as spitting or fondling themselves. Patients are not aware of their behavior or that it is inappropriate. If the patient does not lose consciousness, the seizure is labeled as simple partial and usually lasts less than 1 minute. Older terms for simple partial seizures include *jacksonian* and *focal motor*. If consciousness is lost, it is called a complex partial seizure or psychomotor seizure, and may last from 2 to 15 minutes.

Partial seizures arising from the parietal lobe may cause paresthesias on the side of the body opposite the seizure focus. Visual disturbances are seen if the occipital lobe is the originating site. Involvement of the motor cortex results in involuntary movements of the opposite side of the body. Typically, movements begin in the arm and hand and may spread to the leg and face.

GENERALIZED SEIZURES. Generalized seizures affect the entire brain. Two types of generalized seizures are absence seizures and tonic-clonic seizures. Absence seizures, sometimes referred to as petit mal seizures, occur most often in children and are manifested by a period of staring that lasts several seconds.

Tonic-clonic seizures are what most people envision when they think of seizures. They are sometimes called grand mal seizures or convulsions. Tonic-clonic seizures follow a typical progression. Aura and loss of consciousness may or may not occur. The tonic phase, lasting 30 to 60 seconds, is characterized by rigidity, causing the patient to fall if not lying down. The pupils are fixed and dilated, the hands and jaws are clenched, and the patient may temporarily stop breathing. The clonic phase is signaled by contraction and relaxation of all muscles in a jerky, rhythmic fashion. The extremities may move forcefully, causing injury if the patient strikes furniture or walls. The patient is often incontinent. Biting the lips or tongue may cause bleeding.

The **postictal** period is the recovery period after a seizure. Following a partial seizure the postictal phase may be no more than a few minutes of disorientation. Patients who experience a generalized seizure may sleep deeply for 30 minutes to several hours. Following this deep sleep, patients may complain of headache, confusion, and fatigue. Patients may realize that they had a seizure but not remember the event itself.

Diagnostic Tests

An EEG is the most useful test for evaluating seizures. An EEG can determine where in the brain the seizures start, the frequency and duration of seizures, and the presence of subclinical (asymptomatic) seizures. Sleep deprivation and flashing light stimulation may be used to evaluate the seizure threshold. See Chapter 47 for more information on EEG.

postictal: post—after + ictal—seizure

Therapeutic Interventions

If an underlying cause for the seizure is identified, treatment focuses on correcting the cause. If no cause is found or if the seizures continue despite treatment of concurrent disorders, treatment focuses on the seizure activity.

Numerous anticonvulsant medications are available, each with specific actions, therapeutic ranges, and potential side effects (Table 48.4). Typically, the patient is started on one drug and the dosage is increased until therapeutic levels are attained or side effects become troublesome. If seizures are not controlled on a single drug, another medication is added. Many anticonvulsants require periodic blood tests to monitor serum levels as well as kidney and liver functions. Most of these medications can cause drowsiness, so teach the patient to avoid driving until the effects of the drug are known. Driving is also contraindicated until seizures are under control. If a patient must discontinue an anticonvulsant agent, it should be tapered slowly according to manufacturer directions. Stopping an anticonvulsant abruptly can result in status epilepticus, discussed below. If seizures continue despite anticonvulsant therapy, surgical intervention may be considered.

Surgical Management

The success of surgical intervention for epilepsy depends on identification of an epileptic focus within nonvital brain tissue. The surgeon attempts to resect the area affected to prevent spread of seizure activity. In some cases, seizures may be cured, but in others, the goal is to reduce the frequency or severity of the seizures. If no focus is identified or if it is in a vital area such as the motor cortex or speech center, surgery is not feasible.

TABLE 48.4 ANTICONVULSANT MEDICATIONS

Medication Class/Action	Examples	Route	Side Effects	Nursing Implications
Anticonvulsants				
Suppress abnormal discharge of neurons, suppress spread of seizure activity from focus to other parts of brain	Phenytoin (Dilantin)	PO, IM, IV	Gingival (gum) hyperplasia, nausea, ataxia, rash; aplastic anemia	Regular dental care essential; therapeutic level is 10–20 µg/mL
	Phenobarbital (Luminal)	PO, IM, IV	Drowsiness, respiratory depression	Monitor vital signs. Therapeutic level 15–40 µg/mL.
	Carbamazepine (Tegretol)	PO	Drowsiness and ataxia, blood disorders	Monitor CBC. Therapeutic level 6–12 µg/mL.
	Valproic acid (Depakote)	PO, IV	GI upset, nausea, vomiting	Therapeutic level 50–100 µg/mL
	Gabapentin (Neurontin)	PO	Drowsiness, dizziness	Blood levels not necessary
	Topiramate (Topamax)	PO	Dizziness, drowsiness, impaired memory, psychomotor slowing, vision changes, weight loss	Blood levels not necessary

The preoperative assessment for epilepsy surgery is an extensive multistage process. Thorough assessment and teaching are essential. To adequately identify seizure foci, the patient is weaned off anticonvulsant therapy. Increasing the frequency of seizures with weaning is anxiety provoking to patients and significant others.

Emergency Care

The prime objective in caring for a patient experiencing a seizure is to prevent injury. Side rails, if used, should be padded to prevent injury if the patient strikes his or her extremities against them. If the patient falls to the floor, move furniture out of the way. Maintain a patent airway and, if possible, turn the patient on his or her side to prevent aspiration if vomiting occurs. Do not force an airway or anything else into the patient's mouth once the seizure has begun. The individual should not be restrained because this may also increase the risk of injury. Observe and document the patient's behavior during the seizure, which part of the body was first involved, progression of the seizure, and the length of time the seizure lasted (see Box 48.4 Patient Perspective). After the seizure, assess the patient for breathing. Suction if necessary and initiate rescue breathing or cardiopulmonary resuscitation (CPR) as indicated.

Status Epilepticus

Status epilepticus is characterized by at least 30 minutes of repetitive seizure activity without a return to consciousness. This is a medical emergency and requires prompt intervention to prevent irreversible neurological damage. Abrupt cessation of anticonvulsant therapy is the usual cause of status epilepticus.

Box 48.4

Patient Perspective

Mrs. Rowley

I have had seizures for 35 years, and as a result of falling during seizures have experienced cuts, bruises, and a broken bone. I usually have an aura that lets me know a seizure is about to occur. This is helpful if I can get myself to a safe place to prevent falling or being injured. When a patient is having a seizure you can best help by using padding such as pillows or blankets for protection, talking calmly, and using gentle touch to prevent injury. You should not sit on or hold down someone during a seizure. I have had the frightening experience of waking up with a nurse sitting on me and holding down my arms. After you have protected the patient, let them come out of the seizure on their own. When the seizure is over, I usually want to sleep because seizures are exhausting and uncomfortable. I will rest better knowing you are watching over me to keep me safe.

Seizure activity precipitates a significant increase in the brain's need for glucose and oxygen. This metabolic demand is even greater during status epilepticus. Irreversible neuronal damage may occur if cerebral metabolic needs cannot be fulfilled. Adequate oxygenation must be maintained, if necessary, by intubating and mechanically ventilating the patient. These patients are also at significant risk for aspiration.

Intravenous diazepam (Valium) or lorazepam (Ativan) is given to stop the seizures. Because both of these drugs may cause respiratory depression, careful airway management is required. After obtaining serum drug levels, anticonvulsant therapy is adjusted to achieve therapeutic levels.

If seizures remain resistant to treatment, a barbiturate coma may be induced with intravenous pentobarbital. The last line of treatment for status epilepticus is general anesthesia or pharmacological paralysis. Both of these therapies require intubation, mechanical ventilation, and management in an intensive care unit (ICU) setting. Continuous EEG monitoring is used to verify that the seizures have actually stopped. A patient treated with neuromuscular blockade drugs may still be seizing but have no visible manifestations. For more information, visit the Epilepsy Foundation of America at www.efa.org.

Psychosocial Effects

Finances can be a major concern to patients with seizure disorders. Some patients with epilepsy experience hiring discrimination, or they may not qualify for some jobs in which safety is a concern. Remind patients that falsifying information on job applications may be grounds for dismissal. Refusal of health insurance coverage can create financial hardships for patients on long-term medications. Most patients whose seizures are controlled can work and lead productive lives. You can help patients explore options for financial assistance if necessary.

Patients with poorly controlled seizures should not operate motor vehicles. In today's society a driver's license is a sign of adulthood and independence, and patients who cannot drive may experience lowered self-esteem. Job opportunities may be limited for patients who depend on public transportation. Encourage the patient to obtain a state identification card. This can be used in place of a driver's license for identification.

Patients may limit interpersonal relationships out of fear of having a seizure. The involuntary movements, sounds, and possible incontinence that occur with seizures are embarrassing to patients and can be frightening to lay people. Role playing may help the patient determine when and how to confide in others.

Nursing Process for the Patient with Seizures

Assessment/Data Collection

Perform a general neurological assessment of the patient with a history of seizures. Determine the type of seizure

manifestations and type of aura if any. Assess the patient's knowledge of the disease and its treatment. It is important to assess whether the patient has the resources to purchase prescribed anticonvulsant medications and whether the medication regimen is adhered to. Drug levels may help determine degree of compliance with therapy.

Nursing Diagnosis, Planning, and Implementation **Risk for injury related to seizure activity**

EXPECTED OUTCOME: Patient will remain free from injury.

- Instruct the patient to recognize the aura and to get to safety if it occurs. This may mean lying down away from furniture or other objects. *This helps prevent injury.*
- Institute seizure precautions for the patient admitted to a health-care institution. See Table 48.5 for precautions and interventions *to prevent injury.*
- Encourage all patients to wear medical alert jewelry or other identification *to alert others to the presence of seizure disorder.*
- Assist patients to identify conditions that trigger seizures. Hypoglycemia, hypoxia, and hyponatremia are all potential triggers of hypersensitive neurons. Teach the patient the importance of a consistent schedule of eating and sleeping. *The patient may be able to prevent seizures by avoidance of triggers.*

Risk for ineffective management of therapeutic regimen related to complex regimen and possible lack of resources

EXPECTED OUTCOME: Patient will follow medication regimen as evidenced by therapeutic drug levels and seizure activity controlled.

- Assess patient's ability to obtain and pay for medication. *Sudden discontinuance of a medication can result in status epilepticus.*

TABLE 48.5 INTERVENTIONS FOR SEIZURES

Seizure Precautions

- Pad side rails of hospital bed with commercial pads or bath blankets folded over and pinned in place.
- Keep call light within reach.
- Assist patient when ambulating.
- Keep suction and oral airway at bedside.

Nursing Care During a Seizure

- Stay with patient.
- Do not restrain patient.
- Protect from injury (move nearby objects).
- Loosen tight clothing.
- Turn to side when able to prevent occlusion of airway or aspiration.
- Suction if needed.
- Monitor vital signs when able.
- Be prepared to assist with breathing if necessary.
- Observe and document progression of symptoms.

- Refer patient to a case manager or social worker if necessary *to assist with obtaining resources for medications.*
- Teach the patient about medication action, dose, side effects, schedule, and the importance of not stopping treatment suddenly. *Patients with seizures may have several medications to take several times each day. Patients who understand their regimens are more likely to comply.*
- Teach the patient about the importance of regular blood tests if required. *Therapeutic blood levels help prevent seizures (too low) and toxicity (too high).*

Evaluation

Successful care of a patient with epilepsy is manifested by a decrease in seizures to the lowest possible frequency. Patient verbalization of understanding of needed lifestyle changes is another indication of success. Patients should be able to state measures to prevent injury if a seizure should occur and should verbalize understanding of all medications and their administration schedules. Therapeutic drug levels may be measured to evaluate compliance with the medication regimen.

TRAUMATIC BRAIN INJURY

Traumatic brain injury (TBI) is a major cause of death and disability in adults. Young males make up a large proportion of brain injury victims.

Pathophysiology

Traumatic brain injury is a complex phenomenon with results ranging from no detectable effect to persistent vegetative state. Trauma can result in hemorrhage, contusion or laceration of the brain, and damage at the cellular level. In addition to the primary insult, the brain injury may be compounded by cerebral edema, hyperemia, or hydrocephalus.

Etiology

Motor vehicle accidents account for the largest percentage of traumatic brain injuries. Falls, sports-related injuries, and violence are also common causes of traumatic brain injury.

The brain is susceptible to various types of injury and can be classified in several ways. The term *closed head injury* or *nonpenetrating injury* is used when there has been rapid back and forth movement of the brain causing bruising and tearing of brain tissues and vessels, but the skull is intact. An open head injury or penetrating injury refers to a break in the skull. *Acceleration injury* is the term used to describe a moving object hitting a stationary head. An example of this type of injury is a patient who is hit in the head with a baseball bat. A *deceleration injury* occurs when the head is in motion and strikes a stationary surface. This type of injury is seen in patients who trip and fall, hitting their head on furniture or the floor.

A combination of acceleration-deceleration injury occurs when the stationary head is hit by a mobile object and the head then strikes a stationary surface. A soccer player who sustains a blow to the head and then hits the ground with his or her head may sustain an acceleration-deceleration injury.

Rotational injuries have the potential to cause shearing damage to the brain, as well as laceration and contusions. Rotational injuries may be caused by a direct blow to the head or may occur during a motor vehicle accident in which the vehicle is struck from the side. Twisting of the brainstem can damage the reticular activating system, causing loss of consciousness. Movement of the brain within the skull may result in bruising or tearing of brain tissue where it comes in contact with the inside of the skull.

Types of Brain Injury and Signs and Symptoms

Concussion

Cerebral concussion is considered a mild brain injury. If there is a loss of consciousness, it is for 5 minutes or less. Concussion is characterized by headache, dizziness, or nausea and vomiting. The patient may complain of amnesia of events before or after the trauma. On clinical examination there is no skull or dura injury and no abnormality detected on CT or MRI.

Contusion

Cerebral contusion is characterized by bruising of brain tissue, possibly accompanied by hemorrhage. There may be multiple areas of contusion, depending on the causative mechanism. Severe contusions can result in diffuse axonal injury (DAI). The symptoms of a cerebral contusion depend on the area of the brain involved.

Brainstem contusions affect level of consciousness. Decreased level of consciousness may be transient or permanent. Respirations, pupil reaction, eye movement, and motor response to stimuli may also be affected. The autonomic nervous system may be affected by edema or by hypothalamic injury, causing rapid heart rate and respiratory rate, fever, and diaphoresis.

Hematoma

SUBDURAL HEMATOMA. Subdural hematomas are classified as acute or chronic based on the time interval between injury and onset of symptoms. Acute subdural hematoma is characterized by appearance of symptoms within 24 hours following injury. The bleeding is typically venous in nature and accumulates between the dura and arachnoid membranes (Fig. 48.5). Approximately 24% of patients who sustain a severe brain injury develop an acute subdural hematoma. Damage to the brain tissue may cause an altered level of consciousness. Therefore, it can be difficult to recognize a subdural hematoma based only on clinical examination. As the subdural hematoma increases in size, the patient may exhibit one-sided paralysis of extraocular movement, extremity weakness, or dilation of

FIGURE 48.5 (A) Subdural hematoma is usually venous and forms between the dura and the arachnoid membranes. (B) An epidural hematoma is usually from an arterial bleed and forms between the dura mater and the skull.

the pupil. Level of consciousness may deteriorate further as ICP increases.

Older adults and alcoholic individuals are particularly prone to chronic subdural hematomas. Atrophy of the brain, common in these populations, stretches the veins between the brain and the dura. A seemingly minor fall or blow to the head can cause these stretched veins to rupture and bleed. Often there are no other injuries associated with the trauma. Because a chronic subdural hematoma can develop weeks to months after the injury, the patient may not remember an injury occurring.

The patient with a chronic subdural hematoma may be forgetful, lethargic, or irritable or may complain of a headache. If the hematoma persists or increases in size, the patient may develop hemiparesis and pupillary changes. The patient or significant other may not associate the symptoms with a previous injury and therefore may delay seeking medical care.

EPIDURAL HEMATOMA. Approximately 10% of patients with severe brain injuries develop epidural hematomas. This collection of blood between the dura mater and skull is usually arterial in nature and is often associated with skull fracture (see Fig. 48.5.) Arterial bleeding can cause the hematoma to become large very quickly. Patients with epidural hematoma typically exhibit a progressive course of symptoms. The patient loses consciousness directly after the injury; he or she then regains consciousness and is coherent for a brief period. The patient then develops a dilated pupil and paralyzed extraocular muscles on the side of the hematoma and becomes less responsive. If there is no intervention, the patient becomes unresponsive. Seizures or hemiparesis may occur. Once the patient exhibits symptoms,

the deterioration may be rapid. Airway management and control of ICP must be instituted immediately. If ICP is not controlled, the patient will die.

Diagnostic Tests

CT scan is usually the first imaging test performed on the brain-injured patient. It is faster and more accessible than MRI. This is particularly important for unstable patients or those with multiple injuries. It is easier to identify skull fractures on CT than on MRI. MRI may be used later to identify damage to the brain tissue.

Neuropsychological testing can be useful in assessing the patient's cognitive function. This information helps direct rehabilitation placement, discharge planning, and return to work or school. Neuropsychological testing identifies problems with memory, judgment, learning, and comprehension. Compensation strategies can be suggested to the patient and significant others based on the results.

Therapeutic Interventions

Surgical Management

Surgical treatment of hematomas is discussed under intracranial surgery later in this chapter.

Medical Management

Medical management of traumatic brain injury involves control of ICP and support of body functions. Brain-injured patients may be partially or completely dependent for maintenance of respiration, nutrition, elimination, movement, and skin integrity.

A variety of techniques are used to control intracranial pressure in the patient with moderate or severe brain injury. The first step is to insert an ICP monitor to allow measurement of the ICP. Refer to the section on increased ICP earlier in this chapter for further information.

If ICP remains elevated despite drainage of cerebrospinal fluid, the next step is use of an osmotic diuretic. The most commonly used drug is intravenous mannitol (Osmitrol). Mannitol utilizes osmosis to pull fluid into the intravascular space and eliminate it via the renal system. Serum osmolarity and electrolytes must be carefully monitored when mannitol is being administered. Some patients experience a rebound increase in ICP after the mannitol wears off.

Mechanical hyperventilation is the next step if the patient is still experiencing increased ICP. Hyperventilation is effective in lowering ICP because it causes vasoconstriction. Vasoconstriction allows less blood into the cranium, thereby lowering ICP. Research has demonstrated, however, that aggressive hyperventilation, particularly within the first 24 hours after injury, may induce ischemia in the already compromised brain. Therefore, hyperventilation is now reserved for increased ICP that does not respond to other treatments.

High-dose barbiturate therapy may be used to induce a therapeutic coma, which reduces the metabolic needs of the brain during the acute phase following injury. These patients

are completely dependent for all their needs and care. They will be mechanically ventilated and cared for in an ICU setting. Vasopressors may be required to maintain blood pressure, and the patient's temperature should be kept as normal as possible.

Complications of Traumatic Brain Injury

Brain Herniation

If interventions to control ICP are unsuccessful, the patient may experience uncontrolled edema or herniation of brain tissue (Fig. 48.6). Herniation is displacement of brain tissue out of its normal anatomical location. This displacement prevents function of the herniated tissue and places pressure on other vital structures, most commonly the brainstem. Herniation usually results in brain death.

Patients who experience brain death may be suitable organ donor candidates. For some significant others, the opportunity to donate their loved one's organs provides some sense of purpose in the death. See Box 48.5 Traumatic Brain Injury Summary.

Diabetes Insipidus

Edema or direct injury affects the posterior portion of the pituitary gland or hypothalamus. Inadequate release of anti-

FIGURE 48.6 Herniation of the brain. (A) Normal brain. (B) Herniation of brain tissue into tentorial notch.

Box 48.5**Traumatic Brain Injury Summary**

Signs and Symptoms	Loss or decrease in level of consciousness, depending on severity and type of injury Loss of memory before or after the injury Increased ICP Headache, dizziness Nausea and vomiting Unequal pupils Tachycardia, tachypnea Diaphoresis Hemiparesis
Diagnostic Tests	CT scan, MRI Skull x-rays Routine laboratory tests (hemoglobin, electrolytes, coagulation studies, type and crossmatch) Neuropsychological testing
Therapeutic Interventions	Control intracranial pressure Surgical management of hematoma Maintain respiratory function Maintain diet/nutrition Maintain skin integrity Prevent complications Education
Complications	Increased intracranial pressure Diabetes insipidus Acute hydrocephalus Posttraumatic syndrome Cognitive and personality changes
Possible Nursing Diagnoses	Disturbed thought processes related to cerebral edema or increased intracranial pressure Self-care deficit related to increased intracranial pressure Pain related to cerebral edema

diuretic hormone results in polyuria and, if the patient is awake, polydipsia. Fluid replacement and intravenous vasopressin are used to maintain fluid and electrolyte balance.

Acute Hydrocephalus

Cerebral edema can interfere with cerebrospinal fluid circulation, causing **hydrocephalus**. Initial treatment is with an external ventricular drain, followed by a ventriculoperitoneal

hydrocephalus: hydro—water + cephalus—head

shunt if necessary. A shunt drains excess CSF into the peritoneum, where it is reabsorbed into circulation and excreted.

Labile Vital Signs

Direct trauma to or pressure on the brainstem can cause fluctuations in blood pressure, cardiac rhythm, or respiratory pattern. Treatment is aimed at control of intracranial pressure.

Posttraumatic Syndrome

Patients who sustain a concussion may experience ongoing, somewhat vague symptoms. They complain of headache, fatigue, difficulty concentrating, depression, or memory impairment. Symptoms may be severe enough to interfere with work, school, and interpersonal relationships. Neuropsychological testing may provide objective evidence of cognitive dysfunction and establish the need for cognitive rehabilitation. Symptoms may take 3 to 12 months to resolve.

Cognitive and Personality Changes

Alterations in personality and cognition may be the most difficult long-term complication for patients and significant others to adjust to. The patient may have significant short-term memory impairment. This limits his or her ability to learn new information and may interfere with ability to function at work or school. Impaired judgment can make the patient a safety risk to self or others. It also affects social functioning.

Emotional lability, loss of social inhibitions, and personality changes may occur. These consequences of traumatic brain injury have a profound effect on the patient and significant others. Spouses may state, “This is not the person I married.” If behavior is violent, bizarre, or profane, children may be unwilling to bring their friends home and may become socially isolated. Young children, in particular, have difficulty understanding why the parent is behaving so differently. Disintegration of relationships is not uncommon following traumatic brain injury.

Neuropsychological testing objectively identifies problems. These deficits can then be addressed with cognitive rehabilitation. Individual and family counseling may be of benefit. Support groups for patients and significant others are often helpful.

Motor and speech impairment are additional possible long-term complications of traumatic brain injury. Intensive rehabilitation provides the best opportunity for maximizing recovery. For more information, visit the Brain Injury Association at www.biausa.org.

Nursing Process for the Patient with Traumatic Brain Injury

Acute care is presented below. Also see Box 48.3 Nursing Care Plan for the Patient with a Brain Tumor or Injury.

Assessment/Data Collection

After stabilization in the emergency department, care of the patient with a traumatic brain injury is in the intensive care setting, where ICP can be carefully monitored. Neurological status is assessed frequently, including Glasgow Coma Scale score, pupil responses, muscle strength, and vital signs.

Review Box 48.2 Signs and Symptoms of Increased Intracranial Pressure. Once the patient is stabilized, neurological damage is assessed. Identification of deficits guides nursing care. Assessment of discharge needs should also begin as soon as possible. The patient may require extensive rehabilitation, and early referral may speed transfer to an appropriate facility.

Nursing Diagnosis, Planning, and Implementation **Ineffective cerebral tissue perfusion related to increased ICP**

EXPECTED OUTCOME: Changes in cerebral tissue perfusion are recognized and reported promptly.

- Monitor vital signs for widening pulse pressure or falling blood pressure. *These are signs of increased ICP and should be reported promptly.*
- Monitor Glasgow Coma Scale score and report worsening status promptly. *Decreasing level of consciousness (LOC) may indicate increased ICP and may necessitate emergency intervention.*
- Implement measures to prevent increased ICP. See Table 48.3 for interventions and rationale.

Ineffective airway clearance related to reduced cough reflex and decreased level of consciousness

EXPECTED OUTCOME: Patient will maintain a clear airway as evidenced by clear breath sounds and $SpO_2 = 90\%$.

- Monitor airway and breath sounds. *If the patient has excess secretions and is unable to cough effectively, suctioning may be necessary.*
- Limit suction passes to one or two at a time, a maximum of 5 to 10 seconds each time. *Suctioning can increase ICP.*
- Keep head of bed elevated 30 degrees *to reduce risk of aspirating oral secretions.*
- Turn the patient frequently *to help mobilize secretions.*

Risk for ineffective breathing pattern related to pressure on respiratory center

EXPECTED OUTCOME: The patient will maintain oxygenation within normal limits.

- Monitor respiratory rate and depth, ABGs, and SpO_2 . Report changes. *If respiratory status is deteriorating, mechanical ventilation may be necessary.*

Evaluation

The plan of care has been successful if the patient shows no unexpected worsening of neurological function and injuries and complications are prevented. The airway is clear. The patient is kept comfortable, and self-care needs are met.

Rehabilitation

Once the patient is stabilized, evaluation for discharge to a rehabilitation facility is completed. The patient must be able to physically tolerate the rehabilitation program, in which the patient is taught to function as independently as possible.

The family must be prepared for changes in the patient's ability to function and possible changes in personality. It may take months to years before the patient reaches his or her maximum potential. In some cases of severe brain damage or continued comatose state, rehabilitation is not feasible and the patient is discharged to home or a long-term facility for custodial care.

BRAIN TUMORS

Brain tumors are neoplastic growths of the brain or meninges. These tumors may be characterized by vague symptoms such as headache or visual changes or by focal neurological deficits such as hemiparesis or seizures.

Pathophysiology and Etiology

Brain tumors cause symptoms by either compressing or infiltrating brain tissue. Tumors may arise from central nervous system cells or may metastasize from other locations in the body. Primary brain tumors rarely metastasize. If they do metastasize, it is to the spine.

There is no established cause for primary brain tumors. It is unclear what causes the cells to begin reproducing in an uncontrolled fashion. Brain tumors can be classified in several different ways. The traditional distinction of benign and malignant is less helpful when discussing brain tumors. A benign tumor in the brainstem may be fatal, whereas a malignant tumor in the frontal lobe may not. Location of the tumor can be just as important a factor in outcome as the cell type.

Primary tumors are those arising from cells of the central nervous system. Eighty to 90% of brain tumors are primary in nature. Intra-axial tumors are those that arise from the glial cells within the cerebrum, cerebellum, or brainstem. These tumors infiltrate and invade brain tissue. Extra-axial tumors arise from the skull, meninges, pituitary gland, or cranial nerves. These tumors have a compressive effect on the brain.

Approximately 10% to 20% of brain tumors are secondary; that is, they are metastatic from a primary malignancy elsewhere in the body (Fig. 48.7). These tumors commonly spread via the arterial system. If untreated, they cause increased ICP. This may be the cause of the patient's death rather than the primary malignancy.

Signs and Symptoms

The symptoms of a brain tumor are directly related to the location of the tumor in the brain and to the rate of growth. Slow-growing types of tumors such as meningiomas (a tumor arising from the meninges) (Fig. 48.8) can get to be quite large before causing symptoms. Conversely, glioblastoma multiforme or metastatic tumors may abruptly cause seizures or hemiparesis. Other types of tumors include oligodendroglioma, astrocytoma, and acoustic neuroma. The suffix *-oma* refers to tumor. The prefix denotes the type of cell the tumor arises from.

FIGURE 48.7 Metastatic brain tumor: This patient's primary cancer was in the lung.

Symptoms can include seizures, motor and sensory deficits, headaches, and visual disturbances. If the pituitary gland is involved, additional symptoms such as abnormal growth or fluid volume changes are related to changes in hormone secretion.

Diagnostic Tests

MRI gives the clearest images of a brain tumor. Many health-care providers order a CT scan first because it is cheaper. If the tumor appears to be highly vascular or in close proximity to major blood vessels, an angiogram may be performed. It is now possible to do magnetic resonance angiograms, which involve the intravenous administration

FIGURE 48.8 Meningioma.

of contrast material and is much less invasive than a traditional angiogram. If the tumor is in the region of the pituitary gland, serum hormone levels are evaluated.

Therapeutic Interventions

Surgical treatment involves removal of the tumor or as much of the tumor as possible. Care of the patient undergoing intracranial surgery is discussed later in this chapter.

Medical Treatment

Medical treatment consists of controlling symptoms. Patients who have a seizure are placed on anticonvulsants. If significant cerebral edema is noted on the CT or MRI or if the patient is suffering from headaches or other symptoms, a steroid such as dexamethasone (Decadron) may be prescribed to lessen the edema. Typically, patients do not require narcotics for pain relief.

Radiation Therapy

External beam radiation therapy is standard treatment for many patients with a brain tumor. The therapy is typically given 5 days a week for 6 weeks. Some clinicians use a hyperfractionated schedule, in which the patient has therapy twice a day for less time. Brachytherapy is a means of delivering radiation therapy directly to the tumor. Small catheters are implanted in the tumor and then tiny radioactive particles are inserted into the catheters. The treatment typically takes 3 to 5 days. During this time the patient is confined to a private room and interaction with visitors and staff is kept to a minimum because of radioactivity. This therapy is not appropriate for confused individuals because they may not be able to cooperate with restrictions.

Stereotactic radiosurgery is a technique that utilizes small amounts of radiation directed at the tumor from different angles. A metal frame is affixed to the patient's skull, and the tumor is visualized within the framework on a CT or MRI. A computer plan is generated to direct the radiation. Because multiple small sources are used, the normal brain tissue receives very little radiation while the majority of the radiation accumulates in the tumor.

Chemotherapy

The blood-brain barrier is a protective mechanism that prevents many injurious substances from reaching brain tissue. Unfortunately, it is also effective in preventing most chemotherapeutic agents from reaching the brain. To penetrate the blood-brain barrier, very large doses of chemotherapy may be required. These doses may not be well tolerated by other body systems. New treatments are currently being investigated. Some clinicians place chemotherapeutic substances in the cavity left by surgical resection. Others disrupt the blood-brain barrier with mannitol (an osmotic diuretic) and then deliver intra-arterial chemotherapy under general anesthesia. Gene therapy is also being used in an effort to kill malignant cells.

Complementary Therapies

The rate of success for treatment of brain tumors is not as high as treatment of other neoplasms. Patients may be drawn

to nontraditional therapies both as cures and for treatment of symptoms. Encourage patients to look at each option in a rational manner. Some questions they should ask themselves include the following:

- Will this interfere with any of my other treatments or medications?
- What is the cost?
- What are the side effects?
- Is there any objective information (research) available?
- What does my physician think of this?

Additional information on evaluation of complementary therapies is found in Chapter 4.

Acute and Long-Term Complications

It is difficult to distinguish between symptoms of a brain tumor and complications of treatment. Seizures, headaches, memory impairment, cognitive changes, and ataxia may be symptoms of the tumor or the result of surgery or radiation therapy. Patients may experience hemiparesis or aphasia following surgery. If the tumor continues to grow despite treatment, the patient will experience further decline in function. Gradually the patient becomes more lethargic and unresponsive. Once the patient becomes comatose, death occurs within a matter of days, particularly if artificial nutrition and hydration are not administered.

Nursing Process for the Patient with a Brain Tumor

Nursing care of the patient with a brain tumor is similar to the patient with a brain injury, since both experience neurological deficits. See Box 48.3 Nursing Care Plan for Care of the Patient with a Brain Tumor or Injury.

INTRACRANIAL SURGERY

The primary purpose of intracranial surgery is to remove a mass lesion. These types of lesions include hematomas, tumors, arteriovenous malformations, and, occasionally, contused brain tissue. Other indications for surgery include elevation of a depressed skull fracture, removal of a foreign body, débridement of a wound, or resection of a seizure focus. **Craniotomy** refers to any surgical opening in the skull. A burr hole is an opening into the cranium made with a drill. **Craniectomy** is the term used to describe removal of part of the cranial bone. **Cranioplasty** refers to repair of bone or use of a prosthesis to replace bone following surgery.

The goal of intracranial tumor surgery for a tumor is gross total resection of the tumor. This involves removal of all visible tumor, called *debulking*. Even with the use of an operative microscope, there may be viable tumor cells left behind that can give rise to recurrence. If the entire tumor cannot be removed, the surgeon debulks as much as possi-

ble, thereby giving radiation therapy or chemotherapy less of a burden to combat. In some cases, it is not feasible to attempt more than a biopsy of the tumor. Location of the tumor or the patient's age or medical condition may not allow the patient to tolerate a full craniotomy. The biopsy may be done under local or general anesthesia, depending on the patient's condition. The goal of a biopsy is to obtain tissue that allows pathological diagnosis of the tumor. The diagnosis then guides any further treatment.

Intracranial surgery is usually performed under general anesthesia. Occasionally, a procedure requires that the patient be awake and cooperative.

Preoperative Care

Preoperative care of the patient undergoing intracranial surgery is similar to that of patients having other surgeries (see Chapter 11). The patient undergoes a laboratory work-up and anesthesia evaluation. If the patient has cognitive impairments, it is important that a significant other be available to provide information. A thorough baseline neurological assessment should be documented.

Patient education is important preoperatively. The extent of education depends on the patient's ability to absorb new information. This is influenced by the disease process, cognitive functioning, anxiety, and educational level. Significant others are involved as needed. Information about the disease process and surgery are provided by the surgeon. You can play an important role in reinforcing and clarifying the information presented.

Anxiety is also a significant concern before surgery. The patient is anticipating serious surgery, as well as an unknown outcome. Allow time for the patient and significant others to express their fears and ask questions. Honest and accurate information should be provided.

Significant others should be prepared for how the patient will look after surgery. A preoperative visit to the intensive care unit may help prevent some anxiety postoperatively. Significant others should be accompanied on this visit by a knowledgeable nurse who can explain what they are seeing.

Surgery may last 2 hours for a biopsy to 12 hours or longer for more intricate procedures. Patients and significant others should be prepared for the idea that some or all of the patient's hair will be shaved off. Some people prefer to have all their hair shaved rather than just part. The patient should be prepared to see his or her face swollen after surgery, particularly around the eyes. The periorbital region may be bruised. Many patients wish to wear a scarf or scrub cap after the dressing is removed.

Nursing Process for the Postoperative Care of the Patient Having Intracranial Surgery

Acute care of the postoperative patient is presented below. Also see Box 48.3 Nursing Care Plan for the Patient with a Brain Tumor or Injury.

craniotomy: crani—skull + otomy

Assessment/Data Collection

After intracranial surgery, plan to assist the RN with frequent neurological assessments in addition to routine postoperative monitoring. Patients should have their neurological status assessed every hour for the first 24 hours or as ordered by the physician. Any deterioration in status should be immediately reported to the RN and physician. Many patients undergo a CT scan within the first 24 hours following surgery to assess cerebral edema.

Nursing Diagnosis, Planning, and Implementation

The primary goal following intracranial surgery is prevention of complications. Initial care will be provided in an intensive care unit, and the LPN works with the RN to provide care. Once the patient is stabilized, goals can change to longer term outcomes such as acceptance of changes in body image and understanding of self-care following discharge. If the patient has severe deficits following surgery, rehabilitation or long-term care may become necessary. A consultation with a social worker can help with planning for this transition. Priority nursing diagnoses include the following.

Risk for ineffective cerebral tissue perfusion related to edema of the operative site

EXPECTED OUTCOME: Patient will have adequate cerebral tissue perfusion as evidenced by stable or improving neurological assessments.

- Monitor neurological status as ordered. Report changes promptly. *Deteriorating status may signify increased ICP.*
- Implement measures to prevent increased ICP. See Table 48.3 for interventions and rationales.
- Position patient with the head of the bed at 30 degrees or higher, unless ordered otherwise, *to promote venous drainage and minimize increases in intracranial pressure.* The exception to this is patients who have had a chronic subdural hematoma removed, who must remain flat. Patients may turn from side to side or lie on their back, but should not lie on the operative side.
- Implement seizure precautions *because the patient is at risk for seizures due to cerebral edema.*
- Use caution to protect the many monitoring systems being used. The patient may have an intracranial monitor in place following surgery *to monitor intracranial pressure.* Some patients may also have central venous pressure catheters or pulmonary artery catheters *to monitor fluid status.* Urinary catheters are used during the immediate postoperative period *to accurately monitor fluid balance.*
- Monitor dressings for drainage. *Drainage that is blood tinged in the center with a yellowish ring around it may be CSF leakage. A suspected CSF leak should be reported to the RN or physician immediately.*

Risk for infection related to surgical procedure

EXPECTED OUTCOME: Patient remains free from infection as evidenced by temperature and white cell count within normal limits and incision sites clean and dry.

- Monitor for rise in temperature, purulence at incision site, and increase in white cell count. *These are signs of infection and should be reported immediately.*
- Use strict aseptic technique for all care of the incision, dressing, and monitoring equipment sites *to reduce risk of infection.*

Body image disturbance related to changes in appearance or function

EXPECTED OUTCOME: Patient will display an accepting attitude toward change in appearance, as evidenced by willingness to look in mirror and/or be seen by others.

- Offer a turban, scarf, or hat if the patient desires *to help conceal a shaved head.*
- Portray an accepting attitude toward the patient. *Patients are likely aware of nurses' nonverbal behavior.*
- Allow the patient to express his or her feelings if desired. *Talking may help the patient work through feelings, but it should not be forced.*

Deficient knowledge related to change in treatment regimen following surgery

EXPECTED OUTCOME: The patient and significant others will verbalize correct information for follow-up care at home. They will state they have the resources to manage care effectively.

- Teach the patient and family or significant other home management, including medication regimen, wound care, and ordered activity restrictions, including driving. Have the patient and significant others verbalize the signs of infection or other possible complications to report. *The patient and family will assume responsibility for care after discharge.*
- Teach patient and family seizure precautions and the importance of taking anticonvulsants as ordered. *The patient will be at risk for seizures following surgery. If seizure-free for 1 year, the physician may discontinue anticonvulsants.*
- Consult social worker or case manager for resources if needed. *The patient may benefit from visiting nurse follow-up. Assistance with obtaining medications can also be provided if necessary.*

Evaluation

Interventions have been effective if infection and other complications have been prevented. The patient might be able to look in the mirror and begin to show evidence of acceptance of changes in body image, although this may not happen until after discharge from the hospital. The patient and significant others should be able to describe appropriate follow-up care.

CRITICAL THINKING

Mr. Evans

■ Mr. Evans is a 24-year-old white male who was involved in a motor vehicle accident. His blood alcohol level was 0.24. Mr. Evans has no preexisting medical problems. Emergency medical services personnel report that Mr. Evans was unconscious on their arrival at the scene and then became alert and combative. His CT scan shows a left-sided epidural hematoma. Mr. Evans is admitted to your unit for observation.

1. What symptoms would you expect to see if Mr. Evans's hematoma increases in size?
2. What emergency preparations should you have ready?
3. What psychosocial assessments should you perform?

Suggested answers at end of chapter.

FIGURE 48.9 A herniated disk places pressure on a spinal nerve root.

SPINAL DISORDERS

Herniated Disks

Herniated intravertebral disks are a common health problem. They are characterized by pain and paresthesias that follow a radicular (nerve path) pattern. It is not uncommon for patients to have more than one herniated disk or to have herniated disks in different areas of the spine.

Pathophysiology

When the disk between two vertebrae herniates, it moves out of its normal anatomical position. In most cases, the annulus fibrosus, the tough outer ring of the disk, tears. This allows escape of the nucleus pulposus, the soft inner portion of the disk. Displacement of the disk compresses one or more nerve roots, causing the characteristic symptoms (Fig. 48.9).

Etiology

In some cases, a specific event can be correlated with a herniated disk. The patient may describe a fall, lifting a heavy object, or a motor vehicle accident. In other instances, the patient cannot identify a triggering incident.

Signs and Symptoms

Cervical disk herniation causes pain and muscle spasm in the neck. The patient may exhibit decreased range of motion secondary to pain. Hand and arm pain is unilateral (one sided) and follows the distribution of the spinal nerve root. Patients often complain of numbness or tingling in the extremity. Asymmetrical weakness and atrophy of specific muscle groups may be detected. If weakness involves the entire extremity, it is unlikely that disk herniation is the etiology. The severity of the pain or paresthesia does not correlate directly with the severity of the nerve compression. However, weakness and atrophy are indicators of significant nerve compression.

Thoracic herniated disks are not common. This portion of the spine is the least mobile; therefore, less stress is exerted on the disks. Patients with herniated thoracic disks may complain of pain in the back. It is uncommon to detect muscular weakness.

A herniated lumbar disk is typically characterized by low back pain, pain radiating down one leg, paresthesias, and weakness. The patient may limp on the affected leg or may have difficulty walking on his or her heels or toes. Muscle spasm is often present. Pain and muscle spasm may limit the patient's range of motion. Depending on the disk affected, the knee or ankle deep tendon reflex may be decreased or absent. A severely herniated L5–S1 disk may affect bowel or bladder continence. This is an emergency situation and should be reported immediately.

The WHAT'S UP? mnemonic can be used to assess symptoms of herniated disks at any level:

- W—Where is the pain? Does it radiate into an extremity? In what distribution?
- H—How does it feel? Sharp, stabbing, burning?
- A—Do certain positions or activities alleviate or aggravate the pain? Holding the affected arm above the head may alleviate cervical pain. Sitting places pressure on disks and aggravates lumbar pain. Lying down may relieve it.
- T—Is there a correlation between time and pain? Some patients have more pain at the end of the day. Is the pain constant or intermittent?
- S—Ask the patient to rate the severity of the pain on a scale of 0 to 10. Which is the most painful, the spine or the extremity?
- U—Ask the patient to identify associated symptoms such as numbness, tingling, or weakness.
- P—What is the patient's perception of the pain? Is it interfering with work or other aspects of the patient's life?

Diagnostic Tests

An MRI will detect herniation of a disk and compression or abnormality of the spinal cord. If the patient has previously had surgery in the area of the suspected herniation, the MRI is done with and without contrast to differentiate between scar tissue and a herniated disk.

If the patient cannot tolerate MRI or if the MRI does not provide enough information, a myelogram is done. Refer to Chapter 47 for a description of both tests.

Therapeutic Interventions

Most clinicians and patients prefer to try conservative medical therapy before performing surgery for a herniated disk.

MEDICAL TREATMENT. Rest. In the past, bedrest was advised as part of conservative management. The current recommendation is 1 or 2 days of bedrest, followed by a careful, gradual increase in activity.

Physical Therapy. Physical therapy can be very useful for some patients. A gradually progressive course of exercise strengthens the muscles. This is particularly important in the lumbar spine, where the muscles help stabilize the spine. Techniques such as ultrasound, heat, ice, and deep massage can decrease muscle spasm and allow for increased range of motion. Instructions in proper body mechanics and strategies for avoiding reinjury are important components of physical therapy.

A transcutaneous electrical nerve stimulator (commonly called a TENS unit) is a noninvasive pain-relief technique. Small electrodes are placed on the skin around the area of the pain. The device then transmits a low-voltage electrical current through the skin. The patient feels a tingling or buzzing sensation, which may block the pain impulses. A physical therapist or pain specialist teaches the patient where to place the electrodes and how to operate the unit. The patient decides when to use it and at what settings. This allows the patient to actively participate in his or her care and have some control over the pain level.

Traction. Cervical traction is a noninvasive technique sometimes used by physical therapists for patients with herniated cervical disks. The patient's head is placed in a halterlike device. A series of ropes and pulleys connect the halter to a weight. This gently pulls the head away from the shoulders. The rationale is that this traction slightly separates the vertebral bodies and may allow the disk to return to its proper position. If it is effective in relieving the patient's pain, cervical traction may be done at home on an as-needed basis. Traction is discontinued immediately if it increases the patient's pain. Lumbar traction is not particularly effective because the lumbar paraspinal muscles are very large and strong. The amount of traction needed to overcome the muscular resistance can cause injury.

Medication. Muscle relaxants are often prescribed for patients who are experiencing muscle spasms. These medications decrease pain by decreasing the spasm, helping the patient increase range of motion and activity. Muscle

spasm is actually a protective mechanism. Muscles tighten and become painful, causing the patient to limit movement. This lessens the chance that the disk will be further injured. However, chronic spasm can cause tearing and scarring of the muscles. It is hard to predict which muscle relaxant will be most effective for a given patient. Patients should be warned that drowsiness is a common side effect of many muscle relaxants. They should be cautioned against driving or operating machinery until they determine how well they tolerate the medication. Diazepam is an effective muscle relaxant; however, it has a strong potential for addiction so it is usually used only if muscle spasm cannot be adequately treated with other medications.

Inflammation of the nerve root is caused by compression and irritation from the herniated disk. Nonsteroidal anti-inflammatory drugs (NSAIDs) can be effective in reducing this inflammation, but there is no way of predicting response to a given drug. It may be necessary for the patient to try several nonsteroidal drugs before an effective one is found. Because several of these drugs are now available without prescription, the patient should be cautioned not to use a nonprescription NSAID at the same time as a prescription NSAID. Patients should be instructed to report any stomach upset to the clinician because NSAIDs have the potential to cause gastric bleeding. Occasionally, oral steroids are used on a short-term basis for patients with severe inflammation that does not respond to other treatments. A rapidly tapering dose of steroid over 1 week is often prescribed. Steroids may also cause gastric upset, in addition to elevated serum glucose levels. Instruct patients with diabetes to monitor glucose levels closely and consult a physician if the levels are outside their normal parameters.

Epidural injections are an option for patients who are unable or do not wish to have surgery. A mixture of medications, typically a steroid, long-acting anesthetic, and long-acting pain reliever, is injected into the epidural space. The anesthetic provides immediate relief while the steroid reduces swelling for a longer lasting effect. If relief is obtained, the injection can be repeated every 3 to 4 months.

The use of pain medication is a subject of concern in the treatment of patients with herniated disks. Opioids may be appropriate for short-term use. This includes patients who are trying conservative therapy or those who are not able to have surgery immediately. If surgery is not an option or is not successful, the condition may be a chronic source of pain. In that circumstance, the physician and patient must discuss the potential complications of long-term opioid use, such as constipation, tolerance, and dependence. A referral to a pain clinic for alternative strategies may be appropriate.

SURGICAL MANAGEMENT. Several types of surgery can be done. A **laminectomy** removes one of the laminae, the flat pieces of bone on each side of a vertebra. This may be done to relieve pressure or to gain access for removal of a

laminectomy: lamin—posterior portion of the vertebra + ectomy—surgical removal of

herniated disk. A discectomy removes the entire disk. A spinal fusion uses a bone graft to fuse two vertebrae together if the area is unstable. Surgery may be done through a microscope for less scarring and faster recovery. Most patients are discharged within 24 hours of surgery.

A discectomy is generally done for a herniated cervical disk. This can be accomplished via an anterior or posterior approach. Most surgeons use the anterior approach for cervical herniations because the muscles in the front of the neck are much smaller and more moveable than those in the back of the neck. Therefore, there is less pain and muscle spasm following surgery. It is also safer than the posterior approach, which involves more maneuvering around the spinal cord.

Most surgeons replace the disk with bone or another material. This prevents collapse of the disk space and creates a spinal fusion. If bone is used, it may be harvested from the patient's iliac crest or donated from a cadaver. Mobility of the spine is lost in the area of a fusion. Spinal fusions may also be done to correct instability of the spine from other causes, such as scoliosis or degenerative disorders.

A posterior approach is used for a herniated lumbar disk. Typically, the vertical incision is 1 to 2 inches long. It is necessary to pull some of the muscle away from the bone, which accounts for some of the postoperative pain that patients experience. A laminectomy is done, and the herniated portion of the disk is resected. The remainder of the disk continues to provide a cushion between the intravertebral bodies. The surgeon removes any free fragments and any disk material that appears unstable.

Percutaneous discectomy involves insertion of a large needle into the disk under local anesthesia to aspirate herniated disk material. This technique is not used for severely herniated disks. Laser disk surgery may be used to disintegrate the herniated tissue. Laparoscopic techniques may also be used.

Complications After Surgery

HEMORRHAGE. As with any surgery, intraoperative hemorrhage is possible. It is not common in disk surgery. If a postoperative hemorrhage occurs in a patient who has had an anterior cervical discectomy, the airway may become occluded. The patient is monitored for bleeding from the incision and respiratory distress.

NERVE ROOT DAMAGE. If the nerve root is severed during surgery, the patient has loss of motor and sensory functions in that distribution. This may result in decreased use of the extremity. If the nerve root is damaged or excessive scarring occurs, the patient may experience pain, weakness, or paresthesias. In some cases, physical therapy and NSAIDs may be effective in improving function and lessening pain.

REHERNIATION. Lumbar disks may reherniate. This can occur anywhere from 1 week to several years after the initial surgery. If the reherniation occurs within a few weeks to months after the first surgery, the patient usually undergoes

another microdiscectomy. Reherniation of the cervical disk does not occur because the entire disk is removed.

HERNIATION OF ANOTHER DISK. Fusion of the cervical spine results in loss of movement at that motion segment. This can place increased stress on the disks above and below the fusion. This may increase the risk of another herniated disk, especially if the patient already has degeneration of other disks. The patient should be instructed to maintain an exercise program and to frequently move the spine through range-of-motion exercises.

Nursing Process for the Patient Having Spinal Surgery

Preoperative Care

Routine preoperative care is appropriate for the patient undergoing spinal surgery. In addition to routine teaching, instruct the patient in how to logroll following surgery. This procedure involves keeping the body in alignment and rolling as a unit, without twisting the spine, to prevent injury to the operative site.

Postoperative Care

ASSESSMENT/DATA COLLECTION. In addition to routine postoperative assessment, monitor extremities for changes in circulation, movement, and sensation. Monitor color, warmth, and presence of pulses in the extremities. Assess movement by asking the patient to move the extremities. Assess sensation by gently touching the patient's extremity and asking if feeling is present. Report any changes immediately to the physician because this may indicate nerve or circulatory damage.

Monitor pain frequently. The pain that necessitated surgery should be relieved, but the patient may still have muscular and incisional pain. The patient should be reassured that it will gradually subside. Monitor the surgical dressing and drain (if present) for CSF drainage or bleeding. Any sign of CSF drainage or significant bleeding should be reported to the physician immediately. If bone was taken from a separate donor site, this site must also be monitored. Intake and output are measured to ensure that the patient is able to void. Notify the physician if the patient has difficulty voiding.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION

Goals of nursing are to keep the patient safe and free from injury or complications and free from pain. Gradual return to normal physical activity is expected. Possible postoperative diagnoses include the following.

Pain related to surgical procedure

EXPECTED OUTCOME: Patient will verbalize an acceptable pain level.

- Monitor pain following surgery using a pain scale. *The patient's self-report is the most reliable method for assessing pain.*
- Administer muscle relaxants, analgesics, and NSAIDs as ordered. If a local anesthetic was injected into the surgical site during surgery, the

patient may not have pain immediately postoperatively. *Medications to relieve pain help the patient to mobilize following surgery, which helps prevent complications.*

- Position the patient in bed in correct body alignment. If ordered, keep the patient flat for 6 to 8 hours. *Correct alignment avoids twisting and injury to the operative site.*
- Place a pillow between the legs when lying on the side to promote alignment and comfort.

Risk for impaired urinary elimination related to effects of surgery

EXPECTED OUTCOME: Patient will be able to empty bladder without assistance.

- Monitor urine output for retention. *Patients may have difficulty voiding following lumbar surgery because of anesthesia, immobility, or occasionally because of nerve damage related to surgery.*
- If activity orders allow, assist the patient to get up to urinate (or to stand for men). *This may help the patient urinate.*
- If unable to void, try running warm water over the perineum, or taking a warm bath or shower. *This may stimulate voiding.*
- If difficulty urinating occurs, contact the physician for an order for intermittent catheterization until the problem resolves. *Urinary retention that is not resolved can lead to bladder rupture. Intermittent catheterization is a safe way to empty the bladder.*

Risk for impaired physical mobility related to neuromuscular impairment

EXPECTED OUTCOME: Patient will be able to ambulate and prevent complications of immobility following surgery.

- Assess mobility of affected extremities following surgery. *A reduction in mobility following surgery indicates nerve damage in surgery and should be reported immediately.*
- Assist the patient to logroll to get out of bed and ambulate on the first postoperative day. If spinal fusion has been done, the fused area of the spine will be immobile. *Early mobilization after surgery helps prevent complications.*
- Apply a soft cervical collar to the patient with a cervical laminectomy as ordered for neck support.

EVALUATION. The patient is expected to be free of complications and pain, be able to urinate, be able to move all extremities, and return gradually to preillness activity level.

Spinal Stenosis

Spinal stenosis is a condition in which the spinal canal compresses the spinal cord (Fig. 48.10). Arthritis is a major cause of spinal stenosis. The facet joints of the spine become inflamed and enlarged, narrowing the diameter of the spinal canal and compressing the spinal cord. Patients may complain of pain and weakness. Compression of the cervical

FIGURE 48.10 Stenosis of the cervical spine (left). Compare with normal spinal column (right).

portion of the spinal cord may result in hyperreflexia and weakness of the legs and arms.

A laminectomy may be done to relieve pressure on the spinal cord. The size of the incision depends on the number of vertebrae involved. These patients are often older and may have concurrent illnesses. They may require inpatient rehabilitation before returning home.

SPINAL CORD INJURIES

Injuries to the spinal cord affect people of all ages but take their greatest toll on young people. These injuries are characterized by a decrease or loss of sensory and motor functions below the level of the injury.

Pathophysiology

The spinal cord is made up of nerve fibers that allow communication between the brain and the rest of the body. Damage to the spinal cord results in interference with this communication process. Damage may be caused by bruising, tearing, cutting, edema, or bleeding into the cord. The damage may be caused by external forces or by fragments of fractured bone.

Causes and Types

The causes of spinal cord injury are similar to those of traumatic brain injury. It is not uncommon for a patient to have both a spinal cord injury and traumatic brain injury. Motor vehicle crashes, falls, and sports-related injuries are common causes. Diving into shallow water is often the cause of

cervical cord injury. Assaults may cause cord injury if a knife or bullet penetrates the spinal cord.

Spinal cord injuries may be classified by location or by degree of damage to the cord. A complete spinal cord injury means that there is no motor or sensory function below the level of the injury. An incomplete lesion means that there is some function remaining. This does not necessarily mean that the remaining function will be useful to the patient. Some patients find that having areas where sensation is intact may be more painful than useful.

The cervical and lumbar portions of the spine are injured more often than the thoracic or sacral segments. This is because the cervical and lumbar areas are the most mobile portions of the spine.

Signs and Symptoms

Cervical Injuries

Signs and symptoms depend on the level of cord that is damaged (Fig. 48.11). Cervical cord injuries can affect all four extremities, causing paralysis and paresthesias, impaired respiration, and loss of bowel and bladder control. Paralysis of all four extremities is called **quadriplegia**; weakness of all extremities is called **quadriparesis**. If the injury is at C3 or above, the injury is usually fatal because muscles used for breathing are paralyzed. An injury at the fourth or fifth cervical vertebra affects breathing and may necessitate some type of ventilatory support. These patients typically need long-term assistance with activities of daily living.

Thoracic and Lumbar Injuries

Thoracic and lumbar injuries affect the legs, bowel, and bladder. Paralysis of the legs is called **paraplegia**; weakness of the legs is called **paraparesis**. Sacral injuries affect bowel and bladder continence and may affect foot function. Individuals with thoracic, lumbar, and sacral injuries can usually learn to perform activities of daily living independently.

Spinal Shock

Spinal cord injury has a profound effect on the autonomic nervous system. Immediately following injury, the cord below the injury stops functioning completely. This causes a disruption of sympathetic nervous system function, resulting in vasodilation, hypotension, and bradycardia (neurogenic shock or spinal shock). Dilation of the blood vessels allows more blood flow just beneath the skin. This blood cools and is circulated throughout the body, causing hypothermia. The patient is unable to maintain control of body temperature. Keep the patient covered as much as possible but avoid overheating. In addition, all reflexes below the level of the injury are lost, and retention of urine and feces occurs. Spinal shock can last from a week to many weeks in some patients.

quadriplegia: quad—four + plegia—paralysis

quadriparesis: quad—four + paresis—partial paralysis

paraplegia: para—beside + plegia—paralysis

paraparesis: para—beside + paresis—partial paralysis

Complications

Infection

Impaired respiratory effort, decreased cough, mechanical ventilation, and immobility all predispose the cervical cord-injured patient to pneumonia. Catheterization, whether indwelling or intermittent, places patients at risk for urinary tract infection.

Deep Vein Thrombosis

Lack of movement in the legs inhibits normal blood circulation. Compression stockings, sequential compression devices, and subcutaneous heparin may be used separately or together to reduce the risk of deep vein thrombosis.

Orthostatic Hypotension

Most spinal cord-injured patients no longer have muscular function in their legs to promote venous return to the heart. They also have impaired vasoconstriction. This leads to pooling of the blood in the legs when the patient moves from a supine to a sitting position. If the movement is sudden, the patient may become dizzy or faint. Gradual elevation of the head, use of elastic stockings, and a reclining wheelchair help lessen this response.

Skin Breakdown

Patients or their caregivers must be diligent about relieving pressure on the skin by position changes and cushioning of bony prominences. Development of pressure ulcers can lead to infection and loss of skin, muscle, or bone. Treatment of pressure ulcers is time consuming and expensive and may interfere with work or school.

SAFETY TIP

Assess and periodically reassess each resident's risk for developing a pressure ulcer (decubitus ulcer) and take action to address any identified risk (2006 National Patient Safety Goals from www.jcaho.org).

Renal Complications

Urinary tract infections are an ongoing concern to spinal cord-injured patients. Both urinary reflux and untreated urinary tract infections can cause permanent damage to the kidneys.

Depression and Substance Abuse

Patients with spinal cord injury have a higher than average incidence of depression and substance abuse. Both these factors can interfere with the patient's ability to care for himself or herself. Individual or family counseling may be helpful. Some rehabilitation centers have support groups for spinal cord-injured patients.

Autonomic Dysreflexia

This life-threatening complication occurs in patients with injuries above the T6 level. The spinal cord injury impairs

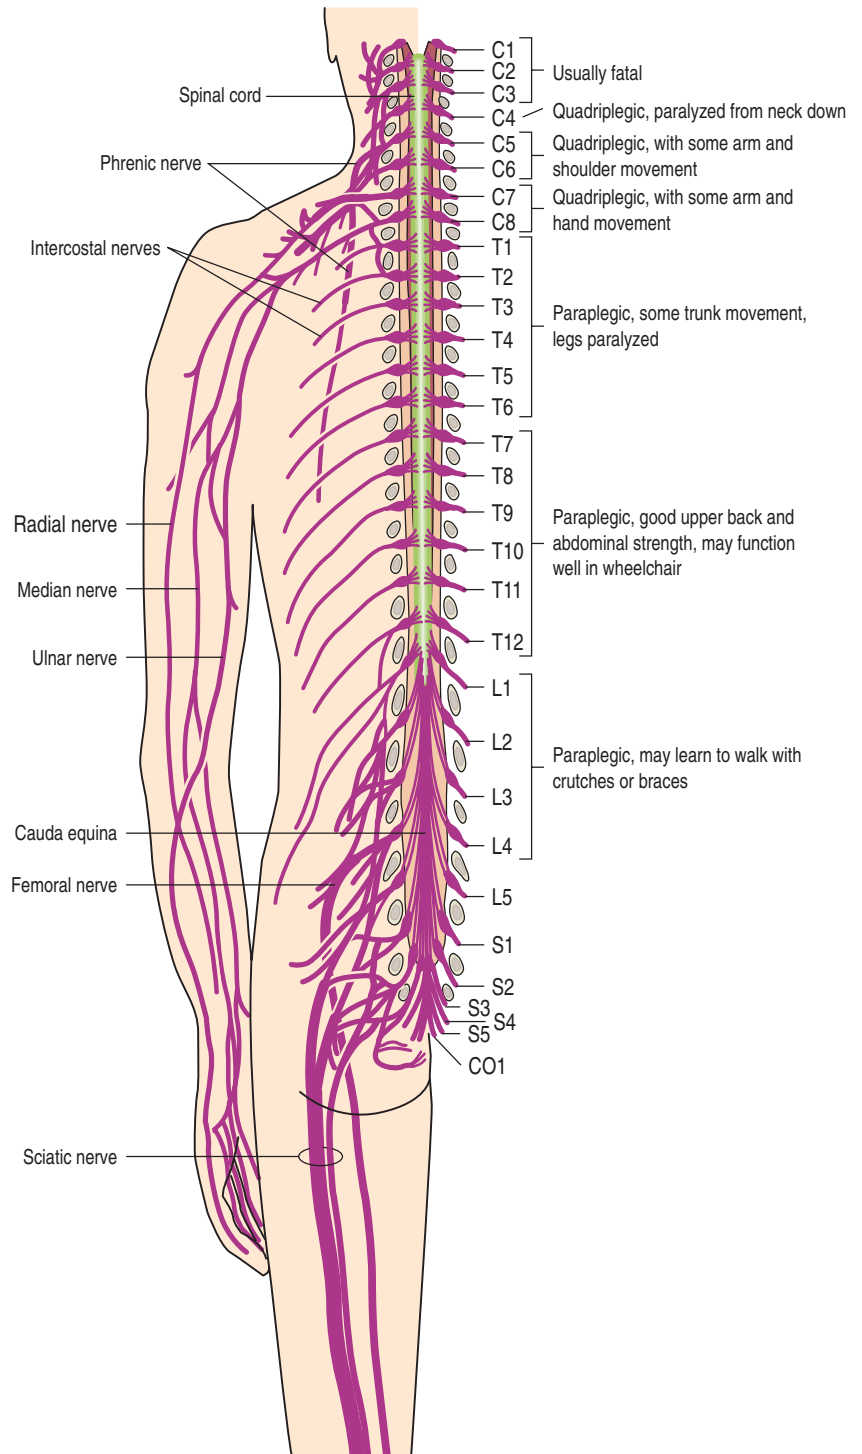

FIGURE 48.11 Spinal cord injury—quadriplegia versus paraplegia. (Modified from Scanlon, VC, and Sanders, T: *Workbook for Essentials of Anatomy and Physiology*, ed. 5. FA. Davis, Philadelphia, 2007, p 163, with permission.)

the normal equilibrium between the sympathetic and parasympathetic divisions of the autonomic nervous system. Some type of noxious stimuli below the spinal cord injury causes activation of the sympathetic system. This response continues unchecked because the parasympathetic responses cannot descend past the spinal cord injury.

The most common cause of autonomic **dysreflexia** is bladder distention. Other causes include bowel impaction,

urinary tract infection, ingrown toenails, pressure ulcers, pain, and labor. Stimulation of the sympathetic nervous system results in cool, pale skin, gooseflesh, and vasoconstriction below the level of the injury. Blood pressure may rise as high as 300 mm Hg systolic. The parasympathetic response results in vasodilation, causing flushing and diaphoresis above the lesion, and bradycardia as low as 30 beats per minute. The patient complains of a pounding headache and nasal congestion secondary to the dilated blood vessels.

dysreflexia: dys—abnormal + reflexia—reflex activity

Diagnostic Tests

Plain radiographs are done to identify fractures or displacement of vertebrae. A CT scan is also useful for identifying fractures. MRI may demonstrate lesions within the cord.

Therapeutic Interventions

Patients with spinal cord injuries typically are brought to the emergency department. They should be kept immobilized until they are assessed by a physician. If injury to the spinal cord is detected, the patient needs to remain immobilized.

Emergency Management

Emergency management involves careful monitoring of vital signs and airway and keeping the patient immobilized. Intubation and mechanical ventilation may be necessary. Intravenous normal saline may be used for fluid replacement. The physician does not rely on fluid administration alone to correct hypotension. It is possible to administer enough fluid to cause pulmonary edema and not correct the hypotension. Vasoactive drugs may be required. Various medications to reduce the extent of injury, including intravenous methylprednisolone (a steroid), are currently being researched.

Respiratory Management

Patients with injuries above C4–5 have some degree of respiratory impairment. The patient may require a tracheostomy and continuous mechanical ventilation or require a ventilator only at night or when fatigued. Some patients are able to breathe by using a phrenic nerve stimulator. This device, similar to a pacemaker, artificially stimulates the phrenic nerve, causing the diaphragm to move. These patients use a mechanical ventilator at night. This lessens the stress on the phrenic nerve and removes the risk of the system failing while the patient is asleep.

Patients may be breathing independently when they first arrive in the emergency department and then experience

respiratory compromise as the spinal cord becomes edematous. Edema can compress the spinal cord above the lesion, leading to symptoms at a higher level. This deterioration is usually temporary. Fatigue of the accessory muscles may also cause respiratory compromise. The intercostal muscles are not normally of major importance in respiration. However, if the diaphragm is paralyzed, the intercostal muscles become very important. As these muscles fatigue, the patient's breathing becomes shallow and rapid. Elective intubation and mechanical ventilation protect the patient from expending huge amounts of energy trying to breathe. Feeling their breathing becoming more labored is terrifying to these patients, and they need to be reassured that it is probably a temporary setback. As the edema recedes and the accessory muscles become stronger, the patient is weaned from the ventilator.

Gastrointestinal Management

Absence of bowel sounds is a common finding on examination. Oral or enteral feedings are not started until bowel function resumes. The metabolic needs of the patients are influenced by the work of breathing and the extent of other injuries. If positioning or paralytic ileus precludes oral or enteral feedings, hyperalimentation is begun.

Genitourinary Management

An indwelling urinary catheter is placed to prevent bladder distention and protect skin integrity until spinal shock resolves. Once it is determined what degree of hand function the patient will have, a bladder management program is devised.

Immobilization

The cervical spine may be immobilized with skeletal traction such as Crutchfield or Gardner-Wells tongs (Fig. 48.12). Some patients have a halo brace, a device that attaches to the skull with four small pins. The skull ring attaches to a rigid plastic vest by four poles (Fig. 48.13).

FIGURE 48.12 Skeletal traction for cervical injuries. (A) Crutchfield tongs. (B) Gardner-Wells tongs.

FIGURE 48.13 Halo brace.

This device keeps the head and neck immobile while fusion and healing take place. The advantage over traction is that the patient is not confined to bed.

Surgical Management

The goal of surgery following spinal cord injury is to stabilize the bony elements of the spine and relieve pressure on the spinal cord. Surgery may or may not improve functional outcome.

Stabilization of the spine allows for earlier mobilization of the patient. This decreases the risk of complications from immobility and quickens the transition to a rehabilitation setting. Patients who have been in cervical traction before surgery may be placed in a halo brace postoperatively.

Unstable thoracic and lumbar fractures may also be treated with surgical implantation of rods to stabilize the spine. It is more difficult to stabilize these areas in the postoperative recovery period. Patients may wear a supportive corset, a rigid brace, or occasionally a body cast to supplement the support provided by the internal fixation devices. For more information, visit the Spinal Cord Injury Information Network at <http://spinalcord.uab.edu>.

Nursing Process for the Care of the Patient with a Spinal Cord Injury

Patients with spinal cord injury need ongoing evaluation of all body systems. Frequent neurological and respiratory assessments are essential. Early assessment of the patient's support systems can help with discharge and rehabilitation planning. Initial goals for the patient include maintenance of safety and prevention of complications. Long-term goals include rehabilitation and maximizing remaining function.

See Box 48.6 Nursing Care Plan for the Patient with a Spinal Cord Injury and Box 48.7 Spinal Cord Injury Summary on page 1093.

NEURODEGENERATIVE DISORDERS AND DISTURBED THOUGHT PROCESSES

Neurodegenerative is a term that can apply to any nervous system disorder that causes degeneration, or wasting, of the neurons in the nervous system. The following disorders are some of the most common neurodegenerative disorders that

neurodegenerative: neuro—nervous system + degenerative—deteriorating

(Text continued on page 1092)

Box 48.6 NURSING CARE PLAN for the Patient with a Spinal Cord Injury

Nursing Diagnosis: Impaired gas exchange related to respiratory muscle weakness

Expected Outcome Patient will maintain $\text{SaO}_2 \geq 90\%$, $\text{PaO}_2 \geq 75$ mm Hg, $\text{PaCO}_2 \leq 45$ mm Hg.

Evaluation of Outcome Are ABGs and SaO_2 within normal limits?

Interventions

Monitor respiratory rate, effort, ABGs and SaO_2 .

Notify physician immediately if SaO_2 or PaO_2 drops, or if PaCO_2 rises.

Rationale

These are indicators of respiratory function. The patient may have difficulty maintaining normal respiration if diaphragm or accessory muscles are weak related to injury.

If patient is unable to maintain blood gases, mechanical ventilation may be necessary.

Evaluation

Are ABGs and SaO_2 within normal limits? Does patient appear distressed?

(Continued on following page)

Box 48.6 NURSING CARE PLAN for the Patient with a Spinal Cord Injury (Continued)

Nursing Diagnosis: Ineffective airway clearance related to ineffective cough and decreased muscle control

Expected Outcome Patient will maintain a clear airway as evidenced by clear breath sounds and $\text{SaO}_2 \geq 90\%$.

Evaluation of Outcome Are breath sounds clear? Is $\text{SaO}_2 \geq 90\%$?

Interventions

Monitor cough and lung sounds.

Suction patient prn if unable to cough effectively.

Once the patient is stable, try assisting the patient to cough to clear secretions. Gently push upward and inward on the patient's chest while the patient coughs as strongly as possible.

Provide humidified air and oral or enteral fluids.

Rationale

Patient may not have adequate muscle strength to cough effectively.

To keep the airway clear.

This may help the patient clear secretions without invasive suctioning.

This is similar to the Heimlich maneuver but not as forceful.

Humidification helps keep secretions thin and mobile.

Evaluation

Is patient able to cough up secretions? Is there evidence that secretions are retained?

Is suctioning effective in clearing airway?

Does the assisted cough technique help the patient to clear the airway?

Are secretions thin and easily expectorated?

Nursing Diagnosis: Risk for autonomic dysreflexia related to stimuli below the level of injury

Expected Outcome The patient does not demonstrate signs of autonomic dysreflexia as evidenced by stable vital signs. If dysreflexia occurs, it is recognized and corrected promptly.

Evaluation of Outcome Is patient free of signs or are signs recognized and promptly treated?

Interventions

Monitor for signs of autonomic dysreflexia: sudden high blood pressure, bradycardia, headache, pale skin below the injury, gooseflesh. Remember that patients with spinal cord injury are typically hypotensive, so a finding of even mild hypertension may represent a dramatic increase from their baseline blood pressure.

If you suspect autonomic dysreflexia, immediately take the patient's blood pressure and continue to monitor it every 5 minutes.

Place the patient in high-Fowler's position. Remove elastic stockings or any other garment that could prevent blood from pooling in the periphery.

Evaluate the indwelling catheter for patency. If it is not patent or a catheter is not in place, obtain an order to insert one immediately. Monitor blood pressure during catheterization.

Rationale

Autonomic dysreflexia must be recognized quickly in order to remove cause and prevent complications such as seizures, intracerebral hemorrhage, or death.

Blood pressure must be continually monitored until it is under control, to prevent complications.

High-Fowler's position utilizes the effect of orthostasis to control blood pressure. Allowing blood to pool in periphery can help reduce blood pressure.

A full bladder can be the cause of the stimuli causing the dysreflexia.

Evaluation

Are signs of dysreflexia present?

Is blood pressure higher than normal for patient? Are emergency interventions warranted?

Does position change reduce blood pressure?

Is catheter patent? Is bladder full? Does emptying bladder resolve dysreflexia?

Interventions

Perform a rectal examination to determine if an impaction is present. Apply anesthetic ointment to the rectum before disimpaction. Simultaneously monitor blood pressure and stop disimpaction if the blood pressure increases.

If bowel or bladder distention is not present, examine the patient for other causative mechanisms. If a cause cannot be identified, or removal of the cause does not relieve hypertension, notify the physician immediately.

If hypertension is treated with medication, continue to carefully monitor blood pressure.

Once the acute episode is past, work with patient and significant others to devise a plan to prevent reoccurrence. Teach the patient how to direct caregivers in treating autonomic dysreflexia.

Rationale

Fecal impaction can be the stimulus causing the dysreflexia. Anesthetic is used because further rectal stimulation may exacerbate symptoms.

If the cause cannot be found and removed, an antihypertensive agent may be ordered.

Blood pressure may decrease rapidly once the cause of the autonomic dysreflexia is corrected.

Episodes of dysreflexia can recur.

Evaluation

Is impaction present? Does removal resolve dysreflexia?

Are other causes identifiable? Is an antihypertensive agent ordered?

Is blood pressure stabilized?

Do patient and caregivers verbalize understanding of how to prevent and treat future episodes of dysreflexia?

Nursing Diagnosis: Total urinary incontinence related to spinal cord damage and no sensation to void and/or inability to control flow of urine

Expected Outcomes Patient's skin will be dry and free of urine; urine elimination will be controlled.

Evaluation of Outcomes Patient will be continent of urine, free of urinary infection (urine clear, yellow, without burning on urination), and have dry and intact skin.

Interventions

Assess patient's ability to control urination.

Monitor appearance of urine, temperature, and white cell count.

Implement a bladder training program utilizing set times for voiding.

Use bladder ultrasound to scan bladder for residual urine.

Teach the patient or caregiver self-catheterization as ordered, if bladder training is not effective.

Consult with physician re Foley catheter if patient is not a candidate for intermittent self catheterization.

Rationale

If patient has some control, a bladder training program may be effective.

Cloudy urine, and an increase in temperature and white cell count indicate urinary tract infection.

Following a voiding schedule can help reduce incontinence.

Incomplete voiding can increase risk for urinary tract infection.

Intermittent self-catheterization is associated with fewer complications than an indwelling catheter.

An indwelling catheter can increase risk for infection, but may be necessary as a last resort for some patients.

Evaluation

Is patient able to sense need to urinate? Is any degree of control present?

Is urine clear, and temperature and white blood cells within normal limits?

Is patient able to avoid incontinence with regular voiding?

Is patient effectively emptying bladder?

Is patient able to perform self-catheterization correctly?

Is Foley catheter necessary? Are signs of infection avoided?

(Continued on following page)

Box 48.6 NURSING CARE PLAN for the Patient with a Spinal Cord Injury (Continued)

Nursing Diagnosis: Constipation related to immobility and nerve damage

Expected Outcome Patient will return to preinjury bowel pattern.

Evaluation of Outcome Does patient pass soft stool at regular intervals?

Interventions

Assess previous and current bowel pattern and continence.

Monitor bowel sounds and abdominal distention.

Institute a bowel management program as soon as oral feedings are resumed. Include a suppository on a scheduled daily or every-other-day basis as ordered.

Provide a high-fiber diet with adequate fluid intake.

Rationale

Decreased or absent sphincter tone, inability to detect the need to defecate, and immobility put the patient at risk for incontinence and constipation.

These monitor bowel function.

A management program including stool softeners and routine suppository use can help to restore regular defecation.

Fiber and fluids help keep stool soft.

Evaluation

What was previous pattern? Is it used to develop goals for patient?

Are bowel sounds present? Is abdomen soft?

Does management program keep bowel movements soft and regular, and maintain continence?

Is patient receiving adequate fiber and fluids?

Nursing Diagnosis: Impaired physical mobility related to hemorrhage, ischemia, and edema of cord as evidenced by paresis or paralysis.

Expected Outcome Patient will maintain maximum mobility and be free from complications of immobility.

Evaluation of Outcomes Is patient kept mobile without contractures? Is skin intact? Can patient complete ADLs with assistance?

Interventions

Determine patient's ability to move independently.

Assess patient's ability to feel pressure and pain.

Reposition every 2 hours, utilizing supportive devices.

Change positions slowly; have patient sit at side of bed before standing (if able) or getting up to chair.

Perform active or passive range of motion exercises at least once every 8 hours. If patient has arm mobility, teach patient to participate in doing as much ROM as possible.

Teach patient importance of repositioning self at least every 2 hours.

Teach patient to direct own care, if unable to reposition independently.

Rationale

Assessment should guide interventions.

If the patient is unable to feel pain or pressure, it will be even more important to monitor skin and prevent prolonged pressure.

Unrelieved pressure on the skin, especially bony prominences, will result in ischemia and necrosis.

Patients with cervical spine injuries or patients remaining immobile for long periods are prone to orthostatic hypotension.

Range-of-motion exercises maintain mobility and prevent contractures.

Patients with some mobility can learn to reposition themselves; this helps prevent total dependence on caregivers.

This allows the patient some control over his or her situation.

Evaluation

What can patient do independently?

Can patient feel pressure and pain?

Is skin intact without redness?

Does patient become dizzy when getting up?

Is patient able to perform range-of-motion exercises with minimal difficulty?

Does patient demonstrate correct repositioning every 2 hours?

Does patient direct own care and prevent complications of immobility?

Nursing Diagnosis: Self-care deficit related to paralysis

Expected Outcome Patient's self-care needs will be met by self or caregivers.

Evaluation of Outcome Are patient's needs met? Does patient verbalize satisfaction with care?

Interventions

Determine patient's level of function and ability to perform ADLs.
Explain the rationale for nursing activities, and encourage the patient and significant others to participate in hands-on care as much as possible
If the patient will not be able to perform self-care, assist him or her to learn to direct care.
Consult with physical and occupational therapy.

Discuss discharge to a rehabilitation facility with patient, physician, and discharge planner.

Assist patients and caregivers to determine contingency plans. These include what to do in the event of a power failure, fire, or illness of the caregiver.
Encourage the patient to establish a relationship with a primary practitioner who is familiar with spinal cord injury.

Rationale

The patient should be encouraged to be as independent as possible. This will help prepare the patient and significant others to assume responsibility for care at home.

This allows the patient some control over his or her care.

Physical and occupational therapy can help the patient learn to adapt to physical limitations; they can provide a wheelchair or other mobility aids.

A rehab facility can teach the patient to function independently. Some patients may require long-term care.

Planning ahead what to do in an emergency can mean the difference between life and death for an immobile patient.

Spinal cord-injured patients experience the same basic health care needs as noninjured individuals.

Evaluation

What is patient able to do? Is it incorporated into plan of care?
Do patient and significant others verbalize understanding of care? Are they able to demonstrate procedures correctly?

Does patient participate by directing care?

Is patient adapting to limitations with help?

Is the patient a candidate for rehabilitation?

Do patient and caregivers have a plan to keep the patient safe?

Does patient have a primary care practitioner who understands his or her unique needs?

Nursing Diagnosis: Risk for impaired skin integrity related to immobility and possible paresthesias

Expected Outcome Skin will remain intact without redness or breakdown.

Evaluation of Outcomes Is skin intact?

Interventions

Monitor skin frequently. When permitted by the physician, turn the patient frequently and assess bony prominences for redness.
Start preventive measures in the emergency department by being sure to remove anything between the patient and the backboard.
Use a pressure-reducing mattress.

Rationale

The patient who does not have sensation is at increased risk of developing pressure ulcers.

Patients have developed pressure ulcers from lying on keys or other objects in their pockets.

Specialty mattresses or beds can reduce pressure, but do not reduce the need to turn the patient.

Evaluation

Is the patient turned and repositioned at least every 2 hours?
Is skin intact?

Are skin surfaces protected from pressure?

Is the patient on an appropriate mattress?

(Continued on following page)

Box 48.6 NURSING CARE PLAN for the Patient with a Spinal Cord Injury (Continued)

Interventions

If on a self-turning bed, make sure the patient is not sliding as the bed turns. Avoid pulling and friction on skin when repositioning patient in bed.

Ensure that the patient's extremities do not get caught in side rails or wheelchair spokes.

If a patient is in traction or a halo brace, assess pin sites frequently. Keep the sites clean and dry and report any sign of infection.

Rationale

Sliding can cause friction and shearing damage to the skin.

The patient may not be aware this is happening, and a pressure ulcer can result.

Skin sites are at risk for infection and breakdown.

Evaluation

Is friction damage to skin avoided?

Are all patient's body parts accounted for and safe?

Are pin sites clean and dry?

Nursing Diagnosis: Risk for ineffective role performance related to effects of injury

Expected Outcome Patient will identify new ways to carry out essential roles.

Evaluation of Outcome Is patient able to identify ways to carry out roles?

Interventions

Allow the patient to verbalize concerns if he or she wishes.

Help patient and family to identify resources.

Consult a social worker to help the patient gain access to appropriate physical and financial assistance.

Provide information about area support groups.

Rationale

This may help to clarify potential role problems for the patient, and begin the process of developing a plan.

Interpersonal relationships can be significantly stressed by spinal cord injury. Friends, family, and members of the patient's religious affiliation can provide emotional and physical help.

Loss of income may be temporary or permanent, and may add to the burden of spinal cord injury. Not all insurance policies cover the extensive inpatient rehabilitation needed by spinal cord-injured patients. Adaptive equipment is expensive and may not be covered by insurance.

Individuals who have been through similar experiences can provide support and information for the patient and family.

Evaluation

Is patient able to identify roles he or she has filled in the past that will be difficult to carry out due to injury?

Does patient have adequate support systems in place to provide help?

Is patient able to access appropriate financial assistance if needed?

Is patient willing to contact support groups?

Nursing Diagnosis: Risk for sexual dysfunction related to autonomic nervous system dysfunction

Expected Outcome The patient will state he or she has an acceptable means for sexual expression.

Evaluation of Outcomes Does patient state satisfaction with sexual function?

Interventions

If a male patient has an erection during a bath or catheterization, discontinue the procedure and continue at a later time if possible. Maintain a matter-of-fact attitude.

Allow patient to voice concerns about sexual function if desired.

Encourage the patient and partner to explore alternative methods of sexual expression.

If a male patient wishes to have children, encourage a consult with a fertility specialist or urologist.

Advise female patients who wish to become pregnant to seek an obstetrician familiar with spinal cord injuries

If the patient does not wish to become pregnant, provide information about contraception. See Table 48.6 for contraception for females with spinal cord injuries.

Encourage partners to verbalize feelings about caregiving activities such as catheterizations and make alternative arrangements for care if possible. Some patients with the financial resources to do so may choose to hire an attendant rather than rely on significant others for personal care.

Rationale

Male patients with quadriplegia may develop an erection during any penile stimulation.

Male patients with paraplegia usually have difficulty achieving and maintaining an erection.

Closeness and touching may be a satisfying alternative.

Males with spinal cord injuries do not ejaculate in the normal manner. A specialist may provide some help for conception if desired.

A specialist may be necessary to meet unique needs of these patients.

Spinal cord injury does not impair female fertility.

Performing tasks such as catheterization or bowel care may interfere with feelings of intimacy between partners.

Evaluation

Is patient's dignity maintained during personal care?

Is patient able to voice concerns? Is a consult with a urologist or other specialist needed?

Is patient able to discuss alternative methods with partner?

Is patient given information about conception if desired?

Is the patient interested in pregnancy? Does she have the information needed related to pregnancy with spinal cord injury?

Does the patient have information and resources to prevent pregnancy if desired?

Are patient and partner able to discuss feelings about caregiving activities, and find alternate arrangements if desired?

Nursing Diagnosis: Anxiety related to change in health status as evidenced by behavioral changes such as insomnia, poor eye contact, and irritability

Expected Outcomes The patient will participate in rehabilitation activities. The patient will be able to verbalize fears, concerns, and expectations.

Evaluation of Outcomes Is the patient able to participate in rehabilitation? Does patient verbalize that anxiety is controlled?

Interventions

Allow patient to voice feelings of fear and anxiety.

Rationale

Communication is vital to assess the patient's coping abilities.

Evaluation

Is the patient able to verbalize anxiety?

(Continued on following page)

Box 48.6 NURSING CARE PLAN for the Patient with a Spinal Cord Injury (Continued)

Interventions

Provide information about what is happening to the patient physiologically and about procedures.

Consult a social worker, pastoral care, and/or support groups.

Encourage the patient to participate in physical and occupational therapy.

Rationale

Understanding of what is happening can help the patient cope with changes.

A social worker or pastor can help provide emotional and spiritual support. Discussing rehabilitation with patients and their families who have had similar experiences can provide insight and encouragement.

Seeing progress toward becoming independent may help reduce anxiety and fear about the future.

Evaluation

Does patient verbalize understanding of what is happening? Does information help keep patient less fearful?

Does patient state talking with support persons help reduce anxiety?

Does patient participate in therapies? Is anxiety lessening?

TABLE 48.6 BIRTH CONTROL ISSUES FOR PATIENTS WITH SPINAL CORD INJURY

Method	Comments
Oral contraceptives	Contraindicated because of the risk of deep vein thrombosis
Diaphragm	May be difficult to insert for a patient with poor hand function
Intrauterine device	Patient may not feel IUD move out of position Patient may not feel perforation of uterus
Norplant	No contraindications
Condom	No contraindications

cause chronic illness. By the year 2030, it is estimated that 150 million Americans will have one or more chronic conditions. Management of chronic conditions does not focus on the short-term stay in the hospital due to an exacerbation of the disease process, but rather on the long-term goal of facilitating the patient and family to cope with the disease process and maintain the patient's independence for as long as possible. Nursing care involves providing information on management of the illness, education related to prevention and treatment of complications, and guidance to support groups or case managers. As patients decline, many families will come to a time when they can no longer care for their loved one in their homes and must consider care in a long-term facility.

Dementia

Dementia is not a disease, but rather is a symptom of a number of different disorders. According to the National Institute of Neurological Disorders and Stroke, "People with dementia have significantly impaired intellectual functioning that interferes with normal activities and relationships. They also lose their ability to solve problems and maintain emotional control, and they may experience personality changes and behavioral problems, such as agitation, delusions, and hallucinations.

While memory loss is a common symptom of dementia, memory loss by itself does not mean that a person has dementia.² Some patients may have mild mental status changes that do not interfere significantly with day-to-day functioning. This is sometimes referred to as mild cognitive impairment, or MCI. Patients with MCI are more likely to go on to develop Alzheimer's disease than those without MCI.

Etiology and Pathophysiology

There are many causes of dementia. Huntington's, Parkinson's, and Alzheimer's diseases are discussed later in this chapter. Multiple "ministrokes" (multi-infarct dementia or vascular dementia) is another common cause. Chronic alcoholism, neurological infections, head injuries, and many medications (Box 48.8 Some Medications That Can Cause Disturbed Thought Processes) can also cause changes in mental status leading to dementia. Although aging is associated with more frequent dementia diagnoses, dementia is not a normal part of aging. Pathophysiologies vary depending on the cause. In general, thinking is affected by changes in the brain that result from reduced blood flow or from structural changes related to disease states.

Much research has been done to determine factors related to dementia, and therefore how it can be prevented. Some studies indicate that patients who have more educa-

Box 48.7**Spinal Cord Injury Summary**

Signs and Symptoms	Flaccid paralysis and paresthesias (depending on level of the lesion) Loss of reflex activity below the level of the lesion Spinal shock initially Risk for autonomic dysreflexia (injuries above sixth thoracic vertebra)
Diagnostic Tests and Findings	Radiograph CT scan MRI
Therapeutic Interventions	Immobilization Maintenance of airway and respiratory status Bowel and bladder training Nutrition/diet Activity/rehabilitation Prevention of dysreflexia Prevention of skin breakdown Sexual counseling Education
Complications	Infection Deep vein thrombosis Paralysis Orthostatic hypotension Pressure ulcers Depression
Possible Nursing Diagnoses	Impaired physical mobility related to hemiparesis/hemiplegia Total urinary incontinence related to spinal cord damage

tion, have higher socioeconomic status, and engage in stimulating intellectual and leisure activities are less likely to develop dementia. Some experts believe these individuals develop a sort of “cognitive reserve” that keeps them functioning at a high level, even when changes in their brains on autopsy indicate dementia. People with less education, fewer leisure activities, and less intellectual stimulation are more likely to develop symptoms of Alzheimer’s disease.

Signs and Symptoms

Most people have occasional memory lapses. Students may have memory lapses during examinations, but they do not generally have dementia. In patients with dementia, recent memories are usually affected first. Patients may have difficulty recalling whether they ate breakfast, or may accuse a family member of not calling when in reality they called just a few hours earlier. This same patient may easily recall an event or even a phone number from childhood.

Box 48.8**Some Medications That Can Cause Disturbed Thought Processes**

- Anticholinergic agents (atropine, some antihistamines)
- Analgesics (meperidine, morphine)
- Cimetidine (Tagamet)
- Central nervous system depressants (sleeping pills, tranquilizers, alcohol)
- Steroids (cortisone, prednisone)

As patients become more forgetful, they may ask the same question repeatedly. They may get lost driving or walking in a familiar neighborhood. They may become disoriented to time, and not be aware of the year. A patient may say that Eisenhower is president, for example, because they remember that as true when they were younger. Later, they may not recognize where they are, and last, they may lose recognition of their own family members.

Later in the course of the dementia, even remote memory may be lost. Patients may forget how to perform simple tasks, such as doing the dishes or making a phone call. They may wander and become lost. Safety is a significant issue with a wandering patient. Patients may develop aphasia and become unable to communicate their needs or follow simple instructions. This can become very frustrating to both the family and nursing caregivers. Behavioral problems may necessitate admission to a long-term care facility. In very late stages, the patient may become totally dependent on caregivers.

Diagnostic Tests

Diagnosis of dementia is twofold: first, dementia must be identified, and then the focus moves to finding the cause of the mental status change. Early diagnosis is essential, since some causes of MCI may be reversible, or early treatment may delay progression. Neuropsychological testing can determine the degree of memory, personality, and behavior changes. The Mini-Mental State Examination is commonly used. The patient should also be tested for depression, since depression can cause mental status changes, but is often easily treated. A review of medications by a knowledgeable nurse, physician, or pharmacist may reveal a medication that can be contributing to the mental changes. MRI, CT scan, positron emission tomographic (PET) scan, and blood tests help diagnose underlying causes.

Therapeutic Interventions

Medical interventions depend on the cause of the dementia. See Table 48.7 for medications that may be used to delay progression of some types of dementia. If medical treatment cannot alter the course of the disease, the focus will shift to delaying progression of symptoms and maintaining patient safety. Excellent nursing care becomes essential for both the

TABLE 48.7 MEDICATIONS USED TO TREAT DISTURBED THOUGHT PROCESSES

Medication Class/Action	Examples	Route	Side Effects	Nursing Implications
Cholinesterase Inhibitors Inhibits cholinesterase, to improve function of acetylcholine in CNS	Donepezil (Aricept) Tacrine (Cognex) Rivastigmine (Exelon) Galantamine (Reminyl)	PO	Headache, diarrhea, nausea	Must be taken regularly; patient may need reminders to take, or family member may need to assist. May improve cognitive function but will not alter course of disease.
NMDA Antagonist Reduces binding of glutamate, an excitatory neurotransmitter	Memantine (Namenda)	PO	Dizziness	

patient and family at this point. An important aspect of care in early dementia is determination of the patient's wishes while the patient is still able to make decisions. Decisions related to resuscitation, guardianship, and powers of attorney for health care and finances are essential. Other difficult decisions relate to the patient's continued ability to drive and live alone.

Nursing Process for the Patient with Dementia

See Box 48.9 Nursing Care Plan for the Patient with Disturbed Thought Processes.

Delirium

In comparison to dementia, **delirium** is a mental disturbance that is temporary, and can have either a rapid or gradual onset. It is considered to be a medical emergency, and should be diagnosed and treated promptly. It is characterized with disorganized thinking and difficulty with staying focused, and is seen most commonly in older adults when experiencing an illness. Many times response to medications is the cause (see Box 48.8 Some Medications That Can Cause Disturbed Thought Processes). It may also be the result of anything that is a stressor to the person's body, such as pain, oxygen deficiency, urinary catheters, fluid and electrolyte imbalances, a change in environment, or nutritional deficiency. Often the most effective nursing intervention is to have a family member present to assist with orientation and reassurance. It is also beneficial to have continuity in nursing personnel.

It is essential that delirium not be mistaken for dementia. If an older adult is hospitalized and exhibits confusion, consider that it might be delirium. Correcting electrolyte levels, controlling pain, changing medications, or administering oxygen can be helpful in reversing delirium. See Box 48.9 Nursing Care Plan for the Patient with Disturbed Thought Processes for nursing interventions.

Parkinson's Disease

Parkinson's disease is a chronic degenerative movement disorder that arises in the basal ganglia in the cerebrum. It usually begins in the fourth or fifth decade of life, with

symptoms becoming progressively worse as the patient ages. The disease is characterized by tremors, changes in posture and gait, rigidity, and slowness of movements. Approximately 1% of people over 65 have a diagnosis of Parkinson's disease.³

Pathophysiology

The substantia nigra is a group of cells located within the basal ganglia, which is situated deep within the brain. These cells are responsible for the production of dopamine, an inhibitory neurotransmitter. Dopamine facilitates the transmission of impulses from one neuron to another. Parkinson's disease is caused by destruction of the cells of the substantia nigra, resulting in decreased dopamine production. Loss of dopamine function results in impairment of semiautomatic movements. Parkinson's disease is sometimes referred to as an extrapyramidal disorder because the extrapyramidal tracts that contain motor neurons are affected.

Acetylcholine, an excitatory neurotransmitter, is secreted normally in individuals with Parkinson's disease. The normal balance of acetylcholine and dopamine is interrupted in these patients, causing a relative excess of acetylcholine, which results in the tremor, muscle rigidity, and **akinesia** (loss of muscle movement) characteristic of Parkinson's disease.

Etiology

The etiology of Parkinson's disease is unknown. It was first described in 1817 by London surgeon James Parkinson. Although scientists now know that the symptoms are caused by death of dopamine-producing cells in the substantia nigra, they do not know what causes the cells to die. There may be a genetic component, especially in younger patients. Certain environmental toxins may also play a role. Parkinson's disease-like symptoms, referred to as parkinsonism, may be associated with use of certain drugs, such as phenothiazines. Parkinsonism was also linked to an outbreak of encephalitis in the 1920s.

akinesia: a—not + kinesia—movement

Box 48.9 NURSING CARE PLAN for the Patient with Disturbed Thought Processes

Nursing Diagnosis: Risk for injury related to impaired memory, thought processes, and judgment

Expected Outcomes Patient will remain free from injury

Evaluation of Outcomes Is patient safe and free from injury? Is environment safe?

Interventions

Monitor patient's ability to maintain safety.
 Keep environment simple and familiar; label doors and objects. Keep patient in familiar environment as long as possible.
 Remove harmful objects (scissors, matches), store medicines in locked cabinet; remove knobs from stoves.
 Make sure patient has eyeglasses and hearing aids if necessary.
 Use night lights, remove throw rugs, use safety gates on stairs.
 Have identification bracelet on patient and sewn into clothes, and locks on doors to prevent leaving. Provide daily walks or exercise.

Rationale

As dementia worsens, the patient's needs will change. Change can result in confusion; even a minor change in furniture arrangement can result in falls.
 Impaired judgment can make safety a major concern for patients who live at home.
 Impaired sensory perception can increase confusion and risk of falls.
 These can reduce the risk for falls.
 Patients may wander, making them prone to injury. Exercise can decrease wandering.

Evaluation

Is patient able to make decisions and negotiate the environment safely?
 Is patient able to remain in the home with minimum confusion and without injury?
 Is the environment safe for the patient?
 Is patient able to see and hear effectively?
 Is environment set up to reduce risk of falling?
 Is wandering confined to a monitored area? Is environment set up to allow movement within a safe area?

Nursing Diagnosis: Imbalanced nutrition: less than body requirements related to impaired thought processes and lack of interest or refusal to eat, poor muscle tone, weight loss

Expected Outcome Patient will maintain adequate food intake and weight within normal limits for height.

Evaluation of Outcomes Does patient maintain appropriate weight?

Interventions

Monitor intake, weight, and serum albumin.
 Develop meal plan to include likes and dislikes, snacks, and protein supplements.
 Offer larger meal when patient has the greatest appetite or serve small meals five to six times a day.
 Offer one food at a time if patient is not successful with a whole plate full.
 Offer finger foods.

Rationale

Loss of weight or serum albumin <3.5 indicates poor nutrition. Using the patient's favorite foods will encourage eating.
 A lot of food at one time may feel overwhelming to the patient.
 Too many choices on a plate may feel overwhelming to the patient.
 Utensils may be difficult for the patient to use and may discourage eating.

Evaluation

Are weight and serum albumin stable and within normal limits?
 Is patient consuming majority of meals?
 Is patient eating meals that are served?
 Does patient eat more if one food at a time is offered?
 Does patient eat more when finger foods are offered?

Also see Box 48.10 Nutrition Notes (Managing Mealtimes for Patients with Dementia).

(Continued on following page)

Box 48.9 NURSING CARE PLAN for the Patient with Disturbed Thought Processes (*Continued*)

Nursing Diagnosis: Disturbed thought processes related to dementia as evidenced by disorientation, inability to concentrate or follow directions.

Expected Outcomes Patient will function at optimal cognitive level.

Evaluation of Outcome Is patient maintaining cognitive function?

Interventions

Monitor changes in thought processes.

Provide a box of safe, familiar items, such as empty thread spools, or pretty handkerchiefs for women.

Place calendars, clocks, personal items, and seasonal decorations in patient's environment.

If patient hallucinates or has delusions, do not attempt to correct. Focus instead on the feelings related to the hallucinations, such as "Do you feel frightened?"

Reduce stressors such as fatigue, overstimulation, or pain.

Maintain patient's usual routines as much as possible.

Communicate clearly: make eye contact, speak slowly and directly to the patient, use nonverbal gestures.

Involve family in care planning and implementation.

Provide video or audiotapes of patient's family members.

Rationale

As cognitive function declines, care plan will need to be revised.

Patients often rummage through drawers, closets, or boxes. These patients may not recognize the difference between their own possessions and those of others. Keeping them occupied with a box of safe items may decrease their need to look for things.

These provide orientation to the present.

Having feelings validated may help develop trust, while not validating the hallucination.

Stress may increase dysfunctional behaviors.

Familiar routines such as sleeping or eating habits are more comfortable for patients. Change can be stressful.

Unclear communication can increase confusion and stress.

The family knows the patient's preferences and routines best.

Familiar sounds and pictures may reduce agitation when family is not present.

Evaluation

Is patient able to correctly identify objects, remember tasks, speak clearly, identify person, place, and time?

Does a box of items keep patient occupied and content?

Can patient identify the season or year?

Does patient respond to refocusing on feelings?

Are stressors eliminated as much as possible? Is patient's behavior calm?

Are routines organized around the patient rather than the staff?

Do all staff communicate clearly and respectfully with the patient?

Does family presence help patient stay calm and function at optimum level?

Do video or audiotapes help calm patient?

Nursing Diagnosis: Caregiver role strain related to demands of caring for patient with declining mental status while balancing other demands

Expected Outcomes Caregiver will have support needed to safely manage care of patient. Caregiver will be able to identify when the patient is too difficult to care for and requires more structured observation.

Evaluation of Outcomes Is caregiver managing demands of caring for patient? Is patient safe? Is additional support or a change in environment for patient indicated?

Interventions

Allow caregiver to verbalize concerns related to burden of caring for patient.

Observe for signs of depression or stress in the caregiver.

Encourage caregiver to identify family and friends that can provide support. If they are involved in a local church or religious organization, encourage caregiver to make his or her needs known.

Refer for assistance with caregiving and/or day care utilizing Alzheimer's support groups and resources.

Encourage caregiver to use support systems identified to allow him or her time to care for self; encourage to take care of own health needs, and enjoy some respite time doing something enjoyable on a regular basis.

Allow the caregiver to grieve over the losses he or she is experiencing: losses in the patient as well as loss of control over his or her own life.

Discuss progression of the disease process and the possibility of transferring the patient to a nursing home.

Rationale

An assessment of caregiver concerns and challenges can help the nurse plan appropriate support.

A stressed or depressed caregiver may have difficulty providing safe care for the patient.

There are often resources in the family or community that can be accessed without cost, and are able to help if they know the need exists.

Formal support systems in the community may be available to help relieve some of the caregiver's burden.

If the caregiver becomes ill due to the stress of caregiving, he or she will no longer be able to assist the patient.

As the disease progresses, the patient gradually loses awareness of the neurological deterioration. Occasional lucid moments can be very difficult for patient and caregiver as they realize what has been lost.

The caregiver may feel guilt over not being able to care for the patient, and may need permission to consider nursing home placement.

Evaluation

Does the caregiver share concerns? What are the caregiver's current support systems?

Are signs of stress present?

Does patient care appear to be suffering?

Can caregiver identify potential resources to contact?

Is caregiver able to obtain support and take some time for him- or herself?

Does caregiver maintain own physical and emotional health?

Is the caregiver able to identify feelings of grief, anger, or sorrow?

Is caregiver able to identify when homecare is too demanding, and choose an alternative arrangement?

Signs and Symptoms

The onset of symptoms in patients with Parkinson's disease is usually gradual and subtle. A substantial percentage of the dopamine-producing cells are nonfunctional before the patient becomes symptomatic. Symptoms may be mistakenly attributed to aging or fatigue. In retrospect, patients and their significant others often identify a long period in which symptoms were present but not identified as symptoms of Parkinson's disease.

The primary symptoms of Parkinson's disease are muscular rigidity, **bradykinesia** (slow movement) or akinesia, changes in posture, and tremors. The brain is no longer able to direct the muscles to perform in the usual manner. This lack of communication between the brain and the muscles can have a profound impact on the patient's ability to ambulate safely, perform ADLs and job functions, or enjoy leisure

bradykinesia: brady—slow + kinesia—movement

Box 48.10

Nutrition Notes

Managing Mealtimes for Patients with Dementia

Dining rooms should be quiet and have adequate lighting. Occupying the same chair for every meal lends familiarity. Serving one course at a time and providing necessary but not extraneous flatware, large handled if necessary, limits distractions. Dishes with high sides enable the patient to scoop the food onto a spoon or fork. Finger foods that the patient can manage may increase intake with minimal staff assistance.

Patients with dementia must be reminded of the steps involved in self-feeding: putting the food on the spoon, directing it to the mouth, swallowing. Use verbal cues or guide the patient's hand to start the necessary movement. Despite the surroundings, common courtesies model social expectations. Introducing the patient to the other persons at the table, providing a cup rather than a carton for milk, and offering foods separately rather than mixing them all together help maintain a person's dignity.

Quiet music with a slow tempo may relax a patient and help block out environmental noises that might otherwise be startling. It might help relax staff also!

activities. The symptoms may also have a significant negative impact on the patient's self-esteem.

The patient may have difficulty in initiating movement; this may be particularly apparent when the patient attempts to start walking, rise from a sitting position, or begin dressing. Because considerable effort is required to move the rigid muscles, the patient performs voluntary movements very slowly. At times, the patient may experience "freezing" of gait, and be unable to initiate ambulation or negotiate a turn during ambulation.

The extensor muscles are more affected by Parkinson's disease than the flexor muscles. This impaired function of the extensor muscles results in the stooped posture typical of patients with Parkinson's disease (Fig. 48.14). Flexion of the hips, knees, and neck shifts the center of gravity forward. The gait is characterized by shuffling, short steps. This shuffling gait may increase in speed once the patient finally gets walking, and the patient may have difficulty stopping. The patient maintains a broad base when making turns to try to compensate for imbalance. These changes place patients at high risk for falls. Slowness of movement and stiff muscles make it much harder for patients to catch themselves if they start to fall or to relax the muscles to minimize injury.

Tremors typically begin in the hand and then progress to the **ipsilateral** foot. In most patients, the tremor then

ipsilateral: ipsi—same + lateral—side

FIGURE 48.14 Manifestations of Parkinson's disease.

moves to the **contralateral** side. Many patients identify one side of the body as being more affected by the tremor than the other. Tremor of the hand has been described as a pill-rolling tremor; the thumb typically moves back and forth across the fingers and looks like the patient is rolling a pill. Tremors typically lessen or disappear during movement and are more noticeable when the extremity is at rest or when trying to hold an object still (this is called a resting tremor). The tremors disappear when the patient is asleep. The inability to hold an object still can make simple acts such as drinking a glass of water or reading a book nearly impossible. The signs and symptoms of Parkinson's disease tend to increase in severity when the patient becomes fatigued.

Another type of tremor, a benign familial (or essential) tremor, may sometimes be mistaken for Parkinson's disease. Treatment is different for each. See Table 48.8 for differen-

contralateral: contra—opposite + lateral—side

TABLE 48.8 SYMPTOMS OF PARKINSON'S DISEASE VERSUS ESSENTIAL TREMOR

Disease	Parkinson's Tremor	Benign Familial
Resting tremor	Yes	No
Intention tremor (with movement)	No	Yes
Pill-rolling tremor	Yes	No
Head/voice tremor	No	Yes
Relieved with beta-blocking medication (propranolol)	No	Yes
Relieved with anti-Parkinson's medications	Yes	No

tiation of these tremors. The secondary symptoms of Parkinson's disease include generalized weakness, muscle fatigue and cramping, and difficulty with fine motor activities. This fine motor dysfunction may make it difficult for the patient to button a shirt or tie shoes. Handwriting typically deteriorates as the disease progresses. A soft, monotone voice and masklike facial expression may make the patient appear to be lacking in emotional responses. It may be necessary to ask patients about their emotional status and help them develop ways of expressing their emotions. The normal blink response is diminished, so the patient and significant others must be educated about eye care to prevent corneal abrasions.

Dysfunction of the autonomic system may be manifested by diaphoresis, constipation, orthostatic hypotension, drooling, dysphagia, seborrhea, and frequent urination. Patients who experience seborrhea and diaphoresis need frequent attention to personal hygiene. Drooling and dysphagia may make the patient reluctant to appear in public. Slowness in initiating walking, balance problems, and frequent urination place the patient at risk for urinary incontinence, which may also increase the patient's reluctance to leave home.

Late in the disease, mental function may become slowed and the patient may develop dementia. This is compounded by the side effects of many anti-Parkinson's drugs. Death is usually from complications of immobility.

Complications

The most typical acute complications of Parkinson's disease are related to the patient's difficulties with mobility and balance. These patients are very prone to falls, which may result in injuries ranging from bruises or fractures to head or spinal cord injuries. Constipation is common because of decreased activity, diminished ability to take in food and fluids, and side effects of anticholinergic medications. Patients are encouraged to increase fiber and fluids in their diet. If constipation is not alleviated by dietary modifications, the patient may need to use stool softeners. The patient should be counseled not to rely on laxatives or enemas.

Muscular rigidity and bradykinesia contribute to joint immobility, which decreases patients' ability to ambulate and care for themselves. Position changes may be painful for patients. A turning sheet and adequate personnel are necessary when turning a patient in bed to prevent stress on the joints. Tremors interfere with ADLs, consume immense amounts of energy, and may prevent the patient from working or performing leisure activities. Swallowing may become so impaired that enteral (tube) feeding is required. Depression is a common complication at any stage of Parkinson's disease and may compromise communication, ability to learn, and performance of ADLs. Patients may require counseling or antidepressants.

Diagnostic Tests

No specific tests are used to diagnose Parkinson's disease. The diagnosis is based on the history given by the patient and a thorough physical examination. An MRI may be done to rule out alternative causes of the patient's symptoms.

Therapeutic Interventions

There is no cure for Parkinson's disease. Treatment is aimed at controlling symptoms and maximizing the patient's functional level. Drugs used to control symptoms are listed in Table 48.9.

Many patients with Parkinson's disease experience fluctuations in motor function related to their drug therapy. This is referred to as the on-off phenomenon. Patients may experience a decreased response to levodopa, or off period, particularly as the dose is wearing off. As the disease progresses, patients may notice that the off periods become less predictable and occur more rapidly. The patient may have a delayed or absent response to the next dose of levodopa, resulting in the patient being stuck in the off stage and being significantly disabled for that period. Fluctuations in motor function may be accompanied by other symptoms, such as pain, diaphoresis, anxiety attacks, hallucinations, or mood swings. These symptoms significantly increase the disability associated with the episodes.

