TEST	NORMAL RANGE FOR ADULTS	SIGNIFICANCE OF ABNORMAL FINDINGS
Serum Studies		
Follicle-stimulating hormone (FSH) (Follitropin)	<i>Men:</i> 1.42-15.4 IU/L <i>Women:</i> follicular phase, 1.37-9.9 units/L; midcycle, 6.17-17.2 units/L; luteal phase, 1.09-9.2 units/L; postmenopause, 19.3-100.6 units/L	Decreased levels indicate possible infertility, anorexia nervosa, neoplasm. Elevations indicate possible Turner's syndrome.
Luteinizing hormone (LH) (Lutropin)	<i>Men:</i> 1.24-7.8 units/L <i>Women:</i> follicular phase, 1.68-15 units/L; midcycle, 21.9-56.6 units/L; luteal phase, 0.61-16.3 units/L; postmenopause, 14.2-52.3 units/L	Decreased levels indicate possible infertility, anovulation. Elevations indicate possible ovarian failure, Turner's syndrome.
Prolactin	<i>Men:</i> 3-13 ng/mL <i>Women:</i> 3-27 ng/mL <i>Pregnant women:</i> 20-400 ng/mL	Elevations indicate possible galactorrhea (breast discharge), pituitary tumor, disease of hypothalamus or pituitary gland, hypothyroidism.

Estradiol	Men: 10-50 pg/mL Women: follicular phase, 20-350 pg/mL; midcycle, 150-750 pg/mL; luteal phase, 30-450 pg/mL; postmenopause, <20 pg/mL	Elevations of estradiol, total estrogens, and estriol in men indicate possible gynecomastia, decreased body hair, increased fat deposits, feminization, testicular tumor; in women, ovarian tumor.
Estriol	Men and nonpregnant women: N/A	Decreased levels of estradiol, total estrogens, and estriol in women indicate possible amenorrhea, climacteric, impending miscarriage, hypothalamic disorders.
Progesterone	Men: 10-50 ng/dL Women: follicular phase, <50 ng/dL; luteal phase, 300-2500 ng/dL; postmenopausal, <40 ng/dL	Decreased levels in women indicate possible inadequate luteal phase, amenorrhea. Elevations in women indicate possible ovarian luteal cysts. Decreased levels may indicate ovarian neoplasm, ovarian dysfunction.
Testosterone	Men: 280-1080 ng/dL Women: <70 ng/dL	Increased levels in men indicate possible testicular tumor, hyperthyroidism. Decreased levels in men indicate possible hypogonadism. Elevations in women indicate possible adrenal neoplasm, ovarian neoplasm, polycystic ovary syndrome.
Prostate-specific antigen	Men: 0-2.5 ng/mL	Increased levels may indicate prostatitis, benign prostatic hyperplasia, prostate cancer.
Urine Studies		
Total estrogens	Men: 4-25 mcg/24 hr Women: 4-60 mcg/24 hr	Elevations indicate possible testicular tumors. Decreased levels indicate possible ovarian dysfunction.
Pregnanediol	Men: 0-1.9 mg/24 hr Women: follicular phase, <2.6 mg/24 hr; luteal phase, 2.6-10.6 mg/24 hr	Elevations indicate possible luteal ovarian cysts, ovarian neoplasms, adrenal disorders. Decreased levels indicate possible amenorrhea.
17-Ketosteroids	Men (20-50 yr): 6-20 mg/24 hr Women (20-50 yr): 6-17 mg/24 hr Values decrease with age	Elevations indicate possible Cushing's syndrome, increased androgen or cortisol production, severe stress. Decreased levels indicate possible Addison's disease, hypopituitarism.

1 mcg, 1 microgram or 1 millionth of a gram; 1 ng, 1 nanogram or 1 billionth of a gram; 1 pg, 1 picogram or 1 trillionth of a gram.

Data from Pagana, K.D., Pagana, T.J., & Pagana, T.N. (2017). *Mosby's diagnostic and laboratory test reference* (13th ed.). St. Louis: Mosby.

The Pap test should be scheduled between the patient's menstrual periods so the menstrual flow does not interfere with laboratory analysis. Teach women not to douche, use vaginal medications or deodorants, or have sexual intercourse for at least 24 hours before the test, because these may interfere with test interpretation.

The American Cancer Society (ACS) advises all women to begin having an annual Pap test at 21 years of age. Women younger than 21 years should not be tested (ACS, 2017a). Between ages 21 and 29 years, women should have a Pap test every 3 years; women between ages 30 and 65 years should have a Pap test plus a human papilloma virus (HPV) test ("co-testing") every 5 years. More information on the HPV test is found later in this chapter. According to the ACS, women older than 65 years who have had regular cervical cancer testing with normal results do not need Pap testing (ACS, 2017a). Recommended guidelines from other health care organizations suggest a Pap test every 3 years for women older than 60 years. Those who have had a history of a serious cervical precancerous lesion should be tested annually for at least 20 years after that diagnosis, regardless of age (ACS, 2017a).

Canadian guidelines are similar and state that women should begin annual Pap testing at either 21 or 25 years of age, depending on the province. Between 30 and 69 years, women should have a Pap test every 3 years. After 70, Pap tests are not needed (Society of Obstetricians and Gynaecologists of Canada, 2013).

Other types of laboratory testing include cytologic vaginal *cultures*, which can detect bacterial, viral, fungal, and parasitic disorders. Examination of cells from the vaginal walls can evaluate estrogen balance.

The **human papilloma virus (HPV) test** can identify many high-risk types of HPV infection associated with the development of cervical cancer. This test can be done at the same time as the Pap test for women older than 30 years and for women of any age who have had an abnormal Pap test result (ACS, 2017a). It does not take the place of the Pap test because it tests for viruses that can cause cell changes in the cervix that, if not treated, could lead to cancer. Cells are collected from the cervix and sent to a laboratory for analysis. Women who have normal Pap test results and no HPV infection are at very low risk for developing cervical cancer. Conversely, women with an abnormal Pap test result and a positive HPV test are at higher risk if not treated.

Serum levels of follicle-stimulating hormone (FSH), luteinizing hormone (LH), and prolactin are helpful in the diagnosis of male and female reproductive tract disorders. No nutrition restrictions are necessary before the test. Serum testing can also detect estrogen, progesterone, and testosterone levels in men and women. See [Chart 69-3](#) for normal values and the significance of abnormal findings.

*Serologic studies* detect antigen-antibody reactions that occur in response to foreign organisms. This form of diagnostic testing is helpful only after an infection has become well established. Serologic testing can be used in the evaluation of exposure to organisms causing syphilis, rubella, and herpes simplex virus type 2 (HSV2). Results may be read as *nonreactive*, *weakly reactive*, or *reactive*. A single titer is not as revealing as serial titers, which can detect the rise in antibody reactions as the body continues to fight the infection.

The *prostate-specific antigen (PSA)* test is used to screen for prostate cancer and to monitor the disease after treatment. PSA levels less than 2.5 ng/mL may be considered normal, although there is no agreement on that value and how it is affected by age. Elevated PSA levels may be associated with prostate cancer. Older men, particularly African-American men, often have a higher than normal PSA, especially as they age (Pagana et al., 2017). Chapter 72 discusses this test in more detail.

## NCLEX Examination Challenge 69-1

### Health Promotion and Maintenance

A 70-year-old client asks the nurse if she needs a Pap smear. Her last Pap smear was 3 years ago, and it was normal. What is the correct nursing response?

- A. "Yes, you need a Pap test this year."
- B. "You aren't due for another Pap test until next year."
- C. "A Pap smear is not needed unless you are sexually active."
- D. "You may not need an annual Pap smear after 65 years of age."

### Imaging Assessment

#### Computed Tomography.

CT scans for reproductive system disorders involve the abdomen and the pelvis. Primary health care providers can detect and evaluate masses and identify lymphatic enlargement from metastasis. This scan can differentiate solid tissue masses from cystic or hemorrhagic structures.

#### Hysterosalpingography.

A **hysterosalpingogram** is an x-ray that uses an injection of a contrast medium to visualize the cervix, uterus, and fallopian tubes. This test is used to evaluate tubal anatomy and patency and uterine problems such as fibroids, tumors, and fistulas. The study should not be attempted for at least 6 weeks after abortion, delivery, or dilation and curettage. Other contraindications include reproductive tract infection and uterine bleeding.

The examination is best performed in the first half (days 1 to 14) of the patient's menstrual cycle, which reduces the chance that the patient may be pregnant. Patients preparing to have a hysterosalpingogram should be instructed to follow the recommendations of their health care provider, which may include taking an over-the-counter pain reliever before the procedure.

On the day of the examination, confirm the date of the patient's last menstrual period. Ask about allergies to iodine dye or shellfish. The primary health care provider provides information about benefits and risks of the procedure with the patient. As the nurse, you may witness the signed informed consent. Be aware that the patient may experience some nausea and vomiting, abdominal cramping, or faintness during the procedure. Provide support and assistance with relaxation techniques as needed.

After the patient is placed in lithotomy position, the health care provider will insert a speculum to view the cervix. Dye is injected through the cervix to fill and highlight the interior of the cervix, uterus, and fallopian tubes. If the fallopian tubes are patent, the contrast material spills into the peritoneal cavity. Usually only two or three views are obtained to show the path and distribution of the contrast medium.

The patient may experience pelvic pain after the study and should receive analgesic medications as ordered. Inform her that she may also have referred pain to the shoulder because of irritation of the phrenic nerve. Provide a perineal pad after the test to prevent soiling of clothes as the dye drains from the cervix. Instruct the patient to contact her primary health care provider if bloody discharge continues for 4 days or longer and to immediately report any signs of infection, such as lower quadrant pain, fever, malodorous discharge, or tachycardia.

## Mammography.

**Mammography** is an x-ray of the soft tissue of the breast. Mammograms assess differences in the density of breast tissue. They are especially helpful in evaluating poorly defined masses, multiple masses or nodules, nipple changes or discharge, skin changes, and impaired COMFORT.

Mammography can detect many cancers that are not palpable by physical examination. However, some actual cancers may not appear on mammography or may appear as benign (ACS, 2017b).

In young women's breasts, there is little difference in the density between normal glandular tissue and malignant tumors, which makes the mammogram less useful for evaluation of breast masses in these women. For this reason, annual screening mammograms are not recommended for women younger than 40 years (ACS, 2017b). In older women, the amount of fatty tissue is higher, and the fatty tissue appears lighter than cancers. Cancer and cysts may have the same density. Cysts usually have smooth borders, and cancers often have starburst-shaped margins.

No dietary restrictions are necessary before the mammogram. Remind the patient not to use creams, lotions, powders, or deodorant on the breasts or underarms before the study because these products may be visible on the mammogram and lead to misdiagnosis. If there is any possibility that the patient is pregnant, the test should be rescheduled. Explain the purpose of the study and its anticipated discomforts. The technician or assistant provides a gown and privacy for the woman to undress above the waist. Allow the patient to express concerns about the mammogram and the presence of any lumps.

When performing a standard mammogram, a technician positions the patient next to the x-ray machine with one breast exposed. A film plate and the platform of the machine are placed on opposite sides of the breast to be examined. The technician includes as much breast tissue as possible between the plates. The woman may experience some temporary discomfort when the breast is compressed (for about a minute for each of four positions). The entire test takes about 15 minutes. The patient usually is asked to wait until the films are reviewed in case a view needs to be repeated.

Most breast imaging centers offer **digital 3D mammography**, also known as digital breast tomosynthesis. This technology allows the radiologist to visualize through layers or "slices" of breast tissue, similar to a CT scan. If a digital mammogram is performed, the images are recorded and saved as computer files (ACS, 2017b). Medicare and most other health insurances pay for this newer and more expensive technology because it improves diagnosis accuracy.

Inform the patient when to expect the report of the results. Because this is a time when she is anxious about the health of her breasts, teach or reinforce the importance of breast self-awareness and provide instructions as needed.

## Ultrasonography.

Ultrasonography (US) is a technique that is used to assess fibroids, cysts, and masses. It can be used to monitor the progress of tumor regression after medical treatment. US is also helpful in differentiating solid tumors from cysts in breast examinations. In men, ultrasound can test for varicoceles, scrotal abnormalities, and problems of the ejaculatory ducts and seminal vesicles and the vas deferens (Pagana, et al., 2017).

For an abdominal, breast, or scrotal scan, the technician exposes the area and applies gel to the area to be scanned, which provides better transmission of sound waves from the transducer through the patient's skin. The transducer is moved in a linear pattern across the area being tested to outline and define soft-tissue masses and to differentiate tumor type, ascites, and encapsulated fluid.

For a *transvaginal* or *transrectal* scan, the transducer is covered with a condom onto which transmission gel has been placed. The transducer is then inserted into the vagina or rectum as indicated. Women should have an empty or only partially filled bladder if they are having a transvaginal ultrasound. For women who are incontinent, a urinary catheter may be inserted and filled with fluid to allow optimal visualization. Patients having an internal ultrasound should be informed that they might feel some mild impaired COMFORT associated with pressure of the probe.

## Magnetic Resonance Imaging.

MRI uses a magnetic field and radiofrequency energy to distinguish between normal and malignant tissues. MRIs are used in addition to mammograms to assess for breast cancer in women who have a genetic risk (ACS, 2017c). The use of MRI in evaluating patients with dense breast tissue may

reduce the need for biopsy. MRI is also used to detect pelvic tumors.

## Endoscopic Studies

### Colposcopy.

A colposcope allows three-dimensional magnification and intense illumination of epithelium with suspected disease. **Colposcopy** is suited for inspection of a female patient's cervical epithelium, vagina, and vulvar epithelium. Because it provides accurate site selection, this procedure can locate the exact site of premalignant and malignant lesions for biopsy.

Inform the patient that she should not douche or use vaginal preparations for 24 to 48 hours before the test. This nearly painless procedure is better tolerated if it is explained in advance and if the actual colposcope instrument is shown to the patient. Explain that the primary health care provider may take a biopsy while performing colposcopy.

Provide the patient with a gown and privacy, and instruct her to undress from the waist down. Assist the patient to the lithotomy position. The primary health care provider locates the cervix or vaginal site through a speculum examination. Lubricants other than water should not be used. Cells in the area may be stained or left unstained to enhance visibility. The cervix will be cleaned and moistened with normal saline to increase the visibility of vascular patterns and the junction between the columnar epithelium and the squamous epithelium. Acetic acid is applied to the cervix to draw moisture from the tissue and to accentuate important features. The primary health care provider then uses a colposcope or colpomicroscope to inspect the area in question, and a biopsy specimen can be taken if abnormal cells are seen. (See Cervical Biopsy section later in this chapter.)

After the procedure, allow the patient to rest for a few minutes, especially if she had a biopsy performed. Provide privacy and supplies to clean the perineum and a perineal pad to absorb any dye or discharge. Inform the patient that she may wish to wear a sanitary pad because mild cramping, spotting, or dark or black-colored discharge (from medication applied to the cervix to reduce bleeding) may occur for several days. Remind the patient to take pain relievers as recommended by her primary health care provider but to avoid aspirin to decrease the chance of bleeding. The patient should be instructed to refrain from douching, using tampons, and having sexual intercourse for 1 week (or as instructed by the primary health care provider).

### Laparoscopy.

**Laparoscopy** is a direct examination of the pelvic cavity through an endoscope. This procedure can rule out an ectopic pregnancy, evaluate ovarian disorders and pelvic masses, and aid in the diagnosis of infertility and unexplained pelvic pain. Laparoscopy is also used during surgical procedures such as:

- Tubal sterilization
- Ovarian biopsy
- Cyst aspiration
- Removal of endometriosis tissue
- Lysis of adhesions around the fallopian tubes
- Retrieval of "lost" intrauterine devices

A laparoscopy may also be used instead of a laparotomy for minor surgical procedures because it uses small incisions, involves less discomfort, and typically does not require overnight hospitalization.

The surgeon describes benefits and risks of the procedure to the patient. Risks include complications associated with the use of anesthesia, postoperative shoulder pain from irritation of the phrenic nerve, effects of carbon dioxide gas and/or peritoneal stretching, irritation at the incision site, and the rare occurrence of infection or electrical burns. As the nurse, you may witness the patient signing the informed consent. A laparoscopy can be performed with a regional or general anesthetic.

After the patient is anesthetized and placed in the lithotomy position, a urinary catheter is inserted to drain the bladder. The operating table is placed in slight Trendelenburg position to allow the intestines to fall away from the pelvis. The cervix is held with a cannula to allow movement of the uterus during laparoscopy (Fig. 69-4). The surgeon inserts a needle below the

umbilicus to infuse carbon dioxide (CO<sub>2</sub>) into the pelvic cavity, which distends the abdomen and permits better visualization of the organs. After the trocar and cannula are in place in the abdominal cavity, the surgeon removes the trocar and inserts the laparoscope. The surgeon can then visualize the pelvic cavity and reproductive organs. Further instrumentation is possible through one or more small incisions. The laparoscope is removed at the end of the procedure, and the abdomen is deflated. The small incision is closed with absorbable sutures and dressed with an adhesive bandage.

**FIG. 69-4** Laparoscopy. CO<sub>2</sub>, Carbon dioxide.

The patient is usually discharged on the day of the procedure. Discomfort from the incision is managed by oral analgesics. The greatest discomfort is caused by referred shoulder pain. Most of these sensations disappear within 48 hours depending on the extent of the procedure. Instruct the patient to change the small adhesive bandage as needed and to observe the incision for signs of infection or hematoma. Remind her also to avoid strenuous activity for the first week after the procedure.

### Hysteroscopy.

**Hysteroscopy** is a procedure that uses a fiberoptic camera to visualize the uterus to diagnose and treat causes of abnormal bleeding. The hysteroscope includes a fiberoptic camera that is inserted into the vagina to examine the cervix and uterus. Diagnostic hysteroscopy is used to diagnose new problems with the uterus or to confirm results from other tests. Hysteroscopy can also be used before or during other procedures (e.g., laparoscopy) for infertility and unexplained bleeding. The procedure is best performed 5 days after menses has ceased to reduce the possibility of pregnancy.

The physician informs the patient of benefits and risks associated with the procedure and obtains consent. You may witness the patient signing the informed consent. The preparation is the same as for a pelvic examination. After the patient is placed in lithotomy position, she is usually anesthetized with a paracervical or other regional block before the cervix is dilated. The physician inserts the hysteroscope through the cervix. Because this distends the uterus, cells can be pushed through the fallopian tubes and into the pelvic cavity. Therefore hysteroscopy is contraindicated in patients with suspected cervical or endometrial cancer, in those with infection of the reproductive tract, and in pregnant patients.

Care is the same as that after a pelvic examination. Analgesics may be prescribed if the patient has cramping or shoulder pain.

### Biopsy Studies

## Cervical Biopsy.

In a cervical biopsy, cervical tissue is removed for cytologic study. A biopsy is indicated for an identifiable cervical lesion, regardless of the cytologic findings. The primary health care provider usually performs a biopsy in conjunction with colposcopy as a follow-up to a suspicious Pap test finding. The procedure may be performed in a clinic or office setting.

Several techniques can be used for a cervical biopsy. If a lesion is clearly visible, an endocervical curettage can be performed as an ambulatory care procedure and with little or no anesthetic.

**Conization** (removal of a cone-shaped sample of tissue) and loop electrosurgical excision procedures (LEEPs) are usually not done unless the cervical biopsy findings are positive or the results of the colposcopy are unsatisfactory (Lowdermilk et al., 2016). Conization can be done as a cold-knife procedure, a laser excision, or an electrosurgical incision.

The biopsy is usually scheduled when the woman is in the early proliferative phase of the menstrual cycle, when the cervix is least vascular. Because a biopsy evaluates potentially cancerous cells, your patient may be anxious and need time to discuss her feelings and fears. The use of relaxation techniques may assist COMFORT. Assist her into the lithotomy position, recognizing that further preparation depends on the type of procedure to be performed.

The physician may anesthetize the patient according to the needs of the chosen procedure. He or she visualizes the cervix and obtains the tissue sample, which is immediately placed into a formalin solution. The type of anesthetic used for the procedure determines the type of immediate care that is needed after the procedure. Discharge instructions can be found in [Chart 69-4](#).

### Chart 69-4

## Patient and Family Education: Preparing for Self-Management

### The Patient Recovering From Cervical Biopsy

- Do not lift any heavy objects until the site is healed (about 2 weeks).
- Rest for 24 hours after the procedure.
- Report any excessive bleeding (more than that of a normal menstrual period) to your health care provider.
- Report signs of infection (fever, increased pain, foul-smelling drainage) to your health care provider.
- Do not douche, use tampons, or have vaginal intercourse until the site is healed (about 2 weeks).
- Keep the perineum clean and dry by using antiseptic solution rinses (as directed by your health care provider) and changing pads frequently.

## Endometrial Biopsy.

Both endometrial biopsy and aspiration are used to obtain cells directly from the lining of the uterus to assess for cancer of the endometrium. Biopsy helps assess menstrual disturbances (especially heavy bleeding) and infertility (corpus luteum dysfunction).

When menstrual disturbances are being evaluated, the biopsy is generally done in the immediate premenstrual period to provide an index of progesterone influence and ovulation. A biopsy performed in the second half of the menstrual cycle (about days 21 and 22) evaluates corpus luteum function and the presence or absence of a persistent secretory endometrium. Postmenopausal women may undergo biopsies at any time.

Menstrual data should be obtained from the patient and are included on the specimen request for the pathologist. Prepare the patient in the same way as you would for a pelvic examination. Advise her that she may experience some cramping when the cervix is dilated. Analgesia before the procedure and relaxation and breathing techniques during the procedure may be helpful to make her more comfortable.

An endometrial biopsy is usually done as an office procedure with or without anesthesia. After the uterus is measured and the cervix dilated, the primary health care provider inserts the curette or intrauterine cannula into the uterus. A portion of the endometrium is withdrawn using either the cuplike end of the curette or suction equipment and is placed into a formalin solution to be sent for histologic examination. The patient will likely have moderate cramping. Allow her to rest on the examining table until the cramping has subsided. Provide a perineal pad and a wipe to clean the perineum. Teach her that spotting may be present for 1 to 2 days but any signs of infection or excessive bleeding should be reported to the physician. Instruct the patient to avoid intercourse or douching until all discharge has ceased.

### Breast Biopsy.

All breast masses should be evaluated for the possibility of cancer. It is important to recognize that breast cancer can occur in both men and women; about 1% of breast cancers occur in men ([National Cancer Institute, 2017](#)). Fibrocystic lesions, fibroadenomas, and intraductal papillomas can be differentiated by biopsy. Any discharge from the breasts is examined histologically.

Provide instructions to the patient, depending on the type of biopsy performed and the type of anesthesia used. The patient usually receives a local anesthetic, and the tissue either is aspirated through a large-bore needle (core-needle biopsy) or is removed using a small incision to extract multiple samples of tissue.

Aspirated fluid from benign cysts may appear clear to dark green–brown. Bloody fluid suggests cancer. These specimens undergo histologic evaluation. If cancer is found, the tissue is evaluated for estrogen receptor analysis. [Chapter 70](#) discusses types of breast cancer and their relationship to estrogen receptors.

Teach that discomfort after the procedure is usually mild and can be controlled with analgesics or the use of ice or heat, depending on the type and extent of the biopsy. Educate the patient about how to assess the area or incision for bleeding and edema. Tell women to wear a properly supportive bra continuously for 1 week after surgery or as recommended by their surgeon. Remind the patient that numbness around the biopsy site may last several weeks. If cancer is identified, provide emotional support and reinforce information about follow-up treatment options.

### Prostate Biopsy.

When prostate cancer is suspected, a biopsy must be performed. This can be done by transurethral biopsy, by inserting a needle through the area of skin between the anus and scrotum, or, most commonly, by transrectal biopsy. Preparation for the procedure depends on the technique used to puncture the gland.

Explain to the patient that he may experience some discomfort. Teach him about breathing and relaxation techniques that may be helpful to use during the procedure. Because the purpose of this procedure is to evaluate prostate cells for cancer, allow him time to discuss his anxieties and fears.

Assist the patient who is undergoing transrectal biopsy into the side-lying position with his knees pulled up toward his chest. The primary health care provider will cleanse the area, apply gel, and then insert a thin ultrasound probe into the patient's rectum to anesthetize (if needed) and guide the biopsy needle into place. The biopsy is collected over a 5- to 10-minute period. The patient may experience a brief, uncomfortable feeling each time the needle collects a sample.

After prostate biopsy, educate the patient to take the entire prescribed antibiotic. Remind him that he may experience slight soreness, light rectal bleeding, and blood in the urine or stools for a few days. Semen may be red or rust colored for several weeks. Teach the patient to contact his primary health care provider if he has prolonged or heavy bleeding, worsening pain, swelling in the area of biopsy, and/or difficulty urinating. Rarely, sepsis can develop after a prostate biopsy. Teach the patient to contact his primary health care provider immediately if he experiences fever, pain when urinating, or penile discharge.

## NCLEX Examination Challenge 69-2

### Physiological Integrity

A client has undergone a breast biopsy. Which postprocedure symptoms will the nurse teach the

client to report **immediately** to the primary health care provider?

- A. Tenderness around the biopsy site
- B. Numbness around the biopsy site
- C. Heavy bleeding from the biopsy site
- D. Slight edema near the biopsy site

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Health Promotion and Maintenance

- Encourage women to follow recommended Pap screening guidelines for early detection of precancerous and cancerous cells from the cervix. **QSEN: Evidence-Based Practice**
- Assess and respect cultural preferences when identifying risks for certain reproductive problems and when evaluating health promotion practices. **QSEN: Patient-Centered Care**

### Psychosocial Integrity

- Allow the patient to express fear or anxiety regarding potential changes in sexual or reproductive function.
- Assess the patient's level of COMFORT in discussing issues related to reproductive health and SEXUALITY. **QSEN: Patient-Centered Care**
- Encourage patients to express feelings of anxiety or impaired COMFORT related to genital examinations and testing of the reproductive system.

### Physiological Integrity

- Urge patients with pain, bleeding, discharge, masses, or changes in reproductive function to see their health care provider. **QSEN: Safety**
- Provide privacy for patients undergoing examination or testing of the reproductive system.
- Recognize that reproductive changes occur with aging, as described in [Chart 69-1](#).
- Recall the selected laboratory tests used for diagnosing reproductive health problems as outlined in [Chart 69-3](#).
- Explain all diagnostic procedures, restrictions, and follow-up care to the patient scheduled for tests.
- Teach women to report symptoms of infection or bleeding to their health care provider after endoscopic procedures and biopsies of the breast, cervix, and endometrium. **QSEN: Safety**
- Instruct men to report symptoms of infection to their health care provider after a transrectal biopsy of the prostate. **QSEN: Safety**

## CHAPTER 70

# Care of Patients With Breast Disorders

Gail B. Johnson, Harriet Kumar

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- CELLULAR REGULATION
- COMFORT

 The CELLULAR REGULATION concept exemplar for this chapter is Breast Cancer, below.

**The interrelated concept for this chapter is SEXUALITY.**

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with interprofessional health care team members to identify community resources for the patient with breast cancer.

### Health Promotion and Maintenance

2. Describe the three-pronged approach to early detection of breast masses: mammography, clinical breast examination (CBE), and breast self-awareness.
3. Teach patients who choose breast self-examination (BSE) as an option to use correct technique.
4. Explain the options available to a person at high genetic risk for breast cancer.
5. Evaluate patient risk factors for impaired CELLULAR REGULATION in breast cancer.

### Psychosocial Integrity

6. Discuss the psychosocial impact for the patient and family who have received a diagnosis of breast cancer.
7. Discuss SEXUALITY issues with the patient having breast surgery.
8. Describe body image changes that can result from breast cancer surgery.

### Physiological Integrity

9. Compare assessment findings associated with benign breast lesions with those of malignant breast lesions.
0. Explain implications of breast reduction and breast augmentation.
  1. Differentiate treatment options for breast cancer.
  2. Use clinical judgment to prioritize nursing care for a patient with breast cancer, including managing impaired COMFORT.
  3. Describe the role of radiation and drug therapy in the care of patients with breast cancer.
  4. Identify the role of complementary and integrative therapy in breast cancer management.

Breast disorders may be benign or malignant. Changes in the breast tissue (CELLULAR REGULATION) can cause a great deal of anxiety and impaired COMFORT for women. [Chapter 2](#) reviews these nursing concepts. Nurses are often in the position of assisting patients by providing accurate information about benign breast disorders and breast cancer.

## Cellular Regulation Concept Exemplar Breast Cancer

### ❖ Pathophysiology

Cancer is a common problem of impaired CELLULAR REGULATION. Cancer of the breast begins as a single transformed cell that grows and multiplies in the epithelial cells lining one or more of the mammary ducts or lobules. It is a heterogeneous disease, having many forms with different clinical presentations and responses to therapy. Some breast cancers present as a palpable lump in the breast, whereas others show up only on a mammogram.

There are two broad categories of breast cancer: noninvasive and invasive. As long as the cancer remains within the mammary duct, it is referred to as *noninvasive*. The more common type of breast cancer is classified as *invasive*; this type grows into surrounding breast tissue. *Metastasis* occurs when cancer cells spread beyond the breast tissue and lymph nodes, via the blood and lymph systems, to distant sites. The most common sites of metastasis are bones, liver, lung, and brain, but breast cancer can spread to any organ. The course of metastatic breast cancer is related to the site affected and the level of functional impairment. The processes involved in cancer development are described in [Chapter 21](#).

### Noninvasive Breast Cancers

**Ductal carcinoma in situ (DCIS)** is an early *noninvasive* form of breast cancer. In DCIS, cancer cells are located within the duct and have not invaded the surrounding fatty breast tissue. Because of more precise mammography screening and earlier detection, the number of women diagnosed with DCIS has increased. Currently there is no way to determine which DCIS lesions will progress to invasive cancer and which ones will remain unchanged. This uncertainty causes anxiety and conflict regarding treatment decisions in many women diagnosed with DCIS. It is important to convey to patients the ways in which DCIS differs from invasive cancer and that DCIS cells lack the biologic capacity to metastasize.

Another type of noninvasive disease is **lobular carcinoma in situ (LCIS)**. The cells look like cancer cells and are contained within the lobules (milk-producing glands) of the breast. LCIS is less common than DCIS and is not thought to be a precursor of invasive cancer. However, a diagnosis of LCIS is a marker for increased risk of developing invasive breast cancer ([ACS, 2017a](#)). It is usually diagnosed before menopause in women 40 to 50 years of age. Traditionally LCIS is treated with close observation only. Women with LCIS and other breast cancer risk factors may want to consider prophylactic treatment options such as tamoxifen, raloxifene, or prophylactic mastectomy ([ACS, 2017a](#)).

### Invasive Breast Cancers

The most common type of invasive breast cancer is **infiltrating ductal carcinoma**. As the name implies, the disease originates in the mammary ducts and breaks through the walls of the ducts into the surrounding breast tissue. Once invasive, the cancer grows into the tissue around it in an irregular pattern. If a lump is present, it is felt as an irregular, poorly defined mass. As the tumor continues to grow, **fibrosis** (replacement of normal cells with connective tissue and collagen) develops around the cancer. This fibrosis may cause shortening of Cooper's ligaments and the resulting typical skin dimpling that is seen with more advanced disease ([Fig. 70-1](#)). Another sign, sometimes indicating late-stage breast cancer, is an edematous thickening and pitting of breast skin called *peau d'orange* (orange peel skin) ([Fig. 70-2](#)).

**FIG. 70-1** Skin dimpling on a breast as a result of fibrosis or breast cancer. (From Mansel, R., & Bundred, N. (1995). *Color atlas of breast disease*. St. Louis: Mosby.)

**FIG. 70-2** Breast edema giving the skin an “orange peel” (*peau d'orange*) appearance. (From Gallager, H.S., Leis, H.P. Jr., Snyderman, R.K., & Urban, J.A. (1978). *The breast*. St. Louis: Mosby.)

A rare but highly aggressive form of invasive breast cancer is **inflammatory breast cancer (IBC)**. It is characterized by diffuse erythema and edema (*peau d'orange*). Patients typically complain of breast pain or a rapidly growing breast lump. Other common symptoms include a tender, firm, enlarged breast and breast itching. Because of its aggressive nature, IBC is usually diagnosed at a later stage than other types of breast cancer and is often harder to treat successfully (ACS, 2017a).

### Breast Cancer in Men

Male breast cancer is rare and accounts for about 1% of all breast cancer cases in the United States and Canada. Similar to women, the incidence of male breast cancer increases with age; however, unlike women, the rates are similar among blacks and whites. Risk factors for male breast cancer include previous radiation, a family history of breast cancer (male or female), *BRCA 1/2* mutation, diabetes, **gynecomastia** (enlarged breasts), testicular disorders, and obesity (ACS, 2017b).

Men usually present with a hard, painless, subareolar mass; gynecomastia may be present. Other symptoms include nipple discharge (often blood stained), rash around the nipple, inverted nipple, ulceration or swelling of the chest, and possibly swollen lymph nodes. Because *men* usually do not suspect breast cancer, they often ignore the symptoms and postpone seeing their primary health care provider. As a result, many men are diagnosed at later stages than women. Treatment of breast cancer in men is the same as in women at a similar stage of disease.

### Breast Cancer in Young Women

Genetic predisposition is a stronger risk factor for younger women than older women. Younger women frequently present with more aggressive forms of the disease; the number of cases of advanced breast cancer in younger women is increasing (Johnson et al., 2013). Screening tools can be less effective for this group because the breasts tend to be denser and mammographic recognition of breast cancer may be impaired in areas of dense tissue. Nurses should encourage women who have symptoms to seek evaluation and not watch and wait. Younger women with

breast cancer face unique issues associated with treatment. These include earlier menopause, infertility after treatment, and impaired SEXUALITY (Kedde et al., 2013).

## Etiology and Genetic Risk

Increased age is the primary risk factor for developing breast cancer in both women and men. Several other factors are known to increase the risk of developing breast cancer; many are not modifiable, such as family history, early menarche, and late menopause. Modifiable risk factors include, but are not limited to, postmenopausal obesity, use of postmenopausal hormone replacement therapy (HRT), alcohol consumption, nulliparity, and lack of breast-feeding (ACS, 2017b).

According to the American Cancer Society (2017c), breast cancer is often diagnosed late in the disease process for lesbian and bisexual women because of their fear of discrimination, negative experiences with health care professionals, and lack of health insurance. In addition, many women in these groups have no children or have a child after they are 30 years of age or older. Having several risk factors for any woman increases one's risk more than having a single risk factor. Table 70-1 lists major breast cancer risk factors according to the varying degree of risk.

**TABLE 70-1**  
**Risk Factors for Breast Cancer**

FACTORS	COMMENTS
Female gender	Ninety-nine percent of all breast cancers occur in women.
Age >65 years	Risk increases across all ages until age 80 years.
Genetic factors	Inherited mutations of <i>BRCA1</i> and/or <i>BRCA2</i> increase risk.
History of a previous breast cancer	The risk for developing a cancer in the opposite breast is five times greater than for the average population at risk.
Breast density	Dense breasts contain more glandular and connective tissue, which increases the risk for developing breast cancer.
Atypical hyperplasia	Biopsy-confirmed atypical hyperplasia is a high relative risk.
Family history	Two first-degree relatives with breast cancer increases risk.
Ionizing radiation	Women who received frequent low-level radiation exposure to the thorax had an increased risk, especially if the exposure occurred during periods of rapid breast formation.
High postmenopausal bone density	High estrogen levels over time both strengthen bone and increase breast cancer risk.
Reproductive history Nulliparity or First child born after age 30 years	Childless women have an increased risk, as do women who bear their first child near or after age 30.
Menstrual history Early menstruation or Late menopause or Both	The risk for breast cancer rises as the interval between menarche and menopause increases. Women who undergo bilateral oophorectomy before age 35 years have less risk for breast cancer than women who undergo natural menopause.
Recent oral contraceptive use	There is a slight increase in breast cancer risk in women taking oral contraceptives. The risk returns to normal after 10 years of stopping the pill.
Recent hormone replacement therapy (HRT)	Use of HRT containing both estrogen and progestin increases risk; risk diminishes after 5 years of discontinuation.
Obesity	Postmenopausal obesity (especially increased abdominal fat), increased body mass, insulin resistance, and hyperglycemia have been reported to be associated with an increased risk for breast cancer.
<b>Other Risk Factors</b>	
Alcohol consumption	Risk is dose dependent; consumption of 3 to 14 drinks per week is associated with a slight increase in risk; risk increases with increased consumption. This includes all forms of alcoholic beverages.
High socioeconomic status	Breast cancer incidence is greater in women of higher education and socioeconomic background. This relationship is possibly related to lifestyle differences, such as later age at first birth.
Jewish heritage	Women of Ashkenazi Jewish heritage have higher incidences of <i>BRCA1</i> and <i>BRCA2</i> genetic mutations.

Data from American Cancer Society. (2017). *Breast cancer facts & figures 2016-2017*. Atlanta: Author.

## Genetic/Genomic Considerations

### Patient-Centered Care OSEN

Mutations in several genes, such as *BRCA1* and *BRCA2*, are related to hereditary breast cancer. People who have specific mutations in either one of these genes are at an increased risk for developing breast cancer and ovarian cancer. However, these account for only 5% to 10% of all female breast cancers (ACS, 2017b). Only women with a strong family history and a reasonable suspicion that a mutation is present have genetic testing for *BRCA* and other mutations known to increase an individual's risk of developing breast cancer. Encourage women to talk with a genetics counselor to carefully consider the benefits and potential consequences of genetic testing before these tests are done.

### Incidence and Prevalence

One of every eight women in the United States will develop breast cancer by age 70 years (ACS, 2017b). Breast cancer is the second leading cause of cancer death in women, exceeded only by lung cancer (ACS, 2017b). Similar statistics can be found in Canada (Canadian Cancer Society, 2015).

Early detection is the key to effective treatment and survival. The 5-year relative survival rate is lower for women who are diagnosed with an advanced stage of breast cancer. The 5-year relative survival rate for localized breast cancer is 99%, whereas the rate drops to 85% when the cancer has spread to the regional lymph nodes (ACS, 2017b). Survival drops dramatically when breast cancer is metastatic (spread to distant sites).

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Overall, Euro-American women older than 40 years are at a greater risk for breast cancer than other racial/ethnic groups, but the rate of breast cancer in African-American women *younger than 40 years* is higher than for others in that age-group. African-American women also have a higher death rate at any age when compared with other women with the disease (ACS, 2017b). In their classic study, Ooi et al. (2011) found that American Indian, African-American, and Hispanic women are also likely to present with more aggressive breast cancer that is harder to treat, such as *triple-negative breast cancer*. In this type of breast cancer, cells lack receptors for estrogen, progesterone, and the protein *HER2*. African-American and Puerto Rican women have the highest risk for triple-negative breast cancer. These cultural disparities should be addressed with targeted interventions that are appropriate for specific cultural and ethnic groups. Nurses need to be culturally aware and competent to assist women to overcome barriers to care.

## NCLEX Examination Challenge 70-1

### Health Promotion and Maintenance

The nurse is caring for these clients. Which client does the nurse recognize as having the **highest** risk for development of breast cancer?

- A. 55-year-old male with gynecomastia and obesity
- B. 60-year-old female whose father died from colon cancer
- C. 65-year-old male whose mother had ovarian cancer
- D. 75-year-old female who was treated for breast cancer 5 years ago

### Health Promotion and Maintenance

The American Cancer Society (ACS) and Canadian Cancer Society (CCS) establish evidence-based guidelines for breast cancer screening in women. Guidelines have not been recommended for screening men in the general population because breast cancer in men is so rare (ACS, 2017a). Encourage men with a strong family history or known genetic mutations to discuss screening with their primary health care provider.

Teach women that no single method for early detection of breast cancer is effective when used alone. The best approach for average-risk women is screening mammogram, clinical breast examination, and breast self-awareness.

### Mammography

In 2015, the American Cancer Society (ACS) updated its breast cancer screening guidelines and recommends that women at average risk of breast cancer begin annual screening mammography at age 45. Women ages 40 to 45 should have the choice to start annual mammograms after the risks and potential benefits have been explained. Women age 55 and older may switch to mammograms every 2 years. Mammography should continue as long as a woman is in good health and has a life expectancy of at least 10 years (ACS, 2017a).

Canadian guidelines for mammography differ from those of the United States: no routine mammography screening is recommended until women reach 50 years of age. After 50, the

recommended guidelines vary slightly across organizations but generally recommend that women after age 50 have mammography every 2 to 3 years until age 70 to 74 ([Canadian Cancer Society, 2015](#)).

### Breast Self-Awareness/Self-Examination

Monthly breast self-examination (BSE) is less emphasized today than in the past several decades. Instead, it is recommended as an option that women increase breast self-awareness by becoming familiar with how their breasts look and feel.

Nurses working with women should teach them the importance of becoming familiar with the appearance and feel of their breasts. Any changes detected by the woman should be reported to her primary health care provider. Teach a woman that lumps are not necessarily abnormal. For premenopausal women, lumps can come and go with the menstrual cycle. Most lumps that are detected and tested are not malignant.

Some women may want to practice regular breast self-examination (BSE) as a method for breast self-awareness. Evidence shows that monthly BSE is no more beneficial than women simply being aware of what is normal for their own breasts and that women are just as likely to find a lump by chance ([ACS, 2017a](#)). However, BSE should be presented as an option to women beginning in their early 20s. In addition to breast self-awareness, place emphasis on mammography and clinical breast examination for early detection of breast cancer. The combined approach is better than any single test ([ACS, 2017a](#)). A woman who chooses to perform BSE should be taught the correct technique and have it reviewed by a health care professional during her clinical breast examination.

The BSE technique is similar for women and men. Use teaching models of normal and abnormal breasts when teaching BSE. Discuss the proper timing for BSE. Instruct premenopausal women to examine their breasts 1 week after the menstrual period. At this time, hormonal influence on breast tissue is decreased, so fluid retention and tenderness are reduced. Teach women whose breast tissue is no longer influenced by hormonal fluctuations, such as after a total hysterectomy or menopause, to pick a day each month to do BSE, such as the first day of the month. [Chart 70-1](#) describes the procedure for breast self-examination and may be used as a patient resource.

#### Chart 70-1

### Best Practice for Patient Safety & Quality Care

#### Performing Breast Self-Examination

1. Lie on your back and place your right arm behind your head. Lying down spreads the breast tissue evenly over the chest wall, making it easier to feel all the breast tissue.
2. Use the finger pads of the three middle fingers on your left hand to feel for lumps in the right breast. Use overlapping dime-size circular motions of the finger pads to feel the breast tissue.
3. Use three different levels of pressure to feel all the breast tissue. Light pressure is needed to feel the tissue closest to the skin; medium pressure to feel a little deeper; and firm pressure to feel the tissue closest to the chest and ribs. It is normal to feel a firm ridge in the lower curve of each breast.
4. Move around the breast in an up-and-down pattern, starting at an imaginary line drawn straight down your side from the underarm and moving across the breast to the middle of the chest bone (sternum or breastbone). Be sure to check the entire breast area, going down until you feel only ribs and up to the neck.
5. Repeat the examination on your left breast, putting your left arm behind your head and using the finger pads of your right hand to do the examination.
6. While standing in front of a mirror with your hands pressing firmly down on your hips, look at your breasts for any changes of size, shape, contour, or dimpling and look at your nipples and breast skin for redness or scaling. (The pressing down-on-the-hips position contracts the chest wall muscles and enhances any breast changes.)

7. Examine each underarm while sitting up or standing and with your arm only slightly raised so you can easily feel in this area. Raising your arm straight up tightens the tissue in this area and makes it harder to examine.

### Clinical Breast Examination

Clinical breast examination (CBE) is typically performed by advanced practice nurses and other health care providers. Clinicians who perform CBE ideally go through simulation training and exposure to patients to become proficient at the technique (Bryan & Snyder, 2013). It is recommended that the CBE be part of a periodic health assessment, at least every 3 years for women in their 20s and 30s and every year for asymptomatic women at least 40 years of age (ACS, 2017a). Teach patients what to expect during this examination. First, they will be asked to undress from the waist up. The examiner inspects the breasts for abnormalities in size and shape and for skin and nipple changes. Then, using the pads of the fingers, the examiner palpates the breasts for any lumps and, if present, whether such lumps are attached to the skin or deeper tissues. The area under both arms is also examined.

## Considerations for Older Adults

### Patient-Centered Care QSEN

As women age, the breast tissue becomes flattened and elongated and is suspended loosely from the chest wall. On palpation, the breast tissue of the older woman has a finer, more granular feel than the lobular feel in a younger woman. The inframammary ridge may be more prominent as a result of atrophy of the breast tissue. Breast examination in older adults may be easier because of tissue atrophy and relaxation of the suspensory ligaments.

Women in nursing homes and other long-term care facilities often do not have clinical breast examinations and may not be deliberately aware of the normal appearance and feel of their breasts. Teach the importance of breast self-awareness and reporting any breast changes the woman may notice.

### Options for High-Risk Women

Women with a personal history of breast cancer are at risk for developing a recurrence or a new breast cancer. Those with known *BRCA1* and/or *BRCA2* genetic mutation have a lifetime risk of breast cancer of about 20% to 25% or greater, according to risk assessment tools that are based mainly on family history or other high-risk factors. Women in this category usually practice *close surveillance* as a prevention option. It is referred to as *secondary prevention* and is used to detect cancer early in the initial stages. In addition to annual mammography and clinical breast examination, high-risk women are recommended to have an annual breast MRI screening (ACS, 2017b). Close surveillance may begin as early as age 30 years, but evidence is limited regarding the best age at which to start screening. *For women with a high risk for breast cancer development due to family history such as cancer in a mother or sister, it is recommended that cancer screening begin at the age that is 10 years younger than the age at which the affected cancer patient was initially diagnosed.* Encourage high-risk women to discuss their personal preferences for close surveillance with their primary health care providers.

Other options currently available for reducing a woman's breast cancer risk are **prophylactic mastectomy** (preventive surgical removal of one or both breasts), prophylactic **oophorectomy** (removal of the ovaries), and antiestrogen chemopreventive drugs. Although each option significantly reduces the risk for breast cancer, no option completely eliminates it. Each option has its own risks and potentially serious complications.

Even though a woman may decide to have a *prophylactic mastectomy*, there is a small risk that breast cancer will develop in residual breast glandular tissue because no mastectomy reliably removes all mammary tissue. Women must also understand that breast reconstruction after a prophylactic mastectomy is very different from breast augmentation. It is a more complex surgical procedure with a greater potential for complications. The decision to have this type of surgery can be a very difficult one to make. Women may find it helpful to reach out to a breast cancer support organization and talk to someone who has been through a prophylactic mastectomy.

Women undergoing *oophorectomy* will likely experience menopausal symptoms, although some estrogen remains in body fat tissue. *Antiestrogen drugs* reduce breast cancer recurrence but carry other risks such as blood clots and endometrial cancer. Encourage women to carefully consider the benefits and risks of breast cancer–risk-reducing options and discuss them with their health care provider.

### ❖ Interprofessional Collaborative Care

#### ◆ Assessment: Noticing

##### History.

Often the history is taken after a mass has been discovered but before a diagnosis has been made for a woman or man with breast cancer. For some patients, the history may be obtained at the time they are seen for treatment of an identified cancer. The interview should focus on three major areas: risk factors, the breast mass, and health maintenance practices.

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Remember that some cultures do not allow the man to be part of a woman's care or only women are allowed to care for her, such as in the Arab Muslim culture. Other cultures are male predominant, and all decisions about female care are made by the man, such as in the Nigerian culture.

Ask specific information on personal and family histories of breast cancer. In addition to increasing the woman's own risk, these factors also affect any sisters' or daughters' risk and should be part of later counseling.

Ask about the woman's gynecologic and obstetric (if any) history, including:

- Age at menarche
- Age at menopause
- Symptoms of menopause
- Age at first child's birth
- Number of children/pregnancies

Prolonged hormonal stimulation (e.g., early menses, late menopause) increases a woman's risk, as do birth of the first child after 30 years of age and nulliparity (having no children).

A history of the breast mass or lump reveals not only the course of the disease but also information related to health care-seeking practices and health-promoting behaviors. Ask the patient about how, when, and by whom the mass was discovered and the time between discovery and seeking care. If the patient found the mass, ask how it was discovered. The answer to this question reveals the need for discussion and teaching about health promotion practices, regardless of whether the mass proves to be cancerous. If there was a delay between discovery and seeing the health care provider, ask what caused the delay. These questions are linked to the psychosocial assessment but also reveal the length of time that the tumor has been present. Ask which procedures have been performed to diagnose the problem. Also ask patients if they have noticed any other changes in their body within the past year. This information can help determine whether there has been obvious cancer spread. Ask especially about the presence of joint or bone pain.

Ask about the use of alcohol intake because this is a factor that may increase breast cancer risk. Ask which prescribed and over-the-counter (OTC) drugs are used (specifically hormonal supplements such as estrogen and natural or herbal substances that stimulate hormones). Estrogen can be taken orally, intravaginally, or via a transdermal patch. Document the type and form of hormones (birth control pills or patches, supplements) and length of use.

### Physical Assessment/Signs and Symptoms.

Document in the electronic medical record any abnormal findings from the clinical breast examination. Describe specific information about a breast mass ([Chart 70-2](#)) such as location, using the “face of the clock” method; shape; size; consistency; and whether the mass is mobile or fixed to the surrounding tissue. Note any skin change, such as *peau d'orange* (dimpling, orange peel appearance), redness and warmth, nipple retraction, or ulceration, which can indicate advanced disease. Document the location of any enlargements of axillary and supraclavicular lymph nodes. Evaluate the presence of pain or tenderness in the affected breast.

### Chart 70-2

## Best Practice for Patient Safety & Quality Care QSEN

### Assessing a Breast Mass

- Identify the location of the mass by using the “face of the clock” method.
- Describe the shape, size, and consistency of the mass.

- Assess whether the mass is fixed or movable.
- Note any skin changes around the mass, such as dimpling of the skin, increased vascularity, nipple retraction, nipple inversion or skin ulceration.
- Assess the adjacent lymph nodes, both axillary and supraclavicular nodes.
- Ask patients if they experience pain or soreness in the area around the mass.