Patients who are taking maximum doses of medication for Parkinson's disease symptoms may benefit from a "drug holiday." During a drug holiday, patients are taken off all drugs for a time, then restarted on lower doses. Hospitalization may be necessary during this time to maintain patient safety.

Surgical Treatment

Pallidotomy is an option for patients whose rigidity, tremor, and bradykinesia are uncontrollable by medical management. During this stereotactic procedure, a destructive lesion is placed in the basal ganglia. The surgery is only performed on one side at a time. The patient remains awake during the surgery to make sure that the lesion is being placed in the appropriate location. These patients need a great deal of education and support before and during the surgery. Some centers have experimented with implanting embryonic stem cells into the brain to develop into dopamine-producing cells, but ethical issues related to use of human embryos have slowed this process. For more information, visit the National Parkinson Foundation at www.parkinson.org.

Nursing Process for the Patient with Parkinson's Disease

ASSESSMENT/DATA COLLECTION. Assess the patient for symptoms of Parkinson's disease and their effect on level of functioning. Observe ability to move, walk, and perform ADLs safely. Determine risk for injury related to immobility or falls. Assess nutritional status and condition of skin. Identify presence of confusion and side effects of medications. Psychosocial assessment includes the patient's and caregiver's responses to the disease, coping strategies, and support systems.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. The patient with Parkinson's disease is at risk for many problems. Typical diagnoses are addressed below. Also see Box 48.9 Nursing Care Plan for the Patient with Disturbed Thought Processes.

TABLE 48.9 MEDICATIONS USED TO TREAT PARKINSON'S DISEASE

Medication Class/Action	Examples	Route	Side Effects	Nursing Implications
Anticholinergic Blocks the action of acetylcholine to control tremor and salivation	Trihexyphenidyl (Artane)	PO	Urine retention, dry mouth, constipation, blurred vision, dizziness, confusion	Monitor I&O for urinary retention; teach patient not to discontinue abruptly; implement measures to prevent constipation.
Dopamine Agonist Facilitates release of dopamine	Amantadine (Symmetrel)	PO	Ataxia, hypotension, dizziness, confusion	Use caution with alcohol and other CNS agents.
Dopamine Agonists Convert into dopamine in the brain	Levodopa (L-Dopa)	PO	Nausea, vomiting, dyskinesias	Teach patient to take food shortly after (not before or with) each dose to prevent gastric irritation. May discolor urine and sweat. Teach patient to take ATC to control symptoms.
	Levodopa/carbidopa combination (Sinemet). Carbidopa prevents peripheral breakdown of levodopa so more is available in the CNS.	PO		
Dopamine Agonist Stimulates dopamine receptors in the brain	Pramipexole (Mirapex)	PO	Nausea, dizziness, weakness; may cause sudden excessive sleepiness; constipation, dry mouth	Patients may fall asleep suddenly; caution patient to avoid driving until effects known. Giving with meals may reduce nausea.
Monoamine Oxidase B Inhibitor Blocks metabolism of central dopamine, increasing dopamine in CNS.	Selegiline (Eldepryl, Carbex)	PO	Nausea, dizziness, confusion, insomnia	May slow progression of Parkinson's disease. Administer daily at noon to prevent insomnia. Can cause dangerous interaction with meperidine (Demerol).
COMT Inhibitor Blocks the enzyme COMT to prevent breakdown of levodopa, prolonging levodopa action. For use with Sinemet.	Entacapone (Comtan)	PO	Dyskinesias, hallucinations, nausea, diarrhea, yellow-orange urine, rhabdomyolysis, neuroleptic malignant syndrome	Report elevated temperature, muscular rigidity, altered LOC, elevated CPK.

LOC = level of consciousness; CPK = creatine phosphokinase; COMT = catechol-O-methyltransferase; ATC = around the clock.

With all anti-Parkinson's disease agents, teach patient to check with physician before taking over-the-counter medications, especially cold preparations. Teach to rise slowly to prevent orthostasis.

Impaired physical mobility related to muscle stiffness and tremor

EXPECTED OUTCOME: Patient will maintain optimal mobility and ability to ambulate as long as possible.

- Assist patient to plan daily activities based on anticipated response to medications. *Certain times of day may be less troublesome than others.*
- Consult with physical and occupational therapies to provide assistive devices to help maintain mobility, and provide diversional activities.
- Provide assistance with range-of-motion exercises to maintain flexibility of muscles.
- Teach patients who have difficulty initiating walking to pick up one foot as though attempting to step over something to take the first step. It may also

help to take several steps in place before starting to walk. *This may help overcome freezing of gait.*

Self-care deficit related to reduced mobility

EXPECTED OUTCOME: Patient's self-care needs will be met.

- Encourage the patient to participate in ADLs as much as possible. This helps the patient maintain independence and self-esteem.
- Consult occupational therapist to assist with devices and strategies for maintaining independence.
- Instruct the patient or family to provide clothing without buttons or shoes with adherent fasteners to help maintain independence.
- Assist the patient and family to make decisions about long-term care. Consult a social worker prn

for assistance. *As the patient ages, so do the significant others who are providing care. The point may be reached at which the caregiver is no longer able to meet the increasing needs of the patient. The decision to place the patient in a skilled nursing facility is extremely difficult and emotional.*

Risk for injury related to reduced mobility and balance

EXPECTED OUTCOME: Patient will remain safe and without injury.

- If the patient is in the hospital or extended care facility, keep the call light within reach at all times. Remind the patient to request assistance with ambulation. *The patient is at risk for injury from falls related to problems with mobility.*
- Maintain bed in the low position, with side rails raised if appropriate (side rails may be prohibited in some institutions). *Maintaining the bed in a low position reduces the risk of injury or fall when getting out of bed. Side rails may increase the risk of injury, and must be used carefully.*
- Use an alarm system that alerts the staff that the patient is getting up *so that staff can assist the patient to get up and ambulate.*
- Avoid use of restraints. *Restraints can increase the risk of injury.*
- Keep environment free from clutter, throw rugs, or other items *that may cause a patient to trip.*
- Provide walkers and other assistive devices *to provide support and prevent falls.*

SAFETY TIP

Implement a fall reduction program and evaluate the effectiveness of the program (2006 National Patient Safety Goals from www.JCAHO.org).

EVALUATION. The care of the patient with Parkinson's disease has been successful if the patient remains as mobile and independent as possible. Self-care needs are met by the patient or others, and the patient should remain safe from injury.

Huntington's Disease

Huntington's disease is a progressive, hereditary, degenerative, incurable neurological disorder. It was first described in 1872 by George Huntington, a general practitioner in New York. The uncontrolled movements associated with Huntington's disease caused some sufferers in the 17th century to be accused of and executed for witchcraft. Many of the cases around the world can be traced back to specific individuals.

Pathophysiology and Etiology

Huntington's disease is inherited in an autosomal dominant manner, which means that each offspring of an affected par-

CRITICAL THINKING

Ms. Simpson

■ Ms. Simpson is a 47-year-old Caucasian woman. She has had Parkinson's disease for the last 5 years, and the symptoms are becoming progressively worse. She is now admitted for a urinary tract infection.

1. What problems do you foresee when caring for Ms. Simpson?
2. What safety measures should you implement?
3. Ms. Simpson is receiving IV fluids of 5% dextrose in 0.45% saline, 1000 mL over 12 hours. The RN on duty is accountable for her IV, but as you are bathing her you notice that the bag is nearly full and it has been hanging for 4 hours. How many milliliters should still be in her IV bag after 4 hours?

Suggested answers at end of chapter.

ent has a 50% chance of inheriting the disorder. It is uncertain what caused the mutation of the gene responsible for Huntington's disease. Structurally the disease is characterized by degeneration of the corpus striatum, caudate nucleus, and other deep nuclei of the brain and portions of the cerebral cortex. This degeneration results in progressive loss of normal movement and intellect.

Signs and Symptoms

Signs and symptoms develop slowly and become progressively more apparent. Cognitive signs may be noticed before movement problems. Patients who are not aware of their hereditary risk for Huntington's disease may be incorrectly diagnosed as being mentally ill or alcoholic.

The patient may display personality changes and inappropriate behavior. The patient may be euphoric or irritable and may rapidly alternate between moods. Paranoia is common, and behavior may become violent as dementia worsens. The patient eventually becomes so demented that he or she is incontinent and totally dependent on others for care. These symptoms are difficult for caregivers, whether family members or professionals, to cope with. They are particularly devastating for offspring, who may or may not know whether they have inherited the disease.

Physical symptoms also develop slowly. Huntington's disease is characterized by involuntary, irregular, jerky, dancelike (choreiform) movements. Initially these symptoms may take the form of mild fidgeting and facial grimacing. In the early stages of the disease, the patient may try to cover the movements by incorporating them into a voluntary movement such as crossing the arms or scratching. The involuntary movements usually start in the arms, face, and neck and progressively involve the remainder of the body. Patients display hesitant speech, eye blinking, irregular trunk movements, abnormal tilt of the head, and constant motion (Fig. 48.15). The gait is wide, and the patient may appear to be dancing. Emotional upset, stress, or trying to perform a

FIGURE 48.15 A 47-year old patient with Huntington's disease. Note constant fidgety movement. (From Spillane, JD: *An Atlas of Clinical Neurology*, Oxford University Press, New York, 1968, p 219, with permission.)

voluntary task can significantly increase the severity and rate of the abnormal movements. The movements typically diminish or disappear during sleep. Dysphagia may significantly impair the patient's nutritional status.

Depression and suicide are common in the earlier stages of the disease, when the patient still has the cognitive ability to carry out a suicidal act. As the disease progresses, the patient becomes more and more dependent. Aspiration resulting in respiratory failure is the primary cause of death. Life span following diagnosis is about 10 to 20 years.

Diagnostic Tests

Huntington's disease has typically been diagnosed based on the clinical examination and a family history of the disease. MRI or CT may be helpful. Genetic testing is available for prenatal use and to determine if an individual has Huntington's disease before he or she becomes symptomatic. This is a significant breakthrough because Huntington's disease does not become symptomatic until patients are in their 30s or 40s, when they may already have children who could be affected (see Box 48.11 Patient Perspective).

Therapeutic Interventions

Because there is no cure, treatment of Huntington's disease focuses on minimizing symptoms and preventing complications. Antipsychotic, antidepressant, and anticholinergic drugs may be used to treat both the involuntary movements and behavioral outbursts. Research has been done on the benefits of transplanting fetal nerve tissue in patients with Huntington's disease, but this is limited by ethical debates about using fetal tissue.

Nursing Management

Patients with Huntington's disease are typically cared for on an outpatient basis. When a patient with Huntington's disease is admitted to an inpatient facility, it is important to obtain as much information as possible about that person's response to medication, daily routine, and emotional and cognitive functioning from the caregivers. For example, knowing that a certain patient is intensely afraid of bathtubs but willingly takes showers can prevent unnecessary struggles and outbursts. Providing some objects from home may

make the new environment seem less threatening. The caregivers may relate that the patient has better cognitive functioning at a particular time of day. As the dementia progresses, the patient responds less to attempts at reasoning. Giving directions in a calm but firm tone may help the patient cooperate with activities. The environment should be modified to keep the patient safe. Keep in mind that forceful, involuntary movements of the patient's extremities can happen at any time. These movements should never be misinterpreted as an attempt to harm caregivers.

Difficulty swallowing typically begins toward the middle of the disease course. Patients exhibit trouble swallowing liquids in particular. At this stage, it may still be possible to teach the patient to hold the chin down to the chest while swallowing, which lessens the chance of aspiration. Patients should sit straight upright while eating. Thickening agents may be added to thin liquids to help prevent aspiration. Adaptive devices may prolong the patient's ability to eat independently. Soft foods that are easily manipulated in the mouth are most suitable. These patients may have difficulty taking in adequate calories to maintain a normal body weight, even if a caregiver assists with feeding them. One of the many ethical issues faced by these patients and their significant others is whether artificial feeding should be used, and if so, for how long. Patients and their significant others should be encouraged to discuss end-of-life decisions early in the course of the disease.

See Box 48.9 Nursing Care Plan for the Patient with Disturbed Thought Processes.

Alzheimer's Disease

Alzheimer's disease (also called dementia of the Alzheimer's type [DAT]) is the most common of several types of dementia. Dementia is a progressive loss of mental functioning that interferes with memory, ability to think clearly and learn, and eventually ability to function (see discussion of dementia earlier in this chapter).

Alois Alzheimer, a German neurologist, first described the disease in 1907. He described pathological changes, now referred to as neurofibrillary tangles and neuritic plaques, that he discovered while performing an autopsy on a patient

**Box 48.11****Patient Perspective****Betty**

I was born the second of six children. My mom was diagnosed with Huntington's chorea (an old name for Huntington's disease) after she had all of us. My brother was diagnosed with Huntington's disease at the age of 60. He started out with terrible mood swings and a bad temper, but eventually he had a lot of movement problems, including pronounced facial and tongue movements.

By the time we knew the disease had affected our family, many of us had children and grandchildren of our own. My kids wanted me to be tested. It is a hereditary disease and you have a 50/50 chance of having it if a parent has it. If I had Huntington's, then my kids would have a 50/50 chance of having it. If I tested negative, then they and their children would not be at risk.

I was very nervous and afraid of being tested. When I went for the initial visit at the University of Michigan, they observed my movements, how I walked and talked, and my facial movements. They made me go to a psychologist to see if I could handle the results if they did the blood test that would tell for sure. I understand the suicide rate is kind of high for people with Huntington's. After talking for an hour and a half, they decided I could handle the results.

At my next visit they just drew blood, which was sent out for testing. I had to return to U of M six weeks later for the results. When I went back, I was a nervous wreck. A friend went with me. When the technician came in, she said the doctor would be with me soon. I immediately had bad thoughts. Then when the technician and doctor came back, they were both smiling and had tears in their eyes—I had tested negative. So my friend, the doctor, the technician, and I all hugged and cried.

It is a very hard disease to live with, whether you or another family member has it. My brother has it very bad. Out of my five siblings, four have it for sure, and we think the fifth has it because of mood swings we have observed.

I am the only one of the six who tested clear. I felt very guilty at first that they all had it and I didn't. I'm starting to get over that, but when I see one of them having a bad time with talking, or temper, or movement, the guilt starts to kick in again.

Etiology and Pathophysiology

Many etiologies have been theorized for Alzheimer's disease, including viral or bacterial infection, and autoimmune dysfunction. Markers associated with Alzheimer's disease can be found on several chromosomes. Chromosome 21 in particular has been associated with Alzheimer's disease, and is also the location of the genetic abnormality responsible for Down's syndrome. Patients older than age 40 who have Down's syndrome usually develop Alzheimer's disease. The exact correlation between the two disorders is still being studied.

Although the exact cause of Alzheimer's disease is unknown, the structural changes associated with it have been well documented. An abnormality exists within the protein of the cell membrane of a neuron. As the axon terminals and dendrite branches disintegrate, they collect in neuritic plaques. Within the normal brain is a precise arrangement of filaments and tubules that are responsible for cell integrity. Individuals with Alzheimer's disease develop neurofibrillary tangles instead of the normal orderly arrangement. Instead of remaining a small area of abnormality, these neuritic plaques and neurofibrillary tangles spread via axons to other areas of the brain.

Advancement of neurofibrillary tangles and neuritic plaques typically affect the hippocampus first, resulting in short-term memory dysfunction. As the tangles and plaques spread to the temporal lobe, the memory impairment becomes more severe. It may be at this point that the patient accesses the health-care system. Personality changes and incontinence are inevitable results of Alzheimer's disease. These symptoms can be attributed to the spread of plaques and tangles to the frontal lobes of the brain.

It is believed that the younger the patient is at the time of onset, the faster the neurofibrillary tangles and neuritic plaques spread. Therefore, these patients tend to deteriorate faster, require complete care earlier, and have a shorter life span.

In addition, patients tend to have a deficiency of acetylcholine in the cerebral cortex. Remember that acetylcholine is a neurotransmitter important for nervous system function.

One area of the brain that is left relatively untouched by Alzheimer's is the subcortical area. This structure is responsible for our subconscious urge to survive. The needs for basic requirements such as shelter, food and water, security, and reproduction are controlled by the subcortical area, as are emotional responses to situations. The patient with Alzheimer's disease may experience hunger but no longer know how to meet that basic need. Left to their own devices, these individuals would starve.

Signs and Symptoms

The signs and symptoms of Alzheimer's disease are typically broken down into three stages. The early stage, stage one, lasts from 2 to 4 years and is characterized by increasing forgetfulness. At this stage, the patient may attempt to cope by using lists and reminders. Interest in day-to-day activities, acquaintances, and surroundings tends to diminish. The patient is reluctant to take on tasks because of

with dementia. Alzheimer's disease is a progressively degenerative disease that is inevitably fatal. The incidence of Alzheimer's disease is more common in women than men and doubles for every 5 years a person lives beyond age 65.

uncertainty in how to perform them. If the patient is still working, his or her performance deteriorates and may result in being terminated from the job.

The middle stage, stage two, is the longest in duration, lasting 2 to 12 years. Progressive cognitive deterioration is demonstrated by difficulty doing simple calculations or answering questions. Patients may become irritable, particularly when asked to perform a task that they know they should be able to perform but cannot. It may help the patient to break down the task into manageable steps. Depression is common. Aphasia and the resulting inability to make themselves understood may exacerbate patients' irritability. It is during the middle stage, as cognitive function significantly deteriorates, that the patient becomes more physically active. The normal sleep-wake cycle is disrupted, and the patient tends to wander aimlessly, particularly at night. The patient may become lost in familiar surroundings, which compounds the anxiety that typically develops during this stage. Hallucinations and seizures may occur. Management of day-to-day activities such as feeding a pet or paying bills becomes overwhelming. Personal hygiene deteriorates, as does appropriate social behavior. Patients may make up stories to cover for deficits, saying that possessions they misplaced were stolen. Some patients hoard food or money.

The third stage of Alzheimer's disease is characterized by progression to complete dependency. The patient loses the ability to converse or control bowel or bladder function. Constant supervision is required, if the patient is still mobile, to protect from wandering and avoid injury. Emotional control and ability to recognize significant others are lost. This lack of recognition is particularly devastating for family members. Eventually the patient is unable to move independently, swallow, or express needs. Death usually occurs from complications of immobility.

The duration of the final stage of Alzheimer's disease, characterized by complete dependence, depends in part on the physical stamina and general health of the individual. The healthier the patient, the longer the body will continue to function. Another factor is the decisions that have been made regarding artificial feeding and respiratory support. Few significant others or health-care practitioners advocate intubation and mechanical ventilation for patients with

Alzheimer's disease. The issue of enteral (tube) feedings, however, is an emotional one with few easy answers. The use of enteral feedings can prolong the patient's life, despite the absence of cognitive functioning. As with patients suffering from Huntington's disease, every effort should be made to determine the patient's wishes before cognitive impairment makes that impossible. See Table 48.10 for a comparison of the symptoms of Parkinson's, Huntington's, and Alzheimer's diseases.

Diagnostic Tests

The only absolute method of confirming a diagnosis of Alzheimer's disease is by pathological examination at autopsy. In actuality, the disease is diagnosed on the basis of clinical examination, history, and elimination of other possible causes of the symptoms. MRI may reveal the presence of the classic neurofibrillary tangles and neuritic plaques. Positron emission tomography (PET) and single photon emission computed tomography (SPECT) scans show areas of neuronal inactivity. Newer tests are being evaluated that hold promise for better diagnosis.

Therapeutic Interventions

There is no known cure for Alzheimer's disease. Treatment has traditionally focused on minimizing the effects of the disease and maintaining independence as long as possible. Acetylcholinesterase (AChE) inhibitors such as donepezil (Aricept) or rivastigmine (Exelon) are thought to inhibit the breakdown of the neurotransmitter acetylcholine (see Table 48.7). Increased levels of acetylcholine in the brain allow better functioning of the remaining neurons. They appear to be most effective for those patients who exhibit mild to moderate symptoms of Alzheimer's disease. It may take some time to notice any effects of the drugs. Use of AChE inhibitors diminishes the amount of medical care and social service interventions required and delays admission to skilled nursing facilities. This delay in institutionalization can result in significant positive impact on quality of life, as well as thousands of dollars in savings.

A new class of medications, NMDA (N-methyl-D-aspartate) antagonists, may prevent overexcitation of NMDA receptors in the brain and allow more normal function. Memantine (Namenda, Axura) is the only drug currently available in this class. These drugs can be given at any

TABLE 48.10 SYMPTOMS OF PARKINSON'S DISEASE, HUNTINGTON'S DISEASE, AND ALZHEIMER'S DISEASE

Symptom	Parkinson's Disease	Huntington's Disease	Alzheimer's Disease
Tremors	Present	Absent	Absent
Bradykinesia/akinesia	Present	Absent	Absent
Muscle rigidity	Present	Absent	Absent
Memory dysfunction	Late	Late	Early
Cognitive dysfunction	Late	Present	Early
Inability to perform ADLs	Progressive	Progressive	Progressive
Involuntary movements	Absent	Present	Absent
Depression	Present	Present	Present

stage of Alzheimer's disease, and like AChE inhibitors, simply slow the patient's decline.

Antidepressants, antipsychotics, and antianxiety drugs may be used as a last resort to control symptoms of depression and behavioral disturbances, but they do not treat the dementia. Patients should be carefully monitored for drug interactions and side effects. For more information, visit the Alzheimer's Association at www.alz.org.

Nursing Process for the Patient with Alzheimer's Disease

See the earlier discussion of dementia and Box 48.9 Nursing Care Plan for the Patient with Disturbed Thought Processes.

CRITICAL THINKING

Mrs. Johnson

■ Mrs. Johnson has just become a resident at the Valley Bend nursing home. She is diagnosed with Alzheimer's disease and is in the second stage with some signs of stage three disease. When you check on her during the evening, you find her walking around her room, talking to herself. What other signs and symptoms are typical for stage two and stage three Alzheimer's disease? How should you address her behavior?

Home Health Hints

To assess a patient's neurological status at home:

- Note whether the patient's clothes are matched and properly fastened. Is the patient clean and well groomed?
- Observe the patient during bathing, grooming, or dressing to assess motor function and coordination.
- Assess energy level by noting if the patient makes frequent requests to sit or lie down.
- Observe the patient's gait for steadiness.

To help the patient perform ADLs easier at home:

- Ask permission to move furniture and small rugs in order to provide a clear path for ambulation.
- Position frequently used items such as a comb, glass of water, eyeglasses, books, tissues, and phone where they are easily accessible.
- Recommend shoes with Velcro closures.
- Use chairs with armrests—the patient can use the armrests to push against to stand.
- Keep the patient cleaner at meals with a clip-on bib such as those used at the dentist's office. Attach clips from suspenders to a piece of elastic and place around the back of the patient's neck. Attach a clean napkin or washcloth for each meal.

To help the patient with Alzheimer's disease who has perceptual deficits:

- Have things used together the same color (e.g., toothbrush and toothpaste).
- Contrast colors in the environment to help patients function independently—slipper color should be different than the floor; a dark-colored placemat can be used under light dishes, and the first and last steps of a stairway can be painted a contrasting color.
- Use a bath or shower seat, hand-held shower head, and soothing music to help the patient feel safe and oriented to the task while bathing.
- Cover doorknobs with a piece of cloth to keep the patient from wandering away or have a caregiver purchase inexpensive child safety devices that can fit over doorknobs and/or cabinet latches.
- Family members may require respite care and homemaker services. Discuss with the registered nurse or physician about having social services complete a visit to assist the family with access to community resources.

REVIEW QUESTIONS

- Which of the following problems predisposes someone to develop meningitis?
 - A sore throat for 3 days
 - A migraine headache
 - A muscle injury in the neck
 - Vision changes
- A patient with meningitis is experiencing photophobia and a severe headache. Which nursing interventions will be most helpful to relieve symptoms?
 - Administer antibiotics as ordered, and prepare the patient for a lumbar puncture.
 - Darken the room and administer analgesics.
 - Administer acetaminophen as ordered and place a cooling blanket on the patient.
 - Check level of consciousness with the Glasgow Coma Scale and monitor pulse pressure.
- Which type of headache is most commonly associated with an aura?

- a. Migraine
 - b. Cluster
 - c. Tension
 - d. Muscle contraction
4. A patient makes an appointment to see a primary care practitioner for recurrent severe headaches. Which instruction by the nurse will help gather the best additional data prior to the appointment?
- a. “Try relaxation and warm moist compresses for your headaches.”
 - b. “Call and come in the next time you have a headache so you can be examined.”
 - c. “Keep track of how many headaches you have before you come in.”
 - d. “Keep a diary of your headaches, recording symptoms, timing, and things that trigger them.”
5. A patient who has had a generalized tonic-clonic seizure is sound asleep 30 minutes after the seizure. Meals are about to be delivered. Which nursing action is most appropriate?
- a. Wake the patient because nourishment is essential following a seizure.
 - b. Wake the patient to do a complete neurological assessment before the meal.
 - c. Let the patient sleep during the postictal state, and keep the meal warm.
 - d. Do not attempt to wake the patient because of the risk of a repeat seizure.
6. A patient with a history of seizures says he thinks he is about to have a seizure. Place the nurse’s interventions in the correct order.
- a. Protect the patient from injury during the seizure.
 - b. Document the events of the seizure.
 - c. Help the patient lie down in a safe place.
 - d. Turn the patient on his or her side to sleep.
7. Which patients should be closely monitored by the nurse for symptoms of increased intracranial pressure? Select all answers that apply.
- a. The patient who has a history of epilepsy.
 - b. The patient admitted with a high fever and severe headache.
 - c. The patient in the post-anesthesia care unit following craniectomy.
 - d. The patient with a brain tumor who is admitted for radiation therapy.
 - e. The patient with a history of migraine headaches, admitted for orthopedic surgery.
8. Which of the following actions should the nurse take to help prevent increased ICP in a patient following a traumatic brain injury?
- a. Cluster care so the patient can have long periods of rest.
 - b. Keep the head of the bed elevated at 30 degrees.
 - c. Suction frequently to keep the airway clear.
 - d. Do not give anything by mouth.
9. How much function can be expected in a patient with a spinal cord injury at the L2 level?
- a. Quadriplegic from neck down
 - b. Quadriplegic with some arm movement
 - c. Paraplegic with some trunk movement
 - d. Paraplegic, may learn to walk with a brace
10. A patient is admitted following a T4 spinal injury. When taking his morning vital signs, the nurse notes that he appears restless and his blood pressure is elevated. Which of the following actions by the nurse is appropriate?
- a. Recheck his blood pressure in 30 minutes.
 - b. No action is necessary. This is an expected finding.
 - c. Check for a full bladder.
 - d. Encourage him to express his anxiety.
11. The symptoms of Parkinson’s disease are caused by depletion of which neurotransmitter?
- a. Dopamine
 - b. Acetylcholine
 - c. Serotonin
 - d. Norepinephrine
12. Which nursing interventions are appropriate for the patient with a neurodegenerative disorder who has difficulty swallowing?
- a. Show the patient how to tuck his or her chin down to the chest during swallowing.
 - b. Provide clear to full liquids; avoid solid foods.
 - c. Place the patient in semi-Fowler’s position for eating.
 - d. Provide adaptive eating utensils.
13. A nursing home resident with Alzheimer’s disease is sitting in a corner, crying loudly that no one is paying attention to her. Several staff members have tried to find out what’s wrong, but the patient won’t answer. She just keeps rocking back and forth and crying that no one is paying attention to her. Which approach by the nurse might best help the patient?
- a. Say in a quiet voice, “What is wrong? We can’t help you if you don’t tell us what’s wrong.”
 - b. Sit quietly by the patient and say, “I’m here; you aren’t alone.”
 - c. Say in a firm voice, “Several staff have asked what you need, now it is time to stop crying.”
 - d. Ignore the continued crying. Continuing to respond to her will encourage the behavior.

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Mr. Chung*

- Be prepared to assist with a lumbar puncture.
- You should use short, simple sentences because he may be very anxious or disoriented. Involve his family. Further education can be provided when he is feeling better.
- Because meningococcal meningitis is contagious, he should be placed in isolation. Gloves, gowns, and masks should be used. Explain the need for these practices to Mr. Chung and his visitors.
- Comfort measures include tepid baths, a quiet, dark environment, and minimal stimulation. Administer acetaminophen and analgesics as ordered.
- The health service at his college should be notified of his diagnosis. Close contacts may require prophylactic treatment. If Mr. Chung lives at home rather than at college, his family should be advised to see their family practitioner and begin prophylactic treatment.

■ *Mr. Evans*

- You might expect to see impaired speech, right-sided weakness, and a rapid decrease in consciousness if Mr. Evans's hematoma is enlarged.
- Intubation equipment, mannitol, and intravenous access should be ready. He should be given nothing by mouth (NPO) and the results of laboratory tests should be ready in the event of emergency surgery. The location of Mr. Evans's next of kin must be known.
- Who are Mr. Evans's support people? Was this drinking episode an isolated incident or a chronic problem that should be addressed?

■ *Ms. Simpson*

- Urinary tract infection is often accompanied by urinary urgency. Ms. Simpson may have difficulty getting to the bathroom quickly and safely.
- Keep a bedside commode nearby if the bathroom is not close. Assist Ms. Simpson to the bathroom or commode at regular intervals to prevent urgency. Remind her to ask for help if she needs to get up. Make sure that her call light is within reach.
-

$$\frac{1000 \text{ mL}}{12 \text{ hours}} \times 4 \text{ hours} = 333 \text{ mL}$$

After 4 hours: $1000 - 333 \text{ mL} = 667 \text{ mL}$ should remain in the bag. If it is still nearly full, the RN should be notified.

■ *Mrs. Johnson*

Being admitted to a new and unfamiliar facility can increase confusion. Signs of second stage Alzheimer's disease include memory loss, wandering at night, sleeplessness, irritability, loss of way in familiar surroundings, losing possessions and searching for them, and neglect of personal hygiene. During the third stage of the disease, the patient will lose weight, recognize hunger but be unable to eat, be unable to communicate verbally or in writing, lose ability to recognize family, become incontinent of urine and feces, and eventually lose ability to stand and walk. Address Mrs. Johnson by her name and ask her what she needs. Reorient her to where she is and assure her that she is safe and being cared for.

Nursing Care of Patients with Cerebrovascular Disorders

WENDY HOCKLEY

KEY TERMS

QUESTIONS TO GUIDE YOUR READING

1. What are the causes, risk factors, and pathophysiology of transient ischemic attack, stroke, and cerebral aneurysm?
2. What are emergency interventions for transient ischemic attack, stroke, and cerebral aneurysm?
3. What are therapeutic interventions for transient ischemic attack, stroke, and cerebral aneurysm?
4. What outcomes can be expected for a stroke victim?
5. What is appropriate nursing care for a patient with a cerebrovascular disorder?

Cerebrovascular disorders are disorders of the vascular system in the brain. When the vessels are unable to supply blood and oxygen to brain cells, brain tissue dies, causing a cerebrovascular accident (stroke). The most common cerebrovascular disorders include transient ischemic attack (TIA), stroke, and subarachnoid hemorrhage (SAH).

TRANSIENT ISCHEMIC ATTACK

Transient ischemic attack (TIA) is a temporary impairment of the cerebral circulation causing neurological impairment that lasts less than 24 hours. It is characterized by a sudden, focal (specific area) neurological deficit caused by a brief period of inadequate perfusion of a portion of the brain. The loss of neurological function causes symptoms similar to those of a stroke (see next section). A TIA typically lasts minutes to hours, and the patient will have complete recovery. Symptoms that last longer than 24 hours but do not cause permanent neurological changes are called reversible ischemic neurological deficits (RINDs). If the symptoms do not reverse because an area of the brain is permanently damaged, then the event is considered to be a cerebral vascular accident (CVA), or stroke. Patients who have had a TIA have an increased risk of having a stroke; about 24% to 29% of patients who experience a TIA will have a stroke within 5 years. The risk is highest in the first month after the TIA. A TIA should be evaluated urgently to start appropriate therapy as soon as possible in order to decrease the risk of stroke.¹

Because TIA is such a significant risk factor for stroke, etiologies, symptoms, diagnostic tests, and therapeutic interventions for TIA are the same as described below for cerebrovascular accident (stroke).

CEREBROVASCULAR ACCIDENT

Cerebrovascular accident is the infarction (death) of brain tissue caused by the disruption of blood flow to the brain. It is characterized by focal neurological deficits specific to the area of the brain involved that do not fully resolve. The patient does not return to baseline functional level. Although strokes are most common in people over the age of 75, they affect approximately 700,000 people of all ages each year; 500,000 first-time strokes and 200,000 recurrent strokes. On average, every 45 seconds someone in the United States has a stroke, and every 3 minutes someone dies of a stroke. Stroke is our nation's number 3 killer and the leading cause of severe, long-term disability. Some population groups, such as African Americans, American Indians, Alaskan natives, and Mexican Americans, have a higher than average risk. Recent studies indicate that the risk of stroke may be higher in women during pregnancy and the 6 weeks following childbirth.²

In order to impress upon practitioners and the community the urgency of treating a stroke quickly, strokes are now

being called *brain attacks* in the public setting. This reminds us that, like a heart attack, stroke is an urgent condition that can be treated if medical care is sought immediately. Patients should understand that if they experience any symptoms of a stroke, they should call 911 and go to the hospital immediately by ambulance. If patients receive treatment within 3 hours of symptom onset, they may be able to receive medication that has the potential to fully resolve their deficits.

Pathophysiology

Cerebral function is dependent on oxygen and glucose delivery to neurons of the brain. When blood flow is severely compromised or absent, the oxygen and glucose needed to meet the brain's metabolic needs are not available. The brain has no capability to store oxygen or glucose, so it relies on a constant supply of these nutrients. If the supply of oxygen and glucose is stopped, the brain tissue dies. In contrast to TIA, a brain attack can cause permanent damage if it is not reversed with timely treatment. For a brief period of time following a stroke, there is an area of brain tissue surrounding the damage, called the **penumbra**, which may be revived if the brain is reperfused quickly.

The particular vessel or vessels involved determine the area of the brain affected and therefore the symptoms that result. The duration of ischemia determines whether the symptoms are transient or permanent. A transient ischemic attack may be a warning of an impending stroke.

Etiology

A stroke can be caused by ischemia or hemorrhage. Most strokes present with sudden or rapidly evolving onset of symptoms. Even the best neurological specialist has difficulty making a diagnosis of stroke using clinical examination and history alone. A CT scan or MRI is necessary to make a diagnosis of stroke, and to determine whether the stroke is due to ischemia or hemorrhage. Etiology must be determined before treatment can be initiated.

Ischemic Stroke

An ischemic stroke can be caused by embolism or thrombosis, with resulting decreased perfusion (Fig. 49.1). Although any vessel may be involved, the bifurcation of the common carotid artery into the internal and external branches is the most common location for cerebral atherosclerosis and subsequent occlusion from an embolism or thrombosis.

When arteries are narrowed due to atherosclerotic plaque, they can become occluded (thrombotic stroke). If emboli break away from plaque, they can travel and lodge in narrowed cerebral vessels (embolic stroke). Either case results in ischemia or infarct of the brain cells that are perfused by the affected vessel.

Emboli in the brain may be arterial or cardiac in origin. Patients in atrial fibrillation can have small clots develop in the atria because the blood is not ejected normally, and as a result pools. These clots can be ejected into the circulation and become emboli. Other commonly recognized cardiac

FIGURE 49.1 Embolism and thrombosis.

sources for embolism include sinoatrial disorder, recent acute myocardial infarction (AMI), subacute bacterial endocarditis, cardiac tumors, and valve disorders. Most strokes of cardiac origin occur in the first weeks after AMI, but some risk for stroke remains for an indefinite time.

Stroke due to decreased perfusion occurs with severe stenosis of the carotid or basilar arteries, or with stenosis of the small deep arteries of the brain. The smallest, most distal vessels are affected first, before the larger proximal vessels, a process termed “watershed infarction.” People with diabetes and hypertension have an increased risk for atherosclerosis and thrombosis.

Decreased perfusion may also occur from vasculitis, an inflammatory condition involving the cerebral blood vessels. Common causes of vasculitis are systemic lupus erythematosus, bacterial or tuberculous meningitis, fungal infection, and herpes zoster arteritis (arterial inflammation).

Hemorrhagic Stroke

Hemorrhagic stroke is caused by the rupture of a cerebral blood vessel. When a cerebral blood vessel ruptures, the brain tissue beyond the vessel does not receive oxygen and nutrients and can die. Additional damage can occur to the brain tissue surrounding the rupture from blood being released in the brain outside of the vascular system. The most common cause of an intracerebral hemorrhage (ICH) is poorly controlled hypertension. Another cause is a ruptured aneurysm. Hemorrhages tend to occur deep within the brain tissue. Subarachnoid hemorrhage (SAH) is caused by rupture of blood vessels on the surface of the brain. This type of infarct has the slowest rate of recovery and the highest probability of leaving the patient with extensive neuro-

logical deficits. A complete discussion of hemorrhagic strokes is presented later in this chapter.

The most common etiology of brain attack in younger patients is illicit drug usage. PCP (phencyclidine), crack, cocaine, amphetamines, and heroin have all been associated with cerebrovascular accident from subarachnoid or intracerebral hemorrhage because these drugs raise the blood pressure and increase pressure within the cerebral vessels.

Risk Factors

Risk factors for ischemic stroke are classified as modifiable or nonmodifiable.

Nonmodifiable risk factors are those things that cannot be altered, such as age, gender, race, prior stroke history, and heredity. Modifiable risk factors are those risks which can be changed by treatment, such as treating high blood pressure, or by lifestyle modification, such as stopping smoking (Box 49.1). Following physician recommendations and medication orders for modifiable risk factors will help individuals reduce stroke risk.

Warning Signs

All patients should be taught to recognize warning signs of a stroke, and to call 911 immediately if they occur. Warning signs include:

- Sudden numbness or weakness of face, arm, or leg, especially on one side of the body
- Sudden confusion, trouble speaking, or understanding
- Sudden trouble seeing in one or both eyes
- Sudden trouble walking, dizziness, loss of balance, or coordination
- Sudden severe headache with no known cause³

Box 49.1

Risk Factors for Stroke

Modifiable Risk Factors

- High blood pressure
- Smoking
- Diabetes mellitus
- Atherosclerosis
- Atrial fibrillation
- Other heart disease
- TIAs
- Sickle cell anemia
- High cholesterol
- Obesity
- Excessive alcohol intake
- Certain illegal drugs

Nonmodifiable Risk Factors

- Older age
- Sex (more common in men)
- Heredity
- Prior stroke or heart attack

TIAs = transient ischemic attacks.

Acute Signs and Symptoms

Symptoms are varied and depend on the area of the brain affected. Common symptoms include visual disturbances, language disturbances, weakness or paralysis on one side of the body, and difficulty swallowing (dysphagia). These signs and symptoms are the same for both ischemic and hemorrhagic stroke. In addition, the patient with a hemorrhagic stroke may experience rapid deterioration, drowsiness, and a severe headache, often described as “the worst headache of my life.” Symptoms can last a few minutes to a few hours or may persist for an indefinite period of time (Table 49.1)

Language Disturbances

Difficulty with language is frequently associated with a TIA and stroke. *Aphasia* refers to the absence of language; *dysphasia* refers to difficulty with speech and is not as severe as aphasia. The patient may experience trouble selecting correct words, use incomprehensible or nonsense speech, have trouble understanding others’ speech, and have trouble writing or reading. Aphasia may be expressive, in which the patient knows what he wants to say but cannot speak or make sense, or receptive, with an inability to understand spoken and/or written words. Global aphasia occurs when both expressive and receptive aphasia are present. Slurred or indistinct speech and abnormal pronunciation of words and articulation because of a motor problem are referred to as dysarthria.

Motor Disturbances

Paralysis, weakness, or numbness can present as clumsiness, heaviness, and facial droop. The onset will be sudden and generally involves one side of the body, the side of the body *opposite* to the damaged area. The deficits may present on both sides of the body if the patient has experienced a brainstem stroke or a vertebrobasilar stroke. The most common paralysis or weakness affects the arm and face together but can present as complete hemiparesis, where the entire one side of the body is flaccid. Another clinical finding that affects mobility is **ataxia**. Ataxia may present as poor balance, a stumbling gait, or staggering. This can be related to damage to the cerebellum, or to poor coordination due to weakness or paralysis on one side of the body. If the muscles of swallowing are affected, dysphagia results.

Visual Disturbances

Visual field disturbances are also a common symptom of a stroke. The visual loss is painless and may involve loss of all

or part of the vision in one eye. Patients often describe a “curtain dropping,” “fog,” “gray-out,” or “black-out” of vision. The involved eye is on the *same* side as the diseased artery. Visual field abnormalities include horizontal (top or bottom half of visual field), bitemporal (outside half), homonymous (same side half), or hemianopsia or quadrantic (one-quarter visual loss) defects (Fig. 49.2). When you are assessing the patient, stop talking and keep moving across the room. If the patient does not track you there is a good chance he or she has a deficit in that visual field.

Diagnostic Tests

A new assessment tool is now available to assist community members and emergency medical technicians in identifying stroke symptoms quickly. The Cincinnati Prehospital Stroke Scale (CPSS) was created to facilitate transporting stroke victims to the hospital as soon as possible. Findings in recent studies show that a patient who has one of three positive findings when the CPSS is used has a 72% probability of having an ischemic stroke. If all three findings are positive, the probability increases to 85%.⁴

The CPSS has three components to review:

- Have the patient smile. Look for subtle signs of facial droop or uneven symmetry of the face.
- Ask the patient to hold the arms out straight in front while closing the eyes. Observe the patient’s arms closely for any signs of drifting downward. This can be performed with the patient standing or sitting down.
- Ask the patient to repeat a phrase, such as “It is a bright and sunny day in Michigan.” Did the patient understand? Did he repeat the phrase exactly? Did he exhibit any slurred speech or difficulty saying words?

If any one of the three tests is positive, the patient should be sent immediately by ambulance to the nearest emergency room or stroke center.

Upon arrival at the emergency department, a computed tomographic (CT) scan will be performed immediately. If the cause of symptoms is a TIA, the CT scan will be negative for stroke since there has been no permanent damage to the brain. However, even an ischemic stroke that causes damage to the brain cells will not be visible on a CT for several days after the event. The purpose of the CT scan is to identify if the symptoms are caused by a hemorrhagic stroke

TABLE 49.1 SYMPTOMS OF STROKE ACCORDING TO ARTERY AFFECTED

	Hemiparesis	Dysphasia	Visual Changes	Altered Level of Consciousness	Ataxia	Dysphagia
Carotid	X	X	X	X		
Middle cerebral	X	X	X	X		
Vertebrobasilar/ cerebellar (brainstem)	Loss on both sides of body	X	X	X	X	X

FIGURE 49.2 Visual deficits in stroke.

so the physician can determine the appropriate course of treatment. Hemorrhagic strokes are treated with a different course of care than ischemic strokes. Care for hemorrhagic strokes is discussed later in this chapter.

Patients may have an electrocardiogram (ECG) to determine if atrial fibrillation is present. An echocardiogram may be done to determine the presence of other heart disease that may increase risk of thrombus formation. Other tests that may be performed in the emergency department include complete blood count (CBC), metabolic panel, blood typing, prothrombin time (PT) and international normalized ratio (INR), and serum pregnancy if indicated. Stools and emesis may be checked for blood if possible. The patient will be placed on a cardiac monitor and pulse oximeter. The emergency department (ED) nurse will complete a dysphagia screen before the patient consumes anything.

ED staff may complete the NIH (National Institutes of Health) Stroke Scale to determine the patient's neurological deficit level. This scale is more involved than the Prehospital Scale. See the Stroke Scale at http://www.ninds.nih.gov/doctors/NIH_Stroke_Scale_Booklet.pdf. If the patient has arrived at the ED within 3 hours of the onset of symptoms, the patient will be evaluated for appropriateness for receiving t-PA (tissue plasminogen activator), a **thrombolytic** agent recently approved for use in strokes. If the patient is not a candidate for t-PA, the patient will be further evaluated for appropriate care.

thrombolytic: thrombo—clot + lytic—causing breakdown

Carotid Doppler testing can determine if stenosis of the carotid arteries exists. This noninvasive test involves bouncing sound waves off the carotid arteries to determine the velocity and turbulence of blood flow. The amount of restricted flow determines if the patient would benefit from a carotid **endarterectomy** to remove the occlusion from the artery. If the patient is symptomatic or the degree of stenosis causes over 70% occlusion of the carotid artery, the patient may be kept at the hospital for surgical intervention.

A cerebral angiogram may be completed to determine the patency of cerebral vessels and the status of any collateral circulation.

Therapeutic Interventions

Initial emergency care is supportive while test results are pending. ABCs (airway, breathing, and circulation) are monitored. Oxygen is administered to maintain oxygen saturation greater than 90%. Vital signs and heart rhythm are monitored. Diagnostic tests are done without delay. When test results verify whether the stroke is hemorrhagic or ischemic, therapeutic interventions are initiated.

Thrombolytic Therapy

Thrombolytic therapy (alteplase or t-PA) is a recent development in the treatment of ischemic brain attack. Other thrombolytic agents that are approved for use in heart attacks

endarterectomy: endo—inside + arter—artery + ectomy—surgical removal of

are being researched for treatment of strokes. Intracerebral hemorrhage must be ruled out before t-PA therapy is instituted because of the risk of worsening a bleeding vessel. The goal of thrombolytic agents is to actually break down the thrombus causing the occlusion, which can potentially prevent or completely reverse the symptoms of stroke. Plasmin is the enzyme that causes thrombi to break down. Thrombolytic agents accomplish thrombus lysis by causing the conversion of plasminogen to plasmin. Patients treated effectively with t-PA may be able to leave the hospital within 1 or 2 days with no residual effects from the stroke.

Cerebral hemorrhage is a major complication of thrombolytic therapy; therefore, it is only used if the patient meets strict criteria. It is crucial to know when the symptoms began because t-PA can only be given within 3 hours of the stroke occurrence. Assessment for appropriateness of t-PA include asking the patient or the family, “When was the last time you (or your family member saw you) were normal?” This question will determine actual onset time of the TIA or stroke. Asking questions regarding what they were doing at the time of the symptom onset assists in determining the time of onset if there are discrepancies regarding the time. There are other inclusion criteria for administering t-PA including:

- Age greater than 18 years
- NIH Stroke Scale score of 4 or greater

Patients who have a history of intracerebral hemorrhage, recent stroke or serious head trauma, surgery within the past 3 weeks, recent lumbar puncture, GI or urinary bleeding, uncontrolled high blood pressure, or any other risk factors for bleeding cannot have t-PA because of the risk of bleeding.

To be effective, t-PA must be administered within 3 hours of the onset of symptoms. This time frame has clear implications for nurses. Patients with neurological symptoms who are seen in the emergency department must be assessed and stabilized promptly. A CT scan and, if an ischemic cause is suspected, an angiogram are performed quickly. Some people may be surprised to learn that there are treatments available for stroke. Because of time constraints, individuals may be asked to make treatment decisions before other family members are able to arrive. This places a significant burden on people who are already experiencing stress. You can help ease this burden by explaining the time factor, repeating information as needed, and ensuring that the individuals involved have the opportunity to ask questions.

Pharmacological Management

Blood pressure control is vital for the patient. Care is taken not to lower the blood pressure too quickly or too far. If the

patient has long-standing hypertension, lowering the blood pressure to a “normal” level may actually cause further ischemia. Current recommendations are to not lower blood pressure more than 10% from baseline at one time. Drugs must be used carefully and blood pressure monitored frequently. If the patient experiences neurological deterioration, the physician may adjust treatment to increase the blood pressure. Some physicians believe that the blood pressure should not be lowered because chronically hypertensive patients require a higher BP to maintain adequate cerebral perfusion.

The patient may receive an antiseizure medication as a prophylactic measure. Sometimes after a hemorrhagic stroke, the patient can experience vasospasm, which could further occlude the arteries and inhibit oxygen and glucose from reaching brain tissue. If this occurs, the patient may be treated with a calcium channel blocker like nimodipine, which relaxes smooth muscles of the vessel wall and reduces the vasospasm. The physician may also order an antifibrinolytic, such as epsilon-aminocaproic acid, to inhibit plasminogen activation. This medication has been reported to reduce the incidence of rebleeding. See Table 49.2 for medications commonly used for cerebrovascular disorders.

Patients suffering from a stroke develop increased intracranial pressure, which further adds to brain damage. Stroke patients are also vulnerable to repeated strokes. Careful serial neurological assessments are needed to promptly detect and report changes.

Postemergent Care

After emergent treatment, medical management focuses on controlling the cause of the transient ischemic attack or stroke. The results of the diagnostic tests assist physicians in determining the course of treatment. If there are residual physical deficits, the physician will order physical, occupational, and speech therapist consultations to evaluate the patient’s functional status and make recommendations for further treatment. The American Stroke Association recommends that patients who have had a TIA or stroke receive an antiplatelet drug within 24 hours of symptom onset. Antiplatelet drugs include clopidigrel (Plavix), aspirin/dipyridamole (Aggrenox), or aspirin. Decreasing platelet aggregation lessens the likelihood of thrombus formation. Antidysrhythmic medication may be used to control atrial fibrillation. The patient in atrial fibrillation may also receive warfarin (Coumadin) to prevent clot development.

Respiratory compromise may occur related to an increase in intracranial pressure. Patients with stroke are prone to aspiration because of decreased level of consciousness or impaired swallowing ability. Patients should be suctioned as needed to keep the airway clear. If the patient vomits, he or she should be turned to the side to reduce the risk of aspiration. Oral feedings should be initiated carefully and progressed slowly only after the patient is alert and the ability to swallow safely has been determined by an appropriate swallowing evaluation.

LEARNING TIP

Time is brain. This means the faster the patient with a stroke receives treatment, the more brain (and brain function) can be saved.

TABLE 49.2 MEDICATIONS USED IN CEREBROVASCULAR DISORDERS

Medication Class/Action	Examples	Route	Side Effects	Nursing Implications
Thrombolytic agents Lyse existing clots	Tissue plasminogen activator (t-PA)	IV	Intracranial, GI, urinary hemorrhage	Must be administered within 3 hours of symptom onset.
Antiplatelet agents Prevent formation of clots	Aspirin	PO/rectal	Dyspepsia, nausea, vomiting, bleeding	Monitor for bruising, change in LOC, prolonged bleeding time.
	Clopidogrel (Plavix)	PO	Bleeding, abdominal pain, skin rash, edema, headache, backache	
	Aspirin/dipyridamole (Aggrenox)	PO	Headache, dyspepsia, pain, fatigue	
Anticoagulants Prolong time to form clots; prevent new clots	Warfarin (Coumadin)	PO/IV	Hemorrhage, purple toe syndrome, necrosis of skin	Monitor for bruising, change in LOC, prolonged bleeding time.
	Heparin	SC, IV	Hemorrhage, erythema, local irritation, hematoma, ulceration	
Peripheral vasodilators Improve collateral circulation	Cyclandelate (Cyclospasmol)	PO	Flushing, tingling, headache, dizziness, tachycardia	Monitor for therapeutic and nontherapeutic effects of administration (to decrease spasm of cerebral vessels).
	Papaverine (Papacon, Pavabid)	PO, parenteral, IV, IM	Increased heart rate and BP, drowsiness, vertigo, headache	
Statins Reduce cholesterol level	Simvastatin (Zocor), pravastatin (Pravachol), atorvastatin (Lipitor), lovastatin (Mevacor)	PO	Irritability, diarrhea, heartburn, hepatitis, dizziness, headache, muscle aches	Patient should notify prescriber if muscle pain or weakness occur.

BP = blood pressure; LOC = level of consciousness.

Surgical Management of Carotid Stenosis

If tests show carotid stenosis greater than 70%, a carotid endarterectomy may be performed. During this surgical procedure, the carotid artery is opened and the plaque removed. Nursing care focuses on careful neurological assessment for signs of deterioration related to ischemia. The incision is monitored for hematoma development and bleeding. Development of a hematoma can compromise the patient's airway. Bleeding at the suture line, particularly of bright red blood, may indicate failure of the sutures. This emergency situation requires prompt response to prevent massive blood loss. Balloon angioplasty for carotid stenosis is being investigated as a potential treatment in large facilities.

Prevention of Stroke

Incidence of stroke can be lessened by reduction of risk factors (see Box 49.1). Keeping hypertension, cholesterol level, weight, and diabetes controlled can go a long way in preventing strokes. Smoking cessation is essential. Emboli may be prevented with warfarin in individuals at high risk from atrial fibrillation. Aspirin or other antiplatelet agents help prevent abnormal clotting. Carotid endarterectomy can be done in patients with carotid stenosis.

It is important to educate all patients about new treatments for stroke and the potential for reversal of symptoms with the use of the thrombolytic agent t-PA. Patients must be educated about symptoms of stroke and the importance of receiving emergency treatment within 3 hours to maximize the potential for prevention of neurological deficits. *Too often patients ignore early symptoms or delay calling for help. This delay can mean the difference between leading a normal life and permanent disability.*

Long-Term Effects of Stroke

Impaired Motor Function and Sensation

The side of the body opposite the side of the cerebral infarct is affected because nerve fibers cross over as they pass from the brain to the spinal cord (Fig. 49.3). Paralysis on one side of the body is called **hemiplegia** (Fig. 49.4). The affected extremities may be weak or totally paralyzed (flaccid). Depending on the artery affected, the arm may be weaker than the leg or vice versa. These patients are particularly prone to contractures, which cause permanent immobility of a muscle or joint from fibrosis of connective tissue.

hemiplegia: hemi—one side + plegia—paralysis

CRITICAL THINKING

Mr. Jankowski

■ You are caring for Mr. Jankowski, a 56-year-old man who has been admitted to your orthopedic unit following knee surgery. As you listen to his lungs during your shift assessment, you notice that his lung sounds are diminished. You ask if he is a smoker and find that he has smoked for 40 years. You realize this places Mr. Jankowski at risk for stroke. What further assessment and intervention should you provide?

Suggested answers at end of chapter.

Adaptation or assistance with activities of daily living (ADLs) is required. Motor involvement often affects swallowing, control of urination, and bowel function. Patients should be mobilized within 24 hours if possible to prevent complications of immobility. Physical, occupational, and speech therapy are provided to maximize functioning and to progress the patient toward a return to baseline functioning.

Sensation changes may prevent the patient from being aware of pressure or injuries on the affected side. Patients must be taught to be aware of these changes and protect the involved limbs.

APHASIA. If the infarct is on the dominant side of the brain, the speech center will probably be affected. Aphasia may be expressive, receptive, or global, as described earlier. Patients may be able to say words but are not able to form coherent

FIGURE 49.4 Note the left-sided weakness in this man's smile as result of a stroke.

speech, such as the patient who picks up a fork but calls it a comb. A patient with receptive aphasia does not understand what is said. In this situation, it is easy to attempt to speak louder to try to help the patient understand. Remember that it is not the patient's hearing that is affected. You need to be very patient and understanding as the patient tries to communicate with you. Speech therapy can help the patient relearn to communicate. See the Nursing Process section for interventions for the aphasic patient.

Emotional Lability

Emotional lability, or instability, is a common consequence of stroke. Patients may move rapidly from profound sadness to an almost euphoric state and back again. Laughing or crying may have no relationship to the patient's situation at any given moment. Families can be upset by this behavior because they do not understand why a once happy person is now crying all the time or why the patient laughs inappropriately. You can help by explaining that these responses probably do not reflect how the patient is feeling, but rather are caused by the stroke damage.

Impaired Judgment

Patients who have had a stroke, particularly those with right-sided lesions, present safety risks. Patients may have poor understanding of their own limitations and believe that they are capable of performing tasks they did before the stroke. Precautions must be taken to protect the patient from injury.

If the frontal lobes are involved, learned social behaviors may be lost. The patient may undress in public, use profanity, or make inappropriate sexual advances. These behaviors are extremely difficult for significant others to cope with. Education and emotional support of the significant others are essential. Allowing them to talk about their frustration and anger may facilitate coping. Distracting the patient from inappropriate behavior may help. The patient should never be reprimanded or punished because he or she no longer has the cognitive ability to control the behaviors.

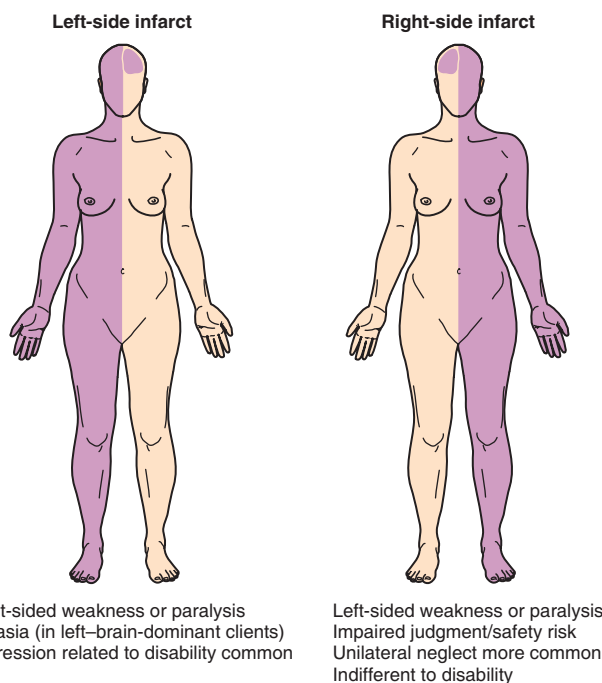

FIGURE 49.3 The side opposite the infarct is affected in a stroke.

Unilateral Neglect

The phenomenon of unilateral neglect is seen predominantly in patients who have right hemisphere infarcts. These individuals do not acknowledge the left side of their environment. In severe cases, the patient may forget to dress the left side of the body. Initially these patients should be approached from the right (or unaffected) side. Place essential items such as the call light and telephone on the patient's right side. Position the bed so that the patient's right side is toward the door. Gradually the health team can begin teaching the patient to focus on the left side. This involves teaching the patient to purposefully check where the left limbs are positioned and to look for safety risks. The patient can learn to turn his or her head and scan the environment. Patients may need reminders to turn their plates during meals to recognize the food on the left side of the plate.

Homonymous Hemianopsia

Visual deficits were described earlier. In particular, homonymous hemianopsia can cause the patient to ignore one side of a meal tray or neglect to care for one side of the body. Again, it is important to teach the patient to check the affected side, and to turn his or her plate to recognize food on both sides.

Other Long-Term Effects

The stroke patient may experience other complications after the acute phase of the stroke has passed. These may include pneumonia, deep vein thrombosis, pulmonary embolism, pressure ulcers, malnutrition, and depression. For the homebound patient, education for the patient and family regarding prevention and recognition of these complications will assist the patient in a successful recovery. If a patient needs to receive rehabilitation in a skilled nursing facility, prevention of these issues will be a part of the care plan at the facility. For more information, visit the National Stroke Association at www.stroke.org.

NURSING CARE TIP

When preparing a room for a patient with stroke, the caretaker should choose a room in which the patient can have the unaffected side toward the door if at all possible.

CEREBRAL ANEURYSM AND SUBARACHNOID HEMORRHAGE

A cerebral aneurysm is a weakness in the wall of a cerebral artery. It may be congenital, traumatic, or the result of disease. If the aneurysm ruptures, a subarachnoid hemorrhage results. It is unknown what causes the formation of congenital aneurysms or what causes them to rupture. Unruptured aneurysms are typically asymptomatic. The exception to this is a very large aneurysm, which can cause symptoms similar to a brain tumor. Aneurysms often affect young, otherwise healthy adults.

Pathophysiology and Etiology

Aneurysms can occur in any of the cerebral arteries. Eighty percent of cerebral aneurysms occur in the circle of Willis. The most common site is at the bifurcation of an artery. It is theorized that increased turbulence at the bifurcation causes an outpouching of a congenitally weak arterial wall.

Subarachnoid hemorrhage is the collection of blood beneath the arachnoid mater following aneurysm rupture. Rupture of an arteriovenous malformation or head trauma may also result in subarachnoid hemorrhage (Fig. 49.5). The presence of blood outside the blood vessels is very irritating to brain tissue. It is believed that irritation from blood breakdown is the major cause of vasospasm, a common complication of subarachnoid hemorrhage.

It is unclear what causes an aneurysm to rupture at a given time. Some individuals experience a subarachnoid hemorrhage while performing Valsalva's maneuver, engaging in sexual activity, or physically exerting themselves. For other patients, the aneurysm ruptures during a quiet, inactive period. If the aneurysm rupture is associated with a particular activity, the patient may be very frightened of engaging in that activity again. This may have a negative effect on the patient's interpersonal relationships if the associated activity was sexual in nature. The patient's partner may feel guilty or responsible for the hemorrhage. Emotional support and confidentiality regarding associated events help both the patient and significant other.

Signs and Symptoms

Some patients experience a small hemorrhage before diagnosis of subarachnoid hemorrhage. This leakage of blood may cause a mild headache, vomiting, or disorientation. The symptoms may be attributed to a flulike syndrome. Patients may dismiss the symptoms and not seek medical care.

The most common presentation of rupture of an aneurysm is sudden onset of a severe headache. Typically, patients state, "I have never had a headache this bad in my

FIGURE 49.5 Arteriovenous malformation. Note tangled vessels.

life.” Patients may hold their heads and moan or cry in pain. Sensitivity to light is a common finding. This may make patients reluctant to cooperate with pupil examinations.

Level of consciousness varies based on the severity of the hemorrhage. Patients may be alert and coherent, may lose consciousness immediately, or may gradually become less responsive. The decreased level of consciousness is caused by increased intracranial pressure and impairment of cerebral blood flow. Patients may experience generalized seizures.

Blood in the subarachnoid space causes meningeal irritation. The patient may exhibit nuchal rigidity. The most commonly affected cranial nerves are III and VI. This is manifested as an enlarged pupil or abnormal gaze. Motor dysfunction may involve one or both limbs on the side opposite the hemorrhage.

Diagnostic Tests

Because of the severe nature of the symptoms, patients with subarachnoid hemorrhage almost always come to the emergency department rather than seek care from a primary health-care provider. A CT scan is done to identify the presence and location of a hemorrhage. Precise diagnosis of an aneurysm requires a cerebral angiogram. The contrast material fills the aneurysm if one exists. For a patient with a severe headache and facing a life-threatening illness, this test can be very frightening. If the patient’s neurological status does not allow him or her to cooperate, sedation may be required before and during the examination.

Therapeutic Interventions

Patients experiencing a subarachnoid hemorrhage are cared for in an intensive care unit setting. They typically have an arterial line and a central venous pressure monitoring catheter. Blood pressure is carefully monitored because high pressures increase the risk of rerupture of the aneurysm and low pressures may be associated with ischemia. Values outside parameters identified by the physician are reported. Typically, the systolic blood pressure is kept between 120 and 160 mm Hg. Vasoactive drugs may be required to maintain blood pressure within the prescribed parameters.

There is no cure for subarachnoid hemorrhage. Treatment consists of correcting the cause of the hemorrhage if possible. Preventing or managing complications and providing supportive care are important aspects of nursing care.

Surgical Management

Definitive treatment of the aneurysm involves performing a craniotomy and exposing the aneurysm. If the aneurysm has a neck (berry aneurysm), it is identified and clamped with a metal clip (Fig. 49.6). An aneurysm without a neck may be wrapped with a sterile plastic or muslin wrap. This provides stability to the aneurysm walls, lessening the chance of rupture. In some situations, it is possible to clamp the artery on either side of the aneurysm, removing that portion of the vessel, and the aneurysm, from the circulation.

Nonsurgical Management

Nonsurgical intervention may be provided for aneurysms that are inoperable because of size, configuration, or the

FIGURE 49.6 Surgical management of aneurysms.

patient’s medical status. A foreign material such as a tiny metallic coil or fibrin glue may be introduced into the aneurysm. A thrombus develops around the foreign body and, if the treatment is successful, occludes the aneurysm. The goal is to fill the aneurysm enough to prevent blood flowing into it without causing rupture.

Complications

Rebleeding

Recurrent rupture of a cerebral aneurysm carries significant morbidity and mortality rates. Patients are at risk for rebleeding until the aneurysm is surgically repaired. If the aneurysm is wrapped or embolized, there is a risk of rebleeding, but it is much less than if the aneurysm is left untreated.

Hydrocephalus

Blood within the ventricular system interferes with the circulation, and reabsorption of CSF and hydrocephalus may develop. Early in the course of subarachnoid hemorrhage, an external ventricular drain may be used to treat hydrocephalus.

Approximately 25% of patients with subarachnoid hemorrhage require placement of a ventriculoperitoneal shunt to treat hydrocephalus (Fig. 49.7). This surgical procedure involves placement of a ventricular catheter. The catheter is then connected to a valve, which regulates the rate of cerebrospinal fluid drainage. Another catheter connects to the valve and is passed down to the peritoneal cavity. The cerebrospinal fluid drains out of the peritoneal catheter and is absorbed into the peritoneal cavity.

Vasospasm

Vasospasm is responsible for the majority of long-term complications of subarachnoid hemorrhage. Vasospasm is the narrowing of a blood vessel diameter. Although it typically begins in the vessel giving rise to the aneurysm, vasospasm may spread to other vessels. This explains why the ischemia or infarct caused by vasospasm can be so widespread and devastating.

The long-term complications of subarachnoid hemorrhage are similar to those of stroke.

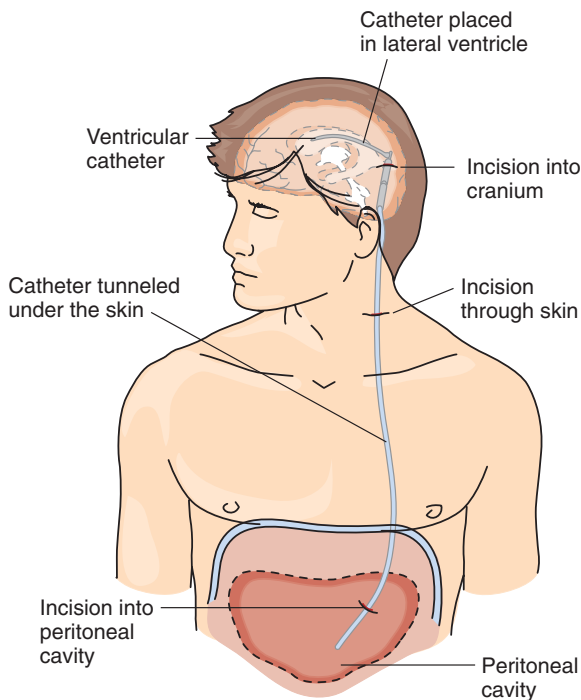

FIGURE 49.7 A ventriculoperitoneal shunt drains cerebrospinal fluid into the peritoneal cavity.

Rehabilitation

If the patient is able to tolerate intensive therapy, discharge from the hospital may be to a rehabilitation center. With rehabilitation, most patients can learn to walk, some with a walker or cane. Speech therapy can help the patient learn to communicate. Many patients can learn to take care of themselves. Some may be able to drive again and even have a job.

Nursing Process for the Patient with a Cerebrovascular Disorder

Assessment/Data Collection

Assess the patient for signs and symptoms of decreased cerebral tissue perfusion: decreased level of consciousness, irritability or restlessness, dizziness, syncope, blurred or dimmed vision, **diplopia**, change in visual fields, unequal pupils or a sluggish or absent pupillary reaction to light, paresthesias, motor weakness, paralysis, or seizures. Reassess frequently and report decline. Monitor vital signs and oxygen levels. Monitor laboratory tests: CBC, lipid profile, and INR/PT if on warfarin (Coumadin). Perform a routine respiratory assessment. Monitor lung sounds for adventitious sounds or a change in breath sounds. Assess pain level since pain can impair an effective breathing pattern. Assess swallowing ability before offering oral intake. Promptly report any increase in dyspnea, changes in vital signs or pulse oximetry, or increased white blood cell count or temperature.

diplopia: diplo—double + opia—sight

CRITICAL THINKING

Mrs. Washington

■ Mrs. Washington is a 68-year-old African American retired office worker. She was admitted to your unit following a right-sided intracerebral hemorrhage. Her daughter states that Mrs. Washington has taken antihypertensive medication for the last 20 years. However, she states that her mother has been “forgetful” lately and that there are five more pills in the medicine bottle than expected. On admission, Mrs. Washington is oriented only to person and has hemiparesis.

1. What may have precipitated Mrs. Washington’s stroke?
2. On which side are Mrs. Washington’s extremities affected?
3. List two safety concerns and strategies to promote patient safety.
4. List at least two educational needs for Mrs. Washington and her daughter.

Suggested answers at end of chapter.

Nursing Diagnosis, Planning, and Implementation

See Box 49.2 Nursing Care Plan for the Patient with Stroke for nursing diagnoses during acute care. Possible post-acute nursing diagnoses are listed below with outcomes and interventions.

Impaired physical mobility related to decreased motor function

EXPECTED OUTCOMES: Patient will maintain physical mobility as evidenced by maximum physical mobility within limitations of deficits. Patient will not experience complications related to immobility.

- Consult physical and occupational therapists to assess the patient’s abilities and make specific recommendations related to mobility.
- Maintain the patient in good body alignment to prevent contractures and promote comfort.
- Support affected extremities with pillows to prevent dislocation injuries and promote comfort.
- Perform range of motion exercises as prescribed by physical therapist to prevent contractures and atrophy.
- Follow physical/occupational therapy recommendations for being up in chair or ambulation. *Prolonged bedrest is associated with complications and poor outcomes.*
- If patient is unable to get out of bed, turn and reposition at least every 2 hours to prevent complications to prevent skin, respiratory, and musculoskeletal complications.

Box 49.2 NURSING CARE PLAN for the Patient with Stroke

Nursing Diagnosis: Ineffective cerebral tissue perfusion

Expected Outcomes The patient will experience improved cerebral tissue perfusion as evidenced by:

- Absence of or reduction in dizziness, syncope, visual disturbances
- Improved mental status
- Pupils equal and reactive to light
- Improved motor and sensory function

Evaluation of Outcomes Is patient free of symptoms of decreased perfusion? Are symptoms improving?

Interventions

Assess neurological status frequently.

Assess vital signs q2hr × 4 hours then q4hr × 72 hours.

Monitor medication for therapeutic and nontherapeutic effects. Monitor coagulation studies if appropriate.

Rationale

A change in status could indicate decreased perfusion and should be reported immediately.

High or low blood pressure can lead to decreased tissue perfusion and recurrent stroke.

Anticoagulant therapy must be closely monitored to make sure it is at a therapeutic level, and not increasing risk for bleeding.

Evaluation

Is there a change in neurological status since the previous documented assessment?

Are vital signs within normal limits? Has there been a change?

Are coagulation studies within normal or therapeutic ranges? Are there signs of bleeding?

Nursing Diagnosis: Ineffective airway clearance related to stasis of secretions associated with decreased mobility and poor cough effort; and airway obstruction resulting from tongue falling back in throat

Expected Outcomes Patient will maintain open airway as evidenced by respirations quiet and unlabored, 12–20 per minute, $SaO_2 \geq 90\%$.

Evaluation of Outcomes Are respirations quiet, 12–20 per minute, with SaO_2 90% or greater?

Interventions

Monitor lung sounds, cough, and respirations.

Position the patient to maintain an open airway.

Consult with RN or physician about an oral airway if airway is not clear.

Encourage to deep breathe and cough if patient is able.

If cough is ineffective, suction as needed.

Rationale

Assessment provides the basis for intervention.

Side lying may keep tongue from obstructing airway.

An oral airway will keep tongue from obstructing airway if needed.

Coughing and deep breathing will help clear secretions from airway and prevent atelectasis.

Suctioning may be necessary if patient is unable to swallow secretions or cough effectively.

Evaluation

Are lung sounds clear? Cough effective? Respirations quiet and easy?

Is patient positioned to keep airway clear?

Is an airway indicated?

Is patient able to deep breathe and cough? Is cough effective?

Is suctioning indicated? Is airway clear after suctioning?

(Continued on following page)

Box 49.2 NURSING CARE PLAN for the Patient with Stroke (Continued)

Nursing Diagnosis: Risk for injury related to seizure or repeat stroke

Expected Outcomes Patient will remain free from injury.

Evaluation of Outcomes Is patient free from injury? Are problems recognized and reported quickly?

Interventions

Monitor neurological status frequently and report changes promptly.

Administer anticonvulsant agent as ordered.

Implement seizure precautions (see Chapter 47).

Assist with transfers and ambulation.

Offer toileting on set schedule.

Rationale

Prompt recognition of a repeat stroke

The patient is at increased risk for seizures following a stroke.

Precautions help protect patient in event of a seizure.

Patient is at risk for falls because of motor and sensory deficits and impaired judgment.

The patient may attempt to get up by her- or himself if no one is available when he or she needs to go to the bathroom.

Evaluation

Are neurological checks WNL?
Are changes reported promptly?

Is patient seizure-free?

Are precautions in place?

Is patient assisted with mobility?
Is patient able to call for help when needed?

Is patient toileted often enough to prevent accidents and falls?

WNL = within normal limits.

Imbalanced nutrition, less than requirements related to impaired swallowing and motor deficits

EXPECTED OUTCOME: Patient will maintain adequate nutrition without aspiration as evidenced by stable weight at appropriate level for height.

- Keep patient NPO until swallowing can be evaluated to prevent aspiration.
- Perform dysphagia screening. *This quick assessment can identify problems before a complete evaluation can be done.*
- Observe for facial weakness or inability to completely close mouth.
- Ask patient to stick out tongue and move it side to side.
- Observe for drooling.
- If swallowing appears to be intact, have patient swallow a sip of water from a cup before offering other foods or fluids. Observe for coughing, choking, or noisy lung sounds. *These are signs of difficulty swallowing.*
- Request speech pathologist evaluation if indicated to diagnose specific swallowing problems and make recommendations.
- Implement measures to prevent aspiration. *Aspiration can lead to pneumonia, which will greatly complicate the patient's recovery.*
 - Stay with patient during meals.
 - Ensure that patient is fully alert before feeding.
 - Have the patient in high-Fowler's position or chair for meals.

- Avoid use of straws.
- Use a thickening agent if swallowing study recommends.
- Place food on unaffected side of mouth.
- Teach the patient to swallow twice after each bite.
- Check the patient's mouth for pocketing of food.
- Have suction equipment available.
- Notify primary care provider if patient is unable to take in adequate oral calories. *A feeding tube may be necessary if patient is unable to take in enough calories to maintain nutrition. Advance directives should be consulted before a feeding tube is placed.*
- Assist with insertion and care of feeding tube if necessary. *If patient is unable to swallow effectively, a feeding tube may be necessary to maintain nutrition.*
- See Box 49.3 Nutrition Notes for additional interventions.

Disturbed sensory perception related to CNS damage

EXPECTED OUTCOME: The patient adapts to sensory-perceptual deficits as evidenced by avoidance of injury to affected areas.

PATIENT CARE TIP

A new stroke patient should never have anything by mouth until a dysphagia screening test has been successfully completed.

Box 49.3

Nutrition Notes

Feeding Patients with Swallowing Disorders

Suggestions for persons who have difficulty swallowing include the following:

- Eat slowly.
- Avoid distractions while eating.
- Do not talk while eating.
- Sit up straight while eating.
- Use a teaspoon, taking only half a teaspoonful at a time.
- Swallow completely between bites or sips.

Possible nursing interventions to aid a person with a swallowing disorder include the following:

- Remove loose dentures.
- Position the head correctly. A speech therapist can help determine the optimum head position. A hemiplegic patient often benefits from turning the head toward the weak side.
- When spoon feeding a patient with hemiplegia, place the food on the unaffected side of the tongue.
- Consult a dietitian concerning appropriate textures for liquids and solids. A multi-disciplinary assessment may be needed to tailor the diet prescription to the patient's strengths and weaknesses. Foods with mixed textures such as vegetable soup are frequently problematic. Often thicker substances are better managed than liquids. Although infant cereal can be an effective thickener, it may be rejected on a psychological basis in favor of instant potato flakes, unflavored gelatin, or a commercial thickener.

- Assist occupational therapist to assess for visual and/or spatial deficits and decreased sensory perception: heat and cold, position of body parts, pressure. *Identification of specific deficits is the first step in creating a plan of care.*
- Teach patient to scan the environment to compensate for a visual deficit.
- Implement plans for skin integrity and mobility to protect patient from complications related to sensory deficits.

Risk for impaired skin integrity: irritation or breakdown related to immobility and incontinence

EXPECTED OUTCOME: Skin integrity is maintained as evidenced by no redness or breakdown.

- Assess the skin frequently for redness or breakdown, especially around bony prominences, dependent areas, and perineum. *Any signs of breakdown must be treated immediately to prevent further damage.*
- Thoroughly cleanse and dry perineal area after each episode of incontinence. *Urine and feces can be very irritating to the skin.*

- If incontinence is unavoidable, use a barrier cream such as zinc oxide to protect skin.
- Turn and position the client at least every 2 hours, or more often if the client experiences breakdown. *Pressure impairs circulation and increases risk of breakdown.*
- Use a lift sheet to move patient in bed to avoid damage from friction.
- Consider the use of a pressure-reducing mattress if patient is not able to be out of bed for long periods. *This helps reduce pressure, but does not eliminate the need to reposition the patient every 2 hours.*
- If breakdown occurs, contact the physician or wound care specialist for treatment recommendations.

Incontinence related to loss of voluntary control of elimination

EXPECTED OUTCOME: Episodes of incontinence are avoided, or if unavoidable, they will be cleaned up quickly and skin complications avoided.

- Monitor for incontinence of bowel or bladder so patient can be cleaned promptly and skin protected.
- Assess for usual pattern of urinary and bowel elimination. *Keeping the patient on his or her regular prehospitalization pattern may help prevent incontinence.*
- Provide assistance with toileting according to the patient's usual schedule. *The patient who is unable to get up unaided may wait too long for help or try to get up alone and be injured.*
- Respond quickly to requests for assistance with toileting to avoid accidental incontinence.

Self-care deficit related to decreased motor function, spatial-perceptual alterations, and fear of injury

EXPECTED OUTCOME: Self-care is accomplished as evidenced by patient's ADL needs being met, and patient becomes increasingly independent.

- Assess patient's ability to perform ADLs. *A good assessment will guide development of a care plan.*
- Work with patient to create a plan for meeting daily physical needs. *The patient will be more likely to participate in a plan if he or she participated in creating it.*
- Encourage highest level of independence possible; facilitate patient's ability to do ADLs. *Providing too much assistance can promote dependence and further loss of mobility.*
 - Place objects within reach and within visual field.
 - Place food/fluids within patient's visual field.
 - Encourage use of assistive devices.
- Assist patient with learning to use nondominant side of body. *If dominant side is affected, the patient may have to use the nondominant side.*
- Provide positive feedback to help reduce discouragement with slow progress.
- Provide education for family members and significant others regarding patient's deficits and recovery

plan. *The family can assist the patient with mobility if they understand what needs to be done.*

Impaired verbal communication: dysarthria related to loss of motor function of the muscles of speech articulation, or aphasia or dysphasia related to ischemia of the dominant hemisphere

EXPECTED OUTCOME: Communication will be effective as evidenced by patient communicating needs and desires effectively, and frustration is avoided.

- Assess for difficulties in verbal communication (difficulty speaking, articulating or incorrect ordering of words, inability to find or name words and objects). *A good assessment will guide planning of care.*
- Consult speech pathologist for assistance in determining types of aphasia or dysphasia and need for follow-up treatment. *A speech pathologist is specially trained to diagnose and treat communication problems, and can work with nursing staff to develop a plan of care.*
- Implement measures to facilitate communication: *These measures help assure the patient has his or her immediate needs met while learning to adapt to communication impairment.*
 - Answer call light in person.
 - Assess needs frequently.
 - Listen carefully: avoid interrupting patient and allow ample time for communication.

- When patient is tired, ask questions that require short answers.
- Provide and use appropriate aids to communication (picture board, magic slate, pencil and paper). See Figure 49.8.
- Provide education to family members and significant others regarding communication problems and interventions *so they can communicate with patient and participate in care.*
- If the patient is unable to communicate, do not assume that he cannot hear and understand. Every effort should be made to speak to the patient and to keep conversation appropriate when it is within the patient’s range of hearing. *The patient may understand exactly what is being said, even if he or she is unable to respond.*
- Contact physician if impairment increases. *This may be a sign of stroke extension.*

Disturbed thought processes related to cerebral ischemia

EXPECTED OUTCOMES: Patient’s thought processes are as clear as possible within limitations of brain damage; patient’s safety is maintained; patient feels calm and safe.

- Assess patient for thought process impairment such as shortened attention span, impaired memory, confusion, slowed or quick and impulsive responses,

FIGURE 49.8 Picture board.

and aggressive and/or inappropriate responses. *Disturbed thinking can be manifested in a variety of ways (see Chapter 48 for care of patients with disturbed thought processes).*

Deficient knowledge related to diagnosis and treatment

EXPECTED OUTCOME: Patient and family have necessary knowledge to make decisions and assist with care.

- Explain what has happened to the patient. Explain tests, procedures, and care activities. *The patient and significant others are likely to be very frightened of what is happening. Correct information about what a stroke is, tests and procedures, and rationale for care activities help reduce anxiety.*
- Present information in small amounts and as simply as possible. *The patient may have difficulty attending to large amounts of information while acutely ill or if thought processes are disturbed.*
- Orient the patient and family to the ICU or other setting and the constant monitoring provided. *This can help reduce anxiety and reassure the patient and significant others that the patient is receiving competent care.*
- If the patient is to be discharged to home, make sure information is provided related to medications, treatments, and follow-up care. *The patient and family need to know how to provide appropriate care at home.*
- Evaluate the need for home nursing, physical, and occupational therapy, and request appropriate referrals. *The patient will likely need continued therapy after discharge to regain as much function as possible.*

Risk for caregiver role strain related to changes in roles, responsibilities, finances, and intimacy

EXPECTED OUTCOMES: Caregiver is comfortable with role as evidenced by statement that she or he understands how to care for the patient and has the needed resources to do so. Caregiver maintains her or his own health.

- Work with caregiver to assess how the patient's functional level will affect their lives. *Assumption of roles or responsibilities previously fulfilled by the patient may be very stressful to significant others. If the caregiver can anticipate the impact, he or she can plan ahead how to make sure needs are met.*
- Encourage patient and caregiver to identify support systems and make use of community resources. Provide a list of resources. *If support is in place before discharge, they are more likely to use it after the patient goes home.*
- Consult social worker or case manager. *These individuals have access to many resources, and can help the patient and caregiver identify appropriate sources of assistance.*
- Provide support if transfer to a skilled nursing facil-

ity is necessary. *This can be a very difficult decision for a patient and caregiver.*

Evaluation

If interventions have been effective, the patient does not experience increased deficits due to decreased perfusion of brain cells. The patient should recover physical limitations or make a good adjustment to remaining deficits and be independent in ADLs. The patient is able to communicate effectively and has needs and desires understood (see Box 49.4 Stroke Summary).

Box 49.4

Stroke Summary

Signs and Symptoms

Dizziness, syncope, visual disturbances, irritability, restlessness, confusion, decreased level of consciousness, unequal pupils, paresthesias, motor weakness, paralysis, seizures, difficulty swallowing, difficulty understanding language, difficulty speaking

Diagnostic Tests

- CT scan
- ECG
- Carotid Doppler
- Echocardiogram
- TEE, angiogram
- Laboratory: INR/PT, metabolic panel, CBC, PTT, serum pregnancy (if appropriate), oxygen saturation

Therapeutic Interventions

- Oxygen
- Antiplatelet, anticoagulant medication
- Physical, occupational, speech therapy
- Carotid endarterectomy
- Knee-high antiembolism stockings

Complications

Stroke evolves causing more deficits, aspiration pneumonia, skin breakdown, malnutrition

Priority Nursing Diagnoses

Ineffective cerebral tissue perfusion
Ineffective airway clearance
Risk for injury

CBC = complete blood count; CT = computed tomography; ECG = electrocardiogram; INR/PT = international normalized ratio/prothrombin time; PTT = partial thromboplastin time; TEE = transesophageal echocardiography.

Home Health Hints

- Work with physical therapist, occupational therapist, and speech therapist to assist the patient with rehabilitation.
- Provide assistive devices to aid the patient to function independently.
- Keep home environment clutter-free to prevent falls.
- Offer frequent praise for all achievements.
- Keep regularly used items close by. If the patient is using a walker have him or her tie a small bag to the top to store these items.
- If the patient does not have a portable phone, encourage the purchase of one. Instruct the patient to keep it near at all times in case of an emergency.
- If necessary, assist the patient with obtaining a medical alert device. If the patient falls he or she can access an emergency medical service by pushing a button.
- Assist with obtaining homemaker or respite care for caregivers if necessary.
- Patients on a pureed diet can make their own food at home using a food processor. Baby food can also be purchased to meet swallowing guidelines.
- Patients with one-sided paralysis following a stroke should be instructed to wear clothes that are easy to get on and off. Examples include pants with elastic waists, shoes with elastic laces or slip-on shoes, and pullover shirts without buttons.
- If the patient has difficulty speaking (dysarthria), try using magnetic alphabet letters. Ask questions that require a yes or no answer. The patient can respond with the letter *y* or *n*. You can also help the patient and caregiver develop a communication board of frequently used words and objects.
- Keep bedside commode lids up with patches of Velcro attached to the seat and the frame.

REVIEW QUESTIONS

- Which of the following are modifiable risk factors for stroke? Choose all answers that are correct.
 - Heredity
 - Age
 - Diabetes
 - Race
 - High cholesterol
 - Obesity
- What is the most important diagnostic test that is completed immediately on the patient with symptoms of stroke in the emergency department?
 - Head CT scan
 - Arteriogram
 - PT/INR
 - CPSS
- How soon after symptom onset must a stroke victim receive thrombolytic treatment?
 - 1 hour
 - 2 hours
 - 3 hours
 - 4 hours
- A patient is experiencing receptive aphasia. This means that he has difficulty with which of the following functions?
 - Swallowing
 - Forming words
 - Hearing
 - Understanding language
- A nurse is caring for a patient who is recovering from an ischemic stroke. Upon entering his room to pick up his supper tray, the nurse notes that he has only eaten half his meal. What should the nurse do?
 - Assist him by handing him finger foods and feeding him items that require a utensil.
 - Remove his tray and do not comment.
 - Encourage him to eat the rest of his meal.
 - Turn his plate 180 degrees and observe his response.
- A nurse is doing an afternoon assessment on a patient transferred to a medical unit from intensive care following a subarachnoid hemorrhage. The patient was alert and oriented during the morning assessment, but complained of being very tired. Now the patient is difficult to arouse. What action should the nurse take?
 - Let the patient sleep; transferring from ICU can be very strenuous.
 - Reassess the patient in an hour. If the sleepiness continues, notify the RN.
 - Call the RN immediately.
 - Call a code.

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Mr. Jankowski*

Ask Mr. Jankowski about other risk factors for stroke, such as his dietary and alcohol habits. Check his chart for history of diabetes, hypertension, or heart disease. Check his weight and cholesterol levels if drawn. Educate him about risk factors for stroke, and how they can be modified. Consider a dietitian consultation, and provide written information on stroke prevention and smoking cessation. As a nurse, you will be in a position to recognize risks and help patients modify risk factors for many problems before they occur.

■ *Mrs. Washington*

1. Uncontrolled hypertension, in the presence of a pre-existing aneurysm, might have precipitated Mrs. Washington's stroke.
2. Her left extremities are affected.

3. Mrs. Washington is disoriented. Her room should be as close to the nurse's station as possible. Reorient her to her surroundings and condition frequently. Keep side rails up when Mrs. Washington is alone.

Mrs. Washington also has hemiparesis. Obtain a commode because Mrs. Washington will probably not be able to walk to the bathroom. Place the call light and telephone on her right side. Assist Mrs. Washington with positioning to prevent injury to her affected limbs.

4. If Mrs. Washington will be going back to her home, you should teach Mrs. Washington and her daughter about the relationship of uncontrolled hypertension to intracranial hemorrhage; options for inpatient, outpatient, and in-home therapy; and memory strategies to prevent missed medication doses (e.g., weekly pill box, keeping medications with breakfast food, or an alarm clock or watch).

Nursing Care of Patients with Peripheral Nervous System Disorders

QUESTIONS TO GUIDE YOUR READING

1. What disorders are caused by disruption of the peripheral nervous system?
2. What are the pathophysiology, major signs and symptoms, and complications of selected peripheral nervous system disorders?
3. What are therapeutic interventions for selected peripheral nervous system disorders?
4. What are the common nursing diagnoses associated with peripheral nervous system disorders?
5. What are priority nursing interventions for patients with peripheral nervous system disorders?
6. How will you know if your nursing care has been effective?

The peripheral nervous system (PNS) consists of all nervous system structures outside the central nervous system (CNS). A variety of disorders affect the PNS. Some of these disorders become chronic and cause **degeneration** of body systems. Some other disorders are of a temporary nature. Two common types of PNS disorders are discussed in this chapter. Neuromuscular disorders compose one group and may include motor or sensory disorders or both. The second group includes cranial nerve disorders. Both types of disorders present a challenge to the nurse caring for the patient and family.

NEUROMUSCULAR DISORDERS

This group of neurological conditions is chronic and degenerative in nature. Neuromuscular disorders involve a disruption of the transmission of impulses between neurons and the muscles that they stimulate. This breakdown in transmission results in muscle weakness. If the muscles of the respiratory system are affected, deadly complications can develop, including pneumonia and respiratory failure. Common neuromuscular disorders include multiple **sclerosis** (MS), myasthenia gravis (MG), **amyotrophic** lateral sclerosis (ALS), and Guillain-Barré syndrome (GBS). An additional neuropathic disorder, Navajo neuropathy, is discussed in Box 50.1 Cultural Considerations.

Multiple Sclerosis

Pathophysiology

Multiple sclerosis is a chronic progressive degenerative disease that affects the myelin sheath of the neurons in the central nervous system. Myelin is responsible for the smooth transmission of nerve impulses. Muscles contract when

nerve impulses stimulate the muscle tissue. If the myelin sheath is damaged (Fig. 50.1), nerve impulses cannot be transmitted to the muscle and contraction of the muscle does not occur. In multiple sclerosis, the myelin sheath begins to break down (degenerate) as a result of the activation of the body's immune system. The nerve becomes inflamed and edematous. Nerve impulses to the muscles slow down. As the disease progresses, sclerosis or scar tissue damages the nerve. Nerve impulses become completely blocked causing permanent loss of muscle function in that area of the body.

Etiology

Damage to the myelin sheath is thought to be from an autoimmune process; however, the disease may be related to viral infections, heredity, and other unknown factors. Some research indicates that there is an inherited tendency to develop MS, and the manifestations of the disease only appear in the presence of environmental triggers. Thus, the cause of MS is not really understood. This disease affects 400,000 persons in the United States and up to 2.5 million people worldwide.¹ Onset of the disease usually occurs between the ages of 20 and 50. Women are affected twice as often as men. The course of the disease is unpredictable, and there are many variations in symptoms, depending on which nerves are affected. Some individuals have mild illness, while others suffer permanent disability or rapid decline and death.

Signs and Symptoms

The patient with MS presents with muscle weakness, tingling sensations, and numbness. Other common symptoms include visual disturbances, usually in one eye at a time; disturbances may be accompanied by pain with eye movement. These symptoms may begin slowly over weeks to months or start suddenly and dramatically. MS affects many systems of

FIGURE 50.1 The myelin sheath breaks down in multiple sclerosis, interrupting transmission of nerve impulses. (A) Normal myelin sheath. (B) Myelin beginning to break down. (C) Total myelin disruption. (Modified from Scanlon, VC, and Sanders, T: *Workbook for Essentials of Anatomy and Physiology*, ed. 5. FA. Davis, Philadelphia, 2007, with permission.)

**Box 50.1****Cultural Considerations**

Navajo neuropathy is unique to the Navajo Indian population. Characteristics include poor weight gain, short stature, sexual infantilism, serious systemic infections, and liver derangement. Manifestations include weakness, hypotonia, areflexia, loss of sensation in the extremities, corneal ulcerations, acral (extremity) mutilation, and painless fractures.² Nerve biopsies show a nearly complete absence of myelinated fibers, which is different from other neuropathies, that presents as a gradual demyelination process. Individuals who survive have many complications and are generally ventilator dependent. None has been known to survive past the age of 24.

the body (Box 50.2 Problems Associated with Multiple Sclerosis). A variety of factors can trigger the onset of symptoms or aggravate the condition, including extreme heat and cold, fatigue, infection, and physical and emotional stress. Hormonal changes after pregnancy may also cause symptom onset or exacerbations. Periods of **exacerbation** and remission of symptoms lead patients with MS to be uncertain about when the disease will flare up and what system of the body will be affected. Intense fatigue is a common complaint among patients; therefore, immobility can become a problem. Accidents and falls are common because of muscular weakness or numbness of the trunk and extremities. Some people with MS suffer with symptoms such as muscle spasticity, bowel or bladder dysfunction, or paralysis. Difficulty with concentration or forgetfulness can also be problematic. Pneumonia can occur from immobility and from weakness

Box 50.2**Problems Associated with Multiple Sclerosis**

Weakness/paralysis of limbs, trunk, or head	Impaired hearing
Diplopia (double vision)	Nystagmus
Slurred speech	Ataxia
Spasticity of muscles	Dysarthria
Numbness and tingling	Dysphagia
Patchy blindness (scotomas)	Constipation
Blurred vision	Spastic (uninhibited) bladder
Vertigo	Flaccid (hypotonic) bladder
Tinnitus	Sexual dysfunction
	Anger, depression, euphoria

**LEARNING TIP**

Myelin facilitates impulse transmission to the muscle. If myelin is interrupted, the impulse cannot get to the muscle efficiently so the muscle response may be sluggish, unpredictable, or absent.

of the diaphragm and intercostal muscles. Death, often resulting from respiratory infection, typically occurs 20 to 35 years after diagnosis.

Diagnostic Tests

Diagnosis is based on the history and signs and symptoms experienced by the patient. MS cannot be diagnosed by a specific test. Analysis of cerebrospinal fluid (CSF) may show an increase in oligoclonal immunoglobulin G (IgG). Magnetic resonance imaging (MRI) may be helpful in diagnosis because sclerotic plaques can be detected.

Therapeutic Interventions

MS has no cure. Many individuals with MS do well with no medication treatment at all. Interferon therapy with beta-interferons such as Betaseron or Avonex may reduce exacerbations and delay disability. Other treatment is supportive and symptomatic. Steroids such as adrenocorticotropic hormone (ACTH), prednisone, and other corticotropics are given to decrease inflammation and edema of the neuron, which may relieve some symptoms. Immunosuppressant drugs such as azathioprine (Imuran) and cyclophosphamide (Cytoxan) may be given to depress the immune system. Anticonvulsants such as phenytoin (Dilantin) and carbamazepine (Tegretol) help relieve neuropathic pain. Valium (Diazepam), baclofen (Lioresal), and tizanidine (Zanaflex) and physical therapy assist in controlling muscle spasms. Bladder problems are treated with parasympathetic agents such as bethanechol (Urecholine) and oxybutynin (Ditropan). Fatigue may be treated with antidepressants or an antiviral agent such as amantadine (Symmetrel). See Table 50.1 for a summary of medications used to treat PNS disorders.

Rehabilitation after an acute episode includes physical, speech, and occupational therapies. Rehabilitation therapy assists the patient and family in adapting the home environment to the patient's special needs. Instruction in the use of assistive devices (e.g., braces, canes, wheelchairs, splints) by physical and occupational therapists allows the patient increased mobility and independence. Patients who develop speech difficulties benefit from speech therapy. For those individuals who suffer sudden severe attacks or who do not respond to high doses of steroids, plasma exchange or **plasmapheresis** may be used to remove antibodies that may be attacking the myelin from the blood (Table 50.2).

plasmapheresis: plasma—liquid of blood + pheresis—removal

TABLE 50.1 MEDICATIONS USED TO TREAT PNS DISORDERS

Medication Class/Action	Examples	Route	Side Effects	Nursing Implications
Cholinesterase Inhibitors Increase acetylcholine at synapses	Neostigmine (Prostigmin) Pyridostigmine (Mestinon) Edrophonium chloride (Tensilon, used in diagnosis)	PO PO, IM, IV IM, IV	Cholinergic toxicity (SLUDGE)	Atropine is antidote.
Glucocorticoids Reduce inflammation	Prednisone Prednisolone Prednisolone acetate or sodium phosphate	PO PO IV, IM	Osteoporosis Risk for infection Elevated blood sugar Sodium and water retention Cushing's syndrome	Provide calcium supplement. Avoid crowds and others with infections. Monitor fluid balance. May need to treat blood sugar with insulin while on medication.
Immunosuppressants Suppress immunity and antibody formation	Azathioprine (Imuran) Cyclophosphamide (Cytoxan)	PO, IV PO, IV	Anorexia, hepatotoxicity, nausea, vomiting, anemia, leukopenia, thrombocytopenia, fever, chills	Monitor blood counts. Protect from bleeding and infection. Administer with meals to reduce nausea.
Antispasmodics/Muscle Relaxants Relax muscles, reduce pain	Dantrolene (Dantrium) Baclofen (Lioresal) Diazepam (Valium)	PO, IV PO PO, IM, IV	CNS depression Nausea Constipation Urinary retention Sedation Muscle weakness Diarrhea (dantrolene)	Avoid operating machinery, driving until effects known. Provide measures to prevent constipation (except dantrolene). Monitor for respiratory depression.
Anticonvulsants Treat nerve pain	Phenytoin (Dilantin) Carbamazepine (Tegretol) Gabapentin (Neurontin) Valproic acid (Depakene)	PO PO PO PO	CNS depression Gingival hyperplasia (phenytoin) Ataxia, vertigo Bone marrow suppression GI upset	Teach good oral hygiene with soft bristle brush, floss, and gum massage (phenytoin). Monitor for fall risk. Monitor blood counts.
Glutamate Antagonist Delays progression of ALS	Riluzole (Rilutek)	PO	Decreased strength, diarrhea, nausea, vomiting, abdominal pain, dizziness, vertigo, sedation	Rest, monitor for respiratory depression; administer on empty stomach; avoid large quantities of caffeine; avoid charcoal-broiled foods.

Nursing Care

See Box 50.3 Nursing Care Plan for the Patient with a Progressive Neuromuscular Disorder.

In addition to routine care, instruct the patient to avoid factors that can exacerbate symptoms. This includes avoiding stressful situations as much as possible. Rest, exercise, and a balanced diet are important self-care steps to control symptoms. In addition, avoiding extreme temperature changes, especially heat, as well as avoiding infection and illness, is important. Any infection, especially respiratory, should be

reported immediately to a physician. Two sources of information on MS are the National Multiple Sclerosis Society at www.nationalmssociety.org and the Multiple Sclerosis Foundation at www.msfocus.org

Myasthenia Gravis

Pathophysiology

Myasthenia gravis (MG) means “grave muscle weakness,” or weakness of the voluntary or skeletal muscles of the body. MG is a disease of the neuromuscular junction (Fig. 50.2).

TABLE 50.2 PLASMAPHERESIS*

Preprocedure Nursing Care	Postprocedure Nursing Care
<p>Teach patient about the procedure and what to expect, including what the machine looks like (similar to but smaller than a dialysis machine), the need for arterial and venous access sites, and the length of the procedure (2 to 5 hours). The physician may order medications held until after the procedure. Assess baseline vital signs and weight. Assess complete blood cell count (CBC), platelet count, and clotting studies. Check blood type and crossmatch for replacement blood products.</p>	<p>Observe the patient for signs of hypovolemia, such as dizziness and hypotension. Apply pressure dressings to access sites. Monitor patient for infection and bruits at the access site. Monitor electrolytes and signs of electrolyte loss. Report imbalances, and administer replacement electrolytes as ordered. Compare preprocedure and postprocedure laboratory data, such as CBC, platelet count, and clotting times.</p>

*Plasmapheresis, also known as plasma exchange therapy, is a procedure that removes the plasma component from whole blood and replaces it with fresh plasma. The goal of this therapy is to remove antibodies through exchanging plasma to suppress the immune response and inflammation.

Box 50.3 NURSING CARE PLAN for the Patient with a Progressive Neuromuscular Disorder

Nursing Diagnosis: Ineffective airway clearance related to respiratory muscle weakness, impaired cough and gag reflexes

Expected Outcomes Patient will maintain a patent airway. Patient will be free of signs and symptoms of respiratory distress.

Evaluation of Outcomes Is patient's airway patent? Is patient free of signs and symptoms of respiratory distress?

Interventions

Monitor respiratory rate and depth, oxygen saturation (SaO₂), and arterial blood gases (as ordered).
Report deterioration.

Encourage patient to cough and deep breathe every 2 hours.
Observe patient for breathlessness while speaking.

Elevate head of bed.

Evaluate cough, swallow, and gag reflexes frequently. Notify physician if absent.

Suction secretions as needed, noting color and amount of secretions.

Rationale

Increasing respiratory distress indicates progressing muscle weakness that may require mechanical ventilation or end-of-life decisions.

Effective coughing helps keep airway clear.

Inability to speak without breathlessness indicates declining respiratory function.

Fowler's position improves lung expansion, decreases work of breathing, improves cough efforts, and decreases risk for aspiration.

Frequent evaluation of reflexes is needed to prevent aspiration, respiratory infections, and respiratory failure.

Muscle weakness may result in inability to clear airway.

Evaluation of Interventions

Is patient's respiratory rate status stable or is intervention indicated?

Does patient have the strength to cough effectively?

Is patient able to finish sentences without needing to take a breath?

Does elevation of head of bed help relieve dyspnea and prevent aspiration?

Is patient able to cough effectively? Is gag reflex intact?

Does patient require suctioning to clear airway? What color are secretions?

Nursing Diagnosis: Impaired physical mobility related to muscle weakness

Expected Outcomes Patient will identify measures to help maintain mobility. Patient will perform exercises that help maintain current mobility. Patient will maintain optimum mobility and activity level.

Evaluation of Outcomes Can patient identify measures that will help maintain mobility? Does patient perform exercises that help maintain mobility? Is optimum activity level maintained?

Interventions

Determine current level of mobility.

Identify factors that affect ability to be mobile and active.

Encourage patient to perform self-care to maximum ability.

Consult physical therapist (PT) or occupational therapist (OT) to provide assistive devices for walking (canes, braces, walker, wheelchair) and other activities.

Reposition frequently when patient is immobile.

Provide active/passive range-of-motion (ROM) exercises on a regular basis.

Plan activities with a balance of frequent rest periods.

Administer medications as ordered.

Rationale

Provides information to formulate plan of care.

Provides opportunity to seek answers for problems.

Promotes sense of control and independence for patient.

Assistive devices decrease fatigue, promote independence, comfort, and safety.

Prevents skin breakdown and stasis of pulmonary secretions.

Prevents contractures and disuse atrophy.

Rest decreases fatigue.

Medications may slow progress of disease and reduce symptoms.

Evaluation of Interventions

What is patient's present level of mobility?

Is patient able to identify factors that help or hinder mobility?

Does patient perform self-care activities? Is assistance required?

Does patient use assistive devices safely during activities? Do they help keep patient active?

Is patient free from complications of immobility?

Does patient have any contractures or atrophy?

Is fatigue controlled?

Are symptoms controlled?

Nursing Diagnosis: Risk for imbalanced nutrition related to weakness or lack of coordination of muscles for chewing and swallowing

Expected Outcomes Patient will maintain body weight within normal limits for height and frame.

Evaluation of Outcomes Is patient's weight stable and within normal limits (WNL)?

Interventions

Evaluate cough, swallow, and gag reflexes frequently. Notify physician if absent.

Offer soft, easy to chew and swallow foods.

Institute swallowing precautions as needed.

Request speech therapy and dietitian consultations as indicated.

Rationale

If patient is unable to swallow, a feeding tube may be indicated, depending on patient's wishes.

Soft foods require less effort to chew and are less fatiguing.

Swallowing precautions help prevent aspiration and allow patient to maintain oral intake as long as possible.

Speech therapy can help evaluate swallowing and make recommendations. Dietitian can provide appropriate foods.

Evaluation of Interventions

Does patient eat and drink without aspirating?

Is patient able to chew and swallow without excessive fatigue?

Do precautions prevent aspiration?

Are consults indicated? Are recommendations implemented?

(Continued on following page)

Box 50.3 NURSING CARE PLAN for the Patient with a Progressive Neuromuscular Disorder (Continued)

Nursing Diagnosis: Impaired verbal communication related to impaired respiratory and muscle function

Expected Outcomes Patient will be able to communicate needs.

Evaluation of Outcomes Does patient indicate that needs are met with a minimum of frustration?

Interventions

Assess ability to speak and communicate.

Request referral to speech therapist for assistance if indicated.

Assess for nonverbal signs of pain or distress, such as restlessness, agitation, grimacing.

Use picture board or paper and pencil. Ask questions that require yes or no answer.

Use nonhurried, calm, and caring approach while providing care.

Explain all procedures.

Rationale

Assessment is essential to planning appropriate communication interventions.

Speech therapist can recommend appropriate alternative communication techniques.

Patient may not be able to tell you if he or she is in pain or distress.

These do not require the patient to speak to communicate.

This will help decrease anxiety and provide emotional support to patient and family

Patient can still hear and needs to know what is happening.

Evaluation of Interventions

Can patient speak or communicate needs?

Is speech therapy referral indicated? Is referral completed?

Are signs of pain or distress present? Are they attended to?

Do alternative methods help patient communicate needs?

Do patient and family appear anxious? Does calm approach help?

Does patient indicate understanding?

Normally, at the neuromuscular junction, the neuron releases the chemical neurotransmitter acetylcholine (ACh), which crosses the synaptic cleft. Receptors on the muscle tissue take up ACh and contraction of the muscle results. In MG, the body's immune system is activated, producing antibodies that attack and destroy ACh receptors at the neuromuscular junction. ACh cannot stimulate muscle contraction because the number of ACh receptors has been reduced, resulting in loss of voluntary muscle strength.

Etiology

Myasthenia gravis is a chronic autoimmune process. No specific cause has been found for MG. However, current thought is that a virus may initiate the disease. Disorders of the thymus gland are often associated with MG. Thymomas or tumors on the thymus gland may account for the malfunction of the immune system that initiates the autoimmune process. All ethnic groups and both genders can develop this disease. Peak age of onset in women is 20 to 30 years. Men are affected more often after age 60. MG occurs slightly more often in women than men.

Signs and Symptoms

MG results in progressive extreme muscle weakness. The hallmark of MG is increased muscle weakness during activ-

ity and improvement in muscle strength after rest. Muscles are strongest in the morning, when the person is rested. Activity causes the muscles to fatigue easily, but rest allows the muscles to regain strength. Activities affected by MG include eye and eyelid movements, chewing, swallowing, speaking, and breathing, as well as skeletal muscle function. Patients often present with drooping of the eyelids (**ptosis**). Facial expressions are masklike. After long conversations, the patient's voice may fade. Falls occur because of weakness of the arm and leg muscles. Patients with MG experience periods of exacerbation and remission of symptoms, similar to patients with multiple sclerosis. Exacerbations can be caused by emotional or physical stress, such as pregnancy, menses, illness, trauma, extremes in temperature, electrolyte imbalance, surgery, and drugs that block actions at the neuromuscular junction.