### Psychosocial Assessment.

A breast cancer diagnosis is usually an unanticipated event in the life of a woman who feels physically well. It initiates a sudden and distressing transition into a potentially life-threatening illness. Feelings of fear, shock, and disbelief are predominant as a woman learns about her disease and faces numerous treatment decisions. Psychological distress is common at cancer diagnosis and at the end of treatment. A previous history of mental illness, age, and life circumstances can contribute to increased psychological distress. Encourage expression of feelings and determine if a referral to a breast cancer support group would be helpful. Talking with someone who has been through the experience is particularly helpful in dealing with the emotional aspects of the disease.

Assess the patient for problems related to **SEXUALITY**. Sexual dysfunction affects most breast cancer survivors in some way. Sometimes the sexual dysfunction is related to the loss of a breast and the threat to one's femininity, but many women also equate a breast cancer diagnosis and treatment effects with the aging process. Lack of libido (sexual desire) related to hormonal changes, psychological distress, and severe anxiety are commonly experienced by women with breast cancer. If the patient does not discuss sexual concerns voluntarily, ask about the frequency of and satisfaction with sexual relations with her partner. Use resources that provide education about alternative expressions of intimacy and a focus on pleasure rather than performance. Refer the patient and her partner to counseling if appropriate.

## Gender Health Considerations

### Patient-Centered Care QSEN

Research is limited about breast cancer and women who identify as lesbian or bisexual. Factors that are more likely to increase the risk of breast cancer in lesbian and bisexual women include nulliparity, increased age at birth of first child, and use of oral contraceptives (ACS, 2017a). Lesbian and bisexual women are less likely to have health insurance and get regular cancer screenings, possibly as a result of fear and distrust of culturally incompetent primary health care providers and/or health care access. They may also be less focused on their breasts and breast cancer risk. Nurses' awareness and sensitivity to these issues help establish trust. Emphasize the importance of screening and early detection. Assess the need for referrals to support organizations such as the National LGBT Cancer Network.

### Laboratory Assessment.

The diagnosis of breast cancer relies on pathologic examination of tissue from the breast mass. After the diagnosis of cancer is established, laboratory tests, including pathologic study of the lymph nodes, help detect possible metastases. Elevated liver enzyme levels indicate possible liver metastases, and increased serum calcium and alkaline phosphatase levels suggest bone metastases.

### Imaging Assessment.

*Mammography* is a sensitive screening tool for breast cancer. The uniqueness of this test results from its ability to reveal preclinical lesions (masses too small to be palpated manually). Most breast centers now use *digital mammography*, a system that is able to read, file, and transmit mammograms electronically. Patient preparation and the procedure for mammography are discussed in [Chapter 69](#). Some women may voice concern about radiation exposure with mammograms. Reassure them that the dose is very small and the risk for harm from radiation is minimal.

Digital breast *tomosynthesis* is a newer technology that is similar to mammography but uses three-dimensional images. It has the potential to improve detection of breast cancer by better

differentiating suspicious from normal tissue (Alakhras et al., 2013). In the United States, currently it is covered by Medicare and most other major health insurances. This advanced technology is also available in Canada.

*Ultrasonography* of the breast is an additional diagnostic tool used to clarify findings on mammography. If the mammogram reveals a lesion, ultrasonography is helpful in differentiating a fluid-filled cyst from a solid mass. Mammography screening combined with ultrasound may be effective for detecting cancers in women with dense breasts, but currently it is not recommended for routine breast cancer screening (ACS, 2017b).

*MRI* is used for screening high-risk women and better examination of suspicious areas found by a mammogram (ACS, 2017b). It is more expensive than mammography. Most insurance companies will cover a portion of the cost if the woman is shown to be high risk. Although higher-quality images are produced, there is concern about high costs and access to quality breast MRI services for high-risk women (ACS, 2017b).

If the patient has an invasive breast cancer, other imaging tests may be done to rule out metastases. A chest x-ray is done to screen for lung metastases. Bone, liver, and brain scans and CT scans of the chest and abdomen can reveal distant metastases.

### Other Diagnostic Assessment.

Although imaging techniques serve as tools for screening and more precise visualization of potential breast cancers, *breast biopsy (pathologic examination of the breast tissue)* is the only definitive way to diagnose breast cancer. Breast tissue is obtained by one of several types of biopsies (see Chapter 69). Tissue samples are analyzed by a pathologist to determine the presence of breast cancer. If breast cancer is identified, it is classified according to the size and type of breast cancer, the histologic grade, and the type of receptors on the cells. These characteristics are used to guide treatment. For example, a small, noninvasive breast cancer may be treated only with lumpectomy and radiation; whereas a larger, aggressive tumor (one with a high histologic grade) may be treated with a mastectomy and chemotherapy, followed by radiation.

Cancer cells that contain estrogen receptors (*ER positive*) or progesterone receptors (*PR positive*) have a better prognosis and usually respond to hormonal therapy. If the type of breast cancer is *HER2*, or one in which the *neu* gene product is overexpressed, it may be treated successfully with trastuzumab (Herceptin), which is a breast cancer *targeted therapy* for this specific type.

Most women, even those with very small tumors, receive some sort of treatment in addition to surgery for breast cancer. Research has focused on ways to predict clinical outcomes so low-risk women may avoid unnecessary treatments. Gene expression profiling systems, such as Oncotype DX and MammaPrint, have been developed to help predict clinical outcomes by analyzing genes in breast cancer tissue. Some clinicians use this information in addition to the pathologic analysis for guiding treatment decisions. These multigene tests have been shown to be accurate predictors of patient prognosis and response to therapy in breast cancer (Jankowitz & Lee, 2013). Their role in clinical practice continues to evolve.

### ◆Analysis: Interpreting

The priority collaborative problems for patients with breast cancer include:

1. Potential for metastasis of cancer to other parts of the body due to lack of treatment or inadequate treatment response
2. Potential for decreased ability to cope due to unanticipated breast cancer diagnosis and its treatment

### ◆Planning and Implementation: Responding

#### Decreasing the Risk for Metastasis

#### Planning: Expected Outcomes.

The patient who is treated for breast cancer is expected to remain free of metastases or recurrence of disease, if possible. If cancer recurs, the patient will experience optimal health outcomes, including potential palliation and end-of-life care.

## Interventions.

There are many surgical and nonsurgical options for breast cancer treatment. Because of the various options, the patient with breast cancer often faces difficult decisions. Although patients are living longer with metastatic disease, the 5-year survival rate remains low. Once cancer is diagnosed, the extent and location of metastases determine the overall therapeutic strategy. The emphasis of breast cancer treatment is on preventing or stopping the spread of tumor cells that leads to distant metastasis. Treatment is tailored specifically to each patient, taking into account other health problems and the patient's ability to tolerate a particular therapy.

## Nonsurgical Management.

For patients with breast cancer at a stage for which surgery is the main treatment, follow-up with adjuvant (in addition to surgery) radiation, chemotherapy, hormone therapy, or targeted therapy is commonly prescribed. For those who cannot have surgery or whose cancer is too advanced, these therapies are used to promote COMFORT (palliation). These options are discussed in the [Adjuvant Therapy](#) section later in this chapter.

## Complementary and Integrative Health.

Women with breast cancer often cope with distressing symptoms related to the disease itself or the side effects of treatment. Common symptoms associated with these therapies include pain, nausea, hot flashes, anxiety, depression, and fatigue. Physical and emotional symptoms associated with breast cancer may be eased with the use of complementary and integrative therapy. The most frequently used strategies are biologically based therapies such as vitamins, special cancer diets, and herbal therapy. Prayer is also widely used. Other types of therapies are mind-body or body based such as guided imagery and massage. Encourage women to seek a practitioner with a certification or license for the specific type of integrative therapy intervention. In some states, a certification or license is required for acupuncture, chiropractic therapy, massage, and shiatsu. Some types of complementary and integrative therapy can be self-taught or done alone after a few sessions of instruction. [Table 70-2](#) lists complementary and integrative therapies for specific symptoms associated with breast cancer and its treatments.

**TABLE 70-2**

### Common Complementary and Integrative Therapies Used by Patients With Breast Cancer

SYMPTOM	COMPLEMENTARY AND INTEGRATIVE THERAPY
<b>Physical</b>	
Pain	Acupuncture, chiropractic therapy, hypnosis, massage, music, reiki, shiatsu
Nausea/vomiting	Acupuncture, aromatherapy, ginger, hypnosis, progressive muscle relaxation, shiatsu
Fatigue	Acupuncture, massage, meditation, reiki, tai chi, yoga
Hot flashes	Acupuncture, flaxseed
Muscle tension	Aromatherapy, massage, shiatsu
<b>Emotional</b>	
Anxiety/stress/fear	Aromatherapy, guided imagery, hypnosis, journaling, massage, meditation, music therapy, progressive muscle relaxation, prayer, support groups, tai chi, yoga
Depression	Aromatherapy, yoga, journaling, progressive muscle relaxation

Although the use of complementary and integrative therapy can improve quality of life, its use does not alter the outcome of breast cancer, and it should not be used in place of standard treatment. Encourage patients who are interested in trying these therapies to check with their health care provider before using them. The website [breastcancer.org](http://breastcancer.org) provides accurate information about complementary therapies and the extent to which they have been researched in breast cancer patients. Cost may be a factor in decision making since not all insurances provide coverage for complementary and integrative therapies. Teach the patient that all ingested complementary agents potentially risk interaction with conventional drugs.

## Surgical Management.

Although controversy exists concerning the best treatment for breast cancer, experts agree that the mass itself should be removed to reduce the risk for local recurrence. A large tumor is sometimes treated with chemotherapy, called *neoadjuvant therapy*, to shrink the tumor before it is surgically removed. An advantage of this therapy is that cancers can be removed by lumpectomy rather than mastectomy.

Axillary lymph nodes are analyzed for the presence of cancer and staging purposes. Axillary lymph node dissection (ALND) is usually done when there are palpable axillary lymph nodes or when cancer is suspected to be at a later stage. Sentinel lymph node biopsy (SLNB) is a much less

invasive approach now preferred by most surgeons for analyzing lymph nodes in early-stage breast cancers with low-to-moderate risk for lymph node involvement. In this method, the sentinel lymph node is identified during breast surgery by injecting the breast with radioisotope and/or dye that travels via lymphatic pathways to the sentinel lymph node. The nodes that take up the dye (or give off a certain level of radiation picked up by a handheld counter) are removed and examined for the presence of cancer cells. It is believed that if cancer cells have traveled through the lymph channels, the cells will lodge in the sentinel nodes. Travel beyond these nodes to higher-level nodes may occur as a secondary event. Therefore the absence of cancer cells in the sentinel nodes is an indicator that no other nodes in the regional area are involved.

### **Preoperative Care.**

Care of the patient facing surgery for breast cancer focuses on psychological preparation and preoperative teaching. Priority nursing interventions are directed toward relieving anxiety and providing information to increase patient knowledge. *Include the spouse, partner, or other family member or significant other who may be experiencing similar stress and confusion, in the health teaching unless the patient's culture does not permit this approach.*

Review the type of procedure planned. Use open-ended questions (e.g., "What type of surgery are you having? Can you explain what will happen?") to assess the current level of knowledge. Provide postoperative information, including:

- The need for a drainage tube
- The location of the incision
- Mobility restrictions
- The length of the hospital stay (if any)
- The possibility of adjuvant therapy
- General preoperative and postoperative information needed by any surgical patient (see [Chapters 14 and 16](#))

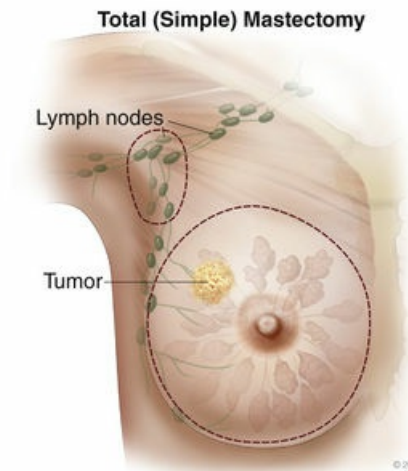

Supplement teaching with written or digital materials for the patient and family. This information should include whom to call in case there are any complications. Address body image issues before surgery to correct misconceptions about appearance after surgery. If available, suggest that patients and their caregivers attend classes before surgery in an ambulatory care setting, such as a breast cancer center, to promote successful early discharge from the hospital. Programs that provide emotional support, information, and opportunities for discussion related to **SEXUALITY**, body image, and preoperative and postoperative care enhance the recovery of the short-stay mastectomy patient.

### **Operative Procedures.**

Types of breast surgeries are shown in [Fig. 70-3](#). During **breast-conserving surgery**, such as a *lumpectomy*, the surgeon removes the tumor and a small amount of tissue rather than the entire breast. A partial mastectomy is surgery to remove part of the breast that contains cancer and some normal tissue around it. *Margins* refer to the distance between the tumor and the edge of the surrounding tissue. The desired outcome of breast-conserving surgery is to obtain *negative margins* in which no cancer cells extend to the edge of the tissue. Typically, radiation therapy follows to kill any residual tumor cells.

Breast-conserving surgery. Dotted lines show the area containing the tumor that is removed and some of the lymph nodes that may be removed.

Total (simple) mastectomy. The dotted line shows where the entire breast is removed. Some lymph nodes under the arm may also be removed.

Modified radical mastectomy. The dotted line shows where the entire breast and some lymph nodes are removed. Part of the chest wall muscle may also be removed.

**FIG. 70-3** Surgical treatment for breast cancer. (©2010 Terese Winslow. U.S. Govt. has certain rights.)

Breast-conserving procedures are usually performed in same-day surgical settings. The cosmetic

results of these surgeries are good to excellent, and the psychological benefits of avoiding breast removal are significant for patients who choose this option.

Despite advances in breast-conserving surgery, mastectomy remains a popular option for breast cancer treatment, and women are increasingly choosing it for prophylactic treatment (McLaughlin, 2013). Typically, indications for a mastectomy include multi-centric disease (tumor is present in different quadrants of the breast), inability to have radiation therapy, presence of a large tumor in a small breast, and patient preference. Mastectomy does not conserve the breast; the affected breast is completely removed. A total (simple) mastectomy is surgery to remove the whole breast that has cancer. A modified radical mastectomy removes the breast tissue, lymph nodes, and sometimes part of the underlying chest wall muscle. If reconstruction is to be performed at the same time as the mastectomy, less-invasive techniques, such as incising a  $\frac{1}{2}$ -inch flap of skin around the nipple (excising the same amount of breast tissue as with conventional mastectomy), may be performed. Skin flaps or expanders may be used to create a breast mound at the time of the original procedure.

### Postoperative Care.

Before the patient returns from surgery, inform the staff to avoid using the affected arm for measuring blood pressure, giving injections, or drawing blood. He or she returns from the postanesthesia care unit (PACU) as soon as vital signs return to baseline levels and if no complications have occurred. Assess vital signs on a schedule of decreasing frequency, such as every 30 minutes for two times, every hour for two times, and then every 4 hours. During these checks, assess the dressing for bleeding.

During a *modified radical mastectomy*, the surgeon places one or two drainage tubes, usually Jackson-Pratt drains, under the skin flaps and attaches the tubes to a small collection chamber. Gentle suction is exerted, and fluid that would accumulate under the flaps and delay healing is collected. Various drains are available, but all allow the drainage to be seen and measured. When taking vital signs, monitor for the amount and color of drainage. Add this information to the intake and output record. Patients undergoing a *lumpectomy* may also have drainage tubes (usually Jackson-Pratt drains) placed if the lump is large or if axillary node dissection is performed.

## Nursing Safety Priority QSEN

### Action Alert

**Per TJC National Patient Safety Goal recommendations, to decrease the chance of surgical site infection, carefully observe the surgical wound after breast surgery for signs of swelling and infection throughout recovery. Assess the incision and flap of the post-mastectomy patient for signs of bleeding, infection, and poor tissue perfusion.** With short hospital stays, drainage tubes are usually removed about 1 to 3 weeks after hospital discharge when the patient returns for an office visit. The drainage amount should be less than 2 to 30 mL in a 24-hour period. Inform the patient that tube removal causes impaired COMFORT, although these tubes lie just under the skin. Provide or suggest analgesia before they are removed. Document all findings and report any abnormalities to the surgeon immediately.

Assess the patient's position to ensure that the drainage tubes or collection device is not pulled or kinked. The patient should have the head of the bed elevated at least 30 degrees, with the affected arm (the arm on the same side as the axillary dissection) elevated on a pillow while awake. Keeping the affected arm elevated promotes lymphatic fluid return after removal of lymph nodes and channels. Provide other basic COMFORT measures, such as repositioning and analgesics as prescribed on a regular basis until pain ceases. Patient-controlled analgesia may be used for some patients for a short time, depending on the type of surgery that was performed.

The hospital stay after breast surgery is short, often same day or just overnight, and recovery is usually not complicated. Because some managed care plans will not authorize an overnight stay in the hospital after a mastectomy, several states have enacted legislation mandating inpatient benefits. The patient who chooses an early discharge should have a home care visit within 24 hours of the discharge.

Ambulation and a regular diet are resumed by the day after surgery. While the patient is

walking, the arm on the affected side may need to be supported at first. Gradually the arm should be allowed to hang straight by the side. Instruct the patient to avoid the hunched-back position with the arm flexed because of the risk for elbow contracture. Beginning exercises that do not stress the incision can usually be started on the first day after surgery. These exercises include squeezing the affected hand around a soft, round object (a ball or rolled washcloth) and flexion/extension of the elbow. The progression to more strenuous exercises depends on the subsequent procedures planned (e.g., reconstruction) and the surgeon's prescription.

As soon as the patient is ambulatory and surgical pain is under control, he or she is discharged to home. Common instructions for exercises after mastectomy are listed in [Chart 70-3](#).

### **Chart 70-3**

## **Patient and Family Education: Preparing for Self-Management**

### **Post-Mastectomy Exercises**

#### **Hand Wall Climbing**

- Face the wall and put the palms of your hands flat against the wall at shoulder level.
- Flex your fingers so your hands slowly “walk” up the wall.
- Stop when your arms are fully extended.
- Slowly “walk” your hands back down the wall until they return to shoulder level.

#### **Pulley Exercise**

- Drape a 6-foot-long rope over a shower curtain rod or over the top of a door. If you use a door for this exercise, have someone put a nail or hook at the top of the door so the rope does not slip off.
- Grab the ends of the rope, one in each hand, and extend your arms out to your sides until they are straight.
- Keeping your arms straight, pull down with your left arm to raise your right arm as high as you can.
- Pull down with your right arm to raise your left arm as high as you can.

#### **Rope Turning**

- Tie a rope to the knob of a closed door.
- Hold the other end of the rope and step back from the door until your arm is almost straight out in front of you.
- Swing the rope in a circle. Start with small circles and gradually increase to larger circles as you become more flexible.

### **NCLEX Examination Challenge 70-2**

#### **Physiological Integrity**

The nurse is assigned to care for a client who has undergone a modified radical right mastectomy for breast cancer. When delegating care, which statements by the nursing assistant would require **further** teaching by the nurse? **Select all that apply.**

- A. "I'll irrigate the drainage tube after I empty it."
- B. "If the client says she is in pain, I'll tell you right away."
- C. "It's important for me to take blood pressure on the client's right arm."
- D. "When helping the client walk, I'll remind her to stand straight."
- E. "I'll let you know if her surgical dressing is intact and dry."

**Breast Reconstruction.**

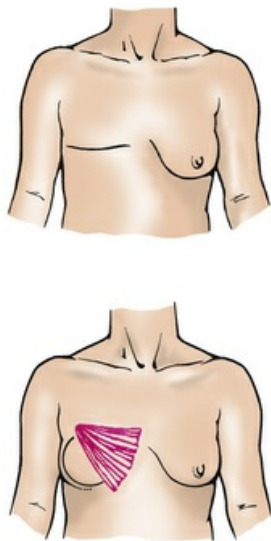

Breast reconstruction after or during mastectomy for women is common with few complications. Patients consult with the plastic surgeon to discuss the type of reconstruction, timing of the procedure, and technique desired. Many women prefer reconstruction immediately after mastectomy using their own tissue (autogenous reconstruction). Breast reconstruction at the time of mastectomy, both autogenous and prosthetic, may lessen the psychological strain associated with undergoing a mastectomy.

The surgeon should offer the option of breast reconstruction before surgery is performed. If the woman does not choose immediate reconstructive surgery, a temporary prosthesis can be used. Refer the patient to the American Cancer Society's *Reach to Recovery* program ([www.cancer.org](http://www.cancer.org)). In this program, a volunteer who has had breast cancer surgery visits the woman at home, offering information on breast forms, clothing, coping with breast cancer, and possible reconstructive options. For this intervention to be as helpful as possible, the volunteer should be about the same age as the patient and have experienced the same surgical procedure.

Evaluate the woman's level of satisfaction with her prosthesis several weeks after surgery. Assess her attitude by asking about future plans for restoring appearance. Although reconstruction is not appropriate for some women and others may not be interested in it, the surgeon should discuss the indications and contraindications, advantages and disadvantages, and typical recovery. If immediate reconstruction is chosen, the surgeon should be aware of this before surgery so plans can be coordinated with those of the plastic surgeon.

Several procedures are available for restoring the appearance of the breast (Table 70-3). Reconstruction may begin during the original operative procedure or later in one to several stages. Common types of breast reconstruction are:

**TABLE 70-3**  
**Examples of Breast Reconstruction Procedures**

PROCEDURE	DESCRIPTION	PROCEDURE	DESCRIPTION
Implantation	An implant matching the size of the other breast is placed under the muscle on the operative side to create a breast mound.	Myocutaneous flaps	A flap of skin, fat, and muscle is transferred from the donor site to the operative area. The flap contains an appropriate amount of fat to match the other breast and is similar in appearance to breast tissue. A blood supply is established by reanastomosis of vessels from the operative area to those with the flap when possible. A new nipple may be created with tissue from areas such as the labia or upper, inner thigh. Nipples can also be created by tattooing.
			

- Breast expanders (saline or gel)
- Autologous reconstruction using the patient's own skin, fat, and muscle

Breast expanders are the most common method of breast reconstruction used today in the United States. A tissue expander is a balloon-like device with a resealable metal port that is placed under the pectoralis muscle. A small amount of normal saline is injected intraoperatively into the expander to partially inflate it. The patient then receives additional weekly saline injections for about 6 to 8 weeks until the expander is fully inflated. When full expansion is achieved, the tissue expander is then exchanged for a permanent implant during surgery in an ambulatory care center. The permanent implant is filled with either saline or silicone gel. Despite earlier claims that silicone gel caused autoimmune diseases such as lupus and arthritis, silicone implants have been used safely in most women who choose this type of breast implant.

Autologous reconstruction using the patient's own skin, fat, and muscle is advantageous because the donor site tissue is similar in consistency to that of the natural breast. Therefore the results more closely resemble a real breast compared with implant reconstruction. Flap donor sites include the latissimus dorsi flap (back muscle); transverse rectus abdominis myocutaneous flap, known as the *TRAM flap* (abdominal muscle); and the gluteal flap (buttock muscle). Reconstruction of the nipple-areola complex is the last stage in the reconstruction of the breast. If necessary, a new nipple may be created with other body tissue, such as from the labia, abdomen, or inner thigh.

Women who have had a mastectomy and breast reconstruction in one breast should have close-surveillance breast cancer screening in the contralateral (opposite) breast, including imaging with mammography or mammography and MRI. Mammography and MRI are not recommended to be done routinely in reconstructed breasts because most local recurrences of breast cancer in the residual tissue are palpable during clinical breast examination. Nursing care of the woman who has undergone breast reconstruction is outlined in [Chart 70-4](#).

## Chart 70-4

### Best Practice for Patient Safety & Quality Care QSEN

#### Postoperative Care of the Patient After Breast Reconstruction

- Assess the incision and flap for signs of infection (excessive redness, drainage, odor) during dressing changes.
- Assess the incision and flap for signs of poor tissue perfusion (duskiness, decreased capillary refill) during dressing changes.
- Avoid pressure on the flap and suture lines by positioning the patient on her nonoperative side and avoiding tight clothing.
- Monitor and measure drainage in collection devices, such as for Jackson-Pratt drains.
- Teach the patient to return to her usual activity level gradually and to avoid heavy lifting.
- Remind the patient to avoid sleeping in the prone position.
- Teach the patient to avoid participation in contact sports or other activities that could cause trauma to the chest.
- Teach the patient to minimize pressure on the breast during sexual activity.
- Remind the patient to refrain from driving until advised by the physician.
- Remind the patient to ask at the 6-week postoperative visit when full activity can be resumed.
- Reassure the patient that optimal appearance may not occur for 3 to 6 months after surgery.
- If implants have been inserted, teach the proper method of breast massage to enhance expansion and prevent capsule formation (consult with the physician).
- Emphasize breast self-awareness; if the patient performs breast self-examination (BSE), review her technique.
- Remind the patient of the importance of clinical breast examination and follow-up surveillance by her physician.

#### Adjuvant Therapy.

The decision to follow the original surgical procedure with additional treatment to help keep the cancer from recurring is known as **adjuvant therapy**. This decision is based on several factors:

- The stage of the disease
- The patient's age and menopausal status
- Patient preferences
- Pathologic examination
- Hormone receptor status
- HER2/neu status
- Presence of a known genetic predisposition

Adjuvant therapy for breast cancer consists of systemic chemotherapy, radiation therapy, or a combination of both. The purpose of radiation therapy is to reduce the risk for local recurrence of breast cancer. The goal of systemic therapy (with chemotherapy, hormone therapy, and targeted therapy) is to reduce the risk of recurrence (locally or at distant sites) and death. These drugs destroy breast cancer cells that may be present anywhere in the body. They are typically delivered after surgery for breast cancer, although neoadjuvant chemotherapy may be given to reduce the

size of a tumor before surgery. Hormonal therapy may also be used as a chemoprevention option for high-risk women with a personal history of breast cancer.

### Radiation Therapy.

Radiation therapy is administered after breast-conserving surgery to kill breast cancer cells that may remain near the site of the original tumor. This therapy can be delivered to the whole breast or to only part of the breast. Whole-breast irradiation is delivered by external beam radiation over a period of 5 to 6 weeks. Partial breast irradiation (PBI) has become a newer option for women with early-stage breast cancer. PBI is a convenient alternative to whole breast radiation. Less time is needed for completion, and outcomes are comparable to those of whole breast radiation (Edwards et al., 2015). The advantage of this type of radiation is that it is delivered over a much shorter time interval, eliminating the need for daily trips for treatment. The types of methods available for delivering *partial-breast irradiation* include the following:

- Interstitial brachytherapy, in which several catheters loaded with a radioactive source are inserted at the lumpectomy cavity and surrounding margin, is given over a period of 4 to 5 days.
- Balloon brachytherapy, also known as *MammoSite*, involves the use of a single balloon-tipped catheter that is surgically placed near the tumor bed. The catheter is loaded with a radiation source and inflated to conform to the total cavity. Ten total treatments are given, with at least 6 hours between each treatment.
- Intraoperative radiation therapy is the most accelerated form of partial breast irradiation. It uses a high single dose of radiation delivered during the lumpectomy surgery.

Nursing care for the patient undergoing radiation therapy includes patient education and side effect management. Skin changes are a major side effect during this therapy (see Chapter 22). If brachytherapy is planned, instruct patients about the procedure. Assure them that they will be radioactive only while the radiation source is dwelling inside the breast tissue.

## Nursing Safety Priority QSEN

### Action Alert

Teach women undergoing brachytherapy for breast cancer that radiation is contained in the temporary implant. The risk for others to be exposed to radiation is very small. Body fluids and items contacted by patients with brachytherapy are not radioactive. However, during the time that radiation is delivered, it is recommended that visitors, including pregnant women and children, be limited.

### Drug Therapy.

*Chemotherapy* for breast cancer is delivered systemically via the central IV route, such as an implantable venous access device (e.g., Port-a-Cath). Its purpose is to kill undetected breast cancer cells that may have left the original tumor and moved to more distant sites. Chemotherapy is recommended for treatment of invasive breast cancer after surgery (adjuvant chemotherapy). It may also be given before surgery to reduce the size of the tumor (neoadjuvant chemotherapy) and is most effective when combinations of more than one drug are used. Chemotherapy drugs are usually delivered in four to six cycles, with each period of treatment followed by a rest period to give the body time to recover from the adverse effects of the drugs. Each cycle is 2 to 3 weeks long. The total treatment time is 3 to 6 months, although treatment may be longer for advanced breast cancer. Many combinations of drugs are used, and no one combination has been proven to be superior over others. A common chemotherapy regimen for breast cancer treatment is doxorubicin (Adriamycin, Caelyx ) , cyclophosphamide (Cytoxan), and paclitaxel (Taxol), which, in the United States, is also known as AC-T (Burchum & Rosenthal, 2016). In early-stage breast cancer, chemotherapy regimens lower the risk for breast cancer recurrence and death. In metastatic breast cancer, chemotherapy regimens reduce cancer size and slow the progression of disease.

Nurses must be very proficient in the preparation and administration of chemotherapy drugs and knowledgeable about various venous access devices. They must also be able to manage the distressing symptoms associated with side effects of these drugs. Chapter 22 discusses chemotherapy in more detail and general nursing management of alopecia, nausea and vomiting,

mucositis, and bone marrow suppression.

Chemotherapy is unpleasant and expensive and can have life-threatening short-term and long-term side effects. Because more women are living longer with breast cancer, more long-term effects are emerging. For example, ovarian suppression from chemotherapy drugs can result in infertility, a devastating effect for women of childbearing age.

## Nursing Safety Priority QSEN

### Action Alert

Teach patients undergoing chemotherapy with anthracyclines such as doxorubicin (Adriamycin) to be aware of cardiotoxic effects. Instruct them to report excessive fatigue, shortness of breath, chronic cough, and edema to the primary health care provider.

*Targeted cancer therapies* are drugs that target specific characteristics of cancer cells, such as a protein, an enzyme, or the formation of new blood vessels. The advantage of targeted therapy over traditional chemotherapy is that targeted therapy is less likely to harm normal, healthy cells and therefore it has fewer side effects. One of the first targeted therapies developed for breast cancer is the monoclonal antibody *trastuzumab* (Herceptin). This drug targets the *HER2/neu* gene product in breast cancer cells. Several other targeted therapies have been developed since Herceptin.

*Hormonal drugs* may also be used in breast cancer prevention and treatment. The purpose of hormonal therapy is to reduce the estrogen available to breast tumors to stop or prevent their growth. *Premenopausal* women whose main estrogen source is the ovaries may benefit from *LH-RH agonists* that inhibit estrogen synthesis. These drugs include leuprolide (Lupron) and goserelin (Zoladex), which suppress the hypothalamus from making luteinizing hormone–releasing hormone (LH-RH). When LH-RH is inhibited, the ovaries do not produce estrogen. Although the suppression of ovarian function decreases breast cancer risk, the drastic drop in estrogen causes significant menopausal symptoms. Therefore the decision to use these drugs is not made lightly.

*Selective estrogen receptor modulators (SERMs)*, on the other hand, do not affect ovarian function. Rather, they block the effect of estrogen in women who have estrogen receptor (ER)–positive breast cancer (Burchum & Rosenthal, 2016). SERMs are also used as chemoprevention in women at high risk for breast cancer and in women with advanced breast cancer. For women with hormone receptor–positive breast cancer, tamoxifen reduces the chances of the cancer coming back by about half (ACS, 2017b). Common side effects of SERMs include hot flashes and weight gain. Rare but serious side effects of these drugs include endometrial cancer and thromboembolic events.

*Aromatase inhibitors (AIs)*, such as letrozole (Femara) and anastrozole (Arimidex), are used in *postmenopausal* women whose main source of estrogen is not the ovaries but, rather, body fat (Burchum & Rosenthal, 2016). AIs reduce estrogen levels by inhibiting the conversion of androgen to estrogen through the action of the enzyme *aromatase*. They are beneficial when given to postmenopausal women for up to 5 years. Treatment with AIs usually follows treatment with tamoxifen. A side effect of AIs, not seen with tamoxifen, is loss of bone density. Women taking AIs are candidates for bone-strengthening drugs and must be closely monitored for osteoporosis. Fulvestrant (Faslodex), a second-line hormonal therapy for postmenopausal women with advanced breast cancer, is used after other hormonal treatments have stopped working.

### Stem Cell Transplantation.

Autologous or allogeneic stem cell transplantation is an option for patients with a high risk for recurrence or who have advanced disease. Autologous bone marrow transplantation (taken from the patient's bone marrow), peripheral blood stem cell transplantation (taken from circulating blood), or allogeneic bone marrow transplantation (taken from a healthy donor's bone marrow or peripheral blood) is performed as a means of rescue therapy after very high doses of chemotherapy. The general care of the patient undergoing bone marrow or stem cell transplantation is discussed in [Chapter 22](#).

### Developing Coping Strategies

### Planning: Expected Outcomes.

The patient with breast cancer is expected to report the use of methods to help increase coping ability and reduce anxiety. The patient will maintain relationships and participate as an active partner in management of the disease.

### Interventions.

The anxiety and uncertainty for the patient with breast cancer begin the moment a lump is discovered or when a mammogram reveals an abnormality. These feelings may be related to past experiences and personal associations with the disease. Assess the patient's perceptions of his or her own situation. Allow him or her to ventilate these feelings even if a diagnosis has not been established.

If the mass has been diagnosed as cancer, many people feel a partial sense of relief to be dealing with a known entity. A feeling of shock or disbelief usually occurs. It is difficult to accept a diagnosis of cancer when one feels basically well. Patients and their families or significant others deal in individual ways with the mix of feelings. Flexibility is the key to nursing care. Adjust your approach to care as the patient's emotional state changes. Those who have an interval between the diagnosis and treatment during which they actively participate in the choice of treatment cope more effectively after surgery, no matter which treatment is chosen.

An integral part of the plan to meet these emotional needs is the use of outside resources. Health care providers working with breast cancer may know other patients willing to make a preoperative visit. For example, the patient who is worried in particular about the side effects of radiation therapy may benefit more from talking to someone who has undergone radiation than from talking to the nurse or primary health care provider. Be sure to assess his or her preference.

Assess the patient's need for knowledge. Some may want to read and discuss any available information. Provide accurate information and clarify any misinformation the patient may have received by the media, on the Internet, or from family and friends.

## Care Coordination and Transition Management

### Home Care Management.

In collaboration with the case manager and members of the interdisciplinary health care team, make the appropriate referrals for care after discharge. Preoperative teaching and arrangements for home care management and referrals (*Reach to Recovery*, social services, home care) can be started before surgery or other treatment.

The patient who has undergone breast surgery can be discharged to the home setting unless other physical disabilities exist. Some are discharged the day after surgery with Jackson-Pratt or other types of drains in place. Many patients are discharged to home on the day of surgery. Older adults should not be sent home without a family member or friend who can stay with them for 1 to 2 days. These patients may need some assistance at home with drain care, dressings, and ADLs because of pain and impaired range of motion of the affected arm. Summaries of continuing care instructions are given in [Charts 70-5](#) and [70-6](#).

### Chart 70-5

## Patient and Family Education: Preparing for Self-Management

### Recovery From Breast Cancer Surgery

- There may be a dry gauze dressing over the incision when you leave the hospital. You may change this dressing if it becomes soiled.
- A small, dry dressing will be around the site where a drain is placed. Often there is some leakage of fluid around the drain. Check the gauze dressing for drainage and change it if it becomes soiled. Some leakage is normal; but, if the dressing becomes soaked more than once a day, call your primary health care provider.
- You have been taught how to empty the reservoir from your drain and how to measure the

volume of drainage. You should empty the reservoir twice a day and record the measurements.

- Drains are generally removed when drainage is less than 30 mL/day for 3 consecutive days.
- You may take sponge baths or tub baths, making certain that the area of the drain and incision stays dry. You may shower after the stitches, staples, and drains are removed.
- You can begin using your arm for normal activities, such as eating or combing your hair. Exercises involving the wrist, hand, and elbow, such as flexing your fingers, circular wrist motions, and touching your hand to your shoulder, are very good. You can usually resume more strenuous exercises after the drains have been removed.
- You can expect some impaired COMFORT or mild pain after surgery; but within 4 to 5 days, most women have no need for pain medication or require medication only at bedtime.
- Numbness in the area of the surgery and along the inner side of the arm from the armpit to the elbow occurs in almost all women. It is the injury to the nerves that causes changes in sensation to the skin in those areas. Women have described sensations of heaviness, pain, tingling, burning, and “pins and needles.” This is neuropathic pain, and short-acting analgesics may be given. These sensations may change over the next several months, becoming less and less noticeable, and may resolve entirely by the end of the first year following surgery.
- Pamphlets on exercises, hand and arm care, and general facts about breast cancer are available from your hospital or from a volunteer visitor of the local or national office on cancer or breast cancer. The American Cancer Society has volunteers who have had surgery similar to yours and are available to visit you.

#### **Chart 70-6**

### Home Care Assessment

#### Patients Recovering From Breast Cancer Surgery

Assess cardiovascular, respiratory, and urinary status:

- Vital signs
- Lung sounds
- Urine output patterns

Assess for pain and effectiveness of analgesics.

Assess dressing and incision site:

- Excess drainage
- Symptoms of infection
- Wound healing
- Intact staples, sutures

Assess drain and site:

- Drainage around site and within drain reservoir
- Color and amount of drainage
- Symptoms of infection

Review patient's recordings of drainage.

Evaluate patient's ability to care for and empty drain reservoir.

Assess status of affected extremity:

- Range of motion
- Ability to perform exercise regimen
- Lymphedema

Assess nutritional status:

- Food and fluid intake
- Presence of nausea and vomiting
- Bowel sounds

Assess functional ability:

- ADLs
- Mobility and ambulation

Assess home environment:

- Safety
- Structural barriers

Assess patient's compliance and knowledge of illness and treatment plan:

- Follow-up appointment with surgeon
- Symptoms to report to health care provider
- Hand and arm care guidelines

Assess patient and caregiver coping skills:

- Whether patient and/or caregiver has looked at incision site
- Patient's and/or caregiver's reaction to incision site

Teach patients that activities involving stretching or reaching for heavy objects should be avoided temporarily. This restriction can be discussed with a family member or significant other who can perform these tasks or place the objects within easy reach.

#### Self-Management Education.

The teaching plan for the patient after surgery includes:

- Care of the incision and drainage device
- Exercises to regain full range of motion
- Measures to avoid lymphedema
- Measures to improve body image, coping, and self-esteem
- Information about interpersonal relationships and roles
- **Measures to avoid injury, infection, and swelling of the affected arm (per The Joint Commission's National Patient Safety Goals)**

#### Postoperative Mastectomy Teaching.

Teach incisional care to the patient, family, and/or other caregiver. The patient may wear a light dressing to prevent irritation. Explain that no lotions or ointments should be used on the area and that the use of deodorant under the affected arm should be avoided until healing is complete. Although swelling and redness of the scar itself are normal for the first few weeks, swelling, redness, increased heat, and tenderness of the surrounding area indicate infection and should be reported to the surgeon immediately. If a lymph node dissection was performed, instruct the patient to elevate the affected arm on a pillow for at least 30 minutes a day for the first 6 months. Ask the patient to have someone bring a loose-fitting, nonwire bra or camisole for her to try before discharge with a soft, cotton-filled or polyester fiber-filled form supplied by the hospital or by *Reach to Recovery*. The patient wears this form until the incision is completely healed and the health care provider approves the fitting of a more sophisticated prosthesis, usually 6 to 8 weeks after discharge. Encourage the patient to dress in loose-fitting street clothes at home, not pajamas, to further enhance a positive self-image.

Teach the patient to continue performing the exercises that began in the hospital. Active range-of-motion exercises should begin 1 week after surgery or when sutures and drains are removed. Emphasize that reaching and stretching exercises should continue only to the point of pain or pulling, never beyond that. Some YWCA locations have a free postmastectomy program that supports women and men following breast cancer surgery. The program includes exercise to music, exercise in water, and peer psychological support. Patients may participate as early as 3 weeks after surgery. Before discharge, the surgeon may prescribe precautions or limitations specific to plans for future procedures such as reconstruction.

**Lymphedema**, an abnormal accumulation of protein fluid in the subcutaneous tissue of the affected limb after a mastectomy, is a commonly overlooked topic in health teaching. Risk factors include injury or infection of the extremity, obesity, presence of extensive axillary disease, and radiation treatment. Once lymphedema develops, it can be very difficult to manage, and *lifelong measures must be taken to prevent it*. Nurses play a vital role in educating patients about this complication. Teach your patient to immediately report symptoms of lymphedema such as sensations of heaviness, aching, fatigue, numbness, tingling, and/or swelling in the affected arm, as well as swelling in the upper chest (Mohler & Mondry, 2013).

### Nursing Safety Priority QSEN

#### Action Alert

Provide information needed to help the patient avoid infection and subsequent lymphedema of the

affected arm after the mastectomy. Teach the importance of avoiding having blood pressure measurements taken on, having injections in, or having blood drawn from the arm on the side of the mastectomy. Instruct the patient to wear a mitt when using the oven, wear gloves when gardening, and treat cuts and scrapes appropriately. If lymphedema occurs, early intervention provides the best chance for control. Nurses should not assume that women with lymphedema are disabled; they are able to live full lives within this limitation. A referral to a lymphedema specialist may be necessary for the patient to be fitted for a compression sleeve and/or glove, to be taught exercises and manual lymph drainage, and to discuss ways to modify daily activities to avoid worsening the problem. Management is directed toward measures that promote drainage of the affected arm. Teach patients, especially those who have had axillary lymph nodes removed, that measures to prevent lymphedema are lifelong and include avoiding trauma to the arm on the side of the mastectomy.

### **Psychosocial Preparation.**

Concerns about appearance after surgery are common and are often a threat to the patient's self-concept as a woman. Before breast surgery, the woman and her partner can benefit from an explanation of the expected postoperative appearance. After a modified radical mastectomy, the chest wall is fairly smooth and has a horizontal incision from the axilla to the midchest area. After breast-conserving surgery, scars vary according to the amount of breast tissue removed. Women are sometimes shown pictures of post-mastectomy reconstruction but are disappointed with their own results. Emphasize that scars will fade and edema will lessen with time. Scars may be red and raised at first, but these features lessen in the first few months. After surgery, encourage the woman to look at her incision when she is ready. Do not push her to accept this body image change immediately.

Much of one's body image is a reflection of how others respond. Therefore the response of the patient's family or partner to the surgery is crucial in determining the effect on self-esteem. These people may also need the support of the nurse. They may have concerns about their ability to accept the changes and need to discuss these feelings with an objective listener. They may also need help with communicating their feelings, both negative and positive, to their loved one. Involving them in teaching may also help reinforce learning and increase retention.

Discuss sexual concerns before discharge. Most surgeons recommend avoiding sexual intercourse for 4 to 6 weeks. Patients may prefer to lay a pillow over the surgical site or to wear a bra, camisole, or T-shirt to prevent contact with the surgical site during intercourse. He or she may be embarrassed to discuss the topic of SEXUALITY. Be sensitive to possible concerns and approach the subject first.

For young women, issues related to childbearing may be a concern. Chemotherapy and radiation are considered serious teratogenic (birth defect-causing) agents. Advise sexually active patients receiving chemotherapy or radiotherapy to use birth control during therapy. The method and length of birth control should be discussed with the primary health care provider.

### **Health Care Resources.**

Resources available to the patient after discharge include personal support and community programs. After discharge, the spouse or partner may need help in planning support for home responsibilities. For example, a partner who may be assuming additional duties at home and work may feel stressed. Discussing the need for ongoing emotional support is also beneficial to both the patient and partner. Leaving the hospital and appearing normal do not end the anxiety and fear. Identifying a support person with whom the patient or couple can explore these feelings and discussing the need to ventilate feelings enhance personal and family recovery.

Numerous support and educational resources are available to those diagnosed with breast cancer. Nurses must provide accurate and current information to patients who may have obtained inaccurate information from various media. There are over 2 million breast cancer survivors in the United States, and many men and women are active in breast cancer support and advocacy organizations. National breast cancer organizations are accessible online, and many of them have local affiliates. Examples of such organizations are Susan G. Komen for the Cure, the National Breast Cancer Coalition, Y-Me, Sisters Network, Young Survival Coalition, and Pink Ribbon Girls. Local support organizations can be accessed through the health care provider, the local hospital, wellness centers, home care agencies, or by word of mouth.

The American Cancer Society (ACS) ([www.cancer.org](http://www.cancer.org)) is a comprehensive resource for information and support in the United States. Breast Cancer.Org ([www.breastcancer.org](http://www.breastcancer.org)) provides evidence-based information in language a lay person can understand.

The Canadian Breast Cancer Foundation ([www.cbcbf.org](http://www.cbcbf.org)) offers information, resources, and support services for breast cancer patients and their families. The Breast Cancer Society of Canada ([www.bcsa.ca](http://www.bcsa.ca)) conducts research on breast cancer in Canada.

## Clinical Judgment Challenge 70-1

### Patient-Centered Care; Safety; Evidence-Based Practice QSEN

A 66-year-old woman is diagnosed with invasive breast cancer and scheduled for a modified right mastectomy and chemotherapy. She tells you that she has feared developing cancer because her mother and aunt “had the BRCA2 gene” and both were both diagnosed with breast cancer in their 40s. She says that she is worried and anxious because her older sister has ovarian cancer and has less than a year to live. The patient is married and has two female adult children who live with their families out of state. The patient tells you that she is very worried that her children may have the genetic predisposition to breast and/or ovarian cancer.

1. What evidence-based risk factors does this patient have for breast cancer?
2. What preoperative teaching will you provide for her and why?
3. What will you teach the patient about chemotherapy to maintain her safety?
4. In an effort to include a whole-person approach to her care, how might you help address the patient's emotional concerns?

### ◆ Evaluation: Reflecting

Evaluate the care of the patient with breast cancer based on the identified priority patient problems. The expected outcomes include that the patient:

- Has no recurrence or metastasis of breast cancer after completion of treatment; if metastasis occurs, have optimal palliative and end-of-life care
- States that she or he is coping with the uncertainty of having breast cancer and its treatment

## Benign Breast Disorders

Benign breast conditions are very common. Noncancerous changes to breast tissue can present as breast lumps, impaired COMFORT or pain, and nipple changes (Amin, et al., 2013). Most breast lumps are benign. Because the incidence of breast disease is related to age, breast disorders are described in the following paragraph in an age-related order (Table 70-4).

**TABLE 70-4**  
**Typical Presentation of Benign Breast Disorders**

BREAST DISORDER	DESCRIPTION	INCIDENCE
Fibroadenoma	Most common benign lesion; solid mass of connective tissue that is unattached to the surrounding tissue	During teenage years into the 30s (most commonly)
Fibrocystic breast condition	Breast pain and tender lumps; the lumps are rubbery, ill defined, and commonly found in the upper outer quadrant of the breast	Onset late teens and 20s; usually subsides after menopause
Ductal ectasia	Hard, irregular mass or masses with nipple discharge, enlarged axillary nodes, redness, and edema; difficult to distinguish from cancer	Women approaching menopause
Intraductal papilloma	Mass in duct that results in nipple discharge; mass is usually not palpable	Women 40 to 55 years of age

### Fibroadenoma

Fibroadenomas are the most common benign tumor in women during the reproductive years. However, they also may occur in a few postmenopausal women. A **fibroadenoma** is a mass of connective tissue that is unattached to the surrounding breast tissue and is usually discovered by the woman herself or during mammography. Although the immediate fear is that of breast cancer, the risk for cancer occurring within a fibroadenoma is very small. On clinical examination, the tumors are oval, freely mobile, rubbery, and vary in size.

Fibroadenomas may occur anywhere in the breast. The primary health care provider may request a breast ultrasound examination or may perform a needle aspiration to establish whether the lump is cystic (fluid filled) or solid. If the lesion is solid, excision in an ambulatory care setting using local anesthesia is sometimes the treatment of choice.

### Fibrocystic Breast Condition

#### ❖ Pathophysiology

Fibrocystic changes of the breast include a range of changes involving the lobules, ducts, and stromal tissues of the breast. Because these changes affect at least half of women over the life span, they are referred to as **fibrocystic breast condition (FBC)** rather than *fibrocystic disease*. This condition most often occurs in premenopausal women between 20 and 50 years of age and is thought to be caused by an imbalance in the normal estrogen-to-progesterone ratio. Typical symptoms include breast pain and tender lumps or swelling in the breasts. The symptoms are more noticeable before a woman's menstrual period (McCance et al., 2014).

The two main features of FBC are fibrosis and cysts. Areas of fibrosis are made up of fibrous connective tissue and are firm or hard. Cysts are spaces filled with fluid lined by breast glandular cells. Microcysts are small, nonpalpable cysts inside the breast glands. Macrocysts occur when fluid continues to build up. They often enlarge in response to monthly hormonal changes, stretching the surrounding breast tissue, and become painful. Symptoms usually resolve after menstruation and then recur before the next menstrual period in a cyclic fashion. Breast ultrasound is used to confirm the presence of a cyst.

Postmenopausal women taking hormone replacement therapy (HRT) may develop FBC or experience worsening of symptoms. Having cysts or fibrosis does not increase a woman's chance of developing breast cancer. However, if a lump is very firm or has other features raising the concern about cancer, mammography is indicated. A needle biopsy or surgical biopsy may be needed to make sure that cancer is not present. Biopsy may be indicated in these situations:

- No fluid is aspirated.
- The mammogram shows suspicious findings.
- A mass remains palpable after aspiration.
- The aspirated fluid reveals cancer cells.

Symptoms often resolve after menopause when estrogen decreases.

### ❖ **Interprofessional Collaborative Care**

Management of FBC focuses on the symptoms of the condition. Suggest supportive measures for women with mild discomfort. The use of analgesics or limiting salt intake before menses to help decrease swelling may be helpful. Teach patients that wearing a supportive bra, even to bed, can reduce pain by decreasing tension on the ligaments. Local application of ice or heat may provide temporary relief of pain. For a small number of women, draining the cysts by needle aspiration can help relieve painful symptoms. Many women find relief with the reduction of dietary caffeine and other stimulants.

In women with severe symptoms of FBC, hormonal drugs such as oral contraceptives or selective estrogen receptor modulators (SERMs) may be prescribed to suppress oversecretion of estrogen and correct luteal insufficiency. Vitamin supplements have also been suggested to relieve symptoms, but research has not consistently shown these to be effective; some may have dangerous side effects if taken in large doses. Diuretics may be prescribed to decrease premenstrual breast engorgement.

## **Nursing Safety Priority** QSEN

### **Drug Alert**

Explain to women the benefits and risks associated with hormonal drug therapy for FBC, such as stroke, liver disease, and increased intracranial pressure. Teach them to seek medical attention immediately if any signs or symptoms of these complications occur.

Encourage the patient to continue prescribed drug therapy and monitor the effectiveness of these interventions. Teach the patient to become familiar with the normal feel and texture of her breasts so she is aware of any changes.

## **Issues of Large-Breasted Women**

Although Western society emphasizes large breasts as a positive attribute, women with excessive breast tissue often have health problems and impaired COMFORT. For instance, a woman with large breasts may have difficulty finding clothes that fit well and in which she feels attractive. The breast size may be out of proportion to the rest of the body, which adds to the problem of finding clothes that fit. Larger bras are expensive and may need to be specially ordered. The woman may have large dents in the shoulders from bra straps. In addition, many large-breasted women develop fungal infections under the breasts, especially in hot weather, because it is difficult to keep this area dry and exposed to air.

Backaches from the added weight are also common. If well-fitting bras do not help and obesity is not part of the problem, the only alternative for this condition may be breast reduction surgery. The surgeon removes excess breast tissue and then repositions the nipple and remaining skin flaps to produce the best cosmetic effect. This operation is a major surgical procedure and is called a **reduction mammoplasty**.

The decision to have the procedure is usually made after years of living with the discomfort of excessive breast size. Listen to the woman verbalize her feelings and reinforce information as appropriate. The nursing care after surgery is similar to that for the woman having reconstructive surgery. (See discussion of Breast Reconstruction earlier in the [Surgical Management](#) section under Breast Cancer.)

## **Issues of Small-Breasted Women**

Some women choose to have **breast augmentation** surgery to increase or improve the size, shape, or symmetry of their breasts. Most health insurers do not pay for this procedure. Most surgeries involve the implantation of saline-filled or silicon prostheses. Some are constructed from the women's own tissue in much the same way as for reconstruction after mastectomy. *Saline* implants are filled with sterile saline and can be filled with the amount needed to get the shape and firmness the woman wants. If the implant shell leaks, the saline will be safely absorbed by the body. *Silicone* implants are filled with an elastic gel, which can leak into the breast and will not be absorbed. The

plastic surgeon reviews the advantages and disadvantages of each implant or natural procedure.

Before breast augmentation surgery, teach the patient to stop smoking (to promote healing); avoid aspirin and other NSAID; and avoid herbs that can cause bleeding during the procedure, such as garlic, *Ginkgo biloba*, and ginseng. Tell her that the incisions will be hidden as much as possible, either under the pectoral muscle or directly behind the breast tissue as a submammary placement. One or more wound drains will be inserted during surgery, and she will need to know how to care for these drains at home. Review possible postoperative complications, including infection and implant leakage, which can cause severe pain and possible fever.

After surgery, the patient can be discharged to home the same day or the day after. Remind the family or significant other that someone should stay with her for at least 24 hours after surgery. The incisions may or may not have dressings, depending on the surgeon and type of surgery.

## Nursing Safety Priority QSEN

### Action Alert

Remind the patient after breast augmentation that for the first few days she should expect soreness in her chest and arms. Her breasts will feel tight and sensitive, and the skin over her breasts may feel warm or may itch. Teach the patient that she will have difficulty raising her arms over her head and should not lift, push, or pull anything until the surgeon permits. Teach her to also avoid strenuous activity or twisting above her waist. Remind the patient to walk every few hours to prevent deep vein thrombi. Tell her to expect some swelling of the breasts for 3 to 4 weeks after surgery.

An important issue for patients who have breast augmentation surgery is breast cancer surveillance. Breast self-examination (BSE) and clinical breast examination (CBE) can still be performed because the prosthesis is placed behind the woman's normal breast tissue, actually pushing it forward. However, screening mammography may not be as sensitive because the amount of visualized breast tissue is decreased. Additional x-rays, called *implant displacement views*, may be used to examine the breast tissue more completely. Although there is no conclusive evidence that breast augmentation increases breast cancer risk, further research is needed regarding diagnosis and prognosis of breast cancer among women with cosmetic breast implants (Lavigne et al., 2013). Teach women desiring cosmetic breast augmentation about the differences in breast cancer screening.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- In collaboration with the health care team, identify community resources for patients with breast cancer, including *Reach to Recovery* of the American Cancer Society. **QSEN: Teamwork and Collaboration**

### Health Promotion and Maintenance

- Identify patients at high risk for breast cancer, especially women with family history of breast cancer at a young age; those who have had early menarche, late menopause, or first pregnancy after 30 years of age; or those who are nulliparous (see [Table 70-1](#)).
- Discuss benefits and risks of options available to women who are high risk for breast cancer, including close surveillance, chemoprevention, and prophylactic surgery.
- Teach women to become self-aware of breasts and any breast changes; teach breast self-examination (BSE) to women who choose this method of breast self-awareness (see [Chart 70-1](#)). **QSEN: Patient-Centered Care**
- Encourage women to have a screening mammography according to recommended guidelines. Baseline screening should begin at 45 years of age and continue yearly. In high-risk women, screening should be started earlier. **QSEN: Evidence-Based Practice**
- Encourage women to have a clinical breast examination (CBE) according to recommended guidelines. **QSEN: Evidence-Based Practice; Informatics**

### Psychosocial Integrity

- Assess and document patients' reactions to the diagnosis of breast cancer and the effect of breast cancer treatment on their body image and SEXUALITY. **QSEN: Patient-Centered Care; Informatics**
- Allow patients opportunities to express feelings of grief, fear, and anxiety.
- Teach women ways to minimize surgical area deformity and enhance body image, such as use of a breast implant (prosthesis) or the option of breast reconstruction.
- Address the reactions of family and significant others to the diagnosis of breast cancer; provide support and education. **QSEN: Patient-Centered Care**

### Physiological Integrity

- Assess benign lumps as mobile and round or oval; assess possible malignant lumps as fixed and irregularly shaped, often in the upper outer breast quadrant (see [Chart 70-2](#)).
- A breast reduction is an option to promote COMFORT for women with very large, heavy breasts.
- A breast augmentation is an elective procedure for women with small breasts or for women who desire reconstruction after breast removal (see [Table 70-3](#)).
- After breast cancer surgery, assess vital signs, dressings, drainage tubes, and amount of drainage. **Clinical Judgment**
- Notify the health care team that the arm of the surgical mastectomy side should not be used for blood pressures, blood drawing, IV therapy, or injections. **QSEN: Safety**
- Assess the return of arm and shoulder mobility after breast surgery and axillary dissection.
- Assess for the presence of lymphedema and assist the patient to perform therapeutic measures to reduce lymphedema in the affected arm. **QSEN: Safety**
- Teach the patient measures to prevent lymphedema after axillary node dissection, including

exercises as listed in [Chart 70-3](#). **QSEN: Evidence-Based Practice**

- Observe for and report other complications of breast cancer surgery or breast reconstruction, especially infection and inadequate vascular perfusion (see [Chart 70-4](#)). **QSEN: Safety**
- After an axillary lymph node dissection, elevate the affected arm on a pillow.
- Teach self-management after breast surgery as listed in [Chart 70-5](#).
- Radiation and drug therapy are used most often as adjuvant therapy after breast surgery but may be used before surgery to shrink the tumor.
- Benign problems of the breast may cause impaired COMFORT (see [Table 70-4](#)).

## CHAPTER 71

# Care of Patients With Gynecologic Problems

Donna D. Ignatavicius

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- SEXUALITY
- COMFORT

 The SEXUALITY concept exemplar for this chapter is Uterine Leiomyoma, below.

**The interrelated concepts for this chapter are:**

- ELIMINATION
- REPRODUCTION

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with members of the health care team when providing safe quality care for patients with gynecologic cancers.

### Health Promotion and Maintenance

2. Teach patients about community-based resources for patients with gynecologic health problems.
3. Identify risk factors for gynecologic cancers.
4. Teach women about evidence-based health promotion and maintenance measures to help prevent or early-detect gynecologic cancers.

### Psychosocial Integrity

5. Identify interventions to help patients adapt to physical changes, including effects on SEXUALITY and REPRODUCTION, caused by gynecologic problems and their treatment.

### Physiological Integrity

6. Develop a teaching plan for a patient to manage or prevent vaginal infections.
7. Prioritize care after surgery for the woman undergoing an anterior and/or posterior repair, including managing impaired COMFORT and ELIMINATION.
8. Develop an evidence-based plan of care for a patient undergoing a laparoscopic or traditional open hysterectomy.
9. Plan self-management education regarding radiation therapy for patients with gynecologic cancers.

Common gynecologic symptoms that women experience are pain or impaired COMFORT, vaginal discharge, and bleeding. Some patients also have urinary ELIMINATION symptoms associated with their gynecologic problem. Women are often hesitant to seek medical attention for these problems because of fear of a life-threatening disease diagnosis or concern about privacy and dignity. Be sensitive to the woman's concerns and encourage discussion about menstrual or other reproductive problems. Assess the effects of gynecologic disorders on SEXUALITY in any setting. These health problems often impair sexual function and therefore can affect the woman's relationship with her

partner. Remember that sexuality affects a woman's sense of being, self-esteem, and body image. See [Chapter 2](#) for a brief review of the concept of SEXUALITY.

## Sexuality Concept Exemplar Uterine Leiomyoma

### Pathophysiology

**Leiomyomas**, also called **fibroids** or **myomas**, are benign, slow-growing solid tumors of the uterine myometrium (muscle layer). They are classified according to their position in the layers of the uterus: intramural, submucosal, and subserosal. *Intramural* leiomyomas are contained in the uterine wall within the myometrium. *Submucosal* leiomyomas protrude into the cavity of the uterus and can cause bleeding and disrupt pregnancy. *Subserosal* leiomyomas protrude through the outer surface of the uterine wall and may extend to the broad ligament, pressing other organs (Fig. 71-1) (McCance et al., 2014).

FIG. 71-1 Classification of uterine leiomyomas.

Although most fibroids develop within the uterine wall, a few may appear in the cervix. Pedunculated leiomyomas are attached by a pedicle (stalk) to the outside of the uterus and occasionally break off and attach to other tissues (parasitic fibroids).

### Etiology and Genetic Risk

Although the cause is not known, leiomyomas develop from excessive local growth of smooth muscle cells. This may be a genetic error causing a lack of ability to halt growth. The growth of leiomyomas may be related to stimulation by estrogen, progesterone, and growth hormone. This explains why fibroids sometimes enlarge during pregnancy and diminish in size after menopause (McCance et al., 2014).

### Incidence and Prevalence

The incidence of leiomyomas increases as women get older. Women who have never been pregnant also are at a high risk. As many as 80% of women are likely to have fibroids (McCool et al., 2014). Many women have asymptomatic fibroids, whereas others have severe symptoms.

### Interprofessional Collaborative Care

#### Assessment: Noticing

#### Physical Assessment/Signs and Symptoms.

Women with fibroids usually do not have impaired COMFORT, although acute pain may occur with

twisting of the fibroid on its stalk. *The patient often seeks medical attention because of heavy vaginal bleeding.* Ask about how many tampons or menstrual pads she uses a day. Determine if she has a feeling of pelvic pressure and altered ELIMINATION patterns, including constipation and urinary frequency or retention. These symptoms result when the enlarged fibroid presses on other organs. The patient may notice that her abdomen has increased in size. Assess the woman's abdomen for distention or enlargement. Ask if she has **dyspareunia** (painful intercourse) and/or infertility (inability to become pregnant).

Abdominal, vaginal, and rectal examinations usually reveal the presence of a uterine enlargement. Further diagnostic procedures are needed to differentiate benign tumors from cancerous ones.

### **Psychosocial Assessment.**

Symptoms such as dyspareunia may significantly lower the patient's quality of life. A woman who is symptomatic may fear that she has cancer or may have anxiety about abnormal bleeding or her failure to conceive. She may also be concerned if surgery is recommended if she desires pregnancy. Assess the woman's feelings and concerns about her symptoms and fears of the unknown. If hysterectomy is recommended, explore the significance of the loss of the uterus for the woman and her partner, including effects on SEXUALITY and sexual function.

### **Diagnostic Assessment.**

A complete blood count may identify iron deficiency anemia (related to heavy or prolonged bleeding). A pregnancy test is done to determine whether pregnancy is the cause of the uterine enlargement. An endometrial biopsy may be performed to evaluate for endometrial cancer.

*Transvaginal ultrasound (US)* alone or with saline infusion (saline sonogram) provides a picture of a submucosal fibroid that may protrude into the uterine cavity. For this procedure, the US probe is placed into the woman's vagina to better visualize the uterine area. The primary health care provider may also choose to directly view a tumor and perform a biopsy using *laparoscopy* (for tumors on the outside of the uterus) or *hysteroscopy* (for tumors accessible inside the uterus). MRI can differentiate between benign and malignant lesions.

### **◆Analysis: Interpreting**

The priority collaborative problem for patients with uterine leiomyoma is *Potential for prolonged or heavy bleeding due to abnormal uterine growth.*

### **◆Planning and Implementation: Responding**

#### **Managing Bleeding**

##### **Planning: Expected Outcomes.**

The expected outcome for the patient who has one or more uterine leiomyomas is that she will not experience or continue to experience heavy (severe) or prolonged bleeding following treatment.

##### **Interventions.**

Asymptomatic fibroids usually do not need treatment. Management depends on the size and location of the tumor and the woman's desire for future pregnancy. Women who want to become pregnant can take drug therapy or have magnetic resonance–guided focused ultrasound surgery or laparoscopic myomectomy to remove the tumor. Uterine artery embolization and hysterectomy are choices for women who no longer desire pregnancy.

#### **Nonsurgical Management.**

If the woman is menopausal, the fibroids usually shrink, and surgery may not be necessary. Teach the patient who is receiving hormone replacement therapy for menopausal symptoms that the fibroids may continue to grow because of estrogen stimulation.

If the woman has few symptoms or desires childbearing, the primary health care provider may recommend intermittent observation and examination. As with dysfunctional uterine bleeding, mild leiomyoma symptoms can be managed with oral contraception.

*Magnetic resonance–guided focused ultrasound* is a noninvasive, painless technique for women with few smaller fibroids who wish to preserve their fertility. The woman lies prone on an MRI scanner, which provides a three-dimensional image of the pelvis. The radiologic clinician then guides a focused pulse of ultrasound to heat the tumor to destroy it.

An alternative to surgery for the woman who does not desire pregnancy is **uterine artery embolization** (also called *uterine fibroid embolization [UFE]*) under moderate sedation or short-term anesthesia. The interventional radiologist uses a percutaneous catheter inserted through the femoral artery to inject polyvinyl alcohol pellets into the uterine artery. The resulting blockage starves the tumor of circulation, allowing it (or them) to shrink.

## Nursing Safety Priority QSEN

### Action Alert

After uterine artery embolization, the woman may have severe cramping within the first 24 hours caused by decreased blood flow to the uterus. Cramping can last from a few days to 2 weeks. Assess the client's pain level and provide analgesics as needed. If a vascular closure device is used at the arterial insertion site (most commonly), raise the head of the bed. Help the patient ambulate about 2 hours after the procedure. If a closure device was not used, keep her on bedrest with the legs immobilized for 4 hours before ambulating to prevent bleeding. Patients generally recover quickly, returning to normal activities within 7 to 10 days after the procedure (Storck, 2012.)

Before discharge, tell the patient to observe for *postembolization syndrome*—a flulike illness that some women develop that lasts about 5 to 7 days. Teach her to resume usual activities slowly and avoid strenuous activity until the surgeon recommends it. Most patients can return to work or daily routine within a week.

### Surgical Management.

When possible, minimally invasive surgical (MIS) techniques are performed, such as a myomectomy, to prevent removing the uterus. If not, a hysterectomy is the procedure of choice.

### Uterus-Sparing Surgeries.

If the woman desires children, the surgeon may perform a laparoscopic or hysteroscopic **myomectomy** (the removal of leiomyomas from the uterus) (Bradley, 2013). During this procedure, a laser may be used to remove the tumors. This MIS procedure is usually performed in the early phase of the menstrual cycle to minimize blood loss and avoid the possibility of interrupting an unsuspected pregnancy. A small percentage of leiomyomas recur after surgery. Scarring makes the uterus more likely to rupture during labor, so future deliveries will be planned cesarean deliveries. Nursing care is similar to that for a woman undergoing a hysterectomy as discussed in the following paragraphs.

In selected cases (e.g., submucous fibroids, menorrhagia), a *transcervical endometrial resection (TCER)* is performed via hysteroscopy. A hysteroscope (endoscope) is inserted into the uterus, and the endometrium is destroyed using diathermy (heat) or radioablation.

## Nursing Safety Priority QSEN

### Critical Rescue

Monitor for rare but potential complications of hysteroscopic surgery, which include:

- Fluid overload (fluid used to distend the uterine cavity can be absorbed)
- Embolism
- Hemorrhage
- Perforation of the uterus, bowel, or bladder and ureter injury

- Persistent increased menstrual bleeding
- Incomplete suppression of menstruation

*Monitor for any indications of these problems and report signs and symptoms, such as severe pain and heavy bleeding, to the surgeon or Rapid Response Team immediately.*

### Hysterectomy.

Leiomyomas are the most common reason for hysterectomies. Hysterectomies may be performed abdominally, vaginally, or with laparoscopic or robotic assistance based on the patient's clinical reason for hysterectomy and the surgeon's area of technical expertise. [Table 71-1](#) defines common terminology associated with gynecologic surgeries.

<b>TABLE 71-1</b> <b>Common Gynecologic Surgeries</b>
<p><b>Total Hysterectomy</b> The entire uterus, including the cervix, is removed. The procedure may be vaginal or abdominal, with laparoscopic or robotic assistance.</p> <p><b>Bilateral Salpingo-Oophorectomy (BSO)</b> Fallopian tubes and ovaries are removed.</p> <p><b>Panhysterectomy</b> Total abdominal hysterectomy and BSO: The uterus, ovaries, and fallopian tubes are removed.</p> <p><b>Radical Hysterectomy</b> The uterus, cervix, adjacent lymph nodes, upper third of the vagina, and surrounding tissues (parametrium) are removed.</p>

### Preoperative Care.

Preoperative teaching by the health care team typically begins in the surgeon's office or surgical clinic. Explain procedures that routinely take place before surgery, including laboratory tests and expected drugs such as a prophylactic antibiotic. Depending on the type of surgical technique planned, teach about the need for turning, coughing, and deep-breathing exercises; incentive spirometry; early ambulation; and pain relief. (See [Chapter 14](#) for a discussion of general patient care before surgery.)

*Psychological assessment and support are essential.* Assess the significance of the surgery for the woman and her partner related to SEXUALITY and REPRODUCTION. Many women relate their uterus to self-image and femininity or believe that their sexual function is related to their uterus. Although surgical menopause by hysterectomy can create loss of libido and vaginal changes if the ovaries are also removed, teach the patient that vaginal estrogen cream, lubricants, and gentle dilation can help with these issues (see [the Evidence-Based Practice box](#)). Reassure her regarding any misperceptions about the effects of hysterectomy, such as association with masculinization and weight gain. Assess the patient's support system and recognize that she may fear rejection by her sexual partner. To be patient centered, include the partner in all teaching sessions (if the patient prefers) *unless this practice is not culturally acceptable or the patient prefers not to do so for other reasons.*

## Evidence-Based Practice OSEN

### Does Having a Hysterectomy Affect a Woman's Sexuality?

Danesh, M., Hamzehgardeshi, Z., Moosazadeh, M., & Shabani-Asrami, F. (2015). The effect of hysterectomy on women's sexual function: A narrative review. *Medical Archives, 69*(6), 387-392.

The authors conducted a narrative systematic review of research using a five-step approach. An

extensive literature review yielded 34 articles to include in the review. Five categories were examined to determine if having a hysterectomy had an effect on these areas summarized in the following points:

- *Sexual desire*: The research showed that most women had an increase in sexual desire after having a hysterectomy.
- *Sexual arousal*: The research showed mixed findings. Some women had an increase in sexual arousal and others had a decrease in arousal.
- *Orgasm*: The research again showed mixed results, with some women experiencing more orgasms and others experiencing fewer orgasms.
- *Dyspareunia*: The research showed little or no change in the incidence of dyspareunia. However, vaginal lubricants and dilators were used at times to prevent discomfort during sexual intercourse.
- *Sexual satisfaction*: The research showed an overall decrease in sexual satisfaction.

### Level of Evidence: 1

The study was a systematic review, which is a strong source of evidence.

### Implications for Research and Practice

Although more studies are needed to more specifically determine sexual function of women who had a hysterectomy, this study suggests that these patients need health teaching regarding sexuality after surgery. If culturally appropriate and if the patient agrees, the woman's sexual partner needs to be included in this health teaching.

### Operative Procedures.

A *total abdominal hysterectomy (TAH)* is usually performed for leiomyomas larger than the size of a 16-week pregnancy. The uterus and cervix are most often removed by laparoscopic-assisted minimally invasive surgery (MIS), which requires one or more very small umbilical incisions. Although not commonly done as often today, the traditional open surgery is performed through a horizontal "bikini" incision. A *total vaginal hysterectomy (TVH)* requires no skin incision because the uterus is removed through the vagina.

Some surgeons use robotic technology to assist in performing a TAH, although it is much more expensive than a traditional vaginal or laparoscopic approach (ACOG, 2013). Robotic surgery is helpful when performing hysterectomies on patients who are extremely obese. In both vaginal and abdominal hysterectomies, the surgeon removes the uterus from supporting ligaments, which are then attached to the vaginal cuff so normal depth of the vagina is maintained.

### Postoperative Care.

Nursing care of the woman who has undergone a *TAH* is similar to that of any patient who has had laparoscopic or traditional open abdominal surgery (see [Chapter 16](#)). Assess ([Chart 71-1](#)):

#### Chart 71-1

### Focused Assessment

#### Postoperative Nursing Care of the Patient After Open Total Abdominal Hysterectomy

Assess cardiovascular, respiratory, renal, and gastrointestinal status, including:

- Vital signs
- Heart, lung, and bowel sounds

- Urine output
- Temperature and color of the skin
- Red blood cell, hemoglobin, and hematocrit levels
- Activity tolerance
- Dressing and drains for color and amount of drainage
- Perineal pads for vaginal bleeding and clots
- Fluid intake (IVs until peristalsis returns and patient is tolerating oral intake)

Teach the patient to use these interventions to prevent postoperative complications:

- Cough and deep-breathing exercises
- Incentive spirometry
- Sequential compression devices
- Ambulation
- Avoidance of heavy lifting or strenuous activity
- Adequate hydration

Assess the home care teaching needs of the patient related to the illness and surgery, including:

- Physiologic effects of the surgery
- Signs or symptoms to report
- Side or toxic effects of medications
- Activity limitations related to driving and use of stairs
- Follow-up care
- Postoperative restrictions related to sexual activity, use of tampons, and bathing

- Care of wound and/or drains

Assess the patient's coping skills and reaction to the diagnosis and surgical procedure.

- Vaginal bleeding (there should be less than one saturated perineal pad in 4 hours)
- Abdominal bleeding at the incision site(s) (a small amount is normal)
- Intactness of the incision(s)
- Urine output per urinary catheter for 24 hours or less (for open surgery only)
- Incisional or abdominal pain
  - Specific postoperative interventions for a *vaginal hysterectomy* include:
- Assessment of vaginal bleeding (there should be less than one saturated pad in 4 hours)
- Urinary catheter care
- Perineal care

## NCLEX Examination Challenge 71-1

### Physiological Integrity

A client returns from surgery after a laparoscopic total abdominal hysterectomy. On initial assessment, which finding by the nurse requires **immediate** intervention?

- A. Decreased bowel sounds in all quadrants
- B. Heavy vaginal bleeding with clots
- C. Temperature of 99° F (37.2° C)
- D. Client statement that pain is 4 on a scale of 0 to 10

### Care Coordination and Transition Management

Discharge teaching, including activity restrictions, depends on the type of surgical procedure performed. Care coordination after discharge is also essential.

#### Home Care Management.

Patients who have *uterus-sparing surgeries* usually go home the same day of surgery. They usually experience less postprocedural pain and fewer complications than patients who have their uterus and cervix removed. Teach patients that they should be able to return to usual daily activities in 2 weeks but sexual intercourse should be avoided for at least 6 weeks or as otherwise instructed by the primary health care provider.

If the patient had a *laparoscopic hysterectomy*, few limitations in activity are needed. For patients who had a *traditional open hysterectomy*, teach them to limit stair climbing for several weeks. If women live alone and are not permitted to drive for several weeks, they may need to arrange for transportation for follow-up surgical visits.

#### Self-Management Education.

Teach the woman who has undergone an abdominal hysterectomy about the expected physical changes, any activity restrictions, diet, sexual activity, wound care (if any), complications, and the need for follow-up care. Some women experience impaired abdominal or shoulder COMFORT because of the introduction of carbon dioxide gas during a *laparoscopic* procedure. For patients who have a *vaginal hysterectomy*, teach them to promptly report excessive or increasing bleeding to their surgeon. [Chart 71-2](#) lists areas to include for health teaching.

### Chart 71-2

## Patient and Family Education: Preparing for Self-Management

### Care After a Total Vaginal or Abdominal Hysterectomy

#### Expected Physical Changes

- You will no longer have a period, although you may have some vaginal discharge for a few days after you go home.
- It will not be possible for you to become pregnant, and birth control methods are no longer needed. (Condoms should still be used to decrease the chance of getting a sexually transmitted infection [STI].)
- If your ovaries were removed, you may have some menopause symptoms such as hot flashes, night sweats, and vaginal dryness.
- It is normal to tire more easily and require more sleep and rest during the first few weeks after surgery.

#### Activity (Typically for Vaginal and Traditional Open Surgeries)

- Limit stair climbing to fewer than five times per day.
- Do not lift anything heavier than 5 to 10 lb.
- Gradually increase walking as exercise, but stop before you become fatigued.
- Avoid the sitting position for any extended period. When you sit, do not cross your legs at the knees.
- Avoid jogging, aerobic exercise, participating in sports, and any strenuous activity for 2 to 6 weeks, depending on which type of surgical procedure was performed.
- Do not drive until your surgeon has told you that it's alright.

#### Sexual Activity

- Do not engage in sexual intercourse for 4 to 6 weeks or as prescribed by your surgeon.
- If you had a vaginal "repair" as part of your surgery, the first time you have intercourse you may have some tenderness or pain because the vaginal walls are tighter. Careful intercourse and the use of water-based lubricants can help reduce this discomfort. It usually goes away with time and stretching of the vagina.

#### Complications

- Take your temperature twice each day for the first 3 days after surgery. Report fevers of over 100° F (38° C).
- Check your incision, if you have any, daily for signs of infection (increasing redness, open areas, drainage that is thick or foul-smelling, incision pain).

#### Symptoms to Report to Your Surgeon

- Increased vaginal drainage or change in drainage (bloodier, thicker, foul-smelling)
- Temperature over 100° F (38° C)
- Pain, tenderness, redness, or swelling in your calves

- Pain or burning on urination

Generally, women are more accepting of surgery if they have completed childbearing, have interests outside the home, work, have no misconceptions about the effects of hysterectomy, and have support from the family, especially their sexual partner. Psychological reactions can occur months to years after surgery, particularly if sexual functioning and libido are diminished. Women identified as being at high risk for psychological problems may need long-term follow-up care or referral. They may need to be counseled about signs of depression. Intermittent sadness is normal, but continued feelings of low self-esteem or loss of interest or pleasure in usual activities and pastimes is not expected and should be evaluated. Provide written materials and focus on the positive aspects of the woman's life to help decrease adverse psychological reactions.

### **Health Care Resources.**

Loss of female reproductive organs causes many women to go through the grieving process. If desired and culturally appropriate, refer the woman to a clergy member or spiritual counselor if needed to discuss feelings of sadness. Suggest that the patient consult with a mental health counselor or clinical psychologist as another option if needed.

### **◆Evaluation: Reflecting**

Evaluate the care of the patient with leiomyomas on the basis of the identified priority problem. The expected outcomes are that she:

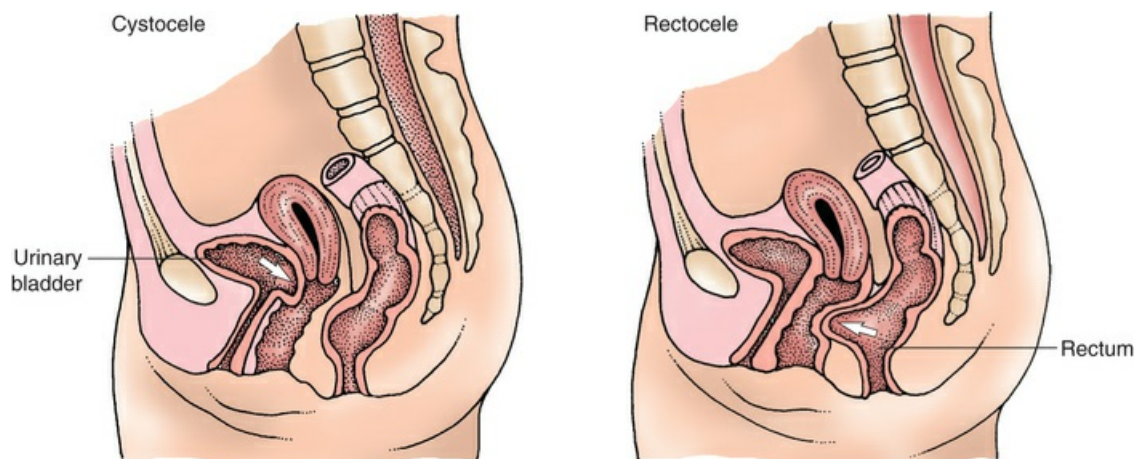

- Has relief of bleeding from the fibroid tumor(s) after effective management
- Verbalizes positive perception of self and is satisfied with her own SEXUALITY

## Pelvic Organ Prolapse

### ❖Pathophysiology

The pelvic organs are supported by a sling of muscles and tendons, which sometimes become weak and no longer able to hold an organ in place. **Uterine prolapse**, the most common type of **pelvic organ prolapse (POP)**, can be caused by neuromuscular damage of childbirth; increased intra-abdominal pressure related to pregnancy, obesity, or physical exertion; or weakening of pelvic support caused by decreased estrogen. The stages of uterine prolapse are described by the degree of descent of the uterus through the pelvic floor.

Whenever the uterus is displaced, other structures such as the bladder, rectum, and small intestine can protrude through the vaginal walls (Fig. 71-2). A **cystocele** is a protrusion of the bladder through the vaginal wall (urinary bladder prolapse), which can lead to stress urinary incontinence (SUI) and urinary tract infections (UTIs). A **rectocele** is a protrusion of the rectum through a weakened vaginal wall (rectal prolapse).

**FIG. 71-2** In cystocele, the urinary bladder is displaced downward, causing bulging of the anterior vaginal wall. In rectocele, the rectum is displaced, causing bulging of the posterior vaginal wall.

### ❖Interprofessional Collaborative Care

#### ◆Assessment: Noticing

Patients with suspected uterine prolapse may report a feeling of “something falling out,” dyspareunia (painful intercourse), backache, and heaviness or pressure in the pelvis. A pelvic examination may reveal a protrusion of the cervix or anterior vaginal wall when the woman is asked to bear down. Listen to her concerns and note signs of anxiety or depression from having long-term symptoms.

Ask the patient whether she has urinary ELIMINATION problems, such as difficulty emptying her bladder, urinary frequency and urgency, a urinary tract infection, or **stress urinary incontinence (SUI)** (loss of urine during activities that increase intra-abdominal pressure, such as laughing, coughing, sneezing, or lifting heavy objects). These symptoms may be associated with a *cystocele* (bladder prolapse).

Diagnostic tests include cystography (to show the presence of bladder herniation), measurement of residual urine by bladder ultrasound, and urine culture and sensitivity testing. Radiographic imaging of urinary anatomy and voiding function is useful in determining the degree of *cystocele* (prolapse).

*Rectocele assessment* usually includes symptoms of constipation, hemorrhoids, fecal impaction, and feelings of rectal or vaginal fullness. A vaginal and rectal examination may show a bulge of the posterior vaginal wall when the woman is asked to bear down.

## ◆Interventions: Responding

Interventions are based on the degree of the POP. Conservative treatment is preferred over surgical treatment when possible.

### Nonsurgical Management.

Teach women to improve pelvic support and tone by doing pelvic floor muscle exercises (PFMEs, or Kegel exercises). Space-filling devices such as pessaries or spheres can be worn in the vagina to elevate the uterine prolapse. Intravaginal estrogen therapy may be prescribed for the postmenopausal woman to prevent atrophy and weakening of vaginal walls. Women with bladder symptoms may benefit from bladder training and attention to complete emptying. Management of a rectocele focuses on promoting bowel elimination. The primary health care provider usually prescribes a high-fiber diet, stool softeners, and laxatives.

### Surgical Management.

Surgery may be recommended for severe symptoms of POP, with preference given to the least invasive approach. Address the fears and concerns of the patient and her family.

Transvaginal repair for pelvic organ prolapse (POP) using surgical vaginal mesh or tape is a commonly performed minimally invasive technique. It is particularly useful for women who are very obese. Depending on the procedure that is planned, the patient has either local or general anesthesia. The surgeon creates a sling with the mesh or tape, and the woman is discharged the same day. Procedures done under local anesthesia can be done in the surgeon's office. Since 2008, patient report of complications associated with the use of transvaginal mesh has required the [U.S. Food and Drug Administration \(2011\)](#) to release a classic report and update advising about the safety and effectiveness of the use of this product for POP. Since that time, multiple legal cases have been filed because of continued problems and complications. Common complications associated with the use of transvaginal mesh for POP include mesh erosion, painful sexual intercourse (dyspareunia), infection, urinary ELIMINATION problems (e.g., stress urinary incontinence [SUI]), and organ perforation (e.g., bladder and bowel) ([U.S. Food and Drug Administration \[USFDA\], 2011](#)).

## 📌Nursing Safety Priority QSEN

### Action Alert

To help the patient decide if she should have any surgical procedure using mesh or tape, be sure that she is provided with information regarding informed consent before surgery. Reinforce information about possible adverse events, the signs and symptoms of infection, and when she should contact her surgeon. Provide the patient with the manufacturer's labeling and written information.

Teach patients who have had the mesh or tape procedure to avoid strenuous exercise, heavy lifting, and sexual intercourse for 6 weeks. After 6 weeks, the patient may gradually begin to return to regular activities but must be educated about prevention of increasing intra-abdominal pressure (e.g., constipation, weight-lifting, cigarette smoking) for a minimum of 3 months to allow proper healing and prevent POP recurrence ([Lazarou, 2012](#)).

Alternatives to minimally invasive surgery are open surgical techniques. An **anterior colporrhaphy** (anterior repair) tightens the pelvic muscles for better *bladder* support. A vaginal surgical approach is used and may be done as a laparoscopic-assisted procedure. Nursing care for a woman undergoing an anterior repair is similar to that for a woman undergoing a vaginal hysterectomy.

After surgery, instruct the patient how to splint her abdomen to protect sutures and to limit her activities. Teach her to *avoid lifting anything heavier than 5 lb (2.27 kg), strenuous exercises, and sexual intercourse for 6 weeks*. For discomfort, she may use heat either as a moist heating pad or warm compresses applied to the abdomen. A hot bath may also be helpful. Sutures do not need to be removed because some are absorbable and others will fall out as healing occurs. Tell the woman to notify her health care provider if she has signs of infection, such as fever, persistent pain, or purulent, foul-smelling discharge. Encourage her to keep her follow-up appointment after surgery.

**Posterior colporrhaphy** (posterior repair) reduces *rectal* bulging. If both a cystocele and a rectocele are present, an *anterior and posterior colporrhaphy (A&P repair)* is performed. In this case, the woman may return from surgery with a urinary catheter in place to keep the surgical area clean and dry.

The nursing care after a posterior repair is similar to that after any rectal surgery. After surgery, a low-residue (low-fiber) diet is usually prescribed to decrease bowel movements and allow time for the incision to heal. Instruct the patient to avoid straining when she does have a bowel movement so she does not put pressure on the suture line. Bowel movements are often painful, and she may need pain medication before having a stool. Provide sitz baths or delegate this activity to unlicensed nursing personnel to relieve the woman's impaired COMFORT. Health teaching for the patient undergoing a posterior repair is similar to that for the patient undergoing an anterior repair. Vaginal hysterectomy may accompany any uterine prolapse repair surgery unless the woman wants to become pregnant. This procedure is described earlier in this chapter.

## **NCLEX Examination Challenge 71-2**

### **Safe and Effective Care Environment**

A client had an anterior and posterior colporrhaphy procedure this morning. What is the nurse's **current priority** assessment when caring for this client?

- A. Monitoring for urinary incontinence
- B. Determining pain level
- C. Checking for bowel sounds
- D. Inspecting the sternal incision

# Endometrial (Uterine) Cancer

## ❖ Pathophysiology

**Endometrial cancer** (cancer of the inner uterine lining) is the most common gynecologic malignancy (Nguyen et al., 2013). This chapter includes two other common gynecologic cancers, but the disease can affect any organ in the reproductive tract.

Endometrial cancer grows slowly in most cases, and early symptoms of vaginal bleeding generally lead to prompt evaluation and treatment. As a result, this type of cancer has a good prognosis. *Adenocarcinoma* is the most common type of tumor. It arises from the glandular part of the endometrium and usually follows endometrial hyperplasia (overgrowth).

The initial growth of the cancer is within the uterine cavity, followed by extension into the myometrium and the cervix. Stage I endometrial cancer is confined to the endometrium. Stage II cancer also involves the cervix, and stage III reaches the vagina or lymph nodes. Stage IV endometrial cancer has spread to the bowel or bladder mucosa and/or beyond the pelvis (McCance et al., 2014).

Metastasis outside the uterus occurs in these ways:

- Through lymphatic spread to the ovaries and parametrial, pelvic, inguinal, and para-aortic lymph nodes
- By blood to the lungs, liver, or bones
- By transtubal or intra-abdominal spread to the peritoneal cavity

Endometrial cancer is strongly associated with conditions causing prolonged exposure to estrogen without the protective effects of progesterone. Risk factors for endometrial cancer are listed in Table 71-2. Although most cases of endometrial cancer do not have a genetic predisposition, it is more common in families who have gene mutations for hereditary nonpolyposis colon cancer (HNPCC) (National Cancer Institute [NCI], 2017).

**TABLE 71-2**  
**Risk Factors for Endometrial (Uterine) Cancer and Cervical Cancer**

ENDOMETRIAL (UTERINE) CANCER	CERVICAL CANCER
<ul style="list-style-type: none"> <li>• Women in reproductive years</li> <li>• Family history of endometrial cancer or HNPCC</li> <li>• Diabetes mellitus</li> <li>• Hypertension</li> <li>• Obesity</li> <li>• Uterine polyps</li> <li>• Late menopause</li> <li>• Nulliparity (no childbirths)</li> <li>• Smoking</li> <li>• Tamoxifen (Nolvadex) given for breast cancer</li> </ul>	<ul style="list-style-type: none"> <li>• Girls and young women</li> <li>• Infection with HPV</li> <li>• Multiparity (multiple births)</li> <li>• Smoking</li> <li>• Younger than 18 years at first intercourse</li> <li>• Multiple sex partners</li> <li>• African American</li> <li>• Oral contraceptive use</li> <li>• History of STIs</li> <li>• Obesity or poor diet</li> <li>• Family history of cervical cancer</li> <li>• HIV/AIDS</li> <li>• Lower socioeconomic status</li> <li>• Sexual partner had a previous partner who developed cervical cancer</li> <li>• Intrauterine exposure to DES</li> </ul>

*AIDS*, Acquired immune deficiency syndrome; *DES*, diethylstilbestrol; *HIV*, human immune deficiency virus; *HNPCC*, hereditary nonpolyposis colon cancer; *HPV*, human papilloma virus; *STDs*, sexually transmitted diseases.

White women get the disease more often than African-American women, but African-American women die more often from the disease. The causes for these differences are not known (NCI, 2017).

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

The main symptom of endometrial cancer is postmenopausal bleeding. Ask the patient how many tampons or menstrual pads she uses each day. Some women also have a watery, bloody vaginal discharge, low back or abdominal pain, and low pelvic impaired COMFORT (caused by pressure of the enlarged uterus). Ask the patient to describe the exact location and intensity of her discomfort. A pelvic examination may reveal the presence of a palpable uterine mass or uterine polyp. The uterus is enlarged if the cancer is advanced.

Several laboratory tests are used to determine the overall condition of the woman with possible or confirmed endometrial cancer. For example, the complete blood count typically shows anemia

because the patient has heavy bleeding. Serum tumor markers to assess for metastasis include CA-125 (cancer antigen–125) and alpha-fetoprotein (AFP), both of which may be elevated when ovarian cancer is present (Pagana et al., 2017). A human chorionic gonadotropin (hCG) level may be taken to rule out pregnancy before treatment for cancer begins.

*Transvaginal ultrasound* and *endometrial biopsy* are the gold standard diagnostic tests to determine the presence of endometrial thickening and cancer. Saline may be infused during the ultrasound to improve the image of the uterine cavity. The clinician then collects an endometrial biopsy from inside the uterus via a thin, flexible suction curette through the cervix (Pagana, et al., 2017).

Other diagnostic tests to determine the patient's overall health status and the presence of metastasis (cancer spread) include:

- Chest x-ray
- Intravenous pyelography (IVP) or excretory urography to assess renal function and to assess for renal metastasis
- Abdominal ultrasound
- CT of the pelvis
- MRI of the abdomen and pelvis
- Liver and bone scans to assess for distant metastasis

During the diagnostic phase, the woman may express fears and concerns about having the disease and the effect on her SEXUALITY and/or REPRODUCTION. After the diagnosis is confirmed, she may express disbelief, anger, depression, anxiety, or withdrawal behaviors. Assess these emotional reactions, and encourage the patient to discuss her feelings. Ask her about how she copes with other stressful events, and assess her support systems.

### ◆Interventions: Responding

Surgical removal and cancer staging of the tumor with adjacent lymph nodes are the most important interventions for endometrial cancer. Cancer staging is often done using minimally invasive techniques, such as laparoscopic or robotic-assisted procedures.

### Surgical Management.

For stage I disease, the gynecology oncologist usually removes the uterus, fallopian tubes, and ovaries (**total hysterectomy** and **bilateral salpingo-oophorectomy [BSO]**) and peritoneum fluid or washings for cytologic examination. Laparoscopic surgery has fewer complications, shorter hospital stay, and less cost. A *radical* hysterectomy with bilateral pelvic lymph node dissection and removal of the upper third of the vagina is performed for stage II cancer. Nursing care for a radical hysterectomy is the same as that for a simple hysterectomy except that the woman's hospitalization is usually longer and her convalescence may be extended. (See earlier discussion of Hysterectomy in this chapter.) Radical surgery and node dissection can also be done as a minimally invasive procedure using laparoscopic or robotic-assisted technology.

### Nonsurgical Management.

Nonsurgical interventions (radiation therapy and chemotherapy) are typically used after surgery and depend on the surgical staging.

### Radiation Therapy.

The oncologist may prescribe radiation therapy to be delivered by external beam and/or brachytherapy for stage II and stage III cancers. Women with stage II disease may use brachytherapy (internal) radiation to prevent recurrence of vaginal cancer and improve survival.

The purpose of *brachytherapy* is to prevent disease recurrence. The radiologist places an applicator within the woman's uterus through the vagina. After the correct position of the applicator is confirmed by x-ray, the radioactive isotope is placed in the applicator and remains for several minutes. This procedure may be repeated between two and five times once or twice a week. Some patients also have external beam radiation while having brachytherapy treatment sessions. There are no restrictions for the woman to stay away from her family or the public between treatments.

While the radioactive implant is in place, radiation is emitted that can affect other people. The amount of time needed for the therapy depends on the amount of radiation emitted from the

source. The radiologist calculates the time needed for a specific dose of radiation.

Inform the patient that she is restricted to bedrest during the treatment session. Excessive movement in bed is restricted to prevent dislodgment of the radioactive source. [Chart 71-3](#) lists the health teaching for the patient having brachytherapy for gynecologic cancer. Teach patients about when to call the primary health care provider after each treatment session.

### Chart 71-3

## Best Practice for Patient Safety & Quality Care QSEN

### Health Teaching for the Patient Having Brachytherapy for Gynecologic Cancer

- Teach the patient to report any of these signs and symptoms to the primary health care provider immediately:
  - Heavy vaginal bleeding
  - Urethral burning for more than 24 hours
  - Blood in the urine
  - Extreme fatigue
  - Severe diarrhea
  - Fever over 100° F (38° C)
  - Abdominal pain
- Teach the patient that she is not radioactive between treatments and there are no restrictions on her interactions with others.

*External beam radiation therapy (EBRT or XRT) may be used to treat any stage of endometrial cancer in combination with surgery, brachytherapy, and/or chemotherapy. Depending on the extent of the tumor, the treatment is given on an ambulatory care basis for 4 to 6 weeks. Tissue around the tumor and pelvic wall nodes also is treated. Teach the patient to monitor for signs of skin breakdown, especially in the perineal area; to avoid sunbathing; and to avoid washing the markings outlining the treatment site.*

Reactions to radiation therapy vary. Some women feel “radioactive” or “unclean” after treatments and may exhibit withdrawal behaviors. Reassure them by correcting any misconceptions. [Chapter 22](#) discusses nursing care of patients receiving radiation therapy in more detail.

#### Drug Therapy.

*Chemotherapy* is used as palliative treatment in advanced and recurrent disease when it has spread to distant parts of the body, but it is not always effective. Although the combination can vary, three of the most common agents used for endometrial cancer are doxorubicin (Adriamycin), cisplatin (Platinol), and paclitaxel (Taxol).

Patients who have chemotherapy may be upset if **alopecia** (hair loss) occurs. Warn them of this possibility before treatment starts. Wigs, scarves, or turbans can be worn until the hair grows back. Many women select these replacements before they lose their hair. Others shave their head and begin wearing them immediately as the treatment begins. Tell women about these options so they can make decisions with which they are personally comfortable.

[Chapter 22](#) describes chemotherapy and general nursing care during treatment.

### **Complementary and Integrative Health.**

Every woman experiences cancer differently. Many complementary and integrative therapies have evidence of benefit in decreasing the side effects of drug therapy and boosting the immune system. Provide your patient with information that will help her make informed, evidence-based decisions. Encourage her to check with her oncologist and/or pharmacist because some integrative therapies can be harmful or interfere with cancer treatment. Current evidence-based information is available at the American Cancer Society ([www.cancer.org](http://www.cancer.org)) and Canadian Cancer Society ([www.cancer.ca](http://www.cancer.ca)) websites about mind-body therapies, healing touch, herbs, vitamins, nutrition, and biologic therapies.

Often patients experience emotional crises because of the physical effects of cancer treatments. Radical hysterectomy may be seen as mutilating. Both radiation and chemotherapy have side effects that change physical appearance and body image. Women may have a grief reaction to these changes. The feelings of loss depend on the visibility of the loss and the loss of function. Help the patient adapt to the body changes. Using a calm and accepting approach, encourage self-management as soon as her physical condition is stable.

### **Care Coordination and Transition Management**

Home care after surgery for endometrial cancer is the same as that after a hysterectomy. (See discussion of Hysterectomy in the Uterine Leiomyoma section.) Patients who are receiving chemotherapy or radiation therapy are treated on an ambulatory care basis. Most women are surprised by the fatigue caused by radiation and chemotherapy. Help the patient and her family plan daily activities around trips to the clinic or the primary health care provider's office.

High doses of radiation cause sterility, and vaginal shrinkage can occur. Vaginal dilators can be used with water-soluble lubricants for 10 minutes each day until sexual activity resumes, generally within 4 weeks (ACS, 2017a). Reassure the woman that she is not radioactive and that her partner will not “catch” cancer by engaging in sexual intercourse.

Death can occur with or without treatment. The patient and family want the woman to pass the 5-year survival mark without a recurrence of disease. If the tumor recurs and cure is not likely, the woman and her family need to think about hospice care and whether she can be cared for in the home. If there is a recurrence, they may be hostile and have signs of a grief reaction. Encourage patients and their families to discuss their feelings. Refer to support services such as a certified hospital chaplain or other spiritual leader, social worker, or counselor. Response to loss and grieving is discussed in [Chapter 7](#).

In the United States, local American Cancer Society chapters provide written materials about endometrial cancer and information about local support groups. Each province in Canada also has a division of the Canadian Cancer Society ([www.cancer.ca](http://www.cancer.ca)). If the patient is in the terminal stages of cancer, hospice care may be appropriate (see [Chapter 7](#)). If nursing care is needed at home, the hospital nurse or case manager makes referrals to a home health care agency. A referral to a social services agency may be needed if the patient cannot meet the financial demands of treatment and long-term follow-up.

# Ovarian Cancer

## ❖ Pathophysiology

Ovarian cancer is the leading cause of death from female reproductive cancers, but it is not the most common type of cancer. Most ovarian cancers are epithelial tumors that grow on the surface of the ovaries. These tumors grow rapidly, spread quickly, and are often bilateral. Tumor cells spread by direct extension into nearby organs and through blood and lymph circulation to distant sites (McCance et al., 2014). Free-floating cancer cells also spread through the abdomen to seed new sites, usually accompanied by ascites (abdominal fluid).

Ovarian cancer seems to be disordered growth in response to excessive exposure to estrogen. This would explain the protective effects of pregnancies and oral contraceptive use, both of which interrupt the monthly estrogen exposure.

Women who have had tubal ligation, used oral contraception, and breast-fed their children have less risk for having the disease (ACS, 2017b). The incidence increases in women older than 50 years, and most are diagnosed after menopause. Family history accounts for a small percentage of cases. These women carry *BCRA1* or *BCRA2* genetic mutations. Of these, some choose to have an elective **bilateral salpingo-oophorectomy (BSO)** (removal of both ovaries and fallopian tubes) to prevent ovarian cancer. Table 71-3 lists known and suspected risk factors for ovarian cancer.