Complications

Major complications associated with MG result from weakness of muscles that assist with swallowing and breathing. Aspiration, respiratory infections, and respiratory failure are the leading causes of death. Sudden onset of muscle weakness in patients with MG resulting from not enough medication is called a myasthenic crisis. Overmedication with

FIGURE 50.2 Myasthenia gravis. (A) Normal neuromuscular junction. (B) Note damaged acetylcholine receptor sites in myasthenia gravis. (Modified from Scanlon, VC, and Sanders, T: *Workbook for Essentials of Anatomy and Physiology*, ed. 5. FA. Davis, Philadelphia, 2007, with permission.)

LEARNING TIP

Symptoms of cholinergic crisis can be remembered with the acronym **SLUDGE**: salivation, lacrimation, urination, diarrhea, gastrointestinal cramping, and emesis. A severe crisis has been described as “liquid pouring out of every body orifice.”

anticholinesterase drugs causes a cholinergic crisis (Table 50.3). Both crises require immediate medical attention.

Diagnostic Tests

Diagnosis of myasthenia gravis is based on history of symptoms and physical examination of the patient. A simple test involves the patient looking upward for 2 to 3 minutes. Increased droop of the eyelids (ptosis) occurs if MG is present. After a brief rest, the eyelids can be opened without dif-

anticholinesterase: anti—against + cholinesterase—chemical that breaks down acetylcholine

TABLE 50.3 COMPARISON OF MYASTHENIC CRISIS AND CHOLINERGIC CRISIS

Myasthenic Crisis	Cholinergic Crisis
Cause Too little medication	Cause Too much medication
Signs and Symptoms Ptosis Difficulty swallowing Difficulty speaking Dyspnea Weakness	Signs and Symptoms Increasing muscle weakness Dyspnea Salivation Nausea or vomiting Abdominal cramping Sweating Increased bronchial secretions Miosis (constriction of pupils)

ficulty. Another test involves an intravenous injection of edrophonium (Tensilon, an anticholinesterase drug). If muscle strength improves dramatically (e.g., the patient can suddenly open the eyes wide), MG is diagnosed. However, improvement is only temporary. An increased number of anti-ACh receptor antibodies in the blood are present in 90% of patients with MG. Electromyography (EMG) may be done to rule out other conditions. Pulmonary function tests may be done to predict or anticipate potential myasthenic crisis leading to respiratory failure.

Therapeutic Interventions

No cure has been found for MG. Treatment is aimed at control of symptoms. Removal of the thymus gland (thymectomy) can decrease production of ACh receptor antibodies and decrease symptoms in most patients. Medications used to treat MG include the anticholinesterase drugs neostigmine (Prostigmin) and pyridostigmine (Mestinon). These drugs improve symptoms of MG by destroying the acetylcholinesterase that breaks down ACh. Remember that ACh causes muscles to contract. If ACh is allowed more time to attach to muscle tissue receptors, the muscle contracts and strength is increased. Steroids such as prednisone and immunosuppressants are used to suppress the body's immune response. Plasmapheresis can be used to remove antibodies from the patient's blood (see Table 50.2).

Nursing Care

See Box 50.3 Nursing Care Plan for the Patient with a Progressive Neuromuscular Disorder.

In addition, schedule anticholinesterase drugs so that peak action occurs at times when increased muscle strength is needed for activities such as meals and physical therapy. Be aware of symptoms and treatment of myasthenic and cholinergic crises, so you can determine what immediate actions need to be taken.

PATIENT EDUCATION. Instruct the patient that nutritious, well-balanced meals provide caloric intake to maintain

strength and resistance to infections. Teach the patient to schedule activities such as grocery shopping or errands at times when medication is at peak action, so that muscle strength is increased. Teach methods to conserve energy, such as sitting down to do grooming and housekeeping activities whenever possible. Explain that resting between activities allows time for muscle strength to be restored. Teach the importance of avoidance of persons with infections and exposure to cold to minimize risk for respiratory infections, which can exacerbate symptoms and increase risk for ineffective airway clearance. Teach signs and symptoms of crisis conditions because both crises constitute medical emergencies and require immediate medical attention (see Table 50.3).

There are many medications that should not be used with patients with MG such as D-penicillamine, alpha-interferon, and botulinum toxin. Other medications should be used with caution such as neuromuscular blocking agents, beta blockers, calcium channel blockers, some antibiotics, quinine, quinidine and procainamide. Many of these can exacerbate muscle weakness. Teach the patient to only use medications that are prescribed by the physician. If multiple providers are used, all medications should be checked with the provider who is treating the MG.

Provide information about support groups that can provide encouragement and assistance to patients and their families. More information can be found at the Myasthenia Gravis Foundation of America website www.myasthenia.org.

CRITICAL THINKING

Jamie

■ Jamie is referred to a neurologist with complaints of muscle weakness.

1. What history can help differentiate between MS and MG?
2. What assessment can be done to differentiate between MS and MG?
3. The neurologist prepares to do a Tensilon test and asks you to prepare 2 mg of Tensilon for IV injection. It is supplied as 10 mg per milliliter. How much should you draw up?

Suggested answers at end of chapter.

Amyotrophic Lateral Sclerosis

Pathophysiology and Etiology

Amyotrophic lateral sclerosis (ALS) (also called Lou Gehrig's disease) is a progressive, degenerative condition that affects motor neurons responsible for the control of voluntary muscles. Within the brain and spinal cord, upper and lower motor neurons begin to degenerate and form scar tissue or die, blocking transmission of nerve impulses. Without

stimulation, **atrophy** of muscle tissue occurs, and muscle strength and coordination decrease. As the disease progresses, more muscle groups, including muscles controlling breathing and swallowing, become involved. However, the ability to think and reason is not affected.

ALS can occur at any age, but usually does not appear until adulthood. A specific cause has not been discovered, although ALS may have a genetic predisposition in some cases. About 5600 people in the United States are diagnosed with ALS each year.³ The usual age of onset is between 40 and 70. ALS is more prevalent in men than women.

Signs and Symptoms

Symptoms are vague early in the course of ALS. Primary symptoms include progressive muscle weakness and decreased coordination of arms, legs, and trunk. Atrophy of muscles and twitching (**fasciculations**) also occur. Muscle spasms can cause pain. Difficulty with chewing and swallowing place the patient at a risk for choking and aspiration as the disease progresses. Inappropriate emotional outbursts of laughing and crying may occur. Speech becomes increasingly difficult. Bladder and bowel functions remain intact, yet problems such as constipation, urinary urgency, hesitancy, or frequency may occur. Late in the disease, communication becomes limited to moving and blinking of eyes in response to questions. Pulmonary function becomes severely compromised to the point of requiring mechanical assistance (ventilator) if the patient chooses. Other complications that may occur include extreme malnutrition, falls, pulmonary emboli, and congestive heart failure. ALS eventually leads to death from respiratory complications (atelectasis, respiratory failure, and pneumonia). Death usually occurs 3 to 5 years after diagnosis.

Diagnostic Tests

Diagnosis is made based on clinical symptoms. Additional tests such as CSF analysis, electroencephalogram (EEG), nerve biopsy, or electromyography (EMG) may be done to rule out other conditions. Blood enzymes may be increased as a result of muscle atrophy.

Therapeutic Interventions

Goals of treatment are aimed at improving function as long as possible and emotionally supporting the patient and family through the illness. Baclofen and diazepam may be given to relieve muscle spasticity. Quinine is used for muscle cramps. Riluzole has recently been approved by the Food and Drug Administration (FDA) to help reduce the damage to the motor neurons and may prolong survival by several months. Nonpharmacological measures such as physical therapy, massage, position changes, and diversional activities may be instituted for pain control. Tube feedings via a surgically placed gastrostomy tube help provide adequate nutrition. Prevention of infections, such as pneumonia and urinary tract infection (UTI), is vital. Meticulous skin care

atrophy: a—without + trophy—nourishment

minimizes the incidence of pressure ulcers. Rehabilitation therapy, including physical, occupational, and speech therapy, allows the patient to maximize function and control. Therapy may also decrease the occurrence of complications such as aspiration, falls, and contractures.

Individuals with speech problems may benefit from the use of augmentative alternative communication (AAC). A variety of AAC systems are available; most use laptop computers that patients can use to type in words or symbols to generate speech. Medicare now will pay at least a portion of the cost for AAC equipment.

Support groups and counseling provide emotional support for the patient and family. Most patients with ALS die within 3 to 5 years of diagnosis of respiratory failure. Ten percent of patients with ALS survive for 10 or more years.

Nursing Care

See Box 50.3 Nursing Care Plan for the Patient with a Progressive Neuromuscular Disorder.

PATIENT EDUCATION. Reinforce information given by the physician to the patient and family about ALS and its prognosis. Support groups can provide emotional support as the patient and family deal with the reality of eventual death. Rehabilitation using assistive devices and exercises helps prevent complications. Teaching family members how to perform physical therapy and other health-care activities allows the patient to spend as much time as possible at home. Teach the patient to avoid exposure to persons with infections because an infection can be deadly to the patient with a debilitating disease.

LEARNING TIP

A person with ALS has an intact mind—it is the body that is deteriorating.

CRITICAL THINKING

Mr. Miller

■ Mr. Miller has been having difficulty swallowing. He is diagnosed with ALS.

1. What are the priority nursing diagnoses for him?
2. How can the patient and his family be supported in coping with this disease?

Suggested answers at end of chapter.

Guillain-Barré Syndrome

Pathophysiology

Guillain-Barré syndrome (GBS) is also called acute inflammatory **polyneuropathy**. This term is more descriptive of

the actual disease process. GBS is an inflammatory disorder characterized by abrupt onset of symmetrical paresis (weakness) that progresses to paralysis. The myelin sheath of the spinal and cranial nerves is destroyed by a diffuse inflammatory reaction. The peripheral nerves are infiltrated by lymphocytes, which leads to edema and inflammation. Segmental **demyelination** causes axonal atrophy, resulting in slowed or blocked nerve conduction. Typically, the demyelination begins in the most distal nerves and ascends in a symmetrical fashion. **Remyelination**, which is a much slower process, occurs in a descending pattern and is accompanied by a resolution of symptoms.

There are four recognized variants of GBS. The most common form is ascending Guillain-Barré syndrome. It is characterized by progressive weakness and numbness that begins in the legs and ascends up the body. The numbness tends to be mild, but the muscle weakness usually progresses to paralysis. The paralysis may ascend all the way to the cranial nerves or stop anywhere between the legs and head. Deep tendon reflexes are either depressed or absent. In approximately 50% of patients with ascending GBS, respiratory function becomes compromised.

Descending GBS is less common. It affects the cranial nerves that originate in the brainstem first. These patients present with difficulty swallowing and speaking. The weakness progresses downward toward the legs. Respiratory compromise is rapid. Numbness is more problematic in the hands than in the feet, and the reflexes are diminished or absent.

Miller Fisher syndrome, a variant of GBS, is rare. Typically, there is no respiratory compromise or sensory loss. The classic symptoms are profound ataxia, absence of reflexes, and paralysis of the extraocular muscles. Some people believe that the fourth form, pure motor GBS, is actually a milder version of ascending GBS. The symptoms are the same except for the lack of numbness or paresthesias.

Etiology

GBS is believed to be caused by an autoimmune response to some type of viral infection or vaccination, although the exact cause is not known. Usually the viral illness occurs within 2 weeks prior to onset of symptoms. Average age at onset is 30 to 50; men and women are equally affected.

GBS has worldwide distribution, is not seasonal, and affects individuals of all races and ages. Higher rates, however, have been found in people 45 years and older. The incidence of the disease is 50% to 60% higher in Caucasians than in African Americans.

Signs and Symptoms

GBS is divided into three stages. The first stage starts with the onset of symptoms and lasts until the progression of symptoms stops. This stage can last from 24 hours to 3 weeks and is characterized by abrupt and rapid onset of muscle weakness and paralysis, with little or no muscle atrophy. Many patients give a history of a recent viral illness or vaccination, supporting the theory that the cause is autoimmune

in nature. The degree of respiratory involvement correlates to the type of GBS and the level of paralysis. Patients with ascending GBS may gradually notice a reduced ability to take deep breaths or carry on conversations and may feel short of breath. These patients are terrified that they will not be able to breathe. Patients with either ascending or descending GBS may require intubation and artificial ventilation.

The autonomic nervous system is often affected by GBS. Patients may experience labile blood pressure, cardiac dysrhythmias, urinary retention, or paralytic ileus. Patient complaints of discomfort range from annoying numbness and cramping to severe pain. The discomfort is exacerbated by the patient's inability to move voluntarily.

The second stage is the plateau stage, when symptoms are most severe but progression has stopped. It may last from 2 to 14 days. Patients may become discouraged if no improvement is evident.

Axonal regeneration and remyelination occur during the recovery phase. This stage lasts from 6 to 24 months. Symptoms slowly improve. Most patients with GBS recover completely within a few months to a year. A few patients experience chronic disability.

Complications

Complications that can occur include respiratory failure, infection, and depression. Fatigue and paralysis of the respiratory muscles lead to insufficient respiratory effort. Some patients with impending respiratory failure attempt to convince the staff that they are not in distress and do not need to be intubated. Discussion of the possible need for intubation early in the patient's illness is important. The decision to intubate in GBS is different than with the other PNS disorders, since GBS patients are expected to recover. Constant monitoring of respiratory parameters and continuous pulse oximetry provide information indicating the need for immediate intervention.

Patients with GBS are prone to pneumonia and UTIs. Maintaining infection control practices and maximizing the patient's nutritional status help decrease the likelihood of infections occurring. Immobility leads to such problems as skin breakdown, pulmonary embolus, deep vein thrombosis, and muscle atrophy. Patients with GBS have little time to adjust to their illness and deterioration. They fear that they will not recover function. Calm, supportive reassurance is important.

Diagnostic Tests

A lumbar puncture is performed to obtain CSF. The CSF analysis shows a normal cell count with an elevated protein level. Electromyographic and nerve conduction velocity tests are done to evaluate nerve function. Pulmonary function testing helps identify impending respiratory problems.

Therapeutic Interventions

During the first stage, patients are partially or completely dependent for all needs. They are often frightened and anxious. Oxygen and mechanical ventilation may be required. Plasmapheresis is used to remove the patient's plasma and

replace it with fresh plasma. This procedure is thought to lessen the body's immune response. To be most effective, plasmapheresis should begin 7 to 14 days from the onset of symptoms. Steroid hormones, although used in the past, are not effective and may have a deleterious effect on the individual.

During the plateau phase, patients may become discouraged because they are not getting any better. Emotional support is important during this phase.

Axonal regeneration and remyelination occur during the recovery phase. Intensive rehabilitation helps the patient regain function during this phase.

Nursing Care

See Box 50.3 Nursing Care Plan for the Patient with a Progressive Neuromuscular Disorder.

The goal of therapy is to support body systems until the patient recovers. Monitor vital capacity and ABGs, and promptly report deterioration in respiratory function. Monitor gag, corneal, and swallowing reflexes so protective interventions can be implemented if necessary. Manage pain with administration of narcotics and nonpharmacological methods such as position changes, massage, and diversional activities. Administer tube feedings or parenteral nutrition as ordered to meet nutritional needs if the patient is unable to swallow. Provide a communication board if needed so the patient can indicate needs to staff. Because recovery can be prolonged, diversional activities such as visits from family and friends, listening to music or relaxation tapes, and watching television or videos can help alleviate boredom, loneliness, and depression. As the patient begins to regain function, encourage participation in therapy and point out any returning function to the patient and family.

PATIENT EDUCATION. All procedures should be explained to the patient and family. The patient and family need to understand the reasons for continuous respiratory monitoring. Patients may deny any respiratory difficulty because of a fear of intubation and mechanical ventilation. Informing the patient about the possible need for temporary respiratory support and the measures taken to alleviate discomfort help decrease anxiety and encourage patient cooperation. Information about the disease, treatments, and recovery should be given because recovery may take months or years. Educating family members about how to perform specific patient care activities encourages participation and prepares the patient and family for discharge.

See Table 50.4 for a summary comparison of MS, MG, ALS, and GB.

Postpolio Syndrome

Pathophysiology and Etiology

Postpolio syndrome is a condition that affects survivors of polio 10 to 40 years after they have recovered from infection caused by the poliomyelitis virus. The severity of this syndrome depends on the degree of residual weakness and disability left from the initial illness.

TABLE 50.4 SUMMARY OF PNS DISORDERS

	Multiple Sclerosis (MS)	Myasthenia Gravis (MG)	Amyotrophic Lateral Sclerosis (ALS)	Guillain-Barré Syndrome (GBS)
Signs and Symptoms	Muscle weakness Muscle paralysis Visual disturbances Fatigue	Progressive severe muscle weakness of voluntary muscles Muscles regain strength with rest Masklike face	Progressive muscle weakness Decreased coordination Muscle twitching Muscle spasms Pain Emotional outbursts Difficulty with speech Intact thought processes	3 Stages: 1. Ascending paralysis 2. Plateau 3. Descending resolution Pain, cramping or numbness
Diagnosis	CSF analysis MRI Interferon therapy Steroids Immunosuppressants Plasmapheresis Anticonvulsants Antiviral agents Muscle relaxants Physical therapy	Ptosis test Tensilon test EMG	CSF analysis EEG Nerve biopsy	CSF EMG Nerve conduction velocity
Therapeutic Interventions	Assistive devices for ADLs Speech therapy	Plasmapheresis Thymectomy Anticholinesterase agents Steroids	Antispasmodics/quinine Riluzole (Rilutek) Physical therapy Massage Muscle relaxants Diversional activities Tube feeding Alternative communications devices	Plasmapheresis Ventilation support
Complications	Falls Muscle spasms Bowel and bladder problems, risk for UTI Forgetfulness Extreme fatigue	Aspiration Respiratory infections Respiratory failure Myasthenic crisis or cholinergic crisis	Communication problems Risk for aspiration Pain Respiratory failure	Respiratory infection Respiratory failure Depression Fatigue UTI Complications of immobility
Priority Nursing Diagnoses	Ineffective airway clearance; Impaired physical mobility; Risk for imbalanced nutrition			

CSF = cerebrospinal fluid; EEG = electroencephalography; EMG = electromyography; MRI = magnetic resonance imaging; UTI = urinary tract infection.

Signs and Symptoms

Postpolio syndrome (PPS) involves a further weakening of the muscles that were affected with the first involvement with the poliovirus. Symptoms range from fatigue to progressive muscle weakness leading to atrophy. Sleeping problems, joint pain, scoliosis, and respiratory compromise can occur. Some individuals suffer great debilitation, while others have little problem.

Diagnostic Tests

Observation and history and excluding other problems are most important in diagnosis of this syndrome.

Therapeutic Interventions

No interventions have been found to be effective at this time. Symptoms seem to be best controlled by rest and moderate exercise without pushing the limits of tolerance.

CRANIAL NERVE DISORDERS

Cranial nerves are the peripheral nerves of the brain. There are 12 pairs of cranial nerves. Areas that the cranial nerves innervate include the head, neck, and special sensory structures. Cranial nerve problems are classified as peripheral **neuropathies**. Disorders may affect the sensory, motor, or both branches of a single nerve. Causes of cranial nerve disorders include tumors, infections, inflammation, trauma, and unknown causes. Two common cranial nerve problems are trigeminal **neuralgia** (tic douloureux) and Bell's palsy.

neuropathies: neuro—nerve + pathies—disease

neuralgia: neur—nerve + algia—pain

Trigeminal Neuralgia

Pathophysiology and Etiology

Trigeminal neuralgia (TN), sometimes called tic douloureux, involves the fifth cranial (trigeminal) nerve. This cranial nerve has three branches that include both sensory and motor functions. The branches innervate areas of the face, including the forehead, nose, cheek, gums, and jaw. Trigeminal neuralgia affects only the sensory portion of the nerve. Irritation or chronic compression of the nerve is suspected to initiate onset of symptoms. This condition is seen more often in women and usually begins around age 50 to 60.

Signs and Symptoms

Intense recurring episodes of pain, described as sudden, jabbing, burning, or knifelike, characterize this condition. Episodes of pain begin and end suddenly, lasting a few seconds to minutes. Attacks can occur in clusters up to hundreds of times daily. However, some patients experience only a few attacks per year. Pain is felt in the skin on one side of the face. A slight touch, cold breeze, talking, or chewing can trigger attacks of pain. The areas of the face where pain is triggered are referred to as trigger zones. Areas affected include the lips, upper or lower gums, cheeks, forehead, or side of the nose (Fig. 50.3). Sleep provides a period of relief from the pain. Therefore, persons with trigeminal neuralgia may sleep most of the time to avoid painful attacks. They may also refrain from activities such as talking, face washing, teeth brushing, shaving, and eating to prevent pain. Frequent blinking and tearing of the eye on the affected side also occurs.

Diagnostic Tests

History of symptoms and direct observation of an attack confirm diagnosis. Radiological studies, including computed tomographic (CT) scan and MRI, may be used to rule out other causes of the pain.

Therapeutic Interventions

Initial management includes the use of anticonvulsants such as phenytoin (Dilantin) and carbamazepine (Tegretol)

to reduce transmission of nerve impulses. Baclofen, clonazepam, gabapentin, and valproic acid may also be effective in controlling the symptoms. Most persons experience relief with medications. These drugs cause bone marrow suppression, so routine complete blood counts are necessary. However, medications do not offer a permanent solution because they lose their effectiveness after a period of time. Another treatment option is nerve blocks using local anesthetics. This option offers 8 to 16 months of relief. If medications and nerve blocks do not provide relief, surgical options are available. Surgery is done to identify and remove the cause of irritation and inflammation of the nerve. Radio frequency ablation is used to destroy some of the nerve branches, resulting in anesthesia of the area. Gamma knife radiosurgery is also an option. The gamma knife creates a lesion on the nerve to block the pain signals.

PATIENT EDUCATION POSTPROCEDURE. Many of the above interventions may still apply following nerve block or ablation. If corneal sensation is lost, goggles and sunglasses should be used as needed to protect the affected eye. An eye patch may be needed at night to prevent injury during sleep. Artificial tears may also be needed to prevent corneal damage.

Bell's Palsy

Pathophysiology and Etiology

In Bell's palsy (BP), the facial nerve (cranial nerve VII) becomes inflamed and edematous, causing interruption of nerve impulses. The cause is thought to be nerve trauma from a viral or bacterial infection. There is ongoing research to determine whether this is another autoimmune disorder. Loss of motor control generally occurs on one side of the face; bilateral facial palsy occurs in less than 1% of cases. Contracture of facial muscles may occur if recovery is slow. Men and women are affected equally. Bell's palsy is more common in the third trimester of pregnancy, in individuals with immune disorders such as HIV infection, and individuals with diabetes. It occurs in all ages (including children) and at all times of the year.

Signs and Symptoms

Onset of symptoms may be sudden or may progress over a 2- to 5-day period. The severity of the paralysis usually peaks within several days of onset of symptoms. Pain behind the ear may precede the onset of facial paralysis. Other vague initial symptoms are dry eye or tingling around the lips with progression to the more recognizable symptoms of Bell's palsy. The patient may be unable to close the eyelid, wrinkle the forehead, smile, raise the eyebrow, or close the lips effectively. The mouth is pulled toward the unaffected side (Fig. 50.4). Drooling of saliva occurs, and the affected eye has constant tearing. Sense of taste is lost over the anterior two-thirds of the tongue. Speech difficulties are present. Fifty percent of these patients will have complete recovery in a short period of time. Thirty-five percent will have full recovery in less than 1 year. See Box 50.4 Patient Perspective for Angela's experience with Bell's palsy.

FIGURE 50.3 Areas innervated by the three main branches of the trigeminal nerve (cranial nerve V) are affected in trigeminal neuralgia.

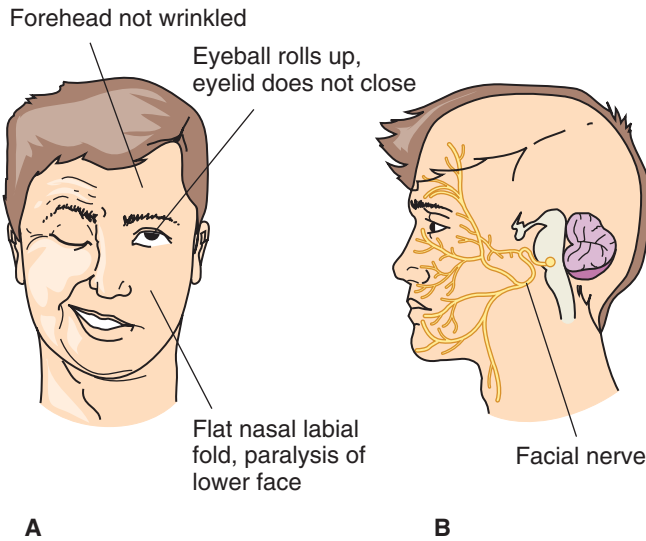

FIGURE 50.4 Bell's palsy. (A) Note weakness of affected side of face. (B) Distribution of facial nerve.

Diagnostic Tests

History of the onset of symptoms is used to diagnose Bell's palsy. Observation of the patient confirms the diagnosis. An EMG may be done. The possibility of a stroke must be ruled out.

Therapeutic Interventions

Prevention of complications is the goal of treatment. Prednisone may be given over 7 to 10 days to decrease edema. Analgesics are given for pain control. Antiviral medication may be prescribed. Moist heat with gentle massage to the face and ear also eases pain. Use of a facial sling aids in eating and supports facial muscles.

Nursing Process for Cranial Nerve Disorders (Trigeminal Neuralgia and Bell's Palsy)

ASSESSMENT/DATA COLLECTION. Assess attacks using the WHAT'S UP? format, being sure to include factors that trigger pain. Are there sensory or motor problems associated with the pain? Assess the effect of the disorder on the patient's life, including nutritional status, general and oral

Box 50.4

Patient Perspective

Angela, Bell's Palsy

I woke up that Thursday morning with the same intense pain in my forehead that I had been experiencing for the last week. When I rolled out of bed, I realized that I didn't have morning breath (or so I thought). Knowing that I had not brushed my teeth yet, I proceeded to do so and noticed that I could not taste the toothpaste. The fruit cup I ate for lunch tasted like Clorox. I chomped up and down on each bite, then carefully attempted to swallow. It was like I had been injected with several shots of Novocain. My throat felt like it had closed up, and each swallow took a concentrated effort. Over the course of eating my fruit, I managed to bite my tongue three times.

I was 35 weeks pregnant and on strict bed rest due to pregnancy-induced hypertension and severe edema (which later spiraled into toxemia). We attributed the numbness in my mouth to the edema. I had already swollen up like a balloon and had experienced intense numbness in my extremities since the 12th week of pregnancy. As the afternoon progressed, I grew more and more concerned. I knew something was not quite right. By 5:30 that evening I had lost control of the entire left side of my face. I called my obstetrician and she said to get to the ER because I was either having a stroke or had developed Bell's palsy. The doctor at the ER confirmed that I had Bell's palsy and prescribed Valtrex and prednisone to treat it.

The symptoms of Bell's that I experienced were

severe pain in my forehead, not being able to breathe out of the left side of my nose, and difficulty chewing, swallowing, and saying most consonants. I completely lost the ability to smile, blink, close my eye, raise my eyebrow, or use a straw or blow. My eyesight in the left eye blurred, and I could not drive at night due to the intense pain behind my eye triggered by head lights and having to use eye drops every 5 to 20 minutes.

I delivered my baby (after induction, 2 days of labor, 2 hours of pushing, and emergency C-section) 2 weeks after being diagnosed with Bell's palsy. During labor, I continuously asked for my eye drops because the pain in my head was so fierce that it overshadowed the contractions.

After delivery, I was desperate for my face to be "fixed." I tried everything that anyone suggested: herbal supplements, chiropractic, facial massage, laser treatments, facial exercise, shock treatments, a neurologist consultation, and physical therapy. The only thing that has worked for me is time (and lots of it)!

For the first 15 weeks after being diagnosed I wanted to hide from the world. However, here it is 7 months later and I have come to terms with it. I am constantly aware of it, though I have regained a tremendous amount of the muscle control. I still have not shared a "real smile" with my daughter and do not blink my left eye. Covering my mouth when I smile or laugh so others do not see has become almost like a reflex now.

hygiene, behavior, and emotional state. Carefully document all findings.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. *Acute pain related to inflammation or compression of the nerve*

EXPECTED OUTCOME: Patient will state pain is controlled

- Assess pain level and response to interventions prn. *Assessment guides intervention.*
- Administer analgesics as needed for pain. *Analgesics decrease pain and increase comfort.*
- Discuss and implement alternative and complementary pain relief measures *to complement analgesics and increase patient's control over pain.*
 - Biofeedback
 - Diversional activities
- Plan hygiene activities when pain relief is at its peak *to decrease discomfort with activities.*
- Provide alternative communication methods. *Patient may not be able to speak clearly or want to speak due to pain.*
 - Paper and pencil/pen
 - Dry erase board
 - Magnetic letters
 - Communication boards
 - Pain scales for pointing to level of pain
- Teach to chew on opposite side of face *to avoid triggering pain and injury.*
- Encourage use of electric razor rather than blades *to prevent injury of numb areas.*
- Provide the following measures for trigeminal neuralgia *to reduce pain triggers.*
 - Provide soft cloths for facial hygiene using lukewarm water.
 - Avoid touching the patient's face.
 - Provide soft bristle toothbrush for oral care.
 - Teach to protect face from cold or wind.
- Provide the following measures for Bell's palsy *to reduce pain and prevent muscle atrophy.*
 - Provide warm, moist compresses prn.
 - Massage face.
 - Assist with facial exercises several times a day.
 - Provide a facial sling.

Imbalanced nutrition: Less than body requirements related to fear of triggering pain

EXPECTED OUTCOME: Patient will maintain sufficient nutrition as evidenced by stable weight

- Weigh each morning and record *to monitor weight loss or gain.*

- Provide small frequent meals *to provide nutrition without increasing pain.*
- Provide soft, easy-to-chew food at lukewarm temperature *to prevent triggering pain.*
- Provide high-protein and high-calorie diet. *Protein and calories are needed for cellular repair.*
- Avoid hot or cold foods and drinks. *Temperature extremes may trigger pain. If foods are associated with pain, the patient may avoid them.*
- Encourage oral hygiene after each meal and at bedtime *to prevent gum and tooth disease as trigger for pain.*
- Insert feeding tube on unaffected side if nutrition is severely impaired *to provide means for nutrient intake while avoiding painful nerve areas.*

Risk for trauma to eye related to inability to blink, and body image disturbance (Bell's palsy)

EXPECTED OUTCOME: Cornea will remain intact without injury.

- Administer eye drops or eye ointment as ordered by the physician *to protect the eye.*
- Teach the patient to use a patch over the affected eye *to protect the eye.*
- Advise the patient to wear glasses or goggles, especially when outside or in areas with multiple particles in the air *to protect the eyes.*

EVALUATION. Nursing care has been successful if the patient reports that pain is controlled, nutrition is maintained with no inappropriate weight loss, and the eyes are intact and without injury.

LEARNING TIP

Trigeminal neuralgia (cranial nerve V) is a sensory disorder; Bell's palsy (cranial nerve VII) is a motor disorder.

See Table 50.5 for a summary comparison of BP and TN.

Home Health Hints

- If a home-bound patient has difficulty speaking (dysarthria), try using magnetic alphabet letters. Ask questions that require a yes or no answer. The patient can respond with the letter y or n.
- Keep bedside commode lids up with patches of Velcro attached to the seat and the frame.

TABLE 50.5 SUMMARY OF CRANIAL NERVE DISORDERS

	Trigeminal Neuralgia	Bell's Palsy
Cranial Nerve Involved	5th sensory	7th motor
Signs and Symptoms	Intense pain on one side of face <ul style="list-style-type: none"> • Sudden onset • Sudden resolution • Jabbing, burning, knifelike Sensitive to temperature and air flow Sensitive to touch Pain exacerbated by talking or chewing Frequent blinking or tearing of the eye on affected side	Loss of motor control, paralysis on one side of face Variable onset of symptoms Facial droop and inability to close affected eye Drooling Loss of taste over anterior one-third of tongue Speech difficulties
Diagnosis	History Observation of attack CT MRI	History EMG

REVIEW QUESTIONS

1. A patient with TN asks the nurse why she was started on carbamazepine (Tegretol). Which response is best?
 - a. "It will help decrease the inflammation in your nervous system."
 - b. "It will depress your immune system, which can slow the progression of the disease."
 - c. "It can help relieve nerve pain."
 - d. "It relaxes the bladder to help control bladder spasms."
2. A patient with ALS asks why he doesn't seem to have enough breath to sing anymore. Which explanation by the nurse is best?
 - a. "ALS can damage the nerves to your bronchi and bronchioles, causing constriction and reduced air-flow."
 - b. "The demyelination of your nerves caused by ALS causes confusion in the impulses to your lungs."
 - c. "ALS can affect your vocal cords, making it difficult to form sounds as you speak or sing."
 - d. "ALS may be affecting the nerves that go to your respiratory muscles, making them weak."
3. A patient who is newly diagnosed with ALS says to the nurse, "I do not want to be kept alive on machines." Which nursing action is best in response?
 - a. Ask the patient if he has advance directives, and provide information about preparing them.
 - b. Reassure the patient that he will not need to make decisions about machines for a long time.
 - c. Inform the patient that individuals with ALS are not candidates for artificial ventilation.
 - d. Explain to the patient that a ventilator will be necessary to keep him breathing as his disease progresses.
4. When caring for a patient admitted with a diagnosis of Guillain-Barré syndrome, which nursing diagnosis should take priority?
 - a. Anxiety
 - b. Imbalanced nutrition
 - c. Impaired gas exchange
 - d. Impaired mobility
5. Which nursing interventions are appropriate for the patient with Bell's palsy? Select all that apply.
 - a. Administer moisturizing eye drops.
 - b. Apply an eye patch.
 - c. Avoid touching the patient's face.
 - d. Apply warm compresses.
 - e. Provide facial massage.
 - f. Teach the patient to protect her face from cool breezes.

6. Which meal would be the best choice for a patient with myasthenia gravis?
 - a. Baked chicken sandwich, fresh carrots, apple
 - b. Meatloaf, mashed potatoes, canned green beans
 - c. Steak, baked potato, green salad
 - d. Tacos, fresh vegetables, sliced peaches
7. How will the visiting nurse caring for a patient with myasthenia gravis and severe muscle weakness know if interventions have been effective?
 - a. The patient verbalizes satisfaction with the plan of care.
 - b. The patient states understanding of the medication regimen.
 - c. The patient and family state that no further home visits are needed.
 - d. The patient is able to perform ADLs with SaO_2 remaining at 95%.

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Jamie*

1. Muscle weakness caused by myasthenia gravis improves with rest.
2. Have Jamie look up for 2 to 3 minutes. If ptosis occurs, let the patient close her eyes for several minutes. If she can open her eyelids and look up, myasthenia gravis is likely.
- 3.

$$\frac{2 \text{ mg}}{10 \text{ mg}} \left| \frac{1 \text{ mL}}{10 \text{ mg}} \right. = 0.2 \text{ mL}$$

■ *Mr. Miller*

1. Nursing diagnoses include ineffective airway clearance related to muscle weakness and risk for aspiration related to muscle weakness. If a patient's respiratory system is compromised by a disease, nursing care should be focused on maintaining pulmonary function to preserve life.
2. Compassionate care for the patient and providing information about the disease and its prognosis to the patient and family establish an honest and supportive environment. Support groups provide resources and emotional support.

QUESTIONS TO GUIDE YOUR READING

1. What is the normal anatomy of the sensory system?
2. What is the normal function of the sensory system?
3. What data should you collect when caring for a patient with a disorder of the sensory system?
4. What are the diagnostic tests commonly performed to diagnose disorders of the sensory system?
5. What nursing care should you provide for patients undergoing each of the diagnostic tests?
6. What are the common therapeutic measures used for patients with disorders of the sensory system?

Our eyes and ears provide us with a great deal of sensory information. It is difficult to imagine what it would be like not to see or hear the world around us. Nurses have an important role in assessing vision and hearing. Patients depend on health-care personnel to assist them in maintaining these primary senses. To learn more about ways to promote vision and hearing health, visit <http://web.health.gov/healthypeople>.

Normal Anatomy and Physiology of the Eye

The eye contains the receptors for vision and a refracting system that focuses light rays on these photoreceptors in the retina.

External Structures

The eyelids are the protective covers for the front of the eyeball; on the border of each lid are eyelashes that help keep dust out of the eyes. The eyelids are lined with a thin transparent membrane called the conjunctiva, which is also folded over the white of the eye on its anterior surface.

Associated with each eyeball is a lacrimal gland located within the bony socket at the upper, outer corner of the eyeball. Small ducts take tears to the front of the eyeball, and blinking helps spread the tears over the surface. Tears contain lysozyme, an enzyme that inhibits the growth of most bacteria on the surface of the eye. The lacrimal canals at the medial corner of each eye collect tears, which then drain into the lacrimal sac, to the nasolacrimal duct, to the nasal cavities.

Structure of the Eyeball

Most of the eyeball is within the orbit, the bony socket that provides protection from trauma. The six extrinsic muscles that move the eyeball are attached to the orbit and to the outer surface of the eyeball. There are four rectus muscles that move the eyeball side to side or up and down and two oblique muscles that rotate the eye. The cranial nerves that innervate these muscles are the oculomotor, trochlear, and abducens (third, fourth, and sixth cranial nerves, respectively).

The wall of the eyeball has three layers: the outer sclera, the middle choroid, and the inner retina. The sclera is made of fibrous connective tissue that is visible as the white of the eye. The most anterior portion is the transparent cornea (Fig. 51.1), which has no capillaries and is the first part of the eye that refracts light rays.

The choroid layer contains blood vessels and the dark pigment melanin, which prevents glare within the eyeball by absorbing light. The anterior of the choroid is modified into the ciliary body and the iris. The ciliary body has a circular muscle that surrounds the edge of the lens and is connected to the lens by suspensory ligaments. The lens is made of a transparent, elastic protein and, like the cornea, has no capillaries. The shape of the lens is changed by the ciliary muscle, which permits the focusing of light from objects at varying distances.

In front of the lens is the circular iris, which is made of two sets of smooth muscle fibers that change the diameter of the pupil, the central opening. Contraction of the radial fibers is a sympathetic response and dilates the pupil. Contraction of the circular fibers is a parasympathetic response (mediated by the oculomotor nerves) and constricts the pupil. Pupillary constriction is a reflex that protects the retina from intense light or that permits more acute near vision.

FIGURE 51.1 Internal anatomy of the eye. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed. 5. F.A. Davis, Philadelphia, 2007, with permission.)

The retina lines the posterior two-thirds of the eyeball and contains the rods and cones, the receptors for vision. Rods detect only the presence of light, whereas cones detect the different wavelengths of light as colors. The fovea centralis is a small depression in the macula lutea of the posterior retina, directly behind the center of the lens, and contains only cones. It is, therefore, the area of most acute color vision. Rods are proportionally more abundant toward the periphery of the retina, and for this reason night vision is best at the sides of the visual field.

Neurons called ganglion cells transmit the impulses generated by the rods and cones. These neurons all converge at the optic disc and pass through the wall of the eyeball as the optic nerve. The optic disc may also be called the blind spot because no rods or cones are present.

Cavities of the Eyeball

There are two cavities divided by the lens within the eye, posterior and anterior. The larger posterior cavity is between the lens and retina and contains vitreous humor. This semi-solid substance helps keep the retina in place.

The anterior cavity is between the cornea and the front of the lens and contains aqueous humor, the tissue fluid of the eyeball that nourishes the lens and cornea. Aqueous humor is formed by capillaries in the ciliary body, flows anteriorly through the pupil, and is reabsorbed by the canal of Schlemm (scleral venous sinus) at the junction of the iris and the cornea. The rate of reabsorption normally equals the rate of production.

Physiology of Vision

Vision involves the focusing of light rays on the retina and the transmission of the subsequent nerve impulses to the visual areas of the cerebral cortex.

The refractive structures of the eye are, in order, the cornea, aqueous humor, lens, and vitreous humor. The lens is the only adjustable part of this focusing system. When the eye is focused on a distant object, the ciliary muscle is relaxed and the lens is elongated and thin. When the eye is focused on a near object, the ciliary muscle contracts and forms a smaller circle and the elastic lens recoils and bulges in the middle and has greater refractive power.

When light rays strike the retina, they stimulate chemical reactions in the rods and cones. Receptors contain a light-absorbing molecule called retinal (a derivative of vitamin A) bonded to a protein called an opsin. In the rods, light stimulates the breakdown of rhodopsin into an opsin and retinal; resultant chemical changes generate a nerve impulse for transmission. The cones also contain retinal, and similar reactions take place. The opsins of the cones are specialized to respond to a portion of the visible light spectrum; there are red-absorbing, blue-absorbing, and green-absorbing cones. The chemical reactions within the cones also generate electrical nerve impulses.

The impulses from the rods and cones are transmitted to the ganglion neurons, which converge at the optic disc and become the optic nerve. The optic nerves from both eyes converge at the optic chiasma, just in front of the pituitary

gland. Here, the medial fibers of each optic nerve cross to the other side. This crossing permits each visual area to receive impulses from both eyes, which is important for binocular vision.

The visual areas are in the occipital lobes of the cerebral cortex. It is here that the upside-down retinal images are righted and the slightly different pictures from the two eyes are integrated into one image; this is binocular vision, which also provides depth perception.

Aging and the Eye

The most common changes in the aging eye are those in the lens (Fig. 51.2). With age, the lens may become partially or totally opaque. The lens also loses its elasticity with age; most people become farsighted as they get older and by age 40 begin to need corrective lenses. Peripheral vision losses may occur. Depth perception decreases and glare is more difficult to adjust to, which can affect safety. Color vision fades with poorer discrimination of blue, green, and violet colors. Red, yellow, and orange colors are seen best.

Nursing Assessment/Data Collection of the Eye and Visual Status

As with most examinations, nursing assessment of the eye begins with the collection of subjective data, then moves to

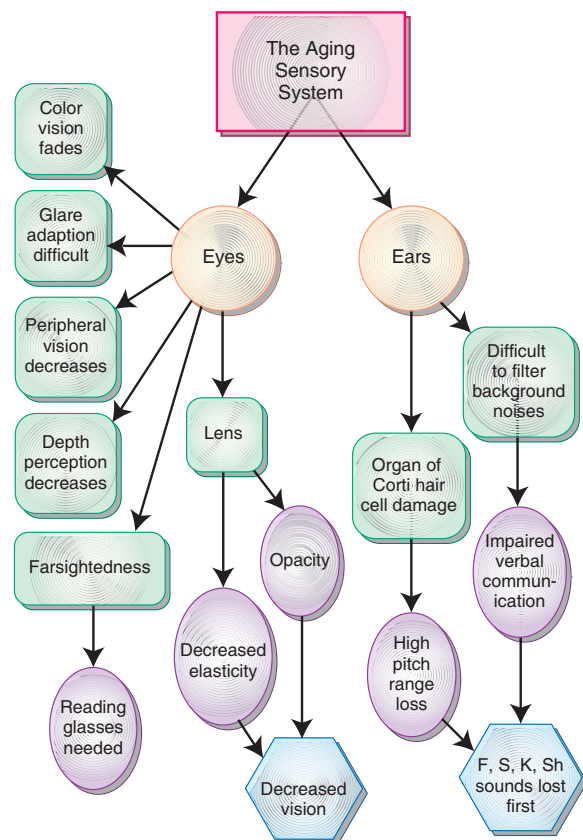

FIGURE 51.2 Legend: Aging and the sensory system. This concept map shows the effects the aging process has on the sensory system.

observation and testing, and finally a more invasive physical examination is performed. Licensed practical nurses/licensed vocational nurses (LPN/LVNs) generally do not conduct invasive examinations on the eye, but rather assist the advanced practitioner in conducting this portion of data collection.

Subjective Data

The nurse interviews patients and collects data about family history that may affect vision, particularly glaucoma, diabetes, blindness, and cataracts. Because many eye disorders are genetically transmitted, this information alerts the nurse to possible alterations in eye health. Patients should be asked about their general health and the presence of diseases such as diabetes and hypertension. The nurse determines the types of medication the patient is taking to assess for any ocular (eye) effects. Last, the nurse asks the patient about any changes in visual acuity or symptoms of abnormality (Table 51.1).

Objective Data

VISUAL ACUITY. Objective data collection begins by checking the patient’s visual acuity (Table 51.2). Visual acuity is measured in a variety of ways but usually starts with the use of **Snellen’s chart**, E chart, or hand-held visual acuity chart (Rosenbaum’s card) to test near and far vision. Snellen’s chart is imprinted with alphabetical letters graduating in size from the smallest on the bottom to the largest on the top (Fig. 51.3). The examiner measures 20 feet and marks the distance on the floor. The examiner then asks the patient to cover one eye with a 3 × 5 card or eye cover

and then read out loud an indicated line of letters. The lowest line on the chart that the patient is able to read accurately is used to indicate visual acuity for that eye. Normal vision is 20/20, which means the patient can read at 20 feet what the normal eye can read at 20 feet. Visual impairment occurs at 20/70 and legal blindness at 20/200 or more with correction. An example of findings is the patient who identifies all the letters correctly on the line marked 30; this patient has a visual acuity of 20/30. This means that the patient can see at 20 feet what the average individual can see at 30 feet. The examination is conducted on both eyes separately, then together, and documented as follows: “oculus dexter (OD) [right eye] 20/30, oculus sinister (OS) [left eye] 20/20, oculus uterque (OU) [both eyes] 20/20.” In addition to identifying the eye tested, the examiner conducts the examination with and without the patient’s corrective lenses, if applicable. When corrective lenses are used, documentation reflects this as “OD 20/100 without correction, OD 20/20 with correction.” The E chart is used for patients who are illiterate. The patient is asked to indicate the direction of the E-shaped figure. The hand-held visual acuity chart is used to indicate visual acuity by having the patient hold the card approximately 14 inches from the eyes. The test is conducted and documented in the same way as the Snellen’s and E chart examinations.

Visual Fields by Confrontation. The examiner also tests peripheral vision, which is the ability of the eye to see objects peripherally while the eye is fixed or kept in one position. This is also known as testing visual fields by confrontation. To do this, the examiner compares his or her

TABLE 51.1 SUBJECTIVE ASSESSMENT OF THE EYE

Category	Questions to Ask During History Assessment	Rationale/Significance
<i>Family History</i>	Do you have any family members with a history of diabetes? Hypertension? Cataracts? Glaucoma? Blindness? Diabetes mellitus? Do any family members wear glasses or contact lenses? Is their vision corrected with the lens?	Many eye disorders are genetically transmitted.
<i>Patient’s General Health</i>	How would you describe your general health? What health problems do you currently have? How are they treated? What health problems have you had in the past? Have you ever had trauma to your eyes? What medications do you take? How often do you have eye examinations? When was the last time you had an eye examination?	Some metabolic disorders are precursors to eye disorders, such as diabetes and hypertension. Assess for ocular effects of systemic medications. Assess preventative practices.
<i>Visual Acuity</i>	Do you wear glasses or contact lenses? Have you had any changes in vision such as difficulty seeing distances, difficulty seeing close up, difficulty seeing at night? Do you see things double? Do you have clouded vision? Do you see halos around lights? Does it look like you are looking through a veil or web? Is there sensitivity to light? Is there pain? Itching? Tearing? Burning? Do you have headaches? If so, what are the precipitating events?	Any of these signs and symptoms could indicate visual disorders/disturbances.

TABLE 51.2 OBJECTIVE ASSESSMENT OF THE EYE

Category	Physical Assessment Findings	Possible Abnormal Findings/Causes
Visual Acuity	Normal vision is 20/20	Hyperopia, myopia, presbyopia, blurred or cloudy vision Possible causes: refractive error, opacity, or disorder of pathway
Visual Fields	Full peripheral fields	Peripheral field loss
Muscle Balance and Eye Movement	Movement in all six cardinal fields of gaze Corneal light reflex test—light is at the same place on both pupils Cover test—steady gaze	Nystagmus Inability to move in all six fields can indicate cranial nerve impairment Asymmetry could mean muscle weakness Drifting eye indicates muscle weakness
Pupillary Reflexes	Pupillary light reflex Accommodation	Dilated, fixed, or constricted pupils Absence of constriction or convergence
External Structures	Inspection and palpation of eyebrows, orbital area, eyelids, palpebral fissure, medial canthus, irises, corneal clarity, anterior chamber	Ptosis (drooping of eyelid) usually indicates nerve dysfunction Opaque whitening of outer rim of cornea can indicate arcus senilis Corneal opaqueness can be from cataract or trauma

own ability to see peripheral objects with that of the patient. This test should be done with an examiner who has normal peripheral vision. The examiner stands 2 feet in front of the patient and instructs the patient to cover one eye. The examiner covers his or her own corresponding eye (e.g., if the patient's right eye is covered, the examiner's left eye is covered). The examiner uses the arm opposite the covered eye, extends it to the space midway between the patient and the examiner, and brings it toward the eye from three directions: superior, inferior, and temporal (middle). The examiner wiggles the finger while moving the arm. The examiner asks the patient to look straight ahead and indicate at what point he or she is able to see the examiner's finger. One eye is tested and then the other. The patient has full visual fields if the point at which the patient sees the finger matches that of the examiner. The examiner documents the

results as “visual fields equal to examiner,” “full visual fields,” or, if abnormal, “visual fields unequal to examiner in. . .” (identify position, e.g., left superior).

MUSCLE BALANCE AND EYE MOVEMENT. The examiner tests extraocular muscle balance and cranial nerve function by instructing the patient to look straight ahead and follow the examiner's finger movement without moving his or her head. As with the confrontation test, the patient and examiner face each other either standing or sitting. The examiner moves his or her finger in the six cardinal fields of gaze, coming back to the point of origin between each field of gaze (Fig. 51.4). If the patient's eyes are able to follow the examiner's finger in all fields of gaze without nystagmus, the patient is assessed to have adequate extraocular muscle strength and innervation. Nystagmus is an involuntary, cyclical, rapid movement of the eyes in response to vertical, horizontal, or rotary movement.

The corneal light reflex test is used to assess muscle balance. This test is conducted by shining a penlight toward the cornea while the patient is staring at an object straight ahead. The light reflection should be at exactly the same place on both pupils. If the eyes lack symmetry, muscle weakness could be present.

FIGURE 51.3 Using Snellen's chart to assess visual acuity.

FIGURE 51.4 Six cardinal fields of gaze.

The cover test is used in conjunction with an abnormal corneal light reflex test to evaluate muscle balance. The patient is asked to look straight ahead at a far object. The examiner covers one of the patient's eyes with a 3 × 5 card. The uncovered eye should have a steady gaze; if it moves, there may be muscle weakness. Next, the cover is quickly removed and the action of this eye is observed. If this eye moves to fixate on the light instead of staring straight ahead, it indicates a drifting of the eye when it was covered, which is a sign of muscle weakness. This deviation of the eye away from the visual axis is known as **tropia**. Deviation of the eye toward the nose is known as **esotropia**, movement laterally is known as **exotropia**, and downward deviation is hypotropia.

PUPILLARY REFLEXES. The pupils are observed. They should be round, symmetrical, and reactive to light. To test pupillary response to light, both consensual and direct examinations should be completed. A slightly darkened room works best. The patient is asked to look straight ahead, and the size of the pupil is noted. A penlight is shone toward the pupil from a lateral position, and the movement of the pupil is observed. The pupil should quickly constrict. The

esotropia: eso—inward + tropia—movement of the eye

exotropia: exo—out + tropia—movement of the eye

size of the pupil is noted when it constricts. This is known as direct response.

To conduct a consensual pupil examination, observe the eye just tested for reaction while shining the penlight into the other eye. The observed pupil should constrict. This is known as **consensual response**. Repeat the procedure for the opposite eye.

The examiner now proceeds to test for **accommodation**. Accommodation is the ability of the pupil to respond to near and far distances. The patient is told to focus on an object far away. The size and shape of the pupils are observed. The examiner continues to observe the pupils as the patient focuses on a near object (the examiner's penlight or finger) held approximately 5 inches from the patient's face. Normally, the patient's eyes turn inward and the pupils constrict. These responses, convergence and constriction, are called accommodation (Box 51.1 Gerontological Issues). Examiners use the acronym PERRLA to indicate pupils equal, round, reactive to light, accommodation. If accommodation is not tested along with the other tests, the examiner may use the acronym PERRL.

INSPECTION AND PALPATION OF EXTERNAL STRUCTURES. The extraocular structures are inspected beginning with the eyebrows. The presence of eyebrows,

Box 51.1

Gerontological Issues

Age-Related Changes in Vision and Hearing

Vision

Older adults commonly have the following changes in their vision:

- Presbyopia, an inability to focus up close because of decreased elasticity in the ocular lens
- Narrowing of the visual field and more difficulty with peripheral vision
- Decreased pupil size and responsiveness to light
- Difficulty with vision in dimly lit areas or at night (requires more light to see adequately)
- Increased opacity of the lens, which causes sensitivity to glare, blurred vision, and interference with night vision
- Yellowing of the lens, which makes the person less able to differentiate low-tone colors of blues, greens, and violets (yellow, orange, and red hues are more clearly visible)
- Distorted depth perception and difficulty correctly judging the height of curbs and steps
- Decreased lacrimal secretions

Because visual accommodation is decreased with aging, older adults have an increased risk of falling. An older person has difficulty making a visual adjustment when moving from a well-lit room into the evening dark-

ness, for example, or when stepping out of a dark area into the sunlight.

The increased time needed to accommodate to near and far and dark and light is often the reason that older adults do not drive at night. Usually they complain that the light from oncoming traffic blinds them or that their eyes do not focus properly.

One of the most simple and effective ways to improve vision for older adults is to assure that eye glasses are clean.

Hearing

Presbycusis is an age-related change in which progressive hearing loss is caused by loss of hair cells and decreased blood supplying the ear, resulting in a decreased ability to hear high-frequency sounds. Deafness or decreased hearing acuity is one of the main reasons that older adults withdraw from social activities. The loss of high-pitched hearing causes the older adult to hear distracting background noises more clearly than conversation.

Older adults who are deaf may require adaptive equipment in their home for safety. The use of a hearing aid can increase hearing for those who do not have nerve damage deafness. The use of flashing lights instead of buzzers or alarms increases the safety of an older adult who is not able to hear a smoke detector or fire alarm.

symmetry, hair texture, size, and extension of the brow are noted. The examiner inspects and palpates the orbital area for edema, lesions, puffiness, and tenderness. Then the eyelids are inspected for symmetry, presence of eyelashes, eyelash position, tremors, flakiness, redness, and swelling. The patient is asked to open and close the eyelids. When open, the eyelid should cover the iris margin but not the pupil. The distance between the upper and lower eyelid, known as the palpebral fissure, is inspected; it should be equal in both eyes. If the palpebral fissure is nonsymmetrical, observe for ptosis, a drooping of the eyelid, which is commonly seen in stroke patients. Next the medial canthus of the lower lid is gently palpated and observed for exudate. The eyelids are palpated for nodules while the eye is palpated for firmness over the closed eyelid.

The lower eyelid is pulled down, and the patient is asked to look upward. The conjunctiva and sclera are inspected for color, discharge, and pterygium (thickening of the conjunctiva). To inspect the upper eyelid, the upper lid is everted over a cotton-tipped applicator. The patient blinks to return the eyelid to its resting position when the inspection is complete.

The external eyes are inspected for color and symmetry of the irises, clarity of the cornea, and depth and clarity of the anterior chamber. Shining a light obliquely across the cornea assesses the clearness of the cornea. The cornea should be transparent without cloudiness. In individuals older than 40 years of age, there may be bilateral opaque whitening of the outer rim of the cornea known as **arcus senilis**. It is caused from lipid deposits and is considered normal. It does not affect vision. The anterior chamber (the area between the cornea and the iris) of the eye is inspected using oblique light. The anterior chamber should be clear when the light shines on it.

INTERNAL EYE EXAMINATION. Examination of the internal eye is done by the advanced practitioner. The LPN/LVN may be required to explain the procedure to the patient and to assist the practitioner in the examination. To perform the internal eye examination, specialized equipment must be used. It is useful, but not always necessary, to have the pupil dilated for the internal eye examination. Having a dark room allows the pupil to dilate, as does the application of anticholinergic mydriatic eye drops.

The instrument used to examine the internal eye is called an **ophthalmoscope**. The ophthalmoscope magnifies the structures of the eye, so the examiner can visualize the retina, optic nerve, blood vessels, and macula. The device is handheld and has a light source that is directed into the patient's internal eye. The patient should be instructed to hold the head still with the eyes focused on a distant object. The patient should be notified that the bright light might be uncomfortable. The **ophthalmologist** may examine the eye using a stationary device called a slit-lamp microscope rather than the hand-held ophthalmoscope. The patient is seated and rests the chin on a support. This examination

allows the examiner to visualize the internal eye by use of a microscope and light source directed into the eye.

Intraocular Pressure. Estimation of intraocular pressure is measured by using one of several types of tonometer. Often, the procedure is performed with anesthetic drops being instilled. One type of tonometer testing uses a puff of air to make an indentation in the cornea to measure intraocular pressure. Readings above the normal range may indicate glaucoma.

Diagnostic Tests

CULTURE. If there is exudate from any portion of the eye or surrounding structure, a culture may be ordered. Results of the culture determine if anti-infective treatment is necessary.

FLUORESCIN ANGIOGRAPHY. Fluorescein angiography is a procedure used to monitor, diagnose, and treat eye diseases. The patient is assessed for dye allergies before the procedure. Then the pupil is dilated and fluorescence dye is injected into the patient's venous system. The dye travels to the retinal arteriovenous circulation, and the eye is examined via a slit-lamp microscope. The blood vessels in the eye are extremely visible with the addition of the dye.

ELECTRORETINOGRAPHY. Electoretinography is useful in diagnosing diseases of the rods and cones of the eye. The procedure evaluates differences in the electrical potential between the cornea and retina in response to light wavelengths and intensity. The test is conducted by placing contact lenses with electrodes directly on the eye.

ULTRASONOGRAPHY. Ultrasound is useful as an examination tool when the internal eye cannot be visualized directly because of obstructions such as corneal opacities or bloody vitreous. The eye is anesthetized with instillation of anesthetic drops, and a transducer probe is placed on the eye to perform the ultrasound. Patients should be instructed to keep the eye and head still during the procedure.

RADIOLOGICAL TESTS. Several radiological examinations are used to assess eye health. X-ray films are used to view bone structure and tumors. Computed tomography (CT) and magnetic resonance imaging (MRI) are used to visualize ocular structures and abnormalities of the eye and surrounding tissues.

Therapeutic Interventions

Nurses have an important role in educating individuals, families, and the community about the care of healthy eyes. Nurses often have the opportunity to screen and educate people about the prevention of disease and impairment. To learn more about ways to promote vision health, visit www.lighthouse.org. For resources to help those persons who are blind, visit the American Foundation for the Blind at www.afb.org or the National Federation of the Blind at www.nfb.org.

Regular Eye Examinations

Regular eye examinations should be encouraged. Individuals who are not known to have visual deficits and do not have diseases associated with visual loss such as diabetes should have their eyes examined at regular intervals throughout their life. Screening tests are usually done during an annual physical examination to detect gross visual deficits. Patients who wear corrective lenses or have disease processes that place them at risk for visual loss should have their eyes examined by an eye care provider at least yearly.

Eye care providers include the **ophthalmologist** and **optometrist**. An ophthalmologist is a physician who specializes in the comprehensive care of the eyes and visual system, including diagnosing and treating eye diseases. An optometrist is a health-care provider who specializes in visual examinations, diagnosis, and treatment of visual problems, such as prescribing lenses. The optometrist is not a physician but is identified as a doctor of optometry. An **optician** is a person trained to grind and fit lenses according to prescriptions written by the ophthalmologist or optometrist.

Eye Hygiene

Individuals should be careful to keep debris out of their eyes to prevent scratching of the eye's delicate surfaces. When a foreign object gets into the eye, such as dirt or an eyelash, the individual should be taught not to rub the eye but to allow tears to wash out the object. This can be done by pulling the eyelid down over the eye for a brief time. When wiping the eyes, the nurse should wipe from the inner canthus to the outer canthus.

Nutrition for Eye Health

Adequate nutrition is important not only for the whole body but for the eye as well (Box 51.2 Nutrition Notes). Eye disorders related to inadequate vitamin intake include corneal damage and night blindness from lack of vitamin A and optic neuritis as a result of vitamin B deficiency.

Eye Safety and Prevention of Injury

Many people in the United States suffer eye injuries each year. Common household activities are responsible for the majority of injuries. Activities such as microwave cooking, lawn care, and shooting rubber bands and BB guns all contribute to eye injury. Many of these injuries could be prevented with education and implementation of safety measures (Table 51.3).

Eye Irrigation

It is sometimes necessary to irrigate foreign bodies or chemical substances out of the eye. The nurse prepares the patient by explaining the procedure. Usually an isotonic solution is used to irrigate the eye. The solution is delivered using IV tubing or a Morgan lens. Refer to Box 51.3 (Eye Irrigation) and Figure 51.5.

Medication Administration

A variety of drugs are available for eye application. Most of the drugs are applied as drops, ointments, or irrigations. The

nurse must know the usual dosage and strength, desired action, side effects, and contraindications of the medication being administered to prevent harm to the patient. Systemic adverse reactions can occur and medical diseases can be exacerbated from the administration of eye medications. The elderly are especially susceptible to this because they have more chronic diseases, as well as long-term use of ophthalmic agents. These agents can interact with other med-

Box 51.2

Nutrition Notes

Interpreting the Role of Antioxidants in Eye Disease

In developing countries, vitamin A deficiency is a leading cause of blindness. In developed countries, antioxidants have been investigated in relation to macular degeneration and cataracts, two conditions that can also lead to severely impaired vision.

Macular Degeneration

High-dose vitamins C and E, beta carotene, and zinc over an average of 6.3 years of follow-up resulted in a 27% reduction in the risk of advanced age-related macular degeneration (ARM). Such a protocol was recommended to ophthalmologists for certain patients.¹ In addition, observational studies have linked high intakes of foods rich in the carotenoids, lutein, and zeaxanthin, such as spinach, broccoli, and eggs with a 40% reduction in risk of ARM.²

Cataracts

The effect of antioxidants on cataract development is less clear. High doses of vitamins C and E and beta carotene had no apparent effect on cataract development or progression in relatively well-nourished older adults over 6.3 years' time,³ but a 60% reduction in risk of cataract was found in women who used vitamin C supplements for 10 years or more.⁴

Recommendations

Because there are other risk factors for both eye diseases and because whole foods contain many components besides antioxidant vitamins, many researchers conclude by recommending diets rich in fruits and vegetables to prevent disease and also note that health-conscious individuals who take vitamin supplements often also consume nutrient-dense diets. If a person chooses to take supplements, a multivitamin and multi-mineral product at Recommended Dietary Allowance levels is advocated rather than separate preparations of individual nutrients.

TABLE 51.3 EYE SAFETY AND INJURY PREVENTION

To Protect From	Use These Eye Safety Measures
Foreign objects	Wear safety goggles. Avoid mowing over rocks or sticks.
Chemical splashes	Always wear safety goggles when using lawn edging yard devices. Use splash shields when working with chemicals such as cleaning solution or body fluids.
Corneal lens abrasions/infections from contact lenses	Close eyes to avoid getting hair spray in them. Follow manufacturer's or eye care professional's directions for length of use and cleaning procedures. Do not overwear lenses.
Ultraviolet light (UV)	Wear UV-protected sunglasses when outdoors. Instruct patients to wear sunglasses with side shields after administration of mydriatics.
Visual deficits in adult with corrective lenses	Wear a hat to shield sun. Update prescription of glasses yearly. Glasses should fit properly, be clean, and be free of scratches.
Eye strain from computer usage	The position of the bottom of the monitor should be 20 degrees below the line of sight and should be positioned 13 to 18 inches from the eyes. The light in the room should prevent glare. Increase the font size on the screen if letters appear too small. If dry eyes are a problem while using a computer, adjust the monitor to a lower level so the eyes do not have to open as wide, which increases evaporation.
Eye injury from sports	Wear protective eye wear with polycarbonate lenses. Wear facemasks or helmets while participating in any high-contact or high-impact sports.

ications the patient is taking. The nurse needs to observe patients for possible reactions.

Chapter 52 discusses specific ophthalmic medications and their uses. To identify the steps in the application of eye medications, see Boxes 51.4 (Administration of Eye Drops) and 51.5 (Administration of Eye Ointments). Whenever eye medications, especially eye drops, are administered, the punctum (tear duct) of the eye should have pressure applied to it by either the nurse wearing gloves or the patient if able for at least 1 minute. This reduces systemic absorption of the medication via the punctum. Some eye medications can have serious cardiac or respiratory effects, and patients have had life-threatening reactions to them. The nurse should educate the patient on the proper instillation of eye medications to reduce these reactions.

LEARNING TIP

Older patients, when instilling their own eye drops, may not feel the drops go in. Teaching patients to refrigerate the drops, if not contraindicated, for 15 to 30 minutes before instillation helps them feel if the drops go into the eye or on the face.

EYE PATCHING. After treating an injured or infected eye, the physician may order the eye to be patched. The nurse applies ointment or drops if ordered, requests that the patient keep the eyelid shut, and then places a disposable, cotton gauze eye patch over the depression of the eye socket. If the

Box 51.3

Eye Irrigation

1. Explain the procedure to the patient.
2. Wash hands.
3. Gather equipment. For low-volume irrigation, a prefilled squeezable bottle is used. For large-volume irrigation, an intravenous (IV) bag of isotonic solution such as normal saline or lactated Ringer's is used. Attach IV tubing to the bag and flush the line.
4. Apply anesthetic drops, if ordered.
5. Place a basin by the side of the patient's head and pad the area with towels to absorb irrigant.
6. Apply gloves.
7. The eye may be irrigated by holding the distal end of the IV tubing at the inner canthus of the eye, or a Morgan lens may be attached. (See Fig. 51.5.) The lens is placed directly on the anesthetized eye, and the tubing is connected to the IV bag tubing. Proceed with irrigation using a slow, steady stream of irrigant. Generally, use of the lens is more comfortable for patients because the eyelids do not need to be held open.
8. Assess patient's tolerance to the procedure.
9. Remove Morgan lens.
10. Remove gloves. Wash hands.
11. Document assessment, type and amount of irrigant, and patient's tolerance to the procedure.

FIGURE 51.5 (A) Morgan lens is used for eye irrigation. (B) Irrigation of eye.

patient has a deep eye socket, the nurse may need to place two pads over the socket to assist the eyelids to remain closed. The purpose of eye patching is to protect the eye from further damage by keeping the lids closed. Sometimes

Box 51.4

Administration of Eye Drops

1. Explain procedure to the patient.
2. Check medication for dosage, strength, side effects, contraindications, and expiration date.
3. Wash hands and apply gloves.
4. Instruct patient to tilt head backward and look up toward the ceiling.
5. Gently pull the lower lid down and out. This forms a pocket to catch the eye drop.
6. Approach the patient's eye from the side and instill the prescribed amount of medication into the pocket. Be careful to avoid touching the patient's eye or surrounding structure with the tip of the dropper. It is helpful for the nurse and the patient who is self-administering eye drops to use the forehead as a stabilizing area for the hand administering the drop.
7. Release the lower eyelid.
8. Gently apply pressure with a tissue to the punctum (over the tear duct) for at least 1 minute to prevent the medication from being systemically absorbed. The nurse or patient can do this.
9. Wipe any excess medication off of the eyelids or cheek.
10. Remove gloves. Wash hands.
11. Document medication administration and the patient's tolerance to the procedure.

Box 51.5

Administration of Eye Ointments

1. Explain procedure to the patient.
2. Check medication for dosage, strength, side effects, contraindications, and expiration date.
3. Wash hands and apply gloves.
4. Instruct patient to tilt head backward and look up toward the ceiling.
5. Gently pull the lower lid down. This forms a pocket into which the ointment is placed.
6. Express the ointment directly into the exposed palpebral conjunctiva in the direction of inner to outer canthus. Be careful to avoid touching the patient's eye or surrounding structure with the tip of the ointment tube.
7. Release the lower eyelid over the ointment.
8. Instruct the patient to gently close the eyes.
9. Remove gloves. Wash hands.
10. Instruct the patient that vision may be blurred while the ointment is in the eye.
11. Document medication administration and the patient's tolerance to procedure.

an additional metal shield is placed over the soft pads to protect the eye from external injury. The patch is taped in place and the patient instructed to rest the eyes. The nurse should suggest quiet activities to the patient such as listening to music or an audiotaped book or sleeping. Watching television or reading is not recommended because the patched eye follows the movement of the unpatched eye.

HEARING

Normal Anatomy and Physiology of the Ear

The ear consists of three areas: the outer ear, the middle ear, and the inner ear (Fig. 51.6). The inner ear contains the receptors for the senses of hearing and equilibrium.

Outer Ear

The outer ear consists of the auricle (or pinna) and the ear canal. The auricle is made of cartilage covered with skin. The ear canal is a tunnel into the temporal bone that curves slightly forward and downward. The canal is lined with skin that contains ceruminous glands. Cerumen, or earwax, is the secretion that keeps the eardrum pliable and traps dust.

Middle Ear

The middle ear is an air-filled cavity in the temporal bone. The eardrum (or tympanic membrane) is stretched across the end of the ear canal and vibrates when sound waves strike it. These vibrations are transmitted through the three auditory bones—the malleus, incus, and stapes. The stapes

FIGURE 51.6 The ear in frontal section through the right temporal bone. (From Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed. 5. F.A. Davis, Philadelphia, 2007.)

then transmits vibrations to the fluid-filled inner ear at the oval window.

The eustachian tube (or auditory tube) extends from the middle ear to the nasopharynx and permits air to enter or leave the middle ear cavity. The air pressure in the middle ear must be the same as the external atmospheric pressure for the eardrum to vibrate properly. Swallowing or yawning opens the eustachian tubes and permits equalization of these pressures.

Inner Ear

The inner ear is a cavity in the temporal bone called the bony labyrinth, lined with membrane called the membranous labyrinth. The fluid between bone and membrane is called perilymph, and that within the membrane is called endolymph. These membranous structures are the cochlear ducts, which are concerned with hearing, and the utricle, saccule, and semicircular ducts, which are all concerned with equilibrium.

The cochlea is shaped like a snail shell and is partitioned internally into three fluid-filled canals. The medial canal is the cochlear duct, which contains the receptors for hearing in the organ of Corti (spiral organ). The receptors are called hair cells (their projections are stereocilia), which contain endings of the cochlear branch of the eighth cranial nerve. A membrane called the tectorial membrane hangs over the hair cells.

The process of hearing involves the transmission of vibrations and the generation of nerve impulses. When sound waves enter the ear canal, vibrations are transmitted by the following structures: eardrum, malleus, incus, stapes,

oval window of the inner ear, perilymph and endolymph within the cochlea, and hair cells of the organ of Corti. When the hair cells bend, they generate impulses that are carried by the eighth cranial nerve to the brain. The auditory areas, for both hearing and interpretation, are in the temporal lobes of the cerebral cortex.

The utricle and saccule are membranous sacs between the cochlea and semicircular canals. Each contains a patch of hair cells embedded in a gelatinous structure that contains otoliths, small crystals of calcium carbonate. The hair cells bend in response to the pull of gravity on the otoliths as the position of the head changes. The impulses generated are carried by the vestibular branch of the eighth cranial nerve to the cerebellum, medulla, and pons. The cerebellum sends this information continuously to the cerebral motor cortex. The cerebellum and brainstem use this information to maintain equilibrium at a subconscious level; the cerebrum provides a conscious awareness of the position of the head.

The three semicircular canals are fluid-filled membranous ovals oriented in three planes. At the base of each is an enlarged portion called the ampulla, which contains hair cells (the cristae) that are affected by movement. As the body moves forward, for example, the hair cells at first bend backward. The bending of the hair cells generates impulses carried by the vestibular branch of the eighth cranial nerve to the cerebellum and brainstem; and then impulses continue on to the cerebral motor cortex. These impulses are interpreted as starting or stopping, turning, or changing speeds, and this information is used to maintain equilibrium while a person is moving.

Aging and the Ear

In the ear, cumulative damage to the hair cells in the organ of Corti usually becomes apparent sometime after the age of 60 (see Fig. 51.2). Hair cells that have been damaged by a lifetime of noise cannot be replaced. Sounds in high-pitched ranges are usually those lost first (presbycusis), whereas hearing may still be adequate for lower pitched ranges. The high-pitched sounds *f*, *s*, *k*, and *sh* are usually lost first. It becomes more difficult to filter out background noises, so noisy environments make it difficult to hear conversations.

LEARNING TIP

Presbycusis is the loss of hearing high-pitched sounds (pitch = cycles per second; loudness = decibels [dB]). Because the ability to hear pitch is lost rather than loudness, it is not helpful to talk louder to a patient with this type of hearing loss. In fact, talking louder can make it more difficult to discriminate sounds. It is important to know the type of hearing loss a patient has.

Nursing Assessment/Data Collection of the Ear and Hearing Status

A nursing assessment of the ear includes obtaining the patient's health history and performing a physical examination. A complete nursing assessment is conducted on admission. Provide privacy and make the patient as comfortable as possible before beginning the nursing assessment. A quiet environment is helpful for an accurate assessment of hearing. During the initial assessment, observe the patient's behavior and note any information the patient shares.

Subjective Data

To understand the patient's ear disorder, perform a focused health history. Use knowledge of pathophysiology to guide questions in an appropriate and complete manner. Assessment of symptoms includes asking the WHAT'S UP? questions: where it is, how it feels, aggravating and alleviating factors, timing, severity, useful data for associated symptoms, and perception of the problem by the patient.

HEALTH HISTORY. Obtaining the patient's self-appraisal of his or her hearing or related symptoms is completed during the health history. You should also gather information about medications, surgeries, treatments, allergies, and habits. The health history helps in formulating the nursing care plan.

Symptoms and complaints related to the ear include decreased or loss of hearing, **otorrhea** (discharge), **otalgia** (ear pain), itching, fullness, tinnitus (ringing, buzzing, or roaring in the ears), or vertigo (dizziness). If any of these

symptoms or complaints is positive, explore the symptoms in more detail using the WHAT'S UP? format. Record all the information accurately and completely.

Other information about the patient's medical history, including previous ear problems and use of **hearing aids** or assistive hearing devices, is obtained. You should also ask about any surgeries, allergies, recent upper respiratory infections, history of infections, injury to the ear, hospitalizations, swimming habits, exposure to pressure changes (flying or diving), medical diseases, and exposure to any loud noises. Positive findings should be assessed using the WHAT'S UP? format and results recorded.

Information about current and past medications should be obtained. Many medications are potentially toxic to the ear and can cause hearing loss or decreased hearing. Pay particular attention to any exposure to medications that are potentially **ototoxic**, such as certain antibiotics or diuretics. (See Chapter 52.)

Family history related to ear disorders includes any hearing problems or hearing loss and family members with Ménière's disease. Significant findings are recorded, including the relationship of the family member with the problem to the patient.

Information about the patient's care of the ears is also gathered. It is important to assess what preventive measures the patient practices and what the patient's learning needs are concerning care and protection of the ears. Determine how the patient cleans the ears, any exposure to loud noises during recreational activities or during work activities, any changes in ability to hear, and any exposure to ototoxic medications. You should determine if the patient has had a hearing evaluation and if there is a history of ear problems. Instruct the patient in ways to care for the ears and maintain ear health (Table 51.4).

Objective Data

Physical data collection of the ear begins by observing the behaviors of the patient. Note how the patient communicates. Observe how the patient talks, noting any slurred speech or words. See Box 51.6 Behaviors Indicating Hearing Loss. Examination of the ear includes inspection, palpation, testing auditory acuity, and, for the advanced practitioner, otoscopic examination (Table 51.5).

INSPECTION AND PALPATION OF THE EXTERNAL EAR.

Inspection of the external ear begins with examining the auricle. A penlight or otoscope may be used to improve visualization of the external ear. The external ear should be inspected for size, symmetry, configuration, and angle of attachment. Note any obvious deformities or scars. The skin should be smooth and without breaks, particularly behind the ear in the crevice. The color should be uniform, without signs of inflammation. To inspect the external ear canal, tip the adult patient's head to the side and use a penlight or otoscope to inspect the canal. Note any drainage or cerumen (wax), including the color, odor, and clarity of the drainage.

otorrhea: oto—related to the ear + rhea—to flow

otalgia: ot—related to the ear + algia—signifying pain

ototoxic: oto—related to the ear + toxic—poison

TABLE 51.4 SUBJECTIVE ASSESSMENT OF THE EAR

Category	Questions to Ask During History Assessment	Rationale/Significance
Family History	Has any family member had any hearing problems or loss? Has any family member had Ménière's disease?	This may give information about the patient's current ear problem.
Patient Health History	What medications are you currently taking? Have you had any surgeries or trauma to the ear? Do you have any allergies to food, medications or other substances? Have you had any recent upper respiratory infections? Do you have a history of upper respiratory infections or ear infections? Do you have any discharge from the ear (otorrhea), ear pain (otalgia), itching, fullness, tinnitus or vertigo? Do you have a fever, nausea, or vomiting? Are you exposed to pressure changes such as with flying or diving?	Many medications are ototoxic and can cause hearing loss (see Chapter 52) Recent trauma or surgeries can affect hearing. Can cause nasal congestion leading to middle ear congestion and/or infections. May indicate outer, middle or inner ear infections. May indicate ototoxicity or other ear diseases. Barotrauma may occur due to pressure changes.
Hearing Impairment	Have you noticed any hearing loss? If so, has it been gradual or sudden? Do you have difficulty understanding certain words or entire conversations? Do you have difficulty hearing when there is a lot of background noise? Do you hear better out of one ear versus the other? Have your friends or family commented on your decreased hearing? Do you wear a hearing aid or other assistive device? If so, what is the device and for which ear is it used? How does your hearing loss affect your daily life? Do you feel embarrassed or frustrated because of your hearing loss? How do your friends and family react to your hearing loss? Are you exposed to loud noises, such as with your current or past job, busy traffic, machinery or loud music?	Could indicate hearing loss and further assessment is needed.
Self-Care Behaviors	Have you had your hearing checked? If so, when? How do you clean your ears? How do you protect your ears from loud noises?	Patient may already have hearing loss in one or both ears. Hearing loss can cause social isolation. Can cause damage to the ear leading to hearing loss over time. Provides information about patient's ear self-care and health.

Box 51.6**Behaviors Indicating Hearing Loss**

Adults with hearing loss may display any or all of the following behaviors:

- Turns up the volume on the television or radio
- Frequently asks, "What did you say?"
- Leans forward or turns head to one side during conversations to hear better
- Cups hand around ear during conversation
- Complains of people talking softly or mumbling
- Speaks in an unusually quiet or loud voice
- Answers questions inappropriately or not at all
- Has difficulty hearing high-frequency consonants
- Avoids group activities
- Shows loss of sense of humor
- Face looks strained or serious during conversations
- Appears to ignore people or aloof, does not participate
- Is irritable or sensitive in interpersonal relations
- Complains of ringing, buzzing, or roaring noise in the ears

The skin should be smooth and without inflammation, edema, or breaks. There should be no lesions, foreign bodies, erythema, or edema observed within the external ear canal. Inspection of the external ear canal should be completed before obtaining an infrared ear temperature because the presence of cerumen can alter the accuracy of the reading.

Next the auricles are palpated and any tophi, lesions, or masses are noted. Tophi are deposits of uric acid crystals that appear as small, hard nodules in the helix (external ear margin); they may also occur in gout. The auricle should be nontender when it is palpated; tenderness can indicate an external ear infection. A downward protrusion of the helix, called Darwin's tubercle, is a normal finding. The mastoid process should be smooth and hard when palpated. The mastoid process can be of different sizes but should not be tender or swollen.

AUDITORY ACUITY TESTING. Auditory function can be grossly evaluated using three different assessment tests. The whisper voice test is one test to check hearing function in each ear. The patient occludes one ear with a finger, and the nurse stands 1 to 2 feet away on the opposite side. The nurse whispers two-syllable words toward the unoccluded ear. The

TABLE 51.5 OBJECTIVE ASSESSMENT OF THE EAR

Category	Physical Assessment Findings	Possible Abnormal Findings/Causes
<i>Inspection and Palpation of the External Ear</i>	Ears should be symmetrical in size, configuration, and angle of attachment. Skin covering the ear should be intact, smooth, and without edema, erythema, or inflammation. Canal should have minimal or no cerumen. No lesions, tophi, or masses should be palpated. No tenderness of auricle when palpated. No odor detected.	Asymmetrical size and placement could indicate congenital deformities. Discharge, breaks in skin, or inflammation can be caused by trauma, external ear infections, poorly fitting hearing aid or skin disorders. Excessive cerumen may be found. This can alter hearing and cause inaccurate tympanic temperature readings. Excess cerumen may need to be removed. Tophi may be present in the patient with gout. Tenderness could indicate an external ear infection.
<i>Auditory Acuity Testing</i>	Patient able to hear whispered words at 1–2 feet away. Rinne’s and Weber’s tests normal (see Table 51.7). Able to understand and converse with examiner.	Patient may have indications of conductive or sensorineural hearing loss.
<i>Balance Testing</i>	Patient is able to sit and walk without difficulty. Patient able to complete Romberg’s test with minimal swaying.	Difficulty sitting and/or walking; increased swaying or falling with Romberg’s test due to balance difficulties. May be due to inner ear infection or disorder.
<i>Otoscopic Examination</i>	Ear canal should be smooth and empty without redness, scaliness, swelling, drainage, excessive cerumen, or foreign objects. Internal otoscope examination is completed by experienced practitioner and should reveal a slightly conical, shiny, smooth, pearly gray eardrum.	Ear canal may be reddened and swollen; drainage may be present; excessive cerumen or foreign object may be present. Caused by infection, improper care, or excessive cerumen production. Eardrum may be dull, bulging or retracted, reddened caused by middle ear infection or blockage.

patient restates the whispered words. The nurse should be by the patient’s side to prevent the patient from lip reading. The nurse’s voice can be increased from a soft, medium, or loud whisper to a soft, medium, or loud voice. The process is repeated on the other ear. The patient is asked if hearing is better in one ear than in the other ear. The patient should be able to hear a soft whisper equally well in both ears. Findings of one ear hearing better than the other or an inability to hear a soft whisper can be indicative of hearing impairment. Results of the test are documented.

A second acuity test is the **Rinne test**. This test is performed with a tuning fork and is useful for differentiating between conductive and sensorineural hearing loss. To per-

form the test, strike the tuning fork and place it on the patient’s mastoid process (Fig. 51.7). Verify that the patient is able to hear the tuning fork and then instruct the patient to say immediately when the sound is no longer heard. When the patient indicates that the sound is not heard, place the vibrating tuning fork 2 inches in front of the ear. (See Fig. 51.7.) Ask the patient if he or she hears the tuning fork and then to indicate when the sound is no longer heard. Normally, air conduction (AC) is heard twice as long as bone conduction (BC). The patient reports this by hearing the tuning fork when placed in front of the ear (AC) after no longer hearing the tuning fork placed on the mastoid process (BC). Normal results are recorded as “AC > BC” (air conduction

FIGURE 51.7 Rinne test. (A) Bone conduction. (B) Air conduction.

is greater than bone conduction). The test is repeated on the other ear and findings recorded. Abnormal findings can indicate conduction or sensorineural problems (Table 51.6).

The **Weber test** is a third test to assess hearing acuity. The Weber test is also performed using a tuning fork. Place the vibrating tuning fork on the center of the patient's forehead or head (Fig. 51.8). Verify that the patient can hear the tuning fork. Then, with a positive answer, ask the patient if he or she hears the sound better in the left ear, better in the right ear, or the same in both ears. It is important to give the patient three choices from which to choose. Normally, the patient hears the sound the same in both ears (see Table 51.6).

BALANCE TESTING. When the patient complains of dizziness, nystagmus, or problems with equilibrium, simple tests can be performed to assess vestibular function. The first test is simply to observe the patient's gait by having the patient walk away from the examiner and then walk back to the examiner. Note the patient's balance, posture, and movement of arms and legs. The patient should be able to walk with an upright position with no difficulties in balance or movement.

Romberg's test, or falling test, is another simple test to assess vestibular function. Instruct the patient to stand with feet together, first with eyes open and then with eyes closed. Normally, the patient has no difficulty maintaining a standing position with only minimal swaying. If the patient has difficulty maintaining balance or loses balance (a positive Romberg's test), it can indicate an inner ear problem. If a fall appears likely, be prepared to support the patient to prevent injury.

OTOSCOPIC EXAMINATION. An otoscope is an instrument consisting of a handle, a light source, a magnifying lens, and an optional speculum for inserting in the ear. Some otoscopes have a pneumatic device for injecting air into the canal to test the eardrum's mobility and integrity. The otoscope is used to visualize the external ear, ear canal, and tympanic membrane. Otoscopic examination is completed to identify specific disorders or infections, remove wax, or remove foreign bodies. Examination of the ear canal should be completed during insertion and removal of the speculum. The ear canal should be smooth and empty. There should be no redness, scaliness, swelling, drainage, nodules, foreign objects, or excessive wax. The internal otoscopic examination is conducted to examine the eardrum and is done by the

FIGURE 51.8 Weber's test.

experienced practitioner. The eardrum should appear slightly conical, shiny, and smooth and be a pearly gray color.

Diagnostic Tests

AUDIOMETRIC TESTING. Audiometric testing is used as a screening tool to determine the type and degree of hearing loss. An audiologist conducts the hearing tests in a sound-proof booth. The audiometer produces a stimulus that consists of a musical tone, pure tone, or speech. To test air conduction, the patient is placed in the booth, wears earphones, and signals the audiologist when and if the tone is heard. Each ear is tested separately as the patient is exposed to sounds of varying frequency or pitch (hertz) and intensity (decibels). By varying the levels of the sound, a hearing level is established (Table 51.7). The use of earphones measures air conduction, level of speech hearing, and understanding of speech. During bone conduction testing, a vibrator is placed on the mastoid process and the earphones are removed. Testing proceeds as with air conduction.

A patient with normal hearing should have the same air conduction as bone conduction hearing levels. Alterations in

TABLE 51.6 AUDITORY ACUITY TUNING FORK TESTS

Test	Expected Results	Conductive Hearing Loss	Sensorineural Hearing Loss
<i>Rinne Test</i>	Air conduction heard longer than bone conduction	Bone conduction heard longer than air conduction in affected ear	Air conduction heard longer than bone conduction in affected ear (may be less than 2:1 ratio)
<i>Weber Test</i>	Tone heard in center of the head; no lateralization	Sound heard louder in affected ear	Sound heard louder in better ear

TABLE 51.7 COMMON NOISE LEVELS

Human Hearing Threshold	0–25 dB
Quiet room	30–40 dB
Conversational speech	60 dB
Heavy traffic	70 dB
Telephone	70 dB
Alarm clock	80 dB
Vacuum cleaner	80 dB
Unsafe noise levels begin	90 dB
Circular saw	100 dB
Rock music	120 dB
Jet planes	120–130 dB
Pain threshold	130 dB
Firearms	140 dB

testing air and bone conduction hearing can provide information about the location and type of hearing loss.

TYMPANOMETRY. Tympanometry is a test used to measure compliance of the tympanic membrane and differentiate problems in the middle ear. Varying amounts of pressure are applied to the tympanic membrane, and the results create a distinctive response recorded on a graph called a tympanogram. The test is useful in determining the amount of negative pressure within the middle ear. The patient is informed that the tympanometry may cause transient vertigo. The patient should report any nausea or dizziness experienced during the test.

CALORIC TEST. The caloric test is used to test the function of the eighth cranial nerve and to assess vestibular reflexes of the inner ear that control balance. The test is performed first on one ear and then the other. Warm (44.5°C [112°F]) or cold (30°C [86° F]) water is instilled into the ear canal. This stimulates the endolymph of the semicircular canals, which stimulates movement of the head. Nystagmus is a normal response. The patient may also experience dizziness. No nystagmus is seen if the patient has a disease of the labyrinth such as Ménière's disease. The test is contraindicated if the patient has a perforated tympanic membrane. Otoloscopic examination should be completed before this test to assess for excessive cerumen or perforated tympanic membrane.

ELECTRONYSTAGMOGRAM. The electronystagmogram is used to diagnose the causes of unilateral hearing loss of unknown origin, vertigo, or ringing in the ears. It is similar to the caloric test. The test is usually completed in a darkened room. Five electrodes are taped to the patient's clean face at certain positions around the eye. The electrodes measure nystagmus in response to vestibular stimulation. Measurements are taken at rest, looking at different objects, with eyes open and closed, in different positions, with water of different temperatures, and with air. Usually tranquilizers, alcohol, stimulants, and antivertigo agents are held for 1 to 5 days before the test. The patient should also avoid tobacco and caffeine on the day of the test. The test is contraindicated

in patients who have pacemakers. The patient may experience nausea, vertigo, or weakness following the test.

COMPUTED TOMOGRAPHY. A CT scan produces radiographs similar to those used in conventional radiography. A special scanner system produces cross-sectional images of anatomical structures without superimposing tissues on each other. CT is useful for visualizing the temporal and mastoid bones, the middle and inner ears, and the eustachian tube. The patient should remove hairpins and jewelry from the area of visualization.

MAGNETIC RESONANCE IMAGING. MRI produces cross-sectional images of the human anatomy through exposure to magnetic energy sources without using radiation. It is useful in differentiating between healthy and diseased tissue. The MRI allows the membranous organs, nerve, and blood vessels of the temporal bone to be examined. The test is contraindicated in patients with implanted heart valves, surgical and aneurysm clips, and internal orthopedic screws and rods. The patient should remove dental bridges and appliances, credit cards, keys, hairclips, shoes, belts, jewelry or clothing with metal fasteners, wigs, and hairpieces before entering the magnetic resonance room.

LABORATORY TESTS. Culture. Culture of drainage from the ear canal or surgical incision is important in diagnosis and treatment of acute infections. Identifying the organism responsible for the infection allows the appropriate antibiotic to be used. Often with chronic infections, the culture is less helpful because gram-negative bacilli cover up the original pathogen. Drainage from the external ear is collected using a sterile cotton-tipped or polyester-tipped swab. Samples should be taken to the laboratory immediately.

Pathological Examination. Pathological examination of tissue obtained during surgery is completed to rule out a malignancy and identify any unusual problems. A cholesteatoma (cyst of epithelial cells and cholesterol found in the middle ear) is usually documented by a pathological examination.

Therapeutic Interventions

Medications

The medications most often used to treat ear disorders include anti-infectives, anti-inflammatories, antihistamines, decongestants, cerumenolytics, and diuretics. Anti-infectives can be administered systemically or as a topical solution. Ear medications are generally in a liquid form for ease in administration as drops. Box 51.7 (Administration of Ear Drops) and Figure 51.9 guide the nurse in administering ear drops. Anti-inflammatories, antihistamines, and decongestants are used with acute infections to reduce nasal and middle ear congestion. Cerumenolytics are used to soften cerumen and remove it from the ear canal. Diuretics are used with some inner ear disorders to reduce pressure caused by fluids.

CRITICAL THINKING

Mr. Frank

■ Mr. Frank's wife expressed concern about his changing behavior during the last 6 months. She reports that Mr. Frank no longer enjoys talking to neighbors or visiting with friends in their church group, is irritable, has lost his sense of humor, and does not always answer her questions appropriately.

1. What do you suspect is happening with Mr. Frank?
2. What examination techniques or tests might you use to gather data related to Mr. Frank's signs and symptoms?
3. What would be the expected findings of these tests?
4. What teaching for these symptoms and their affect on Mr. Frank's lifestyle would be helpful?
5. What safety issues should Mr. Frank be taught to address?

Suggested answers at end of chapter.

Ear Health Maintenance

Routine cleaning and care of the ears should be taught to all patients. Patient education should include prevention of trauma, prevention of hearing loss, and early detection of hearing loss. All patients can benefit from this type of education, as found in Table 51.8.

Assistive Devices

Hearing aids are instruments that amplify sounds. (See Chapter 52.) Certain hearing aids may be designed to amplify sounds and attenuate certain portions of the sound signal. A microphone receives the sounds and converts them to electrical signals. These signals are amplified, and a receiver then converts the signal to sound. A small battery serves as the energy source. Digital hearing aids contain computers that provide clearer and crisper sound that is tai-

FIGURE 51.9 Ear drop administration.

lored to the person's hearing loss. Digital hearing aids are more expensive than analog hearing aids. There are four types of commonly used hearing aids:

1. The in-the-ear aid fits into the ear. It is small and unobtrusive to the wearer and others.
2. The behind-the-ear, or postauricular, aid is the most common type. This fits behind the ear and is comfortable to wear.
3. The all-in-one eyeglass aid combines eyeglasses with a hearing aid and is the least commonly used type.
4. The body-worn aid has a fitted ear mold inserted into the external ear and is connected to a receiver. The receiver is wired to a transmitter, which is worn around the neck. The wearer is not able to hide the receiver and wires.

To care for a hearing aid, ensure that it is turned off and the battery is removed when it is not in use. This reduces battery expense for the patient, who may be on a fixed income. When turning the hearing aid on, the volume should be turned up just until it squeals and then turned down until the patient indicates it is at the appropriate level for hearing. At least weekly, clean the hearing aid mold portion with either a dry cloth or a damp, soapy cloth and rinse with a damp cloth. A brush may come with the hearing aid for cleaning, or a cotton-tipped swab can be used to clean the small tip that fits into the ear.

Another type of hearing aid is the implantable middle ear hearing device, called the Vibrant Soundbridge (MED-EL, Durham, NC), for those with a sensorineural hearing loss. It provides sound perception by enhancing the normal middle ear hearing function. An audio processor picks up environmental sound and transmits it to the receiver implanted under the skin. The sound is then sent to a tiny floating transducer that directly vibrates the ossicles, which sends the message to the cochlea, as in normal hearing. The hair cells in the cochlea stimulate the auditory nerve, and the brain interprets the message as sound. For more information

Box 51.7

Administration of Ear Drops

1. Wash hands.
2. Ensure medication is at room temperature.
3. Position patient sitting up with head tilted toward unaffected side or side lying on unaffected side.
4. Pull auricle down and back on children and pull auricle up and back for adults.
5. Instill prescribed number of drops, being careful not to touch the tip of the dropper to prevent contamination.
6. Have patient remain in position for 2 to 3 minutes.
7. A small cotton plug may be inserted to prevent medication from running out of ear.
8. Wash hands.

TABLE 51.8 PREVENTION OF EAR PROBLEMS

Activity	Patient Education	Rationale
<i>Care of External Ear</i>	Wash external ear with soap and water only. Do not routinely remove wax from the ear canal.	Keeps external ear clean. The ear is generally self-cleaning. Wax is normally removed during showering. Wax serves as a protective mechanism to lubricate and trap foreign material.
<i>Preventing Ear Trauma</i>	Avoid inserting any objects or solutions into the ear. Avoid swimming in polluted areas. Avoid flying when the ear or upper respiratory system is congested.	Prevents traumatizing the ear and tympanic membrane or exposing the ear to infection. Prevents barotrauma due to pressure changes.
<i>Preventing Damage from Noise Pollution</i>	Avoid exposure to excessive occupational noise levels. Avoid other causes of excessive noise such as use of firearms and high-intensity music. Use protective earplugs or earmuffs if exposure to noise cannot be avoided.	Normal speech is 60 dB; heavy traffic is 70 dB. Above 80 dB is uncomfortable. If there is ringing in the ear, damage may be occurring. Occupational noise is the primary cause of hearing loss. Hearing loss can occur due to exposure to loud noises. Protects ears from hearing loss by decreasing exposure to loud noises.
<i>Early Detection of Hearing Loss</i>	Instruct adults to have hearing checked every 2–3 years. Monitor for side effects of ototoxic drugs. Instruct patient to report any dizziness, decreased hearing acuity, or tinnitus when taking ototoxic medications. Caution older patients who use aspirin that it is ototoxic. Instruct patient to report to physician any prolonged symptoms of ear pain, swelling, drainage, or plugged feeling. Instruct patient to blow nose with both nostrils open during upper respiratory infections (colds).	Degenerative changes occur in the ear with aging. Prevents side effects of medications from causing hearing loss. Older patients may have hearing loss and not be able to hear the tinnitus. Many medical problems can be prevented with prompt treatment. Prevents infected secretions from moving up the eustachian tubes into the middle ear.

or to see the Vibrant Soundbridge, visit www.symphonix.com.

A person who is profoundly deaf and has lost all hearing may use a **cochlear implant**. All cochlear implants feature a microelectronic processor for converting the sound into electrical signals, a transmission system to relay signals to the implanted parts, and a long, slender electrode placed in the cochlea to deliver the electrical stimuli directly to the fiber of the auditory nerve. The electrode is surgically placed. Patients commonly have difficulty understanding and learning speech, even with the cochlear implant.

For resources on helping those with hearing impairments, visit the National Association of the Deaf at www.nad.org.

Diet

The patient with an ear problem usually does not have any diet modifications. However, the patient with Ménière's disease may benefit from a lower sodium diet to prevent retention of fluid. Increased fluid may contribute to Ménière's disease symptoms.

Hearing Ear Dogs

Hearing ear dogs are now available to assist those with hearing problems. The dogs are trained to respond to sounds that the person who is hard of hearing cannot hear. Examples include a crying baby, oven timer, and smoke alarm. These dogs provide a valuable service that enriches the lives of those with hearing problems.

REVIEW QUESTIONS

Place the items in correct order. Use all items.

- In what order does a beam of light pass through the refractive structures in the eye?
 - aqueous humor
 - cornea
 - lens
 - vitreous humor

- Which of the following methods can be used to assess visual fields?
 - a. Inspection with an ophthalmoscope
 - b. Fluorescein angiography
 - c. Testing vision with Snellen's chart
 - d. Comparing the patient's visual fields with your own

3. Which of the following patient behaviors would the nurse expect to find in a patient's history who has a hearing loss?
 - a. Turns volume lower on the television
 - b. Is irritable or sensitive in interpersonal relations
 - c. Answers questions appropriately
 - d. Complains of people talking too loudly
 4. The nurse is collecting data during a patient's clinic visit. Which question will best collect data about a patient's preventative ear health?
 - a. "What symptoms are you having?"
 - b. "Tell me about your ear pain."
 - c. "When was your last hearing evaluation?"
 - d. "What medications do you take?"
 5. Which of the following is the most important nursing intervention during Romberg's test?
 - a. Ensure patient safety.
 - b. Whisper softly into each ear.
 - c. Ensure a quiet environment.
 - d. Remove all cerumen from ear canal.
 6. Which of the following patient statements indicates that the patient understands ear care teaching?
 - a. "I should insert a cotton swab into my ear canal for cleaning."
 - b. "I should not get my external ear wet during bathing."
 - c. "I should block one nostril when blowing my nose."
 - d. "Aspirin can be toxic to the ears."
- Multiple response item. Select all that apply.
7. The nurse prepares to provide an eye irrigation to a patient with a methicillin-resistant *S. aureus* (MRSA) infection. Contact precautions are ordered. Which of the following protective items will the nurse need while performing this procedure?
 - a. Gloves
 - b. Gown
 - c. Goggles
 - d. Mask
 - e. Shoe protectors
 8. A patient is taking aspirin. Which of the following findings would indicate to the nurse that the patient is experiencing a toxic effect related to the medication?
 - a. Halos around lights
 - b. Decreased night vision
 - c. Tinnitus
 - d. Vertigo

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Mr. Frank*

1. He is exhibiting behaviors of hearing loss.
2. Ear inspection, a whisper voice test, a Rinne test, and a Weber test might be performed.
3. For inspection of ear, cerumen impaction may be found. For a whisper voice test, the whisper is not heard in affected ear. For a Rinne test, bone conduction is heard longer than air conduction in affected ear. For a Weber test, sound is heard louder in affected ear.
4. Explaining to Mr. and Mrs. Frank symptoms of hearing loss will help them understand Mr. Frank's behaviors. Explore with them the effects of these symptoms in daily life to develop plans for coping with the hearing loss until an intervention is implemented.
5. He may not hear telephones or alarms such as smoke or carbon monoxide detectors, so alternatives such as visual alarms could be considered. If he drives, he may not hear car horns or emergency vehicles of which he should be aware to compensate.

QUESTIONS TO GUIDE YOUR READING

1. How would you explain the pathophysiology of each of the disorders of the sensory system?
2. How would you define blindness and the refractive errors of vision?
3. What are the etiologies, signs, and symptoms of sensory disorders?
4. What care would you provide for patients undergoing tests for sensory disorders?
5. What are the therapeutic interventions for each sensory disorder?
6. What medications are contraindicated for patients with acute angle-closure glaucoma?
7. What are three ototoxic drugs?
8. What data should you collect when caring for patients with disorders of the sensory system?
9. What nursing care will you provide for patients with disorders of the eye or ear?
10. What nursing care interventions would you use for the patient with a hearing impairment?
11. How will you know if your nursing interventions for sensory disorders have been effective?

Early detection and treatment of sensory injuries or diseases can reduce their impact. Any disturbance in vision or hearing disrupts a person's role performance, safety, and activities of daily living (ADLs). Treatment for sensory disturbances, such as glasses for refractive errors or hearing aids, can interfere with an individual's self-concept and body image. Nurses play an important role in recognizing symptoms of visual and hearing disorders and in assisting the individual to follow treatment, prevent recurrence, and learn new adaptive skills.

See Box 52.1 Eye Disorder Summary.

Infections and Inflammation

Infections and inflammation of the eye and surrounding structures can be bacterial or viral in origin. The eye may become aggravated by allergens, chemical substances, or mechanical irritation, leading to infection by microorganisms. Mechanical irritation may be caused by sunburn or bacterial infection. Inflammation results from allergies to environmental substances or by irritation of chemical irritants found in perfumes, make-up, sprays, or plants. Viral agents that cause infection include herpes simplex virus, cytomegalovirus, and human adenovirus. Bacterial agents that infect the eye include *Staphylococcus* and *Streptococcus*.

Box 52.1

Eye Disorder Summary

Signs and Symptoms	Visual disturbances, pain, redness, secretions, itchiness, sensation of pressure in eyes
Diagnostic Tests and Findings	Visual acuity, ophthalmoscopic examination of internal and external eye, Amsler grid (identifies visual field disturbances), slit-lamp examination (identifies abnormalities on cornea and sclera), tonometry (identifies intraocular pressure)
Therapeutic Interventions	Medications: reduce IOP, treat infections, anesthetize the eye
Complications	Worsening vision or loss of vision
Possible Nursing Diagnoses	Acute pain Anxiety related to visual-sensory deficit Deficient knowledge

IOP = intraocular pressure.

Box 52.2

Cultural Considerations

Vision

Trachoma, a form of conjunctivitis, is a common, chronic disease that affects approximately 600 million people worldwide. It is primarily seen among low-income persons in the Mediterranean, Africa, Brazil, and the Far East. Trachoma is caused by a viral strain of *Chlamydia trachomatis* that is highly contagious. Following the acute conjunctivitis phase, the eyelids shrink as a result of scarring. The shrinking tends to pull the eyelashes inward (entropion), which may scratch the cornea. In addition, granulations form on the inner eyelids. This painful condition may eventually lead to corneal ulceration and blindness. Trachoma is medically treated with topical and oral erythromycin or tetracycline.

Staphylococcus. The most common type of acute infection is **conjunctivitis** (Box 52.2 Cultural Considerations).

Conjunctivitis

Conjunctivitis is inflammation of the conjunctiva caused by either a virus or bacteria. Viral conjunctivitis occurs more commonly than bacterial conjunctivitis and is highly contagious. The virus is usually transmitted via contaminated eye secretions on the hand that then touches or rubs an eye, which infects the eye. The virus is hardy and may live on dry surfaces for 2 weeks or more. Viral conjunctivitis lasts 2 to 4 weeks. Bacterial conjunctivitis (commonly called pinkeye) usually is due to staphylococcal or streptococcal bacteria and is also highly contagious. Conjunctivitis can also be caused by the organisms *Haemophilus influenzae*, *Chlamydia trachomatis*, and *Neisseria gonorrhoeae*. Conjunctivitis is commonly transmitted among children and then among family members. Interestingly, conjunctivitis may also be caused by the use of nonprescription decongestant eye drops containing vasoconstrictors. When the eye drops are discontinued, a pharmacologically induced rebound phenomenon may occur. The eye vessels dilate and may become ischemic. This condition eventually subsides.

The symptoms of conjunctivitis include conjunctival redness and crusting exudate on the lids and in the corners of the eyes. Individuals may complain that their eyes itch and are painful. The eyes may tear excessively in response to the irritation.

Viral conjunctivitis is treated by supportive measures, which seek to keep the patient comfortable until the infection resolves on its own. Treatment includes eyewashes or eye irrigations, which cleanse the conjunctiva and relieve the inflammation and pain. Bacterial conjunctivitis is treated

conjunctivitis: conjunctive—joining membrane + itis—inflammation

TABLE 52.1 OPTHALMIC MEDICATIONS

Medication Class/Action	Examples	Route	Side Effects	Nursing Considerations
Diagnostic Aids				
Fluorescein sodium				
Staining of eye. Lesions of foreign objects pick up bright yellow-orange stain so abnormality can be detected.	Fluorescein (AK-Fluor)	Eye drop	Transient stinging or burning	Stain needs to be irrigated out of eye when examination is complete. Stain is colorfast, so caution should be used when irrigating.
Topical Anesthetics				
Provide local anesthesia to area, making examination painless. Also used to reduce pain of injury. Antiangiogenic	Tetracaine (Pontocaine)	Eye drop	Rare	Corneal anesthesia is achieved within 1 minute and lasts about 15 minutes. The eye must be protected because the blink reflex is temporarily lost. The lid should be kept closed to keep eye moist when examination and treatment are completed.
Antivascular Endothelial Growth Factor				
Inhibits growth of new blood vessels and slows progression of wet ARMD	Pegaptanib (Macugen)	Ophthalmic injection every 6 weeks	Burning, eye pain, redness, light sensitivity, vision loss, cataract, blurred vision, hypertension	Sterile technique must be used during injection by ophthalmologist. Monitor for 1 week after to detect infection early. Retinal detachment is a complication.
Anti-infectives				
Antibiotics				
Combat eye infections of bacterial origin	Erythromycin (AK-Mycin)	Eye drop or PO	Inflammation, burning, stinging, and drug hypersensitivity	Patients must be asked about previous allergic reaction to any ophthalmic or systemic medications.
Antivirals				
Combat eye infections of viral origin	Vidarabine (Vira-A)	Eye drop or PO	Inflammation, burning, stinging, and drug hypersensitivity	To minimize systemic absorption of anti-infectives, apply pressure on tear duct up to 5 minutes after medication is applied.
Antifungals				
Combat eye infections of fungal origin	Natamycin (Natacyn)	Eye drop or PO	Inflammation, burning, stinging, and drug hypersensitivity	Follow instructions for instillation.
Anti-inflammatories				
Reduce inflammation of conjunctiva, cornea, or eyelids due to infection, edema, allergic reaction, cataract surgery or burns				
Steroidal				
	Dexamethasone (Decadron)	Eye drop or PO	Transient stinging or burning on application.	To minimize systemic absorption of anti-inflammatories, apply pressure on tear duct up to 5 minutes after medication is applied. Long-term use of corticosteroids can contribute to cataract formation.
Nonsteroidal				
	Ketorolac (Acular)	Eye drop or PO	Transient stinging or burning on application	Use only as prescribed. Solutions preferred for eye infections as ointments can decrease healing.
	Bromfenac (Xibrom)	Eye drop	Headache, abnormal vision, eye pain, pruritus	Reduces ocular inflammation and pain following cataract surgery usually within 2 days of bid treatment.