**TABLE 71-3**  
**Risk Factors for Ovarian Cancer**

<ul style="list-style-type: none"><li>• Older than 40 years</li><li>• Family history of ovarian or breast cancer or HNPCC</li><li>• Diabetes mellitus</li><li>• Nulliparity</li><li>• Older than 30 years at first pregnancy</li><li>• Breast cancer</li></ul>	<ul style="list-style-type: none"><li>• Colorectal cancer</li><li>• Infertility</li><li>• <i>BRCA1</i> or <i>BRCA2</i> gene mutations</li><li>• Early menarche/late menopause</li><li>• Endometriosis</li><li>• Obesity/high-fat diet</li></ul>
--	---

HNPCC, Hereditary nonpolyposis colon cancer.

Survival rates are low because ovarian cancer often is not detected until its late stages. It is important for nurses to teach women to “*think ovarian*” if they have vague abdominal and GI symptoms.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

Most women with ovarian cancer have had mild symptoms for several months but may have thought they were caused by normal perimenopausal changes or stress. They may report abdominal pain or swelling or have vague GI disturbances such as indigestion and gas. Ask the patient if she has had urinary frequency or incontinence, unexpected weight loss, and/or vaginal bleeding.

Complications of advanced metastatic cancer include:

- Pleural effusion
- Ascites
- Lymphedema
- Intestinal obstruction
- Malnutrition

On pelvic examination, an abdominal mass may not be palpable until it reaches a size of 4 to 6 inches (10 to 15 cm). Any enlarged ovary found after menopause should be evaluated as though it were malignant. A Pap smear is of limited value for detecting ovarian cancer.

A cancer antigen test, *CA-125*, measures the presence of damaged endometrial and uterine tissue in the blood. It may be elevated if ovarian cancer is present, but it can also be elevated in patients with endometriosis, fibroids, pelvic inflammatory disease, pregnancy, and even menses (Pagana, et al., 2017). It is also useful for monitoring a patient's progress during and after treatment. Transvaginal ultrasonography, chest radiography, and CT are part of a complete workup to evaluate for metastasis. Complete blood work includes a liver profile if there is ascites.

The woman with ovarian cancer has concerns similar to those described for the patient with endometrial cancer as described earlier in this chapter. Because the cancer is often diagnosed in an advanced stage, thoughts of death and dying, menopause, and loss of fertility come as a shock.

### ◆Interventions: Responding

Nursing care of the patient with ovarian cancer is similar to that for endometrial or cervical cancer. The options for treatment depend on the extent of the cancer and usually include surgery first, followed by chemotherapy. Radiation is used for more widespread cancers.

Diagnosis depends on findings during surgical exploration. Exploratory laparotomy (abdominal surgery) is performed to diagnose, treat, and stage ovarian tumors. A total abdominal hysterectomy, bilateral salpingo-oophorectomy (removal of the ovaries and fallopian tubes), and pelvic and para-aortic lymph node dissection are usually performed. Very large tumors that cannot be removed are debulked (reduction). These procedures can be performed via laparoscopic technique to decrease recovery time, minimize pain, and reduce postoperative complications. Ovarian cancer is staged during surgery.

Nursing care of the patient is similar to that for any patient having abdominal surgery (see [Chapter 16](#)). As for any patient after abdominal surgery, assess vital signs and pain and maintain catheters and drains. Teach her the importance of antiembolism stockings, incentive spirometry, and early ambulation. Infections after ovarian cancer surgery commonly affect the respiratory and urinary tracts. Assess vital signs and monitor the quantity and quality of urine output.

After removing and staging ovarian cancer, *chemotherapy* is the treatment that is used most often. Cisplatin (Platinol), carboplatin, and taxanes of all types are the most common postoperative *drugs* used for treating all stages of ovarian cancer. They may be given IV and/or intraperitoneally. Intraperitoneal (IP) therapy is described in [Chapter 13](#). New drugs continue to be tested that use monoclonal antibodies, hormones, and agents that target cell growth and tumor blood supply. [Chapter 22](#) describes chemotherapy in detail, including associated nursing care.

## Clinical Judgment Challenge 71-1

### Clinical Judgment; Evidence-Based Practice; Informatics QSEN

A 48-year-old woman is scheduled to have a bilateral salpingo-oophorectomy (BSO) and total abdominal hysterectomy (TAH) using a traditional open procedure for ovarian cancer. Her oncologist told her that, after she recovers from surgery, she may need to have adjuvant chemotherapy to destroy any remaining cancer cells. She is married with a teenage daughter who is in the twelfth grade. The patient tells you as her nurse that she is devastated that she “may not live to see her daughter go to the prom and graduate from high school.”

1. How will you respond to the patient at this time?
2. What preoperative teaching will you provide for this patient and why?
3. What will you tell her about chemotherapy that may be necessary after surgery?
4. Where would you search for evidence about her expected quality of life and prognosis?
5. To what community resources would you refer this patient after discharge?

### Care Coordination and Transition Management

Patients having surgery usually return to their home. Teach them to avoid tampons, douches, and sexual intercourse for at least 6 weeks or as instructed by the primary health care provider. Remind them to keep their follow-up surgical appointment and talk with the primary health care provider about resuming usual activities. Refer patients and their families to Gilda's Club ([www.gildasclub.org](http://www.gildasclub.org)) and the National Ovarian Cancer Coalition (NOCC) ([www.ovarian.org](http://www.ovarian.org)) for more information and support groups. In Canada, the National Ovarian Cancer Association ([www.ovariancanada.org](http://www.ovariancanada.org)) is available for the same purpose.

For patients with advanced metastatic disease, collaborate with the case manager, patient, and

family for possible referral to hospice. [Chapter 7](#) discusses end-of-life care and hospice in detail. The woman who is faced with the diagnosis of advanced ovarian cancer understandably is very anxious about dying. Encourage her to discuss her feelings. Provide realistic assurance, as well as accurate information about treatments. Patients report that their most distressing moments in the hospital were when they thought they were not getting adequate information. Encourage them to use their support systems of family members, friends, and clergy, including the hospital chaplain. Grief counseling is very appropriate. A visit from another woman who has survived a similar disease or referral to a support group may decrease fears. Refer the patient who fears passing the *BRCA1* or *BRCA2* gene to her daughter for genetic counseling and testing.

Ovarian cancer has a high recurrence rate. After recurrence, the cancer is treatable but no longer curable. If this occurs, the patient may deny symptoms at first or express feelings of anger and grief. The family is often fearful of the outcome. Provide encouragement and support during this difficult time and help the patient and her family work through their grief and prepare for death.

# Cervical Cancer

## ❖Pathophysiology

The uterine cervix is covered with squamous cells on the outer cervix and columnar (glandular) cells that line the endocervical canal. Papanicolaou (Pap) tests sample cells from both areas as a screening test for cervical cancer. The squamo-columnar junction is the *transformation zone* where most cell abnormalities occur. The adolescent has more columnar cells exposed on the outer cervix, which may be one reason that she is more vulnerable to sexually transmitted infections (STIs) and human immune deficiency virus (HIV). In contrast, in the menopausal woman, the squamo-columnar junction may be higher up in the endocervical canal, making it difficult to sample for a Pap test.

Premalignant changes are described on a continuum from *atypia* (suspicious) to *cervical intraepithelial neoplasia* (CIN) to *carcinoma in situ* (CIS), which is the most advanced premalignant change. It generally takes years for the cervical cells to transform from normal to premalignant to invasive cancer. CIN, sometimes called *dysplasia*, is graded on a scale of 1 to 3, depending on the appearance of the cervical tissue under a microscope (ACS, 2017c). Not much tissue appears abnormal in CIN1 (mild dysplasia), which is thought to be the least serious cervical precancer; more tissue appears abnormal in CIN2 (moderate dysplasia). Most tissue looks abnormal in CIN3 (severe dysplasia as well as *carcinoma in situ*), which is the most serious precancer (ACS, 2017c).

Most cervical cancers arise from the squamous cells on the outside of the cervix. The other cancers arise from the mucus-secreting glandular cells (adenocarcinoma) in the endocervical canal. The disease spreads by direct extension to the vaginal mucosa, lower uterine segment, parametrium, pelvic wall, bladder, and bowel. Metastasis is usually confined to the pelvis, but distant spread can occur through lymphatic spread and the circulation to the liver, lungs, or bones.

Human papilloma virus infection (HPV) is the most common type of sexually transmitted infection (STI) in the United States (Centers for Disease Control and Prevention [CDC], 2017). Almost all women will have HPV sometime in their life, but not all types lead to cancer. Most cases of cervical cancer are caused by certain types of HPV. The high-risk HPV types, especially strains 16 and 18, impair the tumor-suppressor gene and cause most of the cervical cancers. The unrestricted tissue growth can spread, becoming invasive and metastatic (McCance et al., 2014). Risk factors for cervical cancer are listed in Table 71-2. The number of cases of cervical cancer (and deaths from cervical cancer) has decreased significantly over the past 40 years because more women regularly get Pap tests and HPV vaccines are routinely given (CDC, 2017).

## Health Promotion and Maintenance

Girls and young women (ages 9 through 26 years) should receive one of the two currently used HPV vaccines, *Gardasil* and *Cervarix*, ideally before their first sexual contact to receive protection against the highest-risk HPV types that are responsible for most cervical cancers. It is also given for boys and young men (ages 9 through 26 years) to prevent genital warts. Cervarix protects girls and women ages 9 through 25 years against HPV infection to prevent cervical cancer.

Teach all young adults and parents of minors about the importance of receiving the vaccine and the need to have the entire series (three injections over 6 months). Tell them that the most frequent side effects are related to local irritation from the injections (e.g., pain, redness). Other common side effects include nausea, vomiting, dizziness, headache, and diarrhea.

The American Cancer Society (ACS) recommends that women have periodic pelvic examinations and Pap tests to screen for cervical cancer early. Teach women that they should begin these screening precautions at the age of 21 years. Between ages 21 and 29 years, women should have a Pap test every 3 years; women between ages 30 and 65 years should have a Pap test plus a human papilloma virus (HPV) test (“co-testing”) every 5 years. More information on the HPV test is found later in this chapter. In the absence of co-testing, this population should still have a Pap test every 3 years. According to the ACS, women older than 65 years who have had regular cervical cancer testing with normal results should not receive Pap tests. Recommended guidelines from other health care organizations suggest a Pap test every 3 years for women older than 60 years (ACS, 2017c).

Canadian guidelines have also changed as delineated by the Society of Obstetricians and

Gynaecologists of Canada ([www.sogc.org](http://www.sogc.org)). The 2013 recommendations of this group recommend that Pap testing begin at the age of 25 years of age instead of the previous guideline of 21, with regular testing every 3 years until age 70.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

#### Physical Assessment/Signs and Symptoms.

The patient who has pre-invasive cancer is often asymptomatic. *The classic symptom of invasive cancer is painless vaginal bleeding.* Ask the patient if she has had or now has bleeding. It may start as spotting between menstrual periods or after sexual intercourse or douching. As the cancer grows, bleeding increases in frequency, duration, and amount and may become continuous.

Ask the woman if she has a watery, blood-tinged vaginal discharge that becomes dark and foul smelling (occurs as the disease progresses). Leg pain (along the sciatic nerve) or swelling of one leg may be a late symptom or may indicate recurrent disease. Flank pain may be a late symptom of hydronephrosis, indicating advanced cancer pressing on the ureters, backing up the urine into the kidney. Ask the patient if she has had other signs of recurrence or metastasis such as:

- Unexplained weight loss
- **Dysuria** (painful urination)
- Pelvic pain (caused by pressure of the tumor on the bladder or the bowel)
- **Hematuria** (bloody urine)
- Rectal bleeding
- Chest pain

A physical examination may not reveal any abnormalities in early preinvasive cervical cancer. The internal pelvic examination may identify late-stage disease.

#### Diagnostic Assessment.

If Pap results are abnormal, an *HPV-typing DNA test* of the cervical sample can determine the presence of one or more high-risk types. The primary health care provider may perform a colposcopic examination to view the transformation zone. **Colposcopy** is a procedure in which application of an acetic acid solution is applied to the cervix. The cervix is then examined under magnification with a bright filter light that enhances the visualization of the characteristics of dysplasia or cancer. If abnormal tissue is recognized, multiple biopsies of the cervical tissue are performed.

If atypical glandular cells are suspected, the health care provider may perform an *endocervical curettage* (scraping of the endocervix wall) as well. Inform her that a small amount of bleeding is expected for up to 2 weeks after the biopsies.

### ◆ Interventions: Responding

Interventions for the woman with cervical cancer are similar to those for endometrial cancer: surgery, which is possibly followed by radiation and chemotherapy for late-stage disease.

#### Surgical Management.

Early stage I management focuses on one of several local *cervical ablation* procedures, including electrosurgical excision, laser therapy, or cryosurgery. Factors that influence the choice of localized treatment versus surgical intervention include patient overall health, desire for future childbearing, tumor size and stage, cancer cell type, degree of lymph node involvement, and patient preference.

The **loop electrosurgical excision procedure (LEEP)** is short (10 to 30 minutes) and is performed in a physician's office or an ambulatory care setting with a local anesthetic injected into the cervix. A thin loop-wire electrode that transmits a painless electrical current is used to cut away affected tissue. LEEP is both a diagnostic procedure and a treatment because it provides a specimen that can be examined by a pathologist to ensure that the lesion was completely removed. Minimal impaired COMFORT is associated with this procedure. Spotting (very scant bleeding) after the procedure is common. Teach patients to adhere for 3 weeks to the restrictions listed in [Chart 71-4](#).

## Chart 71-4

# Patient and Family Education: Preparing for Self-Management

## Care After Local Cervical Ablation Therapies

- Refrain from sexual intercourse.
- Do not use tampons.
- Do not douche.
- Take showers rather than tub baths.
- Avoid lifting heavy objects.
- Report any heavy vaginal bleeding, foul-smelling drainage, or fever.

The usual time period for these restrictions is 3 weeks. Your primary health care provider may prescribe a different (longer or shorter) time frame for you.

*Laser therapy* is also an office procedure used for early cancers. A laser beam is directed to the abnormal tissues, where energy from the beam is absorbed by the fluid in the tissues, causing them to vaporize. A small amount of bleeding occurs with the procedure, and the woman may have a slight vaginal discharge. Healing occurs in 6 to 12 weeks. A disadvantage of this procedure is that no specimen is available for study.

*Cryotherapy* involves freezing of the cancer, causing subsequent necrosis. The procedure is usually painless, although some women have slight cramping after it. The patient has a heavy watery discharge for several weeks after the procedure. Instruct her to follow the restrictions in [Chart 71-4](#).

In cases of microinvasive cancer, a *conization* can remove the affected tissue while still preserving fertility. This procedure is done when the lesion cannot be visualized by colposcopic examination. A cone-shaped area of cervix is removed surgically and sent to the laboratory to determine the extent of the cancer. Potential complications from this procedure include hemorrhage and uterine perforation. Long-term follow-up care is needed because new cancers can develop.

A *total hysterectomy* may be performed as treatment of microinvasive cancer if the woman does not want children or more children. A laparoscopic approach is commonly used. A radical hysterectomy and bilateral pelvic lymph node dissection may be as effective as radiation is for treating cancer that has extended beyond the cervix but not to the pelvic wall. Care for patients undergoing hysterectomy is found in the Uterine Leiomyoma section earlier in this chapter.

### Nonsurgical Management.

*Radiation therapy* is reserved for invasive cervical cancer. Brachytherapy and external beam radiation therapy are used in combination, depending on the extent and location of the lesion. The procedure is similar to that described in the section on endometrial cancer.

A combination of chemotherapy with cisplatin (Platinol) and radiation may also be used. This treatment modality shows increased survival times but increased toxicity for many patients. Examples of other drugs used alone or in combination include paclitaxel (Taxol), carboplatin, fluorouracil (5-FU), and mitomycin. See [Chapter 22](#) for more information about the general nursing care for the patient on chemotherapy and radiation.

# Vulvovaginitis

## ❖ Pathophysiology

Vaginal discharge and itching are two common problems experienced by most women at some time in their lives. Vaginal infections may be transmitted sexually and nonsexually. Gonorrhea, syphilis, chlamydia, and herpes simplex virus infections are sexually transmitted infections (STIs) discussed in [Chapter 74](#).

**Vulvovaginitis** is inflammation of the lower genital tract resulting from a disturbance of the balance of hormones and flora in the vagina and vulva. It may be characterized by itching, change in vaginal discharge, odor, or lesions. The most common causes of *nonsexually* transmitted infections include:

- Fungus (yeast) (*Candida albicans*)
- Bacterial vaginosis
- Postmenopausal vaginal atrophy
- Changes in the normal flora or pH (from douching)
- Chemical irritant or allergens (vaginal spray, fabric dyes, detergent) or foreign body (tampon)
- Drugs, especially antibiotics
- Immunosuppression from diabetes or human immune deficiency virus (HIV)
- Atrophic vaginitis
- Lichen planus (thickened, leathery skin and possible lesions)
- Vulvar leukoplakia (postmenopausal atrophy and thickening of vulvar tissues)
- Vulvar cancer
- Urinary incontinence

Pediculosis pubis (crab lice, or “crabs”) and scabies (itch mite) are common parasitic infestations of the skin of the vulva that can be *sexually* transmitted.

Some women may have an *itch-scratch-itch cycle*, in which the itching leads to scratching, which causes excoriation that then must heal. As healing takes place, itching occurs again. If the cycle is not interrupted, the chronic scratching may lead to the white, thickened skin of lichen planus. This dry, leathery skin cracks easily, increasing the risk for infection.

## ❖ Interprofessional Collaborative Care

Assess for vulvovaginitis by asking questions about the symptoms, assisting with a pelvic examination, and obtaining vaginal smears for laboratory testing. Ask if the patient is experiencing an itching or burning sensation, **erythema** (redness), edema, and/or superficial skin ulcers. Use a nonjudgmental approach and provide reassurance during the assessment because the patient may be embarrassed or afraid to discuss her symptoms. Encourage her to talk about her problem and its effect on her sexual health.

Interventions for vulvovaginitis depend on the specific vaginal infection. Proper health habits can benefit treatment. Instruct the patient to get enough rest and sleep, observe good dietary habits, exercise regularly, and use good personal hygiene. Teach her about how to manage her infection and prevent further infections ([Chart 71-5](#)).

### Chart 71-5

## Patient and Family Education: Preparing for Self-Management

### Prevention of Vulvovaginitis

- Wear cotton underwear.

- Avoid wearing tight clothing, such as pantyhose or tight jeans, because it can cause chafing. You can also get hot and sweaty, which can increase the risk for infection.
- Always wipe front to back after having a bowel movement or urinating.
- During bath or shower, cleanse inner labial mucosa with water, not soap.
- Do not douche or use feminine hygiene sprays.
- If your sexual partner has an infection of the sex organs, do not have intercourse with him or her until he or she has been treated.
- You are more likely to get an infection if you are pregnant, have diabetes, take oral contraceptive drugs, or are menopausal.
- Practice vulvar self-examination monthly.

Wet compresses, warm or tepid sitz baths for 30 minutes several times a day, and topical drugs such as estrogens and lidocaine can help relieve itching. Encourage the patient to wear breathable fabrics such as cotton and to avoid irritants or allergens in products such as laundry detergents or bath products.

Treatment of pediculosis and scabies is used if needed and includes:

- Applying lindane (Kwell, Kwellada) lotion, shampoo, or cream to the affected area as directed
- Cleaning affected clothes, bedding, and towels
- Disinfecting the home environment (Lice cannot live for more than 24 hours away from the body.)

## Toxic Shock Syndrome

Toxic shock syndrome (TSS) can result from menstruation and tampon use. Other conditions associated with TSS include gynecologic surgical wound infection, nonsurgical infections, and use of internal contraceptives. TSS can be fatal. Extensive public education has led to a dramatically decreased number of women developing the infection.

In infection related to menstruation, menstrual blood provides a growth medium for *Staphylococcus aureus* (or, less frequently, group A *Streptococcus* [GAS], also known as *Streptococcus pyogenes*). Exotoxins produced from the bacteria cross the vaginal mucosa to the bloodstream via microabrasions from tampon insertion or prolonged use.

TSS usually develops within 5 days after the onset of menstruation. Most common symptoms include fever, rash, myalgias, sore throat, edema, and hypotension (Low, 2013). The rash associated with TSS often looks like a sunburn, and patients often develop broken capillaries in the eyes and skin. Educate all women on prevention of TSS (Chart 71-6).

### Chart 71-6

## Patient and Family Education: Preparing for Self-Management

### Prevention of Toxic Shock Syndrome

- Wash your hands before inserting a tampon.
- Do not use a tampon if it is dirty.
- Insert the tampon carefully to avoid injuring the delicate tissue in your vagina.
- Change your tampon every 3 to 6 hours.
- Do not use superabsorbent tampons.
- Use perineal pads (“sanitary napkins”) (instead of tampons) at night.
- Call your primary health care provider if you suddenly experience a high temperature, vomiting, or diarrhea.
- Do not use tampons at all if you have had toxic shock syndrome.
- Not using tampons almost guarantees that you will not get toxic shock syndrome.

Treatment includes removal of the infection source, such as a tampon; restoring fluid and electrolyte balance; administering drugs to manage hypotension; and IV antibiotics. Other measures may include transfusions to reverse low platelet counts and corticosteroids to treat skin changes.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Collaborate with the case manager when planning care for patients with gynecologic cancers. **QSEN: Teamwork and Collaboration**

### Health Promotion and Maintenance

- Teach women to follow the American Cancer Society's screening guidelines to prevent and early-detect for gynecologic cancers. **QSEN: Evidence-Based Practice**
- Teach women to practice safe sex to prevent infection of the reproductive tract.
- Teach women about risk factors for gynecologic cancers as described in [Tables 71-2](#) and [71-3](#).
- Teach women how to prevent toxic shock syndrome (TSS) as listed in [Chart 71-6](#). **QSEN: Safety**
- Refer patients with gynecologic problems to appropriate community resources such as the American Cancer Society.

### Psychosocial Integrity

- Explain all tests, procedures, and treatments, especially if they cause impaired COMFORT during or after the procedures.
- Assess the patient's anxiety before any gynecologic surgery and encourage her to discuss her feelings about self-esteem, SEXUALITY, and REPRODUCTION. **QSEN: Patient-Centered Care**
- Encourage women who are having procedures that may interfere with fertility and/or SEXUALITY to express feelings of fear or grief. **QSEN: Patient-Centered Care**
- Encourage women with chronic or serious health problems to consider using support groups or counseling.

### Physiological Integrity

- Plan postoperative care for women having a laparoscopic or traditional open total abdominal hysterectomy (TAH) as outlined in [Chart 71-1](#).
- Provide health teaching for the woman who had an open TAH or vaginal hysterectomy about self-care after discharge (see [Chart 71-2](#)). **Clinical Judgment**
- Teach patients about specific restrictions after local cervical ablation therapy (see [Chart 71-4](#)).
- When caring for a patient who has a radioactive implant, use best practices as described in [Chart 71-3](#). **QSEN: Safety**
- Teach the patient who is going home after a hysterectomy how to monitor for infection and other complications. **QSEN: Safety**
- Instruct patients receiving external beam radiation to the abdomen to gently wash the area; to not apply creams or lotions (unless prescribed by the radiologist); to not wash off marking; to avoid exposing the area to sunlight or temperature extremes; and to wear soft, nonirritating clothing.
- Assess for symptoms associated with toxic shock syndrome.

## CHAPTER 72

# Care of Patients With Male Reproductive Problems

Donna D. Ignatavicius

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- ELIMINATION
- CELLULAR REGULATION

✚ The ELIMINATION concept exemplar for this chapter is Benign Prostatic Hyperplasia, p. 1474.

✚ The CELLULAR REGULATION concept exemplar for this chapter is Prostate Cancer, p. 1481.

**The interrelated concepts for this chapter are:**

- SEXUALITY
- REPRODUCTION

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with health care team members to provide care for patients with male reproductive health problems.

### Health Promotion and Maintenance

2. Teach men and their partners about community resources for reproductive cancers.
3. Develop a health teaching plan for men to prevent or detect early male reproductive cancers.

### Psychosocial Integrity

4. Explain the psychosocial needs of men who have male reproductive problems, including issues associated with SEXUALITY and REPRODUCTION.

### Physiological Integrity

5. Identify the assessment findings of benign prostatic hyperplasia (BPH) as they affect urinary ELIMINATION.
  6. Describe the nursing implications for safe pharmacologic management of BPH.
  7. Develop an evidence-based postoperative plan of care for a patient undergoing surgery for benign prostatic hyperplasia.
  8. Evaluate risk factors for impaired CELLULAR REGULATION that manifest as male reproductive cancers.
  9. Identify complementary and integrative therapies to incorporate into the patient's plan of care.
0. Discuss treatment options for prostate cancer with patients, partners, and/or families.
    1. Differentiate preoperative teaching for patients having an open or laparoscopic radical prostatectomy.
    2. Identify adverse effects of radiation therapy for male reproductive cancers.
    3. Describe common options for treating erectile dysfunction.
    4. Identify cultural considerations related to male reproductive problems.
    5. Develop a plan of care for a patient with testicular cancer, including fertility issues.

Male reproductive problems can range from short-term infections to long-term health care problems that require end-of-life care, such as cancers. Any health issue that affects the male reproductive system can affect the human need for SEXUALITY, ELIMINATION, and REPRODUCTION. For example, some patients have surgeries that damage essential nerves that are needed to have an erection. Others have disorders that psychologically prevent the patient from engaging in his usual sexual activity. [Chapter 2](#) provides a review of the nursing concepts applied in this chapter.

The role of the nurse and other health care team members is to be open, supportive, and nonjudgmental when caring for men with reproductive problems. Respect the man's privacy at all times.

## Elimination Concept Exemplar Benign Prostatic Hyperplasia

### Pathophysiology

With aging and increased dihydrotestosterone (DHT) levels, the glandular units in the prostate undergo nodular tissue **hyperplasia** (an increase in the number of cells). This altered tissue promotes local inflammation by attracting cytokines and other substances (McCance et al., 2014).

As the prostate gland enlarges, it extends upward into the bladder and inward, causing bladder outlet obstruction (BOO) (Fig. 72-1). In response, urinary ELIMINATION is affected in several ways, causing **lower urinary tract symptoms (LUTS)**. First, the detrusor (bladder) muscle thickens to help urine push past the enlarged prostate gland (McCance et al., 2014). In spite of the bladder muscle change, the patient has increased residual urine (stasis) and chronic urinary retention. The increased volume of residual urine often causes **overflow urinary incontinence**, in which the urine “leaks” around the enlarged prostate, causing dribbling. Urinary stasis can also result in urinary tract infections and bladder calculi (stones).

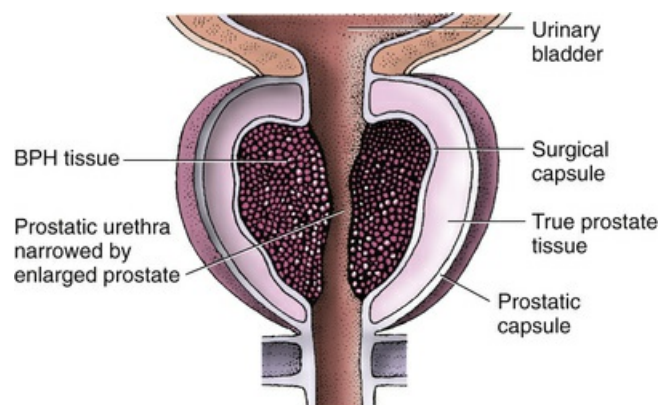

FIG. 72-1 Benign prostatic hyperplasia (BPH) grows inward, causing narrowing of the urethra.

In a few patients, the prostate becomes very large, and the man cannot void (acute urinary retention [AUR]). The patient with this problem requires *emergent* care. In other patients, chronic urinary retention may result in a backup of urine and cause a gradual dilation of the ureters (**hydroneurter**) and kidneys (**hydronephrosis**) if BPH is not treated. These urinary ELIMINATION problems can lead to chronic kidney disease as described in Chapter 68.

### Etiology and Genetic Risk

Benign prostatic hyperplasia (BPH) is a very common health problem, but the exact cause is unclear. It is likely the result of a combination of aging and the influence of androgens that are present in prostate tissue, such as dihydrotestosterone (DHT) (McCance et al., 2014). A genetic or familial predisposition may contribute to the development of BPH in men younger than 60 years of age. Other risk factors for BPH development include (Patel & Parsons, 2014):

- Obesity
- Diabetes mellitus
- Testosterone and other androgen supplements
- Decreased physical activity

### Incidence and Prevalence

Benign prostatic hypertrophy affects 8% of men under 40 years of age, 50% of those under 60 years of age, and 80% of men over 80 years of age. In 2020, 20 million men are expected to be over 60 years of age in the United States (Patel & Parsons, 2014).

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

#### History.

When taking a history, several standardized assessment tools are used to help the health care provider determine the severity of lower urinary tract symptoms (LUTS) associated with prostatic enlargement. One of the most commonly used assessments is the International Prostate Symptom Score (I-PSS), which incorporates the American Urological Association Symptom Index (AUA-SI) (Fig. 72-2) as questions 1 through 7. The additional question included on the I-PSS is the effect of the patient's urinary symptoms on quality of life. Most patients complete the questions as a self-administered tool because it is available in many languages. If the patient is illiterate (does not read) or does not feel like reading the questions, the nurse or health care provider can ask them. Be sure that older men wear their glasses or contact lenses if needed.

## International Prostate Symptom Score (I-PSS)

Patient Name: \_\_\_\_\_ Date of Birth: \_\_\_\_\_ Date Completed: \_\_\_\_\_

In the past month:	Not at All	Less Than 1 in 5 Times	Less Than Half the Time	About Half the Time	More Than Half the Time	Almost Always	Your Score
<b>1. Incomplete Emptying</b> How often have you had the sensation of not emptying your bladder?	0	1	2	3	4	5	
<b>2. Frequency</b> How often have you had to urinate less than every 2 hours?	0	1	2	3	4	5	
<b>3. Intermittency</b> How often have you found you stopped and started again several times when you urinated?	0	1	2	3	4	5	
<b>4. Urgency</b> How often have you found it difficult to postpone urination?	0	1	2	3	4	5	
<b>5. Weak Stream</b> How often have you had a weak urinary stream?	0	1	2	3	4	5	
<b>6. Straining</b> How often have you had to strain to start urination?	0	1	2	3	4	5	
	<b>None</b>	<b>1 Time</b>	<b>2 Times</b>	<b>3 Times</b>	<b>4 Times</b>	<b>5 Times</b>	
<b>7. Nocturia</b> How many times do you typically get up at night to urinate?	0	1	2	3	4	5	
<b>Total I-PSS Score</b>							

**Score:**                                      1-7: Mild                                      8-19: Moderate                                      20-35: Severe

Quality of Life Due to Urinary Symptoms	Delighted	Pleased	Mostly Satisfied	Mixed	Mostly Dissatisfied	Unhappy	Terrible
If you were to spend the rest of your life with your urinary condition just the way it is now, how would you feel about that?	0	1	2	3	4	5	6

### About the I-PSS

The International Prostate Symptom Score (I-PSS) is based on the answers to seven questions concerning urinary symptoms and one question concerning quality of life. Each question concerning urinary symptoms allows the patient to choose one out of six answers indicating increasing severity of the particular symptom. The answers are assigned points from 0 to 5. The total score can therefore range from 0 to 35 (asymptomatic to very symptomatic).

The questions refer to the following urinary symptoms:

Questions	Symptom
1	Incomplete emptying
2	Frequency
3	Intermittency
4	Urgency
5	Weak Stream
6	Straining
7	Nocturia

Question 8 refers to the patient's perceived quality of life.

The first seven questions of the I-PSS are identical to the questions appearing on the American Urological Association (AUA) Symptom Index, which currently categorizes symptoms as follows:

- Mild (symptom score less than or equal to 7)
- Moderate (symptom score range 8 to 19)
- Severe (symptom score range 20 to 35)

The International Scientific Committee (SCI), under the patronage of the World Health Organization (WHO) and the International Union Against Cancer (UICC), recommends the use of only a single question to assess the quality of life. The answers to this question range from "delighted" to "terrible," or 0 to 6. Although this single question may or may not capture the global impact of benign prostatic hyperplasia (BPH) symptoms or quality of life, it may serve as a valuable starting point for a doctor-patient conversation.

The SCI has agreed to use the symptom index for BPH, which has been developed by the AUA Measurement Committee, as the official worldwide symptoms assessment tool for patients suffering from prostatism.

The SCI recommends that physicians consider the following components for a basic diagnostic workup: history; physical examination; appropriate labs such as U/A, creatinine, etc.; and DRE or other evaluation to rule out prostate cancer.

**FIG. 72-2** The International Prostate Symptom Score (I-PSS). (Adapted from the American Urological Association Practice Guidelines Committee. [2003]. Guideline on the management of benign prostatic hyperplasia (BPH). *Journal of Urology*, 170[2 Pt 1], 530-547.)

### Physical Assessment/Signs and Symptoms.

Ask about the patient's current urinary ELIMINATION pattern. Assess for urinary frequency and urgency. Determine the number of times the patient awakens during the night to void (**nocturia**). Other symptoms of LUTS include:

- Difficulty in starting (hesitancy) and continuing urination
- Reduced force and size of the urinary stream ("weak" stream)
- Sensation of incomplete bladder emptying
- Straining to begin urination
- Post-void (after voiding) dribbling or leaking

If frequency and nocturia do not occur with restricted urinary flow, the patient may develop an infection or other bladder problem. Ask whether the patient has had **hematuria** (blood in the urine)

when starting the urine stream or at the end of voiding. BPH is a common cause of hematuria in older men due to infection.

The health care provider examines the patient for physical changes of the prostate gland. Remind him to void before the physical examination. Inspect and palpate the abdomen for a distended bladder. The primary health care provider may percuss the bladder. If the patient has a sense of urgency when gentle pressure is applied, the bladder may be distended. Obese patients are best assessed by percussion or bedside ultrasound bladder scanner rather than by inspection or palpation.

Prepare the patient for the prostate gland examination. Tell him that he may feel the urge to urinate as the prostate is palpated. Because the prostate is close to the rectal wall, it is easily examined by digital rectal examination (DRE). If needed, help the patient bend over the examination table or assume a side-lying fetal position, whichever is the easiest position for him. The primary health care provider examines the prostate for size and consistency. BPH presents as a uniform, elastic, nontender enlargement; whereas cancer of the prostate gland feels like a stony-hard nodule. Advise the patient that, after the prostate gland is palpated, it may be massaged to obtain a fluid sample for examination to rule out **prostatitis** (inflammation and possible infection of the prostate), a common problem that can occur with BPH. If the patient has bacterial prostatitis, he is treated with broad-spectrum antibiotic therapy to prevent the spread of infection (McCance et al., 2014).

### Psychosocial Assessment.

Patients who have nocturia and other LUTS may be irritable or depressed as a result of interrupted sleep and annoying visits to the bathroom. Assess the effect of sleep interruptions on the patient's mood and mental status. Ask him about the impact of symptoms on SEXUALITY and libido (sexual desire).

Post-void dribbling and overflow incontinence may cause embarrassment and prevent the patient from socializing or leaving his home. For some patients, this social isolation can affect quality of life and lead to clinical depression and/or severe anxiety.

### Laboratory Assessment.

A *urinalysis* and urine *culture* are typically obtained to diagnose urinary tract infection and microscopic hematuria. If infection is present, the urinalysis measures the number of white blood cells (WBCs).

Other laboratory studies that may be performed include:

- A *complete blood count* (CBC) to evaluate any evidence of systemic infection (elevated WBCs) or anemia (decreased red blood cells [RBCs]) from hematuria
- *Blood urea nitrogen* (BUN) and serum creatinine levels to evaluate renal function (both are usually elevated with kidney disease)
- A *prostate-specific antigen* (PSA) and a serum acid phosphatase level if prostate cancer is suspected (both are typically elevated in patients who have prostate cancer)
- *Culture and sensitivity* of prostatic fluid (if expressed during the examination)

### Other Diagnostic Assessment.

Imaging studies that are typically performed are *transabdominal ultrasound* and/or *transrectal ultrasound (TRUS)* and an *MRI*. The patient having a TRUS lies on his side while the transducer is inserted into the rectum for viewing the prostate and surrounding structures. A tissue biopsy may also be done if the primary health care provider is uncertain whether the prostatic problem is benign or malignant.

In some cases, the physician uses a cystoscope to view the interior of the bladder, the bladder neck, and the urethra. This examination is used to study the presence and effect of bladder neck obstruction and is usually done in an ambulatory care setting. See [Chapter 65](#) for a detailed description of *cystoscopy* and the nursing care needed for patients having this procedure.

Residual urine may be determined by *bladder ultrasound* immediately after the patient voids. As an alternative, because the patient voids before cystoscopy, residual urine may be measured when the cystoscope is inserted. *Urodynamic pressure-flow studies* may help diagnose and grade bladder outlet obstruction and detrusor muscle function.

## ◆ Analysis: Interpreting

The priority collaborative problems for the patient with benign prostatic hyperplasia (BPH) are:

1. Urinary retention due to bladder outlet obstruction
2. Decreased self-esteem due to overflow incontinence and possible sexual dysfunction with or without surgery

## ◆ Planning and Implementation: Responding

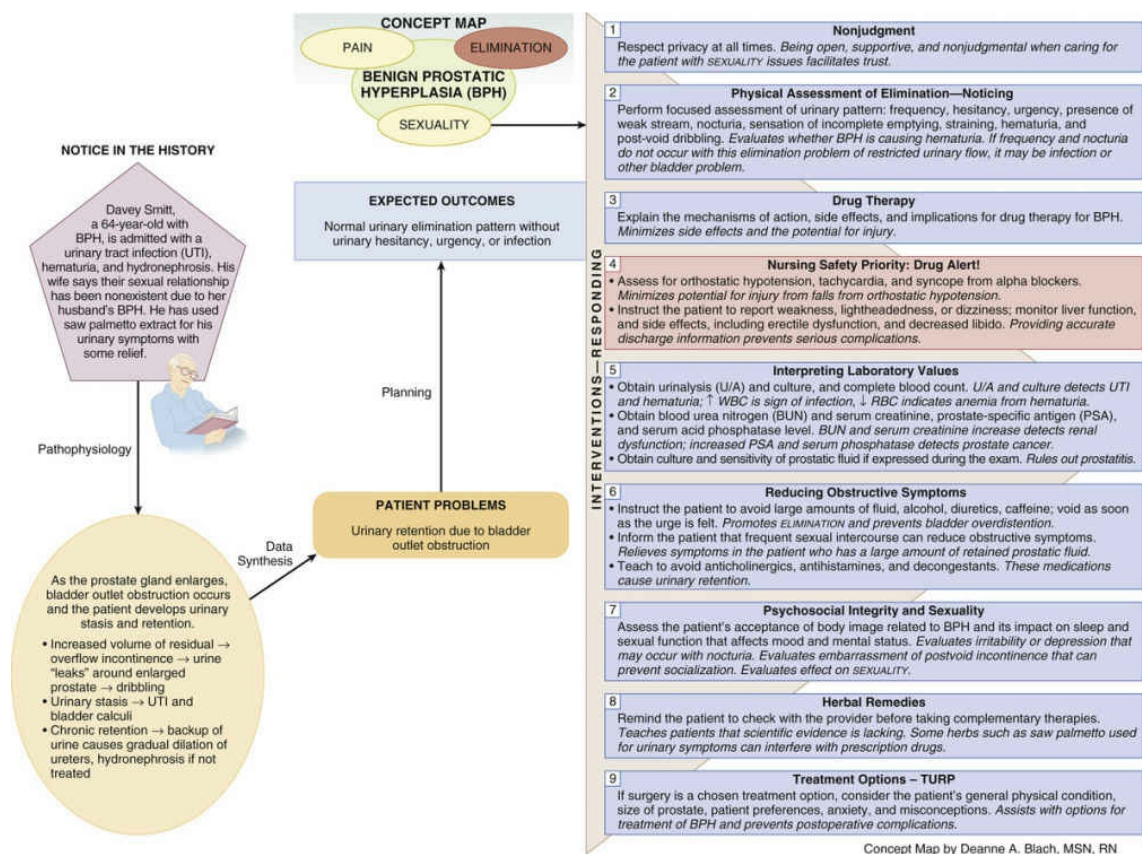

### Improving Urinary Elimination

#### Planning: Expected Outcomes.

The patient with BPH is expected to have a normal urinary ELIMINATION pattern without lower urinary tract symptoms (LUTS) or infection.

#### Interventions.

Patients with symptomatic BPH are first treated with nonsurgical interventions, such as drug therapy. The [Concept Map](#) shows nursing assessment and collaborative interventions for the patient with BPH.

## Nonsurgical Management.

Drug therapy is a popular option for treating BPH. For patients with acute urinary retention (AUR) or those who do not respond to or cannot tolerate drug therapy, a noninvasive procedure or surgery is the treatment of choice for reducing bladder outlet obstruction.

## Drug Therapy.

Drugs from two major categories may be used alone, but most commonly they are given in combination. The health care provider usually prescribes a *5-alpha reductase inhibitor (5-ARI)* as *first-line drug therapy*. Examples of these drugs are finasteride (Proscar) and dutasteride (Avodart) (Burchum & Rosenthal, 2016). Normally, testosterone is converted to DHT in the prostate gland by the enzyme *5-alpha reductase*. By taking an enzyme-inhibiting agent, the patient's DHT levels decrease, which results in reducing the enlarged prostate.

## Nursing Safety Priority QSEN

### Drug Alert

Remind patients who are being treated with a 5-ARI for BPH that they may need to take it for as long as 6 months before improvement is noticed. Teach them about possible side effects, which include erectile dysfunction (ED), decreased libido, and dizziness due to orthostatic hypotension. *Remind them to change positions carefully and slowly!*

The alpha-adrenergic receptors in prostatic smooth muscle enable the prostate gland to respond to *alpha-1 selective blocking agents*, such as tamsulosin (Flomax), alfuzosin (Uroxatral), doxazosin (Cardura, Cardura-1), and silodosin (Rapaflo). Tamsulosin is also available as an over-the-counter (OTC) drug (Burchum & Rosenthal, 2016). These drugs relax smooth muscles in the prostate gland, creating less urinary resistance and improved urinary flow. They also cause peripheral vasodilation and reduced peripheral vascular resistance.

## Nursing Safety Priority QSEN

### Drug Alert

*If giving alpha blockers in an inpatient setting, assess for orthostatic (postural) hypotension, tachycardia, and syncope ("blackout"), especially after the first dose is given to older men. If the patient is taking the drug at home, teach him to be careful when changing position and to report any weakness, light-headedness, or dizziness to the health care provider immediately. Bedtime dosing may decrease the risk for problems related to hypotension. Teach patients taking a 5-ARI or an alpha-blocking drug to keep all appointments for follow-up laboratory testing because both drug classes can cause liver dysfunction.*

The most effective drug therapy approach for many patients is a combination of a 5-ARI drug and an alpha-1 selective blocking agent. A commonly prescribed drug regimen is finasteride and doxazosin. Newer drugs, such as Jalyn, provide a combination of dutasteride and tamsulosin in a once-a-day capsule.

Other drugs may be helpful in managing specific urinary symptoms. For example, low-dose oral desmopressin, a synthetic antidiuretic analog, has been used successfully for nocturia (Burchum & Rosenthal, 2016). Tadalafil (Cialis), a drug usually given to treat erectile dysfunction, has also been approved for some men with BPH because it can improve lower urinary tract symptoms.

### Complementary and Integrative Health.

For many men with BPH, the U.S. Food and Drug Administration (FDA)-approved *Serenoa repens* (saw palmetto extract) helps manage the urinary symptoms associated with BPH and finasteride (Heidari et al., 2014). Results of studies to prove that this herb is effective are mixed. For patients who choose to take saw palmetto products (e.g., Permixon 160 mg twice a day), remind them to check with their health care provider before taking them because of potential interactions with prescribed drugs such as anticoagulants and NSAIDs. Side effects of saw palmetto are rare and mild (Burchum & Rosenthal, 2016).

### Other Nonsurgical Interventions.

Other interventions that may reduce obstructive symptoms include those that cause the release of prostatic fluid such as frequent sexual intercourse. This approach is helpful for the man whose obstructive symptoms result from an enlarged prostate with a large amount of retained prostatic

fluid.

Teach patients with BPH to avoid drinking large amounts of fluid in a short time; to avoid alcohol, diuretics, and caffeine; and to void as soon as they feel the urge. These measures are aimed at preventing overdistention of the bladder, which may result in loss of detrusor muscle tone. Teach patients to avoid any drugs that can cause urinary retention, especially anticholinergics, antihistamines, and decongestants. *Emphasize the importance of telling any health care provider about the diagnosis of BPH so these drugs are not prescribed.*

If drug therapy or other measures are not helpful in relieving urinary symptoms, several noninvasive techniques are available to shrink or destroy excess prostate tissue. For example, a new procedure called **prostate artery embolization** is performed by an interventional radiologist (IR) and is beginning to gain widespread acceptance in the United States. In this procedure, the IR threads a small vascular catheter into the prostate's arteries and injects particles blocking some of the blood flow to shrink the prostate gland. The patient is placed under moderate sedation rather than general anesthesia, which allows a typical discharge from the hospital in as few as 3 hours after the procedure. Most men report marked improvement in LUTS within the first month or so after the procedure.

Other procedures that destroy excess prostate tissue may be done in a primary health care provider's office or another ambulatory care setting. Examples include:

- *Transurethral needle ablation (TUNA)* (low radiofrequency energy shrinks the prostate)
- *Transurethral microwave therapy (TUMT)* (high temperatures heat and destroy excess tissue)
- *Interstitial laser coagulation (ILC)*, also called *contact laser prostatectomy (CLP)* (laser energy coagulates excess tissue)
- *Electrovaporization of the prostate (EVAP)* (high-frequency electrical current cuts and vaporizes excess tissue)

*Prostatic stents* may be placed into the urethra to maintain permanent patency after a procedure for destroying or removing prostatic tissue. All of these highly technical nonsurgical treatments use local or regional anesthesia and do not require an indwelling urinary catheter. They are also associated with less risk for complications such as intraoperative bleeding and erectile dysfunction when compared with traditional surgical approaches. Patients can return to their usual activities in a day or two.

### **Surgical Management.**

For patients who are not candidates for nonsurgical management or do not want to take drugs or have other treatment options, surgery may be performed. The gold standard surgery has been a **transurethral resection of the prostate (TURP)**, in which the enlarged part of the prostate is removed through an endoscopic instrument. However, the holmium laser enucleation of the prostate (HoLEP) procedure, laparoscopic prostatic adenomectomy, and robotic-assisted simple prostatectomy (RASP) are safer minimally invasive surgeries (MISs) that may be performed for BPH. For a few men, an open prostatectomy (entire prostate removal) may be performed. (See discussion of **Surgical Management** in the **Prostate Cancer** section.) Some or all of these criteria indicate the need for surgery:

- Acute urinary retention (AUR)
- Chronic urinary tract infections secondary to residual urine in the bladder
- Hematuria
- Hydronephrosis

### **Preoperative Care.**

When planning surgical interventions, the patient's general physical condition, the size of the prostate gland, and the man's preferences are considered. The patient may have many fears and misconceptions about prostate surgery, such as believing that automatic loss of sexual functioning or permanent incontinence will occur. Assess the patient's anxiety, correct any misconceptions about the surgery, and provide accurate information to him and his family. Regardless of the type of surgery to be performed, reinforce information about anesthesia (see **Chapter 15**). Remind patients taking anticoagulants that the drugs will be discontinued before a TURP or open prostate surgery to prevent postoperative bleeding. Other general preoperative care is described in **Chapter 14**.

The patient may have other medical problems that increase the risk for complications of general anesthesia and may be advised to have regional anesthesia. Epidural and spinal anesthesia are the most common types of anesthesia used for a TURP. Because the patient is awake, it is easier to assess for hyponatremia (low serum sodium), fluid overload, and water intoxication, which can result from large-volume bladder irrigations.

After a TURP, all patients have an indwelling urethral catheter. *Be sure that they know that they will feel the urge to void while the catheter is in place.* Tell the patient that he will likely have traction on the catheter that may cause discomfort. However, reassure him that analgesics will be prescribed to relieve his pain. Explain that it is normal for the urine to be blood tinged after surgery. Small blood clots and tissue debris may pass while the catheter is in place and immediately after it is removed. Some patients also have continuous bladder irrigation (CBI), depending on the procedure performed.

### **Operative Procedures.**

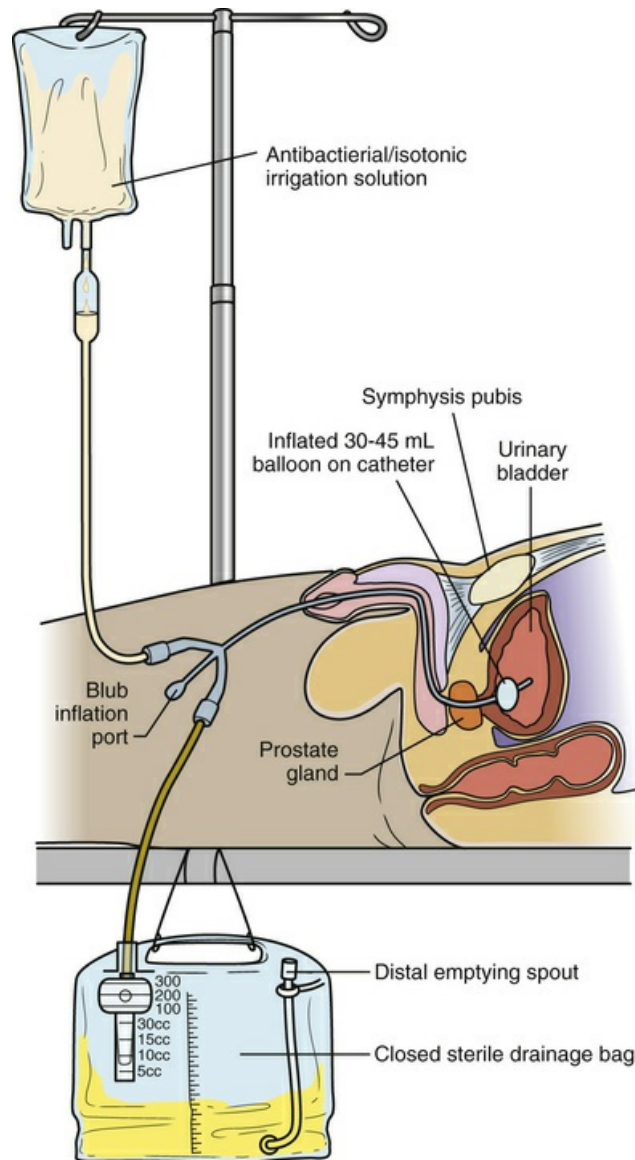

The traditional TURP is a “closed” surgery. To perform the procedure, the surgeon inserts a resectoscope (an instrument similar to a cystoscope, but with a cutting and cauterizing loop) through the urethra. The enlarged portion of the prostate gland is then removed in small pieces (prostate chips). A similar procedure is the transurethral incision of the prostate (TUIP) in which small cuts are made into the prostate to relieve pressure on the urethra. This alternate technique is used for smaller prostates. To prevent bleeding and excess clotting, a fibrinolytic inhibitor such as tranexamic acid (Cyklokapron) may be used during surgery.