(Continued on following page)

TABLE 52.1 OPTHALMIC MEDICATIONS (Continued)

Medication Class/Action	Examples	Route	Side Effects	Nursing Considerations
Lubricants Moisten eyes in healthy and ill persons. Lubricants maintain moisture on eyeball, which contributes to maintenance of the epithelial surface.	Artificial tears (Lacrilube, Tears Plus)	Eye drop or ointment	Rare	Lubricants come in liquid and ointment forms. For patients who have ointments placed in the eye during surgery to prevent eye dryness, inform patients that vision will be distorted in the presence of ophthalmic ointments.
Miotics Lower intraocular pressure by stimulating papillary and ciliary sphincter muscles. This assists in improving blood flow to the retina and flow of aqueous humor.	Pilocarpine (Pilocar) Physostigmine (Isopto Eserine)	Eye drop	Miotic side effects include headache, eye pain, and brow pain. Systemic absorption can cause nausea, vomiting, diarrhea, respiratory attacks in patients with asthma, and respiratory difficulty.	Pilocarpine, a miotic, causes miosis (contraction of the pupil). Expect to see a smaller than normal pupil with little if any reaction to light. Careful administration with gentle pressure on the tear duct for 5 minutes following application will reduce systemic absorption of medications.
Carbonic Anhydrase Inhibitors Used to decrease aqueous humor formation and decrease intraocular pressure. Used primarily for treatment of glaucoma when other miotics have not been successful.	Acetazolamide (Diamox)	Eye drop	Side effects include lethargy, anorexia, depression, nausea, and vomiting. Do not administer to persons allergic to sulfonamides. Carbonic anhydrase inhibitors may also cause photosensitivity.	Careful administration with gentle pressure on the tear duct for 5 minutes following application will reduce systemic absorption. Instruct patient to wear sunglasses and protect eyes from bright lights if photosensitive. Use of the medication may cause dry eyes and dry oral membranes. Encourage patient to maintain eye and oral hygiene.
Osmotics Used to reduce intraocular pressure in emergency situations such as acute open-angle glaucoma or used preoperatively and postoperatively to decrease vitreous humor volume, thereby reducing intraocular pressure.	Mannitol (Osmitol)	Eye drop, PO, or IV	Disorientation, especially in elderly, may be caused by change in electrolytes secondary to use of osmotics	Mannitol may result in digitalis toxicity when given concurrently. Monitor for headache, nausea, vomiting, and confusion.
Beta-adrenergic Blockers Used to reduce intraocular pressure by reducing aqueous humor formation and increasing its outflow.	Timolol (Timoptic) Betaxolol (Betoptic)	Eye drop	Drug may cause transient burning and discomfort. There is limited systemic absorption of beta blockers, which may cause headache, dizziness, cardiac irregularities, and bronchospasm.	Careful administration with gentle pressure on the tear duct for 5 minutes following application will reduce systemic absorption. Monitor for bradycardia, heart block, and wheezing.
Mydriatics Used to dilate the pupils for examination or surgical procedures.	Atropine	Eye drop	Systemic absorption may cause irregular pulse, confusion, dry mouth, fever. Local side effects include blurred vision and photosensitivity.	If pupils are dilated, they can no longer protect the eye from bright light. Instruct patient to wear dark glasses until the effects of the drug have worn off. Monitor for side effects such as irregular pulse, confusion, dry mouth, and fever. Careful administration with gentle pressure on the tear duct for 5 minutes following application will reduce systemic absorption.
Cycloplegics Paralyzes muscles of accommodation for examination or surgical procedures.	Cyclopentolate	Eye drop	Side effects include tachycardia, dry mouth, and symptoms of atropine toxicity.	Contraindicated in patients with glaucoma because of increase in intraocular pressure with use.

ARMD = age-related macular degeneration.

with antibiotic eye drops or ointments (Table 52.1). Eye drops are generally preferred by adults because they do not impair vision. Ointments are commonly used when the eye is resting (at night) or in children, who may squeeze their eyes shut and cry when ocular medications are applied, thus expelling the medication. With either type of conjunctivitis, hand washing is the best means of preventing the spread of the disease.

Blepharitis

Blepharitis, an inflammation of the eyelid margins, is a chronic inflammatory process. There are two types: seborrheic blepharitis and ulcerative blepharitis. The cause may include staphylococcal infection, seborrhea (dandruff), rosacea (a chronic disease of the skin usually affecting middle-aged and older adults), dry eye, or abnormalities of the meibomian glands and their lipid secretions. Seborrheic blepharitis is characterized by reddened eyelids with scales and flaking at base of the lashes. Ulcerative blepharitis produces crusts at eyelashes, reddened eyes, and inflamed corneas. Eyelids chronically infected with *Staphylococcus* may become thickened and eyelashes may be lost.

Treatment requires a commitment to long-term daily cleansing with cotton-tipped swabs dipped in diluted baby shampoo or sterile eyelid cleanser solutions to prevent infection. If infection occurs, antistaphylococcal antibiotic ointment (bacitracin, erythromycin) is applied to the lid margins one to four times a day after the eyelids have been cleansed. Warm compresses may also be used.

Hordeolum and Chalazion

Another type of eyelid infection is a **hordeolum**. An external hordeolum (sty) is a small staphylococcal abscess in the sebaceous gland at the base of the eyelash (either Zeis's glands or the glands of Moll). Use of cosmetics on the eyes may contribute to hordeolum formation. Styes are small, raised, reddened areas. A second type of abscess, **chalazion** (internal hordeolum), may form in the connective tissue of the eyelids, specifically in the meibomian glands. A chalazion is larger than an external hordeolum. Styes may be tender; however, a chalazion often puts pressure on the cornea, causing more discomfort.

Hordeolums usually form and heal spontaneously within a few days and require no treatment. Chalazions may require surgical incision and drainage (I&D) if they do not drain spontaneously. If either type of abscess persists, administration of oral antibiotics may be prescribed along with application of warm compresses to aid healing.

Keratitis

PATHOPHYSIOLOGY AND ETIOLOGY. Keratitis is inflammation of the cornea and may be acute or chronic and superficial or deep. The depth of keratitis is determined by the layers of the cornea that may be affected. Keratitis may be associated with bacterial conjunctivitis, a viral infection such as herpes simplex, a corneal ulcer, or diseases such as tuberculosis and syphilis. Children may develop keratitis from vitamin A deficiency, allergic reactions, or viral

diseases such as mumps or measles. Herpes simplex keratitis is the most common corneal infection in developed countries, with bacterial and fungal infections being more prevalent throughout the rest of the world. People who wear contact lenses or have dry eyes, practice poor contact lens hygiene, have decreased corneal sensation, or are immunosuppressed are at increased risk of keratitis. Overnight wearing of soft contact lenses increases the risk even more. *Pseudomonas aeruginosa* is the pathogen most commonly associated with infection following the wearing of soft contact lenses overnight. If this infection occurs, the patient may be advised to dispose of the contaminated lenses and be treated with antibiotics.

SIGNS AND SYMPTOMS. The cornea has many pain receptors, so any inflammation of the cornea is painful. This pain increases with movement of the lid over the cornea. Other symptoms of keratitis include decreased vision, **photophobia** (sensitivity to light), tearing, and blepharospasm (spasm of the eyelids). The conjunctiva often appears reddened. In advanced cases, the cornea may appear opaque (cloudy).

DIAGNOSTIC TESTS. Assessment of keratitis or corneal ulcer is made by use of a slit lamp or a hand-held light. The cornea is examined by shining the light source obliquely (diagonally) across the cornea to show opacity in the cornea. Fluorescein stain may also be used to outline the area of involvement. When the stained area is viewed with a blue light, the disruption in the corneal surface shows up clear. If the patient is having pain from blepharospasm (contraction of the orbicularis oculi muscle), the examiner may instill a topical ophthalmic anesthetic such as proparacaine.

THERAPEUTIC INTERVENTIONS. Therapeutic interventions may include topical antibiotics, antiviral medications for herpes simplex, cycloplegic agents (to keep the iris and ciliary body at rest), and warm compresses. If the cornea is severely damaged, corneal transplant may be required. The eye may be patched to decrease the amount of eyelid movement over the cornea during healing.

COMPLICATIONS. Corneal infections are usually serious and are often sight threatening. The corneal tissue may become thin and susceptible to perforation. Untreated, keratitis can cause permanent scarring of the cornea, resulting in permanent loss of vision.

Nursing Process for the Patient with Inflammation and Infection of the Eye

ASSESSMENT/DATA COLLECTION. Gather subjective and objective data (Table 52.2). Objective assessment data includes the condition of the conjunctiva, eyelids, and eyelashes; the presence of exudate, tearing, any visible abscess on the palpebral border, or a palpable abscess in the eyelid; opacity of the cornea; and visual acuity testing comparing unaffected and affected eyes.

photophobia: photo—light + phobia—fear of

TABLE 52.2 SUBJECTIVE ASSESSMENT OF EYE INFLAMMATION AND INFECTION CONDITIONS

W	Where is it? What part of the eye is affected? Eyelid, conjunctiva, cornea?
H	How does it feel? Pressure? Itchy? Painful? No pain? Irritated? Spasm?
A	Aggravating and alleviating factors. Is it worse when rubbing eyes or blinking? Is there photosensitivity?
T	Timing. Was there exposure to a pathogen? Previous infection or irritation? How long have symptoms persisted?
S	Severity. Is there visual impairment? Does pain affect ADLs?
U	Useful data for associated symptoms. Is patient infected with lice? Immunosuppression? Do other members of the family or peer group have symptoms? Are decongestant eye drops used? Is there exudate? Are the eyelids stuck together on awakening? Does patient wear contact lenses, soft contact lenses overnight, disposable contact lenses? Does patient have dry eyes? Is patient infected with tuberculosis, syphilis, HIV? What is typical eye hygiene?
P	Perception by the patient of the problem. What does patient think is wrong?

ADLs = activities of daily living; HIV = human immunodeficiency virus.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Acute pain related to inflammation or infection of the eye or surrounding tissues

EXPECTED OUTCOME: Pain is decreased or absent as evidenced by lower rating on pain scale.

- Assess the patient for pain. *Use of dark glasses, rubbing the eye, squinting, and avoiding light may be indicators of pain that should be assessed.*
- Administer eye medications as ordered. Eye pain is generally treated with topical anesthetic drops or ointments, antibiotics, anti-inflammatory agents, or analgesics for severe pain.
- Apply warm or cool packs as ordered *to assist in soothing the eye.*
- Patching of the affected eye may help reduce pain *by decreasing the movement of the eye across the eyelid.*
- Explore additional methods of pain reduction, *such as guided imagery, relaxation techniques, music, or distraction.*

Disturbed sensory perception: visual related to altered sensory reception

EXPECTED OUTCOME: Patient states vision has returned to preillness state.

- Reading and television should be discouraged *if the patient is to rest the eye.*
- Encourage quiet activity, such as listening to music, radio, or a recorded book, which can be carried out

with the eyes closed *to provide distraction and rest for the eye.*

Risk for injury related to visual impairment

EXPECTED OUTCOME: Injury does not occur as a result of visual impairment.

- Assess and plan for visual impairments that may be present *to promote safety.*
- Advise patient with one eye patched that depth perception is altered and not to drive automobile.
- Teach caution when ambulating and reaching for things. *Inflamed eyes often do not focus well and may have exudate, tearing, or ointment present, which can interfere with vision.*

Risk for infection related to poor eye hygiene, use of contact lenses

EXPECTED OUTCOME: Patient does not develop eye infection.

- Administer antibiotics as ordered.
- Teach not to wear contact lenses when the eye or surrounding structure is inflamed.
- Teach contact lenses must be sterilized before use after the inflammation resolves *to prevent reinfection of the eye. Soft contact lenses that cannot be sterilized need to be discarded.*

Deficient knowledge related to eye disease process, prevention, and treatment from lack of previous experience

EXPECTED OUTCOMES: Patient explains disease process, prevention, and treatment measures. Patient demonstrates treatment regimen correctly, such as administration of eye drops.

- Teach patient prevention, care of the affected eye, medication administration, safety issues *for understanding and compliance with therapeutic plan.*
- Have patient demonstrate the administration of ointments or drops after teaching has occurred *to evaluate understanding.*
- Teach patient and family how to prevent spreading infection *if it is contagious.*
- Teach patient good eye hygiene *to prevent further complications.*

EVALUATION. The interventions have been successful if pain is reduced to an acceptable rating, vision improves or returns to preillness level, injury does not occur as a result of visual impairment, infection does not occur as a result of poor eye hygiene or wearing of contact lenses, patient explains disease process, prevention, or treatment regimen accurately, or prescribed treatment is stated or demonstrated correctly (e.g., administering eye drops or ointments).

Refractive Errors

Pathophysiology and Etiology

Refraction refers to the bending of light rays as they enter the eye. Emmetropia, or normal vision, means that light rays

are bent to focus images precisely on the macula of the retina. *Ametropia* is a term used to describe any refractive error. When an image is not clearly focused on the retina, refractive error is present. Refractive errors account for the largest number of impairments in vision. Ametropia occurs when parallel light rays entering the eye are not refracted to focus on the retina. There are four common ametropic disorders: **myopia**, **hyperopia**, **astigmatism**, and **presbyopia**.

HYPEROPIA. Hyperopia, also known as farsightedness, is caused by light rays focusing behind the retina (Fig. 52.1). People who are hyperopic see images that are far away more clearly than images that are close. Physiologically, the globe or eyeball is too short from the front to the back, causing the light rays to focus beyond the retina. Hyperopia is corrected with convex lenses.

MYOPIA. Myopia, commonly referred to as nearsightedness, is caused by light rays focusing in front of the retina. The eyeball is elongated and thus the light rays do not reach the retina. Persons with myopia hold things close to their eyes to see them better. Distance vision is blurred. Myopia is corrected with concave lenses (see Fig. 52.1).

ASTIGMATISM. Astigmatism results from unequal curvatures in the shape of the cornea. When parallel light rays enter the eye, the irregular cornea causes the light rays to be refracted to focus on two different points. This can result in either myopic or hyperopic astigmatism. The person with astigmatism has blurred vision with distortion. The corneal irregularities can be caused by injury, inflammation, corneal surgery, or an inherited autosomal dominant trait.

PRESBYOPIA. Presbyopia is a condition in which the crystalline lenses lose their elasticity, resulting in a decrease in ability to focus on close objects. The loss of elasticity causes light rays to focus beyond the retina, resulting in hyperopia. This condition usually is associated with aging and generally occurs after age 40. If an individual has preexisting hyperopia, the onset of presbyopia may occur earlier than 40 years. Likewise, if an individual has myopia, presbyopia may correct the myopia by projecting the light rays directly on the retina. Because accommodation for close vision is accomplished by lens contraction, people with presbyopia exhibit the inability to see objects at close range. They often compensate for blurred close vision by holding objects to be viewed farther away. Complaints of eyestrain and mild frontal headache are common. These symptoms are relieved with eye rest and corrective lenses.

Signs and Symptoms

Individuals with refractive errors often report difficulty reading or seeing objects. Often the eyestrain that occurs as one attempts to improve visual acuity causes headache. Myopic individuals may hold reading materials close to the eyes. Hyperopic individuals hold reading materials farther away from their eyes.

presbyopia: presby—old age + opia—concerning vision

FIGURE 52.1 Refractive disorders. (A) Hyperopia (farsighted). The eyeball is too short, causing the image to focus beyond the retina. (B) Corrected hyperopia. (C) Myopia (nearsighted). A long eyeball causes the image to focus in front of the retina. (D) Corrected myopia.

LEARNING TIP

To remember the type of vision a person has, use this saying: *You are what you say*. For example, if you say you are farsighted, this means that you have clear vision of far away images but difficulty seeing images that are nearer. If you say you are nearsighted, this means that you have clear vision of near images but difficulty seeing images that are farther away.

Diagnostic Tests

A refractive error may be roughly estimated by use of Snellen's chart or by determining the individual's vision at different distances and comparing it with that of the examiner. To obtain a more definitive refractive error measurement, a retinoscopic examination is necessary. Before this examination, a cycloplegic drug is often instilled (see Table 52.1). A cycloplegic drug dilates the pupil and temporarily paralyzes the ciliary muscle, thus preventing accommodation. During the examination, an ophthalmologist or optometrist examines the internal and external eye and uses trial lenses via a retinoscope to assess the type of lens best suited to correct the refractive error. If convex-shaped trial lenses correct the focusing power of the eyes, the patient is determined to be hyperopic. If concave-shaped trial lenses correct the focusing power, the patient is said to be myopic. The amount of focusing power needed in the trial lens to correct the visual defect indicates the degree of refractive error. Left and right eyes of the same person may not have the same degree of refractive error. If a cycloplegic agent has been used, patients need to be told that blurred vision will be present and sunglasses need to be worn until the agent wears off. In addition, the patient should be instructed that driving and reading are not possible until the effect of the cycloplegic drug is gone.

Therapeutic Interventions

Refractive errors are commonly treated with corrective lenses; either eyeglasses or contact lenses. The lenses bend the parallel light rays so that they converge on the macular portion of the retina. Incisional radial keratotomy and photorefractive keratectomy (PRK) are surgical procedures used to correct refractive error. With incisional radial keratotomy, surgical incisions are made on the cornea to reshape it. PRK utilizes laser technology to accomplish the same goal of reshaping the cornea (Box 52.3 Laser Treatment). The cornea is made flatter for individuals with myopia and more cone shaped for those with hyperopia.

Complications

Complications of corrective lens use are primarily related to safety. Eyeglasses can be broken. Eyeglass lenses can be made with special polymers that do not break as easily as traditional glass. It is a myth that if corrective lenses are not worn, vision becomes worse. Complications of contact lens use include corneal abrasions, infections, and keratitis. Incisional radial keratotomy and PRK both have surgical risks and may not always be successful.

Blindness

Blindness is described in many terms that are often reflective of the degree of visual impairment an individual has. Generally, blindness is the complete or almost complete absence of the sense of sight. Terms such as *profound blindness*, *partially sighted*, and *blind* may all have different meanings. Some people consider the terms *blind* and *partially sighted* to be negative and prefer the term *visually impaired* to describe their condition. For information or resources, visit the following sites:

Box 52.3

Laser Treatment

Laser is an acronym for light amplification by stimulated emission of radiation. Lasers are devices that amplify light and produce synchronized light waves. Lasers are based on the principle that atoms, molecules, and ions can be excited by absorption of thermal, electrical, or light energy. After this energy is absorbed, the atoms, molecules, or ions give off a beam of synchronized light waves. By using this extremely intense, highly directional, pure-colored light, lasers can be used for a variety of purposes, such as making incisions, removing tissue, or stopping bleeding.

- American Foundation for the Blind at <http://afb.org>
- Canadian National Institute for the Blind at www.cnib.ca
- National Federation of the Blind at www.nfb.org

Pathophysiology and Etiology

Few people are born blind. Blindness is caused by a variety of factors, including trauma, complications from various diseases such as hypertension and diabetes, conditions such as **cataracts** and **glaucoma**, and, in children, malnutrition, infectious diseases, and parasitic infestations. Blindness is produced when there is an obstacle to the rays of light on their way to the optic nerve or by disease of the optic nerve or tract of the part of the brain connected with vision. Blindness may be permanent or transient, complete or partial, or may occur only in darkness (night blindness). There are blind people in every age group, but about half the blind people in the United States are older adults.

Signs and Symptoms

Aside from a general loss of vision, patients may describe their visual image as blurred, distorted, or absent in specific areas of the visual field. Objects may appear dark or absent around the peripheral field in glaucoma or retinitis pigmentosa. Retinitis pigmentosa causes this visual disturbance because the pigmented layer of the retina has degenerated. The center of the visual field may appear dark for individuals with diabetic **retinopathy** or **macular** degeneration. Half the visual field may be impaired in patients with hemianopia. This results from a defect in the optic pathways in the brain and is often seen with stroke. Patients may report that the visual field appears blurry or hazy in corneal visual problems, cataracts, diabetic retinopathy, or refractive errors (Fig. 52.2).

Diagnostic Tests

Diagnostic tests are usually done to determine the exact cause of the blindness and may include a visual field exam-

retinopathy: retino—having to do with the retina + pathy—illness, disease, or suffering

FIGURE 52.2 Visual field abnormalities. (A) Normal vision. (B) Diabetic retinopathy. (C) Cataracts. (D) Macular degeneration. (E) Advanced glaucoma.

ination, tonometry, and slit-lamp microscope examination. Retinal angiography is used to follow blood flow through the retinal vessels and to detect vascular changes. Ultrasonography may be used to visualize changes in the posterior eye that cannot be directly examined because of other pathological conditions, such as a cloudy cornea, a bloody vitreous, or an opaque lens.

Therapeutic Interventions

Therapeutic interventions for blindness center on treating the underlying condition and preventing further impairment. Depending on the cause of the blindness, treatment may include medication prescription, surgical intervention, corrective eyewear prescription, and referral to supportive services.

Nursing Process for the Patient with Visual Impairment

ASSESSMENT/DATA COLLECTION. Collection of subjective data for assessment of visual impairment can be made using the WHAT'S UP? format (Table 52.3). Collection of objective data includes observations of the patient. Is there squinting? Rubbing of eyes? Is the patient using compensatory measures—magnifying glass, sitting close to television, using large-print reading materials, avoiding reading, using eyeglasses? Psychosocial data are important because a blind person may be withdrawn or socially isolated, have low self-esteem or poor coping mechanisms, or have poor interpersonal skills as a result of the visual impairment.

NURSING DIAGNOSIS AND PLANNING. Nursing care begins by understanding how to interact with the visually impaired patient (Box 52.4 Interacting with the Visually Impaired Patient). A patient's level of independence must be included in the planning phase. If patients have minimal

visual impairment or have attended rehabilitation, they may be able to function independently. If a patient has recently become visually impaired, he or she may be completely dependent until learning alternative ways of coping with this impairment. Planning focuses on meeting self-care needs, keeping the patient safe from injury, supporting the grieving

TABLE 52.3 SUBJECTIVE ASSESSMENT OF VISUAL DISORDERS

W	Where is it? What part of the visual field is affected? If there is vision, what are the characteristics of what can be seen? Blurry? Hazy? Dark? Halos around lights?
H	How does it feel? Is there associated pain with the visual impairment? Headaches? How does it make the patient feel? Fearful? Anxious? Depressed? Helpless? Hopeless? Accepting?
A	Aggravating and alleviating factors. Is it worse when reading? Is it worse when watching TV? Does it affect the patient only at night? Is vision better at distances or close up?
T	Timing. When did the symptoms start? Do they come and go? Is the impairment progressively getting worse? Was onset sudden?
S	Severity. Does the impairment affect the patient's ADLs? If so, how severely? Does the patient need assistance to cook, dress, bathe, read mail, pay bills, access health care, obtain transportation, maintain household, shop?
U	Useful data for associated symptoms. Does the patient have diabetes, hypertension, a family history of retinitis pigmentosa, a history of eye infection, or eye trauma? Has the patient recently traveled out of the country?
P	Perception of the problem by the patient. What does the patient think is wrong? How severe does the patient perceive the impairment to be?

ADLs = activities of daily living.

Box 52.4**Interacting with the Visually Impaired Patient**

- People entering a room and at each contact with the patient should identify themselves.
- Post a sign on the door or over the bed that identifies the patient's visual status so that others can interact appropriately.
- Remember that the individual is not having hearing problems, so use a normal tone of voice and do not yell.
- Ask visually impaired patients what their needs are; do not assume they need help with everything.
- Do not hesitate to use the words *blind* and *see*.
- Talk directly to the impaired patient, not through a companion.
- At mealtime, explain the location of items on the tray by comparing their position to the numbers on a clock (e.g., milk is at 2 o'clock, peas are at 7 o'clock).
- Explain any activity going on in the room or within the patient's auditory range.
- Explain procedures before beginning them. Speak to the patient before touching.
- When walking, allow the patient to grasp assistant's arm and walk a half step behind. Be aware of obstacles on either side when walking.
- When seating a patient, place the patient's hand on the arm of the chair.
- Tell the patient when leaving the room or area so the patient does not continue conversation in an empty room, which may cause embarrassment.
- When orienting the patient to the hospital room, explain the location of items the patient may need, such as the water pitcher, call light, bed controls, urinal, tissues. Attempt to keep these items in the same place at all times.
- If the patient has a seeing eye dog, do not play with the dog, pet it, or feed it without consulting the patient—the dog is working! Make sure the patient's dog is near the bed, on a mat provided especially for the dog, preferably on the side of the bed that is less likely to be used by staff. Instruct staff and visitors about the seeing eye dog.

process, and helping the patient acquire knowledge of agencies, services, and devices that allow maintenance of independence. Families must be included in the planning phase because they need to understand and be supportive of the self-image and role performance changes that may occur (Box 52.5 Nursing Care Plan for the Patient with Visual Loss).

There are organizations whose mission is to enhance the independence of visually impaired persons. Referring

patients to these resources enhances their ability to maintain independence. Visit the following organizations' websites:

- American Academy of Ophthalmology at www.eyenet.org
- Guide Dogs for the Blind at www.guidedogs.com
- National Association for Visually Handicapped at www.navh.org
- National Eye Institute at www.nei.nih.gov
- Talking books: National Library Service for the Blind and Visually Handicapped at www.loc.gov/nls/index.html

EVALUATION. The outcomes for the visually impaired patient are met if the patient demonstrates the ability to complete activities of daily living with increasing independence, remains free of injury, and demonstrates ability to assess agencies and services for the visually impaired.

Diabetic Retinopathy**Pathophysiology and Etiology**

Retinopathy is a disorder in which there are vascular changes in the retinal blood vessels. The most common incidence of retinopathy is found in persons with diabetes. It is estimated that half of the people with diabetes in the United States have at least early signs of retinopathy. The pathological changes that occur with diabetic retinopathy are related to excess glucose, changes in the retinal capillary walls, formation of microaneurysms, and constriction of retinal blood vessels. Three stages of diabetic retinopathy have been identified: background retinopathy, preproliferative retinopathy, and proliferative retinopathy.

Background retinopathy is the earliest stage, in which microaneurysms form on the retinal capillary walls. These microaneurysms may leak blood into the central retina or macula. If the leakage causes edema, the patient may notice a decrease in color discrimination and visual acuity.

The second stage, preproliferative retinopathy, is characterized by swollen and irregularly dilated veins, which results in sluggish or blocked blood flow. Patients generally are not aware of this stage because there are no symptoms.

Proliferative retinopathy, the third stage, is characterized by the formation of new blood vessels growing into the retinal and optic disc area as an attempt to increase the blood supply to the retina. The newly formed blood vessels are fragile and often leak blood into the vitreous and retina. In addition to leaking, the newer vessels may grow into the vitreous, which causes a traction effect, pulling the vitreous away from the retina and subsequently pulling the retina away from the choroid. This condition is called retinal detachment (discussed later).

Signs and Symptoms

Individuals may experience a reduction in central visual acuity or color vision as a result of macular edema (see Fig. 52.2). Many patients with diabetic retinopathy do not have any symptoms until the proliferative stage, at which point vision is lost. Visual loss at the last stage usually cannot be restored.

Box 52.5 NURSING CARE PLAN for the Patient with Visual Loss

Nursing Diagnosis: Disturbed sensory perception: visual related to altered sensory reception

Expected Outcomes Patient will attain optimum level of sensory stimulation. Patient will become aware of visual impairment and ways to compensate. Patient will demonstrate ability to perform activities of daily living, with assistance if necessary.

Evaluation of Outcomes Patient perceives maximum visual sensory input. Patient is able to compensate for sensory impairment by using other senses and resources. Patient is able to perform activities of daily living as independently as possible.

Interventions

Check visual acuity using a standard Snellen's vision chart. If the individual is unable to read letters, use directional arrows or pictures.

Check visual fields using the cover test or confrontation test.

Structure environment to compensate for visual loss by adding color and contrast (e.g., chairs and carpeting should be in contrasting colors, bright tape or paint on stairs, medicine bottles color coded with colored dot stickers).

Structure environment to compensate for visual loss by use of large-print directional signs and arrows, well-lit areas, nonglare surfaces, consistent placement of objects, traffic areas free of clutter.

Provide for optimum care of assistive appliances such as eyeglasses, including maintenance of proper prescription, fit, and cleaning.

Introduce other assistive devices such as handheld magnifying glasses, tableside magnifiers, television magnifiers, large-print items, and phone dial covers with large numbers, talking watches, alarm clocks, and calculators.

Rationale

Determines patient's ability to see

Identifies deficits in visual fields

Makes the environment easier to visualize and interpret and assists in depth perception and identifying medications

Large directional signs assist the individual in maintaining orientation.

Shiny floors or areas with bright window glass can impair vision. Traffic areas free of clutter assist in preventing injury.

Improperly fitting or dirty eyeglasses may impair vision even further.

Older adults should have their eyeglass prescription checked yearly.

Patients may not be aware of assistive devices, which may help them adapt to visual loss and continue previous activities such as watching TV or reading letters and magazines. Allows people to rely on hearing rather than vision.

Evaluation

Does patient have 20/20 vision? Is there an impairment? If so, how severe is it?

Are visual fields of patient equal to examiner's? Is there a deficit? Is it bilateral or unilateral?

Does the environment have clearly delineated walkways, sitting areas, and doorways?

Are areas with changes in elevation clearly identified using contrasting tape or paint?

Is there a way for patient to safely self-administer medications?

Can the visually impaired individual identify locations such as bathroom, dining room, and office areas? Is the individual able to ambulate freely without safety hazards?

Do eyeglasses fit properly? Are lenses clean? Is prescription current?

Is patient aware of assistive devices that allow participation in previously enjoyed activities such as TV or reading? Is the visually impaired patient able to pay bills? Read mail? Communicate on telephone?

(Continued on following page)

Box 52.5 NURSING CARE PLAN for the Patient with Visual Loss (Cont'd)

Interventions

Allow patient to verbalize feelings and grieving about visual loss.

Identify coping strategies that have been successful for patient in the past.

Refer to specialized clinician such as ophthalmologist or occupational therapist or to specialized resources such as American Federation for the Blind or Prevent Blindness America.

Rationale

Losing a primary sense such as vision can be devastating for patients. Opportunity to ventilate feelings assists in processing the loss.

By identifying successful coping strategies, the nurse assists patient in dealing with stress or visual loss. A positive approach for nurse to use focuses on individual's capabilities rather than deficits.

Specialized clinicians can provide detailed examination and treatment for the disorder. Specialized resource groups have networks in place to assist individuals in coping with loss and assisting with maximizing abilities.

Evaluation

Is patient able to verbalize feelings about visual impairment and its loss?

Is patient able to identify successful coping strategies and use them to deal with the stress of visual impairment?

Does patient know who to call for detailed examination and treatment of problems? Does patient know that there are specialized clinicians and resource groups to help with the visual impairment? Does patient know how to access these specialists?

Diagnostic Tests

Diabetic retinopathy, as well as the other retinopathies, can be diagnosed only on examination of the internal eye. The examination is conducted with an ophthalmoscope following dilation of the pupil using a cycloplegic agent. The examination may be enhanced by use of retinoangiography. In the initial stages, vessels may appear swollen and tortuous (twisted).

Therapeutic Interventions

Treatment of diabetic retinopathy focuses on stopping the leakage of blood and fluid into the vitreous and retina. The leaking microaneurysm is sealed by use of laser photocoagulation (see Box 52.3 Laser Treatment). If blood has already leaked into the vitreous, a vitrectomy is performed. During a vitrectomy, the vitreous humor is drained out of the eye chamber and replaced with saline or silicon oil. The replacement fluid is necessary to support the structures of the eyeball until healing can occur. Further treatment may be needed if the patient has sustained retinal detachment.

Complications

Early treatment for diabetic retinopathy is highly successful in preventing further visual loss; however, visual loss cannot be reversed. For this reason, it is very important for patients with diabetes to have a comprehensive eye examination through dilated pupils at least once each year or as directed by their physician. Careful control of diabetes during the first 5 years following diagnosis reduces the occurrence and delays the onset of diabetic retinopathy.

Nursing Process for the Patient with Diabetic Retinopathy

ASSESSMENT/DATA COLLECTION. Nursing assessment for diabetic retinopathy focuses on risk factors associated with the incidence of the disease. The patient may not have any symptoms. If patients with diabetes do have changes in perceptions of visual acuity or color discrimination, they should immediately contact their physician.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. The planning phase of the nursing process focuses on prevention of visual loss by early detection and treatment. If the patient has entered phase three and is already visually impaired, the nursing care plan for the visually impaired patient is used. Nursing diagnoses, goals, and interventions for diabetic retinopathy include but are not limited to the following:

Risk for (or actual) ineffective therapeutic regimen management

EXPECTED OUTCOME: Patient will state ability to manage therapeutic regimen.

- Determine if visually impaired patient who is diabetic can monitor blood glucose and draw up and administer the correct amount of insulin. *Specialty devices are available that can be preset to draw up amounts of insulin for the visually impaired patient with diabetes. Family members may have to assist the patient.*

- Teach patient importance of yearly comprehensive eye examinations.

Disturbed sensory perception: visual related to altered sensory reception and transmission

EXPECTED OUTCOME: Patient will adapt to altered visual perception.

- Determine patient's abilities and needs to develop plan of action and support needed.
- Assist patient with home and health maintenance as needed.

EVALUATION. Patient goals are met if the patient is able to manage therapeutic regimen and manage visual deficits.

Retinal Detachment

Pathophysiology and Etiology

Retinal detachment is a separation of the retina from the choroid layer of the eye that allows fluid to enter the space between the layers. There are three types of retinal detachment:

1. Rhegmatogenous retinal detachment is caused by a hole or tear in the retina that allows fluid to flow between the two layers. The tears are related to degenerative changes in the retina or vitreous. This type of retinal detachment can also be precipitated by moderate trauma, such as stooping or lifting weights, or by direct trauma to the eye. The incidence of rhegmatogenous detachment increases with age.
2. Nonrhegmatogenous tractional detachment occurs when fibrous tissue in the vitreous humor attaches to the sensory retina and, as it contracts, pulls the retina away from its normal position. It occurs in patients with sickle cell disease or diabetes mellitus.
3. Exudative detachment occurs when fluid or exudate accumulates in the subretinal space and separates the layers. Exudative detachment occurs most often in conditions such as advanced hypertension, preeclampsia, or eclampsia and from intraocular tumors.

Signs and Symptoms

Patients experiencing a retinal detachment report a sudden change in vision. Initially, as the retina is pulled, “flashing lights” are reported, and then “floaters” are seen. The flashing lights are caused by vitreous traction on the retina, and the floaters are caused by the hemorrhage of vitreous fluid or blood. When the retina detaches, the patient describes it as “looking through a veil” or “cobwebs” and finally “like a curtain being lowered over the field of vision,” with darkness resulting. There is no pain because the retina does not contain sensory nerves. On visual examination, the patient generally has a loss of peripheral vision when the visual fields are tested and a loss of acuity in the affected eye.

Diagnostic Tests

Indirect ophthalmoscopy is used by the physician to examine the interior of the eye. This examination allows the examiner to visualize the retina, which may be pale, opaque, and in folds with retinal detachment. The examiner is able to diagnose the type of detachment based on this examination. If there are lesions in the eye, the slit-lamp examination allows the examiner to magnify the lesions.

Therapeutic Interventions

Prompt medical treatment must be sought to prevent loss of vision. One of several procedures may be performed to reattach the retina to prevent blindness.

- Laser reattachment involves focusing a laser beam on the detached area of the retina and causing a controlled burn, which reattaches the layers together by forming an adhesion (see Box 52.3 Laser Treatment). This procedure is used when only a small area of the retina is involved.
- Cryosurgery involves the placement of a super-cooled probe on the sclera. The probe causes injury to the tissue, forming an adhesion; a principle similar to the laser procedure.
- Electrodiathermy, the least used procedure, involves placement of an electrode needle into the sclera to allow fluid that has accumulated to drain. The retina later adheres to the choroid layer.
- Scleral buckling is a surgical procedure that involves placing a silicon implant in conjunction with a beltlike device around the sclera to bring the choroid in contact with the retina. Cryosurgery or laser is used before the buckling procedure to seal the tear and form a scar that helps adhere the retina and choroid layers together.
- Pneumatic retinopexy is a procedure that can be conducted in the physician's office and is time consuming for the patient. This procedure involves injecting air or gas into the chamber to hold the retina in place. The patient must be extremely compliant with the treatment regimen, reclining for about 16 hours before the procedure to allow the retina to fall back toward the choroid. Because air rises, the patient must maintain a position that keeps the air bubble against the detached area for up to 8 hours a day for 3 weeks.

Complications

With any of the retinal reattachment procedures there is risk of increased intraocular pressure (IOP) and recurrent detachment. The patient is also at risk for future breaks in the retina.

Nursing Process for the Patient with Retinal Detachment

ASSESSMENT/DATA COLLECTION. Subjective data collected includes patient observation of the loss of peri-

peripheral vision, any change in visual acuity, and the presence of floaters, flashing lights, cobwebs, or veil-like visual impairments. There should be an absence of pain. Objective data collected includes the patient's visual acuity, visual fields, ability to perform ADLs, and level of anxiety.

NURSING DIAGNOSIS, PLANNING, IMPLEMENTATION, AND EVALUATION. The nursing process for patients with retinal detachment can be found in the section on nursing process for patients undergoing eye surgery.

CRITICAL THINKING

Mr. Samuel

■ Mr. Samuel, age 65, is working in the yard when a branch strikes his right eye. He sees flashes of light and then a short time later a dark shadow out of the right eye.

1. What should Mr. Samuel do?
2. After having a scleral buckling procedure, Mr. Samuel reports nausea. What action should you take?
3. Compazine 7.5 mg IM prn every 6 hours is ordered. Available is Compazine 2 mL of 5 mg/mL. How many milliliters should you give?

Suggested answers at end of chapter.

Glaucoma

Glaucoma is a group of diseases characterized by abnormal pressure within the eyeball. This pressure causes damage to the cells of the optic nerve, the structure responsible for transmitting visual information from the eye to the brain. The damage is silent, progressive, and irreversible until the end stages, when loss of peripheral vision occurs, followed by reductions in central vision and eventually blindness (see Fig. 52.2). Once glaucoma occurs, the patient will always have it and must follow a treatment regimen to maintain stable intraocular eye pressures.

Pathophysiology

The most common form of glaucoma, called primary, consists of two types: primary open-angle glaucoma (POAG) and acute angle-closure glaucoma (AACG). Secondary glaucoma may be caused by infections, tumors, or injuries. A third form, congenital glaucoma, primarily is due to developmental abnormalities.

AACG occurs in people who have an anatomically narrowed angle at the junction where the iris meets the cornea. When nearby eye structures such as the iris protrude into the anterior chamber, the angle is occluded, which blocks the flow of aqueous fluid. This is considered a medical emergency and results in partial or total blindness if not treated. POAG occurs when the drainage system of the eye, the trabecular meshwork and Schlemm's canal, degenerate and subsequently block the flow of aqueous humor.

Etiology and Prevention

The incidence of AACG is highest among Asians, women older than age 45, and nearsighted individuals. The incidence of POAG increases in those older than 40 years of age (older than age 50 for European Americans, older than age 35 for African Americans), in persons with diabetes, and in those with a family history of glaucoma, and is four to five times more prevalent in African Americans than European Americans. Those in high-risk groups should have yearly eye examinations for glaucoma detection.

Signs and Symptoms

An ophthalmic emergency, AACG typically has a unilateral, rapid onset. The patient may complain of severe pain over the affected eye, blurred vision, rainbows around lights, eye redness, a steamy-appearing cornea, photophobia, and tearing. Nausea and vomiting may occur from the increased IOP.

POAG develops bilaterally. The onset is usually gradual and painless, so the patient may not experience noticeable symptoms or after time may experience mild aching in the eyes, headache, halos around lights, or frequent visual changes that are not corrected with eyeglasses.

Diagnostic Tests

Traditionally, tonometry is utilized to detect increased IOP (normal IOP: 12 to 20 mm Hg). Applanation tonometry uses a tiny instrument to apply pressure to the anesthetized cornea. Noncontact tonometry is performed with a tonometer mounted on a slit-lamp microscope using a warm puff of air that flattens an anesthetized area of the cornea to obtain a pressure reading. In contact tonometry, the instrument is placed directly on the anesthetized cornea to measure eye pressure. Tonometry is not adequate to detect glaucoma alone, so three other methods are used. The optic nerve is examined with an ophthalmoscope through dilated pupils, visual field examination looks for loss of peripheral vision, and the angle where the iris meets the cornea is checked. In AACG, IOP may exceed 50 mm Hg. A new glaucoma screening device, the GDx Access (Carl Zeiss Meditec, Dublin, CA), uses infrared laser technology to measure the thickness of the retinal nerve fiber layers to identify damage to the fibers. The advantages of this diagnostic tool are that it catches glaucoma earlier than other tests, which allows greater vision to be saved with treatment, and it is painless.

Therapeutic Interventions

The first-line treatment for glaucoma focuses on opening the aqueous flow by administering cholinergic agents (**miotics**) such as carbachol (Isopto) or pilocarpine (Pilocar) to constrict the pupil. When the pupil is constricted, the iris pulls away from the drainage canal so that the aqueous fluid can flow freely. A second type of medication may be given to slow the production of aqueous fluid. These include carbonic anhydrase inhibitors such as acetazolamide (Diamox), adrenergic agonists such as dipivefrin (Propine), or beta blockers such as timolol (Timoptic). Slowing the aqueous fluid production helps decrease IOP. Additionally, the physi-

cian may order steroid eye drops to reduce inflammation. The patient experiencing an acute attack of AACG is given these medications and mannitol, a hyperosmolar agent, to rapidly reduce IOP, as well as analgesics and is ordered to maintain complete bedrest.

Patients with glaucoma are required to administer life-long eye drop medications twice or more daily. In the absence of symptoms, compliance is often an issue. Other factors that contribute to noncompliance include age of the patient, inability to afford the medication, and lack of understanding of the disease process. Patients need to carry medical alert identification indicating they have glaucoma and what their medications are. This can help prevent administration of contraindicated medications in emergency situations.

Certain medications, regardless of their route, are contraindicated in AACG and can result in blindness if given to a patient with AACG. These medications include any anticholinergics such as atropine and antihistamines such as diphenhydramine (Benadryl) or hydroxyzine (Vistaril) because they are mydriatics. Before a medication is given, it should be determined that it is not contraindicated in AACG to prevent blindness from occurring.

LEARNING TIP

1. Mydriatic medications are contraindicated in acute angle-closure glaucoma because they can cause an acute episode of increased IOP by dilating the pupil and pushing the iris back, blocking the outflow of aqueous humor.
2. Miotic medications constrict the pupil and so may be given to patients with acute angle-closure glaucoma.
3. To remember what miotic medications and mydriatic medications do, so that the appropriate medication is given and contraindicated ones are never given, remember the following:
D = dilate = mydriatic = do not
No D = constricts = miotic = okay to give

Surgical Management

When medication is no longer able to control the flow of aqueous humor, surgical intervention may become necessary. Surgery focuses on creating an area for the aqueous humor to flow freely, thus preventing increased IOP (Fig. 52.3). For AACG, laser peripheral iridotomy or surgical iridectomy is performed. Laser iridotomy is a noninvasive procedure utilizing a laser to remove a portion of the iris, thus allowing aqueous fluid to flow through the area. Prophylactic iridotomy may be performed on the other eye to prevent AACG. POAG is treated with argon laser trabeculoplasty (noninvasive laser beam creates openings in trabecular meshwork), trabeculectomy (part of iris and trabecular meshwork removed), or cyclocryotherapy (cryoprobe destroys part of ciliary body).

FIGURE 52.3 Flow of aqueous humor after trabeculoplasty (arrows).

Nursing Process for the Patient with Glaucoma

ASSESSMENT/DATA COLLECTION. The patient should be assessed for loss of central and peripheral vision, discomfort, understanding of disease and compliance with treatment regimen, and ability to conduct activities of daily living.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. The goal of nursing care for the glaucoma patient is to prevent further visual loss and to promote comfort if the patient is experiencing pain with acute glaucoma. The patient who needs surgical intervention has additional goals (see Nursing Process for the Patient Having Eye Surgery).

Pain related to increased intraocular pressure

EXPECTED OUTCOME: Patient reports pain is relieved.

- Give analgesics as needed for acute glaucoma to relieve pain.

Disturbed sensory perception: visual related to altered sensory reception

EXPECTED OUTCOME: Patient has no further loss of vision.

- Interventions that may be implemented if the patient is experiencing severe visual loss or having surgery are in the nursing process sections for impaired vision and the patient having eye surgery, respectively.

Self-care deficit related to decreased vision

EXPECTED OUTCOME: Patient is able to care for self with assistance if needed.

- Assist with self-care as needed to ensure ADLs are met.

Anxiety related to partial or total visual loss

EXPECTED OUTCOME: Patient states reduced anxiety.

- Encourage patient to verbalize concerns about glaucoma to allow questions to be answered.

Risk for injury related to decreased vision

EXPECTED OUTCOME: Patient does not suffer injury as a result of the visual impairment.

- Refer patient to support services for vision loss *who provide adaptive visual devices.*
- Teach patient and family not to rearrange furniture without patient knowledge *to prevent falls or injury.*

Deficient knowledge related to medical regimen, disease process due to no prior experience

EXPECTED OUTCOME: Patient demonstrates correct instillation of eye medications and is able to verbalize understanding of condition and treatment.

- Teach need for having regular eye examinations through dilated pupils *to monitor disease and detect complications.*
- Teach how to administer medications with a return demonstration *to ensure that eye drops are administered properly.*
- Teach the patient to rest his or her hand on the forehead to steady the hand *if the patient has trouble with a steady hand when administering eye drops.*
- Consider large-print labels or audiotaped directions *if the patient is unable to see the label on the eye drop bottle.*
- Consider using large, multicolored dot stickers placed on medication bottle with a corresponding direction card with a matching colored dot *for patients with multiple medications.*
- Advise family members that they are at increased risk of developing glaucoma and should have regular eye examinations *as glaucoma can be hereditary.*

EVALUATION. Interventions are successful if the patient maintains an acceptable level of comfort, has no further loss of vision, is able to care for self with assistance, expresses concerns and anxieties, does not suffer injury as a result of the visual impairment, and is able to verbalize understanding of condition and treatment.

Cataracts

Pathophysiology and Etiology

A cataract is an opacity in the lens of the eye that may cause a loss of visual acuity (see Fig. 52.2). Vision is diminished because the light rays are unable to get to the retina through the clouded lens.

Factors that contribute to cataract development may include age, ultraviolet radiation (sunlight), diabetes, smoking, steroids, nutritional deficiencies, alcohol consumption, intraocular infections, trauma, and congenital defects.

Signs and Symptoms

Cataracts are painless. Symptoms of cataract formation may include halos around lights, difficulty reading fine print or seeing in bright light, increased sensitivity to glare such as when driving at night, double or hazy vision, and decreased color vision.

Diagnostic Tests

Cataract formation is diagnosed through an eye examination. Visual acuity is tested for near and far vision. The

direct ophthalmoscope and slit-lamp microscope are used to examine the lens and other internal structures.

Surgical Treatment

The only treatment for cataract formation is surgical removal of the cloudy lens. With the no-stitch cataract operation, there are no postoperative activity restrictions and vision is fine in about 2 days. After the lens is removed, there are several treatment options to correct the visual deficit that occurs when the eye is aphakic (absence of lens) and cannot accommodate or refract light properly. One treatment option is to provide the patient with eyeglasses or contact lenses that help correct the visual deficit. Another option is to replace the lens with a synthetic intraocular lens. For more information, visit the American Society of Cataract and Refractive Surgery at www.ascrs.org.

Complications

Complications of cataract surgery are rare but include inflammation, increased IOP, macular edema, retinal detachment, vitreous loss, hyphema, endophthalmitis, and expulsive hemorrhage.

Nursing Process for the Patient with Cataracts

ASSESSMENT/DATA COLLECTION. The patient is assessed for visual deficits to assist care planning, as well as knowledge needs about the disease process, surgical intervention, postoperative care, and medical regimen. The majority of patients undergoing cataract surgery have same-day surgery and then go home. The home situation, the ability of the patient or family member to follow the medical regimen, and transportation to and from the hospital for the patient are evaluated.

NURSING DIAGNOSES, PLANNING, IMPLEMENTATION, AND EVALUATION. Preoperative and postoperative nursing care is the primary nursing responsibility for the patient with cataracts, which is discussed below.

Nursing Process for the Patient Having Eye Surgery

ASSESSMENT/DATA COLLECTION. Subjective assessment data for patients having eye surgery can be collected using the WHAT'S UP? format (Table 52.4). Objective data may include visual acuity and peripheral field measurements. Visual acuity should be tested with and without corrective lenses. Eye tearing, redness, or swelling is noted.

Nursing Diagnosis, Planning, and Implementation

Risk for injury related to altered visual acuity

EXPECTED OUTCOME: Patient will remain free of injury.

- Explain depth perception may be affected by eye surgery, which can result in falls *to help prevent injury.*
- Ambulate with assistance and use clearly marked stairs.
- At home, beverages can be poured and stored in the refrigerator in single-serving glasses *to prevent spills and slippery floors.*

TABLE 52.4 SUBJECTIVE ASSESSMENT FOR PATIENTS HAVING EYE SURGERY

W	Where is the visual disturbance? Is it centrally located? Peripherally? Throughout the entire visual field? Unilateral? Bilateral?
H	How does it feel? Painful? Is there an absence of pain?
A	Aggravating or alleviating factors. Is it worse in bright light or at night? Better when resting eyes or with head of bed elevated?
T	Timing. Was there a sudden onset? Gradual onset?
S	Severity. Does it affect ADLs? Does it affect close-up work?
U	Useful data for associated symptoms. Does the patient suffer from hypertension? Diabetes? Has there been trauma? Vascular disease? What is the level of anxiety? Is the patient older than age 50?
P	Perception of the problem by the patient. Will the visual disturbance impair ability to carry out ADLs? Ability to comply with medical regimen? Ability to manage home maintenance?

ADLs = activities of daily living.

Deficient knowledge related to preoperative and postoperative eye care

EXPECTED OUTCOME: Patient will verbalize preoperative and postoperative care directions.

- Teach disease process, surgical intervention, preoperative and postoperative activity restrictions, use of dark glasses to decrease the discomfort of photophobia, use of correct technique for administration of eye medications, reporting for medical follow-up as instructed, and protecting the eye from further injury.
- In some types of cataract surgery, patients may be advised to avoid activities that might increase intraocular pressure, such as vomiting, coughing, sneezing, straining, or bending over or driving a car.
- Patients are told to seek medical treatment if they experience sudden, worsening pain, increase in watery or bloody discharge, or sudden loss of vision, as *these are signs of hemorrhage or problems*.

Anxiety related to visual alteration and surgery

EXPECTED OUTCOME: Patient will have minimal anxiety surrounding the visual alteration, treatment, and recovery.

- Allow patients the opportunity to discuss their feelings about the visual loss, by answering questions honestly, and by explaining any restrictions in activity to reduce anxiety.

EVALUATION. The patient goals have been met if the patient is free from injury, the patient verbalizes preoperative and postoperative directions, and anxiety is lessened.

Macular Degeneration

Pathophysiology and Etiology

Age-related macular degeneration (ARMD) is the leading cause of visual impairment in U.S. residents older than age 50. It involves a deterioration in the macula, the area on the retina where light rays converge for the sharp, central vision needed for reading and seeing small objects. The macula is also responsible for color vision (Fig. 52.4). There are two types of ARMD: dry (atrophic) and wet (exudative). In the dry form, photoreceptors in the macula fail to function and are not replaced because of advancing age. This accounts for 70% to 90% of the cases. In the wet form, retinal tissue degenerates, allowing vitreous fluid or blood into the subretinal space. New blood vessels are formed and compromise the macular tissue, causing subretinal edema. Eventually, fibrous scar tissue is formed, severely limiting central vision.

People at risk of developing macular degeneration include those older than age 60, those with a family history of macular degeneration, persons with diabetes, people who smoke, those frequently exposed to ultraviolet light, and Caucasian people.

Signs and Symptoms

Macular degeneration of the dry type is characterized by slow, progressive loss of central and near vision (see Fig. 52.2). Although individuals usually have the condition in both eyes, each eye may be affected in different degrees. Macular degeneration of the wet type has the same loss of central and near vision, but the onset is sudden. The loss can occur in one or both eyes. This visual loss is described as blurred vision, distortion of straight lines, and a dark or empty spot in the central area of vision. For some patients, there may be a decreased ability to distinguish colors.

Diagnostic Tests

Examination of the patient begins with visual acuity for near and far vision and an examination of the internal eye structures with an ophthalmoscope. The examiner uses an Amsler grid (Fig. 52.5) to detect central vision distortion and a color vision test to evaluate color differences. Patients are given an Amsler grid to take home and look at on a regular basis to monitor their vision changes. If any of the grid lines look crooked or disappear, the patient should contact the physician. Intravenous fluorescein (dye) angiography to look at the retina may also be utilized to evaluate blood vessel leakage or abnormalities in the eye.

Therapeutic Interventions

Unfortunately, there is no treatment for the dry type of ARMD. Most patients with the dry type do not lose peripheral vision or become totally blind, but most are classified as legally blind (less than 20/200 vision with correction). Special low-vision lenses can enhance remaining vision.

If the wet type of ARMD is diagnosed early, argon laser photocoagulation can seal the leaking blood vessels, slowing the rate of vision loss. If the patient receives argon laser photocoagulation, there is a small, permanent blind

FIGURE 52.4 Macular degeneration. The macula is a small area of the retina responsible for central and color vision.

spot at the point of laser contact with the macula. Photodynamic therapy is also available to stop bleeding in blood vessels. New research is exploring treatment options for wet ARMD. New drugs that are antiangiogenic (angiogenic = formation of new blood vessels) to stop the growth of new blood vessels in the eye are becoming available. These drugs inhibit vascular endothelial growth factor (VEGF), which is a protein involved in making new blood vessels and which increases vessel permeability. Examples of these medications are Pegaptanib (Macugen), which is now on the market, and ranibizumab (Lucentis), which is being studied. These medications are injected into the eye by an ophthalmologist. Macugen is most helpful in the early stages of ARMD. It slows the rate of vision loss but does not repair existing damage. Other studies are looking at the use of photodynamic therapy along with this drug to reduce the need for repeated laser treatments.

With either type of ARMD, patients have significant visual loss and need to adapt their patterns of daily living.

FIGURE 52.5 Amsler grid is used to identify central vision blind spots or distortions.

Research is exploring transplanting retinal pigmented epithelial cells that grow and function normally in an attempt to provide a cure in the future.

Nursing Process for the Patient with Macular Degeneration

See the nursing process section for the visually impaired.

Trauma

Emergencies and trauma of the eye must be assessed immediately so that proper treatment can be initiated. Injuries to the eye include foreign bodies, burns, abrasions, lacerations, and penetrating wounds. Treatment for chemical burns and sudden, painless loss of vision should be initiated within minutes to preserve vision.

Pathophysiology and Etiology

Foreign bodies are the most common cause of corneal injury. Dust particles or propellants may lodge in the conjunctiva or cornea. Patients naturally rub their eyes to dislodge the object, which further irritates the cornea. Burns may occur from chemical, ultraviolet, and direct heat sources. Depending on the agent causing the burn, it may be superficial or deep. Abrasions and lacerations usually occur as a result of something dragging across the eye, such as a fingernail or clothing.

Penetrating wounds are the most serious eye injury. Eye structures may be damaged permanently with complete blindness resulting. A penetrating wound also puts the patient at great risk of infection.

Signs and Symptoms

Foreign bodies produce pain when the eyeball or eyelid moves, causing the foreign body to drag over the opposing

surface. Usually the eye tears excessively in an attempt to irrigate the noxious substance out of the eye.

Injuries that irritate or penetrate layers of the cornea range from mild to severe pain. With corneal abrasions, the pain sensation may be delayed for several hours. Other symptoms that may be seen with abrasions, lacerations, and foreign bodies include conjunctival redness, photosensitivity, decreased visual acuity, erythema, and pruritus.

Acute pain and burning are characteristic symptoms of a burn to the eye. Chemical burns must be treated immediately with an eyewash or irrigation to remove the caustic substance from the eye.

Penetrating wounds may result in a variety of symptoms depending on the area of the eye involved and the extent of the damage. If the nerve has been damaged, the patient may have no pain.

Diagnostic Tests

With any eye trauma or injury, visual acuity must be tested. It is important to establish baseline acuity to evaluate effectiveness of treatment, although many patients resist acuity testing because of the discomfort. Testing includes examination by slit-lamp microscope and direct ophthalmoscope. Fluorescein staining is used to evaluate abrasions.

Therapeutic Interventions

Foreign bodies are treated with a normal saline flush to irrigate the object out of the eye or to a point where it can be removed with a swab. Topical antibiotic ointment is prescribed to prevent infection.

Most chemical burns are treated with a 15- to 20-minute irrigation of either tap water at the work site or sterile solution in the health-care facility. Topical antibiotic ointments are usually prescribed. Burns from heat or ultraviolet (UV) radiation are not irrigated.

Abrasions and lacerations are generally treated with anti-infective ointments or drops after cleansing the eye with a normal saline solution.

An eye specialist treats penetrating wounds. At initial injury, both eyes should be covered to prevent ocular movement. If there is a protruding object, it should be stabilized but not removed until the physician can assess the patient. The nature and extent of the penetrating wound determine treatment.

Complications

If the eye cannot be saved via medical treatment, it may be necessary to surgically remove the eye. This procedure is called **enucleation** (entire eyeball removal).

Nursing Process for the Patient with Eye Trauma
ASSESSMENT/DATA COLLECTION AND EMERGENCY INTERVENTION. Foreign Bodies. The eye is inspected for foreign bodies, which may be visible on the eyeball. The lids should be everted to examine the surface. Then the eye is irrigated.

Burns. Assessment of the type of burn is done because treatment options vary. Immediate irrigation of the eyes is performed once it has been established that a chemical burn has taken place unless contraindicated for the chemical. Medication and eye patching are applied as indicated.

Abrasions and Lacerations. The eye is assessed for visible lacerations and then cleansed with medication and patching of the eye as indicated.

Penetrating Wounds. The patient is kept calm and relaxed to minimize eye movement and increased IOP. If a protruding object is present, the object is stabilized with tape or other supports.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Acute pain related to inflammatory process and injury

EXPECTED OUTCOME: Pain level is within an acceptable range for the patient.

- Administer analgesics as ordered *to reduce pain*.
- Assist patient in remaining calm and relaxed *to reduce pain*.

Risk for infection related to eye trauma

EXPECTED OUTCOME: Patient remains free of infection.

- Use sterile technique when irrigating eye, when applying medications, and during examination *to prevent infection*.

Anxiety related to visual-sensory deficit

EXPECTED OUTCOME: Patient verbalizes a reduction in anxiety.

- Encourage the patient to verbalize feelings about visual impairment *to reduce anxiety*.
- Reassure patient as appropriate.

Deficient knowledge related to medical regimen due to lack of prior experience

EXPECTED OUTCOME: Patient is able to verbalize care of the eye.

- Teach patient about interventions and follow-up care.

EVALUATION. Patient goals have been met if pain level is within an acceptable range for the patient, patient remains free of infection, patient is able to verbalize a reduction in anxiety, and patient is able to verbalize care of the eye.

HEARING

Hearing Loss

Hearing loss is the most common disability in the United States and can be acquired or congenital. Hearing impairment ranges from difficulty understanding words or hearing certain sounds to total deafness (Box 52.6 Hearing Loss Summary). Hearing impairment can affect communication, social activities, and work activities. Hearing impairment

enucleation: e—removed from + nuclear—center

Box 52.6**Hearing Loss Summary****Signs and Symptoms**

Difficulty understanding words or certain sounds, total deafness, changes in social and work activities, turns up volume on TV, asks “What did you say?”, complains of people talking softly, speaks in a quiet or loud voice, answers questions inappropriately, avoids group activities, loss of sense of humor, appears aloof, complains of ringing, buzzing or roaring noise in ears

Diagnostic Tests and Findings

Abnormal Rinne’s and Weber’s tests, audiometric testing indicates hearing loss

Therapeutic Interventions

Ceruminolytics
Anti-infectives
Anti-inflammatories
Assistive devices (hearing aids, implantable middle ear hearing devices, cochlear implants)

Complications

Safety issues related to not hearing; withdrawal from social activities and relationships related to hearing loss

Possible Nursing Diagnoses

Disturbed sensory perception: hearing related to altered sensory reception and transmission
Impaired verbal communication related to impaired hearing
Impaired social interaction related to impaired hearing and decreased communication skills
Disturbed body image related to impaired hearing and use of assistive hearing devices
Ineffective coping related to difficult communication
Deficient knowledge related to care of hearing aid due to lack of prior experience

can diminish the individual’s quality of life. Nurses have a responsibility to communicate with the hearing impaired and provide necessary information regarding health care. For more information on hearing impairment, visit the following sites:

- American Academy of Ear, Nose and Throat at <http://entnet.org>
- Canadian Hard of Hearing Association at www.cyberus.ca/~chhanational/english.html
- National Information Center on Deafness at www.galludet.edu/~nicd
- National Institute on Deafness and Other Communication Disorders at www.nidcd.nih.gov
- National Organization for the Deaf at www.nad.org

Conductive Hearing Loss

Conductive hearing loss is any interference with the conduction of sound impulses through the external auditory canal, the eardrum, or the middle ear. The inner ear is not involved in a pure conductive hearing loss. Conductive hearing loss can be caused by anything that interferes with the ability of the sound wave to reach the inner ear. Conductive hearing loss is a mechanical problem. Causes of conductive hearing loss include cerumen, foreign bodies, infection, perforation of the tympanic membrane, trauma, fluid in the middle ear, cysts, tumor, and **otosclerosis**. Many causes of conductive hearing loss, such as infection, foreign bodies, and impacted cerumen, can be corrected. Hearing devices may improve hearing for conditions that cannot be corrected, such as scarred tympanic membrane or otosclerosis. Hearing devices are most effective with conductive hearing loss when no inner ear and nerve damage are present.

Sensorineural Hearing Loss

Sensory hearing loss originates in the cochlea and involves the hair cells and nerve endings. Neural hearing loss originates in the nerve or brainstem. **Sensorineural** hearing loss results from disease or trauma to the sensory or neural components of the inner ear. Some of the causes of nerve deafness are complications of infections (such as measles, mumps, and meningitis), ototoxic drugs (Table 52.5), trauma, noise, neuromas, arteriosclerosis, and the aging process.

Presbycusis is hearing loss caused by the aging process that results from degeneration of the organ of Corti. This degenerative process usually begins in the fifth decade of life. The individual develops an inability to decipher high-frequency sounds (consonants *s*, *z*, *t*, *f*, and *g*). This interferes with the individual’s ability to understand what has been said, especially in noisy environments. The aging individual commonly has more difficulty understanding higher pitched female voices than lower pitched male voices.

Other Types of Hearing Loss

Mixed hearing loss occurs when an individual has both conductive and sensorineural hearing loss. This can be caused

otosclerosis: oto—ear + sclerosis—hardening

by a combination of any of the disorders previously mentioned. Central hearing loss occurs when the central nervous system cannot interpret normal auditory signals. This condition occurs with such disorders as cerebrovascular accidents and tumors. Functional hearing loss is a hearing loss for which no organic cause or lesion can be found. It is also called psychogenic hearing loss and is precipitated by emotional stress.

Therapeutic Interventions

Medical management consists of improving the patient's hearing. The majority of persons with ear disorders have some degree of hearing loss. With any permanent hearing loss, the use of a hearing aid should always be considered. A hearing aid is designed to amplify sound or attenuate certain portions of the sound signal and amplify other sounds. Various types of hearing aids are available (Fig. 52.6). The in-the-ear aid is a small device that fits in the ear canal. The in-the-ear aid is unobtrusive and may be preferred by the individual. The behind-the-ear aid is worn postauricular.

The all-in-one eyeglass aid is attached to glasses and is positioned behind the ear.

Surgical intervention may be available for patients whose hearing is not improved with hearing aids. Implantable middle ear hearing aids can improve sound perception for patients with moderate-to-severe sensorineural hearing loss. Cochlear implants are surgically placed electrical devices that receive sound and transmit the resulting electrical signal to electrodes implanted in the cochlear of the ear. The signal stimulates the cochlea, allowing the patient to hear. The cochlear implants are able to restore up to half of the patient's hearing.

Nursing Process for the Patient Who Is Hearing Impaired

ASSESSMENT/DATA COLLECTION. Nursing care includes identifying those patients at risk for hearing impairment (Table 52.6). Patients with renal or hepatic disease, using two or more ototoxic drugs, or previously having used ototoxic drugs are at risk for developing hearing impairment. Monitor for signs of vertigo, horizontal nystagmus, nausea, vomiting, and spinning or rocking sensation while sitting still. To collect data for the hearing impaired patient, ask family members, as well as the patient, questions related to the patient's hearing status.

Objective data focus on obtaining a gross screening of hearing function. Assessment should start with engaging in normal conversation with the patient. Observe the patient for any difficulty understanding conversation or interview questions. Clarity of the patient's speech is also determined during the interview. Physical assessment includes the whisper voice, Rinne, and Weber tests. Test results provide an estimate of conductive or sensorineural hearing loss. The patient should be assessed for the underlying cause of the problem to determine if it is an external, middle, or inner ear problem. Examination of the external ear may reveal an external ear problem. The advanced practitioner may examine the ear canal for impacted cerumen or a tympanic mem-

FIGURE 52.6 Hearing aids. (A) Behind-the-ear hearing aid. (B) In-the-ear hearing aid.

TABLE 52.6 SUBJECTIVE ASSESSMENT OF HEARING

W	Where is it? Are both ears affected? Is one side worse than the other?
H	How does it feel? Are certain words unclear, or entire conversations? Are high-frequency sounds (consonants <i>s, t, z, f, g</i> , and female voices) unclear or difficult to understand? Is there any pain associated with the hearing loss? Any tinnitus or vertigo?
A	Aggravating and alleviating factors. Is hearing worse in large groups or when there is a lot of background noise? Is hearing improved in a quiet environment or when speaking only to an individual? Is it easier to understand someone when seeing the person's lips move? Does the patient own or use any assistive hearing devices? Are they effective? What type is used?
T	Timing. When did the hearing loss start? Was it gradual or sudden? Is the hearing loss associated with any illness or traumatic event? Is it associated with any recent flying? Any history of ototoxic drug use?
S	Severity. Does it cause communication impairment? How much? Does it affect ADLs? Does it affect or limit usual social activities? Have family or friends commented on decreased hearing? Does patient avoid communication or social activities because of difficulty hearing? Is patient having difficulties hearing telephone voices, radio, television, or movies?
U	Useful data for associated symptoms. Is there any fever, nausea, vomiting, or dizziness? Is there any history of occupational or environmental exposure to loud noises? What are the usual ear self-care habits? Any history of impacted cerumen? Has patient ever had cerumen removed from ears?
P	Perception of problem by the patient. What does the patient feel is wrong? Does the patient think that he or she has a hearing problem? How does the patient feel about hearing assistive devices? How does the patient perceive the hearing loss, and how is it influencing the patient's life?

brane problem. Any assistive hearing devices should be noted and inspected for proper functioning. The results of the examination are documented and communicated to other health-team members.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Planning focuses on helping the patient optimize hearing, promoting communication, and promoting adjustment to impaired hearing (Boxes 52.7 Communicating with the Hearing Impaired and 52.8 Care of Hearing Aids). Nursing management for the patient with hearing impairment focuses on enhancing communication and quality of life (see Box 52.9 Nursing Care Plan for the Patient with Hearing Loss). Families should be included in discussions about therapeutic hearing devices and their care, enhancing communication, and limiting isolation.

EVALUATION. The patient's goals are met if the patient communicates effectively, engages in usual social activities,

Box 52.7**Communicating with the Hearing Impaired**

1. Get the person's attention before beginning to speak.
2. Face and stand close to the person being spoken to and maintain eye contact.
3. Avoid standing in the glare of bright sunlight or other bright lights.
4. Speak clearly, at a normal rate and volume. Do not shout or overarticulate.
5. Inform the listener of topics to be discussed and when a change of topic occurs. Stick to a topic for a while and avoid quick shifts.
6. Use short sentences and assess for understanding. If the listener does not understand after the message is repeated, rephrase the message. If the listener has difficulty with high-pitched sounds, lower the voice pitch.
7. Allow extra time for the listener to respond and do not rush the listener.
8. Ensure an optimum environment by reducing background noises by turning off television and radio, closing the door, or moving to a quieter area.
9. Encourage nonverbal communication such as touch or gestures as appropriate.
10. If the listener uses a hearing device, ensure that it is operational and in place before beginning to communicate. Give the person time to adjust the hearing device before speaking.
11. Do not smile, chew gum, or cover the mouth when talking.
12. Use active listening with attentive body posture, pleasant facial expressions, and a calm, unhurried manner.
13. Do not avoid conversation with a person who has hearing loss.
14. Use written communication if unable to communicate verbally.

verbalizes acceptance of an assistive hearing device, copes with emotional reaction of hearing impairment, and demonstrates care of hearing aid.

External Ear**Infections**

PATHOPHYSIOLOGY AND ETIOLOGY. Infections are the most common disorder of the external ear, with **external otitis** being the most common infection. Exposure to moisture, contamination, or local trauma provides an ideal environment for pathological growth in the external ear, which results in external otitis. It may be caused by bacterial

Box 52.8**Care of Hearing Aids**

1. Insert hearing aid while over a soft surface such as a pillow to prevent damage if the hearing aid is dropped during insertion.
2. Remove hearing aid before showering or bathing. Do not immerse in water.
3. Turn the hearing aid off when not in use to conserve battery.
4. Do not expose the hearing aid to extreme heat or cold.
5. Clean the hearing aid daily with a dry, soft cloth. Clean ear mold with small brush or toothpick to keep free of earwax.
6. Turn off the hearing aid and turn the volume down before inserting. Turn hearing aid on and increase volume once it is inserted.
7. Minimize whistling noise by ensuring that the volume is not too high, the aid fits securely, and the aid is free from ear-wax.
8. Check battery or lower the volume if sound is not clear or is intermittent. Buzzing noise may indicate that the battery door is not completely closed.
9. Do not expose the hearing aid to medicinal or hair sprays. Apply sprays before inserting hearing aid.

or fungal pathogens. Staphylococci are the most common causative organisms, but other gram-negative or gram-positive bacteria can cause problems. *Pneumocystis* infections have been seen in patients who have human immunodeficiency virus (HIV). A bacterial or fungal external otitis that occurs when water is left in the ear and washes away protective ear wax often after water exposure or trauma is known as swimmer's ear. External otitis occurs more often in the summer months than in the winter months. However, swimmer's ear can be seen year round in patients who swim indoors.

A localized infection called ear canal **furuncle** or abscess results when a hair follicle becomes infected. A **carbuncle** forms when several hair follicles are involved in forming the abscess. Most furuncles and carbuncles erupt and drain spontaneously. Otomycosis is an infection caused by fungal growth and is typically seen after topical corticosteroid or antibiotic use. Otomycosis occurs more often in hot weather. An infection of the auricle is called perichondritis, which can result in necrosis of cartilage.

SIGNS AND SYMPTOMS. The most common sign of infection of the external ear is pain (Box 52.10 External Ear Disorders Summary). An early indication of infection is pain with gentle pulling on the pinna. The patient may also experience pain when moving the jaw or when the otoscope is inserted into the ear canal. Pruritus (itching) is also a

common symptom and can be an early sign of infection. Signs of inflammation are present on the external ear. The ear canal may become swollen or occluded, and as a result hearing may be diminished. Redness, swelling, and drainage can be observed during otoscopic examination. If drainage is present, it usually starts out clear and becomes purulent as the disease progresses. The patient may also be febrile.

DIAGNOSTIC TESTS. Laboratory tests such as a complete blood cell count (CBC) and cultures of discharge may be completed to diagnose infections. The white blood cell (WBC) count may be elevated. Culture and sensitivity tests isolate the specific infective organism, as well as antibiotics to treat the infection. Rinne's and Weber's tests can indicate conductive hearing impairment.

Impacted Cerumen

PATHOPHYSIOLOGY AND ETIOLOGY. Normally, the ear is self-cleaning. However, cerumen (wax) may become impacted, blocking the ear canal. People with large amounts of hair in the ear canal or who work in dusty or dirty areas are prone to cerumen impaction. Improper cleaning can also result in cerumen impaction. The older adult is at risk to develop impacted cerumen. This occurs because the amount of cerumen secreted is decreased and because of increased amounts of keratin. These two factors cause the cerumen to be drier, harder, and more easily impacted. Patients with hearing aids tend to have problems with impacted cerumen. Patients with bony growths secondary to an osteophyte or osteoma are at risk for cerumen impaction.

SIGNS AND SYMPTOMS. The patient may experience hearing loss, a feeling of fullness, or blocked ear if cerumen has become impacted (see Box 52.6 Hearing Loss Summary). Otoloscopic examination reveals cerumen blocking the ear canal.

DIAGNOSTIC STUDIES. Audiometric testing reveals conductive hearing loss in the affected ear. Hearing acuity can be decreased by 45 decibels because of an impacted cerumen. Whisper voice, Rinne's, and Weber's tests also indicate conductive hearing loss (see Chapter 51).

Masses

PATHOPHYSIOLOGY AND ETIOLOGY. Benign masses of the external ear are usually cysts resulting from sebaceous glands. Other benign masses are lipomas, warts, keloids, and infectious polyps. Infectious polyps usually arise from the middle ear and enter the external ear through a hole in the tympanic membrane. Actinic keratosis is a precancerous lesion that can be found on the auricle and may be seen in the elderly. Malignant tumors such as basal cell carcinoma on the pinna and squamous cell in the ear canal may develop. These tumors can spread to surrounding tissue and bones if not treated.

SIGNS AND SYMPTOMS. Changes in the appearance of the skin can occur with benign or malignant masses.

Box 52.9 NURSING CARE PLAN for the Patient with Hearing Loss

Nursing Diagnosis: Disturbed sensory perception: hearing related to altered sensory reception and transmission

Expected Outcomes Patient will attain optimum level of sensory stimulation. Patient will become aware of auditory impairment and ways to compensate. Patient will demonstrate ability to perform activities of daily living, with assistance if necessary.

Evaluation of Outcomes Patient perceives maximum auditory sensory input. Patient is able to compensate for sensory impairment by using other senses and resources. Patient is able to perform activities of daily living as independently as possible.

Interventions

Begin assessment of hearing by inspecting ear canals for mechanical obstruction. If cerumen is found, the use of a softening product is recommended to assist in wax removal. If canal is clear, continue assessment of hearing by use of a tuning fork, loud ticking clock, or verbal cues to determine auditory ability at various distances.

Enhance hearing by giving auditory cues in quiet surroundings.

Enhance understanding of auditory cues by getting patient's attention before speaking, speak slowly with careful enunciation of words, add hand gestures, speak face to face with impaired person, and adjust pitch downward without increasing volume.

Structure environment to compensate for hearing loss by adding visual indicators to telephone ringer, doorbell, smoke detectors, and other emergency sounds.

Provide for optimum care of assistive appliances such as hearing aids by making sure that cerumen has been cleaned from the device, that batteries are charged, and that appliance is placed correctly in ear.

Rationale

Hearing loss may occur due to the buildup of cerumen in the auditory canal.

Determination of hearing ability assists nurse in developing interventions appropriate to the hearing level of patient.

Background noise such as television, radio, or large numbers of people make hearing more difficult.

Hearing is enhanced when additional cues assist the impaired individual in understanding the message. Use of hand gestures to point, lip-reading, facial expression, and lower pitch all assist communication.

Assists in communication and safety.

Appliances that are not functioning properly will not assist patient in hearing.

Evaluation

Is ear canal free of mechanical obstruction?

Is patient able to hear verbal input? If not, how severe is the impairment?

Are auditory cues being delivered in an environment free of extraneous background noises?
Are auditory cues being understood by patient?

Are instructions given in step-by-step format with written cues?

Is patient able to receive input in ways other than auditory?

Is patient's hearing aid in place correctly? Is there cerumen blocking sound conduction?
Do batteries work?

Interventions

Introduce assistive devices such as hearing amplifiers, telephone amplifiers, telephones with extra-loud bells, written communication, and sign language.

Allow patient to verbalize feelings and grieving about hearing loss.

Identify coping strategies that have been successful for patient in the past.

Refer to specialized clinician such as audiologist or occupational therapist or to specialized resources such as National Association of the Deaf or American Speech, Language and Hearing Association.

Rationale

Patients may not be aware of assistive devices, which may help them adapt to hearing loss and continue previous activities such as talking on telephone or listening to television.

Losing a primary sense such as hearing can be devastating for patients. Opportunity to ventilate feelings assists in processing the loss.

By identifying successful coping strategies, the nurse assists patient in dealing with stress of hearing loss. A positive approach for nurses to use focuses on the individual's capabilities rather than deficits.

Specialized clinicians can provide detailed examination and treatment for the disorder.

Specialized resource groups have networks in place to assist individuals in coping with the loss and assisting them with maximizing abilities.

Evaluation

Is patient aware of assistive devices that will allow him or her to continue to verbally communicate with others? Is patient able to use the devices to compensate for auditory impairment?

Is patient able to verbalize feelings about the auditory impairment and its loss?

Is patient able to identify successful coping strategies and use them to deal with stress of hearing impairment?

Does patient know who to call for detailed examination and treatment of problems? Does patient know that there are specialized clinicians and resource groups to help with hearing impairment? Does patient know how to access these specialists?

Usually, impaired conductive or sensorineural hearing loss occurs with masses. Pain is another symptom and is usually described as deep pain radiating inward on the affected side. Ear drainage may be present. As the condition progresses, facial paralysis occurs. Visualization of the mass may be observed during otoscopic examination.

DIAGNOSTIC STUDIES. A biopsy may be obtained to determine if the mass is benign or malignant. Imaging studies are also used to diagnose tumors. Audiometric studies reveal any hearing impairment.

Trauma

PATHOPHYSIOLOGY AND ETIOLOGY. Injuries to the external ear are commonly caused by a blow to the head, automobile accidents, burns, foreign bodies lodged in the ear canal, and cold temperatures. Foreign bodies in the ear canal are common among children, with small toys being the most common object found. Cotton ball pieces and insects are the most common foreign bodies found in adults.

SIGNS AND SYMPTOMS. Lacerations, contusions, hematomas, abrasions, erythema, and blistering are signs seen with thermal or physical trauma. Repeated trauma to the ear can cause swelling, also known as cauliflower ear. This is common among boxers, rugby players, martial artists, and wrestlers. Conductive hearing loss can occur if

the ear canal is partially or totally blocked. Patients who have contusions or hematomas commonly complain of numbness, pain, and paresthesia of the auricle. The patient may or may not have symptoms associated with foreign bodies. These symptoms include decreased hearing, itching, pain, and infection. Examination of the ear canal with a penlight usually reveals the foreign body. Care should be taken during otoscopic examination not to push the foreign body further into the ear canal.

DIAGNOSTIC STUDIES. Imaging studies may be needed to determine the extent of the trauma. Audiometric, whisper voice, Rinne's, and Weber's tests may demonstrate conductive hearing loss.

Complications of External Ear Disorders

Complications can result from delayed treatment, no treatment, or spreading of the external ear disorder. If not treated, infections can spread, causing cellulitis, abscesses, middle ear infection, and septicemia. Metastasis can occur if malignant tumors are not treated. Infection, trauma, and malignant tumors may cause temporary or permanent hearing loss, disfigurement, discoloration, and scarring. Prompt identification and treatment of external ear disorders can prevent many complications.

Box 52.10**External Ear Disorders Summary**

Signs and Symptoms	Pain, pruritus, swelling, redness, drainage, lacerations, contusion, hematomas, abrasion, erythema, blistering, hearing loss, foreign body
Diagnostic Tests and Findings	CBC with elevated WBC with infections; audiometric, Rinne's, Weber's, and whisper voice tests indicate conductive hearing loss with impacted cerumen and trauma; imaging studies to indicate extent of trauma
Therapeutic Interventions	Ceruminolytics to remove ear wax; anti-infectives and anti-inflammatory medications to treat infection; débridement, surgical repair, or application of protective covering with trauma to external ear
Complications	Spread of infection to other parts of the ear, disfigurement, loss of hearing, and scarring
Possible Nursing Diagnoses	Acute pain related to inflammation or trauma Disturbed sensory perception: auditory related to altered sensory reception Risk for injury related to self-cleaning of external ear Deficient knowledge related to care of hearing aid due to lack of prior experience

Therapeutic Interventions for External Ear Disorders

External ear infections are treated with topical antibiotics in the form of drops or ointment. Systemic antibiotics are used for severe infections that are localized or have spread to surrounding tissues. Topical or systemic steroids may be used to treat inflammation. The ear is thoroughly cleaned before starting any topical treatment. If the external ear canal has drainage or is swollen shut, a wick may be inserted. The wick serves to aid in removing drainage or to aid in administering medication into the ear canal. Cerumen may be removed with instillations, a blunt ear curette, or a wire ear curette. Instillation is not used with a history of perforated tympanic membrane (eardrum).

External ear disorders are usually painful, and analgesics are used to control pain.

Débridement, surgical repair, or application of a protective covering may be done when trauma occurs to the external ear. Surgical management consists of incision and drainage of abscesses. Excision of cysts or cutaneous carcinomas may also be required.

Nursing Process for the Patient with External Ear Disorders

ASSESSMENT/DATA COLLECTION. Subjective data are obtained in a patient history. Data include any reports of pain, fullness, previous cerumen impaction, itching, or hearing loss, as well as onset, duration, and severity of symptoms. Additional data include patient's occupation, previous ear problems, use of a hearing aid, and typical ear hygiene. Inspection and palpation are primarily used to obtain objective data. Observe for redness, swelling, drainage, furuncles, carbuncles, lesions, abrasions, lacerations, growths, cerumen, scaliness, or crusting. The patient may report pain when the ear is palpated. Basic hearing acuity tests are conducted to evaluate hearing loss (see Chapter 51).

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Possible nursing diagnoses are listed below.**Acute pain related to inflammation or trauma**

EXPECTED OUTCOME: Patient's pain will be decreased or absent as evidenced by a lower rating on the pain scale

- Assess for nonverbal signs of ear pain *to identify pain.*
- Identify with the patient an optimum analgesic schedule *to promote comfort.*
- Implement nonpharmacological methods such as relaxation, massage, music, guided imagery, or distraction techniques *to relieve pain.*
- Heat may be applied to the area *to promote comfort.*
- Liquid or soft foods may be offered *if the patient experiences pain when chewing.*

Disturbed sensory perception: auditory related to altered sensory reception

EXPECTED OUTCOME: Patient hearing will return to preillness state.

- Teach patient how to administer topical antibiotics and anti-inflammatory medications using aseptic technique *to help restore hearing and relieve blockage of the ear canal.*
- Explain to patient if a wick is inserted into the ear canal *to monitor for drainage and report excessive drainage to health-care provider.*
- Explain procedure if health-care provider is to remove cerumen *for patient understanding and to decrease anxiety* (Box 52.11 Removing Cerumen, Fig. 52.7).

Box 52.11**Removing Cerumen**

Instillations and irrigations should not be used on any person with a history of perforated tympanic membrane. Commercial ceruminolytics or common products such as baby oil, mineral oil, and virgin olive oil can be used to soften impacted cerumen and aid in the removal of the impacted wax. The patient should instill several drops of the solution at bedtime and then place a cotton plug in the ear to hold the solution in place. Excess oil and drainage are removed in the morning. Earwax is usually softened for 3 to 4 days before an irrigation is attempted. Patients prone to cerumen build-up should be taught how to safely remove earwax. A few drops of half-strength peroxide may be instilled into the ear canal during the day and three drops of glycerine instilled at bedtime. This can be repeated each week to minimize wax build-up.

The ear can be irrigated with an ear irrigation syringe or a Water Pik. The irrigation solution, usually water, should be warmed to body temperature. The patient is draped with a protective plastic drape, and a basin is placed below the ear to catch the irrigating solution. The patient sits with the ear toward the nurse and the head tilted toward the opposite ear. (See Fig. 52.7.) The external ear is pulled upward and backward for the adult. A low-pressure stream of water is directed toward the top of the ear canal. Care is taken not to obstruct the canal with the syringe so that the irrigation solutions can flow back out of the canal. Ensure that only the tip of the syringe is in the ear canal to prevent perforation of the eardrum.

Box 52.12**Ear Care**

1. Cleanse the external ear with a wet washcloth. Gently cleanse the helix.
2. Never insert anything into the ear canal, including hairpins, cotton-tipped applicators, matchsticks, safety pins, toothpicks, paper clips, and fingers.
3. An individual with a history of ear infections, perforated tympanic membrane, or swimmer's ear should prevent moisture from entering the ear canal. Avoid swimming in contaminated water. Moisture or water in the ear canal can be prevented by using special earplugs or by using a piece of cotton rolled into a cylinder and covered with petroleum jelly.
4. Avoid home remedies for ear care without consulting a physician.
5. An individual with an upper respiratory infection should gently blow the nose with both nares open to prevent microbes from being forced up the eustachian tubes.

Risk for injury related to self-cleaning of external ear

EXPECTED OUTCOME: Patient explains or demonstrates prescribed treatment.

- Instruct patient how to care for ear to prevent injury.
- Instruct how to complete prescribed treatment to ensure completion of treatment.
- See Box 52.12 (Ear Care) for further instructions on ear care.

FIGURE 52.7 Ear irrigation. (A) Child. (B) Adult. (C) Irrigation.

Deficient knowledge related to lack of information on preventive ear care

EXPECTED OUTCOME: Patient explains or demonstrates procedures to maintain wellness of the external ear.

- Instruct patient to keep external ear clean and dry to prevent problems.
- Teach patient how to use topical antibiotics, oral antibiotics, and/or anti-inflammatory medications to promote healing.
- Teach the patient how to complete the prescribed treatment and maintain ear health (see Box 52.12 Ear Care): include how to administer ear drops or ointments, keep the ear clean and dry, use cotton with petroleum jelly or ear plugs to avoid getting water in the ears during an infection.

EVALUATION. The outcomes for the patient are met if patient indicates pain is decreased or absent as evidenced by a lower rating on a pain scale, hearing improves or returns to preillness level, states or demonstrates prescribed treatment (e.g., administering ear drops or ointments), explains or demonstrates measures to maintain wellness of the external ear.

Middle Ear, Tympanic Membrane, and Mastoid Disorders

Infections

PATHOPHYSIOLOGY AND ETIOLOGY. Otitis media is the most common disease of the middle ear. *Otitis media* is a general term for inflammation of the middle ear, mastoid, and eustachian tube. Inflammation of the nasopharynx causes most cases of otitis media. As inflammation occurs, the nasopharyngeal mucosa becomes edematous and discharge is produced. When fluid, pus, or air builds up in the middle ear, the eustachian tube becomes blocked, and this impairs middle ear ventilation.

There are several types of otitis media in which inflammation can occur alone, with infective drainage, or with noninfective drainage. The first type of otitis media is otitis media without effusion. This is an inflammation of the middle ear mucosa without drainage. The second type of otitis media occurs when there is a bacterial infection of the middle ear mucosa. This is called acute otitis media, suppurative otitis media, or purulent otitis media. The infected fluid becomes trapped in the middle ear. If the infection continues longer than 3 months, chronic otitis media results. The third type of otitis media is otitis media with effusion. Other names include serous otitis media, nonsuppurative otitis media, and glue ear. With this type of otitis media, noninfective fluid accumulates within the middle ear.

SIGNS AND SYMPTOMS. Acute otitis media commonly follows an upper respiratory infection. A fever, earache, and feeling of fullness in the affected ear are common symptoms (Box 52.13 Middle Ear Disorders Summary). As purulent drainage forms, there is pain and conductive hearing loss. Nausea and vomiting may also be present. Purulent drainage may be evident in the external ear canal if the tympanic

Box 52.13

Middle Ear Disorders Summary

Signs and Symptoms

Fever, earache, and feeling of fullness in affected ear following upper respiratory infection; nausea, vomiting; mastoid tenderness; otoscopic examination reveals reddened, bulging tympanic membrane; progressive hearing loss; vertigo; disorientation

Diagnostic Tests

Complete blood count
Ear cultures
Audiometric, Rinne's, Weber's, and whisper voice tests

Therapeutic Interventions

Antibiotics
Analgesics
Myringotomy
Myringoplasty
Stapedectomy

Complications

Perforation of tympanic membrane, cholesteatoma, tympanosclerosis, mastoiditis, permanent hearing loss

Possible Nursing Diagnoses

Acute pain
Fear
Deficient knowledge
Risk for infection

membrane ruptures. Mastoid tenderness indicates that the infection may have spread to the mastoid area. Otoscopic examination reveals a reddened, bulging tympanic membrane.

Symptoms of otitis media with effusion may go undetected in adults because there are no signs of infection. The patient may complain of fullness, bubbling, or crackling in the ear. The patient may have a slight conductive hearing loss or allergies or be a mouth breather. Otoscopic examination can reveal a bulging tympanic membrane with a fluid level, but the eardrum is not reddened.

DIAGNOSTIC STUDIES. Laboratory studies may indicate an elevated WBC count. Ear cultures may be obtained on any drainage to identify the specific infective organism. Conductive hearing loss is usually present on audiometric studies and Rinne's, Weber's, and whisper voice tests. Imaging studies may be done to diagnose infection.

COMPLICATIONS. A perforation may occur with an acute or chronic infection. Build-up of fluid and pressure in the middle ear can cause a spontaneous perforation of the tympanic membrane. The patient usually experiences pain before the rupture and relief of pain after the rupture. The

fluid in the middle ear moves through the perforation into the ear canal, relieving the pressure and pain. A tympanic membrane perforation causes hearing loss. The location and size of the perforation determine the extent of hearing loss. Damage to the ossicles can also occur with perforation.

Repeated infections in the middle ear or mastoid can cause a cholesteatoma, which is an epithelial cystlike sac that fills with debris such as degenerated skin and sebaceous material. The cholesteatoma starts in the external ear canal and spreads to the middle ear through a perforation in the tympanic membrane. Damage occurs in the middle ear structures as a result of pressure necrosis. The cholesteatoma causes conductive hearing loss. As the disease progresses, facial paralysis and vertigo may occur.

Tympanosclerosis is another complication of repeated middle ear infections. Tympanosclerosis consists of deposits of collagen and calcium on the tympanic membrane. The condition can slowly progress over time to the area around the middle ear ossicles. These deposits appear as chalky white plaques on the tympanic membrane and contribute to conductive hearing loss.

Mastoiditis can occur if acute otitis media is not treated. The infection spreads to the mastoid area, causing pain. Since the use of antibiotics, acute mastoiditis is relatively uncommon. Chronic mastoiditis is still seen with repeated middle ear infections.

THERAPEUTIC INTERVENTIONS. Bacterial infections are treated with antibiotics. Amoxicillin (Amoxil), penicillin V (Beepen-VK, Veetids), erythromycin (E.E.S.), cefaclor (Ceclor), and cotrimoxazole (Bactrim) are commonly used. Oral analgesics such as aspirin, acetaminophen, or codeine or ear drops are given to control pain.

Surgical intervention includes several techniques. Paracentesis may be performed with a needle and syringe. The tympanic membrane is punctured with the needle, and the fluid is drained from the middle ear. A **myringotomy** may also be performed. During this procedure, an incision is made in the tympanic membrane and fluid is allowed to drain out or is suctioned out of the middle ear. Another technique is laser-assisted myringotomy, which vaporizes the tympanic membrane. Various types of transtympanic tubes may be inserted to keep the incision open. The transtympanic tube keeps the incision in the tympanic membrane open, equalizes pressure, and prevents further fluid formation and build-up. The transtympanic tubes are left in place until the infection is cured. Most tubes spontaneously extrude in 3 to 12 months and rarely have to be removed.

Reconstructive repair of a perforated tympanic membrane is called a **myringoplasty**. One technique involves placing Gelfoam over the perforation. A graft from the temporal muscle behind the ear or tissue from the external ear is then placed over the perforation and Gelfoam. The Gelfoam is absorbed, and the graft repairs the perforation.

myringoplasty: myringo—tympanic membrane + plasty—surgical repair

A mastoidectomy involves incision, drainage, and surgical removal of the mastoid process if the infection has spread to the mastoid area.

Otosclerosis

PATHOPHYSIOLOGY AND ETIOLOGY. Otosclerosis, or hardening of the ear, results from the formation of new bone along the stapes. With the new bone growth, the stapes becomes immobile and causes conductive hearing loss. The formation of the new bone growth begins in adolescence or early adulthood and progresses slowly. Hearing loss is most apparent after the fourth decade. Otosclerosis is more common in women than in men. The disease usually affects both ears. Although the exact cause of otosclerosis is not known, most patients have a family history of the disease. It is therefore thought to be a hereditary disease.

SIGNS AND SYMPTOMS. The primary symptom of otosclerosis is progressive hearing loss. The patient usually experiences bilateral conductive hearing loss, particularly with soft, low tones. Usually, medical treatment is sought when the hearing loss interferes with the patient's ability to hear conversations. The patient may also experience tinnitus. Otoloscopic examination reveals a pinkish orange tympanic membrane because of vascular and bony changes in the middle ear.

DIAGNOSTIC STUDIES. Audiometric testing indicates the type and extent of the hearing loss. Imaging studies indicate the location and the extent of the excessive bone growth. Whisper voice test and normal conversation show decreased hearing. The patient hears best with bone conduction in the Rinne test, whereas lateralization to the most affected ear occurs with the Weber test.

THERAPEUTIC INTERVENTIONS. There is no cure for otosclerosis, but hearing aids may be used to improve hearing for the patient. The hearing aid is most effective for conductive hearing loss when there is no sensorineural involvement.

Although total restoration of hearing is not possible, reconstruction of necrotic ossicles is done to restore some of the patient's hearing. Various methods are used to reposition and replace some or all of the ossicles. Unfortunately, the surgeries are not always successful over the long term. Ossiculoplasty is the reconstruction of the ossicles. Prostheses made of plastic, ceramic, or human bone are used to replace the necrotic ossicles. Total or partial ossicular replacement prosthesis may be used.

Stapedectomy is the treatment of choice for otosclerosis. Either part or all of the stapes is removed and replaced with a prosthesis. The prosthesis is placed between the incus and the oval window. Advances in surgical treatment include the use of lasers for improved visualization, less trauma, and greater precision during surgery. The goal is to restore vibration from the tympanic membrane to the oval window and allow sound transmission. Many patients experience

stapedectomy: stape(s)—stirrup + ectomy—excision of

improved hearing immediately, others not until swelling subsides. Complications of ossiculoplasty and stapedectomy include extrusion of the prosthesis, infection, hearing loss, dizziness, and facial nerve damage. Some patients may have the surgery repeated if complications develop.

NURSING MANAGEMENT. The operative ear is placed upward when lying in bed. An ear plug may be used to help keep the area aseptic; the proximity of the brain makes this necessary to prevent brain infection. Activity orders may vary. The patient may be dizzy and experience nausea. Antiemetics should be given promptly to prevent vomiting. The patient's safety should be ensured if dizziness occurs. To prevent dislodgment or damage to the prosthesis, patients are instructed not to cough, sneeze, blow their nose, vomit, fly in an airplane, lift heavy objects, or shower. If the patient develops a cold, the physician should be contacted.

CRITICAL THINKING

Mrs. Smith

■ Mrs. Smith is an 83-year-old woman who is scheduled to be discharged from the hospital following a stapedectomy. She lives alone at home and is able to care for herself.

1. How would you communicate with Mrs. Smith to ensure that she understands the discharge instructions?
2. What teaching methods would you use to enhance communication?
3. What ear care instructions would you give her?

Suggested answers at end of chapter.

Trauma

ETIOLOGY AND PHYSIOLOGY. Trauma such as a blasting force, a blunt injury to the side of the head, or sudden changes in atmospheric pressure can cause the tympanic membrane to perforate and middle ear ossicles to fracture. Blast injuries cause injury from the direct pressure on the ear. Blunt injury to the head can cause temporal skull fractures and trauma to both the middle and inner ear. Barotrauma caused by sudden changes in atmospheric pressure in the ears can occur during scuba diving and airplane takeoffs and landings. Pressure changes can occur during normal atmospheric conditions such as nose blowing, heavy lifting, and sneezing. During these rapid changes of pressure, the eustachian tube does not ventilate because of occlusion or dysfunction and a negative pressure develops in the middle ear. The resulting pressure can cause the tympanic membrane to rupture or cause damage to the middle and inner ear.

SIGNS AND SYMPTOMS. Pain and hearing loss are the most common symptoms associated with trauma (see Box 52.12 Ear Care). Other signs and symptoms of barotrauma

TABLE 52.7 SUBJECTIVE ASSESSMENT OF MIDDLE EAR, TYMPANIC MEMBRANE, AND MASTOID DISORDERS

W	Where is it? Are both ears affected? Is it deep within the head?
H	How does it feel? Is there pressure? Fullness? Is it painful—sharp, dull, continuous, intermittent, throbbing, localized? No pain?
A	Aggravating and alleviating factors. Is it worse with change of position? Worse with movement? Is there relief after drainage? Relief with change of position? Relief with heat or analgesics?
T	Timing. When did it start? Has there been any recent upper respiratory infection, airline travel, scuba diving, trauma, or weight lifting? Was it a gradual or sudden onset? How long have symptoms persisted? Has there been a change in symptoms?
S	Severity. Does it cause hearing impairment? How much? Does it affect ADLs?
U	Useful data for associated symptoms. Is there any fever, drainage from the ear canal, nausea, vomiting, dizziness? Is there a family history of otosclerosis? Any previous ear problems or ear surgeries? Any occupational or recreational risk factors, such as scuba diving, weight lifting, or frequent airline travel?
P	Perception by the patient of the problem. What does the patient think is wrong? Has problem occurred before? If so, how was it the same and what was different?

ADLs = activities of daily living.

include fullness of the ears, vertigo, nausea, disorientation, edema of the affected area, and hemorrhage in the external or middle ear. In severe cases of barotrauma when scuba diving, these symptoms can cause drowning or cerebral air embolism from an overly rapid ascent. Otoscopy examination may reveal a retracted, reddened, and edematous tympanic membrane.

DIAGNOSTIC STUDIES. Audiometric studies are completed to determine the hearing loss. Imaging studies may be done to determine the extent of middle and inner ear damage. Conductive or sensorineural hearing loss may be evident, depending on the extent and location of the damage.

Nursing Process for the Patient with Middle Ear, Tympanic Membrane, and Mastoid Disorders

ASSESSMENT/DATA COLLECTION. Assessment of symptoms includes asking the patient for subjective data using the WHAT'S UP? format (Table 52.7).

The external ear should be inspected and palpated to obtain objective data. Pain with palpation is indicative of external ear problems, not middle ear problems. Pain over the mastoid area can indicate a mastoid problem. The middle ear and mastoid cavity cannot be visualized directly. The tympanic membrane is the only middle ear structure that can be directly visualized by the experienced practitioner with an otoscope. Objective assessment should also include vital

signs, noting any elevation in temperature. Hearing acuity should be screened by the experienced practitioner using whisper voice, Rinne's, and Weber's tests. Any drainage from the ear should be noted and described.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Risk for infection related to broken skin, pressure necrosis, chronic disease, or surgical procedure

EXPECTED OUTCOME: Patient exhibits no signs of infection (no drainage from ear, no tenderness over mastoid, negative culture, afebrile).

- Explain to patient not to blow nose by pinching off nares to prevent spread of upper respiratory infections up the eustachean tube.
- Teach patient to never insert anything into ear canal and other ear techniques (see Box 52.12 Ear Care) to prevent ear damage.
- Teach patient how to correctly remove cerumen from ear (see Box 52.11 Removing Cerumen).

Acute pain related to fluid accumulation, inflammation, or infection

EXPECTED OUTCOME: Patient indicates pain is decreased or absent as evidenced by a lower rating on a pain scale.

- Monitor pain using a pain scale to determine baseline and need for treatment.
- Use nonpharmacological measures such as heat, distraction, and relaxation techniques for pain reduction.
- Determine optimum analgesic schedule with patient to maximize pain control.
- Ensure that the patient knows how to administer ear drops and ear ointment to help resolve infection and decrease pain.
- Instruct patient to take all prescribed antibiotics even if symptoms are relieved to ensure that infection is completely resolved.

Fear related to hearing loss and lack of information

EXPECTED OUTCOME: Patient states methods for preventing problems in the middle ear, tympanic membrane, and mastoid process.

- Teach patient to yawn or perform jaw-thrust maneuver (opening mouth wide and moving jaw) to equalize ear pressure to maintain ear health.
- Teach patient to avoid trauma to the ear, loud noise exposure, and environmental or occupational conditions to prevent damage to the ear.
- Instruct patient to seek further medical attention if the patient's pain worsens, hearing decreases, or drainage from ear is present.

Deficient knowledge regarding surgery related to lack of exposure to information due to no prior experience

EXPECTED OUTCOME: Patient states understanding of impending surgery.

- Ask about patient's knowledge regarding surgery to determine learning needs.
- Include family in teaching sessions to enhance learning and assist with retention of information.
- Provide preoperative instructions and postoperative instructions as needed (Table 52.8).
- Teach patient to avoid getting water in ear to prevent moisture from reaching surgical site.
- Teach patient methods of effective communication (see Box 52.9 Nursing Care Plan for the Patient with Hearing Loss).

EVALUATION. The goals for the patient are met if there is no ear drainage or pain over mastoid; has negative culture and remains afebrile, states that no pain is present or pain is decreased, verbalizes care of ears, methods to prevent further infection; describes signs requiring medical attention, verbalizes rationale and outcome for any upcoming surgery as well as preoperative and postoperative instructions.

Inner Ear

Labyrinthitis

PATHOPHYSIOLOGY AND ETIOLOGY. Labyrinthitis is an inflammation or infection of the inner ear and can be caused by either viral or bacterial pathogens. The bacterium or virus enters the inner ear from the middle ear, meninges, or bloodstream. Serous labyrinthitis is a type of acute labyrinthitis that sometimes follows drug intoxication or overindulgence in alcohol. It can also be caused by an allergy. Diffuse suppurative labyrinthitis occurs when acute or chronic otitis media spreads into the inner ear or after middle ear or mastoid surgery. Destruction of soft tissue structures from the infection can cause permanent hearing loss.

SIGNS AND SYMPTOMS. Vertigo, tinnitus, and sensorineural hearing loss are the most common symptoms. Vertigo, or dizziness, occurs when the vestibular structures are involved. Tinnitus, or ringing in the ear, occurs when the infection is located in the cochlea. Sensorineural hearing loss can be caused by infections in the cochlea or vestibular structures. Nystagmus on the affected side may occur. Other signs and symptoms include pain, fever, ataxia, nausea, vomiting, and beginning nerve deafness.

DIAGNOSTIC TESTS. Laboratory tests such as a CBC may be completed to diagnose infection. Thorough hearing evaluation by an audiologist may reveal mild to complete hearing loss. Rinne's and Weber's tests can indicate conductive or sensorineural hearing loss.

THERAPEUTIC INTERVENTIONS. Antibiotics are used to treat bacterial inner ear infections. Viral infections usually run their course in about 1 week. Mild sedation may help the patient relax. Although there is no specific medicine to relieve dizziness, antihistamines can be used if they prove helpful on an individual basis. Patients may be placed on bedrest.

TABLE 52.8 PREOPERATIVE AND POSTOPERATIVE NURSING INTERVENTIONS FOR THE PATIENT HAVING EAR SURGERY

Preoperative Care

Nursing care for the patient undergoing ear surgery begins as soon as the decision to have surgery is made. The nurse collects data, determines if the patient understands the events, notes the patient's mental readiness, and obtains baseline physiological data.

- Ask understanding of the surgery and whether local or general anesthesia will be used.
- Help alleviate the patient's fear by encouraging the patient to ask questions. Ensure that all questions are answered before the surgery by appropriate person.
- Explain the type of pain, any packing or dressings that may be in place postoperatively, and any other postoperative restrictions that may be needed.
- Establish baseline vital signs and document findings.
- Ensure that the operative permit is signed.
- Determine current medications the patient is taking and document in the patient's record.
- Assess if the patient understands that surgery does not always correct impaired hearing.
- Leave any hearing devices in place as long as possible before the surgery.

Postoperative Care

Postoperatively the nurse is responsible for assessing the patient's physiological status. The nurse is also responsible for ensuring that the patient and family members understand discharge instructions.

- Some degree of pain may be expected, even with minor procedures. Explain how and when to take pain medication when the patient is discharged.
- Monitor postoperative vital signs and return to presurgical baseline.
- Tell patients that if an occlusive dressing is in place, hearing may be decreased until the dressing is removed.
- Instruct patients with tubes to avoid getting water in the ear. A shower cap or ear plugs may be used.
- Instruct the patient to seek medical attention if excessive bleeding or drainage occurs. If a cotton plug is to be left in place, instruct the patient to change it daily.
- Teach the patient, unless contraindicated, to blow the nose very gently one side at a time for the first week after surgery. Instruct the patient to sneeze or cough with the mouth open for 1 week after surgery.
- Avoid airplane flights for 1 week after surgery. For sensations of ear pressure, hold nose, close mouth, and swallow to equalize pressure.
- The patient should avoid strenuous work for several weeks. The patient may return to work in a few days, depending on the type of surgery and the type of work the patient does.
- Tell the patient to take prescribed medication and antibiotics as ordered.
- Have the patient arrange for follow-up appointment by calling physician's office.

NURSING MANAGEMENT. Nursing management includes helping the patient manage symptoms and self-care, and educating the patient about safety issues while on bedrest and sedatives. The patient should avoid turning the head quickly to help alleviate the vertigo. The patient is assisted to cope with anxiety that may be present because of the frustration surrounding hearing loss or loss of work.

Neoplastic Disorders

PATHOPHYSIOLOGY AND ETIOLOGY. Inner ear tumors can be benign or malignant. Acoustic neuroma, a tumor of the eighth cranial nerve, is the most common benign tumor. It is slow growing, occurs at any age, and usually occurs unilaterally. As it spreads, it compresses the nerve and adjacent structures. Malignant tumors arising from the inner ear are rare. Squamous and basal carcinomas arise from the epidermal lining of the inner ear.

SIGNS AND SYMPTOMS. Early symptoms of an acoustic neuroma include progressive unilateral sensorineural hearing loss of high-pitched sounds, unilateral tinnitus, and intermittent vertigo. Headache, pain, and balance disorders may also be present. Symptoms progress as the tumor spreads to other structures. Most malignant tumors grow quickly. The symptoms vary depending on the area of the ear that is involved.

DIAGNOSTIC TESTS. Neurological, audiometric, and vestibular testing are used to diagnose neuroma. Auditory

brainstem evoked response (ABR) and electronystagmography (ENG) are completed. Examination of the cerebrospinal fluid shows increased protein. Computed tomography (CT) and magnetic resonance imaging (MRI) are used to determine size and location of the tumor.

THERAPEUTIC INTERVENTIONS. The preferred method of treatment involves surgical removal of the tumor. The labyrinth is destroyed, with a resulting permanent hearing loss. Steroids and radiation may be used to decrease the size of the tumor or for inoperable tumors.

NURSING MANAGEMENT. Nursing management focuses on preparing the patient for surgery and adjusting to the diagnosis and the resulting hearing loss (see Table 52.8)

Ménière's Disease

PATHOPHYSIOLOGY AND ETIOLOGY. Ménière's disease is a balance disorder. Its cause is unknown. With the disease, there is a dilation of the membranous labyrinth resulting from a disturbance in the fluid physiology of the endolymphatic system. The exact etiology is unknown but is thought to stem from hypersecretion, hypoabsorption, deficit membrane permeability, allergy, viral infection, hormonal imbalance, or mental stress. The disease usually develops between 40 and 60 years of age. The symptoms range from vague to severe and debilitating.

SIGNS AND SYMPTOMS. A triad of symptoms of vertigo, hearing loss, and tinnitus characterizes Ménière's disease.

Recurring episodic bouts of the incapacitating triad of symptoms and nausea and vomiting occur with Ménière's disease. The attacks may occur suddenly, or the patient may experience warning signs such as headache or fullness in the ears. During an acute episode, the patient experiences vertigo that lasts 2 to 4 hours. The vertigo is usually accompanied by nausea and vomiting, followed by dizziness and unsteadiness. The patient is uncoordinated and has gait changes when walking. Hearing loss is often described as a fluctuating fullness in the ears. Tinnitus is present. Irritability, depression, and withdrawal are common behavioral changes. The vital signs usually remain normal. It takes several weeks for symptoms to resolve, and hearing loss in the affected ear remains. The patient then enters a stage of remission until the next attack. The acute episodes occur two to three times per year. Eventually the patient has complete remission with some degree of permanent hearing loss.

DIAGNOSTIC TESTS. Diagnostic tests include audiometric studies, neurological testing, and radiographs of the internal ear. Audiometric studies identify the type and magnitude of the hearing loss. Neurological testing and radiographic studies are done to rule out other pathological conditions. A caloric stimulation test may demonstrate a difference in eye movement.

THERAPEUTIC INTERVENTIONS. Medical treatment consists of symptomatic treatment for acute attacks and prophylactic treatment between attacks. Tranquilizers and vagal blockers may be needed during acute attacks. Salt-restricted diet, diuretics, antihistamines, and vasodilators are used during prophylactic treatment. The patient should avoid alcohol, caffeine, and tobacco use. The patient may be placed on bedrest during acute attacks. Most patients respond to medical protocol but continue to have acute attacks. Some patients who do not respond to treatment may be placed on low doses of methotrexate. The goals of medical treatment are to preserve hearing and reduce symptoms.

Surgical treatment is used only when medical management has failed. When involvement is unilateral, a labyrinthectomy is performed. This causes complete loss of hearing in that ear. Another surgical intervention establishes a shunt from the inner ear to the subarachnoid space. This procedure helps drain the fluid and prevent future hearing loss. Another surgical treatment is intratympanic gentamicin injection, which is usually done in the physician's office.

NURSING MANAGEMENT. Nursing management focuses on managing the patient's symptoms and providing safety during the acute attacks. Administer medication, monitor fluid and nutritional status, and ensure safety. Because of the unpredictability of Ménière's disease, the nursing care focuses on emotional support for the patient during periods of remission. Provide emotional support and resources to help the patient cope with the unpredictable nature of the disease and the physical impairments associated with the disease.

Nursing Process for the Patient with Inner Ear Disorders

ASSESSMENT/DATA COLLECTION. Assessment of symptoms for the patient with inner ear disorders includes asking the patient for subjective data using the WHAT'S UP? format (Table 52.9).

Objective data include assessment of gross hearing. Whisper voice, Rinne's, and Weber's tests and a physical examination can be performed. The patient should be assessed for any nutritional deficiencies, including dehydration, weight loss, or weight gain. Any musculoskeletal abnormalities, such as unsteady gait, are also noted. The patient's vital signs are taken to determine if symptoms are associated with an infection. Laboratory data and diagnostic data are examined for abnormal findings.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Planning focuses on helping the patient maintain a normal lifestyle, remain free of injuries, cope with the illness or hearing loss, and maintain adequate nutrition and hydration. The major nursing diagnoses and interventions for internal ear disorders may include:

Anxiety related to unpredictability of sudden and severe acute attacks

EXPECTED OUTCOME: Patient states anxiety is decreased.

- Encourage the patient to explore concerns about hearing loss and the unpredictability of acute attacks.
- Assess for signs of anxiety such as fidgeting, restlessness, apprehension, shakiness, and increased heart rate to determine if anxiety is present.

TABLE 52.9 SUBJECTIVE ASSESSMENT OF INNER EAR DISORDERS

W	Where is it? Are both ears affected?
H	How does it feel? Is there pressure? Fullness? Vertigo? Tinnitus? Is it painful—sharp, dull continuous, intermittent, throbbing, localized? No pain?
A	Aggravating and alleviating factors. Is it worse with change of position? Worse with movement? Is there relief with medications? Is the patient taking current medications? Are there any allergies?
T	Timing. When did it start? Was it a gradual or sudden onset? How long have symptoms persisted? Do symptoms progress in a set timing pattern? Do symptoms occur together or separately? Has there been a change in symptoms?
S	Severity. Does it cause hearing impairment? How much? Does it affect ADLs, nutritional intake, work, or leisure?
U	Useful data for associated symptoms. Any fever, nausea, vomiting, or dizziness? Any previous ear problems or ear surgeries? Headache?
P	Perception by the patient of the problem. What does the patient think is wrong? Has patient had this problem before? If so, what was the same and what was different?

- Explore with patient techniques that have and have not worked in the past *to reduce anxiety*.
- Use a calm reassuring approach *to help reduce patient's anxiety*.
- Provide quiet environment and diversional activities *to reduce anxiety*.
- Provide factual information regarding diagnosis and treatment *to reduce anxiety*.

Risk for injury related to impaired equilibrium

EXPECTED OUTCOME: Patient is not injured from falling due to alterations in equilibrium.

- Institute fall precautions *to help prevent injury*.
- Ensure that environment is safe and free of obstacles *to prevent falls*. Environmental hazards such as throw rugs, electrical cords in walkways, and poor lighting should be removed by the family.
- Monitor for signs of headache or fullness in the ears *which can indicate oncoming Ménière's disease attack*.
- Instruct patient to avoid sudden movement of the head during periods of vertigo *to prevent increasing symptoms*.
- Instruct patient on correct dosage and administration of medications *to help ensure resolution of symptoms*.
- Instruct patient to avoid use of alcohol, caffeine, and tobacco, *which can increase disruptions of equilibrium*.
- Instruct patient to call for assistance when ambulating *to minimize risk of falling*.
- If indicated, instruct patient to remain on bed-rest until symptoms are relieved *to prevent injury*.

Nutrition: less than body requirements related to nausea and vomiting

EXPECTED OUTCOME: Patient experiences adequate nutrition and hydration with relief of nausea and vomiting.

- Monitor for signs of nausea, vomiting, and inadequate hydration *to determine baseline information*.
- Instruct patient to use deep breathing and voluntary swallowing *to suppress the vomiting reflex*.
- Instruct patient to eat slowly.
- Medicate as ordered *to relieve symptoms and prevent episodes of nausea and vomiting*.
- Institute salt-restricted diet, if ordered, and instruct patient on low- and high-sodium foods.

EVALUATION. The goals for the patient are met if signs of anxiety are decreased, patient remains free from injury, patient maintains weight within normal range with no signs of dehydration.

CRITICAL THINKING

■ Mrs. Belmont is a 48-year-old woman diagnosed with Ménière's disease. She is currently in a state of remission. She states she is fearful that the next attack will occur during her daughter's upcoming wedding.

1. What information would you ask Mrs. Belmont about her attacks?
2. What instructions can you provide her regarding treatment during her attacks?
3. How will you handle Mrs. Belmont's fears about future attacks?

Suggested answers at end of chapter.

REVIEW QUESTIONS

1. A patient is diagnosed with otosclerosis and asks the nurse what this disease is. Which of the following is the most appropriate response by the nurse?
 - a. "Infection of the external ear most commonly caused by moisture or contamination."
 - b. "Hardening of the stapes due to new bone growth."
 - c. "Inflammation of the inner ear caused by pathogens."
 - d. "Tumor of the eighth cranial nerve."
2. A patient is diagnosed with a refractive error and asks the nurse what this means. What would be the appropriate explanation by the nurse?
 - a. "You will lose your vision and become blind."
 - b. "You will need corrective lenses in order to see clearly."
 - c. "The pressure in your eyes is higher than normal."
 - d. "Your vision is 20/20."
3. A patient comes to the health clinic for a suspected ear infection. Which of the following data collection findings does the nurse expect with an external ear infection?
 - a. Pain
 - b. Fullness in ears
 - c. Fever
 - d. Dizziness
4. A patient has been prepped for an internal eye examination. Anesthetic drops as well as a mydriatic drug have been administered. Which of the following should the patient be taught for eye safety?
 - a. "Wear sunglasses outdoors."
 - b. "Rub your eye hourly to increase blood circulation."
 - c. "You may reapply contact lenses when eye exam is completed."
 - d. "Flush your eye with water to remove the eye drops."

5. A nurse is working on a postoperative unit for eye surgery. In planning interventions for an eye surgery patient, the nurse understands that which of the following patients needs specific positioning orders postoperatively to prevent complications?
 - a. 19-year-old after removal of congenital cataract
 - b. 30-year-old woman after scleral buckling
 - c. 52-year-old man after trabeculectomy
 - d. 82-year-old man after corneal transplant
- Multiple response item. Select all that apply.
6. Which of the following medications should the nurse question before giving to prevent serious eye complications for a patient who has a history of acute angle-closure glaucoma?
 - a. Morphine
 - b. Cefazolin (Kefzol)
 - c. Atropine
 - d. Ranitidine (Zantac)
 - e. Hydroxyzine (Vistaril)
 - f. Warfarin (Coumadin)
 7. Which of the following medications can cause hearing loss?
 - a. Furosemide (Lasix)
 - b. Acetaminophen (Tylenol)
 - c. Warfarin (Coumadin)
 - d. Penicillin (Pen-Vee K)
 8. Which of the following symptoms would the nurse expect to be in the patient's history who has macular degeneration?
 - a. Loss of peripheral vision
 - b. Sudden darkness
 - c. Dull ache in the eyes
 - d. Loss of central vision
 9. The nurse is contributing to the plan of care for a patient with Ménière's disease. Which of the following is the primary goal for a patient with Ménière's disease that the nurse should recommend be included in the plan of care?
 - a. Prevent dehydration
 - b. Decrease pain
 - c. Prevent injury
 - d. Preserve hearing
 10. The nurse is caring for a patient with presbycusis. Which of the following techniques would be most important for the nurse to use to increase communication with this patient?
 - a. Talk in a very loud voice.
 - b. Lower voice pitch.
 - c. Do not smile or chew gum when talking to the patient.
 - d. Allow extra time for patient to respond.
 11. A patient with acute angle-closure glaucoma reports use of the following medications. Using which of these medications indicates to the nurse that further instruction is needed.
 - a. Acetaminophen
 - b. Cefazolin (Kefzol)
 - c. Ranitidine (Zantac)
 - d. Diphenhydramine (Benadryl)

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Mr. Samuel*

1. Mr. Samuel should seek assistance, patch both eyes, and have someone take him to receive medical treatment immediately.
2. Ensure that an antiemetic is ordered postoperatively on the patient's return to the unit. When Mr. Samuel reports nausea, the antiemetic should be given promptly.
3. Did you recognize that the concentration is 5 mg/1 mL, and the volume of the vial is 2 mL? The concentration is what is needed to calculate the dose.

$$\frac{7.5 \text{ mL} \quad | \quad 1 \text{ mL}}{\quad \quad \quad | \quad 5 \text{ mL}} = 1.5 \text{ mL}$$

■ *Mrs. Smith*

1. Gain her attention, face and stand in her visual field, avoid glare, speak clearly, inform her of topics to be discussed, assess for understanding, allow extra time, reduce background noises, use nonverbal communication, and do not cover your mouth when talking.
2. Use active listening. Use written communication to enhance spoken words. Use demonstration and return demonstration. Allow questions. Do not hurry. Provide information in short segments. Reassess understanding at each session.

3. Place the operative ear upward when lying in bed. Use ear plug as ordered. Do not cough, sneeze, blow nose, vomit, fly in an airplane, lift heavy objects, or shower. If a cold develops, call the physician. If dizzy, be careful when up.

■ *Mrs. Belmont*

1. You would ask Mrs. Belmont about specific signs she may have prior to attacks, such as headache or fullness in the ears. You should also ask her specifically what symptoms she has during attacks. Common symptoms include the triad of vertigo, hearing loss, and tinnitus. She may also have nausea, vomiting, and unsteady gait.
2. Discuss treatment that Mrs. Belmont has used with previous attacks. Ask her which treatments seemed to help. Common treatments you can recommend include taking recommended medication such as tranquilizers and vagal blockers; instruct her to maintain adequate fluid and nutritional intake during attacks; ambulate with assistance; limit salt in diet; avoid alcohol, caffeine, and tobacco use.
3. Discuss with Mrs. Belmont prophylactic treatment such as salt-restricted diet, diuretics, antihistamines, and vasodilators. Discuss the normal progress of the disease. Provide emotional support and discuss methods to help her cope with the disease, such as counseling and relaxation techniques.

QUESTIONS TO GUIDE YOUR READING

1. What is the normal anatomy of the integumentary system?
2. What is the normal function of the integumentary system?
3. What are the effects of aging on the integumentary system?
4. What data should you collect when caring for a patient with a disorder of the integumentary system?
5. What laboratory and diagnostic tests are commonly performed to diagnose integumentary disorders?
6. What common therapeutic measures are used for patients with integumentary disorders?

REVIEW OF NORMAL ANATOMY AND PHYSIOLOGY

The skin, its accessory structures, and the subcutaneous tissue make up the integumentary system, the covering of the body that separates the living internal environment from the external environment. The skin itself is considered an organ and consists of two layers, the outer epidermis and the inner dermis (Fig. 53.1).

Epidermis

The epidermis is made of stratified squamous epithelial tissue and is avascular—meaning that it has no capillaries within it. Its nourishment comes from the dermis beneath it. The epidermis is thickest on the palms of the hands and soles of the feet. The innermost layer of the epidermis is called the stratum germinativum, and it is here that mitosis takes place to produce new epidermal cells. The rate of mitosis is fairly constant, but it may be increased by chronic pressure on the skin, as in callus formation. The new cells produce the protein keratin. As they are pushed to the surface of the skin, they die and become the stratum corneum, the outermost of the epidermal layers.

The stratum corneum consists of many layers of dead cells; all that remains is their keratin. An unbroken stratum corneum is an effective barrier against pathogens and most chemicals, although even microscopic breaks are sufficient to permit their entry. Keratin is relatively waterproof, so it

prevents the loss of water and therefore dehydration, and also prevents the entry of excess water by way of the body surface. As dead cells are worn off the surface of the skin (which contributes to the removal of pathogens), they are continuously replaced by cells from within. Loss of large portions of the stratum corneum, as with extensive third-degree burns, greatly increases the risk for infection and dehydration.

Melanocytes are cells in the lower epidermis that produce the protein melanin; the amount of melanin is a genetic characteristic and gives color to skin and hair. When the skin is exposed to ultraviolet (UV) rays from the sun or artificial lighting, production of melanin increases and it is incorporated into the epidermal cells before they die, making the cells darker. Melanin is a pigment barrier to prevent further exposure of living cells in the stratum germinativum to UV rays. Ultraviolet rays are mutagenic; that is, they are capable of damaging the DNA within cells and causing mutations that may result in malignancy.

Also in the epidermis are Langerhans' cells, a type of macrophage that presents foreign antigens to helper T cells. This is the first step in the destruction of pathogens that have penetrated the epidermis.

Dermis

The dermis consists of two layers: the outer papillary region is made of mainly adipose tissue with fine elastin contribution, and the inner reticular region is of dense irregular

FIGURE 53.1 Structure of the skin and subcutaneous tissue. (Modified from Scanlon, VC, and Sanders, T: *Essentials of Anatomy and Physiology*, ed. 5. F.A. Davis, Philadelphia, with permission.)

connective tissue. This reticular region contains cells called fibroblasts, a large contribution of collagen, and some coarse elastic fibers. Fibroblasts produce the protein fibers collagen and elastin. Collagen fibers form the strength of the dermis; elastin fibers are capable of recoil and make the dermis somewhat elastic. Within the dermis are the hair and nail follicles, glands, nerve endings, and blood vessels. The capillaries in the papillary layer of the dermis are important to nourish the stratum germinativum, which has no capillaries of its own.

Hair

Hair develops in epidermal structures called follicles. At the base of the hair root in its follicle is the matrix, a group of cells that undergo mitosis to produce the hair shaft. The cells quickly die after producing keratin and incorporating melanin. Human hair with significant functions includes the eyelashes and eyebrows, which keep dust and sweat out of the eyes, and nostril hair, which filters air entering the nasal cavities. Hair on the head provides thermal insulation.

Nails

Nail follicles are found at the ends of the fingers and toes, and growth of nails is similar to growth of hair. Mitosis in the nail root is a continuous process to produce new cells, which contain keratin. As these cells die, they form the visible nail. Nails protect the ends of the digits from mechanical injury and are useful for picking up small objects.

Receptors

The sensory receptors in the dermis are those for the cutaneous senses. Free nerve endings are the receptors for heat, cold, and pain; encapsulated nerve endings are specific for touch and pressure. The sensitivity of an area of skin is determined by the number of receptors present.

Sebaceous Glands

Most ducts of sebaceous glands open into hair follicles; a few open directly onto the skin surface. Their secretion is sebum, a lipid substance that inhibits the growth of some bacteria and prevents drying of skin and hair. Skin that is dry tends to crack or fissure more easily, and even these small breaks in the epidermis are potential portals of entry for pathogens.

Sudoriferous (Sweat) Glands

Sudoriferous glands are also known as sweat glands. There are two kinds of sudoriferous glands: apocrine and eccrine. Apocrine glands are really modified scent glands and are most numerous in the axillae and genital area; they are activated by stress and emotions.

Eccrine glands are found throughout the dermis but are most numerous on the face, palms, and soles. They are activated by high temperatures or by exercise and secrete sweat onto the skin surface. The sweat is evaporated by excess body heat, which is a very effective cooling mechanism,

although it does have the potential to lead to dehydration if water is not replaced by drinking.

Modified sweat glands called ceruminous glands are found in the dermis of the ear canals. Their secretion is called cerumen or earwax. Cerumen prevents drying of the outer surface of the eardrum. Excess cerumen, however, may become impacted against the eardrum, prevent it from vibrating properly, and diminish the hearing acuity.

Blood Vessels

The blood vessels in the dermis serve the usual function of tissue nourishment, but the arterioles are also involved in the maintenance of body temperature. Blood carries the heat produced by active organs and distributes it throughout the body. In a warm environment, dilation of blood vessels in the dermis increases blood flow and loss of heat to air or clothing. Constriction of blood vessels in a cold environment decreases blood flow to the skin and conserves body heat.

Stressful situations also bring about vasoconstriction in the dermis, which allows blood to circulate to more vital organs, such as the heart, liver, brain, or muscles.

Other functions of the skin are the formation of vitamin D from cholesterol when the skin is exposed to the UV rays of the sun and the excretion of small amounts of urea and sodium chloride in sweat.

Subcutaneous Tissue

The subcutaneous tissue, between the dermis and the muscles, is made of areolar and adipose connective tissues. Although an unbroken stratum corneum is an excellent barrier to pathogens, even small breaks provide portals of entry. In the subcutaneous tissue are numerous white blood cells that destroy any pathogens that have entered by way of broken skin. Subcutaneous adipose tissue cushions some bones and provides some insulation from cold, but its most important function is energy storage. Excess nutrients are changed to triglyceride and stored as potential energy for times when food intake may decrease.

Aging and the Integumentary System

The effects of age on the integumentary system are often quite visible (Fig. 53.2).

NURSING ASSESSMENT/ DATA COLLECTION

Health History

Skin problems are a fairly common complaint for the patient entering the health system. Many factors can influence the integumentary system. A skin problem may be the only complaint the patient has, or it may be a manifestation of an underlying systemic condition or psychological stress. Most important, the skin can visibly communicate the patient's health. Therefore, the questions that are posed to the patient are important in determining if the skin problem is a disease entity of its own or a sign of a more systemic

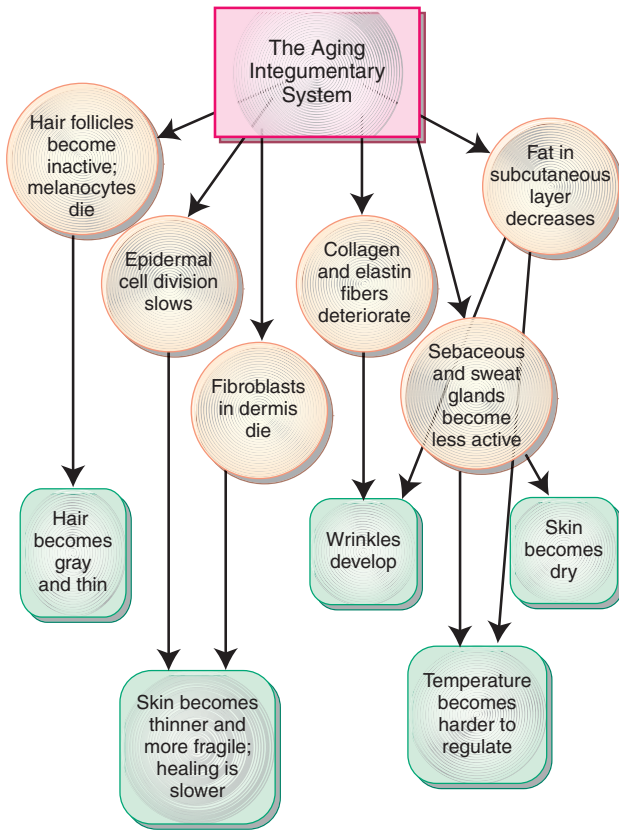

FIGURE 53.2 Aging and the integumentary system.

disorder. Table 53.1 provides examples of general questions that can be asked of the patient to elicit information.

If further assessment of a particular problem area is necessary, the WHAT'S UP? line of questioning can be used. For example, if the patient has a rash, you can respond with the following questions:

Where is it? Is that the only area where you have a rash?

How does it feel? Does it itch? Burn? Hurt?

Aggravating and alleviating factors. Does scratching aggravate it? Does anything else aggravate it, such as soaps and detergents? What relieves it? How have you treated it in the past?

Timing. How long have you had this problem? Does it recur?

Severity. How bad is the discomfort on a scale of 0 to 10, with 0 being comfortable and 10 being unable to touch the area?

Useful other data. Do you have other symptoms besides the rash, such as itching, discharge, tingling, or loss of sensation?

Patient's perception. What do you think is causing your rash?

Physical Assessment

Assessment of the skin involves not only the entire skin area, but also the hair, nails, scalp, and mucous membranes. The main techniques utilized in physical assessment of the

skin are inspection and palpation. Ensure that the patient is disrobed but adequately draped in a well-lighted and warm environment. Use a hand-held magnifying glass or penlight to see small details and further illuminate the area.

Normally the skin is intact, with no abrasions, and is smooth, dry, well hydrated, and warm. Skin **turgor** is firm and elastic. The skin surface is flexible and soft. Skin color ranges from light to ruddy pink or olive in white-skinned patients and light brown to deep brown in dark-skinned patients.

You need to be aware of normal developmental changes when performing an assessment. The skin of the neonate is very thin and friable (easily broken). During adolescence, the skin becomes thicker, with active sebaceous, eccrine, and apocrine glands. Body hair also changes during adolescence as a result of hormonal influences. In older patients, the skin loses some of its elasticity and moisture. There is decreased activity of sebaceous and sweat glands. The older patient's skin is thinner, more fragile, and more wrinkled.

Inspection

Inspect each area of the skin, including nails, hair, scalp, and mucous membranes, for color, moisture, lesions, edema, intactness, vascular markings, turgor, and cleanliness. This examination should be done in an orderly sequence, such as hair, scalp, nails, buccal mucosa, and then the general skin surface from head to toe.

COLOR. Skin color can be influenced by many factors, including the temperature of the patient, oxygenation, blood flow, exposure to UV rays, and positioning. Because skin color can differ genetically from very light to very dark, skin assessment can be difficult for the novice practitioner.

Commonly noted alterations can include pallor, **erythema** (redness), jaundice, cyanosis, and brown color. Pallor is a paleness or decrease in color and can be caused by vasoconstriction, decreased blood flow, or decreased hemoglobin levels from anemia. Pallor is best assessed on the face, conjunctivae, nailbeds, and lips. Erythema, or red discoloration, may indicate circulatory changes and can be caused by vasodilation or increased blood flow to the skin from fever or inflammation. Erythema is best assessed on the face or in an area of trauma.

Jaundice, a yellow-orange discoloration, may occur as a result of liver disease. The best place to inspect for jaundice is in the sclera of the eye. Cyanosis, or bluish discoloration, may indicate a cardiac, pulmonary, or perfusion problem. The best places to inspect for cyanosis are the lips, nailbeds, conjunctivae, and palms. People of Mediterranean descent normally have a bluish tone to their lips; this is not cyanosis.

A brown color may be caused by increased melanin production and can indicate chronic exposure to sunlight or pregnancy. This is best assessed on areas exposed to the sun; changes in pregnancy can be seen on the face, areolae, and nipples. A brownish color may also be the result of chronic peripheral vascular disease, especially noted on the lower extremities.

TABLE 53.1 SUBJECTIVE ASSESSMENT OF THE INTEGUMENTARY SYSTEM

Category	Questions to Ask During History Assessment	Rationale
History	Do you (or does anyone in your family) have a history of dryness, rashes, itching, skin diseases, psoriasis, eczema, dermatitis, asthma, hay fever, hives, or allergies?	These conditions may be hereditary.
Risk Factors	Have you noticed any changes in your skin, such as a sore that does not heal, rashes, lumps, or a change in an existing mole?	<ul style="list-style-type: none"> • Sores that do not heal or moles that change color along with any lumps may indicate cancer. • Slow healing can also be associated with diabetes. • Brown staining of the skin in the lower legs is called hemosiderin stain which is due to red blood cells breaking under the skin in a condition called venous stasis.
	Have you had any recent trauma to your skin?	A break in skin integrity can lead to infection.
	Do you have a tendency to sunburn easily? Do you use sunblock?	Repeat sunburns are a risk factor for skin cancer.
	Do you go to tanning salons or utilize sun lamps or tanning pills?	These are risk factors for skin cancer.
Hair	Do you wear a wig or hairpiece?	Adequate assessment of the scalp requires permission for removal of a wig or hairpiece.
	Have you noticed a change in the growth or loss of your hair?	Hair loss can result from systemic illness or treatment or sometimes from infections or hair care products.
Nails	Have you experienced recent trauma or changes in your nails? Do you wear artificial nails?	Nail changes may be caused by circulatory problems. Artificial nails may mask changes.
Medications	What medications do you take every day (prescription or nonprescription)? What is the dosage and frequency?	The patient may be taking medication for a skin disorder. Many medications cause skin reactions, from hives and photosensitivity to serious inflammatory conditions.
	What medications did you take most recently? When did you take your last dose?	This might help pinpoint the cause of a new reaction.
Exposures	What is your occupation?	Occupational exposures can lead to skin problems.
	How often to you bathe or shower? What kind of soap do you use?	Some soap may cause allergic reactions.
	What recreational activities to you participate in?	Skin disorders can be caused by gym equipment that was not cleaned properly. Poison ivy may result from jogging in wooded areas.
	Do you or any members of your immediate family or your coworkers have recent skin complaints?	Some skin disorders are contagious.
	Have you traveled recently?	This could help to pinpoint causes of suspicious skin changes.
	Is there anything in your current environment, at home or work, that may be causing any skin problems (e.g., animals, plants, chemicals, infections, new carpeting, or new soaps or detergents)?	Various environmental factors can be causes of contact dermatitis; release of some chemicals can cause skin disorders.
	Is there anything that touches your skin that causes a rash?	This may help pinpoint causes of contact dermatitis.

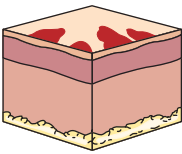

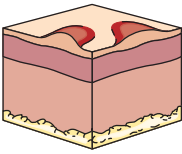

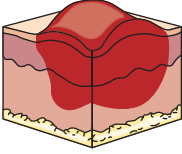

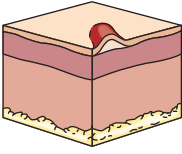

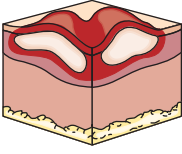

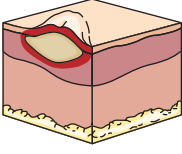

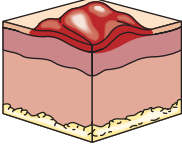

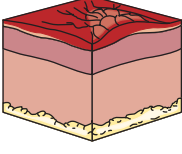

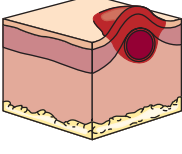

LESIONS. A lesion is any change or injury to tissue. Assessment of skin lesions helps determine the cause of a skin disorder. Lesions are described as primary or secondary. Primary lesions are the initial reaction to a disease process. Secondary lesions are the changes that take place in the primary lesion because of trauma, scratching, infection, or various stages of a disease. Lesions are further described according to type and appearance in Figure 53.3.

When assessing and documenting skin lesions, note the color or colors of the lesion, the size (usually in centimeters), location, distribution, and configuration. *Configuration* refers to the pattern of the lesions; shown in Figure 53.4. Also note any exudate, including amount, color, and odor,

and any accompanying symptoms. Gently stretching the skin over the rash area makes it stand out more for further assessment.

In general, healthy patients with naturally dark skin have a reddish undertone, with pinkish buccal mucosa, tongue, nails, and lips. If a dark-skinned patient is pale, the mucous membranes have an ash-gray color, lips and nailbeds appear paler than usual, and the skin appears yellow-brown to ash gray. Erythema presents as a purplish gray color. Cyanosis presents as a gray cast to the skin. The nailbeds, palms, and soles may have a bluish cast. Jaundice can be noted in the oral mucosa (particularly the hard palate) and in the sclera closest to the cornea.

PRIMARY LESIONS

<p>Macule: Flat, nonpalpable change in skin color, with different sizes, shapes, color; usually smaller than 1 cm (e.g., rubella, scarlet fever freckles)</p>	
<p>Papule: Palpable solid raised lesion that is less than 1 cm in diameter due to superficial thickening in the epidermis (e.g., ringworm, rosea, wart, mole)</p>	
<p>Nodule: Solid elevated lesion that is larger and deeper than a papule (e.g., fibroma, intradermal nevi)</p>	
<p>Vesicle: A small, blister-like raised area of the skin that contains serous fluid, up to 1 cm in diameter (e.g., poison ivy, shingles, chickenpox)</p>	
<p>Bulla: A fluid-filled vesicle or blister larger than 1 cm (e.g., burns, contact dermatitis)</p>	
<p>Pustule: Small elevation of skin or vesicle or bulla that contains lymph or pus (e.g., impetigo, scabies, acne)</p>	
<p>Wheal: Round, transient elevation of the skin caused by dermal edema and surrounding capillary dilatation; white in center and red in periphery (e.g., hives, insect bites)</p>	
<p>Plaque: A patch or solid, raised lesion on the skin or mucous membrane that is greater than 1 cm in diameter (e.g., psoriasis)</p>	
<p>Cyst: A closed sac or pouch which consists of semisolid, solid, or liquid material (e.g., sebaceous cyst)</p>	

SECONDARY LESIONS

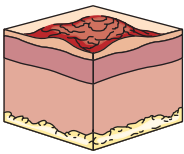

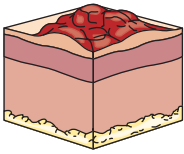

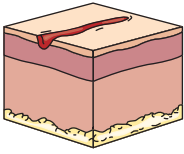

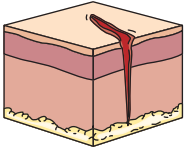

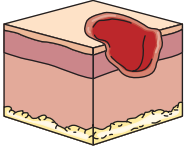

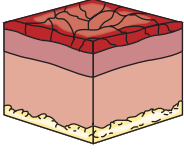

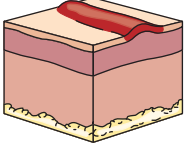

<p>Scale: Dry exfoliation of dead epidermis that may develop as a result of inflammatory changes (e.g., very dry skin, cradle cap, psoriasis)</p>	
<p>Crust: A scab formed by dry serum, pus, or blood (e.g., infected dermatitis, impetigo)</p>	
<p>Excoriation: Traumatized abrasions of the epidermis or linear scratch marks (e.g., scabies, dermatitis, burns)</p>	
<p>Fissure: A slit or cracklike sore that extends into dermis usually due to continuous inflammation and drying (e.g., athlete's foot, anal fissure)</p>	
<p>Ulcer: An open sore or lesion that extends to the dermis (e.g., pressure sores)</p>	
<p>Lichenification: Thickening and hardening of skin from continued irritation such as intense scratching looks like surface of mass</p>	
<p>Scar: A mark left in the skin due to fibrotic changes following healing of a wound or sore or surgical incision</p>	

FIGURE 53.3 Description of skin lesions.

FIGURE 53.4 To assess configuration, observe the relationship of the lesions to each other. Then characterize the configuration by one of the patterns illustrated in the chart.

MOISTURE/DRYNESS. Assessment of moisture provides clues to the patient's level of hydration. Observe the skin for dryness, moisture, scales, and flakes. Moisture may be found in skin fold areas. The skin should normally be smooth and dry. Flaking and scaling of the skin indicate dry skin.

EDEMA. Edema occurs because of a build-up of fluid in the tissues. Edema can cause the skin to become stretched, dry, and shiny. Assess and document the location, distribution, and color of edematous areas. If edema is unilateral, compare it with the opposite side of the body. Measure

edematous extremities to track improvement or worsening of the condition. Dependent edema is edema that occurs in the part of the body that is at the lowest point, typically noted in the feet and ankles or in the sacrum if the patient is lying down.

VASCULAR MARKINGS. Vascular markings can be classified as normal and abnormal. Two common abnormal vascular changes are **petechiae** and **ecchymosis** (see Figures 28.1 and 28.5). Petechiae are reddish purple hemorrhagic spots that are smaller than 0.5 mm in diameter. In the darker skinned patient, petechiae are usually not visible on the skin but can be visualized in the conjunctivae and oral mucosa. Ecchymosis is a bruise in which the color changes from blue-black to greenish brown or yellow over time.

GENERAL INTEGRITY AND CLEANLINESS. Assess the integrity of the skin. Elderly patients have thin, fragile skin that is easily broken or torn. Be sure to check between toes and skin folds and under a pendulous abdomen or breasts. Check over bony prominences for signs of pressure. Note general cleanliness and odors.

Palpation

Palpation is used in conjunction with inspection. Use the dorsum (back) of the hand to palpate temperature because this part of the hand is most sensitive to changes in temperature. Use the fingertips to gently palpate over the skin to determine size, contour (flat, raised, depressed), and consistency (soft or indurated) of lesions. If the lesion is moist or draining, wear gloves to protect against the spread of infectious organisms. Note the degree of pain or discomfort associated with light palpation of lesions.

Assess turgor and texture of the skin. Skin turgor is a measure of the amount of skin elasticity. To assess for turgor, the skin on the back of the forearm or over the sternum is pinched between the thumb and forefinger and then released. Normally, the skin lifts easily and then quickly returns to its normal state. Poor skin turgor is indicated by “tenting” of the skin, with more gradual return to its normal state. Poor skin turgor may indicate dehydration. Normal aging of skin produces some loss of skin elasticity; the preferred place to check skin turgor in the elderly is over the sternum.

If edema is suspected, palpate those areas to assess for tenderness, mobility, and consistency. When pressure from your fingers leaves an indentation, this is called pitting edema. Pitting edema is classified by its depth. Press the edematous area (against bone, if possible) with your thumb for 5 seconds and then release. One way to measure edema is to measure depth of the pitting in millimeters. For example:

1+ edema = 2-mm depth, or trace edema

2+ edema = 4-mm depth of indentation, or a small amount

3+ = 6-mm depth, moderate edema

4+ = 8-mm depth, indentation lasts 2 to 3 minutes, very edematous

ecchymosis: ec—out + cchymos—juice + is—condition

Inspect and/or palpate over the entire body for hair color, quantity, thickness, and texture. Note any areas of **alopecia** (hair loss). Determine any recent changes in color and growth pattern. Note cleanliness, itching, redness, scaling, flakes, and tenderness. If lesions or lice are suspected, use disposable gloves to avoid spread of infection.

Terminal hair is the hair on the scalp, eyebrows, axillae, and pubic areas and on the face and chest of males. Vellus hairs are the soft, tiny hairs covering the body. Normally, body hair has a uniform distribution. Note male or female pubic hair distribution. Scalp hair can normally be thick, thin, coarse, smooth, shiny, curly, or straight. Describe scalp hair distribution and cleanliness.

Nails can reflect the patient's general health. Assess fingers and nails for color, shape, texture, thickness, and abnormalities. Normally, the nails appear pink, smooth, hard, and slightly convex (160-degree angle), with a firm base. The nails of elderly patients may have a yellowish gray color, thickening, and ridges. Brown or black pigmentation between the nail and nail base is normal in dark-skinned patients. Abnormal findings include clubbing, which may indicate hypoxia, and spoon nails (concave nails, also called koilonychia), which may be associated with anemia. Thick nails may indicate fungal infection. Palpate for nail consistency and observe for redness, swelling, or tenderness around the nail area. See Table 53.2 for other nail abnormalities.

Describe any abnormal skin conditions in detail. Include findings such as color of lesion, pain, swelling, redness, location, size, drainage (including amount, color, and odor), and eruption patterns. If equipment is available, an excellent way to supplement documentation is by photographing the area; serial photographs can be mounted in the chart to document healing progression. See Box 53.1 Gerontological Issues for assessment and care specific to the elderly.

DIAGNOSTIC TESTS

Laboratory Tests

Cultures

Skin cultures are done to determine the presence of fungi, bacteria, and viruses. When a fungal infection is suspected, gently scrape scales from the lesion into a Petri dish or other indicated container. The specimen is then treated with a 10% potassium hydroxide (KOH) solution to make fungi more

NURSING CARE TIP

When scraping scales for culture position the patient so that the skin lesion is vertical. Place the slide against the skin below the lesion. Be sure to wear gloves when collecting specimens, and wash your hands before and after.

prominent. The specimen can remain at room temperature until sent to the laboratory.

If a viral culture is ordered, the fluid is expressed (gently squeezed) from an intact vesicle, collected with a sterile cotton swab, and placed in a special viral culture tube. If the lesion has crusts, they are removed or punctured before swabbing. The viral culture tube must be kept in ice and sent to the laboratory as soon as possible.

Bacterial cultures may be collected with a sterile swab or wound culture kit. See Box 53.2 (Steps in Culturing a Wound) for specific instructions.

Skin Biopsy

A skin biopsy is indicated for deeper infections, to establish an accurate diagnosis, or for the evaluation of current treatment. A biopsy is an excision of a small piece of tissue for microscopic assessment. Three common types of skin biopsies are punch, shave, and incisional.

A punch biopsy uses a small round cutting instrument, called a punch, to cut a cylinder-shaped plug of tissue for a full-thickness specimen. An incisional biopsy is performed with a scalpel to make a deep incision and almost always requires sutures for closure. A shave biopsy removes just the area that has risen above the rest of the skin.

For all biopsies, explain the procedure, assist in preparing a sterile field, calm and comfort the patient during the procedure, and assist in dressing the site following the procedure. The most uncomfortable part of the procedure is usually the injection of the local anesthetic agent. Explaining the procedure and calming the patient can make the procedure less traumatic.

Other Diagnostic Tests

Wood's Light Examination

Wood's light examination is the use of ultraviolet rays to detect fluorescent materials in the skin and hair present in certain diseases such as tinea capitis (ringworm). This

TABLE 53.2 ABNORMALITIES OF THE NAILS

Physical Assessment Finding	Description	Possible Causes
Beau's lines	Transverse depressions in the nails	Systemic illnesses or nail injury
Splinter hemorrhages	Red or brown streaks in the nailbed	Minor trauma, subacute bacterial endocarditis, or trichinosis
Paronychia	Inflammation of the skin at the base of the nail	Local infection or trauma

**Box 53.1****Gerontological Issues**

In acute care settings, priorities are determined by medical diagnoses and often center around cardiovascular, respiratory, nutrition, comfort, or other immediate concerns. The feet may be forgotten in the rush to care for the patient and plan a timely discharge.

Feet are also viewed by some as dirty; washing the feet may be seen as a lowly job. It may be assumed that people take care of their own feet. However, many older people are unable to bend down or bring the feet up high enough to see or care for them.

For these reasons it is especially important for the nurse to assess and care for the feet, both in institutional settings and at home. General guidelines for assessment include the following:

- Inspect feet for redness or pressure ulcers over bony prominences.
- Inspect feet for dryness or cracking.
- Inspect between toes for cracking, wounds, or excess moisture.
- Inspect and palpate for callouses.
- Palpate dorsalis pedis and posterior tibial pulses for circulatory status.
- Assess patient's sensation using a wisp of cotton, monofilament, or light touch.

Hints to promote healthy feet:

- Soak the patient's feet briefly in warm water and wash using a gentle soap. Test the water to be sure it is not too warm, especially for the patient with reduced sensation.
- Thoroughly dry the feet, including between the toes. Water left to evaporate can cause drying and cracking.
- Use a pumice stone to help remove dry dead skin over heels or calluses. Work gently, rubbing the stone in one direction only and removing only a small amount of dead skin at any one time.
- Use a cream or lotion that does not contain alcohol to moisturize the feet. Do not apply between toes. Apply it with a gentle massage while moving the patient's feet through range-of-motion exercises. To prevent falls, never apply lotion before the patient steps into the tub or shower.
- Use gauze or a commercially made pad to decrease pressure and friction in areas between toes that cross or other areas where breakdown is likely.
- Encourage the patient to wear cotton or dry weave socks that allow feet to stay dry with perspiration. Encourage wearing shoes or hard soled-slippers to avoid injury to the feet and prevent falls.
- Take extra care to assess and care for feet in patients with diabetes because of their increased risk for injury and slow healing.

Box 53.2**Steps in Culturing a Wound**

1. Use sterile saline to remove excess drainage and debris from the wound. Purulent material may have different bacteria than those actually causing the infection.
2. Using a sterile calcium alginate swab in a rotating motion, swab wound and wound edges 10 times in a diagonal pattern across the entire surface of the wound.
3. Do not swab over eschar.

examination is performed with a hand-held black light in a darkened room.

Skin Testing

Patch and scratch tests are performed when allergic contact dermatitis is suspected. These are usually done by a dermatologist on uninvolved skin, such as the upper back or arms. Any hair in the area must first be shaved.

For the scratch test, the skin is superficially scratched or pricked with an allergen for an immediate reaction. If a reaction such as a wheal occurs, the test is positive for that allergen. Resuscitation equipment should be in the immediate vicinity in the event of a severe allergic (anaphylactic) reaction.

With the patch test, a delayed hypersensitivity reaction develops in 48 to 96 hours. The allergens are applied under occlusive tape patches. For this test, the skin should be free of oils to promote patch adhesion, so cleanse the skin first with alcohol. The test site must remain dry and free from moisture. The patch is removed in 2 days. Any reaction is noted, with a final reading in 2 to 5 days.

**THERAPEUTIC MEASURES****Open Wet Dressings**

Wet compresses may be ordered for acute, weeping, crusted, inflammatory, or ulcerated lesions. The purpose of wet dressings is to decrease inflammation, cleanse and dry the wound, and continue drainage of infected areas. They may be ordered either sterile or clean, depending on the risk for infection. The solutions commonly consist of room temperature to cool tap water or normal saline, aluminum acetate solution (Burow's solution), or magnesium sulfate. The dressing is saturated with the solution before it is applied. Wet dressings are usually applied every 3 to 4 hours for 15 to 30 minutes.

Wet dressings should not be prescribed for more than 72 hours because the skin may become too dry or macerated. If cool compresses are used, they should be reapplied every 5 to 10 minutes because they become too warm from body heat. If warm compresses are used, monitor the skin closely to prevent burns.

**NURSING CARE TIP**

To prevent chilling, no more than one-third of the body should be treated at one time. Keep the patient warm during wet dressing treatment.

Balneotherapy

Balneotherapy (therapeutic bath) is useful in applying medications to large areas of the skin, as well as for débridement, or removing old crusts; for removing old medications; and to relieve itching and inflammation. The temperature of the water should be kept at a comfortable level, avoiding hot baths. The bath should last for 15 to 30 minutes, while maintaining its warmth. Fill the tub half full. Keep the room warm to minimize changes in temperature. Advise the patient to wear loose clothing after the bath.

**NURSING CARE TIP**

A bath mat should be used for treatment baths because some may make the tub slippery.

Water and saline are utilized for weeping, oozing, and erythematous lesions. Colloidal baths (such as oatmeal or Aveeno) are utilized for widely distributed skin lesions, for drying, and for relief of itching. Medicated tar baths, such as Almar-Tar or Bainetar, are used for chronic eczema problems and psoriasis. Any loose skin crusts can be removed after the bath. The room should be well ventilated because tars are volatile.

To increase hydration after the bath, a lubricating agent is applied to damp skin if emollient action is prescribed. Bath oils, such as Alpha-Keri, Avenol, and Lubath, are used for lubrication and to relieve itching.

Topical Medications

Many types of topical medications are used to treat skin conditions. These include lotions, ointments and creams, powders, gels, pastes, and intralesional therapy. Systemic medications may also be given for more serious conditions.

Lotions tend to cool the skin through water evaporation. They may also have a protective effect and may be antipruritic (treat itching). Lotions are usually applied with cotton gauze, gloves, or a soft brush.

Ointments and creams have a varied base (greasy, non-greasy, or penetrating), depending on the drug applied. These medications can protect the skin, provide lubrication, and prevent water loss. They are used for localized or chronic skin conditions. Ointments and creams can cause some reduction in blood flow to the skin. They are applied with a gloved hand or wooden tongue depressor.

Powders usually have a zinc oxide, talc, or cornstarch base. They act as a hygroscopic agent to absorb moisture and reduce friction. Powders are usually applied with a

**NURSING CARE TIP**

Avoid applying too much powder in skin fold areas. Dermatitis can occur with too much powder in these areas. Products with a cornstarch base can provide a good medium for growth of microorganisms.

shaker top. Powders are avoided around patients with respiratory disease or tracheostomies.

Gels, or semisolid emulsions, become liquid with topical application. They are usually greaseless and do not stain. Many topical steroids are prescribed in this manner.

Pastes are semisolid substances comprised of ointments and powders. They are used for inflammatory disorders. Mineral oil can facilitate removal of pastes.

Topical corticosteroids are used to reduce or relieve pain and itching by decreasing inflammation. Steroids should be used sparingly and according to package directions. Overuse of topical steroids can cause thinning of the skin. Caution is needed when used on the face to prevent glaucoma, cataracts, and perioral dermatitis.

Intralesional therapy has an anti-inflammatory action. This procedure utilizes a tuberculin syringe, most often of a sterile suspension of a corticosteroid, injected just below the lesion. Local atrophy may occur if the injection is made into subcutaneous tissue. Common conditions that are treated with this therapy include psoriasis and keloids.

CRITICAL THINKING**Mr. Evans**

■ Mr. Evans comes to the doctor's office with atrophic skin (thin, shiny, pink, with visible vessels) at the area of psoriasis where he is applying his corticosteroid ointment. He states that he has been applying a thick layer of ointment four times a day.

1. What might be the cause of this condition?
2. What should you include when you document his skin condition?

Suggested answers at end of chapter.

Dressings

Dressings may be used to enhance absorption of topical medications, promote retention of moisture, prevent evaporation of medication, and reduce pain and itching. Occlusive dressings (for sealing the wound) are commonly used for skin disorders. An airtight plastic film is applied directly over the topical agent. Corticosteroids are also available as a special plastic surgical tape and can be cut to size. See Box 53.3 Nursing Care Plan for the Patient with an Occlusive Dressing. Proper application of a plastic wrap dressing

Box 53.3 NURSING CARE PLAN for the Patient with an Occlusive Dressing

Nursing Diagnosis: Impaired skin integrity related to open lesions

Expected Outcome Improved skin integrity as evidenced by reduction in size of lesion

Evaluation of Outcome Is there a decrease in wound size?

Interventions

Assess areas of lesions for changes three times a day or as ordered.
 Assess lesions for presence or absence of dead tissue and exudates.
 Cleanse wound as prescribed (see text for specific bathing instructions). Lightly pat dry.
 Apply prescribed topical agent (see text for specifics) to moist skin.
 Apply sparingly or as directed.

 Apply plastic film, cut to size. Cover with an appropriate dressing to seal edges.
 Remove dressing for 12 out of 24 hours.

Rationale

Areas of redness, swelling, pain, and drainage may indicate infection.
 Appearance indicates areas of healing and infection.
 Cleansing helps provide a healthy granulation area for healing.

 Various agents have specific properties (control bacterial growth, prevent itching, have a protective effect, provide lubrication, relieve pain, or decrease inflammation).
 Film enhances absorption of medication and helps retain moisture.

 Continued use may cause skin atrophy, folliculitis, erythema, and systemic absorption of medication.

Evaluation

Are lesions free of redness, swelling, pain, and drainage?
 Are lesions free of exudates and dead tissue?
 Is wound clean and free of debris, crusts, and exudate?

 Does area exhibit signs of healing (e.g., decrease in size and numbers of lesions, free from infection, less itching)?

 Is the topical agent adherent to the skin?

 Are there signs of healthy granulation tissue?
 Is skin pink? Are there less open areas?
 Is dressing removed for at least 12 hours?

Nursing Diagnosis: Disturbed body image related to presence of lesion or wound

Expected Outcomes Patient verbalizes acceptance of condition. Patient is willing to participate in care of lesion or wound.

Evaluation of Outcomes Does patient verbalize acceptance of condition? Does patient participate in care of lesions?

Interventions

Assess patient's feelings regarding condition.

 Care for patient with an accepting attitude.
 Allow opportunities for patient to verbalize concerns about condition.
 Provide referrals to support groups and counselors as appropriate.

 Assist patient in concealing lesion or wound in a safe and appropriate manner.

Rationale

Assessment provides a baseline for care. If patient denies condition, he or she may not comply with care.
 Patient will be aware of nuances in nurse's behavior.
 Verbalizations allow patient to begin to accept and problem solve.
 Patient may benefit from talking to others with similar condition or to another professional for objective evaluation.

 Long sleeves and long pants may help conceal lesions, protect lesions, and prevent further skin damage.

Evaluation

Does patient state willingness to follow care instructions?

 Does patient allow nurse to partake in care of lesion or wound?
 Does patient verbalize feelings appropriately?
 Is patient receptive to appropriate referrals?

 Is patient accepting of appearance of lesions?
 Are lesions or wounds visible?

Nursing Diagnosis: Bathing/hygiene self-care deficit, related to presence of lesions or wound and discomfort

Expected Outcomes Patient verbalizes importance of good hygiene. Patient is willing to participate in bathing/hygiene.

Evaluation of Outcomes Does patient verbalize importance of good hygiene? Is patient clean?

Interventions

Assess patient's level of hygiene.

Instruct patient in appropriate bathing/hygiene:

- Avoid strong detergents and soaps; utilize gentle emollient soaps or prescribed soaps.
- Gently stroke areas of lesions.
- Pat dry; no friction.
- Maintain a little moisture on skin.
- Maintain comfortable environmental temperature.
- Have temperature of bath at a comfortable level to patient, but not too hot.

Rationale

Provides a baseline for care.

Patient needs to be able to properly cleanse lesions to prevent infection. Avoidance of friction and strong soaps prevents further trauma to skin. Patient will not shiver in comfortable temperatures.

Evaluation

Is patient's level of hygiene at an acceptable level?

Is patient able to verbalize understanding, as well as demonstrate good bathing techniques? Are lesions free of infection?

includes washing the area, lightly patting it dry, applying the medication to moist skin, covering the medicated area with plastic wrap, and covering with a dressing to seal the edges. Wet dressings and ointments should only be applied to affected areas, *not* to healthy intact skin, because this can cause maceration of good skin. Plastic wrap dressings should be used for no more than 10 to 12 hours a day.

NURSING CARE TIP

Continued use of occlusive dressings can cause skin atrophy, folliculitis, maceration, erythema, and systemic absorption of the medication. To prevent some of these complications, the dressing is removed for 12 out of every 24 hours.

Other dressings commonly used with topical treatments for skin conditions include gauze or cotton cloth held in place with small, stretchable tubular material (e.g., Surgi-

tube, tube gauze) for fingers, toes, and extremities; disposable polyethylene gloves sealed at the wrist; cotton socks or plastic bags for the feet; cotton cloth held in place with tubular material for the extremities; disposable diapers or cotton diapers for the groin and perineal areas; cotton cloth held in place with dress shields for the axillae; cotton or light flannel pajamas for the trunk; a shower cap for the scalp; and a face mask made from gauze and stretchable dressings with holes cut out for eyes, nose, mouth, and ears. The patient's primary care provider should specify the type of dressing and particular materials needed for this dressing.

A variety of other types of dressing materials are available for wound and skin care. Transparent dressings (e.g., Op-Site, Tegaderm) can be used over skin tears or intravenous insertion sites. Hydrocolloid dressings (e.g., Duoderm, Tegisorb thin) can help protect areas exposed to pressure and treat pressure ulcers in early stages. Gels, pastes, and granules can be used to fill in deep wounds to promote granulation and aid healing. See Chapter 54 for additional dressings used specifically for pressure ulcers.

REVIEW QUESTIONS

1. Which of the following is the protein in epidermal cells that makes the skin relatively waterproof?
 - a. Collagen
 - b. Keratin
 - c. Melanin
 - d. Elastin
- Multiple response item. Select all that apply.
2. What are functions of subcutaneous tissue?
 - a. It nourishes the dermis.
 - b. It cushions bony prominences.
 - c. It lubricates the epidermis.
 - d. It provides insulation.
 - e. It stores energy.

3. Older adults have fewer fibroblasts, and epidermal division slows. How do these changes affect nursing care?
 - a. The nurse should take care to protect fragile skin.
 - b. The nurse should provide blankets to keep the patient warm.
 - c. The nurse should apply lubricating lotions to prevent drying.
 - d. The nurse should massage the skin to enhance circulation.
4. Which skin lesion is typically seen in chickenpox?
 - a. Macule
 - b. Papule
 - c. Vesicle
 - d. Wheal
5. What equipment is most important to have readily available when a patient is undergoing skin testing for allergies?
 - a. Resuscitation equipment
 - b. Flashlight
 - c. Measuring device
 - d. Alcohol and cotton swabs
6. Why should wet dressings be applied only to one-third of the body at one time?
 - a. So the rest of the body can be observed for reaction to the dressing
 - b. To prevent chilling the patient
 - c. To prevent absorption of too much water, causing fluid overload
 - d. To enable the patient to be more mobile

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Mr. Evans*

1. He may be sensitive or allergic to the medication. Most likely, he is applying too much too often. This ointment is applied as a thin layer, and usually only twice daily.
2. Note the size (usually in centimeters), location, color, distribution, and configuration of lesions. Describe exactly what you see, avoiding judgments about what you think it is. Document any teaching you provided related to how his medication should be applied.

QUESTIONS TO GUIDE YOUR READING

1. How would you explain the pathophysiology of each of the skin disorders listed in this chapter?
2. What are the etiologies, signs, and symptoms of each of the skin disorders?
3. What are current therapeutic interventions for each of the skin disorders?
4. What data should you collect when caring for patients with disorders of the integumentary system?
5. What nursing care will you provide for patients with each of the covered skin disorders?
6. How will you know if your nursing interventions have been effective?

Skin disorders cover a wide array of diseases and conditions. These disorders can be generalized or localized, acute, chronic, or traumatic. This chapter discusses common skin disorders encountered by nurses. An excellent resource on skin disorders, with photographs, is at www.nsc.gov.sg/commskin/skin.html. The American Academy of Dermatology can be accessed at www.aad.org.

PRESSURE ULCERS

Pathophysiology and Etiology

Pressure ulcers are often referred to by patients with old terms such as *bedsores*, *decubitus ulcers*, or *pressure sores*. Essentially a pressure ulcer is a lesion caused by prolonged pressure against the skin. This may occur from spending a prolonged period in one position, causing the weight of the body to compress the capillaries against a bed or chair, especially over bony prominences. Pressure ulcers are the result of tissue anoxia and begin to develop within 20 to 40 minutes of unrelieved pressure on the skin. Other causes include pressure from a tight splint or cast, traction, or other device. Those at risk are immobile patients, those with decreased circulation, and those with impaired sensory perception or neurological function.

Mechanical forces (pressure, friction, and shear) lead to the formation of pressure ulcers. The pressure level that closes capillaries in healthy people is 25 to 32 mm Hg. When pressure applied to the skin is greater than the pressure in the capillary bed, it can impair cellular metabolism. It decreases the blood supply to the tissues and eventually causes tissue ischemia. This reduction in blood flow causes **blanching** of the skin. The longer the pressure lasts, the greater the risk of skin breakdown and the development of a pressure ulcer.

Friction is the rubbing of the skin surface with an external mechanical force. Also referred to as “sheet burns,” this can happen when the patient is dragged or pulled across bed linens instead of being lifted.

Shearing occurs when the patient slides down in bed when the head of the bed is raised, or when being pulled or repositioned without being lifted off the sheets. With shearing, the skin and subcutaneous tissue remain stationary and the fat, muscle, and bone shift in the direction of body movement. As a result, there is damage deep within the tissues.

Any patient experiencing prolonged pressure is at risk for a pressure ulcer. Elderly patients have increased risk because of normal aging changes of the skin. Because thin patients have little padding when pressure is present, they have the greatest pressure applied to their capillaries. Obesity also is a contributing factor because adipose tissue is poorly vascularized and is therefore more likely to develop ischemic changes. Impaired peripheral circulation also makes the skin more susceptible to ischemic damage.

Prevention

There are many interventions for the prevention of pressure ulcers. Assess and document the condition of the skin daily, so all are aware of developing problems. Gently cleanse the skin daily with tepid water and mild soap to prevent drying. To reduce friction, pat the skin dry rather than rubbing it dry. After bathing, daily lifelong lubrication of the skin with moisturizers is important to prevent dryness. Thoroughly dry skin-to-skin surfaces, such as under the breasts, skin folds (especially in the groin and abdominal folds), and between the toes, to prevent prolonged exposure to moisture. If incontinence is a problem, clean the skin promptly with tepid water and mild soap, pat dry, and apply a moisture barrier to prevent breakdown. Avoid massaging bony prominences or reddened skin areas; research has shown that blood vessels are damaged by massage when ischemia is present or when they lie over a bone.

Teach patients to shift their weight every 15 minutes if possible when lying or sitting. When the patient is immobile, the highest possible level of mobility should be maintained; frequent active or passive range-of-motion exercises should be performed, as well as turning according to a written repositioning schedule. If patients are on bedrest, turn and reposition them at least every 2 hours, but preferably more often because ischemia development begins after 20 to 40 minutes of pressure. The head of the bed should not be elevated more than 30 degrees to reduce pressure on the coccyx, and to reduce friction and shear damage from sliding down in the bed. When positioning patients on their side, place them at a 30-degree angle or less and not directly on the trochanter because this area is especially sensitive to pressure and can quickly break down. If patients are placed on the trochanter, they usually become restless and squirm around to get off the trochanter. If the patient is seated in a chair, repositioning every hour is important. A mobility program specific to the patient must be developed.

The patient’s heels should not rest on the bed surface. They should be elevated off the bed with pillows placed lengthwise under the calf or with heel elevators. Take care so pressure is not applied on the calf from the pillows. Be sure to also protect the patient’s elbows, sacrum, scapulae, ears, and occipital area from pressure.

Donut-shaped cushions should never be used. They create a circle of pressure that cuts off the circulation to the surrounding tissue, promoting ischemia rather than preventing it. Pad skin contact surfaces, especially bony prominences, so they do not press against each other. (For example, place a small pillow between the knees when the patient is in a side-lying position.) Provide an appropriate pressure-relieving or pressure-reducing mattress and chair cushion for immobile patients. To avoid friction, use a sheet to lift and move patients; provide an overbed trapeze to assist patients to move themselves. Prevent malnutrition and dehydration by ensuring an adequate intake of protein, calories, and fluid; provide 2500 mL of fluid each day if not contraindicated by other medical problems. See

Box 54.1

Gerontological Issues

Interventions to Prevent Skin Breakdown

- Avoid the use of soap and water on dry skin areas. Use a moisture barrier cream or ointment on dry skin areas *before* bathing to protect the skin from the drying effects of water.
- Clean and dry areas between toes.
- Use perineal cleansing products to cleanse urine and feces residue from the perineum and anal areas. These products are specially designed to break down and facilitate the complete removal of urine and feces without irritating the skin.
- Use moisturizing creams that have no alcohol or perfume, which can irritate the skin.
- Avoid areas of skin pressure, especially over bony areas, by assisting the older adult to change positions on a regular schedule.
- Assess skin for areas of redness. If redness occurs, the positioning schedule should be more frequent.
- Keep fingernails short.
- Use pillows and pads to help maintain alignment with position changes. Use specialized mattresses and chair cushions designed to decrease pressure. Keep the patient's heels off the bed with pillows under the calves for support and to prevent pressure.
- Encourage the older adult to be out of bed and active throughout the day. Remember to assess skin and reposition frequently even when out of bed, because areas of pressure occur whether the patient is in or out of bed.
- Remind the patient to change position or shift weight frequently while sitting in a chair to avoid prolonged pressure.
- Provide a high-protein vitamin-rich diet if not contraindicated.

Box 54.1 Gerontological Issues for additional preventive measures.

An important aspect of prevention is identification of patients at risk for pressure ulcer development. Most institutions have adopted assessment tools such as the Braden or Norton scales to assess patients for physical condition, mental status, activity, mobility, and incontinence to determine the risk for pressure ulcers. Advanced age, low diastolic blood pressure, elevated body temperature, and inadequate current intake of protein are all risk factors associated with the development of pressure ulcers. See Table 54.1 for the Braden instrument.

Signs and Symptoms

The most common sites for pressure ulcers are the sacrum, heels, elbows, lateral malleoli, greater trochanters, ischial

LEARNING TIP

Pressure ulcers may be described according to a three-color system.

- Black wounds indicate necrosis.
- Yellow wounds have exudate and are infected.
- Red wounds are pink or red and are in the healing stage.

tuberosities, base of the skull, scapulae, and ears. Most patients experience pain at the ulcer site. A report of pain requires continual assessment, documentation, and treatment.

A wound may contain a mixture of black, yellow, and red colors. Necrotic wounds are the worst because they contain dead tissue. Beefy red wounds are desired because they are healing wounds. It is important to consider treating the worst color present first or healing will be delayed. For example, if a wound is both yellow and black, the dead tissue must be removed first before the infection can be effectively treated. This color system is a helpful system for patients and families to use to describe wounds to the home care nurse because colors are easily recognized and understood by most people.

Complications

Wound infection is a common complication. New ulcers can also appear, and the present ulcer can progress to a deeper wound. Some wounds take a prolonged time to heal or never heal.

Diagnostic Tests

All pressure ulcers are considered to be colonized with bacteria. This means that bacteria are present, but the wound is not necessarily infected. In most cases, adequate cleansing and debridement can prevent bacterial colonization from advancing to clinical infection. Swab cultures and culture and sensitivity tests may be done to identify the causative organism in suspected infection sites. (See Chapter 53 for instructions for obtaining a culture.) Results need to be interpreted to distinguish between true wound infection and bacterial colonization. If the wound is healing by secondary intention, it becomes colonized by bacterial flora on the skin and from the environment. If, however, the wound is extensive, bacterial growth may exceed the local tissue defenses and a true wound infection results.

If the wound does not demonstrate signs of healing or if an ischemic ulcer is suspected, noninvasive and invasive arterial blood supply studies are recommended. Wound biopsies may be performed for large, extensive wounds.

Therapeutic Interventions

Treatment varies according to the size, depth, and stage of the pressure ulcer, as well as special needs of the patient and

(Text continued on page 1218)

TABLE 54.1 BRADEN SCALE FOR PREDICTING PRESSURE SORE RISK

Patient's Name _____	Evaluator's Name _____			Date of Assessment _____
SENSORY PERCEPTION ability to respond meaningfully to pressure-related discomfort	1. Completely Limited Unresponsive (does not moan, flinch, or grasp) to painful stimuli, due to diminished level of consciousness or sedation OR Limited ability to feel pain over most of body	2. Very Limited Responds only to painful stimuli. Cannot communicate discomfort except by moaning or restlessness OR Has a sensory impairment which limits the ability to feel pain or discomfort over 1/2 of body	3. Slightly Limited Responds to verbal commands, but cannot always communicate discomfort or the need to be turned OR Has some sensory impairment which limits ability to feel pain or discomfort in 1 or 2 extremities	4. No Impairment Responds to verbal commands. Has no sensory deficit which would limit ability to feel or voice pain or discomfort.
MOISTURE degree to which skin is exposed to moisture	1. Constantly Moist Skin is kept moist almost constantly by perspiration, urine, etc. Dampness is detected every time patient is moved or turned.	2. Very Moist Skin is often, but not always moist. Linen must be changed at least once a shift.	3. Occasionally Moist Skin is occasionally moist, requiring an extra linen change approximately once a day.	4. Rarely Moist Skin is usually dry, linen only requires changing at routine intervals.
ACTIVITY degree of physical activity	1. Bedfast Confined to bed	2. Chairfast Ability to walk severely limited or nonexistent. Cannot bear own weight and/or must be assisted into chair or wheelchair.	3. Walks Occasionally Walks occasionally during day, but for very short distances, with or without assistance. Spends majority of each shift in bed or chair.	4. Walks Frequently Walks outside room at least twice a day and inside room at least once every two hours during waking hours
MOBILITY ability to change and control body position	1. Completely Immobile Does not make even slight changes in body or extremity position without assistance	2. Very Limited Makes occasional slight changes in body or extremity position but unable to make frequent or significant changes independently	3. Slightly Limited Makes frequent though slight changes in body or extremity position independently	4. No Limitation Makes major and frequent changes in position without assistance
NUTRITION usual food intake pattern	1. Very Poor Never eats a complete meal. Rarely eats more than 1/3 of any food offered. Eats 2 servings or less of protein (meat or dairy products) per day. Takes fluids poorly. Does not take a liquid dietary supplement OR Is NPO and/or maintained on clear liquids or IVs for more than 5 days	2. Probably Inadequate Rarely eats a complete meal and generally eats only about 1/2 of any food offered. Protein intake includes only 3 servings of meat or dairy products per day. Occasionally will take a dietary supplement. OR Receives less than optimum amount of liquid diet or tube feeding	3. Adequate Eats over half of most meals. Eats a total of 4 servings of protein (meat, dairy products) per day. Occasionally will refuse a meal, but will usually take a supplement when offered. OR Is on a tube feeding or TPN regimen which probably meets most of nutritional needs	4. Excellent Eats most of every meal. Never refuses a meal. Usually eats a total of 4 or more servings of meat and dairy products. Occasionally eats between meals. Does not require supplementation.
FRICTION & SHEAR	1. Problem Requires moderate to maximum assistance in moving. Complete lifting without sliding against sheets is impossible. Frequently slides down in bed or chair, requiring frequent repositioning with maximum assistance. Spasticity, contractures, or agitation leads to almost constant friction .	2. Potential Problem Moves feebly or requires minimum assistance. During a move skin probably slides to some extent against sheets, chair, restraints, or other devices. Maintains relatively good position in chair or bed most of the time but occasionally slides down.	3. No Apparent Problem Moves in bed and in chair independently and has sufficient muscle strength to lift up completely during move. Maintains good position in bed or chair.

NO DONUT TYPE DEVICES
MAINTAIN GOOD HYDRATION
AVOID DRYING THE SKIN

health-care provider preference. All pressure must be removed from the affected area for healing to occur. Cleanliness must be maintained. Basic treatment includes debridement, cleansing, and dressing of the wound to provide a moist and healing environment.

LEARNING TIP

The epidermis skates on moisture, so the wound must be kept moist to heal.

Debridement

Debridement is the removal of dead or nonviable tissue from a wound to help clean up the wound and facilitate formation of granulation tissue. It may be done surgically or nonsurgically. Nonsurgical debridement includes mechanical, enzymatic, and autolytic methods. Surgical debridement is used only if the patient has sepsis or **cellulitis**, or to remove extensive **eschar**. Eschar is a black or brown hard scab or dry crust that forms from necrotic tissue. It may hide the true depth of the wound and must be removed for the wound to heal.

MECHANICAL DEBRIDEMENT. Scissors and forceps can be used for mechanical debridement to selectively debride nonviable tissue. Dextranomer beads, another method of mechanical debridement, may also be sprinkled over the wound to absorb exudate and all other products of tissue breakdown, as well as surface bacteria. Whirlpool baths and wet-to-dry saline gauze dressings may also be used for mechanical debridement. For wet-to-dry dressings, the wet gauze is placed directly on the wound (avoiding surrounding healthy tissue) and allowed to dry completely. The drying process causes the gauze to adhere to the wound; when it is pulled off, tissue is pulled off with it. This results in nonselective debridement because viable tissue may also be removed in this process. These methods are painful, so the patient should be premedicated for pain and assessed frequently.

ENZYMATIC DEBRIDEMENT. Enzymatic debridement involves the application of a topical debriding agent. These agents vary as to application methods, so careful reading of instructions is necessary. Most of these debriding agents are proteolytic enzymes that selectively digest necrotic tissue. Be careful to keep them off of healthy tissue.

AUTOLYTIC DEBRIDEMENT. Autolytic debridement is the use of a synthetic dressing or moisture-retentive dressing over the ulcer. The eschar is then self-digested via the action of the enzymes that are present in the fluid environment of the wound. This method is not used for infected wounds.

SURGICAL DEBRIDEMENT. Surgical debridement is the removal of devitalized tissue, slough, or thick, adherent

eschar, utilizing a scalpel, scissors, or other sharp instrument. Slough is a loose yellow to tan stringy necrotic tissue. Slough, like eschar, can be tightly adhered to the wound bed.

Depending on the amount of debridement to be done, this may be performed in the operating room, a treatment room, or the patient's room. Following surgical debridement, grafting may be required to close the wound. This becomes necessary if it is a full-thickness ulcer, if there is loss of joint function, or for cosmetic purposes. For procedures performed without anesthesia, be sure to premedicate the patient. Continually monitor for pain during the procedure, especially if there is a donor site for grafting.

Wound Cleansing

The ulcer should be thoroughly cleansed via whirlpool, hand-held shower head, or irrigating system with a pressure between 4 and 15 pounds per square inch (psi), such as a 30-mL syringe with an 18-gauge needle. Pressure less than 4 psi does not adequately cleanse the wound, and greater than 15 psi may damage tissue. If an irrigating system is used, 250 mL of normal saline (or sometimes tap water for home wound care) should be used to thoroughly cleanse the wound. If the wound is red, gentle irrigation with a needleless 30- to 60-mL syringe should be used to prevent trauma and bleeding. When bleeding occurs, wound healing has been impaired. However, if the wound has been diagnosed as being infected, pressure flushing with a 30- to 60-mL syringe and an 18-gauge needle is needed to help remove bacteria.

LEARNING TIP

Dilution is the solution to wound pollution!

Once the wound is cleansed and debrided, apply a dressing. Wounds heal more rapidly in a moist environment, with minimal bacterial colonization and a healing temperature. This takes 12 hours to occur after the wound is covered with an occlusive dressing. If a dressing is frequently removed, the wound may not reach its healing temperature and healing may be impaired. When possible, the dressing should be left in place for extended periods. Infected wounds are not covered with occlusive dressings; draining wounds may require frequent dressing changes.

Wound Dressings

Dressings vary according to size, location, depth, stage of ulcer, and preference of the ordering practitioner. Commonly used dressing materials include hydrogel dressings, polyurethane films, hydrocolloid wafers, biological dressings, alginates, and cotton gauze. These materials promote an optimum healing environment. Hypoallergenic tape should be used to secure dressings if tape is necessary. Protective paste may be applied to protect nonaffected tissue from topical agents. In all cases, pressure should be kept off the wound. No treatment will be effective if pressure continues to damage the tissue.

cellulitis: cellu—cell + itis—inflammation

eschar: eschara—scab

Negative Pressure Wound Therapy

Negative pressure wound therapy (NPWT) is a relatively new development that is proving effective for healing of large open pressure ulcers (Fig. 54.1). In NPWT, a wound is packed loosely with a sterile sponge, then covered with an occlusive dressing. A vacuum source is placed in the wound and gentle negative pressure is applied. The negative pressure allows excess drainage and infectious material to be removed, which reduces pressure on delicate new tissue. With small vessels decompressed, circulation is increased, and healing is accelerated. NPWT also maintains a moist environment for optimal healing.

Nursing Process for the Patient with a Pressure Ulcer

Assessment/Data Collection

Provide an ongoing assessment of the status of the pressure ulcer, as well as underlying causes and barriers to healing. Monitor for risk factors such as prolonged immobility, incontinence, and inadequate nutrition and hydration.

Use transparency film or a disposable ruler to measure the diameter of the ulcer in centimeters. Imagine a clock superimposed over the wound with 12 o'clock at the head and 6 o'clock at the feet. Measure in centimeters from 12 to 6 o'clock, and from 9 to 3 o'clock. Depth can be measured with a cotton-tipped applicator. Also, gently probe a cotton-tipped applicator under the skin edges to detect tunneling and measure lateral tissue destruction.

There are several different staging systems for pressure sores based on the depth of tissue destroyed. In general, the staging systems are categorized from stage I to stage IV (Fig. 54.2).

- Stage I: The skin is still intact, but the area is red and does not blanch. There may also be warmth, hardness, and discoloration of the skin. Be aware that even though the skin is intact, there may be deeper tissue damage that is difficult to observe.
- Stage II: There is a break in the skin, with partial-thickness skin loss of epidermis, dermis, or both.

FIGURE 54.1 Wound vac therapy.

FIGURE 54.2 Staging criteria for pressure ulcers. Stage I. Nonblanchable erythema of intact skin indicates potential for ulceration. Stage II. Partial-thickness loss involving both epidermis and dermis. Ulcer is still superficial and appears as a blister, abrasion, or very shallow crater. Stage III. Full-thickness loss involving subcutaneous tissue. Ulcer may extend to but not through fascia. A deep crater that may undermine adjacent tissues. Stage IV. Full-thickness loss with extensive involvement of muscles, bone, or supporting structures. This deep ulcer may involve undermining and sinus tracts of adjacent tissues. (From Dillon PM: *Nursing Health Assessment*, 2nd ed. F.A. Davis, Philadelphia, 2007, with permission.)

The ulcer may appear as an abrasion, a shallow crater, or a blister.

- Stage III: There is full-thickness skin loss, which extends to the subcutaneous tissue, but not fascia. The ulcer looks like a deep crater and may have undermining of adjacent tissue. If a wound has eschar you cannot determine depth until the eschar is removed.
- Stage IV: There is full-thickness skin loss with damage to the muscle, bone, or support structures such as tendons. There may be undermining and sinus tracts (tunneling).

Assess wound exudate. Two common types of wound exudate are serosanguineous and **purulent**. Serosanguineous exudate is fluid consisting of serum and blood. It is blood-tinged, amber-colored fluid. Purulent fluid is a fluid that contains pus. It can vary in color and have different

purulent: purulentus—pus

odors, which are suggestive of different wound colonizations. Creamy yellow pus may indicate *Staphylococcus*. Beige pus that has a fishy odor may suggest *Proteus*. Green-blue pus with a fruity odor may indicate *Pseudomonas*. Brown pus with a fecal odor may suggest *Bacteroides*.

Gently palpate the wound with a gloved hand to assess the texture of granulations. Granulation tissue has a budding appearance from the development of tiny new capillaries. If the granulations are healthy, they have a slightly spongy texture.

Document all findings carefully in the medical record, so all health team members can monitor progress of healing. Many institutions have specific forms for drawing pictures of the locations and sizes of wounds. There may be a special instant camera to document progress. Follow policy at the institution where you work.

NURSING DIAGNOSIS, PLANNING, IMPLEMENTATION, AND EVALUATION. See Box 54.2 Nursing Care Plan for the Patient with a Pressure Ulcer.

Box 54.2 NURSING CARE PLAN for the Patient with a Pressure Ulcer

Nursing Diagnosis: Impaired skin integrity related to pressure on skin surface

Expected Outcomes Skin integrity is improved as evidenced by decrease in wound size, no development of additional pressure ulcers.

Evaluation of Outcomes Is there a decrease in wound size? Are there any new pressure ulcers?

Interventions

Assess status of pressure ulcer according to stage, color, exudate, texture, size, and depth.

Assess cause of pressure (e.g., immobility, friction, shearing).

Cleanse wound gently with warm water; rinse; pat dry gently with gauze. Do not rub the area.

Debride wound as prescribed (method depends on patient's condition and goals of care).

Dress wound appropriately for prescribed topical agent. Make sure it stays intact with movement and that edges do not roll, causing more pressure.

Position patient off the ulcer.

If a leg ulcer, provide for frequent rest periods with leg elevated; if immobile, reposition every 2 hours.

Rationale

Provides baseline data on which care is based

Allows for correction and also prevents further trauma

Reduces number of bacteria. Drying prevents maceration of skin. Gentle handling prevents further trauma.

Debridement removes drainage and wound debris. Permits granulation of tissue.

Protects underlying wound and helps promote healing

Prevents further pressure and trauma on ulcer

Prevents further tissue breakdown

Evaluation

What stage is ulcer? Are there any other outstanding characteristics?

What is the cause of this ulcer?

Is wound clean and dry?

Does wound look clean and free of debris?

Is dressing applied appropriately?

Is patient positioned off the ulcer?

Is leg elevated?

Is patient repositioned every 2 hours?

Nursing Diagnosis: Risk for infection related to open wound

Expected Outcomes Patient will not experience wound infection or systemic sepsis. (Total elimination of bacteria is impossible due to nature of the condition.)

Evaluation of Outcomes Is patient free from signs and symptoms of further infection? Is patient free from systemic infection?

Interventions

Assess ulcer at every dressing change or at least every 24 hours. Look for areas of tenderness, swelling, redness, and heat; and drainage.

Monitor temperature at least every 12 hours.

Provide meticulous wound care (see Impaired Skin Integrity).

Use thorough handwashing techniques. Use sterile technique for dressing changes.

Rationale

Allows for early recognition of infection and response to treatment

Elevated body temperature is one sign of infection.

Helps decrease the level of contamination and prevent infection

Prevents cross-contamination

Evaluation

Are signs of infection present?

Is patient afebrile?

Is wound showing signs of healing without purulent drainage?

Does nurse take proper wound precautions?

Nursing Diagnosis: Pain related to ulcer and treatments

Expected Outcomes Patient will be as comfortable and as pain-free as possible as evidenced by statement of increased comfort, statement of decreased pain, and ability to sleep at night.

Evaluation of Outcomes Does patient express comfort? Does patient express a decrease in pain? Is patient able to sleep?

Interventions

Assess level of pain with pain scale, and by observing facial expressions and positioning of body.

Offer analgesics as prescribed. Request order for topical analgesics as needed with dressing changes and cleaning of the wound.

Decrease anxiety with relaxation techniques (e.g., distraction, music).

Maintain a comfortable environment: provide for privacy; position in good alignment and comfortably; and maintain a comfortable room temperature.

Rationale

Monitors level of pain and response to therapy

Analgesics help relieve pain.

Relaxation can lessen pain intensity.

Relaxes patient and lessens intensity of discomfort

Evaluation

At what level is pain? Is it better or worse with treatment?

Do analgesics relieve pain?

Is patient less anxious? Does patient verbalize less pain?

Does patient express an increase in comfort?

NURSING CARE TIP

Many institutions now have nurses who have been specially trained in wound care. Consult one of these nurses for expert wound assessment and treatment recommendations.

CRITICAL THINKING

Mr. Russ

■ Mr. Russ is an 84-year-old man who was admitted from home to the medical surgical unit after a fall that fractured his femur. He has a history of type 2 diabetes. He had an open reduction and internal fixation of his femur and is now in a brace. He is 6 ft tall and weighs 160 pounds. His appetite is poor; his wife states he has lost 15 lb in the last 3 months. He is occasionally incontinent of urine. What preventive measures can be taken to prevent skin breakdown in this patient?

Suggested answers at end of chapter.

INFLAMMATORY SKIN DISORDERS

Dermatitis

Pathophysiology and Etiology

Dermatitis is inflammation of the skin and is characterized by itching, redness, and skin lesions, with varying borders and distribution patterns. Dermatitis can be caused by exposure to allergens or irritants, by heredity, or by emotional stress. Many times the cause is not known; in this case, the terms *eczema* or *nonspecific eczematous dermatitis* may be used. The terms *eczema* and *dermatitis* are sometimes used interchangeably. There are three common types of dermatitis: contact dermatitis, atopic dermatitis, and seborrheic dermatitis. All types tend to be chronic and respond well to treatment, but are prone to recur. See Table 54.2 for common types of dermatitis.

Prevention

The patient should prevent irritation to the skin by avoiding irritants, allergens, excessive heat and dryness, and by controlling perspiration. Baths should be short, and water

dermatitis: derma—skin + itis—inflammation

TABLE 54.2 COMMON TYPES OF DERMATITIS

Type	Description
Contact	Acute or chronic condition; caused by contact with irritant or allergen
Irritant contact	Caused by direct contact with an irritating substance, such as soap, detergent, strong medication, astringent, cosmetic, or industrial chemical
Allergic contact	From contact with an allergen, such as perfume, tanning lotion, medication, hair dye, poison ivy, poison oak; contact results in cell-mediated immune response
Atopic	Chronic inherited condition; may be associated with respiratory allergies or asthma; can vary between bright red maculas, papules, oozing, lichenified , and hyperpigmented areas
Seborrheic	Chronic, inflammatory disease usually accompanied by scaling, itching, and inflammation; seborrhea is excessive production of sebaceous secretions; found in areas with abundant sebaceous glands (scalp, face, axilla, genitocrural areas) and where there are folds of skin; can appear as dry, moist, or greasy scales, yellow or pink-yellow crusts, redness, and dry flakiness; can be associated with emotional stress; genetic predisposition may exist

Contact dermatitis caused by nail polish

Contact dermatitis caused by topical anesthetic

Seborrheic dermatitis

lichenified: leichen—scaly growth + facere—to make

seborrhea: sebum—tallow + rhoia—flow

should be tepid. Deodorant soaps should be avoided; mild superfatted soaps are recommended instead. Dry skin is lubricated with creams, oils, or ointments as appropriate. Itching and scratching are prevented as much as possible.

Signs and Symptoms

Itching and rashes or lesions are the main clinical manifestations of dermatitis. The lesions vary depending on the type and location of dermatitis. Rashes and lesions may present as dry, flaky scales, yellow crusts, redness, fissures, macules, papules, and vesicles. (These are described in Chapter 53.) Scratching can make any of these lesions worse.

NURSING CARE TIP

Itching and scratching can occur during sleep, causing the rash to worsen. Have the patient wear cotton gloves at night.

Complications

The lesion or rash worsens with continued irritation, exposure to offending agents, or scratching. Infections of the skin are common and may be due to the many open areas and breaks in the skin, as well as the patient's reluctance to properly wash the affected area because of pain from the lesions. Some infections can also become systemic.

Diagnostic Tests

Diagnosis is usually based on history, symptoms, and clinical findings. If infection is suspected, cultures of the lesions may be ordered to identify the infecting agent.

Therapeutic Interventions

Treatment varies according to symptoms. Basic treatment objectives are to control itching, alleviate discomfort and pain, decrease inflammation, control or prevent crust formation and oozing, prevent infection, prevent further damage to the skin, and heal the skin as much as possible.

Itching (**pruritus**) and discomfort can be somewhat relieved by antihistamines, analgesics, and antipruritic medications as ordered. Colloidal oatmeal preparations added to baths may also help.

Steroids such as hydrocortisone or methylprednisolone may be used to suppress inflammation. They can be administered as a topical, intralesional, or systemic agent. The specific type and vehicle used depends on the type of lesion, the body area involved, and the extent of the lesion. Topical administration is preferred if possible because systemic steroids can cause serious systemic side effects, including adrenal suppression.

Tub baths and wet dressings help control oozing and prevent further crust formation. These interventions serve to loosen exudates, scales, and other wound debris, providing a clean area for topical application of medication. Skin is protected by lightly patting dry, avoiding friction,

avoiding hot water, and using a sunscreen agent when outdoors.

Nursing Process for the Patient with Dermatitis

ASSESSMENT/DATA COLLECTION. You can use the WHAT'S UP? format to assess the rash, as described in Chapter 53. Also refer to Chapter 53, Table 53.1 for specific questions to ask. Observe the rash or lesions for character, distribution, description, skin tenderness, signs of scratching, and other associated problems.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Impaired skin integrity related to rash, lesions, and scratching

EXPECTED OUTCOME: Skin integrity will improve as evidenced by reduction in lesions; no signs or symptoms of infection.

- Monitor skin condition regularly to determine if treatment is working.
- Cleanse the area as ordered by the physician, taking care not to further irritate the skin to keep area clean and prevent infection.
- Provide cool moist compresses, dressings, or tepid tub baths to help relieve inflammation and itching, debride lesions, and soften crusts and scales.
- Pat the skin dry rather than rubbing to prevent further trauma.
- Apply topical agents as ordered to help suppress inflammation.
- Provide skin care at bedtime to help promote comfortable sleep. Many antihistamines also have a sedative effect.
- Encourage patient to eat a high-protein diet to promote healing and replace lost protein. If lesions are generalized, protein can be lost through oozing of serum.
- Encourage use of gloves or mitts, especially at night, to help prevent scratching.
- Advise the patient to keep fingernails short to prevent scratching.
- Teach the patient that application of slight pressure with a clean cloth may help relieve itching.
- Teach relaxation exercises to help the patient cope with distressing symptoms.

Disturbed body image related to visible rash or lesions

EXPECTED OUTCOME: The patient will have improved body image as evidenced by a statement of acceptance of the condition and ability to socialize with others.

- Allow patients to verbalize concerns only if they wish to do so. Talking about concerns may help patient to begin to work through feelings about body image, but should not be forced.
- Refer to a support group, if available, to receive support from others in similar circumstances.
- Display an accepting attitude while caring for skin lesions. The patient will be quick to pick up

your reaction to the lesions, especially if it is negative.

- Encourage the patient to participate in skin care *to allow more control over the situation.*
- Encourage the patient to wear long sleeves or other appropriate covering if the patient desires *to make the lesions less noticeable and the patient more comfortable.*

Deficient knowledge related to disease and treatment

EXPECTED OUTCOME: The patient will verbalize understanding of the condition and demonstrate ability to perform self-care measures.

- Assess patient's baseline knowledge of condition and treatment. *Teaching should build on baseline understanding.*
- Instruct the patient in application of topical agents and dressings. *Overuse of medications can further traumatize skin, so application of a very thin layer is advised.*
- Instruct the patient in how to recognize changes, improvement, or flare-ups of the disorder and what symptoms to report to the health care provider. *Because most skin conditions are cared for at home, it is important for the patient to have the skills needed to monitor the condition and carry out treatment appropriately.*
- Advise the patient to avoid overexposure to sun and to use sunscreen agents when outdoors *to prevent skin damage.*
- Encourage use of a humidifier in the home *to help maintain hydration of skin and control itching during dry weather, especially in winter.*
- Teach the patient measures to prevent future flare-ups if possible. *Flare-ups may be avoided if the patient understands what triggers them.*

PATIENT CARE TIP

When applying topical medications, more is not better!

EVALUATION. If medical and nursing care have been effective, the lesions will be controlled or in remission, the patient will state that itching and other discomforts are controlled, the patient will be able to socialize without undue difficulty, and the patient will be able to describe and demonstrate self-care measures.

Psoriasis

Pathophysiology and Etiology

Psoriasis is a chronic inflammatory skin disorder in which the epidermal cells proliferate abnormally fast. Usually, epi-

psoriasis: psor—itch + iasis—inflammation

dermal cells take about 27 days to shed. With psoriasis, the cells shed every 4 to 5 days. The abnormal keratin forms loosely adherent scales with dermal inflammation.

Psoriasis is characterized by exacerbations and remissions. The cause is not known; however, often there may be a family history. The average age at onset is 27 years, although it can begin at any age. The condition can be severe if the onset is in childhood. Many factors can influence the suppression and outbreak of lesions, but this varies from individual to individual. Sun and humidity may suppress lesions. Aggravating factors include streptococcal pharyngitis, emotional upset, stress, hormonal changes, cold weather, skin trauma, and certain drugs (e.g., antimalarials, lithium, beta blockers).

Prevention

Because the exact etiology is not known, measures to prevent exacerbation of symptoms are specific to the patient's circumstances. General preventive measures include avoidance of upper respiratory infections, especially streptococcal infections; avoidance of or coping with emotional stress; avoidance of skin trauma, including sunburns; and avoidance of medications that may precipitate a flare-up.

Signs and Symptoms

Signs and symptoms vary according to the patient and the particular type of psoriasis. Lesions are red papules that join to form plaques with distinct borders (Fig. 54.3). Silvery scales develop on untreated lesions. Areas most often affected are the elbows and knees, scalp, umbilicus, and genitals. Other signs and symptoms include nail involvement, intergluteal pinking (involvement in the gluteal fold), itching, and dry or brittle hair.

FIGURE 54.3 Psoriasis. Note bright red scaly plaque with silvery scale. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA. Davis, Philadelphia, 1997, p 258, with permission.)

Complications

Because of the nature of the disease, with its lesions and itching, secondary infections can occur. Psoriatic arthritis may develop after the psoriasis has developed, with nail changes and destructive arthritis of large joints, the spine, and interphalangeal joints. If the psoriasis becomes severe and widespread, fever, chills, increased cardiac output, and benign lymphadenopathy can result.

Diagnostic Tests

Testing depends on the severity of the psoriasis. Normally, this disease is diagnosed by physical assessment alone. Diagnostic tests may be performed to rule out concurrent disease or secondary infections.

Therapeutic Interventions

Treatment varies according to the type and extent of the disease, as well as physical preference. Psoriasis is a chronic disease with remissions and exacerbations. Basic treatment objectives are to decrease the rapid epidermal proliferation, inflammation, and itching and scaling. Usually, the patient is instructed to bathe daily in a tub, using a soft brush to assist in the removal of scales.

Topical therapy includes corticosteroids, salicylic acid, keratolytics, coal tar, anthralin, ultraviolet (UV) light, and, in severe cases, antimetabolite chemotherapeutic agents. Topical corticosteroids may be used for their anti-inflammatory effect. Occlusive dressings are commonly used to enhance penetration of medications. (See Chapter 53.) Keratolytic ointments or gels enhance the effects of salicylic acid to loosen or remove scales.

Tar preparations are usually prescribed along with the corticosteroids for conditions that warrant it. The tar acts as an antimetabolic, slowing the epidermal cell division. Occlusive dressings are not used with tars. Anthralin is a substance extracted from coal tar. It also suppresses mitotic activity. The anthralin may be mixed with salicylic acid in a stiff paste. The patient must be closely observed because the anthralin is a strong irritant and can cause chemical burns. It is usually applied for no longer than 2 hours. Both coal tar and anthralin are commonly used in combination with UV light and are usually administered in inpatient settings or specialized outpatient clinics.

Topical preparations for the scalp are used in shampoo form. Teach the patient to read package instructions; these preparations generally need to be left in the hair for a period of time to work.

Ultraviolet light may be designated as UVB, shorter wavelength, or UVA, longer wavelength. UVA is from an artificial source, such as special mercury vapor lamps. The amount of exposure depends on the patient's condition, pigmentation, and susceptibility to burning. The patient must wear eye guards during treatments. Oral psoralen tablets (a photosensitizing agent) followed by exposure to UVA is called PUVA therapy. PUVA therapy temporarily inhibits DNA synthesis, which is antimetabolic. Because psoralen is a photosensitizing agent, the patient must not only wear

dark glasses during the treatment period, but also for the entire day after a treatment. The long-term safety of PUVA therapy is still unknown. Possible side effects include increased skin carcinomas, premature skin aging, and actinic keratosis (pre-malignant lesions of the skin). The patient should be observed closely for redness, tenderness, edema, and eye changes. Therefore, initial and follow-up eye examinations, skin biopsies, urinalysis, and blood tests may be ordered.

Retinoids are oral agents such as acitretin (Soriatane) that promote skin cell differentiation and inhibit malignancies from forming in the skin. They may be used in combination with UV therapy.

Antimetabolites, usually used for cancer chemotherapy, are reserved for the most severe cases. Methotrexate is the most common agent given. Because of its hepatotoxicity, it is contraindicated in patients with liver disease, alcoholism, renal disease, and bone marrow suppression. Before therapy, a liver biopsy and routine laboratory tests are completed.

CRITICAL THINKING

Mrs. Long

■ Mrs. Long arrives at the health clinic to complain that the prescribed shampoo she is using for her scalp is not working. She states that she washes her hair thoroughly with the medicated shampoo and immediately rinses completely. She wants to know why her scalp shows no signs of improvement. What should you tell her?

Suggested answers at end of chapter.

Nursing Care

Nursing care for the patient with psoriasis is the same as nursing care for the patient with dermatitis. The only addition is to encourage frequent periods of rest to enhance the antimetabolic effects of the therapeutic agents.

INFECTIOUS SKIN DISORDERS

A variety of infections can affect the skin. The most common disorders are discussed in this section. See Table 54.3 for a summary of additional skin infections.

Herpes Simplex

Pathophysiology and Etiology

Herpes simplex virus (HSV) infection is a common viral infection that tends to recur repeatedly. There are two types of herpes simplex: that caused by type I virus (HSV-I), which occurs above the waist and causes a fever blister or cold sore (Fig. 54.4), and that caused by type II virus (HSV-II), which occurs below the waist and causes genital herpes. See Chapter 44 for information on genital herpes.

TABLE 54.3 INFECTIOUS SKIN DISORDERS

Type	Description	Complications	Treatment/Nursing Care
<p>Impetigo Contagiosa</p>  <p>Impetigo on the face.</p>	<p>Common contagious, infectious, inflammatory skin disorders usually caused by <i>Streptococcus</i> or <i>Staphylococcus aureus</i>; sources of infection include swimming pools, pets, dirty fingernails, beauty and barber shops, and contaminated clothing, towels, sheets; may occur secondary to scrapes, cuts, insect bites, burns, dermatitis, poison ivy</p> <p>Primary skin infection can appear on exposed areas of the body (extremities, hands, face, neck) or skin-fold areas (axillae).</p> <p>Rash appears as oozing, thin-roofed vesicle that rapidly grows and develops a honey-colored crust; crusts are easily removed, and new crusts appear; lesions heal in 1 to 2 weeks if allowed to dry.</p>	<p>Glomerulonephritis resulting from a particular strain of streptococcus infection</p> <p>Lesions may spread from one skin area to another.</p> <p>Lesions may persist if not permitted to dry.</p> <p>Secondary pyoderma, or acute inflammatory purulent dermatitis, may occur if lesions are unresponsive to treatment.</p>	<p>Systemic antibiotics are administered as prescribed.</p> <p>Topical antibiotics are used after crust removal.</p> <p>Gentle washing with a mild soap, or soaking with warm, moist compresses, aids in crust removal, removes debris, and provides a clean bed for topical therapy.</p> <p>Appropriate antipyretics are prescribed as necessary.</p> <p>Keep fingernails short and clean.</p> <p>Glove or mitt hands as necessary to prevent scratching.</p> <p>Patient must remain home until all lesions are healed.</p> <p>Teach proper disposal or washing of any material that comes in contact with lesions.</p> <p>Good hygiene must be practiced to prevent skin-to-skin or person-to-person spread.</p> <p>Observe client for 6 to 7 weeks for signs/symptoms of glomerulonephritis.</p> <p>Prevent trauma; avoid squeezing or irritation.</p>
<p>Furuncles and Carbuncles</p>	<p>A furuncle is a small, tender boil that occurs deep in one or more hair follicles and spreads to surrounding dermis; may be single or multiple; usually caused by <i>Staphylococcus</i>; usually occurs on body areas prone to excessive perspiration, friction, and irritation (e.g., buttocks, axillae); can recur; the boil eventually comes to a soft yellow, black, or white head; there is localized pain, tenderness, and surrounding cellulitis; lymphadenopathy may be present.</p>	<p>Furuncles may progress to carbuncles.</p>	<p>Prevent trauma; avoid squeezing or irritation.</p>

pyoderma: pyo—pus + derma—skin

Type	Description	Complications	Treatment/Nursing Care
Furuncles and Carbuncles (cont'd)	A carbuncle is an extension of a furuncle; an abscess of skin and subcutaneous tissue; deeper than furuncle; caused by <i>Staphylococcus</i> ; usually appears where skin is thick, fibrous, and inelastic (e.g., back of neck, upper back, and buttocks); associated symptoms may include fevers, pain, leukocytosis, prostration. Both tend to occur in debilitated clients, and more often in diabetics. Occasionally, scarring may occur.	Carbuncles may progress to infection of bloodstream. Further spread of infection can occur to self and others.	Cleanse surrounding skin with antibacterial soap, followed by application of antibacterial ointment. Surgical incision and drainage may be performed. Cover draining lesion with dressing. Follow standard precautions. Double bag all soiled dressings and dispose of properly. Systemic antibiotic therapy (based on sensitivity studies) is instituted for carbuncles or spreading furuncles. Analgesia and antipyretics are ordered as necessary. Bedrest is advised with carbuncles or furuncles on perineal or anal regions. Cover mattress and pillows with plastic and wipe daily with a disinfectant. Wash all linens, towels, and clothing after each use. Properly discard razor blades after each use. Strict hand washing is maintained to prevent cross-contamination.

The primary infection occurs through direct contact, respiratory droplet, or fluid exposure from another infected person. Following the initial infection, the virus lies dormant in nerve ganglia near the spinal column, where the immune system cannot destroy it. The patient is asymptomatic at this time.

Recurrence of symptomatic infection can happen spontaneously or be triggered by fever, sunburn, stress, illness, menses, fatigue, or injury. The secondary lesion may appear isolated or as groups of small vesicles or pustules on an erythematous base. Crusts eventually form, and the lesions heal in about 1 week. The lesions are contagious for 2 to 4 days before dry crusts form.

Prevention

Avoidance of contact with a known infected lesion during the blistering phase can prevent the primary lesions. Patients should also be taught to avoid sharing contaminated items such as toothbrushes, lipsticks, and drinking glasses. This disease can recur spontaneously. Avoidance of stressors,

FIGURE 54.4 Herpes simplex. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA. Davis, Philadelphia, 1997, p 306, with permission.)

such as sunburn, injury, and fatigue, may delay a recurrence. The use of sunscreens, especially on the lips, may be helpful.

Signs and Symptoms

Some patients may have a prodromal phase of burning or tingling at the site for a few hours before eruption. The area becomes erythematous and swollen. Vesicles and pustules erupt in 1 to 2 days. There may also be redness with no blistering. Lesions can burn, itch, and be painful. The attacks vary in frequency but diminish with age. The patient is contagious until scabs are formed.

Complications

If herpes simplex is present in the vagina at childbirth, the newborn may be infected (meningoencephalitis or a panvisceral infection may occur). If the person touches the affected area and then rubs the eyes, the eyes can become severely infected. Secondary bacterial infection of lesions can occur. Rarely, herpes encephalitis can occur. This is deadly if not treated promptly.

Diagnostic Tests

Cultures of the lesions provide a definitive diagnosis. Most lesions are diagnosed on the basis of history, signs, and symptoms.

Therapeutic Interventions

There is no complete cure for herpes simplex. Recurrences will happen. Topical acyclovir (Zovirax) ointment is the drug of choice for primary lesions, to suppress the multiplication of vesicles. It does not benefit secondary lesions. Oral

acyclovir may be recommended for severe or frequent attacks (six or more attacks per year) or for patients who are immunosuppressed. Various lotions, creams, and ointments may be prescribed to accelerate drying and healing of lesions (e.g., camphor, phenol, alcohol). Antibiotics may be indicated for secondary infections.

Herpes Zoster (Shingles)

Pathophysiology and Etiology

Herpes zoster, or shingles, is an acute inflammatory and infectious disorder that produces a painful vesicular eruption on bright red edematous plaques along the distribution of nerves from one or more posterior ganglia. This eruption follows the course of the cutaneous sensory nerve and is almost always unilateral (one sided) (Fig. 54.5).

Herpes zoster is caused by the varicella zoster virus. This virus appears to be identical to the one that causes chickenpox. It is thought that herpes zoster is a reactivation of this latent varicella virus. The incubation period is 7 to 21 days. The vesicles appear in 3 to 4 days. Eruption usually occurs posteriorly and progresses anteriorly and peripherally along the dermatome. The total duration of the disease can vary from 10 days to 5 weeks.

This disease occurs most commonly in the elderly or in those who have a diminished resistance, such as the patient with acquired immunodeficiency syndrome (AIDS), the patient on immunosuppressant agents, or the patient with a malignancy or injury to the spine or a cranial nerve.

Prevention

Avoidance of the person with this disease during the contagious phase (a few days before eruption until vesicles dry or scab) is the best prevention.

FIGURE 54.5 Herpes zoster (shingles). (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA. Davis, Philadelphia, 1997, p 307, with permission.)

Signs and Symptoms

In addition to the vesicles and plaques, there may be irritation, itching, fever, malaise, and, depending on the location of lesions, visceral involvement. Lesions may be very painful; the likelihood of pain increases with age.

Complications

Postherpetic neuralgia, persistent dermatomal pain, and hyperesthesia are common in the elderly and can last for weeks to months after the lesions have healed. The incidence and severity of these complications increase with age.

Ophthalmic herpes zoster affects the fifth cranial nerve and can be a serious complication. Consultation with an ophthalmologist is imperative because this complication can affect eyesight. Other complications can occur with facial and acoustic nerve involvement, including hearing loss, tinnitus, facial paralysis, and vertigo. Full-thickness skin necrosis and scarring can occur if lesions do not heal properly; systemic infection can occur from scratching, causing the virus to enter the bloodstream.

Diagnostic Tests

Diagnosis is usually confirmed by the clinical picture of the patient and associated signs and symptoms. Cultures may be ordered if secondary bacterial infections are suspected.

Therapeutic Interventions

Treatment is aimed at controlling the outbreak, reducing pain and discomfort, and preventing complications. Acyclovir, either intravenous (IV), oral, or topical, may be prescribed in the early stages of the initial infection, for a severe outbreak, and if the patient is immunosuppressed or debilitated. Acyclovir does not cure, but it may help control the initial outbreak. Analgesics are prescribed for pain and discomfort. Corticosteroids may be administered to prevent postherpetic neuralgia and reduce pain but are not used for ocular involvement. Topical steroids should not be applied if a secondary infection is present because they suppress the immune system. Antihistamines are administered to control itching. Antibiotics are prescribed for secondary bacterial infections.

Fungal Infections

Pathophysiology and Etiology

Dermatophytosis, or a fungal infection of the skin, occurs when there is an impairment of the skin integrity in a warm, moist environment. This infection occurs through direct contact with infected humans, animals, or objects. *Tinea* is the term used to describe fungal skin infections; the name used after tinea indicates the body area affected. For example, tinea capitis is a fungal infection of the scalp. Common fungal infections and treatments are described in Table 54.4.

dermatophytosis: derma—skin + phyton—plant + osis—condition

TABLE 54.4 FUNGAL INFECTIONS

Type	Description	Treatment/Nursing Care
<i>Tinea Pedis (Athlete's Foot)</i>	<p>Common fungal infection, most frequently seen in those with warm, moist, sweaty feet; occlusive shoes; or friction/trauma to the feet</p> <p>Three types: chronic plantar scaling, acute vesicular, and interdigital</p> <p>Chronic plantar scaling will have slight redness and mild to severe scaling; fold lines on sole appear to have white powder because of scaling; there may be toenail involvement; itching is usually not present.</p> <p>Acute vesicular appears as a sudden eruption of small, painful, itchy vesicles; may also accompany chronic plantar scaling.</p>	<p>Chronic plantar scaling may be treated with kerolytics and topical antifungal agents; these agents help in relieving symptoms and improve appearance; they are not curative.</p> <p>Acute vesicular is treated with soaks or baths two or three times a day for 2 to 3 days to dry up blisters; astringent paint is applied to debrided areas; topical corticosteroids help relieve itching.</p> <p>Interdigital may be treated with combined antifungal and antibacterial therapies or antifungals alone; soak feet twice daily and dry well.</p> <p>Teach patient prevention measures: keep feet dry; dry carefully between toes; apply foot powder to absorb perspiration; wear cotton socks to absorb perspiration; if weather permits, use perforated shoes or sandals; avoid plastic or rubber-soled shoes; wear water shoes in public showers and near swimming pools.</p> <p>Apply topical agents properly: apply thin layer; treat for time specified, even after apparent clearing.</p> <p>Teach prevention measures: never share combs, brushes, pillowcases, or headgear.</p> <p>Systemic antifungals are prescribed because of high relapse rate with topical agents; review side effects with patient.</p> <p>Oral corticosteroids are indicated for kerion inflammation to help prevent alopecia; review side effects with client.</p> <p>Instruct family on contagious aspect of disease; assess other family members and pets for organism.</p>
<i>Tinea Capitis (Ringworm of Scalp)</i>	<p>Contagious; commonly causes hair loss in children</p> <p>Appears as scattered round, red, scaly patches; small papules or pustules may be evident at edges of patches; hair is brittle at site, breaks off, and temporary areas of baldness result; may be mild itching; kerion inflammation may occur after weeks</p>	
		
	<p>Tinea capitis.</p>	
<i>Tinea Corporis (Tinea Circinata, Ringworm of Body)</i>	<p>Erythematous macule that progresses to rings of vesicles or scale with a clear center that appears alone or in clusters; usually occurs on exposed areas of body; can be moderately to intensely itchy</p> <p>Infected pet is common source of infection.</p>	<p>Teach prevention measures: keep skin areas, especially folds, dry; use clean towel and wash cloth daily; wear cotton clothing, especially on hot, humid days.</p> <p>Topical antifungals are prescribed for small, localized lesions.</p> <p>Oral antifungals are indicated for severe, widespread, resistant, or follicular cases.</p> <p>Topical corticosteroids are prescribed for itching.</p> <p>Teach patient prevention measures: avoid heat, moisture, and friction.</p>
<i>Tinea Cruris (Ringworm of Groin, Jock Itch)</i>	<p>May extend to inner thighs and buttocks area; may occur with tinea pedis; often in obese people who are athletic</p> <p>Lesion first appears as a small red scaly patch and then progresses to a sharply demarcated plaque with elevated scaly or vesicular borders; itching can range from absent to severe.</p>	<p>Topical antifungals are prescribed; apply in a thin layer to rash and a few centimeters beyond border.</p>

(Continued on following page)

TABLE 54.4 FUNGAL INFECTIONS (*Continued*)

Type	Description	Treatment/Nursing Care
<i>Tinea Cruris (Ringworm of Groin, Jock Itch)</i> (<i>cont'd</i>)	 <p>Tinea cruris. Also called onychomycosis</p>	<p>Oral antifungals may be indicated for widespread cases or those resistant to topical therapy. Topical corticosteroids may be prescribed for itching.</p>
<i>Tinea Unguium (Ringworm of Nails)</i>	<p>Chronic fungal infection of nails, usually the toenails; a lifelong disease There is yellow thickening of nail plate; it is friable and lusterless; eventually crumbly debris accumulates under free edge of the nail and causes nail plate to become separated; over time, the nail may become thickened, painful, and destroyed.</p>  <p>Onychomycosis (<i>tinea unguium</i>).</p>	<p>Systemic antifungals are rarely given for toenail involvement, but may be prescribed for fingernail involvement (review side effects). Topical antifungals are usually ineffective. Nail may have to be surgically removed (nail avulsion). Explain high relapse rate to patient. Keep nails neatly trimmed and buffed flat; gently scrape out any nail debris.</p>

onychomycosis: onyx—nail + myc—fungus + osis—condition

Cellulitis

Pathophysiology and Etiology

Cellulitis is inflammation of the skin and subcutaneous tissue resulting from a generalized infection, usually with *Staphylococcus* or *Streptococcus* bacteria. It can occur as a result of skin trauma or a secondary bacterial infection of an open wound, such as a pressure sore, or it may be unrelated to skin trauma. It most often occurs in the extremities, especially the lower legs.