The disadvantage of a TURP is that, because only small pieces of the gland are removed, remaining prostate tissue may continue to grow and cause urinary obstruction, requiring additional TURPs. Urethral trauma from the resectoscope with resulting urethral strictures is also possible.

In many large medical centers around the world, specialists can perform newer minimally invasive procedures, often using robotic-assisted techniques or laparoscopic procedures. Very little blood is lost during these procedures, and patient recovery is faster than that for the more traditional TURP.

### **Postoperative Care.**

During any surgical procedure for BPH, a urinary catheter is placed into the bladder. Traction is often applied on the catheter by pulling it taut and taping it to the patient's abdomen or thigh. If the catheter is taped to the patient's thigh, instruct him to keep his leg straight. The patient who had a TURP may have a catheter and continuous bladder irrigation (CBI) in place for several days. For the CBI, a three-way urinary catheter is used to allow drainage of urine and inflow of a bladder irrigating solution (Fig. 72-3). Be sure to maintain the flow of the irrigant to keep the urine clear. When measuring the fluid in the urinary drainage bag, be sure to subtract the amount of irrigating solution that was used to determine actual urinary output.

**FIG. 72-3** Continuous bladder irrigation system after a TURP. *TURP*, Transurethral resection of the prostate.

Patients having an MIS procedure do *not* typically have a CBI and are discharged within 24 hours after surgery. Most patients are discharged with the catheter in place.

## NCLEX Examination Challenge 72-1

### Physiological Integrity

A client has continuous bladder irrigation after surgery yesterday. The amount of bladder irrigating solution that has infused over the past 12 hours is 1050 mL. The amount of fluid in the urinary drainage bag is 1825 mL. The nurse records that the client had \_\_\_\_ mL urinary output in the past 12 hours. **Fill in the blank.**

## Considerations for Older Adults

### Patient-Centered Care QSEN

When caring for older men who may become confused after surgery, reorient them frequently and remind them not to pull on the catheter. If the patient is restless or “picks” at tubes, provide a

familiar object such as a family picture for him to hold for distraction and a feeling of security. Do not restrain the patient unless all other alternatives have failed.

Remind the patient that, because of the urinary catheter's large diameter and the pressure of the retention balloon on the internal sphincter of the bladder, he will feel the urge to void continuously. This is a normal sensation, not a surgical complication. Advise him not to try to void around the catheter, which causes the bladder muscles to contract and may result in painful spasms. [Chart 72-1](#) summarizes the nursing care for patients having a TURP.

### **Chart 72-1**

## **Best Practice for Patient Safety & Quality Care**

### **Care of the Patient After Transurethral Resection of the Prostate**

- Monitor the patient closely for signs of infection. Older men undergoing prostate surgery often also have underlying chronic diseases (e.g., cardiovascular disease, chronic lung disease, diabetes).
- Help the patient out of the bed to the chair as soon as permitted to prevent complications of immobility. Older men may need assistance because of underlying changes in the musculoskeletal system (e.g., decreased range of motion, stiffness in joints). These patients are at *high risk* for falls.
- Assess the patient's pain every 2 to 4 hours and intervene as needed to control pain.
- Provide a safe environment for the patient. Anticipate a temporary change in mental status for the older patient in the immediate postoperative period as a result of anesthetics and unfamiliar surroundings. Reorient the patient frequently. Keep catheter tubes secure.
- Maintain the rate of the continuous bladder irrigation to ensure clear urine without clots and bleeding.
- Use normal saline solution for the intermittent bladder irrigant unless otherwise prescribed. Normal saline solution is isotonic.
- Monitor the color, consistency, and amount of urine output.
- Check the drainage tubing frequently for external obstructions (e.g., kinks) and internal obstructions (e.g., blood clots, decreased output).
- Assess the patient for reports of severe bladder spasms with decreased urinary output, which may indicate obstruction.
- If the urinary catheter is obstructed, irrigate it per agency or surgeon protocol.
- Notify the surgeon immediately if the obstruction does not resolve by hand irrigation or if the urinary return looks like ketchup.

## **Nursing Safety Priority**

### **Critical Rescue**

After a TURP, monitor the patient's urine output every 2 to 4 hours and vital signs, including pain assessment, every 4 hours for the first postoperative day or according to agency or surgeon protocol. Assess for postoperative bleeding. *Patients who undergo a TURP are at risk for severe bleeding or hemorrhage after surgery. Although rare, bleeding is most likely within the first 24 hours.* Bladder spasms or movement may trigger fresh bleeding from previously controlled vessels. This bleeding

may be arterial or venous, but venous bleeding is more common.

## Nursing Safety Priority QSEN

### Critical Rescue

If arterial bleeding occurs, the urinary drainage is bright red or ketchup-like with numerous clots. Notify the surgeon immediately and irrigate the catheter with normal saline solution per surgeon or hospital protocol. In rare instances the surgeon may prescribe aminocaproic acid (Amicar) to control bleeding. If this drug does not work, surgical intervention may be needed to clear the bladder of clots and stop bleeding.

If the bleeding is *venous*, the urine output is burgundy, with or without any change in vital signs. Inform the surgeon of any bleeding. Closely monitor the patient's hemoglobin (Hgb) and hematocrit (Hct) levels for anemia as a result of blood loss.

Observe for other possible but uncommon complications of TURP, such as infection and incontinence. Teach the patient that sexual function should not be affected after surgery but that retrograde ejaculation is possible. In this case, most of the semen flows backward into the bladder so only a small amount will be ejaculated from the penis.

## NCLEX Examination Challenge 72-2

### Physiological Integrity

A client had a transurethral resection of the prostate (TURP) with continuous bladder irrigation yesterday. The staff nurse notes that the urinary drainage is pink tinged and clear. What is the nurse's **best** action?

- A. Notify the charge nurse as soon as possible.
- B. Increase the rate of the bladder irrigation.
- C. Document the assessment in the medical record.
- D. Prepare the patient for a blood transfusion.

### Improving Self-Esteem

#### Planning: Expected Outcomes.

The expected outcome is that the patient will experience improved self-esteem by managing incontinence through BPH treatment.

#### Interventions.

The patient with BPH typically has frequent urges to void and may have overflow incontinence at times because of urinary retention. Teach him to keep the surrounding area clean and dry to prevent skin breakdown. Remind him to toilet when he feels the urge and, if needed, to wear a small absorbent pad to prevent undergarment soiling. Involve the patient's sexual partner, if any, in teaching about the cause of the incontinence and any prescribed treatment. Once the patient is treated either with drug therapy or surgery, the incontinence subsides.

### Care Coordination and Transition Management

The patient with benign prostatic hyperplasia (BPH) is typically managed at home. Patients who have nonsurgical interventions or surgery are also discharged to their home or other setting from where they were admitted.

### Home Care Preparation.

Patients having surgery typically are discharged with a urinary catheter in place for about a week or longer. Teach patients not to take a bath or swim to prevent a urinary tract infection while the catheter is in place. When the urinary catheter is removed, the patient may experience burning on urination and some urinary frequency, dribbling, and leakage. Reassure him that these symptoms are normal and will decrease. Instruct him to increase fluid intake to at least 2000 to 2500 mL daily, which helps decrease dysuria and keep the urine clear. *Be aware that an older patient who has renal disease or who is at risk for heart failure may not be able to tolerate this much fluid.*

### Self-Management Education.

Some patients, especially those who have had a TURP, may have temporary loss of control of urination or a dribbling of the urine. Reassure the patient that these symptoms are almost always temporary and will resolve. Also remind him that REPRODUCTION ability should not be affected by surgery.

Help the patient and his family find ways to keep his clothing dry until sphincter control returns. Instruct him to contract and relax his sphincter frequently to re-establish urinary ELIMINATION control (Kegel exercises). External urinary (condom) catheters are not used except in extreme cases because they may give the patient a false sense of security and delay urinary control.

### Health Care Resources.

Patients being managed for BPH usually do not require extensive follow-up care or health care resources. Men who are of advanced age may need one or two visits from a home health care agency to ensure that they are not experiencing complications and can provide self-care.

Teach patients to have follow-up care as recommended by the surgeon. After prostatic surgery, some men experience a return of LUTS and/or erectile dysfunction, which can decrease their quality of life (Yim et al., 2015) (see the Evidence-Based Practice box).

## Evidence-Based Practice OSEN

### What Is the Quality of Life for Patients Who Have Surgery for BPH?

Yim, P.W., Wang, W., Jiang, Y., Zakir, H.A., Toh, P.C., Lopez, V., et al. (2015). Health-related quality of life, physical well-being, and sexual function in patients with benign prostatic hyperplasia after prostatic surgery. *Applied Nursing Research*, 28(4), 274-280.

This research was a cross-sectional descriptive, correlational study using 94 volunteers from one hospital to examine quality of life for men who had previously had surgery for benign prostatic hyperplasia (BPH). The researchers asked these participants to complete five different tools to measure the study variables, including the International Index of Erectile Function and the Short-Form Health Survey. The findings revealed that many men who have surgery for BPH have poor physical health and continue to experience episodes of lower urinary tract symptoms (LUTS) and erectile dysfunction (ED).

#### Level of Evidence: 4

This study used a nonexperimental, correlational research design.

#### Commentary: Implications for Practice and Research

Although the research design prevents generalizability, the implications for practice demonstrate the need for health teaching to ensure that patients who had surgery for BPH receive continued health care follow-up. Problems such as LUTS and ED can cause stress, depression, and a decreased quality of life. This study needs to be replicated using a larger sample across multiple settings and male demographic variables.

#### ◆ Evaluation: Reflecting

Evaluate the care of the patient with BPH based on the identified priority patient problem. The primary expected outcome is that the patient will:

- Have improved urinary ELIMINATION as a result of appropriate and effective collaborative management

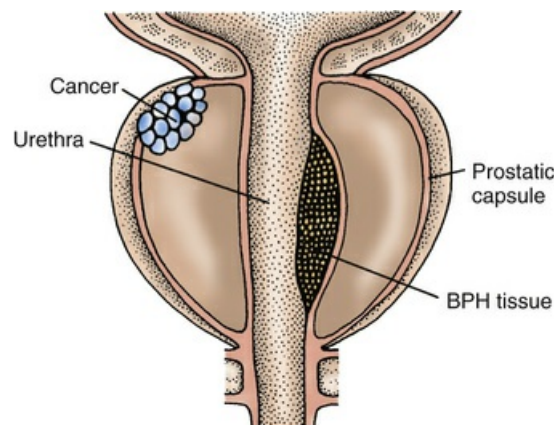

- Experience improved self-esteem as a result of effective BPH management

## Cellular Regulation Concept Exemplar Prostate Cancer

### Pathophysiology

Testosterone and dihydrotestosterone (DHT) are the major androgens (male hormones) in the adult male. Testosterone is produced by the testis and circulates in the blood. DHT is a testosterone derivative in the prostate gland. In some patients, the prostate grows very rapidly, leading to noncancerous high-grade prostatic intraepithelial neoplasia (PIN). This impairment of CELLULAR REGULATION causes men to be at a higher risk for developing prostate cancer than men who do not have that growth pattern.

Many prostate tumors are androgen sensitive (McCance et al., 2014). Most are adenocarcinomas and arise from epithelial cells located in the posterior lobe or outer portion of the gland (Fig. 72-4).

**FIG. 72-4** Prostate gland with cancer and benign prostatic hyperplasia (BPH). Note that cancer normally arises in the periphery of the gland, whereas BPH occurs in the center of the gland.

Of all malignancies, prostate cancer is one of the slowest growing, and it metastasizes (spreads) in a predictable pattern. Common sites of metastasis are the nearby lymph nodes, bones, lungs, and liver (McCance et al., 2014). The bones of the pelvis, sacrum, and lumbar spine are most often affected. Chapter 21 describes staging categories of localized and advanced cancers.

### Etiology

Prostate cancer is caused by a number of factors. Advanced age is the leading risk factor. The risk increases for men who have a first-degree relative (brother, father) with the disease.

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Race is the second most common risk factor for prostate cancer because the disease affects African Americans more often than other ethnic/racial groups, followed by Caucasians (Euro-Americans) and Hispanic-American men (McCance et al., 2014). The reasons for these differences are not known but may be related to socioeconomic factors, health care disparities, and lack of education (ACS, 2017).

Other risk factors that may play a role are eating a diet high in animal fat (e.g., red meat) and refined carbohydrates or having a low fiber intake. Men who have had a vasectomy or those who were exposed to environmental toxins, such as arsenic, may also be at increased risk for the disease (McCance et al., 2014).

## Genetic/Genomic Considerations

### Patient-Centered Care QSEN

Many gene mutations play a role in various types of prostate cancer. Some men with the most aggressive prostate cancers have *BRCA2* mutations similar to those women who have *BRCA2*-associated breast and ovarian cancers. The most common genetic factor that increases the risk for prostate cancer is a mutation in the glutathione *S*-transferase (*GST P1*) gene. This gene is normally part of the pathway that helps prevent cancer (McCance et al., 2014).

### Incidence and Prevalence

Prostate cancer is the second most common type of cancer in men in the world and, if found early, has a nearly 100% cure rate. Men older than 65 years have the greatest risk for the disease. In the United States, one in every six African-American men and one in every eight Euro-American men have the disease (ACS, 2017).

### Health Promotion and Maintenance

Teach men about the most recent American Cancer Society (ACS) guidelines for prostate cancer screening and early detection (ACS, 2017). The current recommendations are that men should make an informed decision about whether to have prostate cancer screening. Although not agreed on by all authoritative sources, starting at the age of 50 years, men should discuss the options of having prostate-specific antigen testing with their primary health care provider. Men at a higher risk for prostate cancer, including African Americans or men who have a first-degree relative with prostate cancer before the age of 65 years, should have this discussion at age 45 years. Men who have multiple first-degree relatives with prostate cancer at an early age should discuss screening at age 40 years (ACS, 2017).

Although a family history of prostate cancer cannot be changed, certain nutritional habits can be altered to possibly decrease the risk for the disease. First, teach men to eat a healthy, balanced diet, including decreasing animal fat (e.g., red meat). Instead of red meat, remind them to eat more fish and other foods high in *omega-3 fatty acids* because they are thought to be helpful in preventing cancer. Also reinforce the need to increase fruits, vegetables, and high-fiber foods.

### Interprofessional Collaborative Care

#### Assessment: Noticing

#### History.

Assess the patient's age, race/ethnicity, and family history of prostate cancer. Ask about his nutritional habits, especially focusing on the intake of red meat, fish, and fruits and vegetables. Assess whether the patient has any problems with urinary ELIMINATION. Take a drug history to determine if he is taking any medication that could affect voiding. The first symptoms that the man may report are related to bladder outlet obstruction, such as difficulty in starting urination, frequent bladder infections, and urinary retention. Ask about urinary frequency, **hematuria** (blood in the urine), and **nocturia** (voiding during the night). Ask if he has had any pain during intercourse, especially when ejaculating. Inquire if he has had or currently has any other pain (particularly bone pain), a symptom associated with advanced prostate cancer. Ask him if he has had any recent unexpected weight loss.

Take a sexual history for recent changes in SEXUALITY, including libido or function. Ask about current or previous sexually transmitted infections, penile discharge, or scrotal pain or swelling.

#### Physical Assessment/Signs and Symptoms.

Most *early* cancers are diagnosed while the patient is having a routine physical examination or is being treated for benign prostatic hyperplasia (BPH). Gross blood in the urine (hematuria) is a common sign of *late* prostate cancer. Assess for pain in the pelvis, spine, hips, or ribs. Pain and swollen nodes indicate advanced disease that has spread. Take and record the patient's weight

because unexpected weight loss is also common when the disease is advanced.

Prepare the patient for a digital rectal examination (DRE). On rectal examination, a prostate that is found to be stony hard and with palpable irregularities or indurations is suspected to be malignant.

### Psychosocial Assessment.

A diagnosis of any type of cancer causes fear and anxiety for most people. Some men, particularly African Americans, develop the disease in their 40s and 50s when they are perhaps planning their retirements, putting their children through college, and/or enjoying their middle years. Assess the reaction of the patient to the diagnosis and observe how his family reacts to the illness. Men may describe their feelings as shock, fear, anger, and “roller coaster.” Expect that patients usually go through the grieving process and may be in denial or depressed. Determine what support systems they have, such as spiritual leaders or community group support, to help them through diagnosis, treatment, and recovery.

One of the biggest concerns for the man may be his ability for sexual function after cancer treatment. Tell him that function will depend on the type of treatment he has. Common surgical techniques used today do not involve cutting the perineal nerves that are needed for an erection. A dry climax may occur if the prostate is removed because it produces most of the fluid in the ejaculate. Refer the patient to his surgeon (urologist), sex therapist, or intimacy counselor if available.

### Laboratory Assessment.

**Prostate-specific antigen (PSA)** is a glycoprotein produced by the prostate. *PSA analysis is used as a screening test for prostate cancer.* If the test is performed, it should be drawn before the DRE because the examination can cause an increase in PSA caused by prostate irritation.

Most authoritative sources agree that the normal blood level of PSA in men younger than 50 years is less than 2.5 ng/mL. PSA levels increase to as high as 6.5 ng/mL when men reach their 70s. *African-American men have a slighter higher normal value, but the reason for this difference is not known. Because other prostate problems also increase the PSA level, it is not specifically diagnostic for cancer.* However, the level associated with prostate cancer is usually much higher than those occurring with problems such as prostatitis and benign prostatic hyperplasia (Pagana et al., 2017).

An elevated PSA level should decrease a few days after a prostatectomy for cancer. An increase in the PSA level several weeks after surgery may indicate that the disease has recurred.

Because PSA is not absolutely specific to prostate cancer, another test, *early prostate cancer antigen (EPCA-2)*, may be a serum marker for prostate cancer. It can detect changes in the prostate gland early and is a very sensitive test. EPCA-2 may also eliminate the need to perform a biopsy of prostate tissue (Pagana et al., 2017).

### Other Diagnostic Assessment.

After assessments by DRE and PSA, most patients have a *transrectal ultrasound (TRUS)* of the prostate in an ambulatory care or imaging setting. The technician inserts a small probe into the rectum and obtains a view of the prostate using sound waves. If prostate cancer is suspected, a *biopsy* is usually performed in the physician's office to obtain an accurate diagnosis. Before the procedure, the physician uses lidocaine jelly on the ultrasound probe and/or injects lidocaine into the prostate gland to promote patient comfort.

## Nursing Safety Priority QSEN

### Action Alert

After a transrectal ultrasound with biopsy, instruct the patient about possible complications, although rare, including hematuria with clots, signs of infection, and perineal pain. Teach him to report fever, chills, bloody urine, and any difficulty voiding. Advise him to avoid strenuous physical activity and to drink plenty of fluids, especially in the first 24 hours after the procedure. Teach him that a small amount of bleeding turning the urine pink is expected during this time. However, bright red bleeding should be reported to the health care provider immediately.

After prostate cancer is diagnosed, the patient has additional imaging and blood studies to determine the extent of the disease. Common tests include lymph node biopsy, CT of the pelvis and abdomen, and MRI to assess the status of the pelvic and para-aortic lymph nodes. A radionuclide bone scan may be performed to detect metastatic bone disease. An enlarged liver or abnormal liver function study results indicate possible liver metastasis.

Patients with advanced prostate cancer often have *elevated* levels of *serum acid phosphatase*. Most men with bone metastasis have *elevated serum alkaline phosphatase* levels and severe pain.

### ◆**Analysis: Interpreting**

The priority collaborative problem for the patient with prostate cancer is *Potential for metastasis due to invasion of cancer cells in other parts of the body*.

### ◆**Planning and Implementation: Responding**

#### **Preventing Metastasis**

##### **Planning: Expected Outcomes.**

The expected outcome is that the patient will not experience metastasis as a result of prompt and effective collaborative management of prostate cancer.

##### **Interventions.**

As with any cancer, accurate staging and grading of prostate tumors guide treatment planning and monitoring during the course of the disease. Patients are faced with several treatment options. A urologist and an oncologist usually collaborate to help patients make the best decision.

##### **Active Surveillance.**

Because prostate cancer is slow growing with late metastasis, older men who are asymptomatic and have other illnesses may choose observation without immediate active treatment, especially if the cancer is early stage. This option is known as **active surveillance (AS)**. This form of treatment involves initial surveillance with active treatment only if the symptoms become bothersome. The average time from diagnosis to start of treatment is up to 10 years. During the AS period, men are monitored at regular intervals through DRE and PSA testing. Factors that are considered in choosing AS include potential side effects of treatment (e.g., urinary incontinence, erectile dysfunction), estimated life expectancy, and the risk for increased morbidity and mortality from not seeking active treatment.

Patients who have very early-stage cancer of the prostate who choose AS require close follow-up by their health care provider. If obstruction occurs, a transurethral resection of the prostate (TURP) may be done. The care of patients having this procedure is described in the discussion of Surgical Management in the Benign Prostatic Hyperplasia section.

Specific management is based on the extent of the disease and the patient's physical condition. The patient may undergo surgery for a biopsy, staging and removal of the tumor, or palliation to control the spread of disease or relieve distressing symptoms. As with AS, the health care provider and patient must weigh the benefits of treatment against potential adverse effects such as incontinence and erectile dysfunction (ED).

##### **Surgical Management.**

*Surgery is the most common intervention for a cure.* Minimally invasive surgery (MIS) or, less commonly, an open surgical technique for radical prostatectomy (prostate removal) is usually performed. A **bilateral orchiectomy** (removal of both testicles) is another palliative surgery that slows the spread of cancer by removing the main source of testosterone.

##### **Preoperative Care.**

Preoperative care depends on the type of surgery that will be done. Minimally invasive surgery (MIS) is most appropriate for localized prostate cancer and is used as a curative intervention. The most common procedure is the *laparoscopic radical prostatectomy (LRP)*, most often with robotic assistance. Other newer procedures include transrectal high-intensity focused ultrasound (HIFU) and cryosurgery. Patients who qualify for LRP must have a PSA less than 10 ng/mL and have had

no previous hormone therapy or abdominal surgeries. Remind the patient that the advantages of this procedure over open surgery include:

- Decreased hospital stay (1 to 2 days)
- Minimal bleeding
- Smaller or no incisions and less scarring
- Less postoperative discomfort
- Decreased time for urinary catheter placement
- Fewer complications
- Faster recovery and return to usual activities
- Nerve-sparing advantages

For the patient undergoing an *open* radical prostatectomy, provide preoperative care as for any patient having surgery (see [Chapter 14](#)).

### Operative Procedures.

For the *LRP procedure*, the patient is placed in lithotomy positioning with steep Trendelenburg. The urologist makes one or more small punctures or incisions into the abdomen. A laparoscope with a camera on the end is inserted through one of the incisions while other instruments are inserted into the other incisions. The robotic system may be used to control the movement of the instruments by a remote device. The prostate is removed along with nearby lymph nodes, but perineal nerves are not affected.

The *open* radical prostatectomy can be performed via several surgical approaches, depending on the patient's desired outcomes and the staging of the disease. The transperineal and retropubic (nerve-sparing) approaches are most commonly used. The surgeon removes the entire prostate gland along with the prostatic capsule, the cuff at the bladder neck, the seminal vesicles, and the regional lymph nodes. The remaining urethra is connected to the bladder neck. The removal of tissue at the bladder neck allows the seminal fluid to travel upward into the bladder rather than down the urethral tract, resulting in retrograde ejaculations.

### Postoperative Care.

Provide postoperative care of the patient after *open* radical prostatectomy as summarized in [Chart 72-2](#). Nursing interventions include all the typical care for a patient undergoing major surgery. Maintaining hydration, caring for wound drains (open procedure), managing pain, and preventing pulmonary complications are important aspects of nursing care. (See general postoperative care in [Chapter 16](#).)

## Chart 72-2

### Best Practice for Patient Safety & Quality Care QSEN

#### Care of the Patient After an Open Radical Prostatectomy

- Encourage the patient to use patient-controlled analgesia (PCA) as needed.
- Help the patient get out of bed into a chair on the night of surgery and ambulate by the next day.
- Maintain the sequential compression device until the patient begins to ambulate.
- Monitor the patient for deep vein thrombosis and pulmonary embolus.
- Keep an accurate record of intake and output, including Jackson-Pratt or other drainage device drainage.
- Keep the urinary meatus clean using soap and water.
- Avoid rectal procedures or treatments.

- Teach the patient how to care for the urinary catheter because he may be discharged with the catheter in place.
- Teach the patient how to use a leg bag.
- Emphasize the importance of not straining during bowel movement. Advise the patient to avoid suppositories or enemas.
- Remind the patient about the importance of follow-up appointments with the surgeon and oncologist to monitor progress.

Assess the patient's pain level and monitor the effectiveness of pain management with opioids given as patient-controlled analgesia (PCA), a common method of delivery during the first 24 hours after surgery. Administer a stool softener if needed to prevent possible constipation from the drugs. Patients having the minimally invasive surgery have much less pain and fewer complications.

The patient has an indwelling urinary catheter to straight drainage to promote urinary ELIMINATION. Monitor intake and output every shift and record or delegate this activity to an supervise unlicensed assistive personnel (UAP). An antispasmodic may be prescribed to decrease bladder spasm induced by the indwelling urinary catheter. The time for catheter removal depends on the type of procedure that is performed and overall patient condition. Those with open surgical procedures use the catheter for 7 to 10 days or longer.

Ambulation should begin no later than the day after surgery. Provide assistance in walking the patient when he first gets out of bed. Assess for scrotal or penile swelling from the disrupted pelvic lymph flow. If this occurs, elevate the scrotum and penis and apply ice to the area intermittently for the first 24 to 48 hours.

Many patients who have the minimally invasive techniques are discharged 1 to 3 days after surgery and can resume usual activities in about a week or two. Those who have open procedures are discharged in 2 to 3 days or longer, depending on their progress.

Remind patients that common potential long-term complications of open radical prostatectomy are erectile dysfunction (ED) and urinary incontinence. For ED, drugs such as sildenafil (Viagra) may be effective. *Urge incontinence* may occur because the internal and external sphincters of the bladder lie close to the prostate gland and are often damaged during the surgery. Kegel perineal exercises may reduce the severity of urinary incontinence after radical prostatectomy. Teach the patient to contract and relax the perineal and gluteal muscles in several ways. For one of the exercises, teach him to:

1. Tighten the perineal muscles for 3 to 5 seconds as if to prevent voiding and then relax
2. Bear down as if having a bowel movement
3. Relax and repeat the exercise

Show him how to inhale through pursed lips while tightening the perineal muscles and how to exhale when he relaxes. To regain urinary control, teach the patient to practice holding an object, such as a pencil, in the fold between the buttock and the thigh. He may also sit on the toilet with the knees apart while voiding and start and stop the stream several times.

### **Nonsurgical Management.**

Nonsurgical management may be an adjunct to surgery or alternative intervention if the cancer is widespread or the patient's condition or age prevents surgery. Available modalities include radiation therapy, hormone therapy, and chemotherapy (less often).

### **Radiation Therapy.**

External or internal radiation therapy may be used in the treatment of prostate cancer or as "salvage" treatments when cancer recurs. It may also be done for palliation of the patient's symptoms.

*External beam radiation therapy (EBRT or XRT)* comes from a source outside the body. Patients are usually treated 5 days a week for 4 to 6 weeks. Three-dimensional conformal radiation therapy (3D-

CRT) can more accurately target prostate tissue and reduce side effects such as damage to the rectum. An advanced type of this radiation called *intensity-modulated radiation therapy* provides very high doses to the prostate. EBRT can also be used to relieve pain from bone metastasis or be given following radical prostatectomy. Teach patients that external beam radiation causes ED in many men well after the treatment is completed.

Teach patients that other complications from EBRT include urinary frequency, diarrhea, and *acute radiation cystitis*, which causes persistent pain and hematuria. Symptoms are usually mild to moderate and subside 6 weeks after treatment. Drugs to prevent urinary urgency such as tolterodine (Detrol LA) may be prescribed. Teach the patient to avoid caffeine and continue drinking plenty of water and other fluids.

**Radiation proctitis** (rectal mucosa inflammation) may also develop but is less likely with 3D-CRT. The man reports rectal urgency and cramping and passes mucus and blood. Teach him to report these symptoms to the primary health care provider. Like cystitis, this problem usually resolves 4 to 6 weeks after the treatment stops. If proctitis occurs, teach patients to limit spicy or fatty foods, caffeine, and dairy products.

*Low-dose brachytherapy* (internal radiation) can be delivered by implanting low-dose radiation seeds, needles, or wires directly into and around the prostate gland. This treatment includes ultrasonically guided interstitial or radioactive implantation. These procedures are done on an ambulatory care basis and are the most cost-effective treatment for early-stage prostate cancer. Reassure the patient that the dose of radiation is low and that the radiation will not pose a hazard to him or others. Teach him that ED, urinary incontinence, and rectal problems do occur in a small percentage of cases. Fatigue is also common and may last for several months after the treatment stops. [Chapter 22](#) describes general nursing care for patients having radiation therapy.

### Drug Therapy.

Drug therapy may consist of either hormone therapy (androgen deprivation therapy [ADT]) or chemotherapy. Because most prostate tumors are hormone dependent, patients with extensive tumors or those with metastatic disease may be managed by androgen deprivation. *Luteinizing hormone–releasing hormone (LH-RH) agonists* or anti-androgens can be used.

Examples of *LH-RH agonists* are leuprolide (Lupron), goserelin (Zoladex), and triptorelin (Trelstar). These drugs first stimulate the pituitary gland to release the luteinizing hormone (LH). After about 3 weeks, the pituitary gland “runs out” of LH, which reduces testosterone production by the testes ([Burchum & Rosenthal, 2016](#)).

## Nursing Safety Priority QSEN

### Drug Alert

Teach patients taking LH-RH agonists that side effects include “hot flashes,” erectile dysfunction, and decreased **libido** (desire to have sex). Some men also have **gynecomastia** (breast tenderness and growth). These drugs can also cause osteoporosis. Bisphosphonates such as pamidronate (Aredia) are prescribed to prevent bone fractures. They can also be used to slow the damage caused by bone metastasis.

*Anti-androgen drugs*, also known as *androgen deprivation therapy (ADT)*, work differently in that they block the body's ability to use the available androgens ([Burchum & Rosenthal, 2016](#)). These drugs are the major treatment for metastatic disease. Examples include flutamide (Eulexin, Euflex), bicalutamide (Casodex), and nilutamide (Nilandron). They inhibit tumor progression by blocking the uptake of testicular and adrenal androgens at the prostate tumor site.

Anti-androgens may be used alone or in combination with LH-RH agonists for total or maximal androgen blockade (hormone ablation). Patients who have this drug combination often have “hot flashes” similar to those experienced by menopausal women, and they can decrease the patient's perceived quality of life. Ask the patient if he has been experiencing this problem. Megestrol acetate may be prescribed for this uncomfortable condition.

Systemic *chemotherapy* may be an option for patients whose cancer has spread and for whom other therapies have not worked. For example, small cell prostate cancer is rare and is more responsive to chemotherapy than to hormone therapy. Docetaxel (Taxotere) plus prednisone given

every 3 weeks is the preferred treatment. A combination of cisplatin (Platinol) and etoposide (VP-16, VePesid) may also be effective for this type of cancer (Burchum & Rosenthal, 2016). Chapter 22 describes general nursing care for patients receiving chemotherapy.

### Care Coordination and Transition Management

Interprofessional collaborative care of the man with prostate cancer should include his partner, if any, and family. The diagnosis and treatment of cancer greatly affect couples who survive the disease. Recognize that the patient and partner have specific physical and psychosocial needs that should be addressed before hospital discharge, and management should continue in the community setting.

Patients with prostate cancer may require care in a wide variety of settings: at the hospital, the radiation therapy department, the oncologist's office, or home at any stage of the disease process. Specific interventions depend on which treatment the patient had or if he had a combination of treatments. Regardless of treatment, care coordination to effectively manage transitions in care is essential. This section focuses on the needs of those who had a *radical prostatectomy*.

### Home Care Management.

Discharge planning and health teaching start early, even before surgery. A patient can better plan home care management when he knows what to expect. Collaborate with the case manager to coordinate the efforts of various health care providers, surgical unit nursing staff, and possibly a home care nurse. As specified by The Joint Commission and other accrediting agencies, continuity of care is essential when caring for this patient because he may need weeks or months of therapies.

### Self-Management Education.

An important area of teaching for the patient going home after an *open* radical prostatectomy may be urinary catheter care. An indwelling urinary catheter may be in place for up to several weeks, depending on the surgical technique that was used. Teach him and his family how to care for the catheter, use a leg bag, and identify signs and symptoms of infection and other complications. See Chart 72-3 for patient and family education.

#### Chart 72-3

### Patient and Family Education: Preparing for Self-Management

#### Urinary Catheter Care at Home

- Once a day, gently wash the first few inches of the catheter starting at the penis and washing outward with mild soap and water.
- Rinse and dry the catheter well.
- If you have not been circumcised, push the foreskin back to clean the catheter site; when finished, push the foreskin forward.
- Change the drainage bag at least once a week as needed:
- Hold the catheter with one hand and the tubing with the other hand and twist in opposite directions to disconnect.
- Place the end of the catheter in a clean container to catch leakage of urine.
- Remove the rubber cap from the tubing of the leg bag or clean

drainage bag.

- Clean the end of the new tubing with alcohol swabs.
- Insert the end of the new tubing into the catheter and twist to connect securely.
- Clean the drainage bag just removed by pouring a solution of one part vinegar to two parts water through the tubing and bag. Rinse well with water and allow the bag to dry.

Encourage the patient to walk short distances. Lifting may be restricted to no more than 15 lb (6.8 kg) for up to 6 weeks if an open procedure was done. Remind him to maintain an upright position and not to walk bent or flexed. Vigorous exercise such as running or jumping should be avoided for at least 6 weeks and then gradually introduced. By contrast, patients having the minimally invasive laparoscopic surgery can usually return to work or usual activities in about a week.

Teach the patient not to strain to defecate. A stool softener may be prescribed to reduce the need for straining. If an opioid is prescribed for pain management, encourage the patient to drink adequate water to prevent constipation.

If the patient had an *open* radical prostatectomy, teach him to shower for the first 2 to 3 weeks rather than soak in a bathtub. Patients who had a *laparoscopic* procedure can usually shower in 1 to 2 days. Teach them to remove the small bandage but leave the Steri-Strips in place (they should fall off in about a week). Show patients how to inspect the incision or puncture site(s) daily for signs of infection. Remind them to keep all follow-up appointments. PSA blood tests are taken 6 weeks after surgery and then every 4 to 6 months to monitor progress.

### Health Care Resources.

Refer the patient and partner to agencies or support groups such as the American Cancer Society's *Man-to-Man* program to help cope with prostate cancer. This program provides one-on-one education, personal visits, educational presentations, and the opportunity to engage in open and candid discussions. Another prostate cancer support group is *Us TOO International* ([www.ustoo.com](http://www.ustoo.com)) sponsored by the Prostate Cancer Education and Support Network. This group provides education and support with national and international chapters. Information can also be obtained from the Prostate Cancer Foundation ([www.prostatecancerfoundation.org](http://www.prostatecancerfoundation.org)) or the National Prostate Cancer Coalition ([www.fightprostatecancer.org](http://www.fightprostatecancer.org)). In Canada, the Prostate Cancer Canada organization ([www.prostatecancer.ca](http://www.prostatecancer.ca)) is dedicated to research and support for this disease. Other personal and community support services such as spiritual leaders or churches and synagogues are also important to many patients.

For same-sex couples surviving prostate cancer, *Malecare* (<http://malecare.org>) is an excellent resource. This nonprofit organization provides support groups for gay and bisexual men and their partners. Another resource is *A Gay Man's Guide to Prostate Cancer*.

Some men have erectile dysfunction (ED) for the first 3 to 18 months after a prostatectomy. Refer them to a specialist who can help with this problem. (ED is discussed later in this chapter.) Refer patients with urinary incontinence to a urologist who specializes in this area. Drug therapy and other strategies may be used. [Chapter 66](#) discusses incontinence management in detail.

### ◆Evaluation: Reflecting

Evaluate the care of the patient with prostate cancer based on the identified priority patient problem. The primary expected outcome is that the patient will not experience cancer metastasis as a result of appropriate and effective collaborative management.

# Testicular Cancer

## ❖ Pathophysiology

Testicular cancer is a rare cancer that most often affects men between 20 and 35 years of age but can affect men of any age. It usually strikes men at a productive time of life and thus has significant economic, social, and psychological impact on the patient and his family and/or partner. With early detection by testicular self-examination (TSE) (Chart 72-4) and treatment, testicular cancer has a 95% cure rate (McCance et al., 2014). It can occur in one testicle or both.

### Chart 72-4

## Patient and Family Education: Preparing for Self-Management

### Testicular Self-Examination

- Examine your testicles monthly immediately after a bath or a shower, when your scrotal skin is relaxed.
- Examine each testicle by gently rolling it between your thumbs and fingers. Testicular tumors tend to appear deep in the center of the testicle.
- Look and feel for any lumps; smooth, rounded masses; or any change in the size, shape, or consistency of the testes.
- Report any lump or swelling to your primary health care provider as soon as possible.

Primary testicular cancers fall into two major groups:

- Germ cell tumors arising from the sperm-producing cells (account for most testicular cancers)
- Non-germ cell tumors arising from the stromal, interstitial, or Leydig cells that produce testosterone (account for a very small percentage of testicular cancers)

Testicular germ cell tumors are classified into two broad categories: seminomas and nonseminomas (Table 72-1). The most common type of testicular tumor is *seminoma*. Patients with seminomas have the most favorable prognoses because the tumors are usually localized, metastasize late, and respond to treatment. They often are diagnosed when they are still confined to the testicles and retroperitoneal lymph nodes.

TABLE 72-1

### Classification of Testicular Tumors

GERM CELL (GERMINAL) TUMORS	NON-GERM CELL (NONGERMINAL) TUMORS
<ul style="list-style-type: none"><li>• Seminoma</li><li>• Nonseminoma:<ul style="list-style-type: none"><li>• Embryonal carcinoma</li><li>• Teratoma</li><li>• Choriocarcinoma</li></ul></li></ul>	<ul style="list-style-type: none"><li>• Interstitial cell tumor</li><li>• Androblastoma</li></ul>

Non-germ cell tumors are classified as either *interstitial cell tumors* or *androblastomas* (testicular adenomas). Most of these tumors do not metastasize. Interstitial cell tumors arise from the Leydig cells, which secrete testosterone into the bloodstream. Androblastomas sometimes secrete estrogen, which accounts for the feminization and **gynecomastia** (breast enlargement) occasionally seen in these men.

The risk for testicular tumors is higher in males who have an undescended testis (**cryptorchidism**) or human immune deficiency virus (HIV) infection (McCance et al., 2014).

## Genetic/Genomic Considerations

## Patient-Centered Care QSEN

Men are at a higher risk for testicular cancer if they have a family history of the disease (Viatori, 2012). The incidence is higher among identical twins, brothers, and other close male relatives. Euro-American men are at a higher risk for testicular cancer than men of other races or ethnicities (Viatori, 2012). The reason for these differences is not known.

Primary testicular cancer is rarely bilateral. Other cancers such as leukemia, lymphoma, and metastatic carcinomas may invade the testes. A man with bilateral testicular tumors is more likely to have metastatic disease to the testes than primary cancer.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

#### Physical Assessment/Signs and Symptoms.

When taking a history from a patient with a suspected testicular tumor, consider the risk factors. Assess for other risk factors, including a history or presence of an undescended testis and a family history of testicular cancer.

The most common report is a painless, hard swelling or enlargement of the testicle. Patients with discomfort such as heaviness or aching in the lower abdomen or scrotum may have metastatic disease. Determine how long any signs and symptoms have been present.

Assess the patient's family situation. Is the patient sexually active? If so, what is his sexual preference? Does he have children? Does he want children in the future? Depending on the treatment plan chosen, would he be interested in sperm storage in a sperm bank?

If the man has one healthy testis, he can function sexually and may not have any problem with REPRODUCTION. If he has a retroperitoneal lymph node dissection or chemotherapy, he may become sterile because of treatment effects on the sperm-producing cells or surgical trauma to the sympathetic nervous system resulting in retrograde ejaculations.

The testes, lymph nodes, and abdomen should be examined thoroughly. Patients may feel embarrassed about having this examination. Provide privacy and explain the procedure to the patient. Inspect the testicles for swelling or a lump that the patient reports is painless. An advanced practice nurse or other health care provider palpates the testes for lumps and swelling that are not visible. The presence of any testicular pain, lymph node swelling, bone pain, abdominal masses, sudden hydrocele (fluid in the scrotum), or gynecomastia often indicates metastatic disease.

#### Psychosocial Assessment.

Because testicular cancer and its treatment often lead to sexual dysfunction, pay close attention to the psychosocial aspects of the disease. *SEXUALITY* is an issue for men of any age, but it may be even more of an issue for younger men. Even if the cancer is detected at an early stage and the patient is cured after surgery, he may be afraid that he will be sexually deficient. He may also think of himself as “less than a whole person.” These fears can disrupt the psychosocial and sexual development of young males and can threaten their identity. The patient may be afraid that he will be unable to perform sexually, will no longer be sexually attractive or desirable, and will face rejection. Feelings of sexual inadequacy may be denied, repressed, or displaced, causing increased stress on the man's personal and work relationships.

Assess the man's support systems, including his partner, family members, and friends. Ask him where he feels that he can be supported, such as a religious or spiritual group, community club, or social group. Friends are often very helpful during this difficult time.

#### Laboratory Assessment.

Common serum tumor markers that confirm a diagnosis of testicular cancer are:

- Alpha-fetoprotein (AFP)
- Beta human chorionic gonadotropin (hCG)
- Lactate dehydrogenase (LDH)

Serum testosterone levels are increased when the tumor affects the Leydig cells, which produce

this hormone. Drugs such as alcohol and antiepileptic drugs can also cause an increase in testosterone (Pagana et al., 2017).

### Other Diagnostic Assessment.

When a patient has a change in testis size, shape, or texture, *ultrasonography* can determine whether the mass is solid or fluid filled. It also can help differentiate benign masses from malignant ones.

After the diagnosis of testicular cancer, the patient should have a CT scan of the abdomen and the chest to identify small metastatic lesions. *Lymphangiography* shows a view of the body's lymph system to look for spread to other areas.

MRI is used to detect enlarged lymph nodes and abnormal nodules in certain organs that may indicate metastasis from the testicles. Chest x-rays and bone scans may also be performed if metastasis is suspected.

### ◆Interventions: Responding.

At diagnosis, the incidence of **oligospermia** (low sperm count) and **azoospermia** (absence of living sperm) is common in patients with testicular cancer. This problem is thought to be related to higher testicular temperatures created by cancer cell metabolism. The man may not discover that he has reduced sperm count until he has a sperm count performed before surgery.

Health teaching about REPRODUCTION, fertility, and SEXUALITY is started in the pretreatment phase. Review the normal reproductive function and the possible effects of cancer and its treatment on reproductive function. Explore with the patient various reproductive options if desired (Chart 72-5). A sperm bank facility provides comprehensive information on semen collection, storage of semen, the storage contract, costs, and the insemination process.

#### Chart 72-5

## Patient and Family Education: Preparing for Self-Management

### Sperm Banking

- You may want to investigate sperm storage in a sperm bank as a way to preserve your sperm for future use.
- No one knows how long sperm can be stored successfully, but pregnancies have resulted from sperm stored for longer than 10 years.
- Check with the sperm bank to see how much it charges to process and store your sperm and whether you must pay when the service is provided.
- Investigate whether your health insurance company will reimburse you for sperm collection and storage.

When preparing the patient for the collection and storage of sperm, assume the role of patient advocate and keep in mind the effect of the cancer diagnosis. The psychological benefit of having stored sperm may be important for the man and may influence his response to treatment. For some men, knowing that the potential for being a father still exists may help them cope with other fears, such as alopecia or erectile dysfunction (ED).

*Suggest that the patient arrange for semen storage, if desired, as soon as possible after diagnosis. Sperm collection should be completed before he begins radiation therapy or chemotherapy or undergoes a radical lymph node dissection. After radiation therapy or chemotherapy has been started, the patient is at increased risk for producing mutagenic sperm, which may not be viable or may result in fetal abnormalities.*

The patient's diagnosis and his physical condition may not allow treatment to be postponed, thus making sperm storage impossible. Also, some men may have personal or religious beliefs that do not allow sperm storage. For those who are not candidates for sperm storage in a sperm bank and those who choose not to bank, discuss other options for REPRODUCTION such as donor insemination

or adoption.

### Surgical Management.

Surgery is the main treatment for testicular cancer. For stage 0 or 1 (localized disease), the surgeon performs a unilateral **orchietomy** to remove the affected testicle. Every effort is made to remove the cancerous testis as an intact organ to prevent releasing cancer cells into the surgical site. Depending on the type and stage of the cancer, radical retroperitoneal lymph node dissection (RPLND) may also be done.

### Preoperative Care.

Like most patients with cancer, the man with testicular cancer is very apprehensive. Offer support and reinforce the teaching provided by the surgeon. Teach the patient and his family or partner about what to expect after surgery. For patients with very early disease, minimally invasive surgery (MIS) using a laparoscope is performed rather than using an open incision. For patients having MIS, teach them that carbon dioxide may be used as part of the surgery. Carbon dioxide can cause chest or shoulder pain from diaphragmatic irritation after the procedure.

### Operative Procedures.

Most patients with seminoma have only one surgery to remove the diseased testicle through the groin (inguinal) for a cure. A frozen section of the tumor is examined to confirm the type and stage of the cancer. A gel-filled silicone prosthesis may be surgically implanted into the scrotum at the time of the orchietomy or later if the patient desires. Reassure the patient that this procedure does not impair fertility or sexual function. He cosmetically appears to have two testes (reconstructive surgery).

Some men have more advanced disease or tumor types that are more aggressive. Two options are available for the lymph node dissection: a traditional open approach and minimally invasive surgery (MIS) using a laparoscope. To perform the *open* approach, the surgeon removes the retroperitoneal nodes in the iliac and lumbar regions. Because the blood supply and the lymphatic vessels of the testes and kidneys are directly related, an extensive midline incision from the xiphoid process to the pubis is necessary. Removal of the sympathetic ganglia eliminates peristalsis in the vas deferens and contractions of the seminal vesicles. This disruption results in sterility because the man's ejaculate no longer contains sperm. However, having a normal erection and experiencing orgasm usually are not affected.

The MIS procedure involves using a laparoscope through several small “keyhole” incisions through which the nodes are dissected for examination. This technique shortens the time the patient is in the operating suite, minimizes bleeding, and causes less pain after surgery. The patient has fewer postoperative complications and a shorter hospital stay.

### Postoperative Care.

Nursing care for the patient after surgery depends on the type of surgical procedure that was performed and the extent of the disease process.

## Nursing Safety Priority QSEN

### Action Alert

Because of the length of the *open* orchietomy and lymph node dissection approach, manipulation of the abdominal and retroperitoneal viscera, and the loss of lymphatic fluid, observe, assess, and report any complications of this major abdominal surgery (e.g., paralytic ileus) (see Chapter 16). Monitor vital signs (including pain), hydration, and pulmonary function carefully for the first 24 to 48 hours. Ambulate the patient as soon as possible and teach him how to use the incentive spirometer. Assess the patency of the urinary catheter. Be sure that the patient wears antiembolism stockings or devices and provide care for surgical incisions and wound drains.

The patient having the *laparoscopic* procedure may have a urinary catheter in place for 1 to 2 days. The other advantages of the MIS procedure are that patients have less pain and fewer complications

than those who had the open surgery. [Chapter 15](#) describes laparoscopic surgery in detail.

## NCLEX Examination Challenge 72-3

### Physiological Integrity

A client had an orchiectomy and laparoscopic radical retroperitoneal lymph node dissection this morning. Which assessment finding will the nurse report to the primary health care provider?

- A. The client's pain level is a 10 on a 0-10 pain scale after pain medication.
- B. The client's urinary catheter is draining clear yellow urine.
- C. The client is concerned about his ability to have an erection.
- D. The client's blood pressure is 132/82 in a sitting position.

### Nonsurgical Management.

Combination *chemotherapy* may be used as adjuvant therapy for nonseminomatous testicular tumors or as primary treatment when there is evidence of metastatic disease. Many drug regimens are used, including varying combinations of bleomycin, etoposide, and cisplatin (BEP). The specific combination of drugs and the frequency, cycling, and duration of treatment vary from patient to patient, depending on the extent of the disease and the protocol being followed. [Chapter 22](#) discusses the general nursing care for the patient receiving chemotherapy.

After orchiectomy for localized disease, *external beam radiation therapy* (EBRT) may be used. The remaining testis is shielded with a lead cup to preserve reproductive function. Even with these precautions, the patient may have a temporary decreased sperm count as a result of radiation scatter. Normally the sperm count returns to the pretreatment level within 24 to 30 months after the radiation treatment is completed. If metastases develop outside the lymphatic system, the man may still be cured with radiation therapy if the area of involvement is limited. If lymphatic involvement is extensive or if the visceral organs are involved, combination chemotherapy is used.

### Care Coordination and Transition Management

The patient is usually hospitalized for multiple days after an *open* radical retroperitoneal lymph node dissection but for just 1 to 2 days for the *MIS* laparoscopic procedure.

After an open *orchiectomy*, unless the patient has a wound complication, he is discharged without a dressing on the inguinal incision. A scrotal support may be needed for several days. He may want to wear a dry dressing to prevent clothing from rubbing on the sutures and causing irritation. Tell him that the sutures will be removed in the physician's office 7 to 10 days after surgery. Patients who also had an *open retroperitoneal lymph node dissection* recover more slowly. They should not lift anything over 15 lb (6.8 kg), should avoid stair climbing, and should not drive a car for several weeks. Be sure that bathroom facilities are on the first floor of the house where he can easily access them.