Prevention

Good hygiene and prevention of cross-contamination are important. If there is an open wound, preventing infection and promoting healing are critical.

Signs and Symptoms

The initial sign of cellulitis is a localized area of inflammation that may become more generalized if not treated prop-

erly. Common clinical manifestations include warmth, redness, localized edema, pain, tenderness, fever, and lymphadenopathy. It may be seen in any areas of an open wound, with skin trauma, and in the lower legs. The infection can worsen rapidly if not treated properly.

Diagnostic Tests

Culture and sensitivity testing of any pustules or drainage is necessary to identify the infecting organism. Blood cultures may also be indicated to rule out bacteremia.

Therapeutic Interventions

Topical and systemic antibiotics are prescribed according to culture and sensitivity test results. Debridement of nonviable tissue is necessary if there is an open wound. Systemic antibiotics are indicated if fever and lymphadenopathy are present. Warm, moist compresses may be ordered, although there is no evidence that this is useful in treating pain or infection.

Acne Vulgaris

Pathophysiology and Etiology

Acne vulgaris is a common skin disorder of the sebaceous glands and their hair follicles that usually occurs on the face, chest, upper back, and shoulders. The etiology is multifocal. The most common cause is hormonal changes during puberty.

The sebaceous glands are under endocrine control, especially the androgens. Stimulation of androgens (e.g., during adolescence or the menstrual cycle) in turn stimulates the sebaceous glands to increase sebum production. This, along with gradual obstruction of the pilosebaceous ducts with accumulated debris, ruptures the sebaceous glands, which causes an inflammatory reaction that may lead to papules, pustules, nodules, and cysts. Acne occurs when the ducts through which this sebum flows become plugged.

Other factors that influence the occurrence and severity of acne include a hereditary tendency, stress, and external irritants such as strong soaps or cosmetics. It is not related to diet, chocolate, sexual activity, or uncleanliness.

Prevention

Acne vulgaris occurs regardless of interventions; however, certain interventions can lessen the severity or prevent complications. Avoidance of “picking” pimples prevents further inflammation and scarring. The patient should avoid excessive washing, irritants, and abrasives.

Signs and Symptoms

The initial lesions are called comedones. Closed comedones, or whiteheads, are small white papules with tiny follicular openings. These may eventually become open **comedones**, or blackheads. The color is not caused by dirt but by lipids and melanin pigment. Scarring occurs as a result of significant skin inflammation; picking can worsen inflammation and lead to further scarring. The resulting inflammation can lead to papules, pustules, nodules (Fig. 54.6), cysts, or abscesses.

Therapeutic Interventions

Medical treatment helps prevent new lesions and helps control current lesions. Effective topical agents include benzoyl peroxide (Desquam-X; Benzagel), which is an antibacterial agent that may help prevent pore plugging; antibiotics (erythromycin, tetracycline) to kill bacteria in follicles; and vitamin A acid (Retin-A, tretinoin) to loosen pore plugs and prevent occurrence of new comedones. Topical agents may be used alone or in combination. It may take 3 to 6 weeks before improvement is seen.

All topical agents should be applied with clean hands to acne-prone areas, not just where the acne occurs. They must be applied to dry skin. Medications should not be applied near eyes, nasolabial folds, or the corners of the mouth because of the potential for irritation. If the patient is ordered a combination of topical agents, unless contraindicated, the tretinoin is used at night and the others in the morning or afternoon. Tretinoin can be neutralized if mixed directly with other agents. The patient must be careful with

FIGURE 54.6 Acne vulgaris. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA. Davis, Philadelphia, 1997, p 351, with permission.)

sun or sunlamp exposure while using tretinoin. Also, remind the patient that it may be necessary to continue treatment even after the skin clears.

Systemic antibiotics (long term, low dose) and isotretinoin (Accutane) are usually reserved for severe cases of acne; the patient must be closely monitored for side effects. Estrogen therapy (oral contraceptives) may also be prescribed for young women; however, the risks often outweigh the benefits. Women should be aware that some antibiotics reduce the effectiveness of oral contraceptives. Systemic corticosteroids may occasionally be prescribed for severe nodular acne, but they are associated with severe side effects.

Other medical treatments include comedone extraction, intralesional injections of corticosteroids, cryosurgery (freezing with liquid nitrogen), mild peeling (UV light, carbon dioxide, liquid nitrogen, mild acid), dermabrasion (deep chemical peel), excision of scars, and injection of fibrin or collagen below the scars. These treatments depend on the severity, age, condition, and physician and patient preference.

NURSING CARE TIP

Topical benzoyl peroxide may bleach colored fabrics. Have the patient wear a white cotton T-shirt under clothing if benzoyl peroxide is used on the back, and use an old or white pillowcase at night.

Nursing Process for the Patient with a Skin Infection

Assessment/Data Collection

Subjective assessment of a skin infection can begin with the WHAT'S UP? acronym. Determine Where the skin infec-

tion is located; **H**ow it feels (does it itch, burn, hurt?); what **A**ggravates and **A**lleviates the symptoms; the **T**iming, or how long it has been present; how **S**evere it is; and **U**seful other data, such as whether there is swelling, drainage, or fever. The **P**atient's **P**erception is important because he or she may have information about the source or cause of the infection.

Objective assessment includes observing the affected area and describing the infection in terms of type and configuration of lesions, color, size, and presence of drainage. Also observe for swelling, and check for elevated temperature. If the patient has cellulitis of an extremity, measure and document the circumference of the extremity daily and prn.

Assess the patient's understanding of the cause of the infection, and of infection control measures.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Risk for spread of infection

EXPECTED OUTCOME: The infected area will not spread to other areas on patient or to other individuals.

- Monitor and document size and location of infected area daily and prn. *Careful monitoring can identify improvement or new spread of infection.*
- Monitor temperature every 8 hours and prn. *An increasing temperature can indicate worsening or systemic infection.*
- Monitor for signs and symptoms of systemic spread of infection. *Systemic infection must be reported and treated promptly to prevent complications, including sepsis.*
- Use standard precautions, including careful hand washing, when providing patient care *to prevent transmission to yourself or to others.*
- Implement appropriate isolation precautions for patients with a contagious infection. Contact precautions are usually sufficient, although airborne precautions may be necessary if immunocompromised individuals are present. *Isolation reduces spread of infection.*
- Instruct the patient on wound care, appropriate hand washing, and disposal of soiled dressings. *The patient must follow precautions to protect self and others.*
- Instruct patient on use of prescribed anti-infective agent, including the importance of taking it exactly as directed *to prevent development of a resistant infection.*
- For the patient with acne:
 - Advise the patient to keep hands away from the face and especially not to touch or squeeze pimples. Keep hair clean and off the face. *These measures help prevent spread and secondary infection.*

Acute pain

EXPECTED OUTCOME: Patient will state that pain is controlled at an acceptable level.

- Monitor pain (if present) using a pain scale. *Assessment provides a basis for nursing intervention.*
- Administer analgesics as ordered, especially prior to dressing changes or treatments. *Analgesics relieve pain and help prevent pain during dressing changes.*
- For the patient with shingles:
 - Apply cool, moist compresses to painful or itching lesions *to help cleanse and dry lesions and reduce itching.*
 - Apply firm dressings such as wraps, stockings, or a snug T-shirt *to reduce pain from postherpetic neuralgia.*
- For the patient with cellulitis:
 - Elevate affected extremity as ordered *to reduce swelling and increase comfort.*

Evaluation

If interventions have been effective, the skin lesions will improve, and will not spread to new areas or to others. The patient will state that pain is manageable.

PARASITIC SKIN DISORDERS

Pediculosis

Pathophysiology and Etiology

Pediculosis is an infestation by lice. There are three basic types: pediculosis capitis (head lice), pediculosis corporis (body lice), and pediculosis pubis (pubic, or crab, lice). Generally, the lice bite the skin and feed on human blood, leaving their eggs and excrement, which can cause intense itching. The lice are oval and are approximately 2 mm in length.

In pediculosis capitis, the female louse lays eggs (nits) close to the scalp, where the nits become firmly attached to hair shafts. The most common areas of infestation are the back of the scalp and behind the ears. The nits are about 1 to 3 mm in length and appear silvery white and glistening. Transmission is by direct contact or contact with infested objects, such as combs, brushes, wigs, hats, and bedding. It is most common in children and people with long hair.

Pediculosis corporis is caused by body lice that lay eggs in the seams of clothing and then pierce the skin. Areas of the skin usually involved are the neck, trunk, and thighs.

Pediculosis pubis is caused by crab lice. It is generally localized in the genital region, but it can also be seen on hairs of the chest, axillae, eyelashes, and beard. The lice are about 2 mm in length and have a crablike appearance. It is chiefly transmitted through sexual contact or to a lesser degree by infested bed linen.

Prevention

Prevention involves avoidance of contact with an infected person or object. Brushes, combs, hats, and other personal items should not be shared. Good personal hygiene and routine clothes washing are other preventive measures; however, even someone with meticulous hygiene can develop this infection if there is contact with the organism.

Signs and Symptoms

Pediculosis capitis can result in no itching or intense itching and scratching, especially at the back of the head. Nits may be noticeably attached to hair. A papular rash may be seen.

Pediculosis corporis may appear as minute hemorrhagic points. Excoriations may be noted on the back, shoulders, abdomen, and extremities. It may also cause intense itching.

Pediculosis pubis results in mild to severe itching, especially at night. Black or reddish brown dots (lice excreta) may be noted at the base of hairs or in underclothing. Gray-blue macules may also be noted on the trunk, thighs, and axillae; this is the result of the insects' saliva mixing with bilirubin.

Complications

Secondary bacterial infections can occur with pediculosis capitis, resulting in impetigo, furuncles, pustules, crusts, and matted hair. Secondary lesions that can occur with pediculosis corporis include parallel linear scratches, hyperemia, eczema, and hyperpigmentation. Most important, body lice may be vectors for rickettsial disease. Complications with pediculosis pubis include dermatitis and the coexistence of other sexually transmitted diseases.

Diagnostic Tests

Diagnosis is through history and physical assessment. The patient may also be tested for other sexually transmitted diseases if pediculosis pubis is present.

Therapeutic Interventions

Medical treatment is aimed at killing the parasites and mechanically removing nits. Pediculicides containing pyrethrins or permethrin are the most commonly recommended compounds. These agents should kill the lice and nits, although some lice develop pesticide resistance, making mechanical removal necessary. Permethrin (Nix) remains active for about a week, killing the adult lice immediately and the nits when they hatch days later. Pyrethrins (RID, A-200 Pynrate) must be reapplied in 1 week to kill newly hatched lice.

Complications are treated, as appropriate, with antipruritics, topical corticosteroids, and systemic antibiotics. Physostigmine ophthalmic ointment is applied to affected eyebrows and eyelashes. Other medications should not be applied to eyebrows or eyelashes.

Patient Education

Reassure the patient and family that head lice can happen to anyone, and this is not a sign of uncleanliness. Lice infestations are treated on an outpatient basis, so patient education is important. Package instructions should be followed for correct usage of all medications.

Instruct the patient to bathe with soap and water and to disinfect combs and brushes in hot, medicated soapy water. A fine-toothed comb dipped in vinegar can be used to remove nits from hairy areas. Nits can be removed from eyebrows and eyelashes with a cotton-tipped applicator after treatment. Clothing, linens, and towels should be laundered in hot water and detergent; unwashable clothing should be

dry-cleaned or sealed in a plastic bag for 10 days. Treatment should be started immediately to prevent rapid spread. Family members and close contacts (sexual contact with pediculosis pubis) should be examined for infestation and should put on clean clothing.

Shampoos and lotions kill nits, but they do not remove them. To loosen nits from the scalp, the hair may be soaked in a solution of equal parts vinegar and water and a shower cap worn for 15 minutes. The hair is then combed with a fine-toothed comb and thoroughly rinsed or shampooed to mechanically remove the nits. Children may return to school after adequate medical treatment, even if dead nits are still present.

NURSING CARE TIP

It is not possible to dry clean or wash all infected items, such as mattresses and upholstered furniture. Adult lice can live away from humans for only 3 to 4 days. Therefore, simply vacuum the upholstered furniture. The lice die in 3 to 4 days without human contact.

Scabies

Pathophysiology and Etiology

Scabies is a contagious skin disease caused by the mite *Sarcoptes scabiei*. It results from intimate or prolonged skin contact or prolonged contact with infected clothing, bedding, or animals (e.g., dogs, cats, other small animals). The parasite burrows into the superficial layer of the skin (Fig. 54.7). These burrows appear as short, wavy, brownish black lines. The patient is asymptomatic while the organism multiplies, but it is most contagious at this time. Symptoms do not occur for almost 4 weeks from time of contact.

Prevention

All persons (and animals) in intimate contact with an infected patient should be treated at the same time to eliminate the mites. The mites survive less than 24 hours without human contact. Therefore, bed linen, clothes, and towels should be washed, but furnishings need not be cleaned. Clean clothing and linens should be applied.

Signs and Symptoms

The major complaints are itching and rash. Itching can be intense, especially at night. The itching occurs 1 month after infestation and may persist for days to weeks after treatment. The rash may appear as small, scattered erythematous papules, concentrated in finger webs, axillae, wrist folds, umbilicus, groin, and genitals. Male patients may exhibit excoriated papules on the penis and groin area.

Complications

Hypersensitivity reactions to the mite can result in crusted lesions, vesicles, pustules, excoriations, and bacterial superinfections.

FIGURE 54.7 Scabies. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. F.A. Davis, Philadelphia. 1997, p 295, with permission.)

Diagnostic Tests

Diagnosis is confirmed by a superficial shaving of a lesion and microscopic evaluation for adult mites, eggs, or feces.

Therapeutic Interventions

Topical scabicides are used for chemical disinfection. Usually, the cream or lotion is applied in a thin layer to the entire body from neck to feet (including genitals, umbilicus, and skin-fold areas), is left on overnight (8 to 12 hours), and is washed off in the morning; however, package instructions should be referred to for each medication. One or two applications are usually curative, depending on the agent prescribed. Antipruritics and corticosteroids may be prescribed for itching.

Patient Education

A warm soapy bath or shower removes scales and skin debris. Advise the patient to apply the topical medication as ordered; not to repeatedly use scabicides because they can increase itching and cause further skin irritation; to follow medication directions; to treat family members and close contacts simultaneously to eliminate mites; to wear clean clothing; and to use clean linens. Remind the patient that itching may continue for up to 2 weeks after treatment, until the allergic reaction subsides. (Dead mites remain in the epidermis until exfoliated.)

NURSING CARE TIP

Animals infested with scabies should be treated by a veterinarian, so they won't infect humans.

PEMPHIGUS

Pathophysiology and Etiology

Pemphigus is an acute or chronic serious skin disease characterized by the appearance of bullae (large fluid-filled blisters) of various sizes on otherwise normal skin and mucous membranes. The etiology is unknown, but it is believed to be an autoimmune disorder. Sun exposure, genetic predisposition, and certain foods and drugs (e.g., penicillamine, captopril, and enalapril) may trigger the disorder. It usually occurs in patients from middle to older age.

The autoimmune response that occurs in pemphigus causes a patient's own antibodies to attack the skin and mucous membranes, and destroy the protein "glue" that holds the cells together. The result is skin that separates from itself, causing the characteristic blisters.

Signs and Symptoms

Successive crops of bullae suddenly appear on skin or mucous membranes. The bullae are fragile and flaccid. They enlarge, rupture, and form painful, raw, eroded, partial-thickness wounds that bleed, ooze, and form crusts. Pemphigus usually originates in the oral mucosa and then spreads to the trunk. Large areas of the body become involved.

Besides the appearance of the blisters, the patient experiences pain, burning, and itching. The lesions have a foul smell. Involvement of the oral mucosa can interfere with chewing, swallowing, and talking. The patient is in constant misery.

Complications

The major complication is a secondary bacterial infection. There is a high morbidity and mortality rate associated with this disease.

Diagnostic Tests

A positive Nikolsky's sign is a characteristic finding. This occurs when there is sloughing or blistering of normal skin when minimal pressure is applied. A biopsy of a blister reveals acantholysis, or separation of epidermal cells from one another.

Therapeutic Intervention

Treatment is aimed at controlling the disease, healing the skin, and preventing complications. Corticosteroids in large doses and cytotoxic agents are prescribed to control the disease and bring about remission. Medicated mouthwashes may be prescribed for mouth lesions. Analgesics and antipruritics are prescribed according to the patient's specific signs and symptoms. Because of fluid, blood, and protein losses through the partial-thickness injury, a high-protein, high-calorie diet is recommended along with appropriate fluid replacement therapy.

pemphigus: pemphix—blister

Nursing Care

Monitor fluid balance with regular intake and output, body weight, and blood pressure measurement. Encourage the patient to maintain adequate fluid intake. Offer cool drinks often to lessen discomfort.

Tepid wet dressings or baths help lessen secondary infection, cleanse the area, decrease odor, and increase comfort. Potassium permanganate baths may decrease infection and clean and deodorize the area. Always thoroughly dissolve potassium permanganate crystals in a small container before adding to tub water. Undissolved crystals may further damage and burn the skin. Dry the patient thoroughly after the bath. Do not use tape on the patient because this may cause further blistering. Talcum powder may be indicated to keep the skin from sticking to linens and bedclothes.

Teach the patient to maintain meticulous oral hygiene. Explain the effects and side effects of medications. Teach the importance of avoiding sun exposure or other triggers. Provide appropriate psychosocial support because of the length of illness, the chronic nature of the condition, and the physical appearance of lesions.

SKIN LESIONS

Skin lesions can be either benign (noncancerous) or malignant. Benign lesions are described in Table 54.5. Malignant lesions are discussed next. See also Box 54.3 Cultural Considerations.

Malignant Skin Lesions

Pathophysiology and Etiology

The most common skin malignancies include basal cell carcinoma, squamous cell carcinoma, and malignant melanoma. The major cause of skin malignancies is overexposure to ultraviolet rays, most commonly sunlight. Other factors include being fair skinned and blue eyed, genetic tendencies, history of x-ray therapy, exposure to certain chemical agents (e.g., arsenic, paraffin, coal tar), burn scars, chronic osteomyelitis, and immunosuppressive therapy.

Basal cell carcinoma arises from the basal cell layer of the epidermis. It is the most common type of skin cancer. This tumor is mainly seen on sun-exposed areas of the body. The lesion appears as a small pearly or translucent papule with a rolled, waxy edge, depressed center, telangiectasia (lesion formed by dilation of vessels), crusting, and ulceration (Fig. 54.8). Metastasis is rare, although it may be locally invasive.

Squamous cell carcinoma arises from the epidermis. This tumor can occur on sun-exposed areas of the skin and mucous membranes and is mainly seen on the lower lip, neck, tongue, head, and dorsa of the hands. It can occur on normal skin or on a preexisting lesion (actinic keratosis). The lesion appears as a single, crusted, scaled, eroded papule, nodule, or plaque (Fig. 54.9). A neglected lesion appears more rough, scaly, and darker colored. The lesion is fragile and prone to oozing and bleeding. This is a truly invasive car-

Box 54.3

Cultural Considerations

Some African American men have facial hair that is kinky, curls back on itself, and penetrates the skin, which can result in pustules and small keloids. Many use depilatories or electric razors to prevent nicking the skin, which can also cause keloids.

Darker skinned people have an increased incidence of birthmarks and Mongolian spots compared with lighter skinned people, Mongolian spots disappear over time. The nurse must be cautious to not mistake these spots for bruising indicating injury or abuse.

Darker skinned people have a tendency toward an overgrowth of connective tissue components concerned with the protection against infection and repair after injury. Keloid formation is one example of this tendency toward overgrowth of connective tissue. Lymphoma and systemic lupus erythematosus may occur due to this overgrowth of connective tissue.

For people with light skin, such as Germans, Polish, and Irish, prolonged exposure to the sun may increase the incidence of skin cancer. The nurse needs to teach patients to protect themselves from sun exposure to reduce their risk of skin cancer. Nevi (freckles and skin discolorations) occur more often in lighter skinned individuals. They are most common in European Americans, followed by Asians, and then darker skinned African Americans.

cinoma. Metastasis is related to histological type, depth of invasion, and size of the lesion.

Malignant melanoma, as the name implies, is a malignant growth of pigment cells (melanocytes) (Fig. 54.10). It is highly metastatic, with a higher mortality rate than basal or squamous cell carcinoma. This tumor can occur anywhere on the body, and about half arise from pre-existing nevi or moles. There are three general types: lentigo maligna, superficial spreading, and nodular.

Lentigo maligna melanoma appears as a slow-growing dark macule on exposed skin surfaces (especially the face) of elderly patients (Fig. 54.11) The lesion has irregular borders and brown, tan, and black coloring. Prognosis is good if treated in the early stage.

Superficial spreading melanoma is the most common melanoma. It can occur anywhere on the body and is usually seen in middle-aged persons. The lesion appears as a slightly elevated plaque with an irregular border. The coloring of the lesion varies in combinations of black, brown, and pink. The fragile surface may bleed or ooze. Eventually the plaque develops into a nodule. The cure rate is excellent when it is in the plaque phase; prognosis is poor with the nodular phase.

(Text continued on page 1238)

TABLE 54.5 BENIGN SKIN LESIONS

Type	Description	Treatment
<i>Cyst</i>	<p>A saclike growth with a definite wall that may contain liquid, semifluid, or solid material</p> <p>An epidermal cyst is a saclike growth of the upper portion of a hair follicle. It is due to blockage of the pilosebaceous follicle. It is a soft hemispherical nodule, usually with an overlying comedo, that is usually seen on the face, neck, or upper trunk. It is usually symptomatic.</p> <p>A pilar cyst, or sebaceous cyst, is a saclike growth of the middle portion of the hair follicle that contains hair and cuticlelike material. It is a hard, hemispherical nodule without a surmounted pore that is usually seen on the scalp.</p>	<p>Treatments include surgical excision, intralesional steroid therapy, low-dose radiation, and pressure garments worn over the area, or a combination of these therapies.</p> <p>If bothersome, it may be surgically excised. If excision is done, the entire cyst wall is removed to prevent recurrence.</p>
		
<i>Seborrheic Keratosis</i>	<p>Epidermoid cyst.</p> <p>A benign skin lesion that is pigmented light tan to dark brown patches. The plaques or papules have a “stuck on” appearance caused by the proliferation of epidermal cells and keratin piled on the skin surface. Cause is unknown, but it tends to occur in middle-aged to older patients, most commonly on the trunk, scalp, face, and extremities.</p>	<p>Treatment is cosmetic only, or if lesion becomes irritated from friction. Liquid nitrogen cryotherapy or light curettage is performed if necessary for removal.</p>
		
<i>Keloid</i>	<p>Seborrheic keratosis.</p> <p>A benign growth of fibrous tissue (scar formation) at the site of trauma or surgical incision; occurs in various sizes. Growth of tissue is out of proportion to what is needed for normal healing. The benign wartlike lesion or nodule extends beyond the original injury and occurs mainly in middle-aged and elderly clients and darker skinned patients.</p>	<p>Treatment varies, is not always successful, and is difficult; a larger scar may ensue.</p>

Type

Pigmented Nevus

Description

A benign, flesh-colored to dark brown macule or papule located randomly over the entire skin surface of the body. Can be inherited or acquired and occurs mostly in light-skinned patients. Usually begin to appear between 1 to 4 years of age, increasing in number into adulthood. Some contain a few hairs. There are many variations.

Rate of transformation to a malignant melanoma is higher in congenital moles and larger lesions. Clinical signs to observe for in differentiating between a mole and a melanoma include change in color or size; inflammation of surrounding skin; irregular borders; spreading borders; variegated colors, especially a bluish pigmentation; bleeding; and oozing, crusting, and itching. Usually nevi larger than 1 cm should be carefully examined.

Dermal mole.

Treatment

Treatment is indicated for any of the previously listed indications of melanoma, unsightly nevi (cosmetic), repeated irritation (rubbing from belt, bra), trauma, large moles, and client report of a change in the mole.

Surgical removal can include excision (preferred) or surgical shave. All excised moles should be examined histologically.

Wart

Small, common, benign growth of the skin resulting from the hypertrophy of the papillae and epidermis. Caused by a virus.

Common warts, often seen on hands and fingers, appear as raised, flesh-colored papules that have a rough surface. These warts may crack, fissure, bleed, and be painful to lateral pinching and direct, firm pressure.

Plantar warts occur on the sole of the foot. They may appear granular, pitted, or protuberant, with a callous of surrounding normal skin.

Incubation period can be several weeks to months.

Virus is spread by direct contact into areas of broken skin or to other nails by nail cuticle biting.

Warts.

If no pain or discomfort, no treatment may be indicated.

Patient should be cautioned not to spread lesions by picking or biting them.

Treatment is indicated for symptomatic warts and for cosmetic purposes. General treatments include kerolytic agents (e.g., salicylic acid plasters) to soften and reduce keratin; cryotherapy (liquid nitrogen); and light electrodesiccation and curettage (requires local anesthesia).

Treatment of choice is usually cryotherapy because local anesthesia is not necessary and it leaves little scarring.

(Continued on following page)

TABLE 54.5 BENIGN SKIN LESIONS (Continued)

Type	Description	Treatment
Hemangioma (Angioma)	Benign vascular tumor of dilated blood vessels that can have varied clinical manifestations Nevus flammeus involves mature capillaries on the face and neck. It is a congenital neoplasm that appears as a pink-red to bluish purple macular patch. Port-wine stains or port-wine angiomas appear as violet-red macular patches, usually singular lesions, growing proportionately as the child grows. These lesions can persist indefinitely. Cherry hemangiomas are commonly seen in the elderly patient. They appear as small round papules that can vary in color from red to purple.	Nevus flammeus is usually treated for cosmetic reasons. Port-wine stains, if large enough, may require surgical excision with skin grafting. Laser therapy may also be used. Noninvasive treatment is the use of cosmetics to camouflage the affected area. Treatment for cherry hemangiomas is usually not prescribed, except for cosmetic purposes.

Nodular melanoma occurs suddenly as a spherical papule or nodule on the skin or in a mole. Coloration is blue-black, blue-gray, or reddish blue color that may have a rim of inflammation. The lesion is fragile and bleeds easily. Metastasis occurs rapidly. This type of melanoma has the least favorable prognosis. Early diagnosis and treatment is imperative.

Prevention

Most types of skin cancer can be prevented by limiting or avoiding direct exposure to ultraviolet rays (sun, tanning booths). If exposure to the sun is necessary, exposure should be avoided during its highest intensity (10 a.m. to 2 p.m.). The patient should use a protective sunscreen with sun protection factor (SPF) of 15 or more. The patient should also wear sun-protective clothing, such as hats and long sleeves. The patient should seek medical advice if there is a change in color, size, shape, sensation, or character of a lesion or mole.

Diagnostic Tests

A preliminary diagnosis can be based on the appearance of the lesion. A definitive diagnosis is made by biopsy. Other

tests are performed based on the results of the pathological examination.

Therapeutic Interventions

Medical treatment depends on the type, thickness, and location of the lesion; the stage of the disease; and the age and general health of the patient. Generally, lesions are surgically excised with a 1- to 2-cm margin. Regional node dissection varies; it may be advised if the nodes in the area drain to one group. Grafting may be necessary for closure or repair. Chemotherapy may be used for metastasis. Radiation therapy may be used as adjunct treatment, or may be recommended for patients with a deeply invasive tumor or those who are poor surgical risks. Other therapies that also may be used include cryosurgery and curettage and electrodesiccation.

Nursing Care

Perform a complete skin assessment. Palpate lesions to determine texture, size, and firmness. Document size, location, color, surface characteristics, pain, discomfort, itching, and bleeding. Note when the patient first discovered the lesion.

FIGURE 54.8 Basal cell carcinoma. Note pearly, flesh-colored papule with depressed center and rolled edge. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA. Davis, Philadelphia, 1997, p 158, with permission.)

FIGURE 54.9 Squamous cell carcinoma. Surface is fragile and bleeds easily. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA. Davis, Philadelphia, 1997, p 237, with permission.)

FIGURE 54.10 Malignant melanoma. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA. Davis, Philadelphia. 1997, p 137, with permission.)

Nursing care of the patient with cancer is documented in Chapter 10. Specific nursing care related to cryosurgery includes preparing the patient for the procedure. Minor discomfort can be expected with little or no local anesthesia. Expect swelling, local tenderness, and hemorrhagic blister formation 1 to 2 days after the procedure. After the procedure, the area is cleansed as ordered and prescribed ointments are applied.

Specific nursing care for curettage and electrodesiccation includes preparing the patient for the procedure. After local anesthesia, a dermal curette is used to scrape away the lesion, followed by electrodesiccation of the remaining wound; the wound heals by secondary intention, usually

FIGURE 54.11 Lentigo maligna. (From Goldsmith, LA, Lazarus, GS, and Tharp, MD: *Adult and Pediatric Dermatology*. FA. Davis, Philadelphia. 1997, p 55, with permission.)

with minimal scarring. After the procedure the wound is cleansed and dressed as prescribed.

DERMATOLOGICAL SURGERY

Plastic or reconstructive surgery is performed to correct certain defects, scars, and malformations, as well as to restore function or prevent further loss of function. This type of surgery is usually an elective procedure; it may be prescribed by the physician or it may be the wish of the patient in hopes of improving his or her body image. Common types of plastic surgical procedures are listed in Table 54.6. Care of the surgical patient is covered in Chapter 11.

TABLE 54.6 COMMON PLASTIC SURGICAL PROCEDURES

Operation	Description	Purpose	Possible Complications	Postoperative Nursing Care Considerations
Rhinoplasty (Nose)	Removal of excessive nasal cartilage, tissue, or bone; reshaping of nose	Correct congenital or acquired septal defects; improve cosmetic shape of nose	Hemorrhage, hematoma; temporary ecchymosis and edema; infection, septal perforation	Monitor dressing and packing for bright-red bleeding; monitor vital signs and level of consciousness; maintain semi-Fowler's position to minimize edema.
Blepharoplasty (Eyelid)	Incisions on upper and lower lids with excision of fat and skin and primary closure	Removal of bags under eyes and wrinkles and bulges	Corneal injury; hematoma; ectropion; rarely visual loss and wound infection	Eye dressings; antibiotic ointment around eyes and lids; discoloration and swelling usually subsides in about 10 days; maintain semi-Fowler's position to minimize edema.

(Continued on following page)

TABLE 54.6 COMMON PLASTIC SURGICAL PROCEDURES (Continued)

Operation	Description	Purpose	Possible Complications	Postoperative Nursing Care Considerations
Rhytidoplasty (Face)	Incision anterior to ear with removal of excessive skin and tissue; the subcutaneous tissue and fascia are folded and stretched	Removal of excessive wrinkling or sagging skin	Hemorrhage; hematoma, ecchymosis, and edema (temporary); wound infection, facial nerve damage	Surgical improvement lasts from 5 to 10 years; apply antibiotic ointment to suture line; maintain semi-Fowler's position to minimize edema.
Otoplasty (Ear)	Incision of ear for correction of defect	Correct congenital defects; correct deformities; improve cosmetic shape of ear	Hemorrhage; hematoma; edema; wound infection	Ear dressing for about 1 week; protect ear at times of sleep for about 3 weeks.

Home Health Hints

- A wound-measuring device that will not be misplaced is your hand. Measure your hand, such as the nailbed of a particular finger or the space between joints. Use these as a guide to determine wound measurements.
- Sanitary pads make great cushions for bony prominences. You can also place them in a cotton sock for better molding.
- A hand-held shower head is useful in debriding some leg ulcers. Do not use it if it is too painful.
- To relieve pruritus (itchy skin), oatmeal baths are sometimes prescribed. An inexpensive way to do this is to place a half cup of quick-cooking oatmeal in a cotton sock. Put it under the faucet as you fill the tub and ring out the sock.
- Instruct patients to prevent red, dried, cracked skin on hands by wearing gloves outside in the cold or windy weather to prevent chapping, avoiding overheating the house, using a humidifier to keep the air moist, applying hand lotion two or three times a day and after each hand washing, using soaps with added oil and avoiding those with deodorants, using sunscreen with an SPF factor of at least 15, and stopping smoking (smoking reduces blood flow to the skin).
- If necessary, a specialty bed or mattress can be obtained to use in a patient's home.
- Instruct patients who are confined to a wheelchair to rise up briefly, using their armrests, and shift weight every 15 minutes to prevent pressure ulcers.
- Instruct patients with dressings to keep them clean and dry. Unless the patient or caregiver has been instructed on how to perform the dressing change, inform him or her to contact the home care agency if the dressing falls off.
- A patient can wear a cast shoe over a dressing on his or her foot. This will help protect the dressing and provide additional support for the patient while ambulating.
- Surgi-net, or a similar stretchy cover, can be used to cover dressings for patients with tape sensitivities. They are also good for additional support to prevent a dressing from falling off.

REVIEW QUESTIONS

1. Psoriasis is an inflammatory skin disorder that is characterized by which underlying pathology?
 - a. Epidermal proliferation
 - b. Excessive subcutaneous fat
 - c. Herpes infection
 - d. Excessive melanin production
2. Which of the following is the most common etiology of malignant skin lesions?
 - a. Fair skin, blue eyes, red hair
 - b. Genetic predisposition
 - c. Overexposure to ultraviolet rays
 - d. Numerous moles on body
3. Which of the following actions by the nurse is appropriate when caring for the patient with dermatitis?
 - a. Bathe in hot oatmeal baths.
 - b. Dry vigorously to prevent moisture build-up.
 - c. Apply gloves to hands at night.
 - d. Apply a thick layer of the prescribed topical agent.

4. A patient develops several wounds on his sacrum and buttocks in spite of being turned and repositioned regularly. Which factors may have contributed to his skin breakdown? Choose all that apply.
 - a. He supplements his regular diet with protein shakes.
 - b. He commonly slides down in his chair.
 - c. Staff use a lift sheet to move him in bed.
 - d. Once repositioned, he often rolls back to his favorite position.
 - e. He is often diaphoretic.
5. Which instruction should the nurse provide to the patient being treated for scabies?
 - a. “Dry-clean all linens, towels, and clothes.”
 - b. “Wash linens, towels, and clothes.”
 - c. “Discard infested mattresses.”
 - d. “Remove infested pets from the home.”
6. A patient with impetigo contagiosa wants to know when he will no longer be contagious. Which response by the nurse is correct?
 - a. One week after treatment is started
 - b. After spread of lesions has stopped
 - c. After all the lesions crust over
 - d. When all lesions are healed

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ *Mr. Russ*

- The nurse should assess the patient’s mobility and bed surface. A specialty pressure-relieving bed should be ordered for the patient.
- Change patient’s position at least every 2 hours if not more frequently. Keep patient’s heels off of the bed at all times by propping them on pillows.
- Request a dietary consult as the body cannot meet the increased healing demands if there is an albumin deficiency. Patients will need increased protein if they do not have renal failure. They also need fats, carbohydrates, vitamins, and minerals for wound healing. A dietitian can help determine the amounts of calories and types of foods for the best healing.

- If the patient is able to sit up in a chair, he will need the proper chair cushion to prevent skin breakdown. There are Roho chair cushions which provide pressure relief for patients while they are sitting.
- If the patient is wearing a brace or a splint that must be removed, examine the underlying tissue for pressure areas. Braces and splints must be padded to avoid skin breakdown.

■ *Mrs. Long*

You should ask Mrs. Long if she read the package instructions. She would find that for medicated scalp shampoos to work properly, they must remain on the scalp for several minutes. Package instructions should be carefully checked for each product because they vary from product to product.

Nursing Care of Patients with Burns

RITA BOLEK TROFINO

KEY TERMS

epithelialization (ep-i-THEE-lee-al-eye-ZAY-shun)

escharotomy (ess-kar-AHT-oh-mee)

QUESTIONS TO GUIDE YOUR READING

1. How would you explain the pathophysiology of burns?
2. What are current therapeutic interventions for burns?
3. What data should you collect when caring for patients with burns?
4. What nursing care will you provide for patients with burns?
5. How will you know if your nursing interventions have been effective?

Many people are hospitalized each year for burns. Burns affect not only the skin but every major body system. Smoke inhalation and wound infections complicate care of the patient who has been burned.

PATHOPHYSIOLOGY AND SIGNS AND SYMPTOMS

Burns are wounds caused by an energy transfer from a heat source to the body, heating the tissue enough to cause damage. Locally, the heat denatures cellular protein and interrupts the blood supply. The three zones of tissue damage that occur with burns are described in Figure 55.1.

The amount of skin damage is related to (1) the temperature of the burning agent, (2) the burning agent, (3) the duration of exposure, (4) the conductivity of tissue, and (5) the thickness of the involved dermal structures. Alterations in normal skin functioning resulting from a major burn injury include loss of protective functions, impaired ability to regulate temperature, increased risk for infection, changes in sensory function, loss of fluids, impaired skin regeneration, and impaired secretory and excretory functions.

Systemic Responses

The alterations in the functional capacity of the skin affect virtually all major body systems.

Fluid Balance

Following a major burn, increased capillary permeability leads to the leakage of plasma and proteins into the tissue,

FIGURE 55.1 Three zones of tissue damage. (Modified from Ruppert, SD, Kernick, JG, and Dolan, JT: *Dolan's Critical Care Nursing*. FA Davis, Philadelphia, 1996, p 942, with permission.)

resulting in the formation of edema and loss of intravascular volume. There is also water loss by evaporation through burn tissue that can be 4 to 15 times normal. Increased metabolism leads to further water loss through the respiratory system.

Cardiac

Cardiac function is affected. There is an initial decrease in cardiac output, which is further compromised by the circulating plasma volume loss. Severe hematological changes resulting from tissue damage and vascular changes occur in patients with major burns. Plasma moves into the interstitial space because of increased capillary permeability. In the first 48 hours after a burn, fluid shifts lead to hypovolemia and, if untreated, hypovolemic shock. Loss of intravascular fluid causes an increase in hematocrit, and there is red blood cell destruction. The intense heat decreases platelet function and half-life. Leukocyte and platelet aggregation may progress to thrombosis.

Metabolic

Metabolic demands are very high in patients with burns. A high metabolic rate proportional to the severity of the burn is usually maintained until wound closure. This hypermetabolism is further compromised by associated injuries, surgical interventions, and the stress response. Severe catabolism also begins early and is associated with a negative nitrogen balance, weight loss, and decreased wound healing. Elevated catecholamine (epinephrine, norepinephrine) levels are triggered by the stress response. This, along with elevated glucagon levels, can stimulate hyperglycemia.

Gastrointestinal

A few of the gastrointestinal problems that can develop with a major burn include gastric dilation, peptic ulcers, and paralytic ileus. Most of these problems occur in response to fluid shifting, dehydration, opioid analgesics, immobility, depressed gastric motility, and the stress response.

Renal

Acute renal insufficiency can occur as a result of hypovolemia and decreased cardiac output. Fluid loss and inadequate fluid replacement can lead to decreased renal blood flow and glomerular filtration rate. With an electrical burn injury, renal damage can occur from direct electrical current or the formation of myoglobin casts (because of the muscle destruction), which can cause acute renal tubular necrosis.

Pulmonary

Pulmonary effects are mostly related to smoke inhalation. However, hyperventilation may occur and is usually proportional to the severity of the burn. There is increased oxygen consumption resulting from the hypermetabolic state, fear, anxiety, and pain.

Immune

With the skin destroyed, the body loses its first line of defense against infection. Major burns also cause a depression of the immunoglobulins IgA, IgG, and IgM.

Classification of Burn Injuries

The severity of a burn injury is influenced by the depth of destruction, percentage of injury, cause of the burn, age of the patient, concomitant injuries, medical history (e.g., heart disease, diabetes), and location of the burn wound. Table 55.1 describes classification of burn depth (Figs. 55.2, 55.3, and 55.4).

CRITICAL THINKING

Mr. Weinberg

■ Mr. Weinberg is admitted to hospital with superficial and deep partial thickness burns. His wife asks how long it will take for the burns to heal. What should you tell her?

Suggested answers at end of chapter.

The size of a burn wound is estimated based on parts of the body affected. A common method is the Rule of Nines. This method divides the body into segments whose areas are either 9% or multiples of 9% of the total body surface, with the perineum being counted as 1% (Fig. 55.5). This formula is easy, but it is not as accurate in assessing children. A more accurate method uses a table with a relative anatomical scale or diagram that estimates total burned area by ages and by smaller anatomical areas of the body.

LEARNING TIP

For a quick estimation of percentage of burn injury, using the Rule of Nines on an adult burn patient, the palm of your hand is about 1%.

FIGURE 55.2 Partial-thickness burn. (From Trofino, RB: *Nursing Care of the Burn-Injured Patient*. F.A. Davis, Philadelphia, 1991, plate 1, with permission.)

ETIOLOGY

Burn injuries have many causes. The most common causes include flame, contact, chemical, electrical, and radiation (Table 55.2).

COMPLICATIONS

A major complication that can occur with a flame burn in an enclosed space is inhalation injury. Infection is another common complication with a major burn. The incidence of infection increases with the size of the burn wound because the first line of defense against microorganisms is the skin.

Neurovascular compromise can also occur with a major burn. Eschar formation creates pressure and contributes to decreasing blood flow to areas distal to the burned area. Other systemic complications were reviewed in the Systemic Responses section earlier in this chapter.

TABLE 55.1 CLASSIFICATION OF BURN DEPTH

Classification	Formerly	Areas Involved	Appearance	Sensitivity	Healing Time
Partial-thickness (superficial)	1st degree to 2nd degree	Epidermis Papillae of dermis	Bright red to pink. Blanches to touch. Serum-filled blisters. Glistening, moist.	Sensitive to air, temperature, and touch	7–10 days
Partial-thickness (deep)	2nd degree	Epidermis, 1/2 to 7/8 of dermis	Blisters may be present. Pink to light red to white. Soft and pliable. Blanching present.	Pressure may be painful from exposed nerve endings.	14–21 days. May need grafting to decrease scarring.
Full-thickness	3rd degree to 4th degree	Epidermis Dermis Tissue Muscle Bone	Snowy white, gray, or brown. Texture is firm and leathery. Inelastic.	No pain as nerve endings are destroyed, unless surrounded by areas of partial-thickness burns	Needs grafting to complete healing

Source: Trofino, RB: *Nursing management of the patient with burns*. In Ruppert, SD, Kernick, JG, and Dolan, JT (eds): *Dolan's Critical Care Nursing*. F.A. Davis, Philadelphia, 1996, p 943.

FIGURE 55.3 Partial-thickness burn. (From Trofino, RB: *Nursing Care of the Burn-Injured Patient*. FA. Davis, Philadelphia, 1991, plate 2, with permission.)

CRITICAL THINKING

Mrs. Rivera

■ Mrs. Rivera is admitted to the emergency room after sustaining injuries from a house fire. Both arms and hands are burned, she has a right leg fracture and a possible neck fracture, her lips are swollen, her face is sooty, and she is spitting up grayish, blackish sputum.

1. What is your priority concern with all of these injuries?
2. An IV is ordered at 1 L over 6 hours. How many milliliters per hour should be set on the controller?

DIAGNOSTIC TESTS

Burns are diagnosed through clinical manifestations. Various diagnostic tests are performed for systemic reactions, infection, and other complications. Common tests for systemic reactions include complete blood cell count (CBC) and differential, blood urea nitrogen (BUN), serum glucose and electrolytes, arterial blood gases, serum protein and albumin, urine cultures, urinalysis, clotting studies, cervical spine series, electrocardiogram, wound cultures, and, if

FIGURE 55.4 Full-thickness burn. (From Trofino, RB: *Nursing Care of the Burn-Injured Patient*. FA. Davis, Philadelphia, 1991, plate 3, with permission.)

FIGURE 55.5 Estimation of extent of burn injury. (From Venes, D [ed]: *Taber's Cyclopedic Medical Dictionary*, ed. 19. FA. Davis, Philadelphia, 2001. Beth Anne Willert, MS, Dictionary Illustrator, with permission.)

there is a suspected inhalation injury, arterial blood gases, bronchoscopy, and carboxyhemoglobin levels.

THERAPEUTIC INTERVENTIONS

Therapeutic interventions vary according to the severity of the burn and the stage the patient is in. Treatment is managed over three overlapping stages (Table 55.3).

Emergent Stage

At the time of injury, the burning process must be stopped. The clothes are removed, and the wound is cooled with tepid water and covered with clean sheets to decrease shivering and contamination. The burn wound itself takes a lower priority to the ABCs (airway, breathing, circulation) of trauma resuscitation. The patient should be stabilized in terms of fractures, hemorrhage, spine immobilization, and other injuries. Inhalation injury is suspected if the patient sustained a burn from a fire in an enclosed space or was exposed to smoldering materials, if the face and neck were burned, if there are vocal changes, and if the patient is coughing up carbon particles. Intravenous fluids are given to prevent and treat hypovolemic shock. The patient is treated for pain with appropriate IV opioid analgesics. Patient-controlled analgesia (PCA) is very effective.

An accurate history of the injury is obtained to determine severity, probable complications, and any associated trauma. The patient's medical history is also obtained. Admission to the facility and burn care treatment are explained to the patient and family.

TABLE 55.2 COMMON CAUSES OF BURNS

Flame	House fire is a common cause. Usually associated with an inhalation injury. Flash injury occurs from a sudden ignition or explosion.
Contact	Hot tar, hot metals, or hot grease produce a full-thickness injury on contact.
Scald	A burn from hot liquid. Common in children less than 5 years and adults older than 65 years. With an immersion scald, there are usually no splash marks; usually involves lower regions of body.
Chemical	Usually occurs in an industrial setting. Extent and depth of injury are directly proportional to concentration and quantity of agent, duration of contact, and chemical activity and penetrability of agent.
Electrical	One of the most serious types of burn injury; can be full thickness with possible loss of limbs, as well as cause internal injuries. Entry wound is usually ischemic, charred, and depressed. Exit wound may have an explosive appearance. Extent of injury depends on voltage, resistance of body, type of current, amperage, pathway of current, and duration of contact. Bones offer greatest resistance to the current; can have much damage. Tissue fluid, blood, and nerves offer least resistance; therefore, the current travels this path.
Radiation	Can occur in an industrial setting, due to treatment of diseases, or from ultraviolet light (sun or tanning salons). Severity depends on type of radiation, duration of exposure, depth of penetration, distance from source, and absorbed dose.

NURSING CARE TIP

Interview all involved family members to determine the cause of the injury, as well as past and current medical history. The patient may not be able to verbalize current medical conditions, current medications, and so forth. Getting a full description of the cause of the injury may lead to the detection of other injuries that may not be readily visible.

Acute Stage

If the patient is in a facility with a special burn unit, multidisciplinary care from a burn team is provided during the acute stage. Management goals include wound closure with no infection, minimum scarring, maximum function, maintenance of comfort as much as possible, adequate nutritional support, and maintenance of fluid, electrolyte, and acid-base

TABLE 55.3 STAGES OF BURN CARE

Stage	Duration
I (Emergent)	From onset of injury to completion of fluid resuscitation
II (Acute)	From start of diuresis to near completion of wound closure
III (Rehabilitation)	From wound closure to return of optimal level of physical and psychosocial function

Source: Trofino, RB: Nursing management of the patient with burns. In Ruppert, SD, Kernick, JG, and Dolan, JT (eds): Dolan's Critical Care Nursing. F.A. Davis, Philadelphia, 1996, p 948.

balance. The patient continues to be medicated for pain as needed, especially before painful treatments. Nutritional support is maintained via a small Silastic nasogastric feeding tube (Box 55.1 Nutrition Notes).

The wound is cleansed and debrided daily to promote healing, prevent infection, and provide a clean bed for grafting. Wound cleansing is achieved by tubbing with a

Box 55.1

Nutrition Notes

Burns

The body's response to severe stress, whether caused by trauma, sepsis, or burns, occurs in three stages: ebb (hypometabolic), flow (hypermetabolic), and anabolic (recovery), each driven by hormonal changes that affect the storage, breakdown, and utilization of various nutrients. In addition, a person does not necessarily progress linearly through the stages but may regress several times, although a burned patient may be hypermetabolic for several weeks. Consequently, multiple means are used to monitor a patient's status and a team effort is required to frequently revise nutrient prescriptions to avoid both underfeeding and overfeeding (also a cause of complications).

The first concern is replacement of fluid that is lost through the burned area, which may receive 10 times the blood flow to normal skin, and provision of sufficient fluid to excrete waste products of metabolism. The next concern is meeting the patient's energy needs since a major burn is the most severe stress a person can sustain, doubling caloric needs if greater than 50% of the body surface is affected. If nutrients are not available from external sources, the body breaks down muscle tissue for this energy requirement. As in other conditions, tube feeding (often into the small intestine rather than the stomach) is preferred to intravenous nutrition if the patient can tolerate it. The patient's condition and ability to utilize the nutrients dictates the mode of nutrition implemented.

Hubbard tank, showering using a shower trolley or shower chair, and bedside care.

Debridement, or the removal of nonviable tissue (eschar), can be mechanical, chemical, surgical, or a combination of these methods. Mechanical debridement can involve the use of scissors and forceps to manually excise loose nonviable tissue, or the use of wet-to-moist or wet-to-dry fine mesh gauze. Chemical debridement involves the use of a proteolytic enzymatic debriding agent that digests necrotic tissue. Surgical debridement is the excision of full-thickness and deep partial-thickness burns. This method is followed by an application of a skin graft.

If the patient has a circumferential burn (one that surrounds an extremity or area), an increase in tissue pressure secondary to tissue edema occurs. The burn then acts like a tourniquet, impeding arterial and venous flow. Common sites for these burns are the extremities, trunk, and chest. If this occurs on the chest and trunk, respiratory insufficiency can occur as a result of restricted chest expansion. An **escharotomy** is immediately necessary to relieve this pressure. An escharotomy is a linear excision through the eschar to the superficial fat that allows for expansion of the skin and return of blood flow (Fig. 55.6).

NURSING CARE TIP

Remember to provide adequate padding of the bed with an escharotomy, as there can be copious amounts of drainage. Provide for appropriate disposal of the drainage.

Once the area is cleaned, the burn dressing and topical treatment are prescribed. The type of dressing and topical agent chosen are dependent on the area involved, extent and depth of injury, and physician preference. Several common topical agents are listed in Table 55.4.

Dressings may be open, closed, biological, synthetic, or a combination. The open method is the use of a topical agent without any dressing. The closed method involves the

FIGURE 55.6 Escharotomy. (From Trofina, RB: *Nursing Care of the Burn-Injured Patient*. FA. Davis, Philadelphia, 1991, plate 16, with permission.)

escharotomy: eschara—scab + otomy—incision

use of an occlusive dressing over the wound. General principles for dressings include the following:

1. Limit the bulk of the dressing to facilitate range of motion.
2. Never wrap skin-to-skin surfaces (e.g., wrap fingers or toes separately; place a donut gauze dressing around the ear).
3. Base dressings on the size of wounds, absorption, protection, and type of debridement.
4. Wrap extremities distal to proximal to promote venous return.
5. Elevate affected extremities.

Biological dressing refers to tissue from living or deceased humans (cadaver skin), deceased animals (e.g., pigskin), or cellular dressings that may use animal tissue, human tissue, and synthetics. Biological dressings assist with wound healing and stimulate **epithelialization**. These dressings may be used as donor site dressings, to manage a partial-thickness burn, and to cover the clean, excised wound before autografting. Some of the cellular wound dressings have varied layers that form a matrix onto which the patient's own cells migrate over a few weeks and form a new dermis. A very thin layer of the person's own skin is then grafted onto this new dermis.

Synthetic dressings are used in the management of partial-thickness burns and donor sites. These dressings are more readily available, less costly, and easier to store than biological dressings. They are made from a variety of materials and come in many different sizes and shapes. Most of these dressings contain no antimicrobial agents.

Biological and synthetic dressings are used as temporary wound coverings over clean partial- and full-thickness injuries. They act as skin substitutes to help maintain the wound surface until healing occurs, a donor site becomes available, or the wound is ready for autografting.

Skin Grafts

An autograft is a skin graft from the patient's unburned skin to be placed on the clean excised burn. The two common types of autografts are the split-thickness skin graft (STSG), which includes the epidermis and part of the dermis, and the full-thickness skin graft (FTSG), which includes the epidermis and entire dermal layer.

An STSG (0.006 to 0.016 inch) may be applied as a sheet graft or a meshed graft. A sheet graft is used for cosmetic effect, such as for a face, neck, upper chest, breast, or hand burn. It is placed on the area as a full sheet. A meshed graft is passed through a mesher that produces tiny splits in the skin, similar to a fishnet, with openings in the shape of diamonds (Fig. 55.7), to permit the skin to expand one and a half to nine times its original size. The meshing allows for coverage of a large burn area with a small piece of skin by stretching it and securing it with sutures or staples. A mesh graft is especially useful when there are extensive burns

epithelialization: epi—over + thele—nipple + ization—condition

TABLE 55.4 COMMON TOPICAL ANTIBIOTIC AGENTS

Medication Class/Action	Examples	Route	Side Effects	Nursing Implications
Broad-spectrum Antibiotics	Silver sulfadiazine 1% cream	Topical	Intermediate penetration of eschar; leukopenia.	Buttered on in thick layer, covered with light dressings once or twice a day.
	Mafenide acetate (Sulfamylon)	Topical	Pain on application. Pulmonary toxicity. Metabolic acidosis. Inhibits wound healing. Hypersensitivity.	Buttered on. Open exposure method. Applied three to four times daily.
	Silver nitrate solution 0.5%	Topical	Poor penetration of eschar. Ineffective on established wound infections. Can cause an electrolyte imbalance. Discoloration of wound and environment makes assessment difficult.	Wet dressings. Change bid. Resoak every 2 hours.
	Bacitracin	Topical	Poor penetration of eschar. Not effective in reducing sepsis in large burns. Occasional allergic sensitivity.	Buttered on. Reapply every 4–6 hours.
	Gentamicin	Topical	Ototoxic, nephrotoxic. Pain on application.	Apply gently three to four times daily.
	Nitrofurazone	Topical	Painful application. May lead to overgrowth of fungus and <i>Pseudomonas</i> .	Apply thin layer directly to wounds or impregnate into gauze. Change dressings twice daily.

resulting in few available donor sites. Graft “take,” or vascularization, is complete in about 3 to 5 days.

Full-thickness skin grafts (0.035 to 0.040 inch) can be sheet grafts or pedicle flaps. FTSGs are used over areas of muscle mass, soft tissue loss, hands, feet, and eyelids. They are not used for extensive wounds because the donor sites usually require an STSG for closure, or closure from the wound edges. A pedicle graft or flap includes the skin flap and subcutaneous tissue that is attached by its pedicle to a blood supply (artery and vein); it is then attached to the area in need of grafting. Once the distal part of the graft takes, it remains in place and the flap is divided, with the remainder returning to the original site. Pedicle flaps are not as popular as free skin flaps because they require more than one sur-

FIGURE 55.7 Meshed graft. (From Trofino, RB: *Nursing Care of the Burn-Injured Patient*. FA. Davis, Philadelphia, 1991, plate 17, with permission.)

gery and take longer for the graft site and donor site to heal. Table 55.5 provides a comparison of split-thickness and full-thickness grafts.

Donor sites are considered a partial-thickness wound. Donor sites usually heal in 10 to 14 days, but this is dependent on thickness and method of grafting and the general health of the patient. Treatment for the donor site varies with the individual patient, the area of the body, and physician preference. Considerations for care include promoting comfort and preventing trauma and infection. Use of semioclusive, transparent dressings such as Op-Site or Tegaderm allow a moist healing environment and are associated with reduced risk of infection. The donor site is very painful. Appropriate pain medications are provided, along with non-pharmacological measures (e.g., back rub, distraction).

With any type of graft, the patient must keep the graft site immobilized until the graft takes to prevent movement or slippage of the grafted skin. Dressings may be bulky to assist in immobilization. These dressings must not be disturbed. The involved area requires frequent circulatory checks (color, warmth, sensation, pulses, and capillary refill). Any involved extremities must be elevated to maintain circulation. Table 55.6 describes factors affecting graft viability. A graft has been successful if there is good adherence of the graft to the wound with no evidence of necrosis or infection.

Rehabilitation Phase

The therapy started during the acute phase continues in the rehabilitation phase. There is wound closure, and the goal is

TABLE 55.5 COMPARISON OF SPLIT-THICKNESS AND FULL-THICKNESS SKIN GRAFTS

	Split-Thickness	Full-Thickness
Layers	Epidermis Partial layer of dermis	Epidermis Entire dermal layer
Advantages	Donor site may be reused Healing of donor site is more rapid, results in good “take”	Allows more elasticity over joints Can reconstruct cosmetic defects Soft, pliable Gives full appearance Provides good color-match Less hyperpigmentation May allow hair growth
Disadvantages	Prone to chronic breakdown Likely to hypertrophy More likely to contract	Donor site takes longer to heal Requires split-thickness graft to heal or closure from wound edges

Source: Konop, D: General local treatment. In Trofino, RB (ed): Nursing Care of the Burn-Injured Patient. F.A. Davis, Philadelphia, 1991, p 61.

to return the patient to an optimum level of physical and psychosocial function. This may take months to years to accomplish, depending on the extent of the injury. Reconstructive surgery can be ongoing for many years.

Two things to keep in mind when caring for the patient with a major burn are that (1) the most comfortable position (flexion) is the position of contracture, and (2) the burn wound will shorten until it meets an opposing force. To

FIGURE 55.8 Burn deformity: contracture. (From Trofino, RB: Nursing Care of the Burn-Injured Patient. F.A. Davis, Philadelphia, 1991, plate 36, with permission.)

avoid contractures (Fig. 55.8), a specific exercise program is begun 24 to 48 hours after injury, along with the use of splinting devices to maintain proper positioning and stretching. Hypertrophic scarring, or a proliferation of scar tissue, can be minimized or prevented through the use of a pressure garment (Fig. 55.9).

The burn affects the patient's psychosocial status in many ways. The magnitude of these effects are related to the age of the patient, location of the burn (e.g., face, hands), recovery from injury, cause of the injury (especially if related to negligence or a deliberate act), and ability to continue at preburn level of normal daily activities. The patient may experience a disruption of role function and general health and coping ability. Treatment involves the patient and significant others. Support groups, counselors, and psychiatrists should be utilized appropriately.

CRITICAL THINKING

Mrs. Potter

■ Mrs. Potter is recovering from partial-thickness burns and skin grafts. She mentions that she and her family will be going on a much needed vacation to the shore. What concerns do you have?

TABLE 55.6 FACTORS AFFECTING GRAFT VIABILITY

Factors Inhibiting Graft “Take”	Factors Promoting Graft “Take”
Infection	Adequate hemostasis
Necrotic skin (tissue)	Anatomical location of graft
Anatomic location of graft	Smooth contour
Perineum	Nonjoint areas
Axillae	Graft secured well
Buttocks	Immobilization of graft area
Poor-quality donor skin	Good nutritional status
Poor nutritional status	
Bleeding	
Mechanical trauma	
Shock

NURSING PROCESS FOR A BURNED PATIENT

Assessment/Data Collection

A major burn is painful and frightening to the patient and frightening to the family. Elicit information from the patient, family, and rescuers. If the injury occurred in an enclosed space with flames or smoldering materials, inhalation injury is suspected. If an electrical injury has occurred, ask about voltage, duration of contact, host susceptibility (wet or dry skin), entry and exit sites, and associated falls. With

FIGURE 55.9 Full-body pressure garment. (From Trofino, RB: *Nursing Care of the Burn-Injured Patient*. FA. Davis, Philadelphia, 1991, plate 39, with permission.)

chemical burns, determine type of agent and duration of exposure.

General information to assess in all burns (in addition to normally assessed data, such as medical history, allergies, and current medications) include extent, depth, type and location of the burn; duration of contact with the burning agent; amount and location of pain; and associated injuries. Determine the immediate first aid treatment provided at the scene. Elicit psychosocial information: other people injured, additional losses (home, pets), whether the patient was at fault, and how this injury affects the patient's role function.

Nursing Diagnosis, Planning, Implementation, and Evaluation

See Box 55.2 Nursing Care Plan for the Patient with a Burn Injury and Box 55.3 Burn Summary on page 1255. For more information on burns, go to the American Burn Association website at www.ameriburn.org.

Box 55.2 Nursing Care Plan for the Patient with a Burn Injury

Nursing Diagnosis: Impaired gas exchange related to upper airway edema, carbon monoxide poisoning, edema of alveolar capillary membranes

Expected Outcomes Gas exchange will be improved as evidenced by patent airway, CO level less than 10%, clear lung sounds, PaO_2 80–100 mm Hg, Paco_2 35–45 mm Hg, responsiveness and awareness.

Evaluation of Outcomes Are blood levels improved: CO, PaO_2 , Paco_2 ? Do the lungs sound clear on auscultation? Is patient aware of surroundings? Are there no signs of respiratory distress (e.g., retractions, nasal flaring, use of accessory muscles)?

Interventions

Assess respiratory status: auscultate breath sounds every 15 minutes or as necessary; note any adventitious breath sounds; observe for chest excursion; monitor ability to cough.

Monitor arterial blood gases and CO level.

Monitor for nasal flaring, retractions, wheezing, and stridor.

Administer humidified 100% oxygen by tight-fitting face mask for the breathing patient.

Elevate head of bed (if no cervical spine injuries or no history of multiple trauma).

Provide appropriate pulmonary care: turn, cough, deep breathe every 2–4 hours. Provide incentive spirometer every 2–4 hours, suction frequently as needed.

Rationale

Detects changes in pulmonary function to alter therapy.

Assesses level of oxygenation. Helps guide oxygen therapy.

Stridor may signal upper airway involvement; nasal flaring, retractions, and wheezing may indicate lower airway involvement.

Provides oxygen for adequate gas exchange.

Decreases swelling of face and neck.

Mobilizes secretions and promotes lung expansion.

Evaluation

What is patient's respiratory status? Are any adventitious lung sounds noted?

What are the patient's blood gas levels? Are they abnormal?

Does patient exhibit nasal flaring, retractions, wheezing, and stridor?

Is oxygen administered appropriately? Are blood gases improving?

Is head of bed elevated? Is there any change in facial or neck swelling?

Is patient on scheduled activities for vigorous pulmonary care?

Interventions

Obtain sputum cultures. Note amount, color, and consistency of pulmonary secretions.

Administer bronchodilators and antibiotics as prescribed.

Rationale

Carbonaceous sputum is diagnostic for smoke inhalation injury. Infection changes color, amount, and consistency of sputum. Culture and sensitivity (C&S) assists in selection of appropriate antibiotic.

Bronchodilators decrease bronchospasms and edema; antibiotics fight infection.

Evaluation

Is patient coughing up any sputum? Has character of sputum been documented?

Are medications given appropriately?

Nursing Diagnosis: Impaired skin integrity related to thermal injury

Expected Outcomes Skin integrity is improved as evidenced by healing of burned areas with no infection present, healing of burning process.

Evaluation of Outcomes Is burned area healed? Is it free from infection? Did burning process stop?

Interventions

Assess burning process. If heat is felt on wound, cool with tepid tap water or sterile water.

Assist registered nurse (RN) or physician to assess the burn area for extent (percentage) and depth (partial thickness, full thickness) of injury.

Remove clothing and jewelry.

Do not apply ice.

Cover patient with clean sheet or blanket.

Obtain history of burning agent.

Initiate immediate copious tepid water lavage for 20 minutes for all chemical burns, along with simultaneous removal of contaminated clothing. (Do not neutralize chemical because this takes too much time and resulting reaction may generate heat and cause further skin injury.)

Rationale

Depth of injury increases with length of exposure to burning agent.

Provides basis for triage of care. Important also for calculating resuscitation fluid therapy.

These items can retain heat and thermal agent, therefore increasing depth of injury. Jewelry can be constrictive when edema develops.

Ice causes vasoconstriction, further increasing wound damage. Ice also causes a decrease in core body temperature, which may promote shock.

Prevents excessive heat loss. Decreases pain from air exposure. Protects patient from environmental contamination.

Provides information related to depth, duration of contact, and resistance of tissues. If fire scenario, provides clues to possible inhalation injury.

Dilution and removal of chemical agent halts burning process. Lavage dissipates heat.

Evaluation

Is heat felt over wounds?

What is the estimation of percentage of burn injury?
What is depth of injury?

Are clothing and jewelry removed?

Is water tepid? Has use of ice been avoided?

Is patient covered?

What caused this thermal injury? How long was patient in contact with agent?

Has lavage been initiated? Were there any injuries to health-care workers?

(Continued on following page)

Box 55.2 Nursing Care Plan for the Patient with a Burn Injury (Cont'd)

Interventions	Rationale	Evaluation
Brush off dry chemicals before lavage.	To prevent further burn damage due to reaction of dry chemical with water.	
Use heavy rubber gloves or thick gauze for removal of clothing.	Gloves and gauze are necessary to protect health care workers from injury.	
Cleanse wound via tubbing or showers.	Promotes healing and helps decrease infection.	Is burn wound clean and free of wound debris?
Assist RN or physician with debriding wound via surgical, chemical, or mechanical means. Apply topical agent as prescribed.	Promotes healing and healthy granulation bed. Most agents prevent infection and promote healing.	Is there any eschar? Is wound free of wound debris? Is agent applied as directed?
Apply dressing as prescribed.	Dressing types vary and are influenced by area, extent, and depth of injury, as well as by topical agent used. Dressing protects burn area and promotes healing.	Is dressing applied appropriately?
<ul style="list-style-type: none"> Do not wrap skin surface to skin surface (e.g., wrap fingers and toes separately; donut bandage around ears). Limit bulk of dressings. 	Wrapping separately prevents webbing and contractures.	
Wrap extremities distal to proximal.	Mobility is enhanced with less bulky dressing. Circulation is increased when extremities are wrapped distal to proximal.	Is wrapping done correctly? Is edema of distal extremity avoided?

Nursing Diagnosis: Deficient fluid volume related to evaporative losses from wound, capillary leak, and decreased fluid intake

Expected Outcomes Patient will maintain adequate circulating volume as evidenced by urine output of 50 mL/hr (in the adult), blood pressure within normal limits, heart rate between 60 and 100 beats per minute (adult), and stabilized body weight.

Evaluation of Outcomes Is urine output maintained at least at 50 mL/hr? Are the blood pressure and heart rate within normal limits? Is patient's weight stable?

Interventions	Rationale	Evaluation
Obtain admission weight and monitor weight daily.	Helps measure fluid loss or gain.	Is patient's weight documented? Is it stable?
Record intake and output (I&O) hourly.	Serves as guide for fluid loss and replacement.	What is patient's I&O?
Assess for signs and symptoms of hypovolemia (hypotension, tachycardia, tachypnea, extreme thirst, restlessness, disorientation).	Fluid volume loss is multifocal (e.g., through increased capillary permeability, insensible loss).	Does patient exhibit any signs or symptoms of hypovolemia?
Monitor electrolytes, complete blood count (CBC).	Serves as guide for electrolyte replacement and blood product replacement.	What are patient's lab values? Are they within normal limits?

Interventions

Administer IV fluids as ordered via large bore IV catheter.

Insert indwelling urinary catheter.

Monitor urine for amount, specific gravity, and hemochromogens.

Administer osmotic diuretics as ordered; monitor response to therapy.

Assess gastrointestinal function for absence of bowel sounds.
Maintain nasogastric tube.

Rationale

Fluid replacement begins immediately. Large vessels are needed for rapid delivery of fluids.

Fluid replacement is titrated based on urine output.

Specific gravity can predict volume replacement; hemochromogens can cause renal tubular damage.

Decreased urinary output can be caused by decreased renal flow (due to myoglobin in urine).

Splanchnic constriction due to hypovolemia can cause a paralytic ileus.

Evaluation

Is patient's fluid replacement adequate? Is catheter patent?

Is catheter patent?

What are patient's urine values?

What is urinary output? Has it changed due to therapy?

Are patient's bowel sounds normal? Is nasogastric tube patent?

Nursing Diagnosis: Pain related to burns or graft donor sites

Expected Outcomes Patient will experience pain control as evidenced by verbalizations of pain tolerance, nonverbal cues: less thrashing; able to rest or sleep; body positioning.

Evaluation of Outcomes Does patient verbalize pain control? How many hours of rest/sleep does patient have in 24 hours? Does patient state she or he feels rested?

Interventions

Assess level of pain: nature, location, intensity, and duration at various times (during procedures, at rest). Rate pain on visual analog scale.

Observe for varied responses to pain: increase in blood pressure, pulse, respiration; increased restlessness and irritability; increased muscle tension; facial grimaces; guarding.

Acknowledge presence of pain.
Explain causes of pain.

Administer narcotics IV. Utilize patient controlled analgesia (PCA) as appropriate.

Offer diversional activities (e.g., music, TV, books, games, relaxation techniques).

Properly position patient.

Elevate burned extremities.
Maintain comfortable environment (e.g., bed cradle; comfortable environmental temperature, 86–91.4°F [30–33°C]; quiet environment).

Rationale

Provides baseline to monitor response to therapy.

Responses to pain are variable. These parameters change in response to pain.

Encourages trust and understanding.

IV administration is necessary due to edema and poor tissue perfusion. Narcotics are necessary for severe burn pain. PCA allows patient more control.

Helps patient focus on something other than pain.

Increases comfort.

Elevation decreases edema and pain. Pressure from bed linens may cause discomfort; with loss of integument, body cannot self-regulate temperature.

Evaluation

Is patient's individual response to pain documented?

What are patient's responses to pain? Do responses change with treatment?

Is patient more trusting of the treatments?

Is patient being medicated for pain appropriately?

Does patient utilize diversional activities? Do they help?

Is patient positioned as comfortably as possible?

Are extremities elevated?

Does patient verbalize comfort of environment?

(Continued on following page)

Box 55.2 Nursing Care Plan for the Patient with a Burn Injury (Cont'd)

Nursing Diagnosis: Ineffective peripheral tissue perfusion related to circumferential burns, blood loss, decreased cardiac output

Expected Outcomes Patient will maintain adequate tissue perfusion as evidenced by presence of peripheral pulses; minimal edema; intact sensation and motion; and warm extremities.

Evaluation of Outcomes Are peripheral pulses present? Are extremities warm, with adequate sensation, motion, and circulation? Is edema decreased?

Interventions	Rationale	Evaluation
Elevate burned extremity above level of the heart.	Enhances venous return and decreases edema formation.	Are all burned extremities elevated above heart level? Is edema decreasing?
Assess pulses on burned extremities every 15 minutes.	Assesses need for escharotomy.	Are pulses present and documented?
Use Doppler as necessary. Assess capillary refill, sensation, color, swelling, and motion.	Assesses peripheral perfusion.	Is the extremity warm, with adequate color, sensation, motion, and capillary refill?
Assess for numbness, tingling, and increased pain in burned extremity.	Can be indicative of increased pressure from edema.	Does patient complain of numbness, tingling, or pain?
Measure circumference of burned extremities.	Monitors edema formation.	Is there evidence of edema? Is it getting better or worse?
Apply burn dressing loosely.	Prevents constriction and allows for expansion as edema forms.	Is dressing too tight?
Assist with muscle compartment pressures.	Helps determine need for escharotomy (if pressure greater than 25 mm Hg).	What is patient's pressure?
Assist with escharotomy as necessary.	If indicated, removal of eschar allows for edema expansion and permits peripheral perfusion.	Does patient require an escharotomy? Is edema relieved?

Nursing Diagnosis: Risk for sepsis related to wound infection

Expected Outcomes Patient will not develop a wound infection or sepsis.

Evaluation of Outcomes Is there healthy granulation tissue on unhealed areas with less than 10^5 colonies of bacteria on wound culture? Are donor sites free of infection? Have skin grafts taken? Is there absence of clinical manifestation of infection (temperature 98.6°F [37°C]; normal white blood cell [WBC] count)?

Interventions	Rationale	Evaluation
Use sterile technique with wound care.	The unhealed burn wound is a culture medium for bacterial growth.	Is sterile technique used for all wound care?
Maintain protective isolation with good hand-washing technique.	Prevents spread of bacteria from patient to patient or nurse to patient.	Do all persons in contact with patient maintain proper precautions?
Administer immunosupportive medications as prescribed: tetanus and gamma globulin.	Immunoglobulins are depressed at time of severe burn injury.	Does patient require these medications?

Interventions

Perform wound care as prescribed, which may include the following: inspect and debride wounds daily; culture wound three times a week or at sign of infection; shave hair at least 1 inch around burn areas (excluding eyebrows); inspect invasive line sites for inflammation (especially if line is through a burn area).

Continually assess for and report signs and symptoms of sepsis: temperature elevation; change in sensorium; changes in vital signs and bowel sounds; decreased output; positive blood/wound cultures.

Administer systemic antibiotics and topical agents as prescribed.

Rationale

Provides quick identification of bacterial wound invasion and decreases incidence of infection. Presence of hair increases medium for bacterial growth.

The burn patient is at risk for sepsis until wound is healed.

Antibiotics prevent or treat infection.

Evaluation

What does wound look like? Is it debrided? What are culture results? Is there any hair near burn or line sites?

Does patient exhibit any signs or symptoms of sepsis?

Does patient require systemic antibiotics? Are they working? Are topical agents applied appropriately? Is wound healing?

Box 55.3**Burn Summary****Signs and Symptoms**

Pain
 Superficial partial thickness—pink to red skin, blisters
 Deep partial thickness—pink to light red or white skin, blisters, blanching
 Full thickness—white, gray, or brown color, firm and leathery

Diagnostic Tests

Wound cultures
 Complete blood count, blood urea nitrogen, glucose, electrolytes, urine studies

Therapeutic Interventions

IV fluid replacement
 Antibiotic/antimicrobial agents
 Analgesics

Complications

Shock
 Wound infection

Priority Nursing Diagnoses

Impaired skin integrity related to thermal injury
 Deficient fluid volume related to evaporative losses from wound, capillary leak, and decreased fluid intake
 Pain related to burns or graft donor sites
 Risk for sepsis related to wound infection

REVIEW QUESTIONS

- A patient is brought to the emergency department following a house fire, with burns over 36% of his body. The areas are blistered and pinkish white, and very painful when pressure is applied. Which type of burn does he have?
 - Superficial partial thickness
 - Deep partial thickness
 - Full thickness
 - Which of the following actions is appropriate initial treatment of a chemical burn?
 - Lavage with water.
 - Neutralize the chemical.
 - Apply the prescribed topical agent.
 - Wrap the patient in sterile sheets.
 - A patient is admitted to the emergency department with flame burns to her entire chest, abdomen, back, and upper extremities. Using the Rule of Nines, what is the approximate percentage of burns?
 - 36%
 - 45%
 - 54%
 - 64%
- Multiple response item. Select all that apply.
- What nursing interventions are appropriate for a patient with a circumferential burn to an extremity?
 - Apply compression bandages starting at the distal end of the extremity.
 - Administer analgesics if numbness or tingling occur.
 - Check neurovascular status hourly.
 - Assist with escharotomy if indicated.
 - Elevate the extremity.
 - How will the nurse know if interventions for impaired gas exchange related to smoke inhalation have been effective?
 - PaCO_2 is >45 mm Hg
 - SaO_2 is $<90\%$
 - pH is 7.34
 - PaO_2 is 88 mm Hg

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ **Mr. Weinberg**

In general, superficial partial-thickness burns usually heal in 7–10 days. Deep partial thickness burns may take up to 3 weeks. All of this depends upon the location of the injury, the health of the patient, and if he or she remains infection free.

■ **Mrs. Rivera**

Mrs. Rivera has an inhalation injury. This takes precedence over the burn and other injuries.

1.

$$\frac{1 \text{ L}}{6 \text{ hours}} \left| \frac{1000 \text{ mL}}{1 \text{ L}} \right. = 167 \text{ mL/hour}$$

■ **Mrs. Potter**

The burned and graft areas will be sensitive to sunlight for up to 1 year. These areas should be covered, and she needs to use sunscreen anytime she is out in the sun. Her physician should offer guidance as to whether any exposure is safe, and if so, what type of sunscreen agent is recommended.

QUESTIONS TO GUIDE YOUR READING

1. What are definitions of mental health and mental illness?
2. What are the components of a mental health status assessment?
3. What is the DSM-IV-TR, and what are other methods for diagnosing mental illness?
4. How can you identify common ego defense mechanisms?
5. What is a therapeutic milieu?
6. What are the classifications, actions, side effects, and nursing considerations for selected classifications of psychoactive medications?
7. What are the methods for psychoanalysis, behavior management, cognitive behavioral therapy, humanistic/person-centered therapy, counseling, electroconvulsive therapy, group therapy, and relaxation therapy?
8. What is the LPN/LVN's role in mental health nursing?

REVIEW OF ANATOMY AND PHYSIOLOGY

Although there is much debate about the cause(s) of mental illness, it is important to review and understand the anatomy and physiology of the brain and central nervous system (CNS). The brain is involved in thinking, decision making, speaking, emotion, memory, motor and sensory activity, and basic functions such as temperature regulation and breathing, to name a few. In mental health, it is important to distinguish between a neurological disorder (delirium, Parkinson's) and a mental disorder (schizophrenia). Sometimes a patient has both a mental disorder and a neurological or other physical disorder. Refer to Chapter 47 to review the nerves, structure of neurons, synapses, neurotransmitters, and the autonomic nervous system, as well as the structure and function of the brain. Also see Table 56.1 for the possible roles of CNS neurotransmitters in mental illness.

MENTAL HEALTH AND MENTAL ILLNESS

There are differing opinions within the mental health community as to what **mental health** and **mental illness** are. *Mental health* has been defined in many ways. These definitions include the ability to do the following:

- Be flexible
- Be successful
- Form close relationships
- Make appropriate judgments
- Solve problems
- Cope with daily **stress**
- Have a positive sense of self

Mental illness is defined as experiencing the following:

- Impaired ability to think
- Impaired ability to feel
- Impaired ability to make sound judgments
- Impaired ability to adapt
- Difficulty or inability in coping with reality
- Difficulty or inability to form strong personal relationships

It is important to remember that mental health and mental illness exist on a continuum. It is natural for emotions to ebb and flow from day-to-day in response to the degree of stress that is experienced. People who remain mentally healthy are able to keep their stress in perspective. Others are not able to do so, and over time they may develop physical or emotional illnesses as a result of the constant stress in their life.

Visualize the seesaw that children play on. Mental health and mental illness are like a seesaw. When children of approximately equal weight get on each end of the seesaw, they can balance each other and keep the seesaw even. Mentally healthy people keep themselves in a state of emotional balance. Sometimes one child weighs just a little more

than the other and the seesaw tips just a little to one side. Mentally healthy people can cope with this fluctuation. Sometimes another child gets on or one child greatly outweighs the other, and the seesaw gets out of balance completely; one end goes way up while the other goes way down, and it stays there until someone alters the balance. Ultimately it must be the patient who finds his or her own balance. When a person's moods are way down or way up, he is not in emotional homeostasis.

Etiologies

The discussion surrounding the etiologies of mental illness continues to revolve around the "nature versus nurture" or "organic versus inorganic or functional" arguments. The connections between physical and emotional health are so closely intertwined that it is sometimes hard to decide if emotional causes trigger physical responses or vice versa. It is important to have a basic understanding of both the nature and nurture schools of thought on the causes of alterations in mental health.

Explanations of mental illness in this unit include concepts from the psychoanalytic (or psychological) and the psychobiological (or biological) theories. When pertinent, other theories (e.g., behavioral, environmental) are also presented. Most mental illnesses have no identifiable cause. Some etiological theories have stronger positive correlations to illnesses than others. When it is appropriate, this unit gives the most current or most widely accepted view of an etiology.

Social and Cultural Environments

Many professionals in the field of psychology believe that social and cultural environments have a great influence on the way people develop and process life experiences. Some psychoanalysts believe that some cultural traditions and beliefs cause disturbances in personal relationships, which can lead to forms of emotional disturbances. It is part of the nurse's role to take time to learn about the traits that are common among people and those traits that are different. It is important to have an understanding of people's customs and beliefs to avoid unrealistic expectations of patients. See Box 56.1 Cultural Considerations for more detailed information about culture and mental health issues.

Spirituality and Religion

Spirituality and religion are extremely important to some patients and unimportant to others. A person's success in recuperating from physical or emotional illness may be deeply tied to her or his spirituality. It is necessary to be comfortable talking to the patient about spiritual needs while being careful not to impose personal values on the patient. If you are not comfortable in these situations, you should offer to call the spiritual or religious leader of the patient's choice.

It is important to keep the lines of communication open. People learn by sharing with each other. It is much

(Text continued on page 1264)

TABLE 56.1 NEUROTRANSMITTERS IN THE CNS

Neurotransmitter	Location/Function	Possible Implications for Mental Illness
I. Cholinergics		
A. Acetylcholine	ANS: Sympathetic and parasympathetic presynaptic nerve terminals; parasympathetic postsynaptic nerve terminals CNS: Cerebral cortex, hippocampus, limbic structures, and basal ganglia Functions: Sleep, arousal, pain perception, movement, memory	Increased levels: Depression Decreased levels: Alzheimer's disease, Huntington's disease, Parkinson's disease
II. Monoamines		
A. Norepinephrine	ANS: Sympathetic postsynaptic nerve terminals CNS: Thalamus, hypothalamus, limbic system, hippocampus, cerebellum, cerebral cortex Functions: Mood, cognition, perception, locomotion, cardiovascular functioning, and sleep and arousal	Decreased levels: Depression Increased levels: Mania, anxiety states, schizophrenia
B. Dopamine	Frontal cortex, limbic system, basal ganglia, thalamus, posterior pituitary, and spinal cord Functions: Movement and coordination, emotions, voluntary judgment, release of prolactin	Decreased levels: Parkinson's disease and depression Increased levels: Mania and schizophrenia
C. Serotonin	Hypothalamus, thalamus, limbic system, cerebral cortex, cerebellum, spinal cord Functions: Sleep and arousal, libido, appetite, mood, aggression, pain perception, coordination, judgment	Decreased levels: Depression Increased levels: Anxiety states
D. Histamine	Hypothalamus	Decreased levels: Depression
III. Amino Acids		
A. Gamma-aminobutyric acid (GABA)	Hypothalamus, hippocampus, cortex, cerebellum, basal ganglia, spinal cord, retina Functions: Slowdown of body activity	Decreased levels: Huntington's disease, anxiety disorders, schizophrenia, and various forms of epilepsy
B. Glycine	Spinal cord and brain stem Functions: Recurrent inhibition of motor neurons	Toxic levels: "glycine encephalopathy," decreased levels are correlated with spastic motor movement
C. Glutamate and aspartate	Pyramidal cells of the cortex, cerebellum, and the primary sensory afferent systems; hippocampus, thalamus, hypothalamus, spinal cord Functions: Relay of sensory information and in the regulation of various motor and spinal reflexes	Increased levels: Huntington's disease, temporal lobe epilepsy, spinal cerebellar degeneration
IV. Neuropeptides		
A. Endorphins and enkephalins	Hypothalamus, thalamus, limbic structures, midbrain, and brain stem; enkephalins are also found in the gastrointestinal tract Functions: Modulation of pain and reduced peristalsis (enkephalins)	Modulation of dopamine activity by opioid peptides may indicate some link to the symptoms of schizophrenia
B. Substance P	Hypothalamus, limbic structures, midbrain, brain stem, thalamus, basal ganglia, and spinal cord; also found in gastrointestinal tract and salivary glands Function: Regulation of pain	Decreased levels: Huntington's disease and Alzheimer's disease Increased levels: Depression
C. Somatostatin	Cerebral cortex, hippocampus, thalamus, basal ganglia, brain stem, and spinal cord Function: Inhibits release of norepinephrine; stimulates release of serotonin, dopamine, and acetylcholine	Decreased levels: Alzheimer's disease Increased levels: Huntington's disease

ANS = autonomic nervous system; CNS = central nervous system.

**Box 56.1****Cultural Considerations**

Among many Haitians, some African Americans, and some other groups, conjuring (practicing magic) and root doctors are believed to know more about mental illness than Western-educated physicians. Some depressive and obsessive behaviors are viewed as culture-bound syndromes. These behaviors are expected of some Haitians, and those affected fulfill some expected roles in the society. Some of these illnesses are viewed as having no cure. Thus, the nurse may need to include folk healers when working with African Americans and patients of Haitian descent.

Smoking, alcoholism, and deaths from suicide or violence are prevalent problems in the American culture. Violent deaths account for high mortality rates among adolescents and young adults of African American, Cuban, Mexican American, and Puerto Rican origin. Programs targeting these populations should be personalized to include adolescents and their families. Given their strong family values, an important approach is to begin early in church groups or family settings.

Hispanic individuals may require lower doses of antidepressants and experience greater side effects than other Caucasians. Thus, careful observations need to be undertaken when observing for side effects of medications in patients of Mexican heritage.

Asian patients require lower dosages and have side effects at lower dosages than Caucasians for a variety of psychoactive drugs (e.g., lithium, haloperidol) even when matched with body weight. Asians commonly believe that Western drugs are too strong for them and take less than prescribed. Most Asians are more sensitive to alcohol, resulting in facial flushing, palpitations, and tachycardia.

Mental illness among the Navajo is perceived as resulting from placing a curse on an individual. In these instances, a healer who deals with dreams or a crystal gazer is consulted. Individuals may wear turquoise to ward off evil; however, an individual who wears too much turquoise is sometimes thought to be an evil person and someone to avoid. In some tribes, mental illness may mean that the affected person has special powers. Additionally, many Native Americans metabolize alcohol at a faster rate than European Americans, resulting in them having a higher tolerance for alcohol.

Newer immigrants from Ireland have a higher incidence of mental illness than the rest of the population. Undocumented Irish immigrants in the United States report more stressors and mental health problems than their legal counterparts. Because many Irish people have difficulty expressing emotions, health-care providers

may need to encourage Irish Americans to express their concerns.

Mental illness is strongly stigmatized among Iranians and is thought to be genetic. Should a family member have mental illness, it is likely to be called a “neurological disorder” so as not to stigmatize the family, which may result in daughters having a lesser chance of marrying. Psychotherapeutic help may be avoided because of stigma or because it is perceived as irrelevant. People prefer a medicine that might cure them. There is a tendency to pay more attention to somatic symptoms when under emotional stress; Iranians consider psychopharmacology most effective, and have a high rate of compliance.

Because of the stigma attached to seeking professional psychiatric help, many Hindus do not access the health-care system. Instead, family and friends seem to be the best help, and a general belief is that time is the best healer. Physical and mental illnesses are considered God’s will, or karma, and are associated with a fatalistic attitude.

Among Greeks, mental illness is accompanied by social stigma for the afflicted individual, as well as the relatives. The shame originates in the notion that mental illness is hereditary, and afflicted individuals are viewed as having lifelong conditions that pollute the bloodline.

Because of social stigma attached to mental illness and retardation, Arabs may keep their family from public view. However, when Arab patients suffer from mental distress, they generally seek medical care. They are likely to have complaints such as abdominal pain, lassitude, anorexia, or shortness of breath. Arabs have an increased tendency to experience elevated blood levels and adverse effects when customary dosages of antidepressants are prescribed. Patients often expect and insist on somatic treatment, at least vitamins and tonics.

African Americans may be at a greater risk for being misdiagnosed with a psychiatric disorder than Caucasians. African Americans with psychiatric disorders are more likely to have hallucinations, delusions, somatization, and hostility, even when controlled for socioeconomic class. Maintaining direct eye contact with some African Americans may be misinterpreted as aggressive behavior. Thus, nurses must take these non-verbal behaviors into consideration when working with the patient with an emotional or mental concern. Additionally, African Americans are more susceptible to toxic side effects with tricyclic antidepressants.

better to ask a person about something (to clarify or explore what was said) than to make an assumption about it. For more information about mental health and illness, visit the National Institute of Mental Health at www.nimh.nih.gov, the American Psychiatric Association at www.psych.org, the American Psychiatric Nurses Association (www.apna.org), or the International Society of Psychiatric Mental Health Nurses (www.ispn-psych.org).

NURSING ASSESSMENT/ DATA COLLECTION

During the data collection/assessment part of the nursing process, the mental status examination is performed. This is a series of questions and activities that evaluate eight areas:

- Appearance and behavior
- Level of awareness and reality **orientation**
- Thinking/content of thought
- Memory, speech, and ability to communicate
- Mood and **affect**
- Judgment
- Perception

There are a number of different tools of varying names, lengths, and formats used to assess the patient's mental capabilities. See Table 56.2 for a sample mental status examination.

After data have been collected, the licensed practical nurse/licensed vocational nurse (LPN/LVN) collaborates with the registered nurse (RN) to develop nursing diagnoses. Box 56.2 Nursing Diagnoses Commonly Used for Patients with Mental Health Problems.

DIAGNOSTIC TESTS

Physicians use a variety of diagnostic criteria to diagnose mental illness. It is important to rule out physical illness as a cause of symptoms. The physician may choose to refer the patient to a psychiatrist or other mental health professional for further testing and diagnosis.

The diagnostic tool that is used most widely by psychiatrists and other mental health professionals is the *Diagnostic and Statistical Manual of Mental Disorders IV-Text Revision*, or DSM-IV-TR. The DSM-IV-TR groups illnesses into categories of clinical disorders. This is a complex diagnostic tool. Although as an LPN you will not be responsible to complete the assessment, you can contribute valuable information.

There are also batteries of psychological tests that can be administered and interpreted by psychiatrists or psychologists. Age, hand tremors, vision, language barriers, educational background, and the interpretation of the psychiatrist, the psychologist, or the advanced practice nurse are some factors that can influence the results of these tests.

Distinguishing Physical Versus Mental Disorders

There are many physical disorders that can mimic mental disorders, therefore tests may be performed to either confirm or rule out a diagnosis of a mental illness:

- Laboratory tests to rule out problems such as electrolyte imbalances, hypothyroidism, infections, dehydration, drug toxicity, or pregnancy.

TABLE 56.2 SAMPLE MENTAL STATUS EXAMINATION

Area of Assessment	Type of Assessment	Normal Parameters	Alterations from Normal
Appearance and Behavior	Observations about dress, hygiene, posture, and appearance and about the patient's actions and reactions to health-care personnel.	Clean, combed hair. Clothing intact and appropriate to weather or situation. Teeth/dentures in good repair. Posture erect. Cooperates with health-care personnel.	Displays either unusual apathy or concern about appearance. Displays uncooperative, hostile, or suspicious behaviors toward health-care personnel.
Level of Awareness and Orientation	Subjective and objective assessment of the patient's degree of alertness (wakefulness) and the degree of the patient's knowledge of self.	Awareness is measured on a continuum that ranges from unconsciousness to mania. "Normal alertness" is the desired behavior. Facilities may provide a standard format for this assessment, but observations can be documented as well if the patient is not able to stay awake for even short intervals or if the patient is overly active and has difficulty staying in one place. Orientation is assessed by asking the patient questions relating to person, place, and time, such as, "Who is this sitting next to you?" "Where are you right now?" Or "What year is it?"	Outcome is not considered within accepted normal limits if the patient is difficult to arouse and keep awake or if the patient has difficulty feeling calm. Abnormal results of orientation are the patient's inability to correctly answer orientation questions or inability to answer commonly known questions, such as "Who is the president?"

Area of Assessment	Type of Assessment	Normal Parameters	Alterations from Normal
Thinking/Content of Thought	Subjective assessment of what the patient is thinking and the process the patient uses in his or her thinking.	Formal testing may be done by the psychologist or psychiatrist to determine the patient's general thought content and pattern. Nurses may contribute to the assessment of thought by documenting statements the patient makes regarding daily care and routines.	Abnormal behaviors include flight of ideas, loose associations, phobias, delusions, and obsessions.
Memory	Subjective assessment of the mind's ability to recall recent and remote (long-term) information.	Recent memory: Recall of events that are immediately past or within 2 weeks before the assessment, such as a recent news event. One measurement technique is to verbally list five items. After 1 minute, can the patient recall four or five of those items? Continue with the assessment, and at 5 minutes the patient should be able to recall three or four of the items. Remote memory: Recall of events of the past beyond 2 weeks before assessment. Patients may be asked where they were born, where they went to grade school, etc.	Inability to accurately perform recent or remote (long-term) recall exercises within parameters. May indicate symptom of delirium or dementia.
Speech and Ability to Communicate	Objective and subjective assessment of how the patient uses verbal and nonverbal communication.	Patient can coherently produce words appropriate to age, education, and life experience. Rate of speech reflects other psychomotor activity (e.g., faster if the patient is agitated). Volume is not too soft or too loud. Stuttering, repetition of words, and words that the patient makes up (neologisms) are also assessed.	Limited speech production. Rate of speech is inconsistent with other psychomotor activity. Volume is not appropriate to situation (speaks louder or softer than appropriate). Presence of stuttering, word repetition, or neologisms may indicate physical or psychological illness.
Mood and Affect	Subjective and objective assessment of the patient's stated feelings and emotions. Affect measures the outward expression of those feelings.	Mood is the stated emotional condition of the patient and should fluctuate to reflect situations as they occur. Facial expression, body language (affect) should match (be congruent with) the stated mood. Affect should change to fluctuate with the changes in mood.	Mood and affect do not match (e.g., facial expression does not appear sad while the patient is expressing sad feelings).
Judgment	Subjective assessment of a patient's ability to make appropriate decisions about his or her situation or to understand concepts.	Give the patient a proverb or situation to solve, such as "You can't teach an old dog new tricks." The patient should be able to give some sort of acceptable interpretation, such as "Old habits are hard to break" or "It is hard to learn something new." Another example is to ask the patient what he or she would do if a small child was lost in a store. An appropriate response might be "Call the manager" or "Try to calm the child."	Patient cannot interpret the sayings in some acceptable manner. Patient cannot complete problem-solving questions appropriately. The patient might answer very literally, "Dogs can't learn anything when they get old" or might say, "I would go through the child's pockets looking for phone numbers."
Perception	Assess the way a person experiences reality. Observe the patient's statements about his or her environment and the behaviors expressed in association with those statements. Document exactly what you see and hear.	All five senses are monitored for the patient's perception of reality. The patient's insight into his or her condition is also assessed.	Presence of hallucinations and illusions may occur with schizophrenia. Patient unable to state understanding of the origin of the illness; associated behaviors inappropriate.

Box 56.2**Nursing Diagnoses Commonly Used for Patients with Mental Health Problems**

Disturbed thought processes
 Ineffective role performance
 Anxiety (mild to panic)
 Disturbed body image
 Dysfunctional grieving
 Impaired religiosity
 Impaired social interaction
 Ineffective coping
 Defensive coping
 Disturbed personal identity
 Powerlessness
 Fear
 Posttrauma syndrome
 Risk for violence (toward self or others)
 Risk for injury
 Risk for suicide
 Self-mutilation
 Self-care deficit
 Low self-esteem (chronic or situational)
 Disturbed sensory perception
 Sexual dysfunction
 Disturbed sleep pattern
 Social isolation

- Computed tomographic (CT) scans or magnetic resonance imaging (MRI) to rule out tumors, lesions, or other physical problems.
- Positron emission tomographic (PET) scans to identify how the parts of the brain are functioning by showing chemical activity or metabolism.

COPING AND EGO DEFENSE MECHANISMS

“Oh, just learn to cope with it.” “Get a grip.” “Don’t make a mountain out of a molehill.” These are pieces of advice that people may have heard or given at some point. But what do they mean? What is **cop**ing? Coping is the way one adapts psychologically, physically, and behaviorally to a **stressor**. Individuals have different methods of coping or dealing with their stressors. Culture, religion, individual belief systems, experience, and personal choice influence an individual’s responses to stress. It is not the value of a behavior that we assess as nurses; it is the desired outcome that is important. What is an effective coping skill? Is it healthy? Does it work? How do we as nurses observe and measure it?

Effective Coping Skills

Effective coping skills offer healthy choices for dealing with stressors. Hospitalization is stressful for patients and fami-

lies. Many things are unknown and unfamiliar. The patient may not understand the illness or the implications of the treatment plan. It is common for patients to use coping mechanisms during hospitalization. The process of effective coping is sometimes called **adaptation**. Allowing the patient to practice new coping techniques will give him or her confidence and will decrease the stress that can accompany change.

Often the dividing line between effective and ineffective coping is the frequency of its use. For instance, mild **anxiety** can be positive. Generally, when there is a little anxiety, people are more alert and ready to respond. The *fight-or-flight mechanism* can actually help one adapt to a new situation. However, too much anxiety begins to cloud the consciousness and interfere with the ability to make appropriate choices and to recall the new adaptive tools one has learned. One of the most helpful roles you can perform is to listen to the patient’s thoughts and feelings about the stressor, assist him or her to identify precipitating factors and patterns to the patient’s stress, encourage the patient to problem solve, and provide assistance to develop alternative solutions.

CRITICAL THINKING

Joe

■ Joe is noted wailing loudly and continuously after the death of his wife. It is disturbing the other patients on the wing, and one of the nurses comments, “He is a real nut case. Get him out of here.”

What is an appropriate response to this nurse and patient? How would you document his behavior?

Suggested answers at end of chapter.

Ineffective Coping Skills

Sometimes coping is ineffective. When conscious techniques are not successful, individuals may unconsciously fall into habits that give the illusion of coping. These habits are called *ego defense mechanisms* (or coping or mental mechanisms). Ego defense mechanisms act as mental pressure valves. The purpose of ego defense mechanisms is to reduce

CRITICAL THINKING

Mrs. Beison

■ Mrs. Beison, a 44-year-old mother of three teenagers, is diagnosed with breast cancer. She is refusing treatment because she does not believe she has cancer. She says if anything is really wrong, her vitamins will take care of it.

What coping mechanism is Mrs. Beison using? Is it effective or ineffective? Why? How can you help?

Suggested answers at end of chapter.

or eliminate anxiety. They give the impression that they are helping alleviate the stress level. When used in very small doses, ego defense mechanisms can be helpful. When they are overused, or are the only means used to deal with anxiety, they can become ineffective and unhealthy. People are

not born with these coping behaviors; they are learned as responses to stress. Many times they develop by the age of 10 years old. They may appear to be conscious, but they are, for the most part, unconscious mechanisms. Some commonly used ego defense mechanisms are listed in Table 56.3.

TABLE 56.3 EGO DEFENSE MECHANISMS

Mechanism	Description	Examples
<i>Denial</i>	Usually the first defense learned and used. Unconscious refusal to see reality. Not conscious lying.	The alcoholic states, “I can quit any time I want to.”
<i>Repression (Stuffing)</i>	An unconscious “burying” or “forgetting” mechanism. Excludes or withholds from consciousness events or situations that are unbearable.	A step deeper than “denial.” A patient may “forget” about an appointment he or she does not want to keep.
<i>Rationalization</i>	Using a logical-sounding excuse to cover up true thoughts and feelings. The most frequently used defense mechanism.	<ol style="list-style-type: none"> 1. “I did not make a medication error; I followed the doctor’s order.” 2. “I failed the test because the teacher wrote bad questions.”
<i>Compensation</i>	Making up for something perceived as an inadequacy by developing some other desirable trait.	<ol style="list-style-type: none"> 1. The small boy who wants to be a basketball center instead becomes an honor roll student. 2. The physically unattractive person who wants to model instead becomes a famous designer.
<i>Reaction Formation (Overcompensation)</i>	Similar to compensation, except the person usually develops the exact opposite trait.	<ol style="list-style-type: none"> 1. The small boy who wants to be a basketball center becomes a political voice to decrease the emphasis on sports in the elementary grades. 2. The physically unattractive person who wants to be a model speaks out for eliminating beauty pageants.
<i>Regression</i>	Emotionally returning to an earlier time in life when patient experienced far less stress. Commonly seen in patients while hospitalized. NOTE: Everyone will not go back to the same developmental age. This is highly individualized.	<ol style="list-style-type: none"> 1. Children who are toilet trained beginning to wet themselves. 2. Adults who may start crying and have a “temper tantrum.”
<i>Projection (Scapegoating)</i>	Blaming others. A mental or verbal “finger-pointing” at another for patient’s own problem. Memory tool: Think of a projector at the movie theater. It “points” the images of the film onto the screen just as a person using this defense mechanism “points” blame on another person or situation.	<ol style="list-style-type: none"> 1. “I didn’t get the promotion because you don’t like me.” 2. “I’m overweight because you make me nervous.”
<i>Displacement (Transference)</i>	The “kick-the-dog syndrome.” Transferring anger and hostility to another person or object that is perceived to be less powerful than oneself.	Parent loses job without notice; goes home and verbally abuses spouse, who unjustly punishes child, who slaps the dog.
<i>Restitution (Undoing)</i>	Make amends for a behavior one thinks is unacceptable. Makes an attempt at reducing guilt.	<ol style="list-style-type: none"> 1. Giving a treat to a child who is being punished for a wrongdoing. 2. The person who sees someone lose a wallet with a large amount of cash does not return the wallet, but puts extra in the collection plate at the next church service.
<i>Conversion Reaction</i>	Anxiety is channeled into physical symptoms. NOTE: Often the symptoms disappear soon after the threat is over.	Nausea develops the night before a major exam, causing the person to miss the exam. Nausea may disappear soon after the scheduled test is finished.
<i>Avoidance</i>	Unconsciously staying away from events or situations that might open feelings of aggression or anxiety.	“I can’t go to the class reunion tonight. I’m just so tired, I have to sleep.”

THERAPEUTIC MEASURES

People who experience alterations in their mental health have special treatment needs. When emotional health is threatened, many other daily activities can be altered as well. **Cognitive** ability (the ability to think rationally and to process those thoughts) can be impaired. Emotional responses can be decreased or even absent in some conditions. This can be extremely frightening and can lead to a worsening of the mental disorder or even the development of another disorder. This section will provide an overview of selected therapies to help patients deal with alterations in mental health.

Therapeutic Communication

Many people take communication for granted. In the mental health setting, communication is a tool used to relate therapeutically with patients. It is important to keep in mind what message we want to communicate to patients. Therapeutic communication is accomplished through the deliberate use of verbal and nonverbal techniques. Other areas to consider when communicating are the patient's personal values, atti-

tudes, beliefs, culture, religion, social status, gender, and age or developmental level.

Verbal therapeutic communication techniques can help facilitate an interpersonal interaction. For instance, if you ask a patient to explain something to you in more detail, you are using the therapeutic communication technique of exploring. Verbal communication is also influenced by the tone, pitch, speed, and volume of speech. Some commonly used therapeutic communication techniques are listed in Table 56.4.

Components of *nonverbal communication* include physical appearance, dress, body movement and posture, touch, facial expression, and eye contact. It is believed that most communication takes place nonverbally so it is possible that while you are saying one thing to a patient, your body language could be saying something else.

There are also barriers to effective communication which are commonly called *communication blocks*. A nurse who tells a patient "Don't worry, everything will be all right" has just given the patient false reassurance. This barrier communicates to the patient that his concerns are not being taken seriously. Some commonly encountered communication blocks are listed in Table 56.5.

TABLE 56.4 THERAPEUTIC COMMUNICATION TECHNIQUES

Technique	Description	Examples
<i>Encouraging Descriptions of Perceptions</i>	Asking the patient what he or she is seeing or hearing	"Tell me what the voices are saying to you."
<i>Encouraging Comparison</i>	Asking the patient to compare similarities or differences	"How is this medication working for you compared to the last time you used it?"
<i>Exploring</i>	Looking deeper into a subject, idea, or experience	"Tell me more about the last time you were depressed."
<i>Focusing</i>	Concentrating on a single idea or event	"Tell me more about how your divorce made you feel."
<i>Formulating a Plan of Action</i>	Assisting the patient to come up with a plan to cope with stress	"When this happens in the future how could you handle it more constructively?"
<i>Giving Broad Openings</i>	Allowing the patient to steer the interaction	"What would you like to work on today?"
<i>Giving Recognition</i>	Acknowledging or showing awareness	"I see you went to your therapy group today."
<i>Making Observations</i>	Verbalizing what is observed	"I notice you seemed upset after your visit."
<i>Offering Self</i>	Extending one's presence	"I am available to talk whenever you would like."
<i>Offering General Leads</i>	Giving the patient encouragement to continue	"I see... "
<i>Placing Event in Time or Sequence</i>	Clarification of events in time	"Go on... "
<i>Presenting Reality</i>	Defining reality in simple terms	"Was this before or after your first hospitalization?"
<i>Restating</i>	Repeating the main idea of what the patient has verbalized	"The voices may seem real to you, but they are a symptom of your illness."
<i>Reflecting</i>	Statements, questions, or feelings are referred back to the patient	"It sounds as if you are feeling frustrated."
<i>Seeking Clarification</i>	Searching for understanding of what was said	"What do you think you should do?"
<i>Verbalizing the Implied</i>	Putting into words what the patient has implied or said indirectly	"Tell me if this is what you meant when you said..."
<i>Using Silence</i>	Gives both the nurse and the patient a chance to collect their thoughts and organize what they are going to say	"You must be feeling very sad right now."

TABLE 56.5 COMMUNICATION BLOCKS

Mechanism	Description	Examples
<i>Agreeing/Disagreeing</i>	Implies that the patient's ideas or feelings are somehow right or wrong	"That is right on target. I agree 100%."
<i>Asking "Why Questions"</i>	Asking why implies that the patient knows the reason for their behavior and feelings.	"Why were you feeling so angry?"
<i>Changing the Subject</i>	Changing the subject takes control of the conversation away from the patient.	Patient: "I am feeling so hopeless." Nurse: "Did you go to group therapy today?"
<i>Giving Advice</i>	Telling the patient what to do implies that the nurse knows what is best.	"I think you should..."
<i>Giving Approval or Disapproval</i>	Passes judgment on the patient's ideas or opinions	"That's right."
<i>Giving False Reassurance</i>	Devalues the patient's feelings	"Everything will be all right."
<i>Self-focusing Behavior</i>	The nurse focuses on his or her own feelings at the expense of the patient's.	"That happened to me once...let me tell you about it."
<i>Double-bind Messages</i>	When the nonverbal message doesn't match the verbal message	"I am listening." As the nurse fidgets in her chair, doesn't make eye contact, and then coughs.

Milieu

One area over which you can have some control is the therapeutic environment. In the mental health setting, this therapeutic environment is called the **milieu** or therapeutic milieu. It is believed that environment has an effect on behavior. Milieu therapy is the systematic management of the social environment as a treatment modality.

A *therapeutic milieu* is an environment that provides containment, support, structure, involvement, and validation during the patient's stay. The goals of milieu therapy are resocialization, ego development, and prevention of regression. Resocialization occurs when patients help govern the running of the unit and attend regular meetings to set rules and assign tasks. Ego development is fostered with structured activities that are provided to assist the patient to learn coping and social skills. Regression is prevented when patients help with washing dishes or other small jobs that foster independence. Common milieu interventions include role modeling, positive reinforcement, a schedule of events, consistent expectations and rules for behavior, and unit meetings. Milieu therapy is more difficult in this era of managed care because of shorter hospital stays.

Psychopharmacology

Psychopharmacology is the use of medications to treat psychological disorders. Since the introduction of the phenothiazine class of drugs in the 1950s (e.g., chlorpromazine), the number of medications available for treating mental health disorders has increased greatly, with newer medications having fewer side effects. The reason for using medications is twofold: first, the medications manage the symptoms, helping the patient feel more comfortable emotionally. Second, the patient is generally more receptive and

able to focus on other types of therapy if medications are effective. More information on psychoactive drugs is provided in Chapter 57.

Psychotherapies

Psychotherapy is the term used to describe the form of treatment chosen by the psychologist, psychiatrist, social worker, or advanced practice psychiatric nurse. The goals of psychotherapy include the following:

- Reduce the patient's emotional discomfort
- Increase the level of the patient's social functioning
- Increase the ability of the patient to behave or perform in a manner appropriate to the situation

Several specific types of therapy that are typically used are described next.

Psychoanalysis

Psychoanalysis was developed from Sigmund Freud's psychoanalytic theory. Freud believed that anxiety was the primary motivation for behavior and therefore all behavior had meaning. Psychoanalytic therapy consists of clarifying the meaning of events, feelings, and behavior and thereby gaining **insight** into them. The role of the patient is to provide the psychoanalyst with clues to the unconscious source of problems and to try to develop with insights into behavior. The role of the therapist is to uncover these unconscious experiences and interpret their meanings to the patient. Some believe that psychoanalysis will lose popularity as we gain a better understanding of the role of the brain, neurotransmitters, and genetics in mental health.

Behavior Management

Behavior management (also called behavior modification) is a treatment method that stems from the studies of behavioral theorists such as Skinner and Pavlov. It is a common

psychopharmacology: psycho—soul or mind + pharmaco—drug or medicine + ology—study of

psychoanalysis: psycho—soul or mind + analysis—dissolving

treatment modality used in long-term care facilities, with children and adolescents, and with individuals who have a low level of cognitive functioning.

According to behavior management theory, all behavior is learned, so it can be unlearned. The belief is that behavior can be changed by either positive or negative reinforcement. *Positive reinforcement* is the act of rewarding the patient with something pleasant when the desired behavior has been performed. For instance, if a patient has the habit of using foul language in an attempt to have a need met, the desired behavior change might be to come to a staff member and ask quietly for what he or she needs. If this patient loves to be outside but is not allowed out except at supervised times, then a suitable positive reinforcement for her might be to allow 15 more minutes outdoors when she remembers to come ask for her needs quietly.

Negative reinforcement is the act of responding to the undesired behavior by taking away a privilege or adding a responsibility. Negative reinforcement can be misinterpreted as punishment. Parents who “ground” their children for unacceptable behavior are using negative reinforcement; requiring the child to perform extra household tasks for a stated period is reinforcing the fact that the behavior has consequences. The child may not repeat the undesired behavior after negative reinforcement has been used. It is necessary to be very careful when performing behavior management with patients to avoid violating the Patient’s Bill of Rights. A signed consent from the patient is advised when using this form of therapy.

The patient must understand the consequences of the behavior to be changed and the purpose for the type of consequence that is chosen. If the person is not capable of understanding the situation or is not able to remember the consequences because of some other problem, behavior management could be considered a questionable alternative to other kinds of treatment.

Cognitive Behavioral Therapy

Cognitive behavioral therapists believe that people teach themselves to be ill because of the way they “think” about their situations. Cognitive behavioral therapy stresses ways of rethinking situations. The therapist confronts the patient with certain distortions of thinking and then works out ways of thinking about them differently.

Feeling sad about an unpleasant experience (such as the death of a loved one) is acceptable and normal, but long-term depression about the death is an extreme emotion and therefore considered to be unhealthy. In this situation, the patient might be helped to see the death as a sad loss. Behavioral techniques are also used more often with phobias or panic disorders, in which fear may interfere with reasoning.

Cognitive therapies are gaining in popularity because they are usually significantly more short term than psychoanalysis and therefore less costly to the patient. It is

commonly performed in groups. The patients are given “homework” that is specific to their needs. Patients practice their assignments between sessions.

Person-Centered/Humanistic Therapy

Abraham Maslow and Carl Rogers are two theorists who are often credited with the concept of person-centered or humanistic therapy. In this form of treatment, caregivers focus on the whole person and work in the “present.” It is not important in humanistic treatment to understand the cause of the problem or what happened in the person’s past; what is important is the here and now. With this therapy, the patient learns to see himself or herself as a person who has value and who is respected by others.

Nursing is very strongly centered in person-centered principles. Three qualities are essential for caregivers: empathy, which is the ability to identify with the patient’s feelings without actually experiencing them with the patient; unconditional positive regard (respect); and genuineness or honesty. Although you may not be an active participant in the actual therapy sessions with patients, it is important to maintain these three qualities in all therapeutic relationships.

Counseling

Counseling is the provision of help or guidance by a health-care professional. The area of counseling is licensed and regulated differently not only state by state but sometimes municipality by municipality. Nurses prepared at an LPN/LVN level or at an RN level can, in some areas and with special advanced education, practice some forms of counseling.

You may be asked or expected to accompany patients to counseling sessions or even to facilitate a group discussion. Remember that these are confidential sessions, even if they are group oriented. Patients are there to work; others are there by invitation for special reasons.

Group Therapy

Groups are formed for many reasons; they can be ongoing or short term, depending on the needs of the patients or the type of disorder. Group therapy is a cost-effective means of providing treatment. For example, Alcoholics Anonymous (AA) and similar 12-step self-help groups are well-established, ongoing groups formed around treatment of a specific problem. Family counseling sessions may occur with individual therapists with a specialty in the problem area for that family. Marriage counseling may be done in a group with other couples. Many times, peer counselors are used.

Therapists and counselors are tools, or facilitators, in the therapeutic process. They do not heal the patient; the patient heals himself or herself. Patients must take the suggestions given by the therapist, try them, and see what works for them. You can help by reinforcing the good work patients

do in learning to stay mentally healthy and develop more effective life skills.

Electroconvulsive Therapy

Electroconvulsive therapy (ECT) is a form of treatment that is used for severely depressed patients who are not responding to psychotropic medications. It uses electric shock to produce a convulsion (seizure). Most mental health professionals believe ECT stimulates an increase in the circulating levels of the neurotransmitters serotonin, norepinephrine, and dopamine in the brain. In essence, ECT impacts neurotransmitter activity much like antidepressants do. ECT may be frightening to patients; it is important for the nurse to provide education and information to the patient and family. Many changes have been made in this form of therapy since the 1940s, and ECT is currently a safe and effective treatment for severe depression.

Procedure

ECT often takes place in the recovery room of an operating suite, where there is ready access to emergency equipment. Informed consent is required and should be obtained by the physician. About 30 minutes before the procedure, the patient is given a medication to dry secretions and counteract stimulation of the vagus nerve, which can cause bradycardia and syncope. Patients are given a short-acting anesthetic before the treatment and a smooth muscle relaxant to minimize injury. Before giving the muscle relaxant, a blood pressure cuff is placed on one of the patient's lower limbs and inflated. This is to ensure that the seizure activity can be visually monitored in this limb. Blood pressure and pulse are carefully monitored before and after the treatment. The patient is oxygenated with pure oxygen during and after the seizure until spontaneous respirations return. During treatment, an electrical stimulus is delivered to the brain via unilateral or bilateral electrodes. The amount of electrical energy used is individualized to the patient. The tonic-clonic (grand mal) seizure must last at least 30 seconds to be effective. The seizure activity is monitored with an electroencephalogram (EEG) and also in the cuffed limb.

Side Effects

Side effects of ECT can be unpleasant, but are usually temporary. The patient may feel confused and forgetful immediately after the treatment. This can be from a combination of the ECT itself and the medication that was used before the treatment. If there has been a strong seizure, the patient may have some muscle soreness.

Electroconvulsive therapy is not used indiscriminately. It is used when other therapies have not been helpful, and it is usually reserved for severe or long-term depression and certain types of schizophrenia (Box 56.3 Patient Perspective).

Nursing Responsibilities

The nurse's responsibilities include careful monitoring of vital signs and accurate documentation relating to the

Box 56.3

Patient Perspective

My mom is now 83 and has had a total of 35 electroconvulsive therapy (ECT) treatments in her lifetime. If you met her, you'd never know; you'd find her delightful. She's a sweet little plump German lady with a big heart. I am a nurse, and when I tell fellow nurses about my mom, they often ask me why I didn't get her on antidepressants. I want to scream, "How dumb do you think I am?!" Of course Mom is on antidepressants. But at intervals they don't work and she sinks into severe depression. My choice then is to help her have ECT or let her stay depressed and miserable and put her in a nursing home. And she would soon die because when she is depressed she refuses to move, doesn't sleep, and is horribly miserable.

The first time my mom was scheduled for ECT, one of the nurses in our local community hospital told her to refuse it, that no one should have to go through that. It was a cruel thing to do. My mom doesn't do well in counseling—she doesn't believe in it. In her mind you don't talk about your "dirty linen." My mom was in an abusive relationship with my father for 47 years, and she hid all the problems away and doesn't talk about them to this day. I'm so grateful to have my mom doing okay and grateful that ECT treatments exist. With ECT my mother is doing well and enjoying life. Without treatment she would be gone. Please understand that there are times when ECT treatments are the best thing for severely depressed people, when other treatments have been ineffective.

patient's subjective and objective responses to the treatment. The patient should receive nothing by mouth (NPO) for at least 4 hours before a treatment. Remind the patient to empty his or her bladder and to remove dentures, contact lenses, hair pins, and other items on the body. Stay with the patient until he or she is oriented and able to care for himself or herself. Oral medications and food should be withheld until the gag reflex returns. Ensuring that the person is kept safe after therapy is a major concern.

Relaxation Therapy

A variety of relaxation techniques can be taught to help patients manage their responses to stress. Relaxation exercises such as deep, rhythmic breathing can increase oxygenation and provide distraction from stressors. Breathing exercises may be coupled with progressive muscle relaxation exercises. For this technique, patients are taught to start at the head and neck and systematically tense and then relax muscle groups as they progress toward the lower

extremities. Soft music may enhance the patient's ability to fully relax.

Imagery is the use of the imagination to promote relaxation. For this technique, the patient is taught to imagine a pleasurable experience from his or her past, such as lying on a beach or soaking in a warm bath. Use of all senses is encouraged—for a beach image, the patient might see a beach, feel the warm sun, smell salt air, and hear waves crashing against the shore. The patient might also be taught to visualize being successful in a problem situation.

Relaxation techniques may be used individually, but they are often used in combination with each other or with other therapies for maximum effect.

Home Health Hints

Assess the safety of the home and patient for:

- Risk of falls (especially if the patient is experiencing orthostatic hypotension from medications)
- Suicide ideation, plan, and means
- Ability to access medications, missed doses, or overdoses
- Need for additional services for activities of daily living (ADLs), such as housekeeping, medication assistance, or safety rails

REVIEW QUESTIONS

1. When assessing mental health, which patient behavior would cause the nurse to be concerned or ask further questions?
 - a. Patient is always happy and smiling.
 - b. Patient can verbalize emotions.
 - c. Patient is able to cope with bad news.
 - d. Patient maintains some close, personal relationships.

Multiple response item. Select all that apply.

2. Which of the following assessments are important parts of a mental health assessment?
 - a. Orientation to reality
 - b. Mobility
 - c. Ability to communicate clearly
 - d. Heart sounds
 - e. Memory
3. A patient being evaluated for depression asks why he has to have his blood drawn. Which response by the nurse is best?
 - a. "Your physical illnesses must be under control before your depression can be treated effectively."
 - b. "The clinician needs to rule out physical causes for your symptoms."
 - c. "Most mental health disorders can be identified with blood tests."
 - d. "If your lab work is out of balance, then correcting the imbalance will reverse your depression."
4. A person who always sounds like he or she is making excuses is displaying which ego defense mechanism?
 - a. Denial
 - b. Fantasy
 - c. Rationalization
 - d. Transference

5. Which of the following best defines a therapeutic milieu?
 - a. An environment that is able to provide for all the patient's physical and emotional needs
 - b. An environment that is locked and supervised
 - c. An environment that is structured to decrease stress and encourage learning new behavior
 - d. An environment designed to be homelike for persons who are institutionalized for life
6. What is the primary reason a patient may be placed on psychopharmacology?
 - a. It can provide a cure for mental illness and substance abuse.
 - b. It is used only when necessary to control violent behavior.
 - c. It is used to alter the pain receptors in the brain.
 - d. It can decrease symptoms and facilitate other therapies.
7. Which of the following is one of the major skills a chemically dependent person and family can learn during treatment?
 - a. Honest communication
 - b. Avoidance of difficult topics
 - c. Denial
 - d. Scapegoating
8. A patient shares some very traumatic life experiences with the LPN. What is the best response by the LPN?
 - a. Assure the patient that the staff will not allow such experiences to happen to the patient again.
 - b. Ask probing questions about the patient's emotional responses to the experiences.
 - c. Encourage the patient to forget the experiences and move on with life.
 - d. Listen attentively to the patient and show empathy.

SUGGESTED ANSWERS TO**CRITICAL THINKING****■ Joe**

Different people cope in different ways. This may be a healthy way to cope in this man's culture. Gently guide the grieving husband to a room where he can express his emotions without disturbing others. Ask if he would like you to contact someone to come in to support him. Document objectively: "Patient's husband weeping loudly; guided to consultation room for privacy."

■ Mrs. Beison

Mrs. Beison is using denial to cope with her cancer diagnosis. Although at times denial can be an effective coping mechanism, if Mrs. Beison continues to deny her disease and refuse treatment, her life will be in danger. You can help Mrs. Beison verbalize her fears about cancer and cancer treatment and can provide accurate information to help her make wise choices. If necessary, a psychiatric evaluation can be requested.

QUESTIONS TO GUIDE YOUR READING

1. What are etiologic theories for mental health disorders?
2. What are the signs and symptoms of common mental health disorders?
3. What therapeutic management can be used for each of the disorders?
4. What are nursing interventions to help patients with mental health disorders?
5. What is the role of the LPN/LVN in care of patients with mental health disorders?

MENTAL HEALTH DISORDERS

Anxiety Disorders

Stress is everywhere in our society. Stress produces anxiety. Most often, stress is associated with negative situations, but the good things that happen to us, such as weddings and job promotions, also produce stress. The stress from positive experiences is called **eustress**. Eustress can produce just as much anxiety as the negative stressors. A stressor is any person or situation that produces an anxiety response. Stress and stressors are different for each person; therefore, it is important to ask patients what their personal stress producers are.

Anxiety is the uncomfortable feeling of dread that occurs in response to extreme or prolonged periods of stress. It is commonly ranked as mild, moderate, severe, or panic. It is believed that a mild amount of anxiety is a normal part of being human and that mild anxiety is necessary to change and develop new ways of coping with stress.

Anxiety may also be influenced by one's culture. It may be acceptable for some people to acknowledge and discuss stress, but others may believe that one does not discuss personal problems with others. This cultural behavior can be a challenge for the nurse during an assessment.

Anxiety is usually referred to as either *free-floating anxiety* or signal anxiety. Free-floating anxiety is described as a general feeling of impending doom. The person cannot pinpoint the cause but might say something like "I just know something bad is going to happen if I go on vacation." *Signal anxiety*, on the other hand, is an uncomfortable response to a known stressor ("Finals are only a week away and I've got that nausea again.") Both types of anxiety are involved in the various anxiety disorders.

Etiological Theories

Psychoanalytical theorists believe that anxiety is a conflict between the id (the "all for me" part of the personality) and the superego (the conscience), which was repressed in early development but emerges again in adulthood.

Biological theory looks at anxiety differently. One biological theory points to the sympathoadrenal (fight-or-flight) responses to stress to explain signs and symptoms of anxiety, and observes that the blood vessels constrict because epinephrine and norepinephrine have been released, causing blood pressure to rise. Another biological theory implicates a lack of the neurotransmitter gamma-aminobutyric acid (GABA) in the etiology of anxiety. GABA is an inhibitory neurotransmitter which prevents postsynaptic excitation. If the body adapts to the stress, hormone levels adjust and body functions return to a homeostatic state. If the body does not adapt to the stress, the immune system is challenged and risk for physical illness increases.

You may observe psychological responses to medical-surgical illness. It is important to recognize the relationship

between physical and emotional responses to stress. Some examples of medical conditions and the effects of the body's adaptation response to stress are shown in Table 57.1.

Differential Diagnosis

Because there are so many symptoms associated with anxiety disorders, it is important for people to have a complete physical examination before diagnosing an anxiety disorder, as some medical disorders, such as hyperthyroidism, may mimic anxiety. More than one condition may occur at the same time.

Types of Anxiety Disorders

PHOBIA. **Phobias** are the most common of the anxiety disorders. There are more than 700 documented phobias. *Simple phobias* are defined as irrational fears of specific objects or situations such as snakes or bridges. *Social phobias* are characterized by a persistent fear of behaving or performing in a way that will be humiliating or embarrassing to the individual, such as public speaking, eating in front of others, or using public restrooms. The person is very aware of the fear and even the fact that it is irrational, but is unable to gain control over the stressor and the fear continues.

The psychoanalytical view implies that it really is not the object that is the source of the fear, but rather the fear is a result of a defense mechanism called **displacement**. For example, the person with a phobia of snakes may have seen a frightening movie in which someone died from a snake bite. The stated object of the phobia would be interpreted as a symbol for the underlying cause of the fear.

PANIC DISORDER. Panic is a state of extreme fear that cannot be controlled. It is also referred to as panic attack, and lay people may not consider it to be a serious disorder.

Panic episodes are recurrent and occur unpredictably. Patients may present themselves at the emergency room because they believe they are having a heart attack or other significant physical illness. Patients must exhibit several episodes within a specified time frame to be given the diagnosis of panic disorder. Some of the symptoms associated with panic disorder include the following:

- Fear (usually of dying, losing control of self, or "going crazy")
- Feelings of impending doom
- Dissociation (feeling that it is happening to someone else or not happening at all)
- Nausea
- Diaphoresis
- Chest pain
- Palpitations
- Shaking

GENERALIZED ANXIETY DISORDER. In generalized anxiety disorder (GAD), the anxiety itself (also referred to as excessive worry or severe stress) is the expressed symptom. These patients worry about everything. Symptoms that may be present in GAD include the following:

- Restlessness or feeling "on edge"
- Shaking

TABLE 57.1 ADAPTATION RESPONSES TO STRESS

Stress-Related Medical Condition	Body's Adaptation to the Stress	Outcome of Stress on the Body
<i>Lowered Immunity</i>	Interferes with effectiveness of the body's antibodies; possibly related to interactions among the hypothalamus, pituitary gland, adrenal glands, and immune system	Increased susceptibility to colds and other viruses and illnesses
<i>Burnout</i> <i>Migraine, Cluster, and Tension Headaches</i>	Associated with stress-related depression Tightening skeletal muscles, dilating of cranial arteries	Emotional detachment Nausea, vomiting, tight feeling in or around head and shoulders, tinnitus, inability to tolerate light, weakness of a limb
<i>Stress (Peptic) Ulcers</i>	Stress contributes to the formation of ulcers by stimulating the vagus nerve and ultimately leading to hypersecretion of hydrochloric acid	Nausea, vomiting, gastrointestinal bleeding, perforation of intestinal walls
<i>Hypertension</i>	Role of stress not positively known; thought to contribute to hypertension by negatively interacting with the kidneys, autonomic nervous system, and endocrine system	Resistance to blood flow through the cardiovascular system, causing pressure on the arteries; can lead to stroke, heart attack, and kidney failure
<i>Coronary Artery Disease</i>	Stressor increases the amount of epinephrine and norepinephrine	Coronary vessels dilate, pulse and respirations increase
<i>Cancer</i>	Stress lowers immune response	Lowered immunity may allow for overcolonization of opportunistic cancer cells
<i>Asthma</i>	Autonomic nervous system stimulates mucus, increases blood flow, and constricts airways; may be associated with other stress-related conditions such as allergy and viral infection	Wheezing, coughing, dyspnea, apprehension; may lead to respiratory infections, respiratory failure, or pneumothorax

- Palpitations
- Dry mouth
- Nausea, vomiting
- Easy frightening
- Hot flashes
- Chills
- Muscle aches
- Hypervigilance (excessive attention to stimuli)
- Polyuria
- Difficulty swallowing

OBSESSIVE-COMPULSIVE DISORDER. Obsessive-compulsive disorder (OCD) is a different type of anxiety disorder. It consists of two parts: the **obsession** (repetitive thought, urge, or emotion) and the **compulsion** (repetitive act that may appear purposeful). An example of obsessive-compulsive disorder is the need to check that the doors are locked numerous times before one is able to sleep or leave the house. This need to repetitively check the locks may prevent the person from sleeping or leaving the house at all. Some individuals wash their hands compulsively to the point of having raw and bleeding hands. Behaviors become very ritualistic. The person with OCD is unable to stop the thought or the action. Performing the action (such as checking the locks or hand washing) is the mechanism that reduces the anxiety. Although you should not interfere with the repetitive acts, OCD patients can be helped by cognitive-behavioral therapy, medications (such as fluoxetine), and therapeutic interventions.

CRITICAL THINKING

Tommy

■ Tommy has come to your clinic with numerous cracks on his hands. They are bleeding and very sore. Tommy tells you that he has to wash his hands all the time. His mother says he washes for 2 to 3 hours at a time and he will not stop when she tells him to. The doctor has diagnosed Tommy with obsessive-compulsive disorder and has explained the illness to Tommy and his mother. When the doctor leaves the room, Tommy's mother begins to cry. "What did he just say? What am I supposed to do? What did I do wrong that Tommy got this illness?" How do you respond?

Suggested answers at end of chapter.

POSTTRAUMATIC STRESS DISORDER. Posttraumatic stress disorder (PTSD) develops in response to some unexpected emotional or physical trauma when there is the *real threat of death or harm* and the patient is helpless to do anything about it. People who have fought in wars, who have been raped, or who have survived violent storms or violent acts (such as terrorist acts) are examples of those who are susceptible to suffering from this disorder.

A condition that is associated with PTSD is *survivor guilt*, which is the feeling of guilt expressed by those who have survived a tragedy. A survivor of an airline crash may

say, “Why me? Why did I make it? I should have died too!” This is especially true if a loved one died in the crash.

Symptoms may appear immediately or may not appear until years later. A key symptom of PTSD is *flashbacks* in which the person may relive the traumatic event as if it were happening at that moment. Sounds and smells associated with the trauma may trigger the flashback.

Signs and symptoms of PTSD include the following:

- Flashbacks
- Social withdrawal
- Feelings of low self-esteem
- Changes in relationships with significant others
- Difficulty forming new relationships
- Hypervigilance
- Irritability and outbursts of anger seemingly for no obvious reason
- Depression
- Chemical dependency

Therapeutic Interventions for Patients with Anxiety Disorders

Treatment is individualized for the patient and may include one or more of the following: psychopharmacology, individual psychotherapy, group therapy, systematic desensitization, hypnosis, imagery, relaxation exercises, and biofeedback.

Psychopharmacology usually involves the antianxiety classification of medications. The benzodiazepines, such as diazepam (Valium) and alprazolam (Xanax), are commonly used and are effective in most cases. Benzodiazepines are used for short-term treatment because of the strong potential for chemical dependency. Individuals who need longer term therapy for anxiety or who have chemical dependency issues can be safely and effectively treated with buspirone (Buspar); clonazepam (Klonopin), the SSRIs paroxetine (Paxil), or sertraline (Zoloft); the antihistamine hydroxyzine hydrochloride (Atarax); or the antihypertensive clonidine (Catapres). See Table 57.2 for a review of medications.

In *systematic desensitization*, the patient is gradually exposed to the object (rating the fear on a scale from 1 to 10) that causes the anxiety. *Hypnosis* places the patient in a subconscious state, then helps the patient recall events that may be producing anxiety so they can be dealt with. Other therapies were discussed in Chapter 56.

Nursing Process for the Patient with Anxiety

ASSESSMENT/DATA COLLECTION. Assess the patient’s anxiety level. Ask about triggers of anxiety and coping mechanisms that have been successful or unsuccessful in the past. Observe for physical symptoms such as changes in vital signs, diaphoresis, or tremor. Assess for the presence of suicidal thoughts and observe for suicidal behavior. It is important to identify anxiety and intervene at the lower levels, before escalation to severe and panic anxiety levels.

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Anxiety

EXPECTED OUTCOMES: The patient will identify precipitants and patterns for anxiety and demonstrate techniques to

control anxiety. The patient will verbalize that anxiety is controlled.

- Assist the patient to identify precipitants and patterns to anxiety. *Recognition of patterns can help guide care and allow the patient to initiate measures to stop anxiety from progressing.*
- Maintain a calm milieu and manner. *A chaotic environment can increase the patient’s anxiety. Anxiety is contagious and may be transmitted from staff to patient.*
- Maintain open communication. Encourage the patient to verbalize thoughts and feelings. Observe nonverbal communication. *Honesty in dealing with patients helps them learn to trust others and enhances their self-esteem.*
- Encourage the patient to use positive self-talk such as “I can do this. Anxiety can’t kill me.” *This helps the patient replace negative anxious thoughts with positive statements to decrease anxiety.*
- Report and document any changes in behavior. Positive or negative alterations in the way a patient responds to the nursing staff, to the treatment plan, or to other people and situations should be reported. *Any change can be significant to the patient’s care.*
- Encourage activities, but avoid placing the patient in a competitive situation. *Activities that are enjoyable and nonstressful provide diversion and give staff an opportunity to provide positive feedback about the progress the patient is making.*
- Encourage problem solving and assist to develop alternative solutions. Assist to identify what has worked in the past. *This can help the patient focus on strategies that were effective in the past, and eliminate those that are not effective.*
- Stay with patients during severe or panic levels of anxiety. *Feelings of being abandoned can increase anxiety. The nurse’s presence will also provide safety for the patient.*
- Implement suicide precautions if indicated. *The patient may need to be protected from self-harm until treatment is effective.*
- Assess your own level of anxiety. *An anxious nurse may make the patient more anxious.*

EVALUATION. Is the patient able to implement strategies to control anxiety? Does the client recognize triggers of anxiety? Does the patient state he or she feels less anxious?

See Box 57.1 Anxiety Summary.

Mood Disorders

Mood disorders (also called affective disorders) are disorders in which the major symptom is extreme changes in mood (emotions) and affect (the outward expression of the mood). Moods involving both highs and lows are bipolar disorders, where as low moods without any highs, are described as depressive disorders. Mood disorders are

(Text continued on page 1280)

TABLE 57.2 MEDICATIONS USED FOR ALTERATIONS IN MENTAL HEALTH

Medication Class/Action	Examples	Route	Side Effects	Nursing Implications
Typical Antipsychotics Block dopamine receptors (<i>used less frequently because of serious side effects</i>)	Chlorpromazine (Thorazine) Haloperidol (Haldol) Fluphenazine (Prolixin)	PO, IM PO, IM, long-acting IM PO, IM, long-acting IM	Extrapyramidal side effects (EPSEs): parkinsonism, akathisia, dystonia, tardive dyskinesia, photosensitivity, orthostatic hypotension, gynecomastia, neuroleptic malignant syndrome	Monitor for EPSEs. Use sunscreen when outside, do not use/take with alcohol or other CNS depressants, avoid use during first trimester of pregnancy, have patient rise slowly to prevent dizziness.
Atypical Antipsychotics Block dopamine and serotonin receptors	Clozapine (Clozaril) Risperidone (Risperdal) Olanzapine (Zyprexa)	PO PO, IM, long-acting IM PO, fast-dissolving tablets	Agranulocytosis (Clozaril), weight gain, type 2 diabetes, dose-related EPSE (Risperdal). Lowers seizure threshold.	Monitor CBC (Clozaril), monitor weight gain and onset of type 2 diabetes.
Selective Serotonin Reuptake Inhibitor (SSRI) Antidepressants Block the reuptake of serotonin at the presynaptic receptor.	Fluoxetine (Prozac) Sertraline (Zoloft) Paroxetine (Paxil) Escitalopram (Lexapro)	PO, Once weekly dosing PO PO	Excitation, nausea and vomiting, decreased libido, anorexia, weight loss	Allow time for side effects to subside; do not administer after 3 p.m. to prevent excitation from affecting sleep; teach patient that it will take 2–4 weeks for therapeutic effects to occur, and possibly longer with Prozac.
Tricyclic Antidepressants Partially block the reuptake of serotonin and norepinephrine at the presynaptic receptor (<i>used less frequently because of side effects</i>)	Amitriptyline (Elavil) Amoxapine (Asendin) Nortriptyline (Pamelor) Imipramine (Tofranil)	PO PO PO PO	Anticholinergic effects, sedation, weight gain, orthostatic hypotension, tachycardia	Decreases effects of antihypertensives, lowers seizure threshold, will affect oral contraceptives. Teach patient that it will take 2–4 weeks for therapeutic effects to occur.
Selective Serotonin Norepinephrine Reuptake Inhibitor (SNRI) Block the reuptake of serotonin and norepinephrine at the presynaptic receptor.	Venlafaxine (Effexor, Effexor XR)	PO	Anxiety, abnormal dreams, dizziness, nervousness	Monitor blood pressure for systolic hypertension
Monoamine Oxidase Inhibitor (MAOI) Antidepressants Block the action of monoamine oxidase	Phenelzine (Nardil) Tranylcypromine (Parnate) Isocarboxazid (Marplan)	PO PO PO	Anticholinergic effects, orthostatic hypotension, will interact with foods containing tyramine and cause hypertensive crisis, headache.	Teach about tyramine-free diet. Interacts with many prescribed and over-the-counter medications. Serious fatal reactions with SSRI or SNRI. Teach patient not to stop taking abruptly.

Medication Class/Action	Examples	Route	Side Effects	Nursing Implications
Benzodiazepines				
Antianxiety				
Potentiate effects of GABA, which causes a calming effect	Alprazolam (Xanax) Diazepam (Valium) Lorazepam (Ativan)	PO PO PO, IM	Sedation, hangover effect, ataxia, confusion, dizziness, anticholinergic effects	Short-term use only; addictive, do not use in pregnancy, caution in the elderly, do not operate heavy machinery, do not abruptly stop taking.
Buspar				
Antianxiety				
Unknown action	Buspirone (BuSpar)	PO	Headaches, dizziness, GI upset, lightheadedness	Teach patient that it will take 3–6 weeks to work; non-habit forming, little sedating effect.
Anticonvulsant Mood Stabilizers				
Antikindling effect, affect GABA receptors	Carbamazepine (Tegretol) Clonazepam (Klonopin) Lamotrigine (Lamictal) Valproic acid (Depakote)	PO PO PO PO	Dizziness, drowsiness, blurred vision, nausea, headache, weight gain, blood dyscrasias Nausea, vomiting, ataxia, dizziness, drowsiness Headache, dizziness, ataxia, nausea, vomiting, photosensitivity, rash, Stevens-Johnson syndrome Nausea, headache, menstrual disturbances, weight gain, hair loss, lethargy, tremors	Use cautiously with MAOIs, elderly, liver, renal, or cardiac disease, and pregnancy. Do not use in pregnancy, caution in elderly, caution in patients with liver or renal disease. Caution patient to use sunscreen and to report any signs of rash immediately. Avoid with breastfeeding. Caution with hepatic toxicity, monitor for signs of bleeding, do not use in pregnancy, loading dose may be ordered for acute mania.
Lithium				
Antimanic				
Decreases postsynaptic receptor sensitivity	Lithium carbonate (Eskalith)	PO	Thirst, nausea and vomiting, weight gain, tremors, skin rash (acne), hair loss, hypothyroidism	Narrow therapeutic range increases risk for toxicity; monitor blood levels; do not use in cardiac or renal disease, do not use with diuretics, do not use in pregnancy.
Antiparkinsonian Agents				
Restore the natural balance of acetylcholine and dopamine in the CNS	Benzotropine (Cogentin) Trihexyphenidyl (Artane) Diphenhydramine (Benadryl)	PO, IM PO, IM PO, IM	Anticholinergic effects, nausea, GI upset, sedation, dizziness, orthostatic hypotension	Caution with hypersensitivity, glaucoma, history of urinary retention.

CNS = central nervous system; GABA = gamma-aminobutyric acid; GI = gastrointestinal.

Box 57.1**Anxiety Summary****Signs and Symptoms**

- Phobia: Irrational fear of object or situation
- Panic disorder: Extreme fear, feelings of impending doom, palpitations
- Generalized anxiety disorder: Worry, restlessness, palpitations
- Obsessive-compulsive disorder: Uncontrollable repetitive thoughts, urges, or actions

Diagnosis

History of symptoms; physical causes for symptoms must be ruled out first

Therapeutic Interventions

Antianxiety medication, selective serotonin reuptake inhibitors, systematic desensitization, psychotherapy, relaxation exercises

Nursing Diagnosis

Anxiety

diagnosed when symptoms begin to interfere with normal day-to-day functioning. People of all age groups and all ethnic and socioeconomic groups can develop mood disorders.

Etiological Theories

Psychoanalytical theory indicates that people who have suffered loss in their lives are at risk for developing depression. This has been supported by recent research. Depression is also associated with unresolved anger and has been explained as “anger turned inward.” In other words, people who cannot or do not deal appropriately with situations that anger them may repress the anger (turn it inside) and become depressed.

Cognitive theorists believe that the way people perceive events and situations may lead to depression. Instead of thinking about failing an examination as being unfortunate and disappointing, some people with tendencies toward depression may exaggerate the emotion and turn the situation into something much deeper, such as thoughts of “I’m stupid” or “I’ll never get anywhere.”

Biological theories offer genetic links and neurotransmitter dysfunctions as two etiologies. Serotonin, norepinephrine, and dopamine have an effect on mood; if these neurotransmitters are elevated, mood is elevated, and if they are low, mood is low. Biological theorists also believe that there is a connection between these neurotransmitters and female hormones.

Differential Diagnosis

Symptoms of depression may occur in conjunction with other disorders, such as schizophrenia or drug side effects or overuse. Heart failure, nutritional deficiencies, drug toxicity, thyroid disease, fluid and electrolyte imbalances, infections, and diabetes can be associated with depression. Depression related to grief is considered a normal reaction unless it is prolonged (unresolved grief).

Types of Mood Disorders

MAJOR (UNIPOLAR) DEPRESSION. Major depression is an episodic condition, and symptoms interfere with the individual’s usual social or occupational functioning. Depressed individuals view the world through “gray tinted glasses.” The *Diagnostic and Statistical Manual of Mental Disorders IV-Text Revision* (DSM-IV-TR) specifies that symptoms of major depression include either a depressed mood or **anhedonia** (the loss of pleasure in things that are usually pleasurable) along with at least five of the following symptoms:

- Significant weight loss or gain
- Increase or decrease in appetite
- Sleep pattern disturbances—insomnia or hypersomnia
- Increased fatigue
- Increased agitation or psychomotor retardation
- Diminished libido
- Anergia
- Social withdrawal
- Decreased ability to think, remember, or concentrate
- Feelings of guilt or hopelessness
- Indecisiveness
- Suicidal ideation

BIPOLAR DISORDER. Approximately 2 million people in the United States suffer from **bipolar** disorder. Bipolar disorder (formerly called manic depressive illness) is a mood disorder in which patients experience both **mania** (extreme elation or agitation) and extreme depression. Bipolar disorder is more severe than major depression. Affected individuals stay depressed longer, relapse more frequently, display more depressive symptoms, have more **delusions** and **hallucinations**, commit suicide more often, require more hospitalizations, and overall experience more incapacitation.

Individuals can cycle slowly (over weeks or months or even years), or they can be “rapid cyclers” who can change moods several times in an hour.

Common signs of depression were covered in the preceding section. Common signs of mania include the following:

- Excessive high (euphoric) moods
- Increased energy, activity, restlessness
- Decreased need for sleep
- Grandiosity (unrealistic belief in one’s abilities or powers)

anhedonia: an—not + hedonia—pleasure

- Extreme irritability and distractibility
- Uncharacteristically poor judgment
- Pressured and rapid speech
- Flight of ideas or subjective experience that one's thoughts are racing
- Increase in goal-directed behavior
- Excessive involvement in pleasurable activities that have a high potential for unpleasant consequences, such as sex, substance abuse, or shopping sprees
- Obnoxious, provocative, or intrusive behavior

Therapeutic Interventions for Patients with Mood Disorders

Approximately 80% of people with major depression respond to treatment. Bipolar disorder is more difficult to treat. Some common medical treatments for *all* mood disorders include the following:

- Antidepressants
- Mood stabilizers
- Psychotherapy
- Electroconvulsive therapy

Lithium was once the drug of choice for the treatment of bipolar disorder. Lithium is an antimanic medication with a very narrow therapeutic range (toxic drug levels can easily develop). Lithium levels must be drawn regularly to assess that serum levels are in the therapeutic range. Antidepressants should be used carefully as they may induce a manic episode. See Table 57.2 for a summary of medications. Also see Box 57.2 Nutrition Notes.

Mood stabilizers like the anticonvulsants valproic acid (Depakote) and lamotrigine (Lamictal) are now more commonly used to treat bipolar disorder. Atypical antipsychotics are also commonly used in conjunction with the mood stabilizer when the patient is in the acute manic state.

Psychotherapy for the patient and family may be helpful for any type of mood disorder. It can help the patient understand the illness and learn problem solving and other new adaptive coping behaviors. For young children, play therapy is the most common and effective form of therapy. Electroconvulsive therapy is an option for individuals with

SAFETY TIP

When you do your nursing assessment, be sure to ask about herbal supplements the patient may use in addition to prescription and over-the-counter medications. Many people take St. John's wort, an over-the-counter herbal supplement, for depression. While it may be effective for some people with mild depression, it can interact with many prescribed medications that influence serotonin levels. If combined with prescription antidepressants, it can cause an excess of serotonin, resulting in agitation, confusion, diarrhea, muscle spasms, and even death.

Box 57.2

Nutrition Notes

Anticipating Food-Drug Interactions in Patients with Mental Health Disorders

Monoamine Oxidase Inhibitors. Some antidepressant drugs (e.g., isocarboxazid, phenelzine, tranylcypromine) are monoamine oxidase inhibitors (MAOIs). These drugs counteract depression by preventing the breakdown of dopamine and tyramine, an intermediate product in the conversion of tyrosine to epinephrine. The increased concentration of these chemicals in the central nervous system elevates the patient's mood.

When a patient taking an MAOI consumes foods high in tyramine, the drug prevents the normal breakdown of tyramine, leading to excessive epinephrine. Hypertension results, sometimes severe enough to cause intracranial hemorrhage. Some other drugs (e.g., furazolidone, isoniazid, linezolid, procarbazine, selegiline) produce similar reactions with tyramine-containing foods.

All food groups except breads and cereals have some items with sufficient tyramine to cause problems for patients taking MAOIs. Examples of common foods to be avoided are bananas, aged cheese, yogurt, bologna, salami, pepperoni, summer sausage, chocolate, beer, and wine.

Lithium Carbonate. Lithium carbonate, used to treat bipolar disorder, is absorbed, distributed, and excreted alongside sodium. Fluctuations in sodium intake affect the metabolism of lithium. Thus, decreased sodium intake with decreased fluid intake may lead to retention of lithium and overmedication. Increased sodium intake from food or medications and increased fluid intake may hasten excretion of lithium, resulting in worsening signs and symptoms of mania.

rapid-cycling bipolar disorder or major depression that is not responsive to conventional treatment on page 1284.

Nursing Process for the Patient with a Mood Disorder

See Box 57.3 Nursing Care Plan for the Patient with Depression. Also see Box 57.4 Depression Summary on page 1284.

Somatoform/Psychosomatic Disorders

The **somatoform** (or **psychosomatic**) disorders are conditions in which physical symptoms occur with no known organic cause. It is believed that the physical symptoms are an expression of psychological pain or distress. Because the patient is not able to control the symptoms, they are considered to be caused by some unconscious mechanism.

psychosomatic: psych(e)—soul or mind + somatic—body

CRITICAL THINKING

Mr. Zenz

■ Mr. Zenz is the manager of a busy office/clinic. His usual behavior is rather sullen and he comes across as “quiet” or “sad” to various members of the staff. He is in his 40s, married, with three children ages 4, 5, and 7. He speaks of them proudly but always comments that they “take after their mother.” His management style in the office is to let people do their jobs; he rarely interferes, although his door is always open and staff members are told they are welcome any time. Recently, however, staff members are noticing a change in Mr. Zenz. He moves quickly, speaks quickly, and has set grandiose goals for the staff. He frequently says he has called the president of the company to tell him of his new ideas. He says he has not slept in several days and he feels terrific. He has changed his wardrobe and has begun pointing out specific performance issues to staff. He jokes with staff. Staff is made aware that he has “bipolar disorder” and has quit taking his medications. His wife has asked for the staff’s help. Remember: He is your boss. How do you respond to Mrs. Zenz? How do you approach him?

Suggested answers at end of chapter.

Etiological Theories

Psychoanalytical theorists believe that the somatoform disorders are rooted in unconscious mechanisms that develop to deny, repress, and displace anxiety. Biological research

suggests the possibility of a genetic predisposition to somatic difficulties.

Types of Somatoform Disorders

There are five separate illnesses within the category of somatoform disorders and two additional illnesses that are closely related. These include **conversion disorder**, hypochondriasis, dysmorphophobia/body dysmorphic disorder, somatization disorder, and somatoform pain disorder. Discussion of all these disorders is beyond the scope of this book. This chapter gives a brief explanation of conversion disorder.

CONVERSION DISORDER. Conversion disorder is an illness that emerges from overuse of the conversion reaction defense mechanism. (See Table 56.2 in Chapter 56.) In conversion disorder there is a loss or decrease in physical functioning that seems to have a neurological connection. Paralysis and blindness are the two most common examples of this disorder. Age of onset is usually adolescence and young adulthood, but it can occur later in life as well.

The symptoms, although not caused by organic disease, are very real to the patient. It should not be conveyed to the patient that you think the person is “faking” the illness; this is not true. Patients are truly experiencing the symptoms.

It is believed that the symptom is allowing the person to avoid some situation that is unacceptable to him or her. The symptom helps the patient relieve the anxiety. This is called primary gain. Secondary gain results from the extra benefits one may acquire as a result of staying ill, such as extra emotional support, sympathy, love, or financial benefits.

Box 57.3 NURSING CARE PLAN for the Patient with Depression

Nursing Diagnosis: Risk for suicide

Expected Outcome The patient will not harm him/herself.

Evaluation of Outcome Did the patient remain free from self-harm during hospitalization?

Interventions

Ask patient directly about suicidal ideations each shift.

Create a safe environment for the patient.

Initiate suicide precautions according to agency protocol.

Encourage the patient to seek out nursing staff when experiencing suicidal thoughts.

Rationale

Ongoing assessment of suicidal risk is essential to patient safety.

Patient safety is a nursing priority.

The patient must be protected until risk is reduced.

Active listening and therapeutic communication by staff provide the patient with empathy and alternatives to acting on suicidal thoughts.

Evaluation

Is the patient verbalizing warning signs of suicide?

Are means of harming self kept from patient?

Is increased surveillance of patient implemented and communicated to all staff?

Does the patient seek out nursing staff when experiencing suicidal thoughts?

Nursing Diagnosis: Ineffective coping

Expected Outcomes The patient will cope effectively as evidenced by (1) verbalizing the ability to cope and asking for help when needed; (2) demonstrating new effective coping strategies.

Evaluation of Outcomes Does the patient exhibit increased ability to problem solve?

Interventions

Use therapeutic communication and encourage the patient to verbalize feelings.

Assist the patient to describe stressors and coping mechanisms used.

Help the patient set realistic goals and identify his or her skills and knowledge.

Encourage the patient to make choices and participate in care.

Rationale

Verbalization of feelings in a supportive environment may assist patient to work through issues.

Reviewing successful coping strategies can strengthen effective coping and diminish ineffective methods.

Providing validation of actual stress and available coping resources and strategies aids in positive adaptation to stress.

Active involvement in care increases the possibility of positive adjustment.

Evaluation

Does the patient verbalize feelings to nursing staff?

Is the patient able to identify stressors and related coping strategies in used in the past?

Does the patient set realistic goals?

Is the patient actively involved in care?

Nursing Diagnosis: Powerlessness

Expected Outcomes The patient will reduce feelings of powerlessness as evidenced by (1) verbal expression of having control over life, situation, or care; (2) participation in care or decision making when opportunities are provided.

Evaluation of Outcomes Does patient identify feelings of powerlessness? Does patient identify factors that are controllable and actively participate in care?

Interventions

Assess for factors contributing to powerlessness.

Help the patient to identify factors not under his or her control.

Encourage the ventilation of feelings.

Encourage the patient to actively participate in care with goal-directed activities.

Rationale

Correct identification of actual or perceived problems is essential to providing appropriate support.

Identifying factors within the patient's control encourages the patient to take some control over the situation.

Sharing feelings can lead to the realization that similar feelings are experienced by others and reduce powerlessness.

Goal-directed behavior increases self-efficacy and empowerment.

Evaluation

Has there been correct identification of factors contributing to powerlessness?

Is the patient able to identify what is controllable and what is not controllable in his or her life?

Is the patient sharing feelings with nursing staff and in therapeutic groups?

Does the patient set realistic goals daily and achieve them daily?

Therapeutic Interventions for Patients with Somatoform Disorders

Because of the physical symptoms, hospitalized patients are usually admitted to a medical unit rather than a psychiatric unit. True physiological causes for symptoms must be ruled out. Treatment is individualized for the patient. Hypnosis

and relaxation techniques are used with many patients. Methods of stress management are taught. Behavior management may be effective for some patients. Patients may resist accepting the fact that their problem is psychological or emotional in nature and may feel insulted and become resistant to treatment.

Box 57.4**Depression Summary****Signs and Symptoms**

- Unipolar: depressed mood, weight changes, anhedonia, sleep disturbance, social withdrawal
- Bipolar: Signs and symptoms of depression cycling with euphoria; delusions, hallucinations

Diagnosis

History; physiological causes must be ruled out

Therapeutic Interventions

Antidepressant medication, mood stabilizers (anticonvulsants), psychotherapy, electroconvulsive therapy

Nursing Diagnosis

Ineffective coping, powerlessness, risk for suicide

Medications are used sparingly. When they are ordered for a patient, the classifications of choice are usually antidepressants, antianxiety agents, or both.

Nursing Management for Patients with Somatoform Disorders

Nursing management for somatoform disorders includes the following:

- *Skillful communication.* Honesty and gaining trust encourage the patient to verbalize thoughts and feelings about the physical and emotional aspects of this disorder. An example of a way to be honest about the situation would be to reinforce what the physician has said to the patient, such as, “Ms. Parks, your doctor can find no physical or life-threatening conditions at this time. We will continue to observe and examine you. We will make every attempt to help you improve.” Sometimes the practitioner helps the patient find a healthy behavior to substitute for the symptom.
- *Therapy.* Keeping the patient focused on other topics than the symptoms may help in the recovery. Spend time with the patient other than when they have physical complaints.
- *Support.* When caring for the patient with a somatoform disorder, you must pay attention to the person but must not reinforce the symptoms. Use a matter of fact approach and don’t imply that the symptoms are not real. A thorough head-to-toe assessment should always be done. Observe and record frequency of complaints. Provide explanations and support during diagnostic tests. The patient will see your concern for his or her health, but you will not

be focusing on the area of dysfunction or reinforcing the problem. All findings should be documented objectively.

Schizophrenia

Schizophrenia is becoming more widely viewed as a group of illnesses rather than a single condition. Onset is often during adolescence or young adulthood. The National Institute of Mental Health estimates that nearly 3 million persons in the United States will develop schizophrenia during the course of their lives.

The term *schizophrenia* (which means “split mind”) was first used by a Swiss psychiatrist, Eugene Bleuler.¹ Schizophrenia is a serious brain disorder of thought and association and is characterized by an inability to distinguish between what is real and what is not, hallucinations, delusions, and limited socialization. People who have schizophrenia may not be able to differentiate between what is “theirs” and what is “everybody else’s” in relation to social functioning. Poor self-esteem may be an issue. It is difficult for them to focus on one topic for any length of time. Schizophrenia is not the same thing as multiple personality disorder.

Schizophrenia has an insidious onset. This means that it develops over time, and symptoms may go unnoticed for a time prior to diagnosis. There are four phases of schizophrenia:

1. *Schizoid Personality.* Individuals in this phase are perceived as being indifferent, cold, and aloof. They are often described as loners and don’t seem to enjoy close relationships with others. In an adolescent, these behaviors may be dismissed as normal for age. Not all individuals with schizoid personality go on to develop schizophrenia.
2. *Prodromal Phase.* Individuals continue to be socially withdrawn and begin to exhibit behavior that is peculiar or eccentric. Role functioning is impaired, personal hygiene is neglected, and disturbances are evident in communication, ideation, and perception.
3. *Schizophrenia.* This is the third and active phase of the disorder. Psychotic symptoms are prominent and include delusions, hallucinations, and impairment in work, social relations, and self-care.
4. *Residual Phase.* Symptoms are similar to the prodromal phase with flat affect and impairment in role functioning.

Positive and Negative Symptoms

Positive symptoms of schizophrenia can be thought of as those symptoms that reflect an “excess” or distortion of normal functioning. Positive symptoms include hallucinations, delusions, disorganized thinking, and disorganized behavior. **Delusions** are fixed, false beliefs that cannot be changed by logic or factual proof. Typically, patients exhibit delusions of grandeur, persecution, or guilt. **Hallucinations** are false sensory perceptions. They can affect any of the five senses; auditory and visual delusions are most common. For exam-

ple, a person might see a person that no one else sees, or hear voices that no one else hears. In contrast, **illusions** are mistaken perceptions of reality. For example, a person may see a glowing sunset and think the horizon is on fire. Both the typical and atypical antipsychotic medications work well on the positive symptoms of schizophrenia.

Negative symptoms of schizophrenia can be thought of as a loss of normal functioning. Negative symptoms include affective blunting or flattening, **alogia**, **avolition**, apathy, anhedonia, and social isolation. It is thought that these are the most debilitating symptoms of schizophrenia because they keep the individual from living a normal life. These symptoms respond to atypical antipsychotic medications, but not the typical antipsychotic agents.

Pathophysiology and Etiology

There are psychoanalytical and biological theories of the causes of schizophrenia. The causes of schizophrenia are highly debated on both sides of the nature-versus-nurture theories.

The psychoanalytical, or nurture, theories refer to the anal stage of Freudian theory. The inability to meet the challenge of oral gratification leaves people in the adolescent and young adult years unable to handle their developing sexuality, according to Freud. Lack of nurturing mother-child relationships can also lead to personalities that are cool or indifferent in their relationships. Freud would also attribute the disruption of effective communication to failure to attain oral gratification.

The role of genetics in schizophrenia (psychobiological, or nature, theory) has been examined in twins studies, family studies, and adoption studies for more than 75 years. Studies of identical twins show that if one twin has schizophrenia, the other has about a 50% chance of developing it also. In fraternal twins that percentage drops to about 10%. It is believed that the more genes twins or family members have in common, the greater the probability of the second twin developing schizophrenia.

Other studies have examined the relationship of dopamine and schizophrenia. Patients with schizophrenia generally have elevated amounts of dopamine or a brain that overreacts to the amount of dopamine that is present. Today, schizophrenia is primarily thought of as a series of brain disorders characterized by brain abnormalities and excessive dopamine transmission.

Types of Schizophrenia

There are several categories of schizophrenia. This chapter discusses only the most common: paranoid schizophrenia. Paranoid schizophrenia is defined as schizophrenia in which the person exhibits unusual suspiciousness and fear. They may also be hostile and aggressive in their behavior.

Patients with paranoid schizophrenia tend to have delusions of persecution or grandeur. Patients experiencing persecutory delusions state that they feel tormented and

followed by people. Patients often integrate people around them into their delusions. They may feel that nursing staff, relatives, or the announcer on the radio or television is trying to harm them. In delusions of grandeur, patients may state that they are God or the President of the United States.

Hallucinations often accompany delusions. The hallucinations can affect any of the five senses but are most commonly auditory followed by visual. Patients with paranoid schizophrenia talk about hearing “voices.” These voices are frightening and derogatory to the patient and are responsible for many of the actions performed by people with paranoid schizophrenia. Patients experience increased fear, anxiety, and suicidal ideation as a result of the voices. You may see or hear patients arguing with what at first appears to be themselves. Actually the patient is arguing with the voices. Describing the voices is difficult, but imagine that you are in a room with six televisions on different stations at the same time. This example comes close to what some patients have described as the voices.

Therapeutic Interventions for the Patient with Schizophrenia

Medications, social skills training, and individual and family psychotherapy are indicated for patients with schizophrenia. Among the classifications of medications that may be prescribed for certain patients are the typical and atypical antipsychotics, which block dopamine action in the brain. There are different dopamine tracts in the brain, and the typical antipsychotics have a greater effect on the motor function tract, resulting in extrapyramidal symptoms such as parkinsonism (see medications in Table 57.2). Anticholinergic medications such as benztropine (Cogentin) or trihexyphenidyl (Artane) are used to combat the extrapyramidal side effects of the typical antipsychotics by helping return balance between dopamine, acetylcholine, and other neurotransmitters. Newer, atypical antipsychotic medications such as clozapine (Clozaril) and risperidone (Risperdal) have fewer extrapyramidal side effects, and are effective in treating both the positive and negative symptoms of schizophrenia.

Psychotherapy may include individual, group, and family therapy. Electroconvulsive therapy (ECT) is used in some severe cases or in cases that are difficult to treat; ECT is usually not used until other methods of therapy have been exhausted. Referral of the patient and family to organizations such as the National Alliance on Mental Illness (NAMI) provides helpful education and support (www.nami.org).

Nursing Process for the Patient with Schizophrenia

ASSESSMENT/DATA COLLECTION. Observe the patient with schizophrenia for positive and negative symptoms, including hallucinations, delusions, or illusions. Observe interactions with others. Monitor for response to medications, including side effects. Determine the individual’s ability to function and manage own activities of daily living (ADLs).

alogia: a—not + logia—(able to) speak

avolition: a—not + volition—energy or initiative to do something

NURSING DIAGNOSIS, PLANNING, AND IMPLEMENTATION. Disturbed thought processes

EXPECTED OUTCOME: Patient will be oriented to person, place, and time; be able to manage medications, perform ADLs, and function in a community.

- Develop trust. Be honest and consistent in all areas of the patient's treatment plan. *Trust is essential to a therapeutic relationship.*
- Allow the patient to verbalize thoughts and feelings when appropriate to the time and place. *Verbalizing feelings can help the patient clarify concerns and feel supported.*
- Whenever possible, maintain consistent staff assignments to ensure the best possible continuity of care and to promote the development of a trusting relationship.
- Never whisper or laugh when the patient cannot hear the whole conversation. Face the patient when having a conversation. *Whispering or turning away may be interpreted as rejection; secretive behaviors can reinforce paranoia and suspiciousness.*
- Avoid placing the patient in situations of competition or embarrassment. *These situations can be threatening to the patient.*
- Never reinforce hallucinations, delusions, or illusions. Orient to reality as needed. *The patient needs to know what is real and what is not.*
- Use distraction to deal with the hallucinations. Assist to connect the delusions and hallucinations to times of increased anxiety. (See Table 57.3.) *This models strategies for the patient to use during times of anxiety.*
- Provide a calm and therapeutic milieu to help reduce anxiety.
- Provide written instructions and information boards to help promote reality and self-responsible behavior.

- Monitor medication use and initiate mouth checks as needed. *Patients may have difficulty maintaining a medication schedule or choose to not take medications as ordered due to paranoia.*
- Keep communication simple. Be brief and clear with all directions. State what is acceptable, giving the rationale and consequences at the same time. State information in positive rather than negative terms: "Eat your food calmly" rather than "Do not throw your food!" *Patients are more likely to process and respond to simple, direct communication.*
- Use touch cautiously. *Perceptions and distortions of reality may cause patients to misconstrue touch.*

EVALUATION. Is the patient alert and oriented? Is he or she able to manage medications, or is there a plan in place to make sure medications are administered? Is the patient able to manage ADLs and live in a community?

See Box 57.5 Schizophrenia Summary.

Substance Abuse Disorders

Alcoholism and chemical dependency are serious conditions. People start using alcohol and drugs for many reasons, but often it is to feel accepted by a peer group or to feel comfortable and reduce anxiety in a social situation. People mistake the temporary high as a stimulant. In reality, alcohol is a depressant. Any chemical can be potentially dangerous.

It is important to understand the following terms and their definitions:

- **Addiction**—the repeated compulsive use of a substance that continues in spite of negative consequences (physical, social, legal).
- **Tolerance**—increased amounts of a substance are needed over time to achieve the same effect as obtained previously with smaller amounts.
- Physical **withdrawal** syndrome—the physiological response to the abrupt stopping or reduction in a

TABLE 57.3 SUGGESTED INTERVENTIONS FOR PATIENTS WITH SCHIZOPHRENIA WHO ARE HALLUCINATING

Suggested Action	Rationale
1. "Mr. R., I don't see any snakes. It is time for lunch. I will walk to the dining room with you."	1. Lets the patient know you heard him, but brings him immediately into the reality of time of day and need to go to the dining room.
2. "I see a crack in the wall, Mr. R. It is harmless; you are safe. Susan is here to take you down to occupational therapy now."	2. This is in response to a probable illusion. It lets the patient know that you see something. It validates his fear, but it tells him what you see and then moves him into the here and now.
3. "I know that your thoughts seem very real to you, Ms. C., but they do not seem logical to me. I would like for you to come to your room and get dressed now, please."	3. Again, you are validating the patient's concern without exploring and focusing on the delusion.
4. "Ms. C, it appears to me that you are listening to someone. Are you hearing voices other than mine?"	4. This is a method of validating your impression of what you see. This is as far as you will go into exploring what she may be hearing.
5. "Thank you, Ms. C. I want to help you focus away from the other voices. I am real; they are not. Please come with me to the reading room."	5. Responds to her in the present and reinforces her response to you. Attempts to redirect her thinking.

Box 57.5**Schizophrenia Summary****Signs and Symptoms**

- Disorganized speech and behavior
- Ineffective thinking and decision making
- Trouble functioning at school and work; self-care deficits
- Positive symptoms: hallucinations, delusions
- Negative symptoms: apathy, flat affect, anhedonia

Diagnosis

History; psychiatric evaluation

Therapeutic Interventions

Antipsychotic medications, anticholinergic agents to control side effects, psychotherapy; family education and therapy

Nursing Diagnosis

Disturbed thought processes

CRITICAL THINKING**Anne**

■ While preparing to invite Anne, a patient receiving chemotherapy on your oncology unit, to a movie in the day room, you observe her standing in the corner of her room trembling. You ask her what's wrong and she responds that she's talking to the woman in the wall. Your first instinct is to giggle, but you ask her, "What woman?" She tells you that you wouldn't understand and says, "You helped put her there and you told me that it is my job to be sure she can't get out." You report this to the charge nurse, who calls the doctor. Tests are run, and it is determined that Anne is not experiencing side effects from the chemotherapy. Further work-up delivers the diagnosis of paranoid-type schizophrenia for Anne. What responses are appropriate for the situation above? What special needs might Anne now experience relating to her chemotherapy, if any? How will you get Anne to the movie or to participate in other care activities?

Suggested answers at end of chapter.

substance used (usually) for a long time. Withdrawal symptoms are specific to the substance used.

The general definitions of substance **abuse** and substance dependence apply to any substance. Substance **dependence** is a condition in which a person has several

(usually three) of the following symptoms for a single 12-month period. The patient:

- Needs more of the substance and at more frequent intervals to achieve the same "high," or desired effect of the substance.
- Spends significant time obtaining the substance.
- Gives up important social or professional functions to use the substance.
- Has tried at least once to quit but still obsesses about the substance.
- Experiences difficulty with job, family, or social activities because of use or withdrawal symptoms.
- Uses the substance regardless of the problems it causes.
- Uses the substance to avoid withdrawal symptoms.

Substance abuse is a maladaptive pattern of substance use leading to clinically significant impairment or distress manifested by one or more of the following within a 12-month period:

- Inability to fulfill major role obligations at work, school, or home
- Recurrent legal or interpersonal problems
- Continued use despite social and interpersonal problems
- Participation in physically hazardous situations while impaired, such as driving

Nurses need to be informed about chemical dependency for several reasons. First, many medical-surgical patients are chemically dependent. This affects their healing and the effect of their medications. Second, as part of the human experience, your chance of being in a close personal relationship with a person who is chemically dependent is great. Third, and perhaps most importantly, you are part of a profession whose members are statistically high users and abusers of drugs and alcohol (Box 57.6 Ethical Considerations). Studies indicate that anywhere from 5% to 20% of nurses in the United States will be chemically impaired at some point in their lifetime.

Substance abuse is not a one-person illness; it affects personal and professional relationships with people who are associated with the user. The term **dysfunctional** is often used to refer to the relationships within an alcoholic family or work environment. Dishonesty and inability to discuss the situation are strong components of the disease. Many times, people who live or work in the dysfunctional group begin to cover up for the user's behaviors and lack of responsibility. Family members or significant others may take sides, begin to be dishonest with each other, and erode the bond within that group. Eventually this leads to a condition called **codependence**, which can be as serious as the use and abuse of the substance. Codependent members of a family group begin to lose their own sense of identity and purpose and exist solely for the abuser. Their actions take away the opportunity for the user to take responsibility for his or her own actions. This is called *enabling*.

dysfunctional: dys—bad or difficult + functional—performance

Box 57.6

Ethical Considerations

Whistle Blowing

Ellen and Julie are LPNs who work on a busy medical unit in a large hospital. They were close friends in nursing school and have been working the night shift together for 3 years. Recently, Ellen went through a difficult and painful divorce, and Julie has noticed that Ellen's personality has changed. Ellen, usually serious and almost compulsive in the completion of her work, has taken on a very lackadaisical attitude and often calls in sick. She also displays hostility toward the hospital administration and seems very irritated when corrected. Julie has observed Ellen taking increasingly large doses of pain medication and fears her friend is losing control.

One evening, Ellen arrives at work with glassy eyes and slurred speech. She asks Julie to watch her patients for her while she "takes a little nap." Julie asks Ellen if she is abusing her pain medication, and after some initial denial, Ellen admits that she has been taking increasingly large doses of medication and alcohol to continue functioning from day to day. Ellen pleads with Julie not to tell anyone else about the problem. Because of their friendship, Julie consents to cover for Ellen this night.

The next night, Ellen again comes to work with obvious signs of intoxication. She again asks Julie to cover for her, swearing that this would be the absolute last time it would happen. Ellen falls asleep while listening to the taped report for the change of shifts. What should Julie do?

Etiological Theories

Why do some people become addicted or dependent and others do not? Can it be the chemical, or is it the person? Some theorists believe in the existence of an addictive personality, which may begin to explain addictions to food, sex, and gambling, as well as alcohol, chemicals, and other dependencies.

Psychoanalytical theorists believe that people who develop addictions to alcohol or other substances are people who failed to successfully pass through the "oral" stage of development.

Biological theories include numerous studies that imply that there is some sort of genetic metabolic disorder. Many of these studies were done on twins born to an alcoholic parent or parents and who were separated from the parents at birth or shortly after birth. The number of twins who were born of alcoholic parents but raised by nonalcoholic adoptive or foster parents and yet developed alcoholism was consistently elevated.

Cognitive-behavioral theorists suggest the way in which a person perceives being high may influence the act of becoming high. It can be a very innocent beginning:

obtaining relief from the medications given by the doctor can, according to cognitive theory, leave people perceiving that the drugs offer a miracle cure. It becomes appealing to want that kind of relief again, and very soon a pattern is formed and other substances may be added.

Differential Diagnosis

Commonly, the alcoholic patient is admitted to the medical unit with primary medical diagnoses including dehydration, hyperemesis, or respiratory infection. Nursing assessment, patient need for frequent pain medication, or symptoms of withdrawal may lead you or the physician to pursue the possibility of chemical dependency. Laboratory tests can rule out physiological problems; drug levels of alcohol or drugs can also be measured. A patient who is uncommonly anxious for early discharge should also be further assessed.

Types

ALCOHOL ABUSE AND DEPENDENCE. Use and abuse of alcohol is present in all walks of life, in all economic levels, and in both genders. Sometimes a very fine line exists between a person who is a social drinker and a person who has an abuse condition. One factor used to make that differentiation is the degree of need or compulsion to drink. There is a high incidence of alcohol use and abuse among the elderly, teenagers, and even younger children. Alcoholism either directly or indirectly decreases a person's life expectancy by an average of 10 to 12 years.

Denial is a common ego defense mechanism used by people who are substance abusers. The alcohol-dependent person often uses statements such as "I can quit anytime I want to" or "I just need a little bump to loosen me up."

Characteristics of dependence were described earlier. In addition, the alcoholic patients may experience:

- Binges usually lasting 2 days or more
- Blackouts (unable to recall what happened during period of drinking)
- Vomiting and dehydration
- Disorientation
- Increased vulnerability to infections, accidents, and other injuries

Sometimes patients who are actively using drugs or alcohol when admitted to an inpatient setting, or who are cut off from their alcohol abruptly, experience a condition called **delirium tremens** (DTs). In DTs, hyperexcitability in the sensory activity of the individual can cause visual hallucinations, tremors, and possibly tonic-clonic seizures. Elevated blood pressure and pulse and cardiac dysrhythmias may also occur. Symptoms of withdrawal begin within 4 to 12 hours after the patient has stopped drinking and will peak in 24 to 48 hours. Hospitalization is necessary to maintain the patient's safety.

Therapeutic Interventions for Alcohol Abuse and Dependence. Treatment for and recovery from alcohol dependency and abuse is a slow process. With very few exceptions, an alcoholic who is recovering cannot ever have

another drink, or he or she will risk the chance of returning to previous abusive patterns. Some treatment options are described below. Several forms of treatment may be used together.

Support Groups. A common and effective treatment for alcoholism is involvement in Alcoholics Anonymous (AA). AA is a 12-step program that offers support through others who have stopped drinking. For more information on AA, go to <http://www.alcoholics-anonymous.org>. Another program for women only is Women for Sobriety (www.womenforsobriety.org).

Cognitive Behavioral Therapy. Cognitive behavioral therapy (CBT) is used as an adjunct therapy for control of substance abuse. CBT advocates believe that with homework and practice, a person can learn to think differently about the event that led to the drinking. When the person changes the belief system about the activating event and the drinking, the consequences of drinking will be less powerful.

Psychotherapy. Psychotherapy provides one-on-one therapy. Because addiction affects an entire family, family therapy is important in reinstating honesty in communications. A commitment to stop drinking is required and therapy will only help with some of the issues resulting from years of drinking.

Medications. Medications are used cautiously because of risk for abuse. It is not always wise to substitute another chemical for alcohol. If, however, the anxiety level prohibits participation in therapy, or if a depressive disorder accompanies the abuse, medications may be prescribed. Antidepressant or nonaddictive antianxiety drugs are most often prescribed.

Disulfiram (Antabuse) is a medication that is sometimes prescribed as a deterrent to using alcohol. Disulfiram should never be administered without full informed consent of the patient. If the patient taking disulfiram ingests alcohol, a severe reaction causes chest pain, nausea, vomiting, confusion, and other symptoms. Persons taking disulfiram can also be adversely affected if they use products that contain alcohol, such as cologne, mouthwash, aftershave, or cough syrup. The effects of disulfiram last 2 to 3 weeks after the last dose.

Acamprosate (Campral) is a new drug that works on neurotransmitters to alter functions of other brain chemicals that have been affected by long-term drinking. Naltrexone (ReVia) may decrease alcohol cravings and impulsive behavior. Use of benzodiazepines (Valium, Ativan) can help prevent symptoms of DTs during acute withdrawal, but are not used long term because of risk for dependence.

Hospitalization. Therapy may range from in-house hospitalizations of 2 weeks or more to step down to halfway houses to eventual independence, usually attending AA meetings. It is common for patients to seek treatment multiple times. This should not be interpreted as a weakness in the individual or the treatment program. It is only a sign that the person is learning more about the disorder and the need to help him- or herself. People with all kinds of chronic disease experiences relapse at times.

Nursing Process for the Patient with Alcohol Abuse and Dependence

Assessment/Data Collection. A common screening tool to determine if a patient has a drinking problem is the CAGE questionnaire²:

- Have you ever felt you should *Cut down* on your drinking?
- Have people *Annoyed* you by criticizing your drinking?
- Have you ever felt bad or *Guilty* about your drinking?
- Have you ever had a drink first thing in the morning (as an “*Eye opener*”) to steady your nerves or get rid of a hangover?

A yes answer to two or more questions suggests a drinking problem.

Alcohol can also have many physiological effects on a patient. See Chapter 32 for assessment of patients with liver disorders.

Nursing Diagnosis, Planning, and Implementation. Nursing diagnoses include ineffective denial and ineffective coping.

EXPECTED OUTCOMES: The patient will accept responsibility for her or his behavior, verbalize acceptance of the relationship between substance abuse and personal problems, and will identify effects of alcohol on the body.

- Expect sobriety. *This establishes sobriety as the norm.*
- Identify recent behavior while under the influence. *Patients need to see the relationship between their substance use and their personal problems.*
- Teach about the physical impact of drugs and alcohol on the body. *Many patients lack correct information about the effects of substance abuse on the body.*
- Be honest. You need to be in touch with your own thoughts and feelings about addictions. *Effective communication is essential for a therapeutic relationship.*
- Provide group support such as a 12-step program. Many chemical dependency units provide group support meetings. *Peer support is an effective treatment that is often more acceptable to patients.*
- Confront the patient immediately if projection, rationalization, or denial behaviors are noted. *Projection, rationalization, and denial are ego defense mechanisms that discourage the patient from accepting responsibility for behavior.*
- Use positive reinforcement. *Positive reinforcement for successes is important when helping a person with an addiction. Every step is a big one in this field; every step taken is a new one.*
- Provide a safe environment. *Patients who are chemically addicted may become suicidal or display other bizarre behavior, especially during DTs. A patient under the influence of alcohol or another chemical may have poor impulse control or judg-*

ment. Maintaining a safe milieu and calm demeanor will help the patient through this difficult time.

- Remain alert to the possibility that the patient may be using a substance even in the hospital. Express suspicions honestly and nonjudgmentally to the patient. Report and document all findings and behaviors that may be potential safety issues for the patient. *The fact that a patient is hospitalized does not guarantee that he or she does not have access to the chemical or even use it in your presence. Unfortunately, family members or friends sometimes smuggle drugs or alcohol in to the patient.*
- Practice “tough love.” “Doing for” patients may be tempting, but it is not in the patient’s best interest most of the time. Praise and validate the patient’s attempts at self-responsible behavior and use therapeutic communication skills to constructively confront behaviors that are inconsistent with the plan of care. *This encourages patients to be responsible for their own healing.*

Evaluation. Does the patient verbalize acceptance of responsibility for own behavior? Does the patient understand the relationship between personal problems and substance abuse? Does the patient understand the effects of substance abuse on their body?

For additional information, go to the National Institute for Alcohol Abuse and Alcoholism at <http://www.niaaa.nih.gov/>.

DRUG ABUSE AND DEPENDENCE. Many substances other than alcohol can be addictive to humans. Caffeine and nicotine are two that are very readily available. Coffee, tea, soda, and cigarettes are everywhere in our society and yet are very addicting. Many experts believe that the single most difficult addiction to overcome is the addiction to nicotine. Illegal substances, such as marijuana, cocaine, crack, and PCP, and prescription medications for pain and mental health treatment are also potentially addictive. Methamphetamine (meth) is becoming a growing substance use/abuse problem affecting families and society.

It is also popular among the youth in the United States to use inhalants such as lighter fluid, paint, paint thinners, and gasoline to get high. The term for this is *huffing*. These are highly toxic substances, potentially lethal, and usually available in the house or garage.

Signs and Symptoms of Drug Abuse and Dependence. The signs and symptoms of drug abuse and dependence can be very similar to those of alcohol abuse. Additional signs of drug abuse include the following:

- Red, watery eyes
- Runny nose
- Hostile behavior
- Paranoia
- Needle tracks on arms or legs

Therapeutic Interventions for Patients with Drug Abuse and Dependence. These include:

- Narcotics Anonymous
- Group therapy

- Psychotherapy
- Methadone programs

Methadone acts as a sort of “step down” for people addicted to certain opiate drugs. Methadone can be legally prescribed and dispensed. It, too, is potentially addicting, and its critics believe it is only a substitute for heroin. It is typically given once a day. Psychotherapy is also provided for patients in methadone programs.

SAFETY TIP

To help prevent misuse of prescription medications:

Implement a process for obtaining and documenting a complete list of the client’s current medications upon the client’s entry to the organization and with the involvement of the client. This process includes a comparison of the medications the organization provides to those on the list.

A complete list of the client’s medications is communicated to the next provider of service when a client is referred or transferred to another setting, service, practitioner, or level of care within or outside the organization. (2006 National Patient Safety Goals from www.jcaho.org/.)

Nursing Interventions for Patients with Drug Abuse and Dependence. Nursing care for people who are drug dependent is essentially the same as for those who are alcohol dependent. It is important to remember that nurses and doctors cannot “fix” the patient who is chemically dependent. The desire to be chemically free must come from the individual who is addicted.

Caring for patients with mental health disorders is challenging and rewarding. You will learn that there are very few absolutes in the area of mental health nursing. There are many guidelines about the illnesses, but caring for the patients who have the illnesses is as individualized as the patients themselves. It is also important to remember to care for the whole person. The mind and body work together, so be sure to take care of the physical, emotional, cognitive, and behavioral parts of patients.

See Box 57.7 Substance Abuse Summary.

MENTAL ILLNESS AND THE OLDER ADULT

It is not uncommon for older adults to be admitted to the hospital for “change in mental status.” It is important to distinguish between physical and mental disorders in these circumstances. Some disorders that affect older adults’ mental status are below.

- *Dementia* is an impairment of mental functioning that interferes with daily activities and relationships.

Box 57.7**Substance Abuse Summary****Signs and Symptoms**

- Inability to fulfill obligations at work, school, or home
- Recurrent legal or interpersonal problems
- Continued use despite social and interpersonal problems
- Participation in physically hazardous situations while impaired

Diagnosis

History, liver function studies, serum drug or alcohol levels; evaluate for other coexisting disorders (bipolar disorder)

Therapeutic Interventions

12-step programs; cognitive behavioral therapy; psychotherapy; disulfiram (Antabuse), acamprosate (Campral), naltrexone (ReVia); benzodiazepines for acute withdrawal

Nursing Diagnosis

Ineffective denial, ineffective coping

Causes of dementia include Alzheimer's disease, vascular dementia, Huntington's disease, and others.

- *Delirium* is an acute change in mental status needing immediate evaluation and treatment. This is

often due to a physiological condition such as an infection, and can be reversed if recognized and the underlying condition corrected. Read more about dementia and delirium in Chapter 48.

- *Pseudodementia* is a condition in which the patient appears to have dementia but is really depressed. Treating the depression can help reverse the mental status changes.

Depression in the elderly should not be viewed as a normal part of aging; it should be diagnosed and treated. Older adults may be dealing with physical and mental decline, loss of function, isolation, and loss of a marriage partner and friends, and may express their depression through bodily complaints such as pain. If not evaluated and treated, depression may lead to suicide. (See Box 57.8 Suicide and the Older Adult). Be sure to review Chapter 14 Nursing Care of Older Adult Patients.

CRITICAL THINKING**Maria**

■ You are a school nurse in your local high school. You notice that Maria, a 17-year-old student, is behaving oddly. She has always been rather loud and even has been referred to as “obnoxious” by several of her peers. Lately you have observed her sitting alone, as if waiting for someone, but when you approach her, she barely greets you and then moves away. What are your concerns about Maria? What are some of the possibilities that might be affecting her? How can you approach her more effectively the next time you see her?

Suggested answers at end of chapter.

**Box 57.8****Gerontological Issues****Suicide and the Older Adult**

Older adults are not immune to suicidal thoughts. White males over the age of 75 have an especially high suicide rate.

Comments by any older adult referring to hopelessness or desire to die must be explored to assess suicide risk. The following comments could be a reflection of suicide potential in an older adult who is depressed:

- “Living is harder than dying could ever be.”
- “I am a used-up old man who is a burden for everyone.”
- “I am useless. I can't do anything anymore.”
- “I don't know why God won't take me.”

To adequately assess suicide potential, the nurse must ask questions that establish whether the older adult has done the following:

- Thought about ending his or her life
- Attempted to end his or her life in the past
- Developed a plan to end his or her life
- Set the plan into action (i.e., bought a gun, has a full bottle of pills in the bed stand)

Any older adult who has a plan to end his or her life and has the ability or resources to do so must be immediately referred for psychological evaluation. Never leave a person with suicidal thoughts alone.

Crisis Intervention for an Older Adult Who Is Suicidal

- Remove any items that the older adult could use to inflict an injury or end his or her life, such as razors, jewelry with pins or sharp points, and mirrors.

(Continued on following page)

Box 57.8 (Continued)

Gerontological Issues

- Make arrangements for direct supervision and observation that are reliable, considering personnel and family resources. Often, hospital admission is the most appropriate intervention for a person at a very high risk for suicide.
- Help the older adult talk about the crisis or life event that has devastated his or her desire to live. For example, encourage reminiscence about the patient's spouse, or allow the older person to express the frustration of being unable to physically meet the daily demands of life.
- Develop a "do no harm" or suicide contract with the older adult. Outline a short-term, structured plan to keep the older adult safe. Focus on decreasing social

isolation by requiring personal social contacts (e.g., stay at daughter's home for a weekend; go to the senior center for lunch; call a specific person who is willing and wants to listen to feelings and concerns; exercise; take a walk outside; volunteer services at a nursing home, hospital, or school).

Older adults often need assistance to develop or enhance skills required to cope with life events. Self-care and personal independence in care choices need to be encouraged. Developing an understanding and a manner of avoiding personal thinking patterns and behaviors that increase depression are important skills to learn as part of managing depression.

Home Health Hints

- Help patients and families identify pharmacies that will deliver medications.
- Set up medications using a system the patient can easily follow.
- Maintain communication with and act as a liaison between the psychiatrist and medical physician.
- Assist the patient and family to identify community resources such as support groups and respite care.
- Assess family members for evidence of caregiver role strain.
- Provide education for family/caregivers related to the patient's illness, medications, and symptom management.

ETHICAL CONSIDERATIONS DISCUSSION

The substance-abusing health professional is one of the most common situations nurses may encounter during their careers. It is estimated that about 40,000 nurses who work in the United States are alcoholics, and drug addiction among nurses is reported to be 30 to 100 times greater than among the general population. Nurses have easy access to drugs in most work settings. Other factors that contribute to the increased drug abuse among nurses include job stress, short staffing, double shifts, unrealistic expectations, frustration and anxiety, personal problems, and lack of autonomy in practice.

The drug-abusing nurse's colleagues may experience professional and emotional conflicts. Underlying the ethical dilemma is the right of the patient to safe and competent treatment versus the nurse's right to **self-determination**. However, the nurse does not have a totally unrestricted right to self-determination. This right has limits when it comes to endangering others, especially the patients assigned to this nurse for their care and safety. Although the National Association

for Practical Nurse Education and Services (NAP-NES) Code does not directly address any obligation to protect the public from practitioners who are unsafe, various elements that are related include faithfulness and responsibility with a general admonition to protect patients.

In this particular situation, Julie does have an obligation to do something about Ellen's drug problem. Covering for Ellen will not solve the problem. Julie should document Ellen's behavior and inform her supervisor. If the institution hierarchy does not take any action, Julie should submit the report to the state board of nursing. Some states have programs where health professionals can be helped without fear of losing their jobs or licenses, as long as they comply with treatment.

To allow Ellen to practice while under the influence of drugs puts Julie in a very serious legal position. If Ellen were to do something wrong and harm a patient and Julie knew that Ellen was under the influence of drugs, Julie could be held legally liable.

REVIEW QUESTIONS

- A patient believes his poor relationship with his mother when he was young is the primary cause of his schizophrenia. Which theory explains this belief?
 - Psychoanalytic theory
 - Genetic theory
 - Biological theory
 - Cognitive theory
- A patient suddenly and dramatically experiences a loss of vision. The onset of blindness doesn't seem to bother the patient. This person is most likely experiencing which of the following?
 - Posttraumatic stress disorder
 - Schizophrenia
 - Conversion disorder
 - Dissociative disorder
- If an extrapyramidal side effect such as dystonia occurs in the patient on antipsychotic medication, which of the following interventions might help?
 - Administer anticholinergic agents as ordered.
 - Discontinue the antipsychotic agent immediately.
 - Administer prn antianxiety agents as ordered.
 - Encourage progressive muscle relaxation and imagery.
- A patient who is a veteran of the Gulf War hears the hospital fire alarm go off during a drill and cries, "There are people hiding behind the pillars! They have guns! Be careful!" What action should the nurse take first?
 - Tell the patient that his behavior is inappropriate and that he is frightening the other patients.
 - Administer a prn antipsychotic medication as ordered.
 - Ask him if he is afraid of the guns.
 - Stay with the patient while calmly reorienting him.
- A patient is being treated on the mental health unit for a somatoform disorder. The patient approaches the nurse and says she feels dizzy, weak, and her heart is racing. Her nursing care plan includes interventions of imagery exercises and prn alprazolam (Xanax) for identified symptoms of anxiety. What should the nurse do first?
 - Instruct the patient to sit and breathe deeply.
 - Give the patient the prescribed prn Xanax.
 - Measure the patient's vital signs.
 - Instruct the patient in an imagery exercise.

SUGGESTED ANSWERS TO

CRITICAL THINKING

■ **Tommy**

You can reassure Tommy's mother that his OCD is not her fault. Tommy can learn to control his illness with medications and therapy. The family must be part of the therapy, for both Tommy's sake and the family's sake. Positive communication between Tommy and his family is encouraged. Tommy's mother can also be encouraged to attend a support group herself.

■ **Mr. Zenz**

It is important to be supportive of Mrs. Zenz while maintaining Mr. Zenz's confidentiality and privacy. Encouraging Mrs. Zenz to talk to Mr. Zenz's physician is appropriate. Showing empathy with statements such as, "It must be confusing and difficult to watch your husband change moods so quickly" are good tools to use. It may be a bit more challenging to approach him as your boss. You may certainly ask him if you can speak frankly and share specific observations. You may share your concern, such as "Mr. Zenz, you are a wonderful boss, but I am frightened when you become loud and boisterous." This may help him to reflect. Chances are, however, that if he is in manic stage, he will not hear your concern. It may require delicate talking to the next in the corporate chain of command. This is a tough one. Good luck!

■ **Anne**

Appropriate communication skills include being positive, reassuring, and not reinforcing the hallucinations. "I don't see or hear a woman, Anne. It is time for the movie. I'd like you to come with me for a while at least" is an example of an appropriate verbal interaction. Reinforcing expectations is also appropriate. "Anne, part of your care plan includes attending one major activity per day. This is the last opportunity for you to meet your care plan objective for today" is also acceptable. At all times, nurses need to be aware of drug interactions. Anne will most likely be medicated for her schizophrenia and those medications may interact unfavorably with her chemotherapy. Good nursing data collection skills are essential.

■ **Maria**

A number of options may explain Maria's behavior, including depression, drug use, schizophrenia, anorexia, or bulimia. Next time you see Maria you might try constructively confronting her behavior by saying something like, "Maria, you used to be much more outgoing. We always were friendly and now you leave when I'm near. That change in you concerns me. I'm here if you want to talk." Or, "Maria, I see your behavior is changing. You are loud one moment and very quiet the next. That is unusual for you. What is happening?"

North American Nursing Diagnosis Association (NANDA) Nursing Diagnoses

Activity Intolerance [specify level]	Family Processes: alcoholism, dysfunctional	Nutrition: more than body requirements, imbalanced
Activity Intolerance, risk for	Family Processes, interrupted	Nutrition: more than body requirements, risk for imbalanced
Adjustment, impaired	Family Processes, readiness for enhanced	Nutrition, readiness for enhanced

Troponin T	<0.20 µg/L	
Urea nitrogen (BUN)	8–21 mg/dL	2.9–7.5 mmol/L
Uric acid		
Male	4.4–7.6 mg/dL	0.26–0.45 mmol/L
Female	2.3–6.6 mg/dL	0.14–0.39 mmol/L

URINALYSIS

Reference Value:	
Dipstick pH	5.0–9.0
Protein	<20 mg/dL
Glucose	Negative
Ketones	Negative
Hemoglobin	Negative
Bilirubin	Negative
Urobilinogen	Up to 1 mg/dL
Nitrite	Negative
Leukocyte esterase	Negative
Microscopic examination	
Red blood cells	Less than 5/hpf
White blood cells	Less than 5/hpf
Renal cells	None seen
Transitional cells	None seen
Squamous cells	Rare; usually no clinical significance
Casts	Rare hyaline; otherwise, none seen
Crystals in acid urine	Uric acid, calcium oxalate, amorphous urates
Crystals in alkaline urine	Triple phosphate, calcium phosphate, ammonium biurate, calcium carbonate, amorphous phosphates
Bacteria, yeast, parasites	None seen

HEMATOLOGICAL VALUES

Determination	Reference Range					
	Conventional	SI				
Coagulation screening tests:						
Bleeding time (template)	2.5–10 minutes					
Prothrombin time	11–13.5 seconds					
<i>International Normalized Ratio (INR) = Less than 2.0 for patients not receiving anticoagulation therapy; 2.0 to 3.0 for patients receiving treatment for venous thrombosis, pulmonary embolism, and valvular heart disease; 2.5 to 3.5 for patients with mechanical heart valves and/or receiving treatment for recurrent systemic embolism.</i>						
Partial thromboplastin time (activated)	25–38 sec	25–38 sec				
Complete blood count (CBC)						
Hematocrit						
Male	43–49	0.43–0.49				
Female	38–44	0.38–0.44				
Hemoglobin						
Male	13.2–17.3 g/dL	132–173 mmol/L				
Female	11.7–15.5 g/dL	117–155 mmol/L				
White blood cell count and differential						
White Blood Cell Count and Differential	SI Units	Neutrophils	Lymphocytes	Monocytes	Eosinophils	Basophils
	WBC × 10 ³ /mm ³ or cells/mL	Total (Absolute) and %	Bands (Absolute) and %	Segments (Absolute) and %	(Absolute) and %	(Absolute) and %
Adult	4.5–11.0	(1.8–7.7) 59%	(0–0.7) 3.0%	(1.8–7.0) 56%	(1.0–4.8) 34%	(0–0.8) 4.0%
Erythrocyte count						
Male		4.71–5.14 million cells/mm ³			4.71–5.14 × 10 ¹² cells/L	
Female		4.20–4.87 million cells/mm ³			4.20–4.87 × 10 ¹² cells/L	
Red Blood Cell Indices			MCV (fl)	MCH (pg/cell)	MCHC (g/dL)	RDW
MCV = mean corpuscular volume; MCH = mean corpuscular hemoglobin; MCHC = mean corpuscular hemoglobin concentration; RDW = RBC distribution width index.						
Male			85–95	28–32	33–35	11.6–14.8
Female			85–95	28–32	33–35	11.6–14.8
Platelet count		150–450 × 10 ³ /μL/mm ³			181–521 × 10 ⁹ /L	

THERAPEUTIC DRUG LEVELS

Determination	Reference Range	
	Conventional	SI
Carbamazepine	4.0–12.0 mg/mL	17–51 μmol/L
Digoxin	0.5–2.0 ng/mL	0.6–2.6 nmol/L
Ethanol	0 mg/dL	0 mmol/L
Lithium	0.6–1.4 mEq/L	0.6–1.4 mmol/L
Phenobarbital	15–40 μg/mL	65–172 μmol/L
Phenytoin (Dilantin)	10–20 μg/mL	40–79 μmol/L
Salicylate	15–20 mg/dL	1.1–1.4 mmol/L

MISCELLANEOUS VALUES

Determination	Reference Range	
	Conventional	SI
Carcinoembryonic antigen (CEA)	0–2.5 ng/mL	0–2.5 μ g/L
Gastrin	25–90 pg/mL	25–90 ng/L
Immunologic tests:		
Alpha-1-antitrypsin	126–226 mg/dL	1.26–2.26 g/L
Antinuclear antibodies	Negative at a 1:8 dilution of serum	

Reference range values may differ from one institution to another. Most data from VanLeeuwen, A, Kranpitz, T, Smith, L: *Davis's Comprehensive Handbook of Laboratory and Diagnostic Tests with Nursing Implications*, 2/E. FA Davis: Philadelphia, 2005.

 Chapter 57: 1. a; 2. c; 3. a; 4. d; 5. c

Appendix D

Medical Abbreviations

ABG	arterial blood gas	lb.	pound
ac	before a meal	lmp	last menstrual period
AD	advance directive	mEq	milliequivalent
ad lib	freely; as desired	mg	milligram
ALT	alanine aminotransferase	mL	milliliter
AM	morning	mm	millimeter
A-P	anterior-posterior	MRI	magnetic resonance imaging
AST	aspartate aminotransferase	MS	mitral stenosis; multiple sclerosis
AV	atrioventricular	mEq	microequivalent
bid	twice a day	mg	microgram
BM	bowel movement	npo	nothing by mouth
BP	blood pressure	NSAID	nonsteroidal anti-inflammatory drug
BUN	blood urea nitrogen	NSR	normal sinus rhythm
c̄	with	OB	obstetrics
cap	a capsule	O.C.	oral contraceptive
CBC	complete blood count	O.D.	right eye
cc	cubic centimeter	O.S.	left eye
cm	centimeter	O.U.	both eyes
CNS	central nervous system	oz	ounce
CSF	cerebrospinal fluid	p̄	after
CV	cardiovascular	pc	after meals
D & C	dilatation and curettage	Pco ₂	carbon dioxide pressure
dc	discontinue	PERRLA	pupils equal, regular, react to light and accommodation
dL	deciliter	pH	hydrogen ion concentration
DNR	do not resuscitate	PM	afternoon/evening
DOA	dead on arrival	PMI	point of maximal impulse
dr	dram	post	posterior
Dx	diagnosis	pr	through the rectum
ECF	extracellular fluid	prn	as needed
ECG	electrocardiogram	qhr	every hour
ECT	electroconvulsive therapy	q2hr	every 2 hours
EEG	electroencephalogram	q3hr	every 3 hours
EMG	electromyogram	qid	four times a day
EMS	emergency medical service	qs	as much as is needed
ENT	ear, nose, and throat	RBC	red blood cell; red blood count
EOM	extraocular muscles	s	without
ER	Emergency Room	SA	sinoatrial
ESR	erythrocyte sedimentation rate	SC, sc,	subcutaneous(ly)
F	Fahrenheit	SOB	shortness of breath
g, gm	gram	s.o.s	if necessary
GERD	gastroesophageal reflux disease	sq	subcutaneous(ly)
GI	gastrointestinal	stat.	immediately
gr	grain	STD	sexually transmitted disease
Gtt, gtt	drops	T	temperature
GYN	gynecology	tab	medicated tablet
h, hr	hour	temp	temperature
hgb	hemoglobin	tid	three times a day
hor som, hs	bedtime	top	topically
IM	intramuscular	URI	upper respiratory infection
IUD	intrauterine device	USP	United States Pharmacopeia
IV	intravenous	UTI	urinary tract infection
IVP	intravenous pyelogram	WBC	white blood cell; white blood count
J	joule	WF/BF	white female/black female
kg	kilogram	WM/BM	white male/black male
KUB	kidney, ureter, and bladder	wt.	weight
L	liter

Prefixes, Suffixes, and Combining Forms

- a-, an-**. Without; away from; not.
ab-, abs-. From; away from; absent.
abdomin-, abdomino-. Abdomen.
-ad. Toward; in the direction of.
aden-, adeno-. Gland.
adip-, adipo-. Fat.
-aemia. Blood.
aer-, aero-. Air.
-algesia, -algia. Suffering; pain.
andro-. Man; male; masculine
angi-, angio-. Blood or lymph vessels.
aniso-. Unequal; asymmetrical; dissimilar.
ankyl-, ankylo-. Crooked; bent; fusion
 or growing together of parts.
ante-. Before.
antero-. Anterior; front; before.
ant-, anti-. Against.
arteri-, arterio-. Artery.
arthr-, arthro-. Joint.
-ase. Enzyme.
-asis, esis, -iasis, -isis, -sis. Condition;
 pathological state.
aut-, auto-. Self.
axo-. Axis; axon.
bacteri-, bacterio-. Bacteria; bacterium.
bi-, bis-. Two; double; twice.
bili-. Bile.
bio-. Life.
blast-, -blast. Germ; bud; embryonic state
 of development.
blephar-, blepharo-. Eyelid.
brady-. Slow.
bronch-, bronchi-, broncho-. Airway.
cardi-, cardio-. Heart.
cat-, cata-, cath-, kat-, kata-. Down;
 downward; destructive; against; accord-
 ing to.
cent-. Hundred.
cephal-, cephalo-. Head.
cervic-, cervice-. Head; the neck of an
 organ.
chrom-, chromo-. Color.
-cide. Causing death.
contra-. Against; opposite.
crani-, cranio-. Skull; cranium.
cry-, cryo-. Cold.
cyan-, cyano-. Blue.
cyst-, cysto-, -cyst. Cyst; urinary bladder.
cyt-, cyto-, -cyte. Cell.
derm-, derma-, dermato-, dermo-. Skin.
di-. Double; twice; two; apart from.
dors-, dorsi-, dorso-. Back.
-dynia. Pain.
dys-. Difficult; bad; painful.
ec-, ecto-. Out; on the outside.
-ectomy. Excision.
ef-, es-, ex-, exo-. Out.
electr-, electro-. Electricity.
-emesis. Vomiting.
-emia. Blood.
- en-**. In; into.
end-, endo-. Within.
ent-, ento-. Within; inside.
enter-, entero-. Intestine.
ep-, epi-. Upon; over; at; in addition to;
 after.
erythr-, erythro-. Red.
eury-. Broad.
ex-. Out; away from; completely.
exo-. Out; outside of; without.
extra-. Outside of; in addition;
 beyond.
-facient. Causing; making happen.
-ferous. Producing.
ferri-, ferro-. Iron.
fluo-. Flow.
fore-. Before; in front of.
-form. Form.
-fuge. To expel; to drive away; fleeing.
gaster-, gastero-, gastr-, gastro-
 Stomach.
gen-. Producing; forming.
-gen, -gene, -genesis, -genetic, -genic
 Producing; forming.
glosso-. Tongue.
gluc-, gluco-, glyc-, glyco-. Sugar; glyc-
 erol or similar substance.
gyn-, gyne-, gynec-, gyno-. Woman;
 female.
hem-, hema-, hemato-, hemo-. Blood.
hemi-. Half.
hepat-, hepato-. Liver.
heter-, hetero-. Other; different.
histo-. Tissue.
homo-. Same; likeness.
hydra-, hydro, hydr-. Water.
hyp-, hyph-, hypo-. Less than; below;
 under.
hyper-. Above; excessive; beyond.
hyster-, hystero-. Uterus.
-ia. Condition, esp. an abnormal state.
-iasis. SEE: *-asis*.
-iatic. Medicine; medical profession;
 physicians.
in-. In; inside; within; intensive action;
 negative.
infra-. Below; under; beneath; inferior to;
 after.
inter-. Between; in the midst.
intra-, intro-. Within; in; into.
ipsi-. Same.
irid-, irido-. Iris.
-ism. Condition; theory.
iso-. Equal.
-itis. Inflammation of.
kera-, kerato-. Horny substance; cornea.
kolp-, kolpo, colp-, colpo-. Vagina.
kypho-. Humped.
leuk-, leuko-. White; colorless; rel. to a
 leukocyte.
- lip-, lipo-**. Fat.
-lite, -lith, lith-, litho-. Stone; calculus.
-logia, -logy. Science of; study of.
lumbo-. Loins.
-lysis. 1. Setting free; disintegration.
 2. In medicine, reduction of; relief
 from.
macr-, macro-. Large; long.
mal-. Ill; bad; poor.
med-, medi-, medio-. Middle.
mega-, megal-, megal-. Large; of great
 size.
-megalia, -megaly. Enlargement of a
 body part.
melan-, melano-. Black.
mening-, meningo-. Meninges.
-meter. Measure.
metr-, metra-, metro-. Uterus.
micr-, micro-. Small.
mon-, mono-. Single; one.
muc-, muc-, muco-, myxa-, myxo-
 Mucus.
multi-. Many; much.
musculo-, my-, myo-. Muscle.
my-, myo-. SEE *musculo-*.
myel-, myelo-. Spinal cord; bone marrow.
naso-, nose-. Nose.
necr-, necro-. Death; necrosis.
neo-. New; recent.
neph-, nephra-, nephro-. Kidney.
neur-, neur-, neuro-. Nerve; nervous
 system.
non-. No.
normo-. Normal; usual.
oculo-. Eye.
-ode, -oid. Form; shape; resemblance.
-odynia, odyno-. Pain.
olig-, oligo-. Few; small.
-ology. Science of; study of.
-oma. Tumor.
onco-. Tumor; swelling; mass.
oo-, ovi-, ovo-. Egg; ovum.
oophor-, oophoro-, oophoron-. Ovary.
ophthalm-, ophthalm-. Eye.
-opia. Vision.
optico-, opto-. Eye; vision.
orchi-, orchid-, orchido-. Testicle.
orth-, ortho-. Straight; correct; normal;
 in proper order.
os-. Mouth; bone.
-osis. Condition; status, process; abnormal
 increase.
oste-, osteo-. Bone.
ostomosis, -ostomy, -stomosis, -stomy
 A created mouth or outlet.
ot-, oto-. Ear.
-otomy. Cutting.
-ous. 1. Possessing; full of; 2. Pertaining
 to.
pan-. All; entire.

para-, -para. 1. Prefix: near; alongside of; departure from normal. 2. Suffix: Bearing offspring.
path-, patho-, -path, -pathic, -pathy. Disease; suffering.
ped-, pedi-, pedo-. Foot.
-penia. Decrease from normal; deficiency.
peri-. Around; about.
perineo-. Perineum.
phaco-. Lens of the eye.
phag-, phago-. Eating; ingestion; devouring.
-phil, -philia, -philic. Love for; tendency toward; craving for.
phlebo-. Vein.
-phobia. Abnormal fear or aversion.
photo-. Light.
phren-, phreno-, -phrenia. Mind; diaphragm.
-phylaxis. Protection.
-plasia. Growth; cellular proliferation.
plasm-, -plasm. 1. Prefix: Living substance or tissue. 2. Suffix: To mold.
-plastic. Molded; indicates restoration of lost or badly formed features.
-plegia. Paralysis; stroke.
pneo-. Breath; breathing.
pneum-, pneuma-, pneumato-. Air; gas; respiration.

-poiesis, -poietic. Production; formation.
poly-. Much; many.
post-. After.
pre-. Before; in front of.
presby-. Old age.
pro-. Before; in behalf of.
proct-, procto-. Anus; rectum.
pseud-, pseudo-. False.
psych-, psycho-. Mind; mental processes.
pulmo-. Lung.
py-, pyo-. Pus.
pyro-. Heat; fire.
ren-, reno-. kidneys.
retro-. Backward; back; behind.
rheo-, -(r)rhea. Current; stream; to flow; to discharge.
rhino-. Nose.
-(r)rhage, -(r)rhagia. Rupture; profuse fluid discharge.
-(r)rhaphy. A suturing or stitching.
salping-, salpingo-. Auditory tube; fallopian tube.
sclero-. Hard; relating to the sclera.
-scopy. Examination.
semi-. Half.
sero-. Serum.
somat-, somato-. Body.
sperma-, spermat-, spermato-. Sperm; spermatozoa.
steno-. Narrow; short.

-stomosis, -stomy. SEE: *-ostomosis*.
sub-. Under; beneath; in small quantity; less than normal.
super-. Above; beyond; superior.
supra-. Above; beyond; on top.
tachy-. Swift; rapid.
tel-, tele-. 1. End. 2. Distant; far.
tendo-, teno-. Tendon.
thorac-, thoraci-, thoraco-. Chest; chest wall.
thrombo-. Blood clot; thrombus.
thyro-. Thyroid gland; oblong; shield.
-tomy. Cutting operation; excision.
top-, topo-. Place; locale.
tox-, toxi-, toxico-, toxo-, -toxic. Toxin; poison; toxic.
tracheo-. Trachea; windpipe.
trans-. Across; over; beyond; through.
-tropin. Stimulation of a target organ by a substance, esp. a hormone.
tympano-. Eardrum; tympanum.
ultra-. Beyond; excess.
-uria. Urine.
uter-, utero-. Uterus.
vaso-. Vessel (e. g., blood vessel).
veno-. Vein.
ventro-, ventr-, ventri-. Abdomen; anterior surface of the body.
vertebro-. Vertebra; vertebrae.
vesico-. Bladder; vesicle.

Glossary

- Ablation:** (uh-BLAY-shun) Removal of part, pathway, or function by surgery, chemical electrocautery, or radiofrequency.
- Abrasion:** (a-BRAY-zhun) A scraping away of skin or mucous membrane as a result of injury or by mechanical means.
- Abuse:** (uh-BYOOS) Misuse; excessive or improper use. May refer to substances or individuals.
- Accommodation:** (uh-KOM-uh-DAY-shun) A reflex action of the eye for focusing.
- Acidosis:** (ass-i-DOH-sis) An actual or relative increase in the acidity of blood caused by an accumulation of acid or a loss of base.
- Acquired immunodeficiency syndrome (AIDS):** (uh-KWHY-erd IM-yoo-noh-de-FISH-en-see SIN-droh-m) Suppression or deficiency of the cellular immune response, acquired by exposure to human immunodeficiency virus (HIV).
- Active immunity:** (AK-tiv im-YOO-ni-tee) Acquired immunity attributable to the presence of antibodies or of immune lymphoid cells formed in response to antigenic stimulus.
- Activities of daily living (ADLs):** (ak-TIV-i-tees of DAY-lee LIV-ing) Those activities and behaviors that are performed in the care and maintenance of self (e.g., bathing, dressing, eating).
- Acupuncture:** (ak-yoo-PUNGK-chur) Technique using needles inserted at specific points to create anesthesia or treat certain conditions.
- Acute coronary syndromes:** (a-KEWT KOR-un-na-ree sin-DROMES) Group of conditions, including unstable angina, non-Q wave myocardial infarction, and ST segment elevation myocardial infarction, caused by a lack of oxygen to the heart muscle.
- Acute pulmonary hypertension:** (ah-KEWT PULL-muh-NAIR-ee HIGH-per-TEN-shun) Sudden obstruction of the pulmonary artery causes excessive buildup of pressure in the pulmonary arteries.
- Adaptation:** (ad-dap-TAY-shun) Adjustment to changes in internal or external conditions or circumstances; coping.
- Addiction:** (uh-DIK-shun) Psychological dependence characterized by drug seeking and craving for an opioid or other substance for effects other than the intended purpose of the substance.
- Adjunct:** (ADD-junkt) An addition to the principal procedure or course of therapy.
- Adjuvant:** (ad-JOO-vant) Something that assists something else, such as a second form of treatment added to treat a disease.
- Administrative laws:** (ad-MIN-i-STRAY-tiv LAWZ) Establish the licensing authority of the state to create, license, and regulate the practice of nursing.
- Adnexa:** (ad-NECK-sah) Appendages or accessory organs.
- Advance Medical Directive:** (ad-VANS MED-ik-uhl dur-EK-tiv) A set of documents (Living Will and Durable Medical Power of Attorney) that explain a person's end-of-life wishes and direct care when the patient is no longer able to do so.
- Adventitious:** (ad-ven-TI-shus) Abnormal or extra; often refers to extra breath sounds, such as wheezes or crackles.
- Advocate:** (ADD-voh-kut) Someone who makes sure a person's wishes are adhered to; someone who represents the best interests of the patient.
- Aerobic:** (air-O-bick) Living only in the presence of oxygen.
- Affect:** (AF-feckt) Emotional tone.
- Afterload:** (AFF-ter-lohd) The forces impeding the blood flow out of the heart (vascular pressure, aortic compliance, blood mass, and viscosity).
- Agensis:** (ay-JEN-uh-sis) Failure of an organ or part to develop or grow.
- Agonist:** (AG-un-ist) A type of opioid that binds to opioid receptors in the central nervous system to relieve pain.
- Akinesia:** (a-ki-NEE-zee-ah) Absence or loss of the power of voluntary movement.
- Alkalosis:** (al-ka-LOH-sis) An actual or relative decrease in the acidity of blood caused by loss of acid or accumulation of base.
- Allopathic:** (AL-oh-PATH-ik) Method of treating disease with remedies that produce effects different from those caused by the disease.
- Alopecia:** (AL-oh-PEE-she-ah) The loss of hair from the body and the scalp.
- Amenorrhea:** (ay-MEN-uh-REE-ah) The absence or suppression of menstruation. Amenorrhea is normal before puberty, after menopause, and during pregnancy and lactation.
- Amputation:** (am-pew-TAY-shun) The removal of a limb or other appendage or outgrowth of the body.
- Anaerobic:** (AN-air-ROH-bik) Able to live without oxygen.
- Analgesic:** (AN-uhl-JEE-zik) A drug that relieves pain.
- Anaphylactic shock:** (AN-uh-fi-LAK-tik) Systemic reaction that produces life-threatening changes in the circulation and bronchioles.
- Anaphylaxis:** (AN-uh-fi-LAK-sis) A sudden severe allergic reaction.
- Anastomose:** (uh-NAS-tuh-MOS) To surgically connect two parts.
- Anemia:** (uh-NEE-mee-yah) A condition in which there is reduced delivery of oxygen to the tissues as a result of reduced numbers of red cells or hemoglobin.
- Energy:** (AN-er-jee) Diminished ability of the immune system to react to an antigen.
- Anesthesia:** (AN-es-THEE-zee-uh) Lack of feeling or sensation; artificially induced loss of ability to feel pain.
- Anesthesiologist:** (an-es-THEE-zee-uh-la-just) A physician who specializes in anesthesiology.
- Aneurysm:** (AN-yur-izm) A sac formed by the localized dilation of the wall of an artery, a vein, or the heart.
- Angina pectoris:** (an-JIGH-nah PEK-tuh-riss) Severe pain and pressure in the chest caused by insufficient supply of blood and oxygenation to the heart.
- Angioedema:** (AN-gee-o-eh-DEE-ma) A localized edematous reaction of the deep dermis or subcutaneous or submucosal tissues appearing as giant wheals.
- Anion:** (AN-eye-on) Electrolyte that carries a negative electrical charge.
- Anisocoria:** (an-i-soh-KOH-ree-ah) Inequality in size of the pupils of the eyes.
- Ankylosing spondylitis:** (ANG-ki-LOH-sing SPON-da-LIGHT-is) Inflammatory disease of the spine causing stiffness and pain.
- Annuloplasty:** (AN-yoo-loh-PLAS-tee) Repair of a cardiac valve.
- Anorexia:** (AN-oh-REK-see-ah) Absence or loss of appetite for food. Seen in depression, with illness, and as a side effect of some medications.
- Anorexia nervosa:** (AN-oh-REK-see-ah ner-VOH-sah) Refusal to maintain body weight over a minimal normal weight for age and height.
- Antagonist:** (an-TAG-on-ist) Medication used to counteract the effects of an opioid (e.g., naloxone).