## Nursing Safety Priority QSEN

### Action Alert

For the patient who has undergone testicular surgery, emphasize the importance of scheduling a follow-up visit with the surgeon to examine the incision for healing and complications. Instruct him to notify the surgeon if chills, fever, increasing tenderness or pain around the incision, drainage, or dehiscence of the incision occurs. These signs and symptoms may indicate infection for which antibiotics are needed. Instruct the patient who had a laparoscopic orchiectomy that he will be able to resume most of his usual activities within 1 week after discharge. He can take a shower 1 or 2 days after surgery, but be sure that he does not remove the Steri-Strips. These strips will loosen and fall off about a week after surgery.

Explain the importance of performing monthly testicular self-examination (TSE) on the remaining testis and scheduling follow-up examinations with the physician. The patient who has had testicular cancer should schedule tests for urinary and serum levels of tumor markers and CT or MRI studies as part of his routine follow-up for at least 3 years.

The man who has testicular cancer needs emotional support. If permanent sterility occurs and sperm storage has not been feasible, he may desire counseling about other reproductive options. Refer the patient to agencies or support groups, such as the American Fertility Society ([www.theafa.org](http://www.theafa.org)) or RESOLVE: The National Infertility Association ([www.resolve.org](http://www.resolve.org)) (organizations for infertile couples).

# Erectile Dysfunction

## ❖ Pathophysiology

**Erectile dysfunction (ED)**, also known as *impotence*, is the inability to achieve or maintain an erection for sexual intercourse. It affects millions of men throughout the world. There are two major types of ED: organic and functional.

*Organic ED* is a gradual deterioration of function. The man first notices diminishing firmness and a decrease in frequency of erections. Causes include (McCance et al., 2014):

- Inflammation of the prostate, urethra, or seminal vesicles
- Surgical procedures such as prostatectomy
- Pelvic fractures
- Lumbosacral injuries
- Vascular disease, including hypertension
- Chronic neurologic conditions, such as Parkinson disease or multiple sclerosis
- Endocrine disorders, such as diabetes mellitus (a major cause) or thyroid disorders
- Smoking and alcohol consumption
- Drugs, such as antihypertensives
- Poor overall health that prevents sexual intercourse

If the patient has episodes of ED, it usually has a *functional* (psychological) cause. Men with functional ED usually have normal nocturnal (nighttime) and morning erections. Onset is usually sudden and follows a period of high stress.

## ❖ Interprofessional Collaborative Care

If possible, the health care provider determines the cause of the ED through a variety of diagnostic testing, including measuring serum hormone levels and using Doppler ultrasonography to determine blood flow to the penis. The most common intervention for ED is drug therapy. Other interventions include vacuum devices, intracorporal injections, intraurethral applications, and prostheses (implants).

First-line oral drugs used to manage ED, phosphodiesterase-5 (PDE-5) inhibitors, work by relaxing the smooth muscles in the corpora cavernosa so blood flow to the penis is increased. The veins exiting the corpora are compressed, limiting outward blood flow and resulting in penile **tumescence** (swelling). Teach patients to take the pill 1 hour before sexual intercourse. For some drugs, such as sildenafil (Viagra) and vardenafil (Levitra), sexual stimulation is needed within  $\frac{1}{2}$  to 1 hour to promote the erection. With other drugs, such as tadalafil (Cialis), erection can be stimulated over a longer period (Burchum & Rosenthal, 2016). Because the erection occurs more naturally compared with other treatment options, most men and their partners prefer this option.

## ❑ Nursing Safety Priority QSEN

### Drug Alert

Instruct patients taking PDE-5 inhibitors to abstain from alcohol before sexual intercourse because it may impair the ability to have an erection. Common side effects of these drugs include dyspepsia (heartburn), headaches, facial flushing, and stuffy nose. If more than one pill a day is being taken, leg and back cramps, nausea, and vomiting also may occur. *Teach men who take nitrates to avoid PDE-5 inhibitors because the vasodilation effects can cause a profound hypotension and reduce blood flow to vital organs (Burchum & Rosenthal, 2016).* For patients who cannot take these drugs or do not respond to them, other methods are available to achieve an erection.

The basic design of a *vacuum constriction device (VCD)* is a cylinder that fits over the penis and sits firmly against the body. Using a pump, a vacuum is created to draw blood into the penis to

maintain an erection. A rubber ring (tension band) is placed around the base of the penis to maintain the erection, and the cylinder is removed.

*Injecting the penis* with vasodilating drugs can make the penis erect by engorging it with blood. The most common agents used for this purpose include (Burchum & Rosenthal, 2016):

- Alprostadil (Caverject), a synthetic vasodilator identical to prostaglandin E<sub>1</sub> produced in the body
- Paverine, also a vasodilator
- Phentolamine (Regitine), an alpha-1, alpha-2 selective adrenergic receptor antagonist
- A combination of any or all of these drugs

Adverse drug effects include priapism (prolonged erection), penile scarring, fibrosis, bleeding, bruising at the injection site, pain, infection, and vasovagal responses.

*Penile implants* (protheses) are used when other modalities fail. Devices include semirigid, flexible, or hydraulic inflatable and multi-component or one-piece instruments. The three-piece inflatable device is the most commonly implanted prosthesis. A reservoir is placed in the scrotum. Tubes carry the fluid into the inflatable pieces that are placed in the penis. To inflate the prosthesis, the man squeezes the pump located in the scrotum. To deflate the prosthesis, a release button is activated. Advantages include the man's ability to control his erections. The major disadvantages include device failure and infection. The device is implanted as an ambulatory care surgical procedure. *Teach the patient to observe the surgical site for bleeding and infection.*

## **NCLEX Examination Challenge 72-4**

### **Health Promotion and Maintenance**

The nurse is teaching a client about taking sildenafil (Viagra) for erectile dysfunction. Which statement by the client indicates a need for further teaching?

- A. "I should have sex within an hour after taking the drug."
- B. "I should avoid alcohol when on the drug or it might not work well."
- C. "I can expect to maybe feel flushed or get a headache when I take the drug."
- D. "If I have chest pain during sex, I should take a nitroglycerin tablet."

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Teach patients with prostate cancer about American Cancer Society's *Man-to-Man* program and the American Foundation for Urologic Disease's *Us TOO International* program to help men and their partners cope with prostate cancer; contact the Prostate Cancer Canada organization for more research on prostate cancer in Canada.

### Health Promotion and Maintenance

- Teach men at risk for prostate cancer to follow the current American Cancer Society's screening and early detection guidelines. **QSEN: Evidence-Based Practice**
- Teach men how to perform testicular self-examination as described in [Chart 72-4](#).
- Teach uncircumcised men the importance of keeping the penis clean to prevent penile cancer.

### Psychosocial Integrity

- Because most patients with testicular cancer are young and middle-age adults, assess their reaction to the possible loss of REPRODUCTION ability and SEXUALITY issues.
- Because of the high incidence of erectile dysfunction after radical prostatectomy, assess the patient's adjustment to these changes in body function. **QSEN: Patient-Centered Care**
- Assess the patient's anxiety before prostate surgery and allow him to express feelings of fear or grief. **QSEN: Patient-Centered Care**

### Physiological Integrity

- Perform a focused physical assessment for patients reporting lumps or swelling in their genital area; inspect and palpate bladder and scrotum.
- Observe for and report complications after radical prostatectomy, including infection, severe pain, urinary infection, urinary ELIMINATION problems, and erectile dysfunction. **Clinical Judgment**
- Observe for and report bloody urine with clots after TURP; increase continuous bladder irrigation or irrigate the bladder per agency or surgeon protocol. **QSEN: Safety**
- Teach patients to report signs of infection when caring for a urinary catheter in the home. **Safety**
- Maintain traction on the urinary catheter and continuous bladder irrigation after a TURP. **Safety**
- Teach patients about drug therapies (5-ARIs and alpha blocking agents) used to treat BPH, including side effects such as orthostatic hypotension, erectile dysfunction, decreased libido, dizziness, and liver dysfunction. **QSEN: Safety**
- Teach patients to avoid any drugs that can cause urinary retention, especially anticholinergics, antihistamines, and decongestants if BPH is present. **QSEN: Evidence-Based Practice**
- Remind patients wanting to use complementary and integrative therapies to check with their primary health care providers before using them.
- Eating a well-balanced diet with plenty of fish and fruits and vegetables may help prevent prostate cancer.
- Reinforce the man's option for managing prostate cancer; some procedures and drugs cause erectile dysfunction and incontinence either temporarily or permanently.
- Use the information listed in [Chart 72-3](#) to teach patients urinary catheter care after prostate cancer surgery.

- Teach patients about not lifting more than 15 lb (6.8 kg) after open prostate surgery. **QSEN: Safety**
- Options for erectile dysfunction (ED) include drug therapy (most common), vacuum-assist devices, penile injections, transurethral suppositories, or penile implants.
- Be aware that African-American middle-age men are the most at risk for prostate cancer; Euro-American young men are the most at risk for testicular cancer.
- Teach patients and their partners about hormone therapy used to manage prostate cancer: LH-RH agonists and anti-androgen drugs.

## CHAPTER 73

# Care of Transgender Patients

Donna D. Ignatavicius, Stephanie M. Fox

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- PATIENT-CENTERED CARE
- HEALTH CARE DISPARITIES

**The interrelated concepts for this chapter are:**

- SEXUALITY
- REPRODUCTION

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Describe the need to collaborate with members of the health care team to provide high-quality care for transgender patients.
2. Explain the role of the nurse as a leader in promoting advocacy for transgender people to provide quality care and minimize HEALTH CARE DISPARITIES.

### Health Promotion and Maintenance

3. Develop a health teaching plan for transgender patients who take hormone therapy and/or have gender reassignment surgery.
4. Identify appropriate resources for accurate trans-health information and ongoing preventive health care.

### Psychosocial Integrity

5. Discuss how to use culturally sensitive terminology when providing care for transgender patients.
6. Identify the major sources of stress that contribute to transgender health issues.
7. Explain the major challenges for transgender patients in obtaining health care.

### Physiological Integrity

8. Describe the side effects and adverse effects of feminizing and masculinizing hormone therapy, including effects on SEXUALITY and REPRODUCTION.
9. Identify laboratory test values that require monitoring for patients taking hormone therapy.
0. Describe the preoperative care needed for male-to-female or female-to-male patients having genital surgery.
1. Prioritize PATIENT-CENTERED postoperative nursing CARE for patients having feminizing or masculinizing genital surgery.

The American Nurses Association (ANA) *Code of Ethics* states that the nurse practices with compassion and respect for the dignity and worth of every patient (ANA, 2015). The Institute of Medicine (now the National Academy of Medicine [NAM]) and the Quality and Safety Education for Nurses (QSEN) Institute further identified the need for nurses to be competent in PATIENT-

CENTERED CARE (see [Chapter 1](#) for review of this concept). This competency ensures that nurses provide care with sensitivity and respect for diverse patients, even if those patients have values and preferences different from their own (ANA, 2015). Diversity is often discussed as ethnicity and race, but other cultural aspects such as sexual orientation and gender identity are part of the diverse human experience.

People of minority sexual and gender identities are often grouped under one population category described by the acronym **LGBTQ**—lesbian, gay, bisexual, transgender, and queer/questioning (people who do not feel they belong in any other subgroup) ([Table 73-1](#)) ([Eliason et al., 2013](#)). Some literature includes only “LGBT.” These evolving labels are misleading regarding people who identify as transgender. The grouping of **SEXUALITY** (sexual attraction and behavior) and *gender identity* (sense of maleness or femaleness) suggests that these two concepts are related or dependent on one another, but they are very different. *LGB* refers to specific sexual orientation. However, transgender people may identify as heterosexual, homosexual, both, or neither. Nurses and other health care professionals should not assume that transgender patients have the same experiences or health care needs as those who identify as lesbian, gay, or bisexual.

**TABLE 73-1**  
**Appropriate Terminology Associated With Transgender Health**

TERM	DEFINITION
Coming out	A lesbian, gay, bisexual, transgender, and queer/questioning (LGBTQ) person's public disclosure regarding sexual orientation or gender identity
Female-to-male	An adjective to describe people who were identified as female at birth and are changing (or have changed) to a more masculine body or male
Gender dysphoria	Emotional or psychological distress caused by an incongruence between one's natal (birth) sex and gender identity
Gender identity	A person's inner sense of being a male, a female, or an alternative gender (e.g., genderqueer)
Genderqueer	An identity label used by some people whose gender identity does not conform to one of the two categories of male or female
Male-to-female	An adjective to describe people who were identified as male at birth and are changing (or have changed) to a more feminine body or female
Sex (also called <i>natal sex</i> )	The gender assigned at one's birth
Gender reassignment surgery (also called <i>sex reassignment surgery [SRS], gender-affirming surgery, or gender-confirming surgery</i> )	A group of surgical procedures that change primary and/or secondary sex characteristics to affirm a person's gender identity
Transgender	An adjective to describe a person who crosses or transcends culturally defined categories of gender
Transition	The period of time when transgender people change from the gender role associated with their sex to a different gender role
Transsexual	Term often used by health care professionals to describe people who want to change or have changed their primary and/or secondary sex characteristics

## Patient-Centered Terminology

Commonly, gender is categorized as one of two terms: *male* and *female*. For the majority of people, these descriptors are accurate. However, some people do not clearly fit into either category and may define themselves as *transgender*. Identifying oneself as transgender is not a choice or lifestyle but, rather, an inner sense of being born in the wrong body. When transgender people pursue ways of affirming their physical body and appearance with their gender identity, their interaction with the health care system requires knowledge, respect, compassion, and specialized nursing care.

Using appropriate terminology is essential to demonstrating respect (see [Table 73-1](#)). Of utmost importance is the distinction between gender and sex. Gender, also known as **gender identity**, describes a person's inner sense of maleness or femaleness and is not related to REPRODUCTION anatomy. Gender identity describes one's social role as a man or a woman ([American Psychiatric Association \[APA\], 2013](#)). Sex, also known as *biological* or **natal sex**, refers to a person's genital anatomy present at birth ([Edwards-Leeper & Spack, 2013](#)).

When babies are born, the gender of the child is determined by the genitalia present, but there is no way of knowing the child's true sense of gender. The sense of gender and feelings toward maleness or femaleness can develop in children as early as age 2 years and is usually present in most children during the early elementary years. Transgender people feel a mismatch between their gender identity and natal sex, often extending back into early childhood. When this incongruence occurs, they can experience **gender dysphoria**, or discomfort with one's natal sex ([APA, 2013](#); [Edwards-Leeper & Spack, 2013](#)). Some people who have gender dysphoria may seek interventions to transition to the identified gender.

The term *transgender* is often used as an umbrella description for all people whose gender identity and presentation do not conform to social expectations. In this text, **transgender** describes patients who self-identify as the opposite gender or a gender that does not match their natal sex ([Merryfeather & Bruce, 2014](#)). For proper usage, transgender should be used only in adjective form. For example, a patient "is transgender," "identifies as transgender," or "is a transgender patient." Note that "transgender" never ends in "-ed." The term *transgender* should not be used as a noun, and a patient should never be described as "a transgender."

According to *The Diagnostic and Statistical Manual of Mental Disorders* ([APA, 2013](#)), prevalence of gender dysphoria worldwide ranges from 5 to 14 in 1000 natal males and from 2 to 3 in 1000 natal females. However, these data describe the number of people who experience discontent with the gender they were assigned at birth and do not give an accurate estimate of the number of people who identify as transgender. Other data on the transgender population indicate that there are approximately 1.4 million adults in the United States who identify as transgender ([Flores et al., 2016](#)). Most scholars suggest that the prevalence is much higher, and more research is needed to collect accurate demographic data for this population. Statistical data for the number of adults who identify as transgender in Canada are not available.

Another common term is **transsexual**, which generally describes a person who has modified his or her natal body to match the appropriate gender identity, either through cosmetic, hormonal, or surgical means ([Merryfeather & Bruce, 2014](#)). "Transsexual" can be used as both an adjective and a noun, such that a patient can be described "as transsexual" or "as a transsexual." (*NOTE: As with other terms, use terminology only if the patient identifies as such*). People who were born with anatomically male parts but identify as and/or live as female are known as "male-to-female" or "MtF." Male-to-female people are also known as "transwomen," with the gender descriptor indicating the current-lived gender identity. Conversely, "transmen" are natal females who identify as and/or live as men. They are described as "female-to-male" or "FtM."

Transgender people are sometimes described as "transvestites" or "cross-dressers," often in a judgmental or negative manner. These terms should not be used unless the patient identifies as such. Other terms, such as *tranny*, *he-she*, or *shemale*, are offensive and hurtful. These terms and other negative comments should never be used.

A patient may self-identify with any of the above terms or choose not to be defined at all. Become familiar with appropriate terms and concepts, but do not force definitions on your patients. *Instead, if you are unsure how to address patients, during your nursing assessment ask them how they define their gender identity.*

## Transgender Health Issues

Transgender people (also referred to as *trans-people*) encounter frequent discrimination and are faced with numerous stressful situations related to their identity. Sources of stress such as job discrimination and bias-related harassment can have an impact on patients' physical and psychological health. In the most recent large-scale national survey on discrimination, the majority of transgender people had experienced mistreatment in the workplace. Also, almost half of transgender respondents reported loss of job or denial of promotion because of their transgender identity. As a result, they may be homeless, use alcohol or illicit drugs as coping mechanisms, and ignore their health needs (Grant et al., 2011). In some cases, they may turn to sex work (prostitution) as a mechanism for survival (Chestnut et al., 2013; Grant et al., 2011). Only a small subset of primarily MtF transgender people engage in sex work, which can expose them to human immune deficiency virus (HIV) and sexually transmitted infection (STI).

Transgender people are also vulnerable to bias-related violence and verbal harassment, including threats and intimidation. MtF people are more than two times more likely to experience physical violence and discrimination than non-transwomen; the likelihood of harassment is even greater for transwomen of color (Chestnut et al., 2013). A recent report indicated that half of LGBTQ-related hate-crime homicides in the United States were committed against transwomen (Chestnut et al., 2013). Factors that increase this risk for violence include poverty, homelessness, and sex work.

Having an identity that puts a person at risk for violence and mistreatment can lead to emotional distress, particularly if the person has been victimized directly. Transgender people who have experienced traumatic situations may demonstrate symptoms of posttraumatic stress disorder (PTSD) and/or depression. They may turn to a variety of coping strategies to deal with distress, some of which can negatively impact physical health. In a classic large-scale national survey, 26% of transgender people reported current or previous alcohol or illicit drug use to cope with discrimination and mistreatment; however, the number of people who use substances recreationally may be higher (Grant et al., 2010). Rates of smoking in the transgender community are higher than the rates in the LGB community and general population of U.S. adults. Most important, major life stressors, emotional distress, and lack of resources can lead to suicidal ideation or suicide attempt when all other methods of coping have failed. In a sample of over 7000 transgender adults, 41% reported at least one suicide attempt in their lifetime (Grant et al., 2010). Data support similar trends in Canada (Bauer & Scheim, 2015).

## Stress and Transgender Health

Transgender people have additional sources of stress when attempting to access health care, such as lack of health insurance due to unemployment and lack of health care–professional knowledge. This barrier to health care causes them to postpone both acute and preventive medical care. For people who are insured, coverage for health care related to gender transition, such as hormone use and surgery, is usually denied.

When transgender people gain access to health care, they are often fearful and anxious about the providers and setting. In particular, they may be hesitant to disclose their transgender status because of fear of discrimination or ridicule (Redfern & Sinclair, 2014). They may also fear that this information will be documented in health records and shared with family members. This reluctance is increased if they have had previous negative experiences with primary health care providers. One national survey found that 19% of transgender adults were refused health care services due to their gender identity, and 28% reported receiving verbal harassment in a health care setting. Male-to-female transgender people were more likely to encounter discrimination and avoid health care because of these experiences (Grant et al., 2010). Even with providers who seem tolerant and caring with transgender patients, there is still a risk for patients overhearing jokes in the hallway and defamatory comments (Rounds et al., 2013).

Another source of stress faced by many transgender people is lack of health care–professional knowledge regarding health care needs (Rounds et al., 2013). When this situation occurs, transgender patients are put in a position of acting as health care experts, which can limit the quality of their care. Although most transgender patients generally expect their providers to have some level of knowledge or know where to seek answers, at least half of them find that they have to teach their providers (Rounds et al., 2013). When they encounter primary health care providers who are unfamiliar with the specific health care needs of their population, patient confidence is likely to diminish drastically and affect desire for future health care.

Although transgender patients may encounter health care professionals who do not understand or who overlook their gender identity, some may encounter those who over-focus on it. Although it is important to be generally knowledgeable about a patient's gender status and understand how it may affect health care needs, this factor is not always relevant for every health problem. For example, transgender patients with fractures or influenza do not need to be questioned extensively about their gender identity. Although there are instances in which the presenting problems require transgender-specific care, many other instances require the same health care that all patients receive. At these times, most transgender patients prefer to be treated as any other patient (Rounds et al., 2013). Therefore use sound clinical judgment to decide if one's gender identity impacts patient assessment and care.

## The Need to Improve Transgender Health Care

During the past few years, several national documents were published by the U.S. Department of Health and Human Services and private health care organizations that call for improvement in LGBTQ health care. These important publications include:

- Healthy People 2020
- The Institute of Medicine's (IOM) (now NAM) report on LGBT health
- The Joint Commission field guide for care of LGBT patients
- World Professional Association for Transgender Health (WPATH) standards of care

The U.S. Department of Health and Human Services' *Healthy People 2010* publication did *not* include the need to improve health care for LGBT people. As a result of this omission, a companion document was developed by the Gay and Lesbian Medical Association (GLMA) to address special health care needs of this population across the life span. Ten common health problems affecting the LGBT group were identified, including cancer, nutrition and weight, and sexually transmitted infection.

The *Healthy People 2020* agenda added objectives for improving the health of LGBT people, including the need to recognize and address the special health needs of transgender patients of all ages. One major objective is to develop a system to identify patients who identify as LGBTQ. This objective is similar to the recommendation in the IOM's (now NAM's) publication entitled *The Health of LGBT People: Building a Foundation for Better Understanding* (IOM, 2011).

The IOM LGBT health report calls for the need for more research to identify the special health care concerns of LGBT people of all ages. To help meet this outcome, the document outlined the need to collect more demographic data to better identify this population. LGBTQ people need to feel safe when disclosing this very personal information.

In 2011, The Joint Commission (TJC) published a similar document that recommends ways for health care agencies to create a welcoming and safe environment for LGBT patients. In response to growing attention to the need for cultural competence for all health care professionals and to provide quality health care for sexual and gender minority patients, TJC published a field guide for health care agencies to improve LGBT patient care (TJC, 2011). [Chart 73-1](#) lists the recommendations for health care agencies in designing a safe environment for LGBT patient care. [Fig. 73-1](#) shows an example of a "safe zone" image that should be used to reassure these patients that they are in a safe place where they can receive respectful and knowledgeable quality care.

### ©Chart 73-1

#### Best Practice for Patient Safety & Quality Care QSEN

##### The Joint Commission Recommendations for Creating a Safe, Welcoming Environment for LGBTQ Patients

- Post the *Patients' Bill of Rights* and nondiscrimination policies in a visible place.
- Make waiting rooms inclusive for LGBTQ patients and families, such as posting *Safe Zone*, rainbow, or pink triangle signs.
- Designate unisex or single-stall restrooms.
- Ensure that visitation policies are equitable for families of LGBTQ patients.
- Avoid assumptions about any patient's sexual orientation and gender identity.
- Include gender-neutral language on all medical forms and documents (e.g., "partnered" in addition to married, single, or divorced categories).
- Do not limit gender options on medical forms to "male" and "female."

- Reflect the patient's choice of terminology in communication and documentation.
- Provide information on special health concerns for LGBTQ patients.
- Become knowledgeable about LGBTQ health needs and care.
- Refer LGBTQ patients to qualified health care professionals as needed.
- Provide community resources for LGBTQ information and support as needed.

Adapted from The Joint Commission (TJC). (2011). *Advancing effective communication, cultural competence, and patient- and family-centered care for the lesbian, gay, bisexual, and transgender community*. [www.jointcommission.org/lgbt](http://www.jointcommission.org/lgbt).

**FIG. 73-1** The Safe Zone—rainbow or pink triangle signs welcome LGBTQ patients in a health care agency.

Also in 2011, the World Professional Association for Transgender Health (WPATH) updated its Standards of Care (Coleman et al., 2011). As of press time, this edition of the Standards of Care (SOC) remains the most current. The SOC document outlines core principles that nurses and other health care professionals should follow when caring for transgender patients (Table 73-2).

**TABLE 73-2**

**Core Principles for Health Care Professionals Who Care for Transgender Patients**

- Become knowledgeable about the health care needs of transgender and other gender-nonconforming people.
- Become knowledgeable about the treatment options for transgender patients and required follow-up care.
- Do not assume that all transgender patients are the same; treat each one as an individual and develop an individualized plan of care.
- Demonstrate respect for patients with nonconforming gender identities.
- Provide culturally sensitive care and use appropriate terminology that affirms the patient's gender identity.
- Facilitate patient access to appropriate and knowledgeable health care providers.
- Seek informed consent before providing treatment.
- Offer continuity of care or refer patients for ongoing quality health care.
- Advocate for patients within their families and communities.

Data from Coleman, E., Bockting, W., Botzer, M., Cohen-Kettenis, P., DeCuypere, G., Fladman, J., et al., (2011). Standards of care for the health of transsexual, transgender, and gender-nonconforming people (Version 7). *International Journal of Transgenderism*, 13, 165-232; and Rounds, K.E., McGrath, B.B., & Walsh, E. (2013). Perspectives on provider behaviors: A qualitative study of sexual and gender minorities regarding quality of care. *Contemporary Nurse*, 44(1), 99-110.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

As with any patient, it is best to ask during the nursing history and physical assessment how he or she prefers to be addressed. For example, for non-transgender patients, some people may go by a nickname or by their middle name and prefer to be addressed as such. For transgender patients, it is not uncommon for driver's licenses, insurance cards, and other forms of identification to retain their birth names (and by extension, birth sex) because it can be difficult to change this information, particularly if a person is in the process of transitioning. Therefore nurses may receive patient documentation with misleading patient data. For example, a nurse may receive a health care record listing a male name and birth sex yet encounter a patient presenting as female in appearance. It can be offensive and embarrassing for the patient who clearly identifies as female to be called "Mister," "sir," or the male birth name. Not only does it communicate disrespect, it also signals to the patient that she may receive inadequate care or that the environment is unsafe.

In addition to preferred names, correct pronoun usage is also important. Each patient has his or her own preference. For example, an MtF patient may visit a clinic during lunch hour at work. Because the patient has not disclosed the transgender identity at work, this patient maintains male dress and demeanor at the office. Although the patient may identify as female and live as female at home, the patient may request the nurse to use male pronouns (he, him, his) to match the patient's current presentation and may not disclose the transgender identity to the nurse. Conversely, even though the patient presents at the time as male, the patient may ask the nurse to use female pronouns (she, her, hers) because the patient identifies with a female gender identity.

*In general, use pronouns that match the patient's physical presentation and dress unless the patient requests otherwise.* Even though the biologic sex may not match, patients presenting as female should be addressed as female, and patients presenting as male should be addressed as male. With changing styles and trends, it can sometimes be difficult to assess by clothing alone. However, with a patient whose birth sex is listed as female yet presents in traditionally male attire, facial hair, and a men's hairstyle, it is most appropriate to address this patient as male. Understandably, the clinical setting can be fast paced, and nurses may encounter multiple patients at a time; however, taking time to use clinical judgment is important. Appropriately interacting with a transgender patient can sometimes mean the difference between the patient continuing to seek health care or not.

In some cases, patients may not identify as male or female and prefer not to use male or female pronouns. These patients often feel that the binary gender system in which a person must fit clearly into one category or the other is too limiting. Although this is a small subset of the transgender population, it is important to be aware of this subculture in case you encounter a patient who refuses to identify with a specific gender. Some patients may request the use of gender-neutral pronouns, or they may use these pronouns in the nurse's presence. Some examples of gender neutral pronouns are "they/their/theirs" and "ze/hir/hirs."

Getting used to using the correct name or pronoun can take some time. Occasionally, nurses know their patient's preferred name or pronoun but accidentally say the wrong one. Transgender patients encounter this situation often and typically anticipate an error at times. When this error occurs, it is best to self-correct and continue with care rather than make a prolonged apology. Focusing too much on the error may make the patient more uncomfortable because more attention has been drawn to the situation. Most transgender patients, particularly those who live full time in their gender-affirming role, wish to be treated like any other patient.

### History.

Interventions for transgender people who experience gender dysphoria (discomfort with one's natal

sex) include one or more of these options (Coleman et al., 2011):

- Changes in gender expression that may involve living part time or full time in another gender role
- Psychotherapy to explore gender identity and expression, improve body image, or strengthen coping mechanisms
- Hormone therapy to feminize or masculinize the body
- Surgery to change primary and/or secondary sex characteristics (e.g., the breasts/chest, facial features, internal and/or external genitalia)

During the health history, inquire about which interventions the patient has had, if any, or if there are plans to have them in the future. Ask about current use of *drug therapy*, including hormones, and other feminizing or masculinizing agents, including silicone injections. These medications are usually prescribed by endocrinologists or other specialists in transgender health care, but some patients may obtain them from nonmedical sources, including the Internet.

Exogenous hormone therapy can cause adverse health problems and requires careful patient monitoring, including laboratory testing. For example, estrogen therapy can cause increased health risks such as increased blood clotting causing venous thromboembolism (VTE), elevated blood glucose, hypertension, estrogen-dependent cancers, and fluid retention. Smoking and obesity increase these risks. The risks also increase with higher doses of the medication. Ask the patient about a history of these problems.

Inquire about the patient's *surgical history*. For the MtF patient, ask about breast surgery and any surgical changes to the genitalia, such as a penectomy (removal of the penis) and vaginoplasty (creation of a vagina). The MtF patient still has a prostate gland. For older patients, ask about any problems with prostate health problems, such as urinary dribbling and retention. For the FtM patient, ask whether a hysterectomy, bilateral salpingo-oophorectomy (BSO), mastectomy, phalloplasty (creation of a penis), and/or scrotoplasty (creation of a scrotum) was performed.

Keep in mind that health insurance usually does not cover the cost of the transition process and patients may seek alternative care. For example, hormones may be obtained illegally or from countries that do not have quality controls for medication. MtF patients may seek silicone for creating breasts from nonmedical people, causing a high risk for hepatitis C and silicone complications. Ask patients about the use of these alternatives as a part of their transition process.

### Physical Assessment.

Be sure to review the transgender patient's health record carefully before performing a physical assessment. Be culturally sensitive, nonjudgmental, and respectful during the assessment. Be aware that transgender patients may be young, middle-age, or older adults. To help increase the patient's comfort with examinations and the purpose of the assessment, explain why the information or examination is important to their health care (Redfern & Sinclair, 2014)

## Considerations for Older Adults

### Patient-Centered Care QSEN

Transgender patients who are older than 65 years lived in an era when most of them concealed their sexual orientation and true gender identity because of social stigma. These people have not been well studied as a group, but research indicates that those who lived with a partner have fewer mental health problems and better self-esteem than those who lived alone (Brennan et al., 2012).

When assessing transgender patients, be aware that they will be in varying stages of transition. Some patients present with no obvious physical signs that they are in the process of transitioning. Others have had gender reassignment surgery such that their new appearance matches their gender identity. Realize that a transgender patient's genitalia may not match his or her physical appearance.

### Psychosocial Assessment.

If gender and SEXUALITY are relevant to the patient's presenting health problem, ask specific questions to determine how these factors may impact care. Again, it is helpful to share with patients

why this information is relevant to their treatment. Reassure patients that their responses are confidential and will not be shared with any family, friends, or significant others without the patient's permission. However, evidence of abuse must be reported as mandated by law. Appropriate screening questions about psychosocial functioning related to gender and sexuality include:

- Are you experiencing any challenges, concerns, or anxiety related to your sexuality?
- Related to your gender, how do you identify?
- Are you experiencing any sadness, depression, or thoughts of hurting yourself?
- Have you experienced any violence or discrimination in your personal or work life?
- Are you currently being seen by a counselor or psychologist related to your sexuality and gender identity? If so, why?

If the responses to these questions indicate that the patient has potential or actual mental health problems, consult with the health care provider for further evaluation by a qualified mental health care professional, such as a licensed counselor or clinical psychologist.

### ◆ **Interventions: Responding**

Nurses care for transgender patients who are transitioning or have completed gender reassignment. They may care for them for health problems related to their transition process or for problems that are unrelated to the patient's SEXUALITY or gender identity. In general, care for transgender patients with most health problems is the same as for any other patient. However, some interventions such as hormone therapy may affect nursing assessment and care. As a leader in health care, advocate for transgender patients and provide health teaching to promote their health. Encourage them to include their sexual partner, if any, in discussions about the transition process.

### **Nonsurgical Management.**

The primary nonsurgical interventions for transgender patients include drug (hormone) therapy, counseling about REPRODUCTION and reproductive health, and vocal therapy. The type of intervention depends on whether the patient is transitioning from MtF or FtM.

#### **Drug Therapy.**

Drug therapy may be started after a psychosocial assessment by a qualified mental health care professional and informed consent has been obtained. According to WPATH's most recent standards of care, the criteria for hormone therapy include:

- Continuing and well-documented gender dysphoria
- Patient ability to make a fully informed decision and give consent to treatment
- Patient older than 18 years
- Well-controlled existing medical or mental health problems, if any

#### **Drugs for MtF Patients.**

Patients transitioning from male to female (MtF) typically take a combination of estrogen therapy and androgen-reducing medications to achieve feminizing effects. Expected physical changes from *estrogen therapy* are breast enlargement, thinning hair, decreased testicular size, decreased erectile function, and increased body fat compared with muscle mass (Table 73-3). Because oral estrogen (ethinyl estradiol) can increase the risk for venous thromboembolism, transdermal estrogen (Climara) or injectable estradiol is preferred for use in transgender patients. The typical dosing is two 0.1-mg patches changed twice weekly. Injectable estradiol is usually prescribed in a dose between 5 and 20 mg IM every 2 weeks. Progesterone may also be prescribed for 10 days each month (Burchum & Rosenthal, 2016).

**TABLE 73-3**

**Feminizing Drug Therapy for MtF Patients: Expected Changes and Monitoring**

Expected Physical Changes
<ul style="list-style-type: none"> <li>• Enlargement of breast tissue (gynecomastia)</li> <li>• Decreased testicular size</li> <li>• Decreased erectile function</li> <li>• Decreased libido (sex drive)</li> </ul>

<ul style="list-style-type: none"> <li>• Decreased body hair growth</li> <li>• Decreased male pattern baldness</li> <li>• Increased fat compared with muscle</li> <li>• Softening of skin</li> </ul>
<b>Laboratory/Imaging Studies</b>
<ul style="list-style-type: none"> <li>• Chemistry panel (including glucose and electrolytes)</li> <li>• Liver function tests</li> <li>• Lipid profile</li> <li>• Complete blood count</li> <li>• Prostate-specific antigen (PSA) if recommended for age-group</li> <li>• Mammogram (when breast tissue develops)</li> <li>• Papanicolaou (Pap) smear (if vagina present)</li> </ul>

## Nursing Safety Priority QSEN

### Drug Alert

Before the first dose of transdermal estrogen, teach the patient to apply the patch to an area that is hairless to ensure good contact with the skin. When changing to a new patch, wash any excess drug from the skin where the previous patch was applied.

Teach patients taking any form of estrogen about side effects such as headache, breast tenderness, nausea/vomiting, and weight gain (often due to fluid retention) or loss. Tell them to report increased feelings of anxiety or depression to their primary health care provider. Estrogens can also cause estrogen-dependent cancers, hypertension (due to fluid retention), venous thromboembolism (VTE) such as deep vein thrombosis (DVT), and gallbladder disease. Teach patients to follow up with their primary health care provider to monitor for these potential adverse drug effects. Diagnostic testing is part of follow-up and monitoring, as listed in [Table 73-3](#).

## NCLEX Examination Challenge 73-1

### Physiological Integrity

The nurse provides health teaching for a client receiving estrogen therapy. Which statement by the client indicates that the teaching was effective? **Select all that apply.**

- A. "I need to check my blood pressure frequently when taking this drug."
- B. "I'll call my doctor if I have any redness or swelling in my legs."
- C. "I'll drink extra fluids because this drug will cause me to urinate a lot."
- D. "I know that the drug will cause my breast to feel tender."
- E. "I can get frequent headaches from taking this drug."

In addition to estrogen therapy, androgen-reducing agents (anti-androgens) are often given to block the effects of testosterone, including ([Burchum & Rosenthal, 2016](#)):

- Spironolactone (Aldactone), a low-cost diuretic that also inhibits testosterone secretion and androgen binding to androgen receptors
- 5-alpha reductase inhibitors (e.g., finasteride [Proscar]), drugs typically used to treat benign prostatic hyperplasia (BPH) (These drugs block the conversion of testosterone to a more active ingredient to decrease the hair loss associated with estrogen therapy and shrink prostate tissue.)
- GnRH agonists (e.g., goserelin [Zoladex]), neurohormones that block the gonadotropin-releasing hormone receptor, thus inhibiting the release of the follicle-stimulating hormone (FSH), and luteinizing hormone (LH) (These drugs are more expensive and are available only as implants and parenteral preparations.)

## Nursing Safety Priority QSEN

### Drug Alert

Teach patients taking *spironolactone* to monitor their blood pressure and have periodic laboratory tests to assess for hyperkalemia if the health care provider determines them to be at risk for these drug effects. Remind them that increased serum potassium can cause cardiac dysrhythmias and skeletal muscle spasticity.

Common side effects of finasteride and other *5-alpha reductase inhibitors* include dizziness, cold sweats, and chills. These symptoms typically decrease over time. If patients continue to have them, instruct them to contact their primary health care provider.

Teach patients receiving *GnRH agonists* how to self-administer subcutaneous injections. Major side effects of these drugs are tachycardia and other cardiac dysrhythmias. Remind patients to follow up with their health care provider to monitor heart rate and rhythm. Teach them to call 911 if they experience chest pain (Burchum & Rosenthal, 2016).

### Drugs for FtM Patients.

Testosterone is the major drug used for achieving masculinizing effects in transgender people transitioning from female to male; however, much of the available drug converts to estrogen in the body. This drug can be taken orally, transdermally, or parenterally (IM). Buccal and implantable forms of testosterone are also available. Oral testosterone (Andriol) is the least effective form of the drug. Depo-Testosterone, the most common IM preparation, is usually started in a low dose and increased to 100 to 200 mg every 1 to 2 weeks (Burchum & Rosenthal, 2016). Teach patients the importance of not sharing needles to prevent bloodborne diseases such as hepatitis C.

AndroGel and Androderm are topical forms that are more expensive than other testosterone preparations but may provide more consistent (although slower) results. A newer topical form of the drug, Axiron, can be applied to the armpits to increase serum testosterone levels. For all topical testosterone preparations, be sure that the patient washes his hands between applications and covers the area with clothing.

Expected effects of testosterone therapy include deepening of the voice, increased libido (sex drive), increased body hair growth, breast and ovarian atrophy, clitoral enlargement, and cessation of menses (Table 73-4). Teach the patient taking testosterone that some of these changes take up to a year to appear. If menses does not stop in the first few months of drug therapy, the patient is placed on Depo-Provera (progesterone) every 3 months until the testosterone becomes effective.

**TABLE 73-4**  
**Masculinizing Drug Therapy for FtM Patients: Expected Changes and Monitoring**

<b>Expected Changes</b>
<ul style="list-style-type: none"> <li>• Voice deepening</li> <li>• Body hair growth (hirsutism)</li> <li>• Breast atrophy</li> <li>• Increased libido</li> <li>• Increased aggression</li> <li>• Clitoral growth</li> <li>• Redistribution of fat</li> <li>• Laryngeal prominence</li> </ul>
<b>Laboratory/Imaging Studies</b>
<ul style="list-style-type: none"> <li>• Lipid profile</li> <li>• Liver function tests</li> <li>• Complete blood count</li> <li>• Papanicolaou (Pap) smear (if vagina present)</li> <li>• Mammogram (if breast tissue present)</li> </ul>

Common side effects of testosterone therapy include edema, acne, seborrhea (oily skin), headaches, weight gain, and possible psychotic symptoms. Before taking this medication, the patient is screened for a history of liver and heart disease. Testosterone therapy can cause increased liver enzymes, increased low-density lipoproteins (LDLs, or “bad” cholesterol), and decreased high-density lipoproteins (HDLs, or “good” cholesterol). Increased blood glucose and decreased clotting factors can also occur when taking the drug. Teach patients that these changes can lead to diabetes, heart disease, and stroke. Therefore remind patients that they need to follow up with their primary health care providers for careful monitoring for these complications, including having extensive diagnostic and laboratory testing (see Table 73-4).

### Reproductive Health Options.

Using feminizing or masculinizing hormone therapy affects reproductive health, especially fertility. Therefore be sure that patients know their options for REPRODUCTION, if desired, *before* transition

begins. MtF patients may want to consider sperm banking before drug therapy or gender reassignment surgery if they desire to have a biologic child. FtM patients may want to consider oocyte (egg) or embryo freezing. These frozen gametes or embryo could be implanted in a surrogate woman to become pregnant and carry to birth. Inform patients that these options are expensive, but be sure that all patients are informed. Be sure to include the patient's sexual partner, if any, in discussions related to reproductive options.

### **Voice and Communication Therapy.**

Communication is an essential aspect of human behavior and gender expression. Voice deepening for transgender people who are transitioning from female to male is accomplished by taking masculinizing hormones, such as testosterone. However, feminizing hormones have no effect on the adult MtF voice.

MtF patients may seek assistance from a voice and communication specialist to help them develop certain vocal characteristics, such as pitch and intonation. Vocal therapy can assist in management of gender dysphoria and be a positive step in the transition process. Specialists include speech-language pathologists and speech-voice clinicians. Remind patients to seek a specialist who is licensed, is knowledgeable in transgender health, and has specialized training in assessment and development of communication skills for transgender patients.

The purpose of vocal therapy is to help patients adapt their voice and communication such that it is authentic and reflects their gender identity. The voice therapist should take the patient's communication preferences and style into consideration as part of the assessment process to develop an individualized treatment plan. Some patients choose follow-up sessions for vocal therapy following voice feminization surgery, also called *feminization laryngoplasty*. This surgery is described in the next section.

### **Surgical Management.**

Many transgender people are satisfied with their gender identity, role, and self-expression without surgery. Surgery, particularly procedures that affect the external or internal genitalia, is usually the last and most carefully considered option for transitioning from one's natal sex to one's inner gender identity. These procedures are often referred to as **gender or sex reassignment surgery (SRS)** but are also known as gender-affirming surgery or gender-confirming surgery. The patient has a number of surgical options to achieve either feminizing or masculinizing effects. Regardless of the procedure performed, the nurse collaborates with the patient, family, and health care team to promote positive outcomes for the transition process.

Gender reassignment surgeries are procedures that alter anatomically healthy structures. Not all surgeons feel comfortable in performing procedures that could "harm" transgender patients. However, these procedures help treat gender dysphoria. Some patients elect to undergo the full range of surgeries, whereas others choose to have only some or none of them, typically because of the profound medical expense.

Genital surgeries "below the waist" are the most invasive procedures. The criteria for genital surgery depend on the type of surgery being requested. For example, most surgeons (usually urologists or plastic surgeons) require 12 months of hormone therapy plus one or two referrals from qualified psychotherapists for MtF patients who desire an orchiectomy (removal of testes). The same requirements are needed for FtM patients who desire a hysterectomy (uterus removal) and bilateral salpingo-oophorectomy (BSO), or removal of both fallopian tubes and ovaries.

The psychotherapist assesses the patient's readiness for genital surgery and hormone therapy, including a discussion of risks and out-of-pocket costs. The patient's support system is assessed to ensure that the patient makes the best possible decision and achieves the desired outcomes.

For MtF patients requesting a vaginoplasty (creation of a vagina) or FtM patients desiring a phalloplasty (creation of a penis), the required criteria include 12 continuous months of living in a gender role that is congruent with the patient's gender identity. It is also recommended that these patients have regular visits with a mental health care professional (Coleman et al., 2011).

### **Feminizing Surgeries for MtF Patients.**

Feminizing surgeries are performed for MtF patients to create a functional and/or aesthetic (cosmetic) female anatomy, including:

- Breast/chest surgeries, such as breast augmentation (mammoplasty to increase breast tissue)

- Genital surgeries, such as partial penectomy (removal of the penis), orchiectomy (removal of the testes), vaginoplasty and labiaplasty vulvoplasty (creation of a vagina and labia/vulva), and clitoroplasty (creation of a clitoris)
- Other surgeries, such as facial feminizing surgery (to achieve feminine facial contour); liposuction (fatty tissue removal), often from the waist or abdominal area; vocal feminizing surgery; and other body-contouring procedures.

*Breast augmentation* creates breast tissue for the MtF patient through the use of silicone or saline implants. Although not a prerequisite, it is recommended that MtF patients take feminizing hormones for 12 months before surgery for the best results (Coleman et al., 2011).

*Voice surgery*, such as reduction thyroid chondroplasty, is performed to decrease the size of the “Adam’s apple.” The procedure is done through a bronchoscope for cosmetic purposes. Nursing care of the patient having a bronchoscopy is discussed in Chapter 27.

The most common “below the waist” genital surgeries for MtF patients are bilateral *orchiectomy* to remove the testes and vaginoplasty with partial penectomy. Orchiectomy procedures and associated nursing care are the same for the transgender patient as they are for other natal males (see Chapter 72 for a detailed discussion).

A **vaginoplasty** is the construction of a neovagina (new vagina), usually with inverted penile tissue (obtained during a partial penectomy) or a colon graft. The procedure also includes creating a clitoris and labia using scrotal or penile tissue and skin grafts.

### Preoperative Care.

In addition to the required criteria to qualify for a vaginoplasty (also called *transvaginal surgery*), the transgender patient is medically evaluated like any other presurgical patient. Patients who have poorly controlled diabetes with vascular complications, coronary artery disease, or other systemic disease that limits functional ability are not candidates for gender reassignment surgery. Chapter 14 describes general preoperative care for any patient.

The surgeon explains the options for selected procedures, postoperative care expectations, and potential for complications after surgery. Postoperative recovery for transvaginal surgery takes a long time and has a high complication rate. Overweight patients have a higher incidence of wound infection and may have problems with adequate ventilation (breathing) and ambulation after surgery. Refer these patients for nutritional counseling as needed.

Written and verbal preoperative instructions are provided by the surgeon, including optional methods of body hair removal. A bowel preparation may be started 24 hours before surgery and includes a clear liquid diet, laxatives, and Fleet’s enemas. Increased fluids are recommended until the patient goes to bed the night before surgery because the bowel “prep” can be very dehydrating. Antimicrobials such as neomycin sulfate and metronidazole (Flagyl) are typically given on the day of surgery to minimize the risk for infection.

Some surgeons require that the patient take supplements to prevent bruising and promote tissue healing, such as vitamin C. Patients who are very thin are encouraged to eat a high-protein diet. A powdered protein supplement with arginine (an amino acid) may also be prescribed to promote wound healing.

Patients have a number of laboratory tests to ensure that they are healthy before surgery. Adequate hemoglobin and hematocrit (H&H) levels are especially important because some blood is lost during surgery. For patients who have low H&H levels, an erythropoietin such as epoetin alfa (Procrit) or IM testosterone with iron is given. Most patients choose testosterone because it is a lower-cost drug.

### Operative Procedures.

Because surgery requires multiple procedures to create a female anatomy, the patient is on the operating table for many hours. The surgery may be performed in a hospital or specialized center for transgender surgeries. After general or epidural anesthesia is administered, the patient is placed in a lithotomy position (feet in stirrups) for the procedure. Epidural anesthesia is preferred for patients who are asthmatic or obese. The patient is transferred to the postanesthesia care unit (PACU) with a perineal dressing and packing, Jackson-Pratt drain, and indwelling urinary catheter.

### Postoperative Care.

Provide general postoperative care as described in Chapter 16. In addition, immediately after

surgery, apply an ice pack to the perineum to decrease pain and bruising. Monitor the patient's pain level carefully and offer analgesia as needed. Genital surgery is painful because there is a high concentration of nerve endings in the perineum.

Although not a common postoperative complication, monitor the patient for bleeding. Observe the surgical dressing and surrounding area for oozing or bright red blood. Report and document any indication of bleeding immediately to the surgeon and keep the patient in bed.

Encourage the patient to drink liquids after surgery; discontinue the patient's IV line once oral fluids are tolerated. Evaluate the patient's intake and output every 8 to 12 hours.

## Nursing Safety Priority QSEN

### Action Alert

Patients are in a lithotomy position for an extended period during surgery. Therefore, after surgery, monitor lower-extremity neurovascular status and encourage the patient to move the legs often during the first 24 hours after surgery. Report and document any unexpected findings, such as continued numbness or inability to move the lower legs or feet. Patients who had epidural anesthesia are not able to move their legs for several hours after surgery until the effect of the drug diminishes.

All patients stay in the hospital for at least one night after surgery, but some patients may stay longer, depending on the number and complexity of the surgical procedures. Some agencies transfer the patient the day after surgery to a local hotel for continued follow-up and monitoring by a health care professional (usually a nurse). Collaborate with the case manager for discharge planning and follow-up care.

The Jackson Pratt drain is removed typically 3 to 5 days after surgery when drainage is less than 15 to 20 mL in a 24-hour period. About a week after surgery, the surgical pressure dressing, packing, and external sutures are removed.

At this time, patients are taught how to douche and insert vaginal stents to dilate the vagina. Sexual intercourse also helps keep the vagina dilated. Remind patients that routine douching and douching after intercourse are needed to prevent infection in the new vagina. A solution of vinegar and water or a commercial product such as Massengill can be used. Vaginal stents (also called *dilators*) must be inserted several times a day for months after surgery. The stent should remain in the vagina for 30 to 45 minutes or as instructed by the surgeon. Teach patients the importance of using the stents with water-based lubrication. Collaborate with the surgeon to determine patient-specific instructions.