- Anteflexion:** (AN-tee-FLECK-shun) The abnormal bending forward of part of an organ.
- Anteversion:** (AN-tee-VER-zhun) A tipping forward of an organ as a whole, without bending.
- Anthrax:** (AN-thrax) A disease caused by the spore-forming bacterium *Bacillus anthracis* that has three clinical forms in humans: inhalational, cutaneous, and gastrointestinal. It can be used as a biological weapon.
- Antibodies:** (AN-ti-baw-dees) An immunoglobulin molecule having a specific amino acid sequence that gives each antibody the ability to adhere to and interact only with the antigen that induced the synthesis.
- Anticholinesterase:** (AN-ti-KOH-lin-ESS-ter-ays) A substance that breaks down acetylcholinesterase.
- Antidiuretic:** (AN-ti-DYE-yoo-RET-ik) Lessening urine excretion.
- Antigen:** (AN-tih-jen) A protein marker on the surface of cells that identifies the type of cell.
- Antitussive:** (an-tee-TUSS-iv) An agent that prevents or relieves cough.
- Anuria:** (an-YOO-ree-ah) Complete suppression of urine formation by the kidney.
- Anxiety:** (ang-ZIGH-uh-tee) The uncomfortable feeling of apprehension or dread that occurs in response to a known or unknown threat.
- Aphasia:** (ah-FAY-zee-ah) Defect or loss of the power of expression by speech, writing, or signs, or of comprehension of spoken or written language, caused by disease or injury of the brain centers, such as stroke syndrome.
- Apthous stomatitis:** (AF-thus STOH-mah-TIGH-tis) Small, white, painful ulcers (also known as canker sores) that appear on the inner cheeks, lips, gums, tongue, palate, and pharynx. They tend to recur.
- Apnea:** (ap-NEE-ah) Temporary absence of breathing.
- Appendicitis:** (uh-PEN-di-SIGH-tis) Inflammation of the vermiform appendix.
- Arcus senilis:** (AR-kus se-NILL-us) A benign white or gray opaque ring in the corneal margin of the eye.
- Arrhythmia:** (uh-RITH-mee-yah) Irregular rhythm, especially heart-beat.
- Arteriosclerosis:** (ar-TIR-ee-oh-skle-ROH-sis) Term applied to a number of pathological conditions in which there is gradual thickening, hardening, and loss of elasticity of the walls of the arteries.
- Arthritis:** (are-THRYE-tis) Inflammation of a joint.
- Arthrocentesis:** (ar-THROW-sen-tee-sis) Puncture of a joint space with a needle to remove fluid accumulated in the joint.
- Arthroplasty:** (AR-throw-PLAS-te) Repair of a joint. Also called joint replacement.
- Arthroscopy:** (are-THROSS-scop-ee) Examination of the interior of a joint with an arthroscope.
- Articular:** (ar-TIK-yoo-lar) Pertaining to a joint.
- Artificial feeding:** (ART-ih-FISH-uhl FEE-ding) Feeding via a tube into the stomach or intestine when a person is unable to take oral nutrition.
- Artificial hydration:** (ART-ih-FISH-uhl hy-DRAY-shun) Administration of water via intravenous or gastric tube when a person is unable to take oral fluids.
- Ascites:** (a-SIGH-teez) Abnormal accumulation of fluid in the peritoneal cavity.
- Asepsis:** (ah-SEP-sis) A condition free from germs, infection, and any form of life.
- Aseptic:** (ah-SEP-tik) Free of pathogenic organisms; asepsis.
- Asphyxia:** (as-FIX-ee-a) A condition in which there is a deficiency of oxygen in the blood and an increase in carbon dioxide in the blood and tissues.
- Aspiration:** (ASS-pi-RAY-shun) Accidental drawing in of foreign substances into the throat or lungs during inspiration.
- Assessment:** (ah-SESS-ment) An appraisal or evaluation of a patient's condition.
- Asterixis:** (AS-ter-ICK-sis) Hand flapping tremor and involuntary movements of tongue and feet; may be present in hepatic encephalopathy.
- Astigmatism:** (uh-STIG-mah-TIZM) An error of refraction in which a ray of light is not sharply focused on the retina but is spread over a more or less diffuse area.
- Ataxia:** (ah-TAK-see-ah) Failure of muscular coordination; irregularity of muscular action.
- Atelectasis:** (AT-e-LEK-tah-sis) Collapsed or airless condition of the lung or portion of lung, caused by obstruction or hypoventilation.
- Atheroma:** (ATH-er-OMA) Fatty deterioration or thickening of the walls of the larger arteries occurring in atherosclerosis.
- Atherosclerosis:** (ATH-er-oh-skle-ROH-sis) A form of arteriosclerosis characterized by accumulation of plaque, blood, and blood products lining the wall of the artery, causing partial or complete blockage of an artery.
- Atrial depolarization:** (AY-tree-uhl DE-poh-lahr-i-ZAY-shun) Electrical activation of the atria.
- Atrial systole:** (AY-tree-uhl SIS-tuh-lee) The contraction of the atria.
- Atrioventricular node:** (AY-tree-oh-ven-TRICK-yoo-lar NOHD) Located in lower right atrium; receives an impulse from the sinoatrial (SA) node and relays it to the ventricles.
- Atrophy:** (AT-ruh-fee) Without nourishment; wasting.
- Atypical:** (ay-TIP-i-kuhl) Deviating from normal.
- Augmentation:** (AWG-men-TAY-shun) The act or process of increasing in size, quantity, degree or severity.
- Auscultation:** (AWS-kul-TAY-shun) Process of listening for sounds within the body, usually sounds of thoracic or abdominal viscera, to detect an abnormality.
- Autoimmune:** (AW-toh-im-YOON) A condition in which the body does not recognize itself and the immune system attacks normal cells.
- Ayurvedic:** (AY-YUR-VAY-dik) An ancient Hindu system of medicine that improves health by harmonizing mind and body.
- Azotemia:** (AY-zoh-TEE-me-ah) An increase in nitrogenous bodies in the blood, especially urea, as measured by the serum blood urea nitrogen (BUN) level.
- Bacteria:** (back-TEER-e-ah) One-celled organisms that can reproduce but need a host for food and supportive environment. Bacteria can be harmless, normal flora, or disease-producing pathogens.
- Balanitis:** (BAL-uh-NIGH-tis) Inflammation of the skin covering the glans penis.
- Bariatric:** (BAR-ry-AT-rick) Branch of medicine that deals with the prevention, control, and treatment of obesity.
- Basal cell secretion test:** (BAY-zuhl SELL see-KREE-shun TEST) Part of a gastric analysis; measures the amount of gastric acid produced in 1 hour.
- Behavior management:** (be-HAYV-er MAN-ij-ment) Treatment method that uses positive and negative reinforcement to alter behavior.
- Belief:** (bee-LEEF) Something accepted as true. Does not have to be proven.
- Beneficence:** (buh-NEF-i-sens) To provide good care; to do good for patients. One of the oldest requirements for health care providers.
- Benign:** (bee-NINE) Not progressive; for example, a tumor that is not cancerous.
- Beta-hemolytic streptococci:** (BAY-tuh-HEE-moh-LIT-ick STREP-toh-KOCK-sigh) Gram-positive bacteria that, when grown on blood-agar plates, completely hemolyze the blood and produce a clear zone around the bacteria colony. Group A beta-hemolytic streptococci cause disease in humans.
- Bigeminy:** (bye-JEM-i-nee) Occurring every second beat, as in bigeminal premature ventricular contractions.
- Bilateral salpingo-oophorectomy:** (by-LAT-er-uhl sal-PINJ-oh-ah-fuh-RECK-

- tuh-mee) Surgical removal of both fallopian tubes and ovaries.
- Bimanual:** (by-MAN-yoo-uhl) With both hands.
- Biofeedback:** (BYE-oh-FEED-bak) A form of therapy that uses provision of visual or auditory evidence to a person of the status of an autonomic body function such as heart rate, blood pressure, or respiratory rate.
- Biopsy:** (BY-ahp-see) A sample of tissue removed for examination.
- Bioterrorism** (BYE-oh-TER-oh-RIZ-um) Biological agent use or threat of use with a pathological organism for terrorist purposes.
- Bipolar:** (bye-POH-ler) Having two poles or pertaining to both poles. Bipolar disorder is characterized by episodes of manic and depressive behavior.
- Blanch:** (BLANCH) To lose color.
- Bleb:** (BLEB) An irregularly shaped elevation of the skin, such as a blister. May also occur in lung tissue.
- Blepharitis:** (BLEF-uh-RIGH-tis) Inflammation of the glands and lash follicles along the margin of the eyelids.
- Blindness:** (BLYND-ness) Lack or loss of ability to see.
- Bolus:** (BOH-lus) A dose of intravenous medication injected all at once.
- Bone:** (BOWN) The hard, rigid form of connective tissue constituting most of the skeleton of vertebrates, composed chiefly of calcium salts.
- Botulism** (BOTCH-u-liz-um) A paralytic illness caused by a potent neurotoxin produced by *Clostridium botulinum*, an anaerobic, spore-forming bacterium. It can be used as a biological weapon.
- Bowel sounds:** (BOW'L SOWNDS) Gurgling and clicking sounds heard over the abdomen caused by air and fluid movement from peristaltic action. Normal bowel sounds occur every 5 to 15 seconds at a rate of 5 to 35 sounds per minute. Absent—no bowel sounds heard after 5 minutes of listening in each quadrant. Hyperactive—bowel sounds that are frequent, high-pitched, and loud. Hypoactive—bowel sounds that occur at a rate of one every minute or longer.
- Bradycardia:** (BRAY-dee-KAR-dee-yah) A slow heartbeat characterized by a pulse rate below 60 beats per minute.
- Bradykinesia:** (BRAY-dee-kin-EE-zee-ah) Abnormal slowness of movement; sluggishness.
- Breakthrough pain:** (BRAYK-throo) Pain that occurs while medicated with long-acting analgesics.
- Bronchiectasis:** (BRONG-key-EK-tah-sis) Chronic dilation of a bronchus or bronchi, usually associated with secondary infection and excessive sputum production.
- Bronchitis:** (brong-KIGH-tis) Inflammation of the mucous membrane of the bronchial airways; may be viral or bacterial.
- Bronchodilator:** (BRONG-koh-DYE-lay-ter) A drug that expands the bronchial tubes by relaxing bronchial smooth muscle.
- Bronchospasm:** (BRONG-koh-spazm) Spasm of the bronchial smooth muscle resulting in narrowing of the airways; associated with asthma and bronchitis.
- Bruit:** (BROUT) A humming heard when auscultating a blood vessel that is caused by turbulent blood flow through the vessel.
- Bulimia nervosa:** (buh-LEE-mee-ah ner-VOH-sah) Recurrent episodes of binge eating and self-induced vomiting.
- Bulla:** (BUHL-ah) A large blister or skin lesion filled with fluid. May also occur in lung tissue.)
- Bundle of His:** (BUN-duhl of HISS) A bundle of fibers of the impulse-conducting system of the heart. Originates in the atrioventricular (AV) node.
- Bursae:** (BURR-sah) A small fluid-filled sac or saclike cavity situated in tissues such as joints where friction would otherwise occur.
- Calculi:** (KAL-kyoo-lye) An abnormal concentration, usually composed of mineral salts, occurring within the body, chiefly in the hollow organs or their passages. Also called stones, as in kidney stones and gallstones.
- Cancer:** (KAN-sir) A general name for over 100 diseases in which abnormal cells grow out of control; a malignant tumor.
- Cannula:** (KAN-yoo-lah) A flexible tube that can be inserted into the body guided by a stiff, pointed rod. For example, an intravenous cannula is guided by a metal needle.
- Capillary permeability:** (KAP-i-lar-ee PER-me-a-BILL-i-tee) The ability of substances to diffuse through capillary walls into tissue spaces.
- Capillary refill:** (KAP-i-lar-ee RE-fill) The amount of time required for color to return to the nailbed after having been compressed; normally 3 seconds or less. Indicator of peripheral circulation.
- Caput medusae:** (KAP-ut mi-DOO-see) Dilated veins around the umbilicus, associated with cirrhosis of the liver.
- Carbuncle:** (KAR-bung-kull) A necrotizing infection of skin and subcutaneous tissue composed of a cluster of boils.
- Carcinoembryonic antigens (CEA):** (KAR-sin-oh-EM-bree-ah-nik AN-ti-jens) A class of antigens normally present in fetal cells; CEA level is elevated in many cancers and is measured to guide cancer treatment.
- Carcinogen:** (kar-SIN-oh-jen) Specific agent known to promote the cancer process.
- Cardiac output:** (KAR-dee-yak OWT-put) A measure of the pumping ability of the heart; amount of blood pumped by the heart per minute.
- Cardiac tamponade:** (KAR-dee-yak TAM-pon-AID) The life-threatening compression of the heart by the fluid accumulating in the pericardial sac surrounding the heart.
- Cardiogenic shock:** (KAR-dee-o-JEN-ick SHOCK) Occurs when the heart muscle is unhealthy and contractility is impaired.
- Cardiomegaly:** (KAR-dee-oh-MEG-ah-lee) Enlargement of the heart.
- Cardiomyopathy:** (KAR-dee-oh-my-AH-pah-thee) A group of diseases that affect the myocardium's (heart muscle's) structure or function.
- Cardioplegia:** (KAR-dee-oh-PLLEE-jee-ah) Arrest of myocardial contraction, as by use of chemical compounds or cold temperatures in cardiac surgery.
- Cardioversion:** (KAR-dee-oh-VER-zhun) An elective procedure in which a synchronized shock is delivered to attempt to restore the heart to a normal sinus rhythm.
- Cataract:** (KAT-uh-rakt) Opacity of the lens of the eye.
- Cation:** (KAT-eye-on) Electrolyte that carries a positive electrical charge.
- Ceiling effect:** (SEE-ling e-FEKT) The dose of medication at which the maximum therapeutic effect is achieved. Increasing the dose beyond the therapeutic dose will not result in increased relief and may result in undesirable side effects.
- Cell-mediated immunity:** (SELL ME-dee-ay-ted im-YOO-ni-tee) Production of lymphocytes by thymus in response to antigen exposure.
- Cellulitis:** (sell-yoo-LYE-tis) Inflammation of cellular or connective tissue.
- Cerebrovascular:** (SER-ee-broh-VAS-kyoo-lur) Pertaining to the blood vessels of the cerebrum or brain.
- Chalazion:** (kah-LAY-zee-on) A small eyelid mass resulting from chronic inflammation of a meibomian gland.
- Chancre:** (SHANK-er) A hard, syphilitic primary ulcer, the first sign of syphilis, appearing approximately 2 to 3 weeks after infection.
- Chemotherapy:** (KEE-moh-THER-uh-pee) The treatment of disease with medication; often refers to cancer therapy.
- Chiropractic:** (ky-RUH-prak-tik) Treatment modality that uses manual adjustment of the vertebral column and extremities to remove interference with nerve function.
- Cholecystitis:** (KOH-lee-sis-TIGH-tis) Inflammation of the gallbladder.
- Cholelithiasis:** (koh-LED-oh-koh-li-THIGH-ah-sis) Gallstones in the common bile duct.

- Choledochoscopy:** (KOH-LED-oh-KOS-koh-pee) An endoscopic test of the gallbladder and common bile duct.
- Cholelithiasis:** (KOH-lee-li-THIGH-ah-sis) Gallstones in the gallbladder.
- Chorea:** (kaw-REE-ah) A nervous condition marked by involuntary muscular twitching of the limbs or facial muscles.
- Chronic illness:** (KRAH-nick ILL-ness) An illness that is long-lasting or recurring, which usually interferes with a person's ability to perform activities of daily living. Medical care and hospitalization are often required on an ongoing basis.
- Circumcise:** (SIR-kuhm-size) Surgical removal of the foreskin covering the head of the penis.
- Cirrhosis:** (si-ROH-sis) Chronic disease of the liver, associated with fat infiltration and development of fibrotic tissue.
- Civil law:** (SIV-il LAW) Provides the rules by which individuals seek to protect their personal and property rights.
- Claudication:** (KLaw-di-KAY-shun) Severe pain in the calf muscle from inadequate blood supply.
- Clubbing:** (KLUB-ing) A condition in which the ends of the fingers and toes appear bulbous and shiny, most often the result of lung disease.
- Cochlear implant:** (KOK-lee-er IM-plant) A device consisting of a microphone, signal processor, external transmitter, and implanted receiver to aid hearing.
- Code of ethics:** (KOHD of ETH-icks) A traditional compilation of ideal behaviors of a professional group.
- Codependence:** (KO-de-PEN-dense) A situation in which the significant others in a family group begin to lose their own sense of identity and purpose and exist solely for the abuser.
- Cognitive:** (KAHG-ni-tiv). The ability to think rationally and to process thoughts.
- Colectomy:** (koh-LEK-tuh-me) Excision of the colon or a portion of it.
- Colic:** (KAH-lick) Spasm of a hollow organ or duct, causing pain.
- Colitis:** (koh-LYE-tis) Inflammation of the colon.
- Collateral circulation:** (koh-LA-ter-al SIR-kew-LAY-shun) Small branches off of larger blood vessels that will increase in size and capacity next to a main blood vessel that is obstructed.
- Colonization:** (COLLIN-i-ZAY-shun) The presence of pathogenic microbes in the body, without development of a symptomatic infection.
- Colonoscopy:** (KOH-lun-AHS-kuh-pee) Examination of the upper portion of the rectum with a colonoscope.
- Colostomy:** (koh-LAH-stuh-me) An artificial opening (stoma) created in the large intestine and brought to the surface of the abdomen for evacuating the bowels.
- Colporrhaphy:** (kohl-POOR-ah-fee) Surgical repair of the vagina.
- Colposcopy:** (kul-POS-koh-pee) Examination of the vulva, vagina, and cervix by means of a magnifying lens and a bright light.
- Comedone:** (KOH-me-doh) Skin lesion that occurs in acne vulgaris (closed form: whitehead; open form: black-head).
- Commissurotomy:** (KOM-i-shur-AHT-oh-mee) Surgical incision of any commissure as in cardiac valves to increase the size of the orifice.
- Compliance:** (kom-PLIGH-ens) The ability to alter size or shape in response to an outside force; the ability of the lungs to distend.
- Compulsion:** (kum-PUHL-shun) A recurrent, unwanted, and distressing urge to perform an act.
- Conductive hearing loss:** (kon-DUK-tiv HEER-ing LOSS) Impaired transmission of sound waves through the external ear canal to the bones of the middle ear.
- Condylomata acuminata:** (KON-di-LOH-ma-tah ah-KYOOM-in-AH-tah) Warts in the genital region caused by the human papillomavirus (HPV); a contagious sexually transmitted disease.
- Condylomatous:** (KON-di-LOH-ma-tus) Pertaining to a condyloma.
- Confidentiality:** (KON-fi-den-she-AL-i-tee) Maintaining privacy of patient information. Patient and patient's care can be discussed only in the professional setting.
- Congestive heart failure:** (kon-JESS-tive HART FAIL-yur) Results from inability of heart to pump sufficient amounts of blood because of impaired pumping function and sodium and water retention. Congestion refers to the buildup of fluid that ranges from mild to life-threatening (pulmonary edema). With left-sided heart failure, the fluid buildup occurs in the lungs and if severe, immediate treatment is required or death can occur. With right-sided heart failure, the fluid buildup is seen systemically (lower legs/feet, sacral area in bedridden persons, jugular veins, liver, spleen).
- Conization:** (KOH-ni-ZAY-shun) The removal of a cone of tissue, as in partial excision of the cervix uteri.
- Conjunctivitis:** (kon-JUNK-ti-VIGH-tis) Inflammation of the conjunctiva of the eye.
- Consensual response:** (kon-SEN-shoo-uhl ree-SPONS) Reaction of both pupils when one eye is exposed to greater intensity of light than the other.
- Constipation:** (KON-sti-PAY-shun) A condition of sluggish or difficult bowel action/evacuation.
- Contraceptive:** (KON-truh-SEP-tiv) Any process, device, or method that prevents conception.
- Contracture:** (kon-TRACK-chur) Abnormal accumulation of fibrosis connective tissue in skin, muscle, or joint capsule that prevents normal mobility at that site.
- Contralateral:** (KON-truh-LAT-er-uhl) Originating in or affecting the opposite side of the body.
- Conversion disorder:** (kon-VER-zhun dis-OR-der) An illness that emerges from overuse of the conversion reaction defense mechanism, in which there is impaired physical functioning that appears to be neurological, but no organic disease can be identified.
- Coping:** (KOH-ping) The process of contending with the stresses of daily life in an effort to overcome or work through them.
- Coronary artery disease:** (KOR-uh-naree AR-tuh-ree di-ZEEZ) Narrowing of the coronary arteries sufficient to prevent adequate blood supply to the myocardium.
- Cor pulmonale:** (KOR PUL-mah-NAH-lee) Hypertrophy or failure of the right ventricle from disorders of the chest wall, lungs, and pulmonary vessels, as with increased pulmonary pressure caused by chronic obstructive pulmonary disease (COPD).
- Craniectomy:** (KRAY-nee-EK-tuh-me) Excision of a segment of the skull.
- Cranioplasty:** (KRAY-nee-oh-plas-tee) Any plastic repair operation on the skull.
- Craniotomy:** (KRAY-nee-AHT-oh-mee) Any incision through the cranium.
- Crepitation:** (crep-i-TAY-shun) A dry, crackling sound or sensation, such as that produced by the grating of the ends of a fractured bone.
- Crepitus:** (KREP-i-tuss) Crepitation.
- Criminal law:** (KRIM-i-nuhl LAW) Regulates behaviors for citizens within a country.
- Critical thinking:** (KRIT-i-kuhl THING-king) Use of knowledge and skills to make the best decisions possible in client care situations.
- Cryotherapy:** (KRY-oh-THER-uh-pee) The therapeutic use of cold.
- Cryptorchidism:** (kript-OR-ki-dizm) A birth condition in which one or both of the testicles have not descended into the scrotum.
- Culdocentesis:** (KUL-doh-sen-TEE-sis) The procedure for obtaining material from the posterior vaginal cul-de-sac by aspiration or surgical incision through the vaginal wall, performed for therapeutic or diagnostic reasons.

- Culdoscopy:** (kul-DOS-koh-pee) Direct visual examination of the female viscera through an endoscope introduced into the pelvic cavity through the posterior vaginal fornix.
- Culdotomy:** (KUL-DOT-uh-mee) Incision or needle puncture of the cul-de-sac of Douglas through the vagina.
- Cultural awareness:** (KUL-chur-uhl a-WARE-ness) Being aware of history and ancestry and having an appreciation of and attention to the crafts, arts, music, foods, and clothing of various cultures.
- Cultural competence:** (KUL-chur-uhl KOM-pe-tens) Having an awareness of one's own culture and not letting it have an undue influence over another person's culture. Having the knowledge and skills about a culture that are required to provide care.
- Cultural diversity:** (KUL-chur-uhl di-VER-si-tee) Representing two or more cultures; the differences among cultures. For example, the United States includes people from many different countries.
- Cultural sensitivity:** (KUL-chur-uhl SEN-si-TIV-i-tee) Being aware of and sensitive to cultural differences. Avoiding behavior or language that may be offensive to another person's cultural beliefs.
- Culture:** (KUL-chur) The socially transmitted behavior patterns, beliefs, values, customs, arts, and all other characteristics of people that guide their worldview.
- Curet:** (kyoo-RET) A loop, ring, or spoon-shaped instrument, attached to a handle and having sharp or blunt edges; used to scrape tissue from a surface.
- Custom:** (KUS-tum) A custom is the usual way of acting in a given circumstance or something that an individual or group does out of habit. For example, many people eat turkey on Thanksgiving.
- Cyanosis:** (SIGH-uh-NOH-sis) Slightly bluish, grayish, or dark purple discoloration of the skin caused by the presence of abnormal amounts of reduced hemoglobin in the blood.
- Cystic:** (SIS-tik) Pertaining to cysts or the urinary bladder.
- Cystitis:** (sis-TIGH-tis) Inflammation of the urinary bladder.
- Cystocele:** (SIS-toh-seel) A bladder hernia that protrudes into the vagina.
- Cystoscopy:** (sis-TAHS-koh-pee) A diagnostic procedure using an instrument (cystoscope) via the urethra to view the bladder.
- Cytomegalovirus:** (sigh-TOW-meg-ul-low-vigh-rus) Species-specific herpesvirus; usually harmless to those with functional immune systems. May cause fatal pneumonia in those who are immunocompromised. Affects retina and may cause blindness in those with acquired immunodeficiency syndrome.
- Cytotoxic:** (SIGH-toh-TOCK-sick) Destructive to cells.
- Data, objective:** SEE objective data.
- Data, subjective:** SEE subjective data.
- Data:** (DAY-tuh) A group of facts or statistics.
- Debridement:** (day-breed-MAHNT) The removal of foreign material and contaminated and devitalized tissues from or adjacent to a traumatic or infected area until surrounding healthy tissue is exposed.
- Decerebrate:** (dee-SER-e-brayt) Posture of an individual with absence of cerebral function.
- Decorticate:** (dee-KOR-ti-kayt) Posture of an individual with a lesion at or above the upper brain stem.
- Defibrillation:** (dee-FIB-ri-lay-shun) Use of an electrical device that applies countershock to the heart through electrodes placed on the chest wall to stop fibrillation of the heart.
- Degeneration:** (de-jen-er-AY-shun) Deterioration.
- Dehiscence:** (dee-HISS-ents) A splitting open (i.e., rupture) of an incision.
- Dehydration:** (DEE-high-DRAY-shun) A condition resulting from excessive loss of body fluid that occurs when fluid output exceeds intake.
- Delirium tremens:** (dee-LIR-ee-uhm TREE-menz) An acute alcohol withdrawal syndrome marked by acute, transient disturbance of consciousness.
- Delusions:** (dee-LOO-zhuns) False beliefs that are firmly maintained in spite of incontrovertible proof to the contrary.
- Dementia:** (dee-MEN-cha) A broad term that refers to cognitive deficit, including memory impairment.
- Demyelination:** (dee-MY-uh-lin-AY-shun) Loss of myelin from neurons.
- Deontology:** (DA-on-TOL-o-gee) The study of moral obligations and commitments, including medical ethics.
- Dependence:** (di-PEN-dens) A state of reliance on something. Psychological craving for a drug that may or may not be accompanied by a physiological need.
- Depression:** (dee-PRESS-shun) A mental disorder marked by altered mood with loss of interest.
- Dermatitis:** (DER-mah-TIGH-tis) Inflammation of the skin.
- Dermatophytosis:** (DER-mah-toh-fye-TOH-sis) A fungal infection of the skin.
- Dermoid:** (DER-moyd) Resembling the skin.
- Developmental stage:** (DEE-vell-up-MEN-tal STAYJ) An age-defined period with specific psychological tasks that need to be accomplished to maintain ego as proposed by Erik Erikson, a psychoanalyst.
- Diabetes mellitus:** (DYE-ah-BEE-tis mel-LYE-tus) A chronic disease characterized by impaired production or use of insulin and high blood glucose levels.
- Diarrhea:** (DYE-uh-REE-ah) Passage of fluid or unformed stools.
- Diastolic blood pressure:** (dye-ah-STAH-lik BLUHD PRE-shure) The amount of pressure exerted on the wall of the arteries when the ventricles are at rest. The bottom number in a blood pressure reading.
- Diffusion:** (di-FEW-zhun) The tendency of molecules of a substance (gaseous, liquid, or solid) to move from a region of high concentration to one of lower concentration.
- Dilation and curettage:** (DIL-AY-shun and kyoor-e-TAHZH) A surgical procedure that expands the cervical canal of the uterus (dilation) so that the surface lining of the uterine wall can be scraped (curettage).
- Diplopia:** (dip-LOH-pee-ah) Double vision.
- Displacement:** (dis-PLAYSS-ment) Transference of emotion from the original idea with which it was associated to a different idea, allowing the client to avoid acknowledging the original source.
- Disseminated intravascular coagulation:** (dis-SEM-i-NAY-ted IN-trah-VAS-kyoo-lar koh-AG-yoo-LAY-shun) A pathological form of coagulation that is diffuse (widespread) rather than localized, as would be the case in normal coagulation. Clotting factors are consumed to such an extent that generalized bleeding may occur.
- Distributive justice:** (dis-TRIB-yoo-tiv JUS-tiss) The right of individuals to be treated equally regardless of race, sex, marital status, sexual preference, medical diagnosis, social standing, economic level, or religious belief.
- Distributive shock:** (dis-TRIB-yoo-tiv) Excessive dilation of the venules and arterioles, leading to decreased distribution of blood, resulting in shock.
- Diverticulitis:** (DYE-ver-tik-yoo-LYE-tis) Inflammation of a diverticulum (a sac or pouch in the walls of a canal or organ, usually the colon), especially inflammation involving diverticula of the colon.
- Diverticulosis:** (DYE-ver-tik-yoo-LOH-sis) The presence of diverticula in the absence of inflammation.
- Do Not Resuscitate:** (DOO not re-SUSS-i-TATE) An order not to do CPR at the end of life.

- Dormant:** (DOOR-mant) Condition of greatly reduced metabolic activity permitting long-term survival and possible reactivation of bacterial endospores, protozoan cysts, larval stages of worm parasites, and viruses.
- Dressler's syndrome:** (DRESS-lers SINDroh-m) Postmyocardial infarction syndrome; pericarditis.
- Durable Medical Power of Attorney:** (DUR-uh-buhl POW-ur uv uh-TUR-nee) Person legally designated to speak for a patient when the patient is no longer able to speak for himself or herself.
- Dysarthria:** (dis-AR-three-ah) Imperfect articulation of speech caused by disturbances of muscular control resulting from central or peripheral nervous system damage.
- Dysfunctional:** (dis-FUNCK-shun-uhl) Family or work environment that does not function effectively, sometimes because of other problems of members.
- Dysmenorrhea:** (DIS-men-oh-REE-ah) Pain in association with menstruation.
- Dyspareunia:** (DIS-puh-ROO-nee-ah) Occurrence of pain in the labia, vagina, or pelvis during or after sexual intercourse.
- Dysphagia:** (dis-FAYJ-ee-ah) Inability to swallow or difficulty swallowing.
- Dysplasia:** (dis-PLAY-zee-ah) Abnormal development of tissue.
- Dyspnea:** (DISP-nee-ah) Subjective sense of labored breathing that occurs because of insufficient oxygenation.
- Dysreflexia:** (DIS-re-FLEK-see-ah) State in which an individual with a spinal cord injury at or above T6 experiences an uninhibited sympathetic response to a noxious stimulus.
- Dysrhythmia:** (dis-RITH-mee-yah) Abnormal, disordered, or disturbed cardiac rhythm.
- Dysuria:** (dis-YOO-ree-ah) Difficult or painful urination.
- Ecchymoses:** (ECK-uh-MOH-sis) A bruise of varying size, the color of which may be blue-black, changing to greenish yellow or yellow with time.
- Ectasia:** (ek-TAY-zee-ah) Replacement of normal tissue with fibrous tissue.
- Ectopic:** (eck-TOP-ick) Ectopic hormones are secreted from sites other than the gland where they would normally be found.
- Edema:** (uh-DEE-muh) Collection of excess fluid in body tissues.
- Ejaculation:** (ee-JAK-yoo-LAY-shun) The release of semen from the male urethra.
- Electrocardiogram:** (ee-LECK-troh-KAR-dee-oh-GRAM) A recording of the electrical activity of the heart.
- Electrocautery:** (ee-LECK-troh-CAW-tur-ee) Cauterization using platinum wires heated to red or white heat by an electric current, either direct or alternating.
- Electrocoagulated:** (ee-LECK-troh-coh-AG-yoo-LAY-ted) Coagulation of tissue by means of a high-frequency electric current.
- Electroconvulsive therapy (ECT):** (ee-LEK-troh-kun-VUL-siv THER-uh-pee) A type of somatic therapy in which an electric current is used to produce convulsions to treat such conditions as depression.
- Electroencephalogram:** (ee-LEK-troh-en-SEFF-uh-loh-gram) A record produced by electroencephalography; tracing of the electrical impulses of the brain.
- Electrolyte:** (ee-LEK-troh-lite) A substance that when dissolved in water can conduct electricity.
- Electroretinography:** (ee-LEK-troh-RET-in-AHG-ruh-fee) Measurement of the electrical response of the retina to light stimulation.
- Emboli:** (EM-boh-li) Solid, liquid, or gaseous masses of undissolved matter traveling with the fluid current in a blood or lymphatic vessel.
- Embolism:** (EM-buh-lizm) Foreign substance or blood clot that travels through the circulatory system until it obstructs a vessel.
- Empathy:** (EM-puh-thee) Objective awareness of and insight into the feelings, emotions, and behavior of another person.
- Emphysema:** (EM-fi-SEE-mah) Distention of interstitial tissue by gas or air; chronic pulmonary disease marked by terminal bronchiole and alveolar destruction and air trapping.
- Empyema:** (EM-pigh-EE-mah) Pus in a body cavity, especially the pleural space.
- Encephalitis:** (EN-seff-uh-LYE-tis) Inflammation of the brain.
- Encephalopathy:** (en-SEFF-uh-LAHP-ah-thee) Dysfunction of the brain.
- Endarterectomy:** (end-AR-tur-ECK-tuh-mee) Excision of thickened atherosclerotic areas of the innermost coat of an artery.
- Endogenous:** (en-DAH-jen-us) Produced or originating from within a cell or organism.
- Endometritis:** (EN-doh-me-TRY-tis) Inflammation of the endometrium of the uterus.
- Endorphins:** (en-DOR-fins) Naturally occurring opioids in the body, many times more potent than analgesic medications.
- Endoscope:** (EN-doh-skohp) A device consisting of a tube and optical system for observing the inside of a hollow organ or cavity. Can be flexible or rigid.
- Enkephalins:** (en-KEF-e-lins) One type of endorphin.
- Enteritis:** (en-ter-EYE-tis) Inflammation of the intestines, particularly of the mucosa and submucosa of the small intestine.
- Enucleation:** (ee-NEW-klee-AY-shun) Removal of an organ or other mass intact from its supporting tissues, as of the eyeball from the orbit.
- Epidemiological:** (EP-i-DEE-me-ah-LAHJ-i-kuhl) The study of the distribution and determinants of health-related states and events in populations and the application of this study to the control of health problems.
- Epididymitis:** (EP-i-DID-i-MY-tis) Inflammation or infection of the epididymis.
- Epidural:** (EP-i-DUHR-uhl) Situated on or outside the dura mater.
- Epinephrine:** (EP-i-NEFF-rin) A hormone secreted by the adrenal medulla in response to stimulation of the sympathetic nervous system.
- Epispadias:** (EP-i-SPAY-dee-ahz) A congenital male defect in which the opening of the urethra is on the dorsum of the penis, instead of the tip.
- Epistaxis:** (EP-iss-TAX-iss) Nosebleed.
- Epithelialization:** (ep-i-THÉE-lee-al-eye-ZAY-shun) The growth of skin over a wound.
- Equianalgesic:** (EE-kwee-AN-uhl-JEE-zik) Drugs having equal pain killing effect. The same degree of pain relief may require different doses when different medications are given or medications are given by different routes.
- Erectile dysfunction:** (e-RECK-tile dis-FUNCK-shun) Inability to have an erection sufficient for sexual intercourse.
- Erection:** (e-REK-shun) Enlargement and hardening of the penis caused by engorgement of blood.
- Erythema:** (ER-i-THÉE-mah) Diffuse redness over the skin.
- Eschar:** (ESS-kar) Hard scab or dry crust that results from necrotic tissue.
- Escharotomy:** (ess-kar-AHT-oh-mee) Removal of a slough or scab formed on the skin and underlying tissue of severely burned skin.
- Esophagogastroduodenoscopy:** (e-SOFF-ah-go-GAS-troh-doo-AH-den-AHS-kuh-pee) An endoscopic procedure that allows the physician to view the esophagus, stomach, and duodenum.
- Esophagoscopy:** (ee-soff-ah-GAHS-kuh-pee) Examination of the esophagus using an endoscope.
- Esotropia:** (ESS-oh-TROH-pee-ah) Strabismus in which there is deviation of the visual axis of one eye toward that of the other eye, resulting in diplopia. Also called cross-eyed.

- Essential hypertension:** (e-SEN-shul HIGH-per-TEN-shun) Chronic elevation of blood pressure resulting from an unknown cause.
- Ethical:** (ETH-i-kuhl) Describes behavior guided by a system of moral principles or standards.
- Ethnic:** (ETH-nick) Pertaining to a religious, racial, national, or cultural group. For example, individuals may identify with the Jewish, Catholic, or Islamic religions.
- Ethnocentrism:** (ETH-noh-SEN-trizm) The tendency to think that one's own ways of thinking, believing, and acting are the only right ways. People who are different are seen as strange or bizarre. An example is one who believes that his or her religious beliefs are the only right beliefs and other religions are wrong.
- Eustress:** (YOO-stress) Stress from positive experiences.
- Euthyroid:** (yoo-THY-royd) Normal thyroid function.
- Evaluation:** (e-VAL-yoo-AY-shun) The judgment of anything.
- Evisceration:** (E-VIS-sir-a-shun) Extrusion of viscera outside the body, especially through a surgical excision.
- Exacerbation:** (egg-sass-sir-BAY-shun) Aggravation of symptoms.
- Exophthalmos:** (ECKS-off-THAL-mus) Abnormal protrusion of the eyeball.
- Exotropia:** (EKS-oh-TROH-pee-ah) Abnormal turning outward of one or both eyes; divergent strabismus.
- Expectorant:** (ek-SPEK-tuh-rant) Agent that promotes removal of pulmonary secretions.
- Expectorate:** (eck-SPECK-tuh-RAYT) The act or process of coughing up materials from the air passageways leading to the lungs.
- External otitis:** (eks-TER-nuhl oh-TIGH-tis) Inflammation of the external ear.
- Extracardiac:** (EX-trah-KAR-dee-ack) Outside the heart.
- Extracellular:** (EX-trah-SELL-yoo-ler) Outside the cell.
- Extracorporeal shock wave lithotripsy (ESWL):** (ECKS-trah-koar-POR-ee-uhl SHAHK WAYV LITH-oh-TRIP-see) Noninvasive treatment using shock waves to break up gallstones or kidney stones.
- Extravasation:** (eks-TRA-vah-ZAY-shun) The escape of fluids into surrounding tissue.
- Extrinsic factors:** (eks-TRIN-sik FAK-ters) External variables.
- Exudate:** (EKS-yoo-dayt) Accumulated fluid in a cavity; oozing of pus or serum; often the result of inflammation.
- Fasciculation:** (fah-SIK-yoo-LAY-shun) Twitching.
- Fasciotomy:** (fash-e-OTT-oh-me) Incision of fascia.
- Feminist:** (FEM-un-nist) A person who advocates for women the same rights as men.
- Fetor hepaticus:** (FEE-tor he-PAT-i-kus) Foul breath associated with liver disease.
- Fibrocystic:** (FIGH-broh-SIS-tik) Consisting of fibrocysts, which are fibrous tumors that have undergone cystic degeneration or accumulated fluid.
- Fidelity:** (fi-DEL-i-tee) The obligation to be faithful to commitments made to self and others.
- Filtration:** (fill-TRAY-shun) The process of removing particles from a solution by allowing the liquid portion to pass through a membrane or other partial barrier.
- Fissure:** (FISH-er) A narrow slit or cleft, especially one of the deeper or more constant furrows separating the gyri of the brain.
- Fistula:** (FIST-yoo-lah) Any abnormal, tubelike passage within body tissue, usually between two internal organs, or leading from an internal organ to the body surface.
- Flaccid:** (FLA-sid) Weak, lax, soft muscles.
- Flail chest:** (FLAY-ul chesst) Condition of the chest wall caused by two or more fractures on each affected rib resulting in a segment of rib that is not attached on either end; the flail portion moves paradoxically in with inspiration and out with expiration.
- Flora:** (FLOOR-a) Microbial life adapted for living in a specific environment such as the intestines, skin, or urinary tract.
- Fluoroscope:** (FLAW-or-oh-skohp) A device consisting of a fluorescent screen suitably mounted, either separately or in conjunction with an x-ray tube, by means of which the shadows of objects interposed between the tube and the screen are made visible.
- Fluoroscopy:** (fluh-RAHS-kuh-pee) The use of a fluoroscope for medical diagnosis or for testing various materials by roentgen rays.
- Full-thickness burn:** (FUL-THICK-ness BERN) Burn in which all of the epithelializing elements and those lining the sweat glands, hair follicles, and sebaceous glands are destroyed.
- Fungi:** (FUNG-guy) A general term for a group of eukaryotic organisms (e.g., mushrooms, yeasts, molds).
- Furuncle:** (FYOOR-ung-kull) An acute circumscribed inflammation of the subcutaneous layers of the skin or of a gland or hair follicle.
- Gastrectomy:** (gas-TREK-tuh-mee) Any surgery that involves partial or total removal of the stomach.
- Gastric acid stimulation test:** (GAS-trik ASS-id STIM-yoo-LAY-shun TEST) A test that measures the amount of gastric acid for 1 hour after subcutaneous injection of a drug that stimulates gastric acid secretion.
- Gastric analysis:** (GAS-trik ah-NAL-i-sis) A test performed to measure secretions of hydrochloric acid and pepsin in the stomach.
- Gastric lavage:** (GAS-trik la-VAHJ) Washing out of the stomach; used to empty the stomach when the contents are irritating.
- Gastritis:** (gas-TRY-tis) Acute—The inflammation of the stomach mucosa; also known as heartburn or indigestion. Chronic—Gastritis that is recurrent; classified as type A (asymptomatic) or type B (symptomatic).
- Gastroduodenostomy:** (GAS-troh-DOO-oh-den-AHS-toh-mee) Excision of the pylorus of the stomach with anastomosis of the upper portion of the stomach to the duodenum.
- Gastroepiploic:** (GAS-troh-EP-i-PLOH-ick) Pertaining to the stomach and greater omentum.
- Gastrojejunostomy:** (GAS-troh-JAY-joo-NAHS-toh-mee) Subtotal excision of the stomach with closure of the proximal end of the duodenum and side-to-side anastomosis of the jejunum to the remaining portion of the stomach.
- Gastroparesis:** (GAS-troh-puh-REE-sis) Paralysis of the stomach, resulting in poor emptying.
- Gastroplasty:** (GAS-troh-PLAS-tee) Plastic surgery of the stomach. Used to decrease the size of the stomach to treat morbid obesity.
- Gastroscopy:** (gas-TRAHS-kuh-pee) Examination of the stomach and abdominal cavity by use of a gastro-scope.
- Gastrostomy:** (gas-TRAHS-toh-mee) Surgical creation of a gastric fistula through the abdominal wall.
- Gavage:** (gah-VAZH) Feeding with a stomach tube or with a tube passed through the nares, pharynx, and esophagus into the stomach. The food is in liquid or semiliquid form at room temperature.
- Generalization:** (JEN-er-al-i-ZAY-shun) An assumption about a group or an individual item or person that leads to seeking additional information to determine if the generalization fits the individual. Whereas generalizations are true for the group, they may not be true for the individual.
- Glaucoma:** (glaw-KOH-mah) A group of eye diseases characterized by increased intraocular pressure.
- Glomerulonephritis:** (gloh-MER-yoo-loh-ne-FRY-tis) A form of nephritis in which the lesions involve primarily the glomeruli.

- Glossitis:** (glah-SIGH-tis) An inflammation of the tongue.
- Glycosuria:** (GLY-kos-YOO-ree-ah) Abnormal amount of glucose in the urine, often associated with diabetes mellitus.
- Goitrogens:** (GOY-troh-jenz) Foods or medications that cause a goiter.
- Gravida:** (GRAV-id-ah) Number of times a woman has been pregnant.
- Gummas:** (GUM-ahs) A soft granulomatous tumor of the tissues characteristic of the tertiary stage of syphilis.
- Gynecomastia:** (JIN-e-koh-MASS-tee-ah) Excessive breast tissue on a male.
- Hallucinations:** (huh-LOO-si-NAY-shuns) False perceptions having no relation to reality and not accounted for by any exterior stimuli.
- Hand hygiene** (hand HY-jeen) Cleansing of the hands with hand washing as defined by the Centers for Disease Control and Prevention (CDC) or an alcohol-based hand sanitizer solution
- Health:** (HELLTH) A condition in which all functions of the body and mind are normally active.
- Hearing aid:** (HEER-ing AYD) An instrument to amplify sounds for those with hearing loss.
- Heatstroke:** (HEET-strohk) An acute and dangerous reaction to heat exposure, characterized by high body temperature, usually higher than 105°F (40.5°C).
- Helicobacter pylori:*** (HEH-lick-co-back-tur PIE-lori) Bacterium that causes some peptic ulcers.
- Hemarthrosis:** (HEEM-ar-THROH-sis) Bleeding into a joint.
- Hematochezia:** (HEM-uh-toh-KEE-zee-uh) Blood in the feces.
- Hematoma:** (HEE-muh-TOH-mah) A localized collection of extravasated blood, usually clotted, in an organ, space, or tissue.
- Hematuria:** (HEM-uh-TYOOR-ee-ah) Blood in the urine.
- Hemiparesis:** (hem-ee-puh-REE-sis) Weakness affecting one side of the body.
- Hemipelvectomy:** (hem-ee-pell-VEC-toe-me) The surgical removal of half of the pelvis and the leg.
- Hemiplegia:** (hem-ee-PLÉE-jee-ah) Paralysis of only one side of the body.
- Hemodialysis:** (HEE-moh-dye-AL-i-sis) A method for replacing the function of the kidneys by circulating blood through tubes made of semipermeable membranes.
- Hemolysis:** (he-MAHL-e-sis) The destruction of the membrane of red blood cells with the liberation of hemoglobin, which diffuses into the surrounding fluid.
- Hemophilia:** (HEE-moh-FILL-ee-ah) A hereditary blood disease marked by greatly prolonged coagulation time, with consequent failure of the blood to clot and abnormal bleeding.
- Hemoptysis:** (hee-MOP-ti-sis) Coughing up of blood from the respiratory tract.
- Hemorrhoids:** (HEM-uh-royds) A mass of dilated, tortuous veins in the anorectum involving the venous plexuses of that area.
- Hemothorax:** (HEE-moh-THAW-raks) Blood in the pleural space; may be associated with trauma, tuberculosis, or pneumonia.
- Hepatitis:** (HEP-uh-TIGH-tis) Inflammation of the liver, most often viral.
- Hepatomegaly:** (HEP-uh-toh-MEG-ah-lee) Enlargement of the liver.
- Hepatorenal syndrome:** (hep-PAT-oh-REE-nuhl SIN-droh-m) A deadly kidney failure that sometimes accompanies liver disease.
- Hepatosplenomegaly:** (he-PA-toh-SPLE-noh-MEG-ah-lee) Enlargement of the liver and spleen.
- Hernia:** (HER-nee-uh) The protrusion or projection of an organ or a part of an organ through the wall of the cavity that normally contains it.
- Herpetic:** (her-PET-ick) Pertaining to herpes.
- Hiatal hernia:** (high-AY-tuhl HER-nee-ah) A condition in which part of the stomach protrudes through and above the diaphragm.
- High-density lipoprotein (HDL):** (HIGH DEN-si-tee LIP-oh-PROH-teen) Plasma lipids bound to albumin consisting of lipoproteins. It has been found that those with high levels of HDL have less chance of having coronary artery disease.
- Histamine:** (HISS-ta-mean) A substance produced in the body that increases gastric secretion, increases capillary permeability, and contracts the bronchial smooth muscle. Plays a role in allergic reaction.
- Homans' sign:** (HOH-manz SIGHN) An assessment for venous thrombosis in which calf pain with dorsiflexion occurs if thrombosis is present.
- Homeopathy:** (HO-mee-AH-pa-thee) System of medicine based on the theory that "like cures like," and uses tiny doses of a substance that create the symptoms of disease.
- Homeostasis:** (HOH-mee-oh-STAY-sis) Maintaining a constant balance, especially whenever a change occurs.
- Hopelessness:** (HOHP-less-ness) Subjective state in which a person sees limited or unavailable alternatives; lacking energy.
- Hordeolum:** (hor-DEE-oh-lum) Sty.
- Hospice:** (HOS-pis) A service provided to patients and their families in the last 6 months of life to manage pain and provide emotional support.
- Host:** (HOE-st) The organism from which a parasite obtains its nourishment.
- Human immunodeficiency virus (HIV):** (HYOO-man im-YOO-noh-dee-FISH-en-see VIGH-rus) A retrovirus that causes acquired immunodeficiency syndrome (AIDS).
- Humoral:** (HYOO-mohr-uhl) Pertaining to body fluids or substances contained in them.
- Hydrocele:** (HIGH-droh-seel) A collection of fluid in the scrotal sack.
- Hydrocephalus:** (HIGH-droh-SEF-uh-luhs) A condition caused by enlargement of the cranium caused by abnormal accumulation of cerebrospinal fluid within the cerebral ventricular system.
- Hydronephrosis:** (HIGH-droh-ne-FROH-sis) Abnormal dilation of kidneys caused by obstruction of urine flow.
- Hydrostatic:** (HIGH-droh-STAT-ik) Pertaining to the pressure of liquids in equilibrium and to the pressure exerted by liquids.
- Hypercalcemia:** (HIGH-per-kal-SEE-mee-ah) An excessive amount of calcium in the blood.
- Hyperglycemia:** (HIGH-per-gligh-SEE-mee-ah) Excess glucose in the blood.
- Hyperkalemia:** (HIGH-per-kuh-LEE-mee-ah) An excessive amount of potassium in the blood.
- Hyperlipidemia:** (HIGH-per-LIP-i-DEE-mee-ah) Excessive quantity of fat in the blood.
- Hypermagnesemia:** (HIGH-per-MAG-nuh-ZEE-mee-ah) Excess magnesium in the blood.
- Hypnatremia:** (HIGH-per-nuh-TREE-mee-ah) Excess sodium in the blood.
- Hyperopia:** (HIGH-per-OH-pee-ah) Farsightedness.
- Hyperplasia:** (HIGH-per-PLAY-zee-ah) Excessive increase in the number of normal cells.
- Hypertension:** (HIGH-per-TEN-shun) Abnormally elevated blood pressure.
- Hypertensive emergency:** (HIGH-per-TEN-siv) Systolic blood pressure above 180 mm Hg and diastolic blood pressure above 120 to 130 mm Hg.
- Hypertonic:** (HIGH-per-TAHN-ik) Exerts greater osmotic pressure than blood.
- Hypertrophy:** (high-PER-truh-fee) An increase in the size of an organ or structure, or of the body, owing to growth rather than tumor formation.
- Hyperuricemia:** (HIGH-per-yoor-a-SEE-me-ah) An excess of uric acid or urates in the blood.
- Hyperventilation:** (HIGH-per-VEN-ti-LAY-shun) Increased ventilation that results in a lowered carbon dioxide (CO₂) level (hypocapnia).

- Hypervolemia:** (HIGH-per-voh-LEE-mee-ah) An abnormal increase in the volume of circulating blood.
- Hypocalcemia:** (HIGH-poh-kal-SEE-mee-ah) Reduced amount of calcium in the blood.
- Hypoglycemia:** (HIGH-poh-gligh-SEE-mee-ah) Below-normal amount of glucose in the blood.
- Hypokalemia:** (HIGH-poh-kuh-LEE-mee-ah) Reduced amount of potassium in the blood.
- Hypomagnesemia:** (HIGH-poh-MAG-nuh-ZEE-mee-ah) Reduced amount of magnesium in the blood.
- Hyponatremia:** (HIGH-poh-nuh-TREE-mee-ah) Reduced amount of sodium in the blood.
- Hypophysectomy:** (HIGH-pah-fi-SECK-tuh-mee) Surgical removal of the pituitary gland.
- Hypoplasia:** (HIGH-poh-PLAY-zee-ah) Underdevelopment of a tissue organ or body.
- Hypospadias:** (HIGH-poh-SPAY-dee-ahz) A congenital male defect in which the opening of the urethra is on the underside of the penis, instead of the tip.
- Hypostatic:** (HIGH-poh-STA-tik) Hypostatic pneumonia occurs from congestion in the lungs associated with lack of activity.
- Hypotension:** (HIGH-poh-TEN-shun) Abnormally low blood pressure below 90 mm Hg systolic.
- Hypothermia:** (HIGH-poh-THER-mee-ah) Body temperature below 95° F (35° C).
- Hypotonic:** (HIGH-poh-TAHN-ik) Pertaining to defective muscular tone or tension; having a lower concentration of solute than intracellular or extracellular fluid.
- Hypovolemia:** (HIGH-poh-voh-LEE-mee-ah) The most common form of dehydration resulting from the loss of fluid from the body; results in decreased blood volume.
- Hypovolemic shock:** (HIGH-poh-voh-LEEM-ick SHAHK) Shock that occurs when blood or plasma is lost in such quantities that the remaining blood cannot fill the circulatory system despite constriction of the blood vessels.
- Hypovolemic:** (HIGH-poh-voh-LEEM-ick) Low volume of blood in the circulatory system.
- Hypoxemia:** (HIGH-pock-SEE-mee-ah) Deficient oxygenation of the blood.
- Hypoxia:** (high-POCK-see-ah) Diminished availability of oxygen to the body tissues.
- Hysterectomy:** (HISS-tuh-RECK-tuh-mee) Surgical removal of the uterus through the abdominal wall or vagina.
- Hysterosalpingogram:** (HIS-tur-oh-SAL-pinj-oh-gram) Radiograph of the uterus and fallopian tubes.
- Hysteroscopy:** (HIS-tur-AHS-koh-pee) Endoscopic direct visual examination of the canal of the uterine cervix and the cavity of the uterus.
- Hysterotomy:** (HISS-tuh-RAH-tuh-mee) Incision of the uterus.
- Icterus:** (ICK-ter-us) Yellowing of the skin and the sclera of the eye.
- Idiopathic thrombocytopenic purpura:** (ID-ee-oh-PATH-ik THROM-boh-SIGH-toh-PEE-nik PUR-pew-rah) The total number of circulating platelets is greatly diminished, even though platelet production in the bone marrow is normal, resulting in slowed blood clotting.
- Ileostomy:** (ILL-ee-AH-stuh-me) An artificial opening (stoma) created in the small intestine (ileum) and brought to the surface of the abdomen for the purpose of evacuating feces.
- Illness:** (ILL-ness) The state of being sick.
- Illusions:** (i-LOO-zhuns) Mistaken perceptions of reality.
- Imagery:** (IM-ij-ree) The use of the imagination to promote relaxation.
- Immunocompromised:** (IM-yoo-noh-KAHM-prah-mized) Having an immune system that is not capable of reacting to a pathogen or tissue damage.
- Impaction:** (im-PAK-shun) An immovable accumulation of feces in the bowels.
- Imperforate:** (im-PER-foh-rate) Without an opening.
- In situ:** (in-SIT-yoo) Localized, not invading surrounding tissue.
- In vitro fertilization:** (in VEE-troh FER-ti-li-ZAY-shun) Fertilization in a test tube.
- Induction:** (in-DUCK-shun) The process or act of causing to occur, as in anesthesia induction.
- Induration:** (IN-dyoo-RAY-shun) Area of hardened tissue.
- Infective endocarditis:** (in-FECK-tive EN-doh-kar-DYE-tis) Inflammation of the heart lining caused by microorganisms.
- Inspection:** (in-SPEK-shun) Use of observation skills to systematically gather data that can be seen.
- Insufficiency:** (IN-suh-FISH-en-see) The condition of being inadequate for a given purpose, such as heart valves that do not close properly.
- Insufflation:** (in-suff-LAY-shun) Used to inflate the abdomen during laparoscopic or endoscopic procedures to enhance visualization of structures.
- Intermittent claudication:** (IN-ter-MIT-ent KLAW-di-KAY-shun) A symptom associated with arterial occlusive disease. It refers to pain in the calf of a lower extremity, usually brought on by activity or exercise, and ceases with rest.
- International normalized ratio:** (IN-ter-NASH-uh-nul NOR-muh-lized RAY-she-oh) The World Health Organization's standardization for reporting the prothrombin time assay test when the thromboplastin reagent developed by the first International Reference Preparation is used. The reagent was developed to prevent variability in prothrombin time testing results and provide uniformity in monitoring therapeutic levels for coagulation during oral anticoagulation therapy.
- Interstitial:** (IN-ter-STISH-uhl) Fluid between tissues.
- Intervention:** (in-ter-VEN-shun) One or more actions taken in order to modify an effect.
- Intracellular:** (IN-trah-SELL-yoo-ler) Fluids located within the blood cell.
- Intracranial:** (IN-trah-KRAY-nee-uhl) Within the cranium or skull.
- Intraoperative:** (IN-trah-AHP-er-uh-tiv) Occurring during a surgical procedure.
- Intravascular:** (IN-trah-VAS-kyoo-lar) Fluids located within the blood vessels.
- Intravenous:** (IN-trah-VEE-nus) Within or into a vein.
- Intrinsic factors:** (in-TRIN-sik FAK-ters) Internal variables.
- Intussusception:** (IN-tuh-suh-SEP-shun) The slipping of one part of an intestine into another adjacent to it.
- Ipsilateral:** (IP-si-LAT-er-uhl) On the same side; affecting the same side of the body.
- Ischemia:** (iss-KEY-me-ah) Condition of inadequate blood supply.
- Isoelectric line:** (EYE-so-e-LEK-trick LINE) The period when the electrical tracing is at zero and is neither positive nor negative.
- Isolated systolic hypertension:** (EYE-suh-lay-ted sis-TAH-lik high-per-TEN-shun) The systolic pressure is 160 mm Hg or more, but the diastolic pressure is lower than 95 mm Hg.
- Isotonic:** (EYE-so-TAHN-ik) A fluid that has the same osmolarity as the blood.
- Jaundice:** (JAWN-diss) Yellowing of the skin and the sclera of the eye.
- Joint:** (JOYNT) An articulation. The point of juncture between two bones.
- Kaposi's sarcoma:** (ka-POE-sees SARCO-mah) A vascular malignancy that is often first apparent in the skin or mucous membranes but may involve the viscera.
- Ketoacidosis:** (KEE-toh-ass-i-DOH-sis) A condition in which fat breakdown produces ketones, which cause an acidic state in the body; may be associated with weight loss or diabetes mellitus.

- Kussmaul's:** (KOOS-mahlz) Term describing deep respirations of an individual with ketoacidosis.
- Laceration:** (la-sir-A-shun) A wound or irregular tear of the flesh.
- Lactic acid:** (LAK-tik ASS-id) By-product of anaerobic metabolism.
- Laminectomy:** (LAM-i-NEK-toh-mee) The excision of a vertebral posterior arch, usually to remove a lesion or herniated disk.
- Laparoscopy:** (LAP-uh-roh-SKOP-ee) Exploration of the abdomen with an endoscope.
- Laparotomy:** (LAP-uh-RAH-tuh-mee) The surgical opening of the abdomen; an abdominal operation.
- Laryngeal edema:** (lah-RIN-jee-uhl uh-DEE-muh) Sudden swelling of the larynx occurring with severe allergic reactions.
- Laryngectomy:** (lar-in-JEK-tah-mee) Surgical removal of the larynx.
- Laryngitis:** (lare-in-JIGH-tiss) Inflammation of the larynx.
- Laser ablation:** (LAY-zer uh-BLAY-shun) Therapeutic destruction of a growth or part of a growth by laser treatment.
- Lavage:** (lah-VAZH) Washing out of a cavity.
- Law:** (LAW) The further formalization of moral considerations.
- Leiomyoma:** (LYE-oh-my-OH-ma) A myoma consisting principally of smooth muscle tissue.
- Leukemia:** (loo-KEE-mee-ah) A malignancy of the blood-forming cells in the bone marrow.
- Leukocytosis:** (LOO-koh-sigh-TOH-sis) An increase in the number of leukocytes in the blood, generally caused by presence of infection and usually transient.
- Leukopenia:** (LOO-koh-PEE-nee-yah) Abnormal decrease of white blood cells, usually below 5000/mm³.
- Liability:** (LYE-uh-BIL-i-tee) The level of responsibility that society places on individuals for their actions.
- Libido:** (li-BEE-doh) Sexual drive, conscious or unconscious.
- Lichenified:** (lye-KEN-i-fyed) Thickened or hardened from continued irritation.
- Limitation of liability:** (lim-i-TAY-shun OF LYE-uh-BIL-i-tee) Steps that health care professionals can take to limit their liability.
- Living Will:** (LIV-ing WIL) A document instructing health-care workers about a patient's preferences when he or she is no longer able to communicate. Implementation of Living Wills varies by state.
- Lobectomy:** (loh-BEK-tuh-mee) Surgical removal of a lobe of any organ or gland.
- Lower gastrointestinal series (lower GI):** (LOH-er GAS-troh-in-TES-ti-nuhl SEER-ees) The use of barium sulfate as an enema to facilitate x-ray and fluoroscopic examination of the colon.
- Lymphadenopathy:** (lim-FAD-e-NAH-puh-thee) Any disorder of the lymph nodes.
- Lymphangitis:** (lim-FAN-je-EYE-tis) Inflammation of lymphatic channels or vessels.
- Lymphedema:** (LIMPF-uh-DEE-mah) An abnormal accumulation of tissue fluid (potential lymph) in the interstitial space.
- Lymphocytes:** (LIM-foh-sites) Cells present in the blood and lymphatic tissue that provide the main means of immunity for the body; white blood cells.
- Lymphoma:** (lim-FOH-mah) A usually malignant lymphoid neoplasm.
- Macular degeneration:** (MACK-you-lar-dee-JEN-uh-RAY-shun) Age-related breakdown of the macular area of the retina of the eye.
- Malignant:** (muh-LIG-nunt) Growing, resisting treatment; used to describe a tumor of cancerous cells.
- Malpractice:** (mal-PRAK-tiss) A breach of duty arising out of the relationship that exists between the patient and the health care worker.
- Mammography:** (mah-MOG-rah-fee) Use of radiography of the breast to diagnose breast cancer.
- Mammoplasty:** (MAM-oh-PLAS-tee) Plastic surgery of the breast.
- Mania:** (MAY-nee-ah) Mental disorder characterized by excessive excitement.
- Marsupialization:** (mar-SOO-pee-al-i-ZAY-shun) Process of raising the borders of an evacuated tumor sac to the edges of the abdominal wound and stitching them there to form a pouch.
- Mastalgia:** (mass-TAL-jee-ah) Pain in the breast.
- Mastectomy:** (mass-TECK-tuh-mee) Excision of the breast.
- Mastitis:** (mass-TIGH-tis) Inflammation of the breast.
- Mastopexy:** (MAS-toh-PEKS-ee) Correction of a pendulous breast by surgical fixation and plastic surgery.
- Mediastinum:** (ME-dee-ah-STYE-num) A septum or cavity between two principal portions of an organ.
- Megacolon:** (MEG-ah-KOH-lun) Extremely dilated colon.
- Melena:** (muh-LEE-nah) Black, tarry feces caused by action of intestinal secretions on free blood.
- Menarche:** (me-NAR-kee) The initial menstrual period, normally occurring between the ninth and seventeenth year.
- Ménière's disease:** (ma-NEARS di-ZEEZ) A recurrent and usually progressive group of symptoms including progressive deafness, ringing in the ears, dizziness, and a sensation of fullness or pressure in the ears.
- Meningitis:** (men-in-JIGH-tis) Inflammation of the membranes of the spinal cord and brain.
- Menopause:** (MEN-oh-pawz) The period that marks the permanent cessation of menstrual activity, usually occurring between the ages of 35 and 58.
- Mental health:** (MEN-tuhl HELLTH) State of being adjusted to life; able to be flexible, successful, maintain close relationships, solve problems, make appropriate judgments, and cope with daily stresses.
- Mental illness:** (MEN-tuhl ILL-ness) Any illness that affects the mind or behavior.
- Metastasis:** (muh-TASS-tuh-sis) Movement of bacteria or body cells (especially cancer cells) from one part of the body to another.
- Milieu:** (me-LYU) Environment.
- Miotic:** (my-AH-tik) An agent that causes the pupil to contract.
- Morality:** (muh-RAL-i-tee) A social barometer that dictates what is good or bad in a society.
- Morbidity:** (more-BID-it-ee) State of being diseased.
- Mortality:** (more-TAL-it-ee) Condition of being mortal; number of deaths in a population.
- Mucolytic:** (MYOO-koh-LIT-ik) Agent that liquefies sputum.
- Mucopurulent cervicitis:** (MYOO-koh-PYOOOR-uh-lent SIR-vi-SIGH-tis) Inflammation of the cervix producing mucus and purulent discharge.
- Mucositis:** (MYOO-koh-SIGH-tis) Inflammation of a mucous membrane.
- Multifocal:** (MUHL-tee-FOH-kuhl) Many foci (areas) or sites.
- Murmur:** (MUR-mur) An abnormal sound heard on auscultation of the heart and adjacent large blood vessels.
- Muscle:** (MUSS-uhl) A bundle of long slender cells or fibers that have the power to contract and hence to produce movement.
- Myalgia:** (my-AL-jee-ah) Muscle pain or tenderness.
- Myectomy:** (my-ECK-tuh-mee) Surgical removal of a hypertrophied muscle.
- Myelogram:** (MY-e-loh-gram) The film produced by radiography of the spinal cord after injection of a contrast medium into the subarachnoid space.
- Myocardial infarction:** (MY-oh-KAR-dee-yuhl in-FARK-shun) Death of cells of an area of the heart muscle, myocardium, as a result of oxygen deprivation, which in turn is caused by obstruction of the blood supply. Commonly referred to as a heart attack.
- Myocarditis:** (MY-oh-kar-DYE-tis) The inflammatory process that causes nodules to form in the myocardial tissue;

the nodules become scar tissue over time. Inflammation of the heart muscle.

Myocardium: (MY-oh-KAR-dee-um)
Heart muscle.

Myomectomy: (my-oh-MECK-tuh-mee)
Removal of a portion of muscle or muscular tissue.

Myopia: (my-OH-pee-ah) The error of refraction in which rays of light entering the eye parallel to the optic axis are brought to a focus in front of the retina; nearsightedness.

Myringoplasty: (mir-IN-goh-PLASS-tee)
Surgical reconstruction of the tympanic membrane.

Myringotomy: (MIR-in-GOT-uh-mee)
Incision of the tympanic membrane, usually performed to relieve pressure and allow for drainage of either serous or purulent fluid in the middle ear behind the tympanic membrane.

Myxedema: (MICK-suh-DEE-mah)
Condition resulting from hypofunction of the thyroid gland.

Nasoseptoplasty: (NAY-zoh-SEP-toh-plass-tee)
Surgical correction of the nasal septum.

Naturopathy: (NAY-chur-AH-pa-thee)
System of medicine that uses natural therapies such as nutrition, herbs, hydrotherapy, counseling, physical medicine, and homeopathy to treat disease, promote healing, and prevent illness.

Negligence: (NEG-li-jense) An unintentional tort.

Neoplasm: (NEE-oh-PLAZ-uhm) New abnormal tissue growth, as in a tumor.

Nephrectomy: (ne-FREK-tuh-mee) Surgical removal of a kidney.

Nephrogenic: (NEFF-roh-JEN-ick)
Caused by the kidneys.

Nephrolithotomy: (NEFF-roh-li-THOT-uh-mee)
Incision of a kidney for removal of kidney stones.

Nephropathy: (ne-FROP-uh-thee) Any disease of the kidney.

Nephrosclerosis: (NEFF-roh-skle-ROH-sis)
Hardening of the kidney associated with hypertension and disease of the renal arterioles.

Nephrostomy: (ne-FRAHS-toh-mee)
Creation of a permanent opening into the renal pelvis.

Nephrotoxin: (NEFF-roh-TOCK-sin) A toxin having a specific destructive effect on kidney tissue.

Neuralgia: (new-RAL-jee-ah) Nerve pain.

Neurogenic: (NEW-roh-JEN-ik) Originating in the nervous system.

Neuropathic pain: (NEW-roh-PATH-ik PAYN)
Pain resulting from peripheral nerve injury.

Neuropathy: (new-RAH-puh-thee) A general term denoting functional disturbances and pathologic changes in the peripheral nervous system.

Neutrophils: (NEW-troh-fils) Granular leukocytes (white blood cells) having a nucleus with three to five lobes connected by threads of chromatin and cytoplasm containing very fine granules.

Nociceptive: (NOH-see-SEP-tiv) Pain sensitive.

Nocturia: (nock-TYOO-ree-ah) Excessive urination at night.

Nodal or junctional rhythm: (NOHD-uhl or JUNGK-shun-uhl RITH-uhm) A cardiac rhythm with its origin at the atrioventricular (AV) node.

Nonmaleficence: (NON-muh-LEF-i-sens)
The requirement that health care providers do no harm to their patients, either intentionally or unintentionally.

Norepinephrine: (NOR-ep-i-NEFF-rin)
A hormone produced by the adrenal medulla, similar in chemical and pharmacological properties to epinephrine, but chiefly a vasoconstrictor with little effect on cardiac output.

Normotensive: (nor-moh-TEN-siv)
Normal blood pressure.

Nosocomial infection: (no-zoh-KOH-mee-uhl in-FECK-shun) Infection acquired in a health care agency.

Nuchal rigidity: (NEW-kuhl re-JID-i-tee)
Rigidity of the nape, or back, of the neck.

Nursing diagnosis: (NER-sing DYE-ag-NOH-sis) A standardized label placed on a patient's problem to make it understandable to all nurses.

Nursing process: (NER-sing PRAH-sess)
An orderly, logical approach to administering nursing care so that the patient's needs for such care are met comprehensively and effectively.

Nystagmus: (nis-TAG-muss) Involuntary, rapid, rhythmic eye movement.

Obesity: (oh-BEE-si-tee) Abnormal amount of fat on the body from 20% to 30% over average weight for age, sex, and height.

Objective data: (ob-JEK-tiv DAY-tuh)
Factual data obtained through physical assessment and diagnostic tests; objective data are observable or knowable through the five senses.

Obsession: (ub-SESH-un) Repetitive thought, urge, or emotion.

Obstipation: (OB-sti-PAY-shun)
Intractable constipation.

Obstructive shock: (ub-STRUCK-tive SHAHK)
Shock caused by indirect pump failure.

Occult blood test: (ah-KULT BLUHD TEST) A chemical test or microscopic examination for blood, especially in feces, that is not apparent on visual inspection.

Oliguria: (AWH-li-GYOO-ree-ah)
Diminished urination.

Oncology: (on-CAW-luh-jee) The study of cancer and cancer treatment.

Oncovirus: (ON-koh-VIGH-russ) Viruses linked to cancer in humans.

Onychomycosis: (ON-i-koh-my-KOH-sis) Disease of the nails caused by fungus.

Ophthalmia neonatorum: (ahf-THAL-mee-ah NEE-oh-nuh-TOR-uhm)
Conjunctivitis in the newborn resulting from exposure to infectious or chemical agents.

Ophthalmologist: (AHF-thal-MAH-luh-jist) A physician who specializes in the treatment of disorders of the eye.

Ophthalmoscope: (ahf-THAL-muh-skohp) An instrument used for examining the interior of the eye, especially the retina.

Opioid: (OHP-ee-OYD) A narcotic drug with morphine-like effects. True opioids are derived from opium.

Optician: (ahp-TISH-uhn) One who specializes in filling prescriptions for corrective lenses for eyeglasses and contact lenses.

Optimum level of functioning: (OP-teh-mum LEV-uhl of FUNK-shun-ing)
Highest level of patient activity considering the patient's condition.

Optometrist: (ahp-TOM-uh-trist) A doctor of optometry who diagnoses and treats conditions and diseases of the eye per state laws.

Orchiectomy: (or-ki-EK-toh-mee)
Removal of one or both testicles; a treatment for prostate cancer.

Orchitis: (or-KIGH-tis) Inflammation of a testis.

Orgasm: (OR-gazm) Pleasurable physical release sensation related to physical, sexual, and psychological stimulation.

Orientation: (OR-ee-en-TAY-shun) The ability to comprehend and to adjust oneself in an environment with regard to time, location, and identity of persons.

Orthopnea: (or-THOP-knee-a) Labored breathing that occurs when lying flat; relieved when sitting up; associated with left ventricular heart failure.

Osmolality: (ahs-moh-LAL-i-tee)
Osmotic concentration; ionic concentration of the dissolved substances per unit of solvent.

Osmosis: (ahs-MOH-sis) The passage of solvent through a semipermeable membrane that separates solutions of different concentrations.

Osteomyelitis: (AHS-tee-oh-my-LIGHT-tis) Inflammation of bone, especially the marrow, caused by a pathogenic organism.

Osteopathy: (AHS-tee-ah-PATH-ee)
System of medicine emphasizing the inter-relationship of the body's nerves, muscles, bones, and organs; involves treating the whole person, and stresses the importance of diet, exercise, and fitness, with a focus on prevention.

- Osteoporosis:** (AHS-tee-oh-por-OH-sis) A condition in which there is a reduction in the mass of bone per unit volume.
- Osteosarcoma:** (AHS-tee-oh-sar-KOH-mah) A malignant sarcoma of a bone.
- Otalgia:** (oh-TAL-jee-ah) Pain in the ear.
- Otorrhea:** (OH-toh-REE-ah) Inflammation of the ear with purulent discharge.
- Otosclerosis:** (OH-toh-skle-ROH-sis) A condition characterized by chronic, progressive deafness, especially for low tones.
- Ototoxic:** (OH-toh-TOK-sik) Having a detrimental effect on the eighth cranial nerve or the organs of hearing.
- Pain:** (PAYN) An unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage. Is whatever the patient says it is whenever the patient says it occurs.
- Palliation:** (pal-ee-AY-shun) The relief of symptoms without cure.
- Palpation:** (pal-PAY-shun) Use of the fingers or hands to feel something.
- Pancreatotomy:** (PAN-kree-uh-TECK-tuh-mee) Removal of all or part of the pancreas.
- Pancreatitis:** (PAN-kree-uh-TIGH-tis) Inflammation of the pancreas.
- Pancytopenia:** (PAN-sigh-toh-PEE-nee-ah) Abnormal depression of all the cellular elements of the blood.
- Panhysterectomy:** (PAN-hiss-tuh-RECK-tuh-mee) Excision of the entire uterus, including the cervix uteri.
- Panmyelosis:** (PAN-my-e-LOH-sis) Increased level of all bone marrow components, red blood cells, white blood cells, and platelets.
- Para:** (PAR-ah) Number of deliveries a woman has had from pregnancies after 20 weeks gestation.
- Paradoxical respirations:** (PAR-uh-DOK-si-kuhl RES-pi-RAY-shuns) Chest movement on respiration that is opposite to that expected.
- Paranoia:** (PAR-uh-NOY-uh) Behavior that is marked by delusions of persecution or delusional jealousy.
- Paraparesis:** (PAR-ah-pah-REE-sis) Partial paralysis of the lower extremities.
- Paraphimosis:** (PAR-uh-figh-MOH-sis) Uncircumcised foreskin that has swollen and stuck behind the head of the penis.
- Paraplegia:** (PAR-ah-PLÉE-jah) Paralysis of the lower body, including both legs, resulting from a spinal cord lesion.
- Paresis:** (puh-REE-sis) Weakness; incomplete paralysis.
- Paresthesia:** (PAR-es-THEE-zee-ah) A heightened sensation, such as burning, prickling, or tingling.
- Paroxysmal nocturnal dyspnea:** (PEAR-ox-IS-mall knock-TURN-al DISP-knee-a) Sudden attacks of shortness of breath that usually occur during sleep. Person wakes gasping for breath and sits up to relieve symptoms; associated with left ventricular heart failure.
- Partial-thickness burn:** (PAR-shul THICK-ness BERN) Burn in which the epithelializing elements remain intact.
- Passive immunity:** (PASS-iv im-YOO-ni-tee) Reinforcement of the immune system with immune serum for such conditions as tetanus, diphtheria, and venomous snake bite.
- Paternalism:** (puh-TER-nuhl-izm) A unilateral and sometimes unreasonable decision by health care providers that implies they know what is best, regardless of the patient's wishes.
- Pathogen:** (PATH-o-jen) A microorganism or substance capable of producing a disease.
- Pathological fracture:** (PATH-uh-LAH-jik-uhl FRAHK-chur) Fracture resulting from weakening of the bone structure by pathological processes such as neoplasia or osteomalacia.
- Patient-controlled analgesia (PCA):** (PAY-shent kon-TROHLD an-uhl-JEE-zee-ah) An apparatus that delivers an intravenous analgesic to relieve pain, which is controlled by the patient.
- Pedicle:** (PED-i-kuhl) The stem that attaches a new growth.
- Pediculosis:** (pe-DIK-yoo-LOH-sis) Infestation with lice.
- Pemphigus:** (PEM-fi-gus) Acute or chronic serious skin disease characterized by the appearance of bullae (blisters) of various sizes on normal skin and mucous membranes.
- Penumbra:** (puh-NUM-bra) An area of brain tissue surrounding damage from a stroke that may be revived if the brain is reperfused quickly.
- Peptic ulcer disease:** (PEP-tick UL-sir di-ZEEZ) A condition in which the lining of the esophagus, stomach, or duodenum is eroded.
- Perception:** (per-SEP-shun) A unique impression of events by an individual. These impressions are strongly influenced by personality, cultural orientation, attitudes, and life experiences.
- Percussion:** (per-KUSH-un) A tapping technique used by physicians and advanced practice nurses to determine the consistency of underlying tissues.
- Percutaneous:** (PER-kyoo-TAY-nee-us) Through the skin; may refer to an injection, a medication application, or a biopsy.
- Perfusion:** (per-FEW-zhun) Supplying an organ or tissue with blood.
- Pericardial effusion:** (PER-ee-KAR-dee-uhl ee-FYOO-zhun) A buildup of fluid in the pericardial space.
- Pericardial friction rub:** (PER-ee-KAR-dee-uhl FRICK-shun RUB) Friction sound heard over the fourth left intercostal space near the sternum; a classic sign of pericarditis.
- Pericardial tamponade:** (PER-ee-KAR-dee-uhl TAM-pon-AID) Compression of the heart by an abnormal filling of the pericardial sac with blood.
- Pericardiectomy:** (PER-ee-kar-dee-ECK-tuh-mee) Excision of part or all of the pericardium.
- Pericardiocentesis:** (PER-ee-KAR-dee-oh-sen-TEE-sis) Surgical perforation of the pericardium.
- Pericardiotomy:** (PER-ee-KAR-dee-AH-tah-mee) Incision of the pericardium.
- Pericarditis:** (PER-ee-kar-DYE-tis) Inflammation of the pericardium.
- Perimenopausal:** (PER-ee-MEN-oh-PAWS-uhl) The phase before the onset of menopause, during which the cycle of a woman with regular menses changes, perhaps abruptly, to a pattern of irregular cycles and increased periods of amenorrhea.
- Perinatal:** (PAIR-ee-NAY-tuhl) Concerning the period beginning after the 28th week of pregnancy and ending 28 days after birth.
- Perioperative:** (PER-ee-AHP-er-uh-tiv) Occurring in the period immediately before, during, and after surgery.
- Peripheral arterial disease:** (puh-RIFF-uh-ruhl ar-TIR-ee-uhl di-ZEEZ) Disease of the peripheral arteries that interferes with adequate flow of blood.
- Peripheral parenteral nutrition:** (puh-RIFF-uh-ruhl par-EN-te-ruhl new-TRISH-un) Nutrition by intravenous injection.
- Peripheral vascular resistance:** (puh-RIFF-uh-ruhl VAS-kyoo-lar ree-ZIS-tense) Opposition to blood flow through the vessels.
- Peristalsis:** (paris-TALL-sis) Progressive, wave-like movement that occurs involuntarily in hollow tubes of the body such as the alimentary (digestive) canal; causes contents of tube to be moved onward.
- Peristomal:** (PER-i-STOH-muhl) Area around a stoma.
- Peritoneal dialysis:** (PER-i-toh-NEE-uhl dye-AL-i-sis) The employment of the peritoneum surrounding the abdominal cavity as a dialyzing membrane for the purpose of removing waste products or toxins accumulated as a result of renal failure.
- Peritonitis:** (per-i-toh-NIGH-tis) Inflammation of the peritoneum.
- Personal protective equipment (PPE):** (PUR-sun-al proh-TEK-tiv i-KWIP-mant) Items worn to protect oneself and one's patients from direct transmission of

- organisms that includes gloves, surgical masks, goggles, gowns, and shoe booties based on the task to be performed and the type of isolation precautions in use.
- Petechiae:** (pe-TEE-kee-ee, puh-TEE-kee-eye) Small, purplish, hemorrhagic spots on the skin that appear in certain illnesses and bleeding disorders.
- Phagocytosis:** (fay-go-sigh-TOH-sis) Ingestion and digestion of bacteria and particles by phagocytes, cells that have the ability to ingest and destroy particulate substances such as bacteria, protozoa, and cell debris.
- Pharyngitis:** (fair-in-JIGH-tiss) Inflammation of the mucous membranes and lymph tissues of the pharynx, usually caused by infection.
- Pheochromocytoma:** (FEE-oh-KROH-moh-sigh-TOH-mah) Rare tumor of the adrenal system that secretes catecholamines.
- Phimosis:** (figh-MOH-sis) Uncircumcised foreskin that cannot be moved down from the head of the penis.
- Phlebitis:** (fla-BYE-tis) Inflammation of a vein; may be due to irritating IV fluids or thrombosis.
- Phlebotomy:** (fle-BAH-tuh-mee) Entry into a vein for the removal or withdrawal of blood.
- Phobia:** (FOH-bee-ah) A persistent, irrational, intense fear of a specific object, activity, or situation.
- Photophobia:** (FOH-toh-FOH-bee-ah) Abnormal visual intolerance to light.
- Physical dependence:** (FIZ-ik-uhl dee-PEN-dens) A pharmacologic phenomenon characterized by signs and symptoms of withdrawal when medication is withdrawn.
- Phytoestrogens:** (FI-toh-ES-troh-jens) Naturally occurring plant sterols that have an estrogenlike effect.
- Plague:** (PLAYG) A severe febrile illness caused by the gram-negative coccobacillus *Yersinia pestis* that is usually transmitted by the bite of an infectious flea. It can also be used as a biological weapon in which primary pneumonic plague would likely occur.
- Plaque:** (PLAK) A deposit of fatty material on the lining of an artery.
- Plasmapheresis:** (PLAS-mah-fer-EE-sis) Removal of blood to separate cells from plasma.
- Pleurodesis:** (PLOO-roh-DEE-sis) Creation of adhesions between the parietal and visceral pleura to treat recurrent pneumothorax.
- Pneumocystis carinii* pneumonia:** (new-mo-SIS-tis ca-RIN-ee-eye new-MOH-nee-ya) An acute pneumonia caused by *Pneumocystis carinii*, a fungus. It occurs in immunodeficient adults and is a defining opportunistic infection of AIDS.
- Pneumonectomy:** (NEW-moh-NEK-tuh-mee) Surgical removal of all or part of a lung.
- Pneumothorax:** (NEW-moh-THAW-raks) Air in the pleural space.
- Poikilothermy:** (POY-ki-loh-THER-mee) The absence of sufficient arterial blood flow, causing the extremity to become the temperature of the environment.
- Point of maximal impulse:** (POYNT of MAKSI-i-muhl IM-puls) The area of the chest where the greatest force can be felt with the palm of the hand when the heart contracts or beats. Usually at the fourth to fifth intercostal space in the midclavicular line.
- Polycythemia:** (PAH-lee-sigh-THEE-mee-ah) Excessive red cells in the blood.
- Polydipsia:** (PAH-lee-DIP-see-ah) Excessive thirst.
- Polymyositis:** (PAH-lee-my-oh-SIGH-tis) A rare, inflammatory disease of the skeletal muscle tissue characterized by symmetric weakness of proximal muscles of the limbs, neck, and pharynx.
- Polyneuropathy:** (PAH-lee-new-RAH-puh-thee) A disease involving multiple nerves.
- Polyphagia:** (PAH-lee-FAY-jee-ah) Excessive eating.
- Polyuria:** (PAH-lee-YOOR-ee-ah) Excessive urination.
- Portal hypertension:** (POR-tuhl HIGH-per-TEN-shun) Persistent blood pressure elevation in the portal circulation of the abdomen.
- Postcoital:** (post-KOH-i-tal) Following sexual intercourse.
- Postictal:** (pohst-IK-tuhl) Occurring after a sudden attack, such as an epileptic seizure.
- Postmortem Care:** (post-MOR-tum KARE) Care after death.
- Postoperative:** (post-AHP-er-uh-tiv) Following a surgical operation.
- Postprandial:** (POST-PRAN-dee-uhl) After a meal.
- Powerlessness:** (POW-er-less-nes) Perceived lack of control over a situation.
- Preload:** (PREE-lohd) End-diastolic stretch of cardiac muscle fibers; equals end-diastolic volume.
- Preoperative:** (pre-AHP-er-uh-tiv) Preceding an operation.
- Preprandial:** (PREE-PRAN-dee-uhl) Before a meal.
- Presbycusis:** (PRESS-by-KYOO-sis) Progressive, bilaterally symmetrical perceptible hearing loss occurring with age; usually occurs after age 50 and is caused by structural changes in the organs of hearing.
- Presbyopia:** (PREZ-by-OH-pee-ah) Diminution of accommodation of the lens of the eye occurring normally with aging, and usually resulting in hyperopia, or farsightedness.
- Pressure ulcer:** (PRESS-sure ULL-sir) An open sore or lesion of the skin that develops because of prolonged pressure against an area.
- Priapism:** (PRY-uh-pizm) Erection that lasts too long.
- Primary hypertension:** (PRY-mare-ee HIGH-per-TEN-shun) Abnormally elevated blood pressure of unknown cause. Also called essential hypertension.
- Proctitis:** (prock-TIGH-tis) Inflammation of the rectum and anus.
- Proctosigmoidoscopy:** (PROK-toh-SIG-moy-DAHS-kuh-pee) Visual examination of the rectum and sigmoid colon by use of a sigmoidoscope.
- Prodrome:** (PROH-droh-m) A symptom indicating the onset of a disease.
- Prostaglandins:** (PRAHS-tah-GLAND-ins) Chemical neurotransmitters usually associated with pain at the site of an injury, periphery.
- Prostatectomy:** (PRAHS-tuh-TEK-tuh-mee) Removal of the prostate gland.
- Prostatitis:** (PRAHS-tuh-TIGH-tis) Inflammation or infection of the prostate gland.
- Protozoa:** (pro-tow-ZOH-ah) Single-celled parasitic organisms that can move and live mainly in the soil.
- Pruritus:** (proo-RYE-tis) Severe itching.
- Pseudoaddiction:** (soo-doh-ad-DICK-shun) Syndrome in which behaviors similar to addiction appear as a result of inadequate pain control and patients fear not receiving adequate pain medications and pain relief.
- Psoriasis:** (suh-RYE-ah-sis) Chronic inflammatory skin disorder in which epidermal cells proliferate abnormally fast.
- Psychoanalysis:** (SIGH-koh-uh-NAL-i-sis) Form of therapy based on the theories of Sigmund Freud, regarding the dynamics of the unconscious.
- Psychogenic:** (SIGH-koh-JEN-ick) Of mental origin.
- Psychological dependence:** (SY-ko-LAW-ick-al dee-PEN-dens) Obsession of obtaining drugs for use other than medicinal; addiction.
- Psychopharmacology:** (SIGH-koh-FAR-meh-KAHL-uh-jee) The study of the action of drugs on psychological functions and mental states.
- Psychosomatic:** (SIGH-koh-soh-MAT-ik) Having bodily symptoms of psychological, emotional, or mental origin; illness traceable to an emotional cause.
- Psychotherapy:** (SIGH-koh-THER-uh-pee) A method of treating disease (especially mental illness) by mental rather than pharmacological means.
- Ptoxis:** (TOH-sis) Drooping of eyelid.

- Puerperal:** (pyoo-ER-per-uhl) Concerning the puerperium, or period of 42 days after childbirth.
- Pulmonary edema:** (PULL-muh-NAIR-ee uh-DEE-muh) Acute heart failure in which there is severe fluid congestion in the alveoli of the lungs; life-threatening.
- Pulse deficit:** (PULS DEF-i-sit) A condition in which the number of pulse beats counted at the radial artery is less than those counted in the same period of time at the apical heart rate.
- Purpura:** (PUR-pur-uh) Hemorrhage into the skin, mucous membranes, internal organs, and other tissues.
- Purulent:** (PURE-u-lent) Fluid that contains pus.
- Pyelogram:** (PIE-loh-GRAM) A diagnostic procedure involving x-ray of the kidneys; may be done after injection of a dye into the bloodstream or directly into the kidneys.
- Pyelonephritis:** (PYE-e-loh-ne-FRY-tis) Inflammation of the kidney and renal pelvis.
- Pyoderma:** (PYE-oh-DER-mah) Any acute, inflammatory, purulent bacterial dermatitis.
- Quadripareisis:** (kwod-ri-par-E-sis) Weakness involving all four limbs caused by spinal cord injury.
- Quadriplegia:** (KWA-dri-PLÉE-jah) Paralysis of all four limbs caused by spinal cord injury.
- Radiation therapy:** (RAY-dee-AY-shun THER-uh-pee) Cancer treatment with ionizing radiation.
- Range of motion (ROM):** (RANJE of MOH-shun) The range of movement of a body joint.
- Raynaud's disease:** (ra-NOHZ di-ZEEZ) A primary or idiopathic vasospastic disorder characterized by bilateral and symmetrical pallor and cyanosis of the fingers.
- Reality orientation:** (ree-AL-i-tee OR-ee-en-TAY-shun) A process to orient a person to facts such as names, dates, and time, through the use of verbal and nonverbal repeating messages.
- Rectocele:** (RECK-toh-seel) Protrusion or herniation of the posterior vaginal wall with the anterior wall of the rectum through the vagina.
- Regurgitation:** (ree-GUR-ji-TAY-shun) A backward flowing, as in the backflow of blood through a defective heart valve.
- Remyelination:** (ree-MY-uh-lin-AY-shun) Replacement of myelin or neurons.
- Replantation:** (re-plan-TAY-shun) The replacement of an organ or other structure, such as a digit, limb, or tooth, to the site from which it was previously lost or removed.
- Reservoir:** (REZ-er-VWAR) A person, animal, arthropod, plant, soil, or substance in which an infectious agent normally lives and multiplies, on which it depends for survival.
- Respiratory excursion:** (RES-pi-rah-TOR-ee eks-KUR-zhun) Downward movement of the diaphragm with inspiration.
- Respite care:** (RES-pit CARE) Short-term, intermittent care for the chronically ill; provides rest for the family members or caregivers from the stress of sustained caregiving.
- Respondeat superior:** (ress-POND-ee-et sue-PEER-ee-or) An institution that employs a worker may be liable for the acts or omissions of its employees.
- Retinopathy:** (RET-i-NAH-puh-thee) Disease of the retina of the eye.
- Retroflexion:** (RET-roh-FLECK-shun) A bending or flexing backward.
- Retrograde cholangiopancreatography:** (RET-roh-grayd koh-LAN-jee-oh-PAN-kree-ah-TOG-rah-fee) An endoscopic procedure that permits the physician to visualize the liver, gallbladder, and pancreas using an endoscope, dye, and x-ray examinations.
- Retrograde:** (RET-roh-grayd) Moving backward; degenerating from a better to a worse state.
- Retroversion:** (RET-roh-VER-zhun) A turning, or a state of being turned back; the tipping of an entire organ.
- Rheumatic carditis:** (roo-MAT-ick kar-DYE-tis) Serious complication of rheumatic fever in which all layers of the heart become inflamed.
- Rheumatic fever:** (roo-MAT-ick FEE-ver) A hypersensitivity reaction to antigens of group A beta-hemolytic streptococci.
- Rhinitis:** (rye-NIGH-tis) Inflammation of the nasal mucosa, usually associated with congestion, itching, sneezing, and nasal discharge.
- Rhinoplasty:** (RYE-noh-plass-tee) Plastic surgery of the nose.
- Rickettsia:** (ra-KET-see-ah) A genus of bacteria of the tribe Rickettsiae that multiply only in host cells.
- Rinne test:** (RIN-nee TEST) A test of hearing made with tuning forks.
- Romberg's test:** (RAHM-bergs TEST) A test to determine if a person has the ability to maintain body balance when the eyes are shut and the feet are close together.
- Roux-en-Y:** (roo-ehn-Y) Gastric bypass surgery. A small stomach pouch the size of a thumb is created with staples, then a Y-shaped section of the small intestine is attached to the pouch to allow food to bypass the lower stomach and duodenum.
- Rule of nines:** (ROOL of NINES) A formula for estimating percentage of body surface area, particularly helpful in judging the portion of skin that has been burned.
- Sacral radiculopathy:** (SAY-krul ra-DICK-yoo-LAH-puh-thee) Pathology of sacral nerve roots.
- Salpingitis:** (SAL-pin-JIGH-tis) Inflammation of a fallopian tube.
- Salpingoscopy:** (SAL-ping-AHS-koh-pee) Endoscopic visualization of the fallopian tubes.
- Scleroderma:** (SKLER-ah-DER-ma) A chronic manifestation of progressive systemic sclerosis in which the skin is taut, firm, and edematous, limiting movement.
- Sclerosis:** (skle-ROH-sis) A hardening or induration of an organ or tissue, especially from excessive growth of fibrous tissue.
- Seborrhea:** (SEB-oh-REE-ah) Disease of the sebaceous glands marked by increase in the amount and often alteration of the quality of sebaceous secretions.
- Secondary hypertension:** (SEK-un-DAR-ee HIGH-per-TEN-shun) High blood pressure that is a symptom of a specific cause, such as a kidney abnormality.
- Semipermeable:** (SEM-ee-PER-mee-uh-buhl) Partly permeable; said of a membrane that will allow fluids but not the dissolved substance to pass through it.
- Sensorineural:** (SEN-soh-ree-NEW-ruhl) Hearing loss caused by impairment of a sensory nerve.
- Sensory deprivation:** (SEN-suh-ree DEP-ri-VAY-shun) No or minimal stimulation of the senses that creates the potential for maladaptive coping.
- Sensory overload:** (SEN-suh-ree OH-ver-lohd) Excessive stimulation of the senses that creates the potential for maladaptive coping.
- Sepsis:** (SEP-sis) Systematic infection caused by microorganisms in the bloodstream.
- Serologic:** (SEAR-uh-LAJ-ick) Study of substances present in blood serum.
- Serosanguineous:** (SEER-oh-SANG-gwin-ee-us) Fluid consisting of serum and blood.
- Serotonin:** (SER-ah-TOH-nin) A chemical neurotransmitter important in sleep-wake cycles. Reduced serotonin levels are associated with depression.
- Shock:** (SHAHK) A clinical syndrome in which the peripheral blood flow is inadequate to return sufficient blood to the heart for normal function, particularly transport of oxygen to all organs and tissues.
- Sinoatrial node:** (SIGH-noh-AY-tree-al NOHD) Node at the junction of the superior vena cava and right atrium, regarded as the starting point of the heartbeat.
- Sinusitis:** (SINE-u-SIGH-tiss)

- Inflammation of the sinuses; may be due to viral or bacterial infection, or to allergies.
- Smallpox:** (small-POX) A disease characterized by high fever and a rash caused by variola virus, an orthopoxvirus unique to humans that has a 30% fatality rate.
- Snellen's chart:** (SNEL-ens CHART) A chart imprinted with lines of black letters graduating in size from smallest on the bottom to largest on top; used for testing visual acuity.
- Somatoform:** (soh-MAT-uh-form) Denoting psychogenic symptoms resembling those of physical disease; psychosomatic.
- Spider angioma:** (SPY-der an-jee-OH-mah) Thin reddish-purple vein lines close to the skin surface.
- Spirituality:** (SPIHR-it-u-AL-it-tee) Sense of connectedness with all of life and the universe.
- Splenectomy:** (sple-NEK-tuh-mee) Excision of the spleen.
- Splenomegaly:** (SPLEE-noh-MEG-ah-lee) Enlargement of the spleen.
- Standard of best interest:** (STAND-erd OF BEST IN-ter-est) A type of decision made about patients' health care when they are unable to make an informed decision about their own care.
- Standard precautions:** (STAN-derd pre-KAW-shuns) Guidelines recommended by the Centers for Disease Control and Prevention to reduce the risk of the spread of infection.
- Stapedectomy:** (stay-pee-DEK-toh-mee) Excision of the stapes in order to improve hearing, especially in cases of otosclerosis.
- Staphylococcus:** (STAFF-il-oh-KOCK-uss) A genus of gram-positive bacteria; they are constantly present on the skin and in the upper respiratory tract and are the most common cause of localized suppurating infections.
- Status asthmaticus:** (STAT-us az-MAT-ikus) Prolonged period of unrelieved asthma symptoms.
- Steatorrhea:** (STEE-ah-toh-REE-ah) Fat in the stools; may be associated with pancreatic disease.
- Stenosis:** (ste-NOH-sis) The constriction or narrowing of a passage or orifice, such as a cardiac valve.
- Stent:** (STENT) Any mold or device used to hold tissue in place or to provide a support, graft, or anastomosis while healing is taking place.
- Stereotype:** (STER-ee-oh-TIGHP) An opinion or belief about an individual or group that may not be true.
- Sternotomy:** (stir-NAH-tuh-mee) The operation of cutting through the sternum.
- Stoma:** (STOH-mah) A mouth, small opening, or pore.
- Stomatitis:** (STOH-mah-TIGH-tis) Inflammation of the mouth.
- Stress:** (STRESS) The physical (gravity, mechanical, pathogenic, injury) and psychological (fear, anxiety, crisis, joy) forces that are experienced by individuals.
- Stressor:** (STRESS-er) Any person or situation that produces an anxiety response.
- Striae:** (STRIGH-ee) A line or band of elevated or depressed tissue; may differ in color or texture from surrounding tissue.
- Subarachnoid:** (SUB-uh-RAK-noyd) Below or under the arachnoid membrane and the pia mater of the covering of the brain and spinal cord.
- Subdural:** (sub-DUHR-uhl) Beneath the dura mater.
- Subjective data:** (sub-JEK-tiv DAY-tuh) Information that is provided verbally by the patient.
- Suffering:** (SUFF-er-ing) A state of severe distress associated with events that threaten the intactness of the person. Emotional pain associated with real or potential tissue damage.
- Sumons:** (SUM-muns) A notice of suit.
- Suprapubic:** (SOO-pruh-PEW-bik) Bone of the groin (or region) located above the pubic arch.
- Surgeon:** (SURGE-on) A medical practitioner who specializes in surgery.
- Synovitis:** (sin-oh-VIGH-tis) Inflammation of the synovial membrane that may be the result of an aseptic wound, a subcutaneous injury, irritation, or exposure to cold and dampness.
- Systolic blood pressure:** (sis-TAL-ik BLUHD PRESS-ur) Maximal pressure exerted on the arteries during contraction of the left ventricle of the heart. The top number of a blood pressure reading.
- Tachycardia:** (TAK-ee-KAR-dee-yah) An abnormal rapidity of heart action, usually defined as a heart rate greater than 100 beats per minute in adults.
- Tachydysrhythmia:** (TACK-ee-dis-RITH-mee-yah) An abnormal heart rhythm with rate greater than 100 beats per minute in an adult.
- Tachypnea:** (TAK-ip-NEE-ah) Abnormally rapid respiratory rate.
- Tamponade:** (TAM-pon-AYD) Compression of a part.
- Tension pneumothorax:** (TEN-shun NEW-moh-THOR-raks) Abnormal accumulation of air with buildup of pressure in the pleural space.
- Teratoma:** (ter-uh-TOH-muh) A congenital tumor containing one or more of the three primary embryonic germ layers.
- Terminal illness:** (TERM-in-al ILL-ness) An illness that will probably cause death in 6 months or less.
- Tetanus:** (TET-nus) A highly fatal disease caused by the bacillus *Clostridium tetani* and characterized by muscle spasm and convulsions.
- Tetany:** (TET-uh-nee) Muscle spasms, numbness, and tingling caused by changes in pH and low serum calcium.
- Thoracentesis:** (THOR-uh-sen-TEE-sis) Insertion of a large-bore needle into the pleural space to remove fluid.
- Thoracotomy:** (THAW-rah-KAH-tah-mee) Surgical incision into the chest wall.
- Thrill:** (THRILL) Abnormal vessel that has a bulging or narrowed wall; a vibration is felt.
- Thrombi:** (THROM-by) Blood clots.
- Thrombocytopenia:** (THROM-boh-SIGH-toh-PEE-nee-uh) Abnormal decrease in the number of blood platelets.
- Thrombolytic:** (throm-bo-LIT-ik) Agent that dissolves or splits up a thrombus, an aggregation of blood factors.
- Thrombophlebitis:** (THROM-boh-fle-BYE-tis) The formation of a clot and inflammation within a vein.
- Thrombosis:** (throm-BOH-sis) Formation, development, or presence of a thrombus, an aggregation of blood factors.
- Tidaling:** (TIGH-dah-ling) Rise and fall; may refer to water in water-seal chamber of a chest drainage system.
- Titration:** (tigh-TRAY-shun) Adjustment of medication up or down to meet patient needs.
- Tolerance:** (TALL-er-ens) The response of the body to medication that requires increased medication administration to achieve the same effect. Often refers to opioids.
- Torts:** (TORTS) Lawsuits involving civil wrongs.
- Toxemia:** (tock-SEE-me-ah) Spread of poisonous products of bacteria throughout the body.
- Tracheostomy:** (TRAY-key-AHS-tuh-me) A surgical opening in the neck into the trachea to provide an airway when the trachea is obstructed.
- Tracheotomy:** (TRAY-key-AH-tuh-me) An opening in the neck into the trachea.
- Traditions:** (tra-DISH-uns) Practices and customs handed down through the generations, often by word of mouth.
- Transcellular:** (trans-SELL-yoo-lar) Across cell membranes.
- Transdermal:** (trans-DER-mal) Entering through the dermis, or skin, as in administration of a drug applied to the skin in ointment or patch form.
- Transillumination:** (TRANS-i-loo-mi-NAY-shun) The passage of strong light through a body structure to permit inspection of an observer on the opposite side.

- Transjugular intrahepatic portosystemic shunt (TIPS):** (TRANZ-jug-yoo-lar intra-hep-PAT-ik POR-toh-sis-TEM-ik SHUNT) Shunt that side-tracks venous blood around the liver to the vena cava for treatment of ascites.
- Transmyocardial** (TRANS-my-o-KAR-dee-yah) Across all layers of the heart.
- Trauma:** (TRAW-mah) Physical injury caused by an external force.
- Trendelenburg's position:** (tren-DELL-en-bergz POH-si-shun) A position in which the patient's head is low and the body and legs are on an elevated and inclined plane.
- Triage:** (TREE-ahj) To sort.
- Trigeminy:** (try-JEM-i-nee) Occurring every third beat, as in trigeminal premature ventricular contractions.
- Tropia:** (TROH-pee-ah) A manifest deviation of an eye from the normal position when both eyes are open and uncovered.
- T-tube:** (TEE-toob) A T-shaped tube in the bile duct that allows drainage of bile following gallbladder surgery.
- Tumor:** (TOO-mur) An abnormal growth of cells or tissues; tumors may be benign or malignant.
- Turbid:** (TER-bid) Cloudy.
- Turgor:** (TER-ger) The resistance of the skin to being grasped between the fingers. Dehydration causes poor skin turgor.
- Unifocal:** (YOO-ni-FOH-kuhl) Coming or originating from one site or focus.
- Upper gastrointestinal series (upper GI, UGI):** (UH-per GAS-troh-in-TES-ti-nuhl SEER-ees) X-ray and fluoroscopic examinations of the stomach and duodenum after the ingestion of a contrast medium.
- Uremia:** (yoo-REE-mee-ah) An excess in the blood of urea, creatinine, and other nitrogenous end products of protein and amino acid metabolism.
- Urethritis:** (YOO-ree-THRIGH-tis) Inflammation of the urethra.
- Urethroplasty:** (yoo-REE-throh-PLAS-tee) Plastic repair of the urethra.
- Urinary incontinence:** (YOOR-i-NAR-ee in-KON-ti-nents) Inability to control urine excretion creating accidental urinary leakage.
- Urodynamic:** (YOO-roh-dye-NAM-ik) The study of the holding or storage of urine in the bladder, the facility with which it empties, and the rate of movement of urine out of the bladder during urination.
- Urosepsis:** (YOO-roh-SEP-sis) Septicemia resulting from urinary tract infection.
- Urticaria:** (UR-ti-CARE-ee-ah) Hives signifying an allergic reaction.
- Utilitarian:** (yoo-TILL-I-TAR-I-en) Consequences or outcomes of a dilemma are the most important element.
- Vaginosis:** (VAJ-i-NOH-sis) Inflammation of the vagina caused by *Gardnerella vaginalis*.
- Values:** (VAL-use) Ideals or concepts that give meaning to an individual's life.
- Valvotomy:** (val-VAH-tuh-mee) Cutting through a valve.
- Valvuloplasty:** (VAL-vyoo-loh-PLAS-tee) Plastic or restorative surgery on a valve, especially a cardiac valve.
- Varices:** (VAR-i-seez) Dilated veins.
- Varicocele:** (VAR-i-koh-seel) Varicose veins of the scrotum; can lead to infertility.
- Varicose veins:** (VAR-i-kohs VAINS) Swollen, distended, and knotted veins, usually in the subcutaneous tissue of the leg.
- Vasculitis:** (VAS-kue-LIGH-tis) Inflammation of a vessel.
- Vasectomy:** (va-SEK-tuh-mee) Surgically cutting and sealing the vas deferens to prevent sperm from getting outside the body. Used as a birth control method for men.
- Vector:** (VECK-tur) Living organism that transmits disease.
- Venous stasis ulcers:** (VEE-nus STAY-sis UL-sers) Poorly healing ulcers that result from inadequate venous drainage.
- Ventricular diastole:** (ven-TRICK-yoo-lar dye-AS-tuh-lee) The period of relaxation of the two ventricles.
- Ventricular escape rhythm:** (ven-TRICK-yoo-lar es-KAYP RITH-uhm) The naturally occurring rhythm of the ventricles when the rest of the cardiac conduction system fails.
- Ventricular repolarization:** (ven-TRICK-yoo-lar RE-pol-lahr-i-ZAY-shun) Reestablishment of the polarized state of the muscle after contraction.
- Ventricular systole:** (ven-TRICK-yoo-lar SIS-tuh-lee) The contraction of the two ventricles.
- Ventricular tachycardia:** (ven-TRICK-yoo-lar TACK-ee-KAR-dee-yah) A series of at least three beats arising from a ventricular focus at a rate greater than 100 beats per minute.
- Verrucous:** (ve-ROO-kus) Wartlike, with raised portions.
- Vertebrae:** (VER-te-bray) Any of the 33 bony segments of the spinal column: 7 cervical, 12 thoracic, 5 lumbar, 5 sacral, and 4 coccygeal vertebrae.
- Vesicant:** (VESS-i-kant) Agent that causes blistering of tissue.
- Vesicular:** (ve-SICK-yoo-ler) Pertaining to vesicles or small blisters.
- Virulence:** (VEER-you-lence) The power of an organism to cause disease.
- Virus:** (VIGH-rus) The smallest organism identified by use of electron microscopy; intracellular parasites that may cause disease.
- Viscosity:** (vis-KAH-si-tee) Thickness, as of the blood.
- Volvulus:** (VOL-view-lus) A twisting of the bowel on itself, causing obstruction.
- Vulvovaginitis:** (VUL-voh-VAJ-I-NIGHTIS) Inflammation of the vulva and vagina.
- Weber test:** (VAY-ber TEST) A test for unilateral deafness.
- Welfare rights:** (WELL-fare RIGHTS) Also called legal rights; rights that are based on a legal entitlement to some good or benefit.
- White blood cells:** (WIGHT BLUHD SELLS) Leukocytes; the body's primary defense against infection.
- Withdrawal:** (with-DRAW-ul) Symptoms caused by cessation of administration of a drug, especially a narcotic or alcohol, to which the individual has become either physiologically or psychologically addicted.
- Worldview:** (WERLD-vyoo) The way individuals look on the world to form values and beliefs about life and the world around them.
- Xerostomia:** (ZEE-roh-STOH-mee-ah) Dry mouth caused by reduction in secretions.

Index

Note: Page numbers in *italics* indicate figures. Page numbers followed by t indicate tables and by b indicate boxes.