The urinary catheter is removed between postoperative day 7 and 12. Early removal can cause urinary retention, but prolonged placement can lead to catheter-associated urinary tract infection (CAUTI).

Patients should continue follow-up visits with their primary health care provider for signs and symptoms of complications. One of the worst complications is a vaginal-rectal fistula, which is caused by rectal perforation during surgery. Teach patients to report any leakage of stool into the vagina immediately to their surgeon. The treatment for this complication is a temporary colostomy and fistula wound management for many months. Other surgical complications of vaginoplasty are listed in [Table 73-5](#).

**TABLE 73-5**  
**Postoperative Complications of Vaginoplasty Surgery**

<b>Most Serious Complications</b>
<ul style="list-style-type: none"> <li>• Vaginal-rectal fistula</li> <li>• Rectal perforation</li> <li>• Bleeding</li> </ul>
<b>Other Complications</b>
<ul style="list-style-type: none"> <li>• Surgical wound infection</li> <li>• Urinary leakage/incontinence</li> <li>• Chronic urinary tract infections</li> <li>• Urinary meatus stenosis</li> <li>• Vaginal stenosis</li> <li>• Vaginal collapse</li> <li>• Labial hematoma</li> <li>• Inadequate vaginal length or width</li> <li>• Lack of sensation</li> <li>• Lack of sexual pleasure</li> </ul>

In addition to physical complications after surgery, some MtF patients are not satisfied with the quality of the results. For example, the neovagina may not be functional for sexual intercourse. Some patients request another surgery to achieve more satisfying results.

## NCLEX Examination Challenge 73-2

### Physiological Integrity

A client is admitted to the postanesthesia care unit (PACU) following a vaginoplasty. For which surgical complications will the nurse monitor in the PACU? **Select all that apply.**

- A. Bleeding
- B. Rectal perforation
- C. Urinary incontinence
- D. Surgical site infection
- E. Urinary retention

### Masculinizing Surgeries for FtM Patients.

Masculinizing surgeries are performed for FtM patients to create a functional and/or aesthetic male anatomy, including:

- Breast/chest surgeries, usually a bilateral mastectomy (removal of both breasts) and chest reconstruction
- Genital surgeries, such as a hysterectomy and bilateral BSO, vaginectomy (removal of the vagina), phalloplasty (creation of an average-size male penis) with ureteroplasty (creation of a urethra) or metoidioplasty (creation of a small penis using hormone-enhanced clitoral tissue), and scrotoplasty (creation of a scrotum) with insertion of testicular prostheses
- Other surgeries, such as liposuction, pectoral muscle implants, and other body-contouring procedures

Care of transgender patients having a mastectomy, hysterectomy, and bilateral salpingo-oophorectomy (BSO) is similar to care for any patient having these procedures as described elsewhere in this text. If the patient has not had previous abdominal surgery, a laparoscopic procedure is preferred for the hysterectomy and BSO surgery.

Procedures to create a male anatomy are not performed as often as MtF surgeries. Phalloplasties are the most difficult reconstructive genital surgeries to perform and usually require several stages. Skin flaps from the radial forearm, anterior lateral thigh, or back are used to create the penis. Fat grafts may be needed to increase penile girth, and buccal mucosal tissue may be used to create the urethra. A penile prosthesis or implant is not inserted until months after surgery when the initial surgical healing has occurred.

Complications from phalloplasty include urinary tract stenosis, donor graft site scarring, and occasionally necrosis of the neopenis (new penis). In addition to these physical problems, the patient may not be satisfied with the results of the surgery, such as an inadequate length of the penis. For these reasons, most FtM patients do not have this procedure and prefer to have only a laparoscopic hysterectomy and BSO.

## Clinical Judgment Challenge 73-1

### Patient-Centered Care; Teamwork and Collaboration **QSEN**

A 58-year-old male-appearing patient visits the gender identity clinic to discuss the desire to have gender reassignment surgery. As the clinical nurse, you take the patient's history and find that the patient was married to a woman for 30 years and had three children. The couple divorced 3 months ago when the patient's wife discovered that her husband identified as a woman. The

couple's children have had no contact with the patient since that time. The patient is employed as the vice-president of a large commercial construction company and has health insurance. The patient is interested in learning about options for male-to-female transitioning.

1. How would you address this patient?
2. What other data do you need to collect for the patient's history and why?
3. What options for transitioning to a female does this patient have?
4. After a physical examination, the clinic physician prescribed transdermal estrogen and spironolactone for the patient. What instructions will you provide for the patient before beginning drug therapy?

### Care Coordination and Transition Management

Transgender patients often take hormone therapy for many years. Teach them that ongoing follow-up with a qualified health care professional is needed to maintain health and detect any complications, such as diabetes or cardiovascular problems, as early as possible.

Long-term follow-up with the surgeon after gender reassignment is essential to detect and treat the frequent complications that occur. Assess the patient's support systems and coping strategies, including financial status and health insurance benefits. Collaborate with the case manager to ensure a smooth transition into the community, including the possible need for any ongoing mental health counseling or therapy.

Urogenital care is also needed for patients who have gender reassignment surgery. FtM patients usually do not have a vaginectomy and therefore may experience vaginal atrophy causing itching and burning. Recommend that they seek gynecologic care to treat this problem, although the examination can be physically and emotionally painful.

MtF patients need counseling about SEXUALITY, genital hygiene, and prevention of sexually transmitted diseases. They are also at a high risk for frequent urinary tract infections as a result of a shortened urethra and urinary incontinence as a result of genital surgery. Teach patients the importance of having follow-up care for these problems.

Preventive health care screenings for transgender patients are also important. For example, the MtF patient requires prostate health care screenings that natal males need. Mammograms are also recommended to monitor for early signs of breast cancer.

A number of community resources and organizations are available for transgender support and information, such as:

- National Coalition for LGBT Health (<http://lgbthealth.webolutionary.com/content/resources>)
- Services and Advocacy for Gay, Lesbian, Bisexual, and Transgender Elders ([www.sageusa.org](http://www.sageusa.org))
- Transgender Health Information Program ([www.transhealth.phsa.ca](http://www.transhealth.phsa.ca))
- University of San Francisco Center for Transgender Health ([www.transhealth.ucsf.edu](http://www.transhealth.ucsf.edu))
- World Professional Association for Transgender Health ([www.wpath.org](http://www.wpath.org))

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Depending on identified health care needs, collaborate with the primary health care provider, mental health professional, surgeon, pharmacist, and/or vocal/speech specialist when caring for the transgender patient. **QSEN: Teamwork and Interprofessional Collaboration**
- Advocate for the transgender patient who may be distrustful of health care professionals and fearful when seeking health care. **QSEN: Patient-Centered Care**

### Health Promotion and Maintenance

- Teach patients taking hormone therapy about the need for ongoing health care monitoring for adverse drug events and health complications (see [Tables 73-3](#) and [73-4](#)). **QSEN: Safety**
- Refer the transgender patient and significant others, as appropriate, to community resources for information and support, such as the University of San Francisco Center for Transgender Health and the Transgender Health Information Program through Vancouver Coastal Health. Be knowledgeable about local resources and refer patients as needed.

### Psychosocial Integrity

- Use culturally sensitive and accurate language when communicating with transgender patients; use pronouns that match the patient's physical appearance and dress unless the patient requests a specific term (see [Tables 73-1](#) and [73-2](#)). **QSEN: Patient-Centered Care**
- Provide PATIENT-CENTERED transgender CARE with dignity and respect for all patients. **Ethics**
- Be aware that transgender people may experience gender dysphoria, which presents an inner conflict between the person's natal (birth) sex and perceived gender identity.
- Assess transgender patients for sources of stress in the community that can lead to health issues, such as depression, anxiety, and substance use.
- Be aware that transgender patients may avoid health care settings because they are often unemployed, have no health insurance, and/or fear lack of respect and understanding based on previous experiences. These concerns contribute to HEALTH CARE DISPARITIES for this population. **QSEN: Patient-Centered Care**

### Physiological Integrity

- Monitor for expected, side, and adverse effects of hormone therapy, including effects on SEXUALITY and REPRODUCTION, as described in [Tables 73-3](#) and [73-4](#).
- Recognize that patients receiving hormone therapy need to have periodic laboratory testing to monitor for complications as listed in [Tables 73-3](#) and [Table 73-4](#). **QSEN: Evidence-Based Practice**
- Provide preoperative care for a patient having a vaginoplasty, including teaching about bowel preparation, food and fluid intake, hair-removal methods, and the need for informed consent.
- Monitor for potentially life-threatening complications of gender reassignment surgery, such as fistula development, bleeding, and wound infection (see [Table 73-5](#)).

## CHAPTER 74

# Care of Patients With Sexually Transmitted Infections

Donna D. Ignatavicius

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- COMFORT
- SEXUALITY

✚ The SEXUALITY concept exemplar for this chapter is Pelvic Inflammatory Disease, p. 1514.

**The interrelated concepts for this chapter are:**

- REPRODUCTION
- HEALTH CARE DISPARITIES

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Maintain patient confidentiality and privacy related to sexually transmitted infection (STI).

### Health Promotion and Maintenance

2. Educate patients with STIs and their partners on self-care measures.
3. Describe the role of expedited partner therapy in reducing STI recurrence.
4. Develop a teaching plan for young adults and other at-risk people about risk factors, prevention, and treatment for STIs.
5. Explain the importance of respect for patients' personal values and beliefs regarding practices associated with SEXUALITY.
6. Describe HEALTH CARE DISPARITIES associated with the incidence and management of STIs.

### Psychosocial Integrity

7. Assess patients' and their partners' responses to a diagnosis of STI.
8. Reduce the psychological impact for the patient who has been diagnosed with STI.

### Physiological Integrity

9. Develop a health teaching plan for patients on how to self-manage their STI, including antibiotic therapy.
0. Describe the assessment findings, including impaired COMFORT, that are typical in patients with STIs.
1. Determine typical assessment findings for women with pelvic inflammatory disease (PID).
2. Develop a patient-centered collaborative plan of care for a patient with PID, including its possible impact on REPRODUCTION.

## Overview

Sexually transmitted infections (STIs) are caused by infectious organisms that have been passed from one person to another through intimate contact—usually oral, vaginal, or anal intercourse. Some organisms that cause these diseases are transmitted only through sexual contact. Others are transmitted also by parenteral exposure to infected blood, fecal-oral transmission, intrauterine transmission to the fetus, and perinatal transmission from mother to neonate. If the STI continues to recur and become chronic, the term **sexually transmitted disease (STD)** is used. STD continues to be the most acceptable term used by the Centers for Disease Control and Prevention (CDC).

Improved diagnostic techniques, increased knowledge about organisms that can be sexually transmitted, and changes in SEXUALITY (see [Chapter 2](#) for a review) and sexual practices have led to an increasing number of reported cases of STIs. *Sexual issues are often sensitive, personal, and controversial, and nurses must respect the patients' lifestyle. Providing confidentiality is essential for patients to receive correct information, make informed decisions, and obtain appropriate care.*

The prevalence of STIs is a major public health concern worldwide. Populations at greatest risk for acquiring STIs and suffering from their complications are pregnant women, adolescents, and men who have sex with men (MSM). External factors such as an increasing population, cultural factors (e.g., earlier first intercourse), political and economic policies, incidences of sexual abuse and human trafficking, and international travel and migration affect the prevalence of STIs.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Another factor contributing to STI prevalence is the increasing number of older adults that will continue as baby boomers age. People older than 50 years may not realize their risk for STIs or feel comfortable discussing their SEXUALITY with health care providers. Health care professionals may also lack awareness of the sexual activity of older adults. Be sure to teach older adults who are sexually active about their risk for developing STIs.

In the United States, one of the greatest factors associated with STI prevalence is the secrecy that surrounds SEXUALITY, sexual behavior, and intimacy in the American culture. The stigma of STIs in the United States has been associated with higher rates of these infections compared with rates in other developed countries. The prevalence of STIs is also affected by changing human physiology patterns such as earlier onset of menarche, comorbidities associated with human immune deficiency virus (HIV) and diabetes, treatments given for cancer or organ transplantation, and HEALTH CARE DISPARITIES (see [Chapter 1](#) for a review of this concept). Substance use disorder has also been identified as a significant risk factor because of the effects that illicit drugs have on sexual risk-taking behavior.

STIs cause complications that can contribute to severe physical and emotional suffering, including infertility, ectopic pregnancy, cancer, and death. Some of the most common complications caused by sexually transmitted organisms are listed in [Table 74-1](#).

**TABLE 74-1**  
**Complications Caused by Sexually Transmitted Organisms**

COMPLICATION	CAUSATIVE ORGANISMS
Salpingitis, infertility, and ectopic pregnancy	<i>Neisseria gonorrhoeae</i> <i>Chlamydia trachomatis</i> <i>Mycoplasma hominis</i> <i>Ureaplasma urealyticum</i>
Puerperal infection	<i>N. gonorrhoeae</i> <i>C. trachomatis</i>
Perinatal infection	Hepatitis B virus Human immune deficiency virus Human papilloma virus <i>N. gonorrhoeae</i> <i>C. trachomatis</i> Herpes simplex virus <i>Treponema pallidum</i> Cytomegalovirus Group B streptococcus
Cancer of genital area	Human papilloma virus
Male urethritis	<i>M. hominis</i>

	Herpes simplex virus <i>N. gonorrhoeae</i> <i>C. trachomatis</i> <i>U. urealyticum</i>
Vulvovaginitis	Herpes simplex virus <i>Trichomonas vaginalis</i> Bacterial vaginosis <i>Candida albicans</i>
Cervicitis	<i>N. gonorrhoeae</i> <i>C. trachomatis</i> Herpes simplex virus
Proctitis	<i>N. gonorrhoeae</i> <i>C. trachomatis</i> Herpes simplex virus <i>Campylobacter jejuni</i> <i>Shigella</i> species <i>Entamoeba histolytica</i>
Hepatitis	<i>T. pallidum</i> Hepatitis A, hepatitis B, and hepatitis C viruses
Dermatitis	<i>Sarcoptes scabiei</i> <i>Phthirus pubis</i>
Genital ulceration or warts	<i>C. trachomatis</i> Herpes simplex virus Human papilloma virus <i>T. pallidum</i> <i>Haemophilus ducreyi</i> <i>Calymmatobacterium granulomatis</i>

Chlamydia infection, gonorrhea, syphilis, chancroid, human immune deficiency virus (HIV) infection, and acquired immune deficiency syndrome (AIDS) are reportable to local health authorities in every state ([Centers for Disease Control and Prevention \[CDC\], 2017c](#)). Other STIs such as genital herpes (GH) may or may not be reported, depending on local legal requirements. Positive results can be reported by clinicians and laboratories. Reports are kept strictly confidential.

Nurses in a variety of settings are responsible for identifying people at risk for STIs, caring for patients with diagnosed STIs, and preventing further cases through education and case finding. Nurses in primary care community settings and acute care settings have a responsibility to recognize patients who are at risk for or who have STIs, possibly while being treated for another unrelated health problem.

The CDC provides regularly updated guidelines for treatment of STIs. These best practice guidelines provide information, treatment standards, and counseling advice to help decrease the spread of these diseases and their complications ([CDC, 2015](#)).

## Gender Health Considerations

### Patient-Centered Care QSEN

Because of the very vascular and large surface area of the mucous membranes of the vagina, women are more easily infected with STIs and are at greater risk for STI-related health problems than are men. Young women who are sexually active with men have the greatest risk for contracting an STI. Younger adults have greater rates of sexual activity, including more partners and more unprotected sex than older adults. Women are also more vulnerable to infections because of the exposure of cervical basal epithelium cells. Lesbian women have a *decreased* risk for STIs because of fewer partners, although many have or have had sex with men.

Some young women may also be at high risk because they:

- Lack knowledge about the risk for disease
- Believe that they are not vulnerable to disease
- Mistakenly believe that contraceptives also protect them from STIs
- Drink alcohol in binges, which promotes risky sexual behavior

Postmenopausal women also may be at risk for STIs because many perceive that pregnancy is no longer likely and thus do not use barrier protection. Changing social relationships (e.g., divorce and widowhood in the middle years) have changed risk for exposure to STIs. Physiologic changes during menopause such as mucosal tears from vaginal atrophy may also place them at risk.

Women have more asymptomatic infections that may delay diagnosis and treatment. Many infectious organisms reside in the cervical os and cause little change in vaginal discharge or vulvar tissue, so women are not aware that they are infected. This delay increases the likelihood of complications, including ascending infections that may cause reproductive organ damage and

illness. Embarrassment, denial, or fear about STIs may further delay treatment, increasing the potential for serious complications.

## Health Promotion and Maintenance

One of the *Healthy People 2020* objectives is to completely eliminate syphilis in the United States (U.S. Department of Health and Human Services [USDHHS], 2017) (Table 74-2). One of the primary tools for prevention of sexually transmitted diseases (STIs), including syphilis, is education. All people, regardless of age, gender, ethnicity, socioeconomic status, education level, gender identity, or sexual orientation, are susceptible to these diseases. Health literacy, motivation, and perceived risk can affect the health status of any patient. STIs are largely preventable through safer sex practices. Do not assume that a person is not sexually active because of his or her age, education, marital status, profession, or religion. Discuss prevention methods, including safer sex, with all patients who are or may become sexually active.

**TABLE 74-2**

### Meeting *Healthy People 2020* Objectives and Targets for Improvement: Sexually Transmitted Infections/Diseases

- Reduce the proportion of adolescents and young adults with *Chlamydia trachomatis* infections (by 10%).
- Reduce the proportion of females ages 15 to 44 years who have ever required treatment for pelvic inflammatory disease (by 10%).
- Reduce gonorrhea rates (by 10%).
- Reduce sustained domestic transmission of primary and secondary syphilis (by 10%).
- Reduce the proportion of females with human papilloma virus (HPV) infection (no specific target).
- Reduce the proportion of young adults with genital herpes due to herpes simplex type 2 (by 10%).

**Safer sex practices** are those that reduce the risk for nonintact skin or mucous membranes coming in contact with infected body fluids and blood. These practices include:

- Using a latex or polyurethane condom for genital and anal intercourse
- Using a condom or latex barrier (dental dam) over the genitals or anus during oral-genital or oral-anal sexual contact
- Wearing gloves for finger or hand contact with the vagina or rectum
- Abstinence
- Mutual monogamy
- Decreasing the number of sexual partners

# Genital Herpes

## ❖ Pathophysiology

**Genital herpes (GH)** is an acute, recurring, incurable viral disease. It is the most common STI in the United States. The prevalence among African Americans is higher than for Euro-Americans, disproportionately affecting African-American women more than men (CDC, 2017c).

Two serotypes of herpes simplex virus (HSV) affect the genitalia: type 1 (HSV-1) and type 2 (HSV-2) (McCance et al., 2014). Most *nongenital* lesions such as cold sores are caused by HSV-1, transmitted via oral-oral contact. Historically HSV-2 caused most of the genital lesions. However, this distinction is academic because the transmission, symptoms, diagnosis, and treatment are nearly identical for the two types. Either type can produce oral or genital lesions through oral-genital or genital-genital contact with an infected person. HSV-2 recurs and sheds asymptotically more often than HSV-1. Most people with GH have not been diagnosed because they have mild symptoms and shed virus intermittently.

The incubation period of genital herpes is 2 to 20 days, with the average period being 1 week. Many people do not have symptoms during the primary outbreak. Whether the patient is symptomatic or not, the virus remains dormant and recurs periodically. *Therefore, recurrences are not caused by re-infection. However, there is viral shedding, and the patient is infectious.* Long-term complications of GH include the risk for neonatal transmission and an increased risk for acquiring HIV infection (McCance et al., 2014).

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

The diagnosis of GH is based on the patient's history and physical examination (Chart 74-1). Ask the patient if he or she felt itching or a tingling sensation in the skin 1 to 2 days before the outbreak, known as the *prodrome*. These sensations are usually followed by the appearance of **vesicles** (blisters) in a typical cluster on the penis, scrotum, vulva, vagina, cervix, or perianal region at the site of inoculation. The blisters rupture spontaneously in a day or two and leave painful ulcerations that can become extensive. Assess for other symptoms such as headaches, fever, general malaise, and swelling of inguinal lymph nodes. Ask if urination is painful. External dysuria is a painful symptom when urine passes over the eroded areas. Patients with urinary retention may need to be catheterized. Lesions resolve within 2 to 6 weeks.

### Chart 74-1

## Focused Assessment

### The Patient With a Sexually Transmitted Infection

Assess history of present illness:

- Chief concern
- Onset
- Symptoms by quality and quantity, precipitating and palliative factors
- Any treatments taken (self-prescribed or over-the-counter products)

Assess past medical history:

- Major health problems, including any history of STIs/PID or immunosuppression
- Surgeries: obstetric and gynecologic, circumcision

Assess current health status:

- Menstrual history for irregularities
- Sexual history:
  - Type and frequency of sexual activity
  - Number of lifetime and past 6 months sexual contacts/partners; monogamous
  - Sexual orientation
  - Contraception history
  - Medications
  - Allergies
  - Lifestyle risks: drugs, alcohol, tobacco

Assess preventive health care practices:

- Papanicolaou (Pap) tests
- Regular STI screening
- Use of barrier contraceptives to prevent STIs and pregnancy

Assess physical examination findings:

- Vital signs
- Oropharyngeal findings
- Abdominal findings
- Genital or pelvic findings
- Anorectal findings

Assess laboratory data:

- Urinalysis
- Hematology
- ESR or CRP if PID is being considered
- Cervical, urethral, oral, rectal specimens
- Lesion samples for microbiology and virology
- Pregnancy testing

*CRP*, C-reactive protein; *ESR*, erythrocyte sedimentation rate; *PID*, pelvic inflammatory disease; *STI*, sexually transmitted infection.

After the lesions heal, the virus remains in a dormant state in the sacral nerve ganglia. Periodically the virus may activate, and symptoms recur. These recurrences may be triggered by many factors, including stress, fever, sunburn, poor nutrition, menses, and sexual activity. Assess the patient for these risk factors to provide anticipatory guidance for prevention of outbreaks.

GH is confirmed through a viral cell culture or polymerase chain reaction (PCR) assays of the lesions. PCR is the more sensitive test and is currently the gold standard; however, it is very expensive and usually not available. Fluid from inside the blister obtained within 48 hours of the first outbreak will yield the most reliable results because accuracy decreases as the blisters begin to heal. Serology testing, which is glycoprotein G antibody based, can identify the HSV type, either 1 or 2. Serologic tests are used to identify infection in high-risk groups such as HIV-positive patients, patients who have partners with HSV, or men who have sex with men (MSM) (CDC, 2017a). Antibodies may take up to 12 weeks to develop, so false-negative results can occur if tested too soon after the initial infection.

#### ◆ **Interventions: Responding**

The desired outcomes of treatment for HSV-infected patients are to decrease the impaired COMFORT from painful ulcerations, promote healing without secondary infection, decrease viral shedding, and prevent infection transmission (Chart 74-2).

### 📊 **Chart 74-2**

## **Best Practice for Patient Safety & Quality Care** QSEN

### **Care of or Self-Management for the Patient With Genital Herpes**

- Administer oral analgesics as prescribed.
- Apply local anesthetic sprays or ointments as prescribed.
- Apply ice packs or warm compresses to the patient's lesions.
- Administer sitz baths three or four times a day.
- Urge an increase in fluid intake to replace fluid lost through open lesions.
- Encourage frequent urination.

- Pour water over the patient's genitalia while voiding or encourage voiding while the patient is sitting in a tub of water or standing in a shower.
- Catheterize the patient as necessary.
- Encourage genital hygiene, and encourage keeping the skin clean and dry.
- Wash hands thoroughly after contact with lesions and launder towels that have had direct contact with lesions.
- Wear gloves when applying ointments or making any direct contact with lesions.
- Advise the patient to avoid sexual activity when lesions are present.
- Advise the patient to use latex or polyurethane condoms during all sexual exposures.
- Instruct the patient in the use, side effects, and risks versus benefits of antiviral agents.
- Advise the patient to discuss the diagnosis of genital herpes (GH) with current and new partners.

### Drug Therapy.

Antiviral drugs are used to treat GH. The drugs decrease the severity, promote healing, and decrease the frequency of recurrent outbreaks but do not cure the infection.

Drug therapy should be offered to anyone with an initial outbreak of GH regardless of the severity of the symptoms. Topical therapy is not recommended. Acyclovir (Zovirax, Avirax), famciclovir (Famvir), or valacyclovir (Valtrex) may be prescribed. The main differences in these drugs are cost and frequency of use. Dosage and length of treatment differ for primary outbreaks (7 to 10 days) and recurrent outbreaks (1 to 5 days). Therapy for recurrent outbreaks is most beneficial if it is started within 1 day of the appearance of lesions or during the period of itching or tingling before lesions appear. Intermittent or continuous (daily) suppressive antiviral therapy is offered to patients to lessen the severity and frequency of or to prevent outbreaks, even for those with infrequent recurrent episodes (Burchum & Rosenthal, 2016).

Suppression reduces recurrences in most patients, but it does not prevent viral shedding, even when symptoms are absent. Patients receiving continuous therapy should periodically (possibly once a year) be reassessed for recurrences, usually by stopping the antiviral drug temporarily.

IV acyclovir and hospitalization may be indicated for patients with severe HSV infections, such as disseminated (systemic) disease or encephalitis (brain infection). These are severe complications of genital herpes and may be fatal.

### Self-Management Education.

Nursing interventions focus on patient education about the infection, sexual transmission, potential for recurrent episodes, and correct use and possible side effects of antiviral therapy. Frank discussion about sexual activity, including whether the patient has new or multiple partners, is an essential component of the nurse's intervention.

## Nursing Safety Priority QSEN

### Action Alert

Remind patients to abstain from sexual activity while GH lesions are present. Sexual activity can be painful, and likelihood of viral transmission is higher. Urge condom use during all sexual exposures because of the increased risk for HSV transmission from viral shedding, which can occur even when lesions are not present. Teach the patient about how to use condoms (Chart 74-3).

### Chart 74-3

## Patient and Family Education: Preparing for Self-

## Management

### Use of Condoms

- Use latex or polyurethane condoms rather than natural membrane condoms.
- Use a condom with every sexual encounter (including oral, vaginal, and anal).
- Female condoms (Reality)—polyurethane or nitrile sheaths in the vagina—are effective in preventing transmission of viruses, including HIV.
- Condoms infrequently (2 per 100) break during sexual intercourse.
- Keep condoms (especially latex) in a cool, dry place, out of direct sunlight.
- Do not use condoms that are in damaged packages or are brittle or discolored.
- Always handle a condom with care to avoid damaging it with fingernails, teeth, or other sharp objects.
- Put condoms on before any genital contact. Hold the condom by the tip and unroll it on the penis. Leave a space at the tip to collect semen.
- If you use a lubricant with condoms, make sure that the lubricant is water based and washes away with water. Oil-based products damage latex condoms.
- Use of spermicide (nonoxynol-9) with condoms, either lubricated condoms or vaginal application, has *not* been proven to be more or less effective against STIs than use without spermicide. Spermicide-coated condoms have been associated with *Escherichia coli* urinary tract infections in women. *Nonoxynol-9 may increase risk for transmission of HIV during vaginal and anal intercourse. Its use is discouraged.*
- If a condom breaks, replace it immediately.
- After ejaculation, withdraw the erect penis carefully, holding the condom at the base of the penis to prevent the condom from slipping off.
- Never use a condom more than once.

*HIV*, Human immune deficiency virus; *STI*, sexually transmitted infection.

Modified from Centers for Disease Control and Prevention (CDC). (2015). Sexually transmitted diseases treatment guidelines, 2015. *Morbidity and Mortality Weekly Report*, 64(RR-3), 1-137.

Assess the patient's and partner's emotional responses to the diagnosis of genital herpes. Many people are initially shocked and need reassurance that they can manage the disease. Infected patients may have feelings of disbelief, uncleanness, isolation, and loneliness. They may also be angry at their partner(s) for transmitting the infection or fear rejection because they have it. Help patients cope with the diagnosis by being sensitive and supportive during assessments and interventions. Encourage social support and refer patients to support groups (e.g., local support groups of the National Herpes Resource Center [[www.ashsexualhealth.org/std-sti/Herpes.html](http://www.ashsexualhealth.org/std-sti/Herpes.html)]) and therapists. Symptomatic care may include oral analgesics, topical anesthetics, sitz baths, and increased oral fluid intake. People who have tested serology positive to HSV-1 or HSV-2 but have never had GH symptoms should be counseled with the same information as those who have symptoms.

# Syphilis

## ❖ Pathophysiology

**Syphilis** is a complex sexually transmitted infection (STI) that can become systemic and cause serious complications, including death. The causative organism is a spirochete called *Treponema pallidum*. The infection is usually transmitted by sexual contact and blood exposure, but transmission can occur through close body contact such as kissing.

Syphilis progresses through four stages: primary, secondary, latent, and tertiary. The appearance of an ulcer called a **chancre** is the first sign of *primary* syphilis. It develops at the site of entry (inoculation) of the organism from 10 to 90 days after exposure (3 weeks is average). Chancres may be found on any area of the skin or mucous membranes but occur most often on the genitalia, lips, nipples, and hands and in the mouth, anus, and rectum.

During this highly infectious stage, the chancre begins as a small papule. Within 3 to 7 days, it breaks down into its typical appearance: a painless, indurated, smooth, weeping lesion. Regional lymph nodes enlarge, feel firm, and are not painful. Without treatment, the chancre usually disappears within 6 weeks. However, the organism spreads throughout the body, and the patient is still infectious.

*Secondary* syphilis develops 6 weeks to 6 months after the onset of primary syphilis. During this stage, syphilis is a systemic disease because the spirochetes circulate throughout the bloodstream. Commonly mistaken for influenza, manifestations include flulike symptoms (malaise, low-grade fever, headache, muscular aches, sore throat) and a generalized rash. There is no typical appearance of this rash except for its presence on the palms and soles of the feet and on mucous membranes. It can appear as diffuse macules (reddish brown), papules (usually less than 5 mm) or pustules, scaly psoriasis-like lesions (Fig. 74-1), or gray-white wartlike lesions (condylomata lata). *All of these lesions are highly contagious and should not be touched without gloves.* Patchy alopecia on the scalp or facial hair (missing part of the eyebrow, “moth-eaten” appearance) is another symptom. The rash subsides without treatment in 4 to 12 weeks (McCance et al., 2014).

**FIG. 74-1** Palmar and plantar secondary syphilis. (From Morse, S., Ballard, R., Holmes, K., & Moreland, A. (2003). *Atlas of sexually transmitted diseases and AIDS* (3rd ed.). Edinburgh: Mosby.)

After the second stage of syphilis, there is a period of latency. *Early latent* syphilis occurs during the first year after infection, and infectious lesions can recur. *Late latent* syphilis is a disease of more than 1 year's duration after infection. This stage is not infectious except to the fetus of a pregnant woman. Patients with latent syphilis may or may not have reactive serologic test (e.g., Venereal Disease Research Laboratory [VDRL]) findings.

*Tertiary, or late,* syphilis occurs after a highly variable period, from 4 to 20 years. This stage develops in untreated cases and can mimic other conditions because any organ system can be

affected. Signs and symptoms of late syphilis include (McCance et al., 2014):

- Benign lesions of the skin, mucous membranes, and bones
- Cardiovascular syphilis, usually in the form of aortic valvular disease and aortic aneurysms
- Neurosyphilis, causing central nervous system symptoms (e.g., meningitis, hearing loss, generalized paresis [weakness])

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

HEALTH CARE DISPARITIES exist between racial and ethnic groups in the incidence of primary and secondary syphilis. In the most recent report from the CDC (2017c), the rates increased among Hispanics, American Indians/Alaska Natives, Euro-Americans, and most dramatically among Asian/Pacific Islanders; rates have *decreased* among African Americans. Nevertheless, African Americans have a seven times greater rate of acquiring syphilis than whites. Compared with Euro-Americans, the 2014 rate for Hispanics was two times higher (CDC, 2017c). The reason for these differences is unclear, but status of health literacy and lack of access to health care may be factors.

## Gender Health Considerations

### Patient-Centered Care QSEN

Unique needs regarding sexual health and prevention and treatment of STIs for lesbian, gay, bisexual, transgender, and questioning (LGBTQ) patients should be identified and addressed by the nurse. Because of discrimination, HEALTH CARE DISPARITIES, and health care provider lack of understanding, the overall health status of people in these populations may be poor. LGBTQ people may have difficulty finding health care that identifies and addresses their particular risks and concerns. Taking a health history that provides opportunity for the patient to identify his or her sexual orientation, gender identity, and sexual activity is crucial. Especially among transgender people, opportunities for physical examination are avoided or missed by both the patient and care provider because of fears of being misunderstood or inadequately prepared to give or receive appropriate care (CDC, 2017a). The CDC does not currently collect or report the incidence or prevalence of STIs among transgender people.

Men who have sex with men (MSM) are at greatest risk for contracting primary and secondary syphilis and made up 75% of cases of these diseases in 2012 (CDC, 2017a). These men are 17 times more likely to have anal cancer than heterosexual men, and those infected with HIV are at even greater risk. Infection with high-risk human papilloma virus (HPV) has been associated with greater risk for anal cancers among this population (CDC, 2017a).

Assuming that lesbian women or gay men have sex only with same-gender partners or similarly assuming that heterosexual patients never have sexual encounters with partners of their same sex may limit the accuracy of the nurse's risk assessment. Nurses must be aware that patients may not reveal that they are bisexual. Establish a trusting relationship and be culturally sensitive and nonjudgmental when working with LGBTQ patients. Chapter 1 describes recommendations for communicating with this population. Chapter 73 discusses the special health care needs of transgender patients.

## Interprofessional Collaborative Care

### Assessment: Noticing

Assessment of the patient who has signs and symptoms of syphilis begins with a history to gather information about any ulcers or rash. Take a sexual history and conduct a risk assessment to include whether previous testing or treatment for syphilis or other STDs has ever been done (see [Chart 74-1](#)). Ask about allergic reactions to drugs, especially penicillin. A woman may report inguinal lymph node enlargement resulting from a chancre in the vagina or cervix that is not easily visible to her. She may state a history of sexual contact with a male partner who had an ulcer that she noticed during the encounter. Men usually discover the chancre on the penis or scrotum.

Conduct a physical examination, including inspection and palpation, to identify signs and symptoms of syphilis. *Wear gloves while palpating any lesions because of the highly contagious treponemes that are present.* Observe for and document rashes of any type because of the variable presentation of secondary syphilis.

After the physical examination, the health care provider obtains a *specimen of the chancre* for examination under a darkfield microscope. Diagnosis of primary or secondary syphilis is confirmed if *T. pallidum* is present.

Blood tests are also used to diagnose syphilis. The usual screening and/or diagnostic nontreponemal tests are the *Venereal Disease Research Laboratory (VDRL)* serum test and the more sensitive *rapid plasma reagin (RPR)*. These tests are based on an antibody-antigen reaction that determines the presence and amount of antibodies produced by the body in response to an infection by *T. pallidum*. They become reactive 2 to 6 weeks after infection. VDRL titers are also used to monitor treatment effectiveness. The antibodies are not specific to *T. pallidum*; and false-positive reactions often occur from conditions such as viral infections, hepatitis, and systemic lupus erythematosus (SLE) (Pagana et al., 2017).

If a VDRL result is positive, the primary health care provider requests or the laboratory may automatically perform a more specific treponemal test, such as the *fluorescent treponemal antibody absorption (FTA-ABS)* test or the *microhemagglutination assay for T. pallidum (MHA-TP)*, to confirm the infection. These tests are more sensitive for all stages of syphilis, although false-positive results may still occur. Patients who have a reactive test will have this positive result for their entire life, even after sufficient treatment. This poses a challenge when receiving a positive result for a patient who denies a history of or does not know that he or she had syphilis.

#### ◆Interventions: Responding

Interprofessional collaborative care includes drug therapy and health teaching to resolve the infection and prevent infection transmission to others. Benzathine penicillin G given IM as a single 2.4 million-unit dose is the evidence-based treatment for primary, secondary, and early latent syphilis (CDC, 2015). Patients in the late latent stage receive the same dose every week for 3 weeks (CDC, 2015). A different regimen, found in the CDC's 2015 STD Treatment Guidelines, is recommended for patients who are HIV-infected or pregnant.

### 📌Nursing Safety Priority QSEN

#### Drug Alert

Allergic reactions to benzathine penicillin G can occur. Monitor for allergic manifestations (e.g., rash, edema, shortness of breath, chest tightness, anxiety). Penicillin desensitization is recommended for penicillin-allergic patients. *Keep all patients at the health care agency for at least 30 minutes after they have received the antibiotic so manifestations of an allergic reaction can be detected and treated. The most severe reaction is anaphylaxis. Treatment should be available and implemented immediately if symptoms occur.* Chapter 20 describes the management of drug allergies in detail.

After treatment, the CDC recommends follow-up evaluation, including blood tests at 6, 12, and 24 months. Repeat treatment may be needed if the patient does not respond to the initial antibiotic.

The *Jarisch-Herxheimer reaction* may also follow antibiotic therapy for syphilis. This reaction is caused by the rapid release of products from the disruption of the cells of the organism. Symptoms include generalized aches, pain at the injection site, vasodilation, hypotension, and fever. They are usually benign and begin within 2 hours after therapy with a peak at 4 to 8 hours. This reaction may be treated symptomatically with analgesics and antipyretics (Burchum & Rosenthal, 2016).

*Discuss with the patient with syphilis the importance of partner notification and treatment, including the risk for re-infection if the partner goes untreated. All sexual partners must be prophylactically treated as soon as possible, preferably within 90 days of the syphilis diagnosis.*

Inform the patient that the disease will be reported to the local health authority and that all information will be held in strict confidence. Encourage him or her to provide accurate information for this follow-up to ensure that all at-risk partners are treated appropriately. Provide a setting that offers privacy and encourages open discussion. Urge the patient to keep follow-up appointments. For primary and secondary syphilis, drug therapy is provided at the first visit, which may suggest

to the patient that no further visits are indicated or important. Remind the patient that follow-up for partners and assessment that symptoms have resolved are imperative and part of continuing care. Recommend sexual abstinence until the treatment of both the patient and partner(s) is completed.

The emotional responses to syphilis vary and may include feelings of fear, depression, guilt, and anxiety. Patients may experience guilt if they have infected others or anger if a partner has infected them. If further psychosocial interventions are needed, encourage the patient to discuss these feelings or refer him or her to other resources such as psychotherapy, self-help support groups, or STI/STD clinics.

## **NCLEX Examination Challenge 74-1**

### **Physiological Integrity**

The nurse gives a client an IM dose of penicillin G for primary syphilis. Which client statement indicates a need for further teaching?

- A. "I'll wait in the clinic for 30 minutes to be sure I don't have a reaction."
- B. "When I get home, I'll call my partner to tell them about my diagnosis."
- C. "If I have sex with someone, I don't have to worry about spreading the disease."
- D. "I plan to return to see my primary care provider for follow-up in 6, 12, and 24 months."

## Condylomata Acuminata (Genital Warts)

### ❖ Pathophysiology

Condylomata acuminata (also known as *genital warts*) are caused by certain types of *human papilloma virus (HPV)*, most of which are types 6 and 11 or low-risk HPV. These types *rarely* result in invasive cancer of the genital tract such as cervical cancer. However, HPV types 16, 18, 31, 33, and 35, considered high-risk HPV, can be found on the skin of the genitalia and increase the risk for genital cancers, especially cervical cancer (McCance et al., 2014). Infection with several HPV types can occur at the same time. The presence of one strain increases the risk for acquiring a higher-risk strain. Genital warts are the most common viral disease that is sexually transmitted and are often seen with other infections.

*HPV infection has been established as the primary risk factor for development of cervical cancer.* Sites commonly affected by infection include the urinary meatus, labia, vagina, cervix, penis, scrotum, anus, and perineal area. The incubation period is usually 2 to 3 months. There is growing evidence that HPV infection through oral and anal sex, especially in men who have sex with men (MSM), may be a risk factor for developing oral and anal cancers (CDC, 2017a).

### ❖ Interprofessional Collaborative Care

#### ◆ Assessment: Noticing

The diagnosis of condylomata acuminata is made by examination of the lesions. They are initially small, white or flesh-colored papillary growths that may grow into large cauliflower-like masses (Fig. 74-2). Multiple warts usually occur in the same area. Bleeding may occur if the wart is disturbed. Warts may disappear or resolve on their own without treatment. They may occur once or recur at the original site. Warts can occur on the external or internal surfaces of the genitalia, including the mucosal surfaces of the vagina and urethra.

**FIG. 74-2** Perianal condylomata acuminata. (From Morse, S., Ballard, R., Holmes, K., & Moreland, A. [2003]. *Atlas of sexually transmitted diseases and AIDS* [3rd ed.]. Edinburgh: Mosby.)

Screening for HPV and dysplasia of the cervix is done by obtaining cervical specimens for Papanicolaou (Pap) and HPV DNA testing. Identifying high-risk strains of HPV and correlating with abnormal Pap smear findings are the standard of care (CDC, 2015). High-risk HPV may coexist with low-risk HPV, the likely cause of the warts. The diagnosis should include consideration of condyloma lata or secondary syphilis since STIs frequently coexist. A VDRL test, HIV test, and

cultures for chlamydia and gonorrhea infections are done. Condylomata lata (secondary syphilis) can resemble condylomata acuminata (genital warts). If a wartlike lesion bleeds easily, appears infected, is atypical, or persists, a biopsy of the lesion is performed to rule out other pathologic problems such as cancer. A biopsy of warts that are seen on the cervix should be performed before any treatment to eradicate them.

### ◆Interventions: Responding

The outcome of treatment is to remove the warts. No current therapy eliminates the HPV infection, and recurrences after treatment are likely. It is not known whether removal of visible warts decreases the risk for disease transmission.

### Drug Therapy.

Patients may apply podofilox (Condylox) 0.5% cream or gel twice daily for 3 days with no treatment for the next 4 days. This regimen should be repeated for four cycles. Other options are imiquimod (Aldara) 5% cream applied topically at bedtime three times a week and sinecatechins 15% ointment (made from green tea extract) applied three times a day, both until the warts disappear or for up to 16 weeks. Imiquimod boosts the immune system rather than simply destroying the warts (Burchum & Rosenthal, 2016). These self-treatments are less expensive than those performed in the health care provider's office, but they take longer for healing. *Teach patients that over-the-counter (OTC) wart treatments should not be used on genital tissue.*

Cryotherapy, trichloroacetic acid (TCA) or bichloroacetic acid (BCA), and podophyllin (Pododerm) are provider-applied treatments. **Cryotherapy** (freezing), usually with liquid nitrogen, can be used every 1 to 2 weeks until lesions are resolved. TCA/BCA (80% to 90%) can be applied weekly. Podophyllin resin can be applied weekly but needs to be washed off 1 to 4 hours after application. Extensive warts have been treated with the carbon dioxide laser, intra-lesion interferon injections, and surgical removal (CDC, 2015).

### Self-Management Education.

The priority nursing intervention is patient and sexual partner education about the mode of transmission, incubation period, treatment, and complications, especially the association with cervical cancer. Reinforce instructions about local care of the lesions or patient-applied treatment for self-management.

## ■Nursing Safety Priority QSEN

### Drug Alert

Teach patients that, after treatment with cryotherapy, podophyllin, or TCA, they may experience impaired COMFORT, bleeding, or discharge from the site or sloughing of parts of warts. Instruct them to keep the area clean (shower or bath) and dry. Teach them to be alert for any signs or symptoms of infection or side effects of the treatment.

Inform patients that recurrence is likely, especially in the first 3 months, and that repeated treatments may be needed. Urge all patients to have complete STI testing, since exposure to one STI may increase risk for contracting another. Sexual partners should also be evaluated and offered treatment if warts are present. Teach patients to avoid intimate sexual contact until external lesions are healed. Recommend condoms to help reduce transmission even after warts have been treated (see Chart 74-3). Encourage women to have a Pap test annually, starting at age 21 years; after they have had three normal smears, they should have a Pap test every 3 years if no new risk factors are present (e.g., new partner, other STIs). The presence of warts should increase suspicion that the patient may have had exposure to other STDs, which warrants additional testing.

*Gardasil* is used to provide immunity for HPV types 6 and 11 (predominantly types causing warts, low risk for cervical cancer) and 16 and 18 (high risk for cervical cancer). Initially approved for females, the vaccine is also recommended for males ages 9 to 26 years. Cervarix may be given to 9- to 25-year-old females and protects only against HPV types 16 and 18 (Burchum & Rosenthal, 2016). Both vaccines are recommended before onset of sexual activity (and before age 26 years) and

possible exposure to HPV. Because exposure to HPV is likely for most sexually active young adults, vaccination protects them against the strains to which they have not yet been exposed. Vaccination is also especially encouraged for MSM and immunocompromised young adults up to the age of 26 years ([CDC, 2015](#)).

# Chlamydia Infection

## ❖ Pathophysiology

*Chlamydia trachomatis* is an intracellular bacterium and the causative agent of genital chlamydia infections. It invades the epithelial tissues in the reproductive tract. The incubation period ranges from 1 to 3 weeks, but the pathogen may be present in the genital tract for months without producing symptoms.

*C. trachomatis* is reportable to local health departments in all states. Diagnosed cases continue to increase yearly, which reflects more sensitive screening tests and increased public health efforts to screen high-risk people. Because it is frequently asymptomatic, the estimated incidence is about double that reported. African-American women between 15 and 24 years of age are at the highest risk for the disease (CDC, 2017c). The exact reason for this health care disparity is not known.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

Obtain a complete history, including a genitourinary system review, psychosocial history, and sexual history (see Chart 74-1). In particular, ask about:

- Presence of symptoms, including vaginal or urethral discharge, **dysuria** (painful urination), pelvic pain, irregular bleeding
- Any history of sexually transmitted diseases (STIs)
- Whether sexual partners have had symptoms or a history of STIs
- Whether patient has had a new or multiple sexual partner(s)
- Whether patient or partner has had unprotected intercourse

About 70% of chlamydia infections are asymptomatic in women. For men and women, their history may reveal only risk factors associated with *C. trachomatis*, such as new or multiple sexual partners, age younger than 26 years and female, or a male having sex with a male (MSM). As with all interviews concerning sexual behavior, use a nonjudgmental approach and provide privacy and confidentiality.

## Gender Health Considerations

### Patient-Centered Care QSEN

For men, ask about dysuria, frequent urination, and a mucoid discharge that is more watery and less copious than a gonorrheal discharge. These signs and symptoms indicate urethritis, the main symptom of chlamydia infection in men. Some men have the discharge only in the morning on arising. Complications include epididymitis, prostatitis, infertility, and Reiter's syndrome, a type of connective tissue disease.

In contrast, many women have no symptoms. Those with symptoms have mucopurulent vaginal discharge (typically yellow and more opaque), urinary frequency, and abdominal discomfort or pain. Cervical bleeding, from infected and therefore fragile tissue, may present as spotting or bleeding between menses and frequently after intercourse. Complications of infection with *C. trachomatis* include salpingitis (inflammation of the fallopian tubes), pelvic inflammatory disease (PID), and REPRODUCTION problems including ectopic pregnancy and infertility. These health problems are discussed in detail in maternal-child textbooks.

Diagnosis is made by sampling cells from the endocervix, urethra, or both, easily obtained with a swab. Because chlamydiae can reproduce only inside cells, cervical (or host) cells that harbor the organism (or parts of it) are required in the sample. Tissue culture (the gold standard) obtained from the cervical os during the female pelvic examination or from male urethral examination obtained by swabbing has been replaced by genetic tests. As with gonorrhea, the nucleic acid amplification tests (NAATs) and gene amplification tests (ligand chain reaction [LCR], and

polymerase chain reaction [PCR] transcription-mediated amplification) are the newest methods of detecting *Chlamydia* in endocervical samples, urethral swabs, and urine. They are more sensitive than the tissue culture. Samples can be obtained by swab by the examining clinician or by a patient-collected urine specimen. This urine self-collection method has been found to be more acceptable and highly sensitive and specific. The acceptability of urine testing has resulted in increased identification of asymptomatic people.

All sexually active women 24 years old or younger and all women older than 25 years with new or multiple partners should be screened annually for *Chlamydia*. There is no recommendation for or against screening asymptomatic men, regardless of age or other risk, and low-risk asymptomatic women.

### ◆Interventions: Responding

The treatment of choice for chlamydia infections is azithromycin (Zithromax) 1 g orally in a single dose or doxycycline (Monodox, Doxy-Caps, Doxycin) 100 mg orally twice daily for 7 days. The one-dose course, although more expensive, is preferred because of the ease in completing the treatment. Directly observing the patient taking the medication in the health care setting assures the nurse of compliance. Drugs that are prescribed for patients with allergies to these drugs include erythromycin, ofloxacin, and levofloxacin, all for 7 days (CDC, 2015).

Sexual partners should be treated and tested for other STDs. Expedited partner therapy, or patient-delivered partner therapy, shows signs of reducing chlamydia infection rates (CDC, 2015). **Expedited partner therapy (EPT)** is the practice of treating sexual partners of patients diagnosed with chlamydia infection or gonorrhea by providing prescriptions or medication to the patient, which they can take to their partner(s), without the primary health care provider examining the partner(s). When patients have been given the drug to give to their partner, rates of infection have decreased, and more partners have reported receiving treatment (CDC, 2015).

Patient and partner education is a crucial nursing intervention. Explain:

- The sexual mode of transmission
- The incubation period
- The high possibility of asymptomatic infections and the usual symptoms if present
- Treatment of infection with antibiotics and need for completion of course of treatment
- The need for abstinence from sexual intercourse until the patient and partner(s) have all completed treatment (7 days from the start of treatment, including a single-dose regimen)
- That women should be re-screened for re-infection 3 to 12 months after treatment because of the high risk for PID; also, that there is less evidence of the need for re-screening of treated men, but it should be considered
- The need to return for evaluation if symptoms recur or new symptoms develop (most recurrences are re-infections from a new or untreated partner)
- Complications of untreated or inadequately treated infection, which may include PID, ectopic pregnancy, or infertility

# Gonorrhea

## ❖ Pathophysiology

Gonorrhea is a sexually transmitted bacterial infection that occurs in both men and women. The causative organism is *Neisseria gonorrhoeae*, a gram-negative intracellular diplococcus. It is transmitted by direct sexual contact with mucosal surfaces (vaginal intercourse, orogenital contact, or anogenital contact) (McCance et al., 2014).

The first symptoms of gonorrhea may appear 3 to 10 days after sexual contact with an infected person. The disease can be present without symptoms and can be transmitted or progress without warning. In women, ascending spread of the organism can cause pelvic infection (pelvic inflammatory disease [PID]), **endometritis** (endometrial infection), **salpingitis** (fallopian tube infection), and pelvic peritonitis.

## 🏠 Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Significant HEALTH CARE DISPARITIES exist between age and racial groups. Young (ages 15 to 24 years) African-American women have the highest gonorrhea rate, followed by young African-American men (CDC, 2017c). The reasons for these differences are not known, although lack of access to health care may be a factor.

## ❖ Interprofessional Collaborative Care

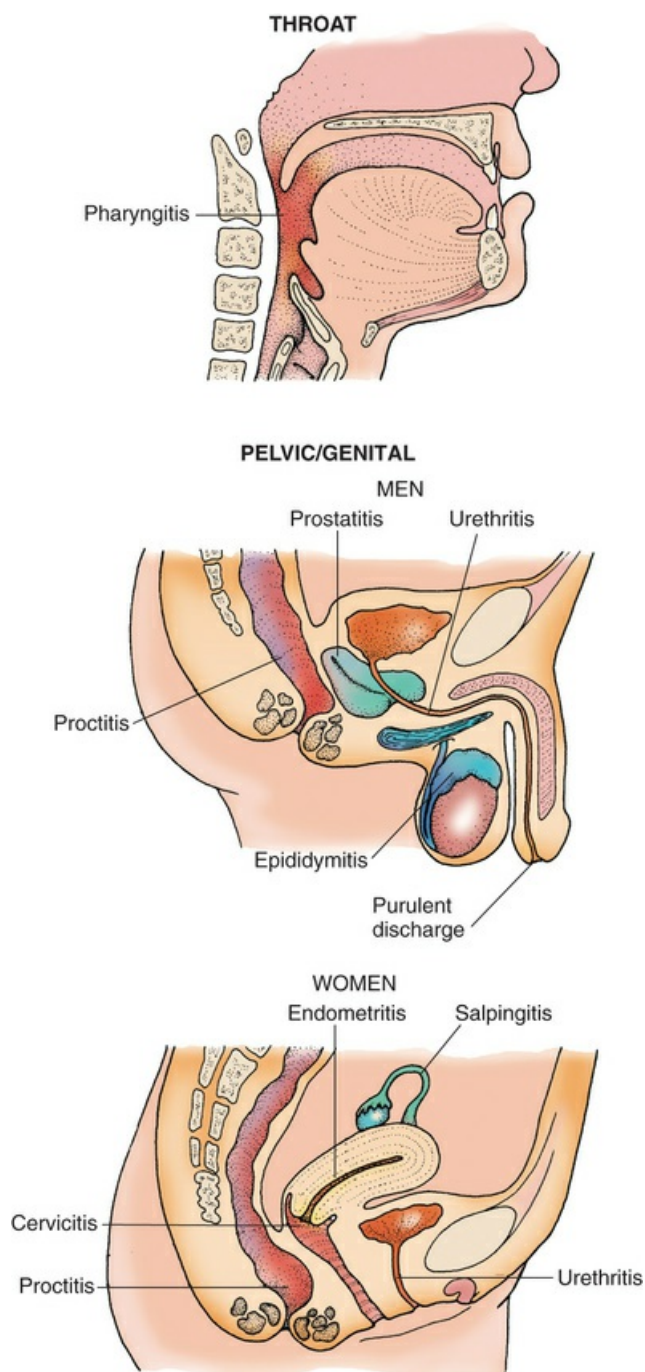

### ◆ Assessment: Noticing

A complete history includes reviewing the genitourinary systems, including taking a sexual history that includes sexual orientation and sites of sexual exposure or intercourse. Assess for allergies to antibiotics (see [Chart 74-1](#)). Establish a trusting relationship and use a nonjudgmental approach to gather more complete information. This approach may decrease the patient's anxiety and fear about having an STI.

The infection can be asymptomatic in both men and women, but women have asymptomatic, or “silent,” infections more often than do men. If symptoms are present, men usually notice dysuria and a penile discharge that can be either profuse, yellowish-green fluid, or scant, clear fluid. The urethra is most commonly affected, but infection can extend to the prostate, the seminal vesicles, and the epididymis. Men seek curative treatment sooner, usually because they have symptoms, and thereby avoid some of the serious complications.

Women may report a change in vaginal discharge (yellow, green, profuse, odorous), urinary frequency, or dysuria. The cervix and urethra are the most common sites of infection.

Anal signs and symptoms may include itching and irritation, rectal bleeding or diarrhea, and painful defecation. Assess the mouth for a reddened throat, ulcerated lips, tender gingivae, and lesions in the throat. [Fig. 74-3](#) shows common sites of gonococcal infections.

**FIG. 74-3** Areas of involvement of gonorrhea in men and women.

If fever occurs, this may be a sign of an ascending (PID or epididymitis) or systemic infection (disseminated gonococcal infection). Symptoms could include joint or tendon pain, either in a single joint or as migratory arthralgias, especially of the knees, elbows, fingers, or toes, and a rash usually on the palms and soles.

Clinical symptoms of gonorrhea can resemble those of chlamydia infection and need to be differentiated. *Molecular testing for N. gonorrhoeae is currently the most widely used standard and preferred over cultures or microscopic examinations.* These nucleic acid amplification tests (NAATs) are highly sensitive and specific. During examination, providers can swab the male urethra or female cervix to obtain specimens. These specimens can be placed in medium for molecular testing, cultured on chocolate agar (gold standard), or viewed microscopically after Gram staining (male urethral specimens only). Patient-collected urine or vaginal swabs can also be used to diagnose both gonorrhea and chlamydia infections, allowing for testing without a full examination.

In men, gonorrhea can be diagnosed by Gram staining smears of urethral discharge that has been

swabbed onto a glass slide, dried, and stained. The presence of gram-negative diplococci is diagnostic for gonococcal urethritis in men. If the man has symptoms, Gram stains are very sensitive and specific for gonorrhea and allow for immediate diagnosis and treatment in the clinical setting. Without symptoms, Gram stains are less reliable. Smears do not confirm the diagnosis in women because the female genital tract normally harbors other *Neisseria* organisms that resemble *N. gonorrhoeae* (Pagana et al., 2017).

All patients with gonorrhea should be tested for syphilis, chlamydia, hepatitis B and hepatitis C, and HIV infection and, if possible, examined for HSV and HPV because they may have been exposed to these STIs as well. Sexual partners who have been exposed in the past 30 days should be examined, and specimens should be obtained.

### ◆Interventions: Responding

Uncomplicated gonorrhea is treated with antibiotics. Chlamydia infection, which is four times more common, is frequently found in patients with gonorrhea. Because of this, patients treated for gonorrhea should also be managed with drugs that treat chlamydia infection.

### Drug Therapy.

Drug therapy recommended by the CDC is ceftriaxone (Rocephin) 250 mg IM *plus* azithromycin (Zithromax) 1 g orally in a single dose *or* doxycycline (Monodox, Doxy-Caps, Doxycin) 100 mg orally twice daily for 1 week to treat a presumed co-infection with *Chlamydia* (up to 40%), unless a negative *Chlamydia* result has been obtained. These combinations seem to be effective for all mucosal gonorrheal infections; treatment failure is rare (CDC, 2015). A test of cure is not required for treatment with ceftriaxone. Advise the patient to return for a follow-up examination if symptoms persist after treatment. Re-infection is usually the cause of these symptoms.

Sexual partners must be treated, not just evaluated, to prevent re-infection. Sexual partners also need to receive education about the infection.

Because the best treatment for gonorrhea is injected Rocephin (ceftriaxone), expedited partner therapy (EPT) is not ideal for treating it. If there is concern that the partner may not come to a health care facility for treatment, providing oral cefixime as an alternative has been recommended by the CDC (2015). Because of the potential for resistance of gonorrhea to cefixime, a test of cure is recommended after treatment is completed.

Gonorrhea infection can become disseminated, requiring hospitalization and IV or IM ceftriaxone 1 g every 24 hours. If symptoms resolve within 24 to 48 hours, the patient may be discharged to home to continue oral antibiotic therapy (cefixime 400 mg twice a day) for at least a week (CDC, 2015).

### Self-Management Education.

Teach the patient about transmission and treatment of gonorrhea. The use of medication to treat chlamydia infection at the same time as treating gonorrhea should be explained to the patient since the likelihood of co-infection is high. Discuss the possibility of re-infection, including the risk for pelvic inflammatory disease (PID) (see discussion of PID later in this chapter). Instruct patients to cease sexual activity until the antibiotic therapy is completed and they no longer have symptoms; but, if abstinence is not possible, urge men and women to use condoms. Explain that gonorrhea is a reportable disease.

When a diagnosis of gonorrhea is made, patients may have feelings of fear or guilt. They may be concerned that they have contracted other STIs or consider the disease a punishment for promiscuity or “unnatural” sex acts. They may believe that acquiring gonorrhea (or any STI) is a risk that they must take to pursue their desired lifestyle. Such feelings can impair relationships with sexual partners. Encourage patients to express their feelings and offer other information and professional resources to help them have a correct understanding of their diagnosis and treatment. Ensuring privacy during your discussion with them and maintaining confidentiality of personal health information are essential in meeting psychosocial needs.

## Clinical Judgment Challenge 74-1

Patient-Centered Care; Evidence-Based Practice **QSEN**

A 20-year-old man has been diagnosed with a chlamydial infection and provided with treatment for the infection. After learning how the infection is transmitted, he states that he is engaged to be married and realizes that his fiancée obviously had sex with someone else who gave her the infection, which he now has. He expresses his anger and states that he is breaking up with her immediately. As the nurse, you explain that medication treatment is available with expedited partner therapy (EPT) for his fiancée and the person with whom she had sexual intercourse. The patient becomes angry and says, "I don't ever want to speak to her again!"

1. What is the best therapeutic approach for working with this patient?
2. What emotional feelings is this patient experiencing? How will you respond to the patient's statement?
3. What is the value of EPT?
4. What health teaching is required about this infection for the patient, including drug therapy and sexual activity?

## Sexuality Concept Exemplar Pelvic Inflammatory Disease

### Pathophysiology

**Pelvic inflammatory disease (PID)** is a complex infectious process in which organisms from the lower genital tract migrate from the endocervix upward through the uterine cavity into the fallopian tubes. The spread of infection to other organs and tissues of the upper genital tract occurs from direct contact with mucosal surfaces or through the fimbriated ends of the tubes to the ovaries, parametrium, and peritoneal cavity (Fig. 74-4). This may involve one or more pelvic structures, including the uterus, fallopian tubes, and adjacent pelvic structures. The most common site is the fallopian tube. Resulting infections include:

FIG. 74-4 The spread of pelvic inflammatory disease.

- Endometritis (infection of the endometrial cavity)
- Salpingitis (inflammation of the fallopian tubes)
- Oophoritis (ovarian infection)
- Parametritis (infection of the parametrium)
- Peritonitis (infection of the peritoneal cavity)
- Tubal or tubo-ovarian abscess

Usually multiple pathogens are involved in the development of PID. Sexually transmitted organisms are most often responsible, especially *C. trachomatis* and *N. gonorrhoeae*. Organisms that are part of the vaginal flora can also cause PID, including *Gardnerella vaginalis*, *Haemophilus influenzae*, *Staphylococcus*, *Streptococcus*, *Mycoplasma*, *Escherichia coli*, and other aerobic and anaerobic organisms. There is increasing evidence that the anaerobes involved in bacterial vaginosis may have a role in the development of PID and increase the risk for infection with HIV, *N. gonorrhoeae*, *C. trachomatis*, and HSV (CDC, 2017b).

The organisms invade the pelvis from an infection ascending from the vagina or cervix. Infections are spread during sexual intercourse, during childbirth (including the postpartum period), and after abortion. *Sepsis and death can occur, especially if treatment is delayed or inadequate.*

PID is one of the leading causes of infertility and is related to the increase in the number of ectopic pregnancies reported in the United States. These complications are discussed in maternal-

newborn textbooks. PID is an acute syndrome resulting in tenderness in the tubes and ovaries (adnexa) and, typically, dull pelvic pain. However, many women experience only mild impaired COMFORT or menstrual irregularity, whereas others have acute pain, which can affect their gait (Table 74-3). Others experience no symptoms at all (i.e., so-called “silent” or “subclinical” PID).

**TABLE 74-3**  
**Diagnostic Criteria for Pelvic Inflammatory Disease**

<p><b>Minimum Criteria for Initiating Empiric Treatment for Pelvic Inflammatory Disease</b></p> <ul style="list-style-type: none"> <li>Sexually active woman and at risk for STIs</li> <li>Pelvic or lower abdominal pain</li> <li>No other cause for illness can be found (e.g., appendicitis)</li> </ul> <p><b>And</b></p> <ul style="list-style-type: none"> <li>Uterine tenderness <i>or</i></li> <li>Adnexal tenderness <i>or</i></li> <li>Cervical motion tenderness (chandelier sign)</li> </ul>
<p><b>Additional Criteria to Increase the Specificity of the Diagnosis of PID</b></p> <ul style="list-style-type: none"> <li>Oral temperature &gt;101° F (&gt;38.3° C)</li> <li>Abnormal cervical or vaginal mucopurulent discharge</li> <li>Presence of white blood cells on saline microscopy of vaginal secretions</li> <li>Elevated erythrocyte sedimentation rate</li> <li>Elevated C-reactive protein</li> <li>Laboratory documentation of cervical infection with <i>Neisseria gonorrhoeae</i> or <i>Chlamydia trachomatis</i></li> </ul>
<p><b>Definitive Criteria for Diagnosing PID, Warranted in Selected Cases</b></p> <ul style="list-style-type: none"> <li>Histopathologic evidence of endometritis on endometrial biopsy</li> <li>Transvaginal sonography or MRI techniques showing thickened, fluid-filled tubes with or without free pelvic fluid or tubo-ovarian complex or Doppler studies suggesting pelvic infection</li> <li>Laparoscopic abnormalities consistent with PID</li> </ul>

PID, Pelvic inflammatory disease; STDs, sexually transmitted diseases.

Modified from Centers for Disease Control and Prevention (CDC). (2015). Sexually transmitted diseases treatment guidelines, 2015. *Morbidity and Mortality Weekly Report*, 64(RR-3), 1-137.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

#### History.

Obtain a complete history of the symptoms with menstrual, obstetric, sexual, and family history and a history of previous episodes of pelvic inflammatory disease (PID) or other sexually transmitted infections (see Chart 74-1). Assess for contraceptive use, a history of reproductive surgery, and other risk factors previously discussed. Ask the patient if sexual abuse has occurred. If so, encourage her to discuss what happened and whether she was seen by a primary health care provider.

Many of the same factors that place women at risk for STIs also place them at risk for PID. Risk factors for sexually active women include:

- Age younger than 26 years
- Multiple sexual partners
- Intrauterine device (IUD) placed within the previous 3 weeks
- Smoking
- A history of PID
- Chlamydial or gonococcal infection; bacterial vaginosis
- A history of sexually transmitted diseases (STIs)

#### Physical Assessment/Signs and Symptoms.

One of the most frequent symptoms of PID is lower abdominal or pelvic pain. Conduct a complete pain assessment. Other symptoms include irregular vaginal bleeding (spotting or bleeding between periods), dysuria (painful urination), an increase or change in vaginal discharge, **dyspareunia** (painful sexual intercourse), malaise, fever, and chills.

Observe whether the patient has impaired COMFORT with movement. Often she has a hunched-over gait to protect her abdomen. She may find it difficult to independently get on the examination table or stretcher. Assess for lower abdominal tenderness, possibly with rigidity or rebound tenderness. A pelvic examination by the primary health care provider may reveal yellow or green cervical discharge and a reddened or friable cervix (a cervix that bleeds easily). Criteria for accurate diagnosis of PID are listed in Table 74-3. The diagnosis of PID is usually based on health history,

physical examination, and laboratory tests. Imaging studies and laparoscopy are not generally used to make the diagnosis.

### Psychosocial Assessment.

The woman who has symptoms of PID is usually anxious and fearful of the examination and unknown diagnosis. She may need much reassurance and support during the physical examination because her abdomen may be very tender or painful. Explain what is taking place to help promote comfort during the examination.

Because PID is often associated with an STI, the woman may feel embarrassed or uncomfortable discussing her symptoms or history. Use a nonjudgmental approach and encourage the patient to express her feelings and concerns. Determining her ability to follow through with the interprofessional collaborative plan of care is essential in deciding whether hospitalization should be considered.

### Laboratory Assessment.

The health care provider obtains specimens from the cervix, urethra, and rectum to determine the presence of *N. gonorrhoeae* or *C. trachomatis*. The white blood cell (WBC) count, erythrocyte sedimentation rate (ESR), and C-reactive protein may be elevated but are not specific for PID. A sensitive test that detects human chorionic gonadotropin (hCG) in urine or blood should be performed to determine whether the patient is pregnant (Pagana et al., 2017). Microscopic examination of vaginal discharge should be done to evaluate for the presence of WBCs.

### Other Diagnostic Assessment.

Abdominal *ultrasonography* may be used to determine the presence of appendicitis and tubo-ovarian abscesses that need to be ruled out when the diagnosis of PID is made. Transvaginal ultrasound and MRI are used in some cases to detect tubal wall thickening, fluid-filled tubes, and free pelvic fluid or a tubo-ovarian abscess, all associated with PID. *Endometrial biopsy* also has been used to increase the accuracy of the diagnosis.

#### ◆Analysis: Interpreting

The priority collaborative problem for patients with pelvic inflammatory disease (PID) is *Infection due to invasion of pelvic organs by sexually transmitted pathogens*.

#### ◆Planning and Implementation: Responding

### Managing Infection

#### Planning: Expected Outcomes.

The patient with PID is expected to have her infection resolved, be free of abdominal pain, and prevent re-infection.

#### Interventions.

Interprofessional collaborative care includes antibiotic therapy and self-management measures.

Uncomplicated PID is usually treated on an ambulatory care basis. The CDC (2017b) recommends hospitalization for PID if the patient:

- Has appendicitis, ectopic pregnancy, or other surgical emergency that has not been excluded
- Is pregnant
- Does not respond to oral antibiotic therapy
- Is unable to follow or tolerate treatment on an ambulatory care basis
- Has severe illness, nausea and vomiting, or high fever
- Has a tubo-ovarian abscess

There are no recommendations about whether HIV-infected women should be hospitalized. Assess the ability of high-risk women for self-management at home. The patient's health status and availability of support systems are important considerations for home care. If the infection has not responded to treatment, the patient may need to be hospitalized for IV antibiotic therapy and

further evaluation.

The CDC recommends oral and/or parenteral antibiotics for PID (CDC, 2017b). Drug therapy is required for 14 days. If the woman has not responded to oral antibiotics, she is hospitalized for IV antibiotic therapy and further evaluation. Inpatient therapy involves a combination of several IV antibiotics until the woman shows signs of improvement (e.g., decreased pelvic tenderness for at least 24 hours). Then oral antibiotics are continued at home until the course of treatment has lasted 14 days.

Antibiotic therapy relieves pain by destroying the pathogens and decreasing the inflammation caused by infection. Other pain-relief measures include taking mild analgesics and applying heat to the lower abdomen or back. As with any infection, encourage the patient to increase her intake of fluids and eat nutritious foods that can promote healing. *Teach the patient to rest in a semi-Fowler's position and encourage limited ambulation to promote gravity drainage of the infection that may help relieve pain.*

## Nursing Safety Priority QSEN

### Action Alert

Instruct women who are being treated for PID on an ambulatory care basis to avoid sexual intercourse for the full course of treatment and until their symptoms have resolved. Ask them to check their temperature twice a day. Teach them to report an increase in temperature to their health care provider. Remind them to be seen by the health care provider within 72 hours from starting antibiotic treatment and then 1 and 2 weeks from the time of the initial diagnosis.

In a small number of patients, the pain and tenderness may not be relieved by antibiotic therapy. The surgeon may perform a laparoscopy to remove an abscess through one or more subumbilical incisions to provide better access to the fallopian tubes. Before surgery, provide information about hospital routines and procedures. After surgery, the care of the woman with PID is similar to that of any patient after laparoscopic abdominal surgery. One difference is that she may have a wound drain for drainage of abscess fluid that may not have been completely removed during surgery. Observe, measure, and record wound drainage every 4 to 8 hours as requested.

### Care Coordination and Transition Management.

If the woman is hospitalized, collaborate with the case manager or discharge planner before she is discharged to home. Teach the patient with PID to see her primary health care provider for follow-up to assess for complications and confirm that the infection has resolved. Establish an atmosphere of trust that encourages the woman to return frequently, if needed, for education or reassurance.

### Home Care Management.

Parenteral antibiotic therapy may be given at home, but usually the health care provider changes the treatment regimen to oral antibiotics before hospital discharge. Home care for the patient who had laparoscopic surgery is discussed in [Chapter 16](#).

### Self-Management Education.

Patient teaching focuses on providing information about PID, identifying symptoms that suggest persistent or recurrent infection (persistent pelvic pain, dysmenorrhea, low backache, fever), and urging completion of antibiotic treatment, rest, and healthy nutrition to resolve the infection and prevent complications. Review information for oral antibiotic therapy ([Chart 74-4](#)).

## Chart 74-4

# Patient and Family Education: Preparing for Self-Management

## Oral Antibiotic Therapy for Sexually Transmitted Infections

- Take your medicine for the number of times a day that it is prescribed and until it is completed.
- Your sexual partner must be treated if you have a sexually transmitted infection (STI). Expedited partner therapy is one way to ensure that partners are treated.
- Be sure to return for your follow-up appointment after completing your antibiotic treatment.
- Call if you have any questions or concerns.
- Do not have sex until after you and your partner complete your antibiotic therapy. This should be at least 7 days, even if treatment is one dose.
- Drink at least 8 to 10 glasses of fluid a day to help heal your infection, while taking your antibiotics.
- Do not take antacids containing calcium, magnesium, or aluminum, such as Tums, Maalox, or Mylanta, with your antibiotics. They may decrease the effectiveness of the antibiotic.
- Take your antibiotics on an empty stomach unless your health care provider instructs you to take them with food.

Counsel the patient to contact her sexual partner(s) for examination and treatment. All sexual partners should be treated for gonorrhea and chlamydia infection regardless of whether they have symptoms. Remind the patient about follow-up care, and counsel her about the complications that can occur after an episode of PID. These problems include increased risk for recurrence, ectopic pregnancy, and infertility. Chronic pelvic pain may also develop.

Discuss contraception and the patient's need or desire for it. This discussion includes the use of condoms that can decrease the risk for future episodes of PID. Consider the likelihood that the patient had unprotected (from pregnancy and STIs) intercourse, which resulted in PID. Contraception that includes the use of condoms is an important health message to be communicated. Help the patient understand that having sexual intercourse with multiple partners increases the risk for recurrent episodes. Douching has also been suggested as a risky behavior for development of PID and/or infection with *Chlamydia* or *N. gonorrhoeae*.

Psychosocial concerns may require counseling. A patient who has PID may exhibit a variety of feelings (guilt, disgust, anger) about having a condition that may have been transmitted to her sexually. These feelings may affect her relationship with significant others and future sexual partners. She may also have concerns about future fertility if PID has damaged or scarred the fallopian tubes and other reproductive organs. Provide nonjudgmental emotional support and allow time for her to discuss her feelings. The primary provider of care may refer the patient to a mental health care provider as another appropriate option.

## NCLEX Examination Challenge 74-2

### Physiological Integrity

Which assessment findings will the nurse expect for a client who is suspected of having pelvic inflammatory disease? **Select all that apply.**

- A. Vaginal bleeding
- B. Fever
- C. Lower abdominal pain
- D. Constipation
- E. Rigid abdomen

### **Health Care Resources.**

The cost of antibiotics for patients with PID and other STIs may be a concern for those who are uninsured, underinsured, or impoverished. In collaboration with the case manager or social worker, help locate community resources for free or discounted drugs for women who cannot afford them. Ask the patient directly if she has the ability to pay for the drug and her follow-up visits, regardless of her apparent financial status.

If infertility is a result of PID, the patient may need referral to a clinic specializing in infertility treatment and counseling. She can also contact support groups for infertile couples, which exist in many local communities.

### **◆Evaluation: Reflecting**

Evaluate the care of the patient with PID based on the identified priority patient problem. The expected outcomes include that the patient should:

- Show evidence that the infection has resolved
- Report or demonstrate that pain is relieved or reduced and that she feels more comfortable
- Demonstrate a plan for ensuring treatment of her partner, obtaining antibiotics, and returning for follow-up care

# Get Ready for the NCLEX<sup>®</sup> Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Maintain patient and partner confidentiality and privacy at all times. **QSEN: Patient-Centered Care**
- Use gloves when examining the patient's genitalia or skin lesions. **QSEN: Safety**

### Health Promotion and Maintenance

- Teach patients not to have sexual intercourse during their treatment for sexually transmitted infection (STI). **QSEN: Safety**
- Assume that all adult patients may be sexually active, regardless of age or stage of life. Sexually transmitted infections are still spread within the older-adult population because perception of risk is lower.
- Educate young women about increased vulnerability to STIs; women's vaginal mucous membranes place them at higher risk for contracting an STI, and young women statistically have more partners and more unprotected sex, which further increases their risk. **QSEN: Safety**
- Teach the patient about the availability of expedited partner therapy; be sure that both the patient and the partner take all doses of the drug.
- Encourage all patients who are sexually active to use condoms during sexual intimacy (see [Chart 74-3](#)).
- Urge sexually active people, especially those younger than 26 years (or those older than 26 years if at high risk), to have STI screenings at least annually.
- Treat all patients, regardless of diagnosis, gender identity, or sexual orientation, with respect. **QSEN: Patient-Centered Care**
- Respect the sexual choices and practices of all patients. **QSEN: Patient-Centered Care**

### Psychosocial Integrity

- Provide privacy for patients undergoing examination or testing for STIs.
- Allow the patient to express fears and/or anxiety regarding a diagnosis of STI. **QSEN: Patient-Centered Care**
- Refer patients newly diagnosed with an STI to local resources and support groups as needed based on their response. **QSEN: Teamwork and Collaboration**
- Encourage all patients who have an STI to inform their sexual partner(s) of their health status.

### Physiological Integrity

- Assess patients with STI using the guidelines in [Chart 74-1](#). **QSEN: Evidence-Based Practice**
- Recognize that each stage of syphilis has unique symptoms and it is important not to overlook symptoms that resolve.
- Understand that patients without symptoms may still be infected with an STI.
- Encourage patients to adhere to their entire anti-infective drug regimen (see [Chart 74-4](#)), even after they begin to feel better.
- Teach patients the expected side effects and possible adverse reactions to prescribed drugs, particularly antibiotics. **QSEN: Safety**
- Teach patients about the short-term and long-term complications of STI using the information in

Table 74-1.

- Be aware that PID is diagnosed based on the criteria in [Table 74-3](#). **QSEN: Evidence-Based Practice**
- Place the hospitalized patient with PID in semi-Fowlers position. **QSEN: Safety**
- Teach patients with PID about possible complications, the importance of drug therapy adherence, and sexual activity restrictions.

---

# Glossary

---

## A

**abdominal acute compartment syndrome (AACS)** A complication after abdominal trauma that occurs when the intraabdominal pressure is sustained at greater than 200 mm Hg.

**abdominoperineal (AP) resection** The surgical removal of the sigmoid colon, rectum, and anus through combined abdominal and perineal incisions. This resection is performed when rectal tumors are present.

**ablative** The process or act of removing.

**abscess** A localized collection of pus caused by an inflammatory response to bacteria in tissues or organs.

**absolute neutrophil count (ANC)** The percentage and actual number of mature circulating neutrophils; used to measure a patient's risk for infection. The higher the numbers, the greater the resistance to infection.

**absorption** The uptake from the intestinal lumen of nutrients produced by digestion.

**acalculia** Difficulty with math calculations; caused by brain injury or disease.

**acalculous cholecystitis** Inflammation of the gallbladder occurring in the absence of gallstones; typically associated with biliary stasis caused by any condition that affects the regular filling or emptying of the gallbladder.

**acceleration-deceleration** Types of forces that involve rapid or sudden movement forward and then backward.

**acclimatization** The process of adapting to a high altitude; involves physiologic changes that help the body compensate for less available oxygen in the atmosphere.

**accommodation** The process of maintaining a clear visual image when the gaze is shifted from a distant object to a near object. The eye adjusts its focus by changing the curvature of the lens.

**achlorhydria** The absence of hydrochloric acid from gastric secretions.

**acid** A substance that releases hydrogen ions when dissolved in water. The strength of an acid is measured by how easily it releases hydrogen ions in solution.

**acid-base balance** The maintenance of arterial blood pH between 7.35 and 7.45 through control of hydrogen ion production and elimination.

**acidosis** An acid-base imbalance in which blood pH is below normal.

**acinus** The structural unit of the lower respiratory tract consisting of a respiratory bronchiole, an alveolar duct, and an alveolar sac.

**Acorn cardiac support device** A polyester mesh jacket that is placed over the ventricles to provide support and to avoid overstretching the myocardial muscle in the patient with heart failure; reduces heart muscle hypertrophy and assists with improvement of ejection fraction.

**acoustic neuroma** A benign tumor of cranial nerve VIII; symptoms include damage to hearing, facial movements, and sensation. The tumor can enlarge into the brain, damaging structures in

the cerebellum.

**active euthanasia** Purposeful action that directly causes death; not supported by most professional organizations, including the American Nurses Association.

**active immunity** Resistance to infection that occurs when the body responds to an invading antigen by making specific antibodies against the antigen. Immunity lasts for years and is natural by infection or artificial by stimulation (e.g., vaccine) of the body's immune defenses.

**active surveillance (AS)** Observation for cancer without immediate active treatment.

**activities of daily living (ADLs)** The activities performed in the course of a normal day, such as bathing, dressing, feeding, and ambulating.

**activity therapist** See *recreational therapist*.

**acute** Having relatively greater intensity; marked by a sudden onset and short duration.

**acute adrenal insufficiency** A life-threatening event in which the need for cortisol and aldosterone is greater than the available supply. Also called *addisonian crisis*.

**acute arterial occlusion** The sudden blockage of an artery, typically in the lower extremity, in the patient with chronic peripheral arterial disease.

**acute compartment syndrome (ACS)** A complication of a fracture characterized by increased pressure within one or more compartments and causing massive compromise of circulation to the area. Compartments are sheaths of inelastic fascia that support and partition muscles, blood vessels, and nerves in the body.

**acute coronary syndrome (ACS)** A disorder, including unstable angina and myocardial infarction, that results from obstruction of the coronary artery by ruptured atherosclerotic plaque and leads to platelet aggregation, thrombus formation, and vasoconstriction.

**acute gastritis** Inflammation of the gastric mucosa or submucosa after exposure to local irritants. Various degrees of mucosal necrosis and inflammatory reaction occur in acute disease. Complete regeneration and healing usually occur within a few days.

**acute glomerulonephritis** Inflammation of the glomerulus that develops suddenly from an excess immunity response within the kidney tissues.

**acute hematogenous infection** An infection resulting from bacteremia, disease, or nonpenetrating trauma that is disseminated by the blood through the circulation.

**acute kidney injury (AKI)** A rapid decrease in kidney function, leading to the collection of metabolic wastes in the body; formerly called *acute renal failure (ARF)*.

**acute pain** The unpleasant sensory and emotional experience associated with tissue damage that results from acute injury, disease, or surgery.

**acute pancreatitis** A serious inflammation of the pancreas characterized by a sudden onset of abdominal pain, nausea, and vomiting. It is caused by premature activation of pancreatic enzymes that destroy ductal tissue and pancreatic cells and results in autodigestion and fibrosis of the pancreas.

**acute paronychia** Inflammation of the skin around the nail, which usually occurs with a torn cuticle or an ingrown toenail.

**acute pericarditis** An inflammation or alteration of the pericardium, the membranous sac that encloses the heart; may be fibrous, serous, hemorrhagic, purulent, or neoplastic.

**acute pyelonephritis** Active bacterial infection in the kidney.

**acute respiratory distress syndrome (ARDS)** Respiratory failure marked by hypoxemia that persists even when 100% oxygen is given, as well as decreased pulmonary compliance, dyspnea,

noncardiac-associated bilateral pulmonary edema, and dense pulmonary infiltrates on x-ray.

**acute sialadenitis** Inflammation of a salivary gland; can be caused by infectious agents, irradiation, or immunologic disorders.

**acute-on-chronic kidney disease** A condition in which acute kidney injury occurs in addition to chronic kidney disease.

**adaptive immunity** The immunity that a person's body makes (or can receive) as an adaptive response to invasion by organisms or foreign proteins; occurs either naturally or artificially through lymphocyte responses and can be either active or passive.

**addisonian crisis** Acute adrenal insufficiency; a life-threatening event in which the need for cortisol and aldosterone is greater than the available supply.

**adenocarcinoma** Tumor that arises from the glandular epithelial tissue.

**adenohypophysis** The anterior lobe of the pituitary gland, which makes up about 70% of the gland.

**adiponectin** An anti-inflammatory and insulin-sensitizing hormone.

**adipose** Fatty.

**adjuvant therapy** Chemotherapy that is used along with surgery or radiation.

**adjuvant** A substance that aids another substance, such as a cancer treatment that uses chemotherapy in addition to surgery.

**adrenal crisis** Acute adrenocortical insufficiency, which can be life threatening.

**adrenal Cushing's disease** An excess of glucocorticoids caused by a problem in the adrenal cortex, usually a benign tumor (adrenal adenoma). This usually occurs in only one adrenal gland.

**advance directive (AD)** A written document prepared by a competent person to specify what, if any, extraordinary actions he or she would want when no longer able to make decisions about personal health care.

**adverse drug event (ADE)** An unintended harmful reaction to an administered drug.

**adverse events** Variations in the standard of care that are usually below the standard.

**aerosolization** Transmission via fine airborne droplets.

**aesthetic plastic surgery** Plastic surgery that is cosmetic and aims to alter a person's physical appearance.

**afferent arteriole** The smallest, most distal portion of the renal arterial system that supplies blood to the nephron. From the afferent arteriole, blood flows into the glomerulus, a series of specialized capillary loops.

**after-drop** A continued decrease in core body temperature after a victim is removed from a cold environment; results from equilibration of core and peripheral blood temperature and counter-current cooling of the blood perfusing cold tissue.

**afterload** The pressure or resistance that the ventricles must overcome to eject blood through the semilunar valves and into the peripheral blood vessels; the amount of resistance is directly related to arterial blood pressure and blood vessel diameter.

**agglutination** A clumping action that results during the antibody-binding process when antibodies link antigens together to form large and small immune complexes.

**agnosia** A general term for a loss of sensory comprehension; may include an inability to write, comprehend reading material, or use an object correctly.

**agraphia** Loss of the ability to write; caused by brain injury or disease.

**Airborne Precautions** Infection control guidelines from the U.S. Centers for Disease Control and Prevention; used for patients with infections spread by the airborne transmission route, such as tuberculosis. Negative airflow rooms are required to prevent the airborne spread of microbes.

**akinesia** Slow or no movement, as seen in a patient with Parkinson disease. Also called *bradykinesia*.

**albuminuria** The presence of albumin in the urine.

**alcoholic hepatitis** Liver inflammation caused by the toxic effect of alcohol on hepatocytes. The liver becomes enlarged, with cellular degeneration and infiltration by fat, leukocytes, and lymphocytes.

**aldosterone** The chief mineralocorticoid produced by the adrenal cortex. Aldosterone increases kidney reabsorption of sodium and water, thus restoring blood pressure, blood volume, and blood sodium levels. Aldosterone secretion is regulated by the renin-angiotensin system, serum potassium ion concentration, and adrenocorticotrophic hormone.

**alert** Awake, engaged, and responsive.

**alexia** Complete inability to understand written language; caused by brain injury or disease.

**alkaline reflux gastropathy** A complication of gastric surgery in which the pylorus is bypassed or removed. Endoscopic examination reveals regurgitated bile in the stomach and mucosal hyperemia. Symptoms include early satiety, abdominal discomfort, and vomiting. Also called *bile reflux gastropathy*.

**alkalosis** An acid-base imbalance in which blood pH is above normal.

**allele** An alternate form (or variation) of a gene.

**allergen** A foreign protein that is capable of causing a hypersensitivity response, or allergy, that ranges from uncomfortable (itchy, watery eyes or sneezing) to life threatening (allergic asthma, anaphylaxis, bronchoconstriction, or circulatory collapse); causes a release of natural chemicals, such as histamine, in the body.

**allergy** An increased or excessive response to the presence of a foreign protein or allergen (antigen) to which the patient has been previously exposed.

**allogeneic bone marrow transplantation** The transplantation of bone marrow from a sibling.

**allograft** A graft of tissue or bone between individuals of the same species but a different genotype; the donor may be a cadaver or a living person, either related or unrelated. Also called *homograft*.

**alopecia** Hair loss.

**alveolitis** Inflammation of the alveoli.

**amaurosis fugax** A transient, brief episode of blindness in one eye.

**ambulatory aid** Assistive device such as a cane or a walker.

**ambulatory pump** Infusion therapy pump generally used with a home care patient to allow a return to his or her usual activities while receiving infusion therapy.

**ambulatory** A term that refers to a patient who goes to the hospital or physician's office for treatment and returns home on the same day.

**amenorrhea** The absence of menstrual periods in women.

**amnesia** Loss of memory.

**amputation** The removal of a limb or other appendage of the body.

**amylase** An enzyme that converts starch and glycogen into simple sugars; found most commonly in saliva and pancreatic fluids.

**amyotrophic lateral sclerosis (ALS)** A progressive and degenerative disease of the motor system that is characterized by atrophy of the hands, forearms, and legs and that results in paralysis and death. There is no known cause, no cure, no specific treatment, no standard pattern of progression, and no method of prevention. Also called *Lou Gehrig's disease*.

**anaerobic cellular metabolism** Metabolism without oxygen.

**anaerobic** Lacking adequate oxygen.

**anal fissure** A painful ulcer at the margin of the anus.

**analgesia** Pain relief or pain suppression.

**anaphylaxis** The widespread reaction that occurs in response to contact with a substance to which the person has a severe allergy (antigen); characterized by blood vessel and bronchiolar smooth muscle involvement causing widespread blood vessel dilation, decreased cardiac output, and bronchoconstriction; results in cell damage and the release of large amounts of histamine, severe hypovolemia, vascular collapse, decreased cardiac contraction, and dysrhythmias, and causes extreme whole-body hypoxia.

**anasarca** Generalized edema.

**anastomosis** Surgical reattachment. Also a general term meaning "a connection."

**anatomic dead space** Places in which air flows but the structures are too thick for gas exchange.

**anemia** A clinical sign of some abnormal condition related to a reduction in one of the following: number of red blood cells, amount of hemoglobin, or hematocrit (percentage of packed red blood cells per deciliter of blood).

**anergy** The inability to mount an immune response to an antigen.

**anesthesia** An induced state of partial or total loss of sensation with or without loss of consciousness.

**aneuploid (aneuploidy)** An abnormal karyotype with more or fewer than 23 pairs of chromosomes.

**aneurysm** A permanent localized dilation of an artery (to at least 2 times its normal diameter) that forms when the middle layer (media) of the artery is weakened, stretching the inner (intima) and outer (adventitia) layers. As the artery widens, tension in the wall increases and further widening occurs, thus enlarging the aneurysm.

**aneurysmectomy** A surgical procedure performed to excise an aneurysm.

**angina pectoris** Literally, "strangling of the chest"; a temporary imbalance between the ability of the coronary arteries to supply oxygen and the demand for oxygen by the cardiac muscle. As a result, the patient experiences chest discomfort.

**angioedema** Diffuse swelling resulting from a vascular reaction in the deep tissues; can occur in a patient having an anaphylactic reaction.

**anion** Ion that has a negative charge.

**anisocoria** A difference in the size of the pupils.

**ankle-brachial index (ABI)** A ratio derived by dividing the ankle blood pressure by the brachial blood pressure; this calculation is used to assess the vascular status of the lower extremities. To obtain the ABI, a blood pressure cuff is applied to the lower extremities just above the malleoli. The systolic pressure is measured by Doppler ultrasound at both the dorsalis pedis and posterior

tibial pulses. The higher of these two pressures is then divided by the higher of the two brachial pulses.

**anomia** Inability to find words.

**anorectal abscess** A localized induration and fluctuance that is caused by inflammation of the soft tissue near the rectum or anus and is most often the result of obstruction of the ducts of glands in the anorectal region by feces, foreign bodies, or trauma.

**anorectic drugs** Drugs that suppress appetite, which reduces food intake and, over time, may result in weight loss; may be prescribed for obese patients in a comprehensive weight reduction program.

**anorexia nervosa** An eating disorder of self-induced starvation resulting from a fear of fatness, even though the patient is underweight.

**anorexia** The loss of appetite for food.

**anorexin** Neuropeptide that decreases appetite.

**anoxic** Completely lacking oxygen.

**antalgic (gait)** A term that refers to an abnormality in the stance phase of gait. When part of one leg is painful, the person shortens the stance phase on the affected side.

**anterior colporrhaphy** Surgery for severe symptoms of cystocele in which the pelvic muscles are tightened for better bladder support.

**anterior nares** The nostrils or external openings into the nasal cavities.

**antibody-mediated immunity (AMI) or antibody-mediated immune system** The defense response that produces antibodies directed against certain pathogens. The antibodies inactivate the pathogens and protect against future infection from that microorganism.

**antidepressants** A group of drugs that help manage clinical depression.

**antiepileptic drugs (AEDs)** A class of drugs used to control seizures. Also called *anticonvulsants*.

**antigen** A foreign protein or allergen that is capable of causing an immune response; protein on the surface of a cell.

**anuria** Complete lack of urine output; usually defined as less than 100 mL/24 hr.

**aortic regurgitation** The flow of blood from the aorta back into the left ventricle during diastole; occurs when the aortic valve leaflets do not close properly during diastole and the annulus (the valve ring that attaches to the leaflets) is dilated or deformed.

**aortic stenosis** Narrowing of the aortic valve orifice and obstruction of left ventricular outflow during systole.

**aphasia** Inability to use or comprehend spoken or written language due to brain injury or disease.

**apheresis** A procedure in which whole blood is withdrawn from the patient, a blood component (e.g., stem cells) is filtered out, and the plasma is returned to the patient.

**aphonia** Inability to produce sound; complete but temporary loss of the voice.

**aphthous stomatitis** Noninfectious stomatitis.

**apical impulse** The pulse located at the left fifth intercostal space in the midclavicular line in the mitral area (the apex of the heart). Also called the *point of maximal impulse*.

**apolipoprotein E** One of several regulators of lipoprotein metabolism.

**appendectomy** Surgical removal of the inflamed appendix.

**appendicitis** Acute inflammation of the vermiform appendix, which is the blind pouch attached to the cecum of the colon, usually located in the right iliac region just below the ileocecal valve.

**approximated** In a clean laceration or a surgical incision to be closed with sutures or staples, the act of bringing together the wound edges with the skin layers lined up in correct anatomic position so they can be held in place until healing is complete.

**apraxia** The loss of the ability to carry out a purposeful motor activity.

**aqueous humor** The clear, watery fluid that is continually produced by the ciliary processes and fills the anterior and posterior chambers of the eye. This fluid drains through the canal of Schlemm into the blood to maintain balanced intraocular pressure (pressure within the eye).

**arcus senilis** An opaque ring within the outer edge of the cornea caused by fat deposits. Its presence does not affect vision.

**areflexic bladder** Urinary retention and overflow (dribbling) caused by injuries to the lower motor neuron at the spinal cord level of S2 to S4 (e.g., multiple sclerosis and spinal cord injury below T12). Bladder emptying may be achieved by performing a Valsalva maneuver or tightening the abdominal muscles. The effectiveness of these maneuvers should be ascertained by catheterizing the patient for residual urine after voiding. Also called *flaccid bladder*.

**arrhythmogenic right ventricular cardiomyopathy (dysplasia)** A form of cardiomyopathy that results from the replacement of myocardial tissue with fibrous and fatty tissue.

**arterial revascularization** The surgical procedure most commonly used to increase arterial blood flow in the affected limb of a patient with peripheral arterial disease.

**arterial ulcers** A painful complication in the patient with peripheral arterial disease. Typically, the ulcer is small and round, with a “punched out” appearance and well-defined borders. Ulcers develop on the toes (often the great toe), between the toes, or on the upper aspect of the foot. With prolonged occlusion, the toes can become gangrenous.

**arteriography** Angiography of the arterial vessels; this invasive diagnostic procedure involves fluoroscopy and the use of a contrast medium and is performed when an arterial obstruction, narrowing, or aneurysm is suspected.

**arteriosclerosis** A thickening, or hardening, of the arterial wall.

**arteriotomy** A surgical opening into an artery.

**arteriovenous malformation (AVM)** An abnormality that occurs during embryonic development, resulting in a tangled mass of malformed, thin-walled, dilated vessels. The congenital absence of a capillary network in these vessels forms an abnormal communication between the arterial and venous systems and increases the risk that the vessels may rupture, causing bleeding, such as into the subarachnoid space or into the intracerebral tissue with brain AVMs. In the absence of the capillary network, the thin-walled veins are subjected to arterial pressure.

**arthralgia** Pain in a joint.

**arthritis** Inflammation of one or more joints.

**arthrodesis** The surgical fusion of a joint.

**arthrogram** An x-ray study of a joint after contrast medium (air or solution) has been injected to enhance its visualization.

**arthroscopy** Procedure in which a fiberoptic tube is inserted into a joint for direct visualization of the ligaments, menisci, and articular surfaces of the joint.

**articulations** Joint surfaces.

**artifact** In the electrocardiogram, interference that is seen on the monitor or rhythm strip and may

look like a wandering or fuzzy baseline; can be caused by patient movement, loose or defective electrodes, improper grounding, or faulty equipment.

**ASA Physical Status Classification System** From the American Society of Anesthesiologists (ASA), a system that assesses the fitness of patients for surgery.

**ascending tracts** Groups of nerves that originate in the spinal cord and end in the brain.

**ascites** The accumulation of free fluid within the peritoneal cavity. Increased hydrostatic pressure from portal hypertension causes this fluid to leak into the peritoneal cavity.

**assistive technology** Electronic equipment that increases the ability of disabled patients to care for themselves.

**assistive/adaptive device** Any item that enables the patient to perform all or part of an activity independently.

**asterixis** A coarse tremor characterized by rapid, nonrhythmic extensions and flexions in the wrists and fingers; a motor disturbance seen in portal-systemic encephalopathy. Also called a *liver flap* or *flapping tremor*.

**asthma** A chronic respiratory condition in which reversible airway obstruction occurs intermittently, reducing airflow.

**asthma** A chronic respiratory condition in which reversible airflow obstruction in the airways occurs intermittently.

**astigmatism** A refractive error caused by unevenly curved surfaces on or in the eye (especially of the cornea) that distort vision.

**ataxia** Gait disturbance or loss of balance.

**atelectasis** Collapse of alveoli.

**atelectrauma** Shear injury to alveoli from opening and closing.

**atherectomy** An invasive nonsurgical technique in which a high-speed, rotating metal burr uses fine abrasive bits to scrape plaque from inside an artery while minimizing damage to the vessel surface.

**atherosclerosis** A type of arteriosclerosis that involves the formation of plaque within the arterial wall; the leading contributor to coronary artery and cerebrovascular disease.

**atrial fibrillation (AF)** A cardiac dysrhythmia in which multiple rapid impulses from many atrial foci, at a rate of 350 to 600 times per minute, depolarize the atria in a totally disorganized manner, with no P waves, no atrial contractions, a loss of the atrial kick, and an irregular ventricular response.

**atrial gallop** An abnormal fourth heart sound that occurs as blood enters the ventricles during the active filling phase at the end of ventricular diastole; may be heard in patients with hypertension, anemia, ventricular hypertrophy, myocardial infarction, aortic or pulmonic stenosis, and pulmonary emboli.

**atrioventricular (AV) junction** In the cardiac conduction system, the area consisting of a transitional cell zone, the atrioventricular (AV) node itself, and the bundle of His. The AV node lies just beneath the right atrial endocardium, between the tricuspid valve and the ostium of the coronary sinus.

**atrophic gastritis** A type of gastritis that involves all layers of the stomach and includes diffuse inflammation and destruction of deeply located glands.

**attenuated** The quality of making a substance weaker; for example, antigens that are used to make vaccines are specially processed to make them less likely to grow in the body.

**atypical angina** Angina that manifests itself as indigestion, pain between the shoulders, an aching jaw, or a choking sensation that occurs with exertion. Many women experience atypical angina.

**atypical migraine** The least common of the three types of migraine headaches, after migraines with aura and migraines without aura; the atypical category includes menstrual and cluster migraines.

**aura** A sensation that signals the onset of a headache or seizure; the patient may experience visual changes, flashing lights, or double vision.

**autoamputation of the distal digits** A condition in which the tips of the digits fall off spontaneously; can occur in severe cases of Raynaud's phenomenon.

**autoantibodies** Antibodies directed against self tissues of cells.

**autocontamination** The occurrence of infection in which the patient's own normal flora overgrows and penetrates the internal environment.

**autodigestion** Self-digestion. Specifically, the process of the stomach digesting itself if there is a break in its protective mucosal barrier.

**autogenous** Belonging to the person, such as a person's vein being moved from one part of the body to another.

**autoimmune pancreatitis** A chronic inflammatory form of pancreatitis that can also affect the bile ducts, kidneys, and other major connective tissues.

**autologous blood transfusion** Reinfusing the patient's own blood during surgery.

**autologous bone marrow transplantation** A type of bone marrow transplant in which patients receive their own stem cells, which were collected before high-dose chemotherapy.

**autologous donation** The donation of a patient's own blood before scheduled surgery for use, if needed, during the surgery to eliminate transfusion reactions and reduce the risk of bloodborne disease.

**autolysis** The spontaneous disintegration of tissue by the action of the patient's own cellular enzymes.

**automaticity** The ability of a cell to initiate an impulse spontaneously and repetitively; in cardiac electrophysiology, the ability of primary pacemaker cells (SA node, AV junction) to generate an electrical impulse.

**autonomic dysreflexia (AD)** A syndrome that affects the patient with an upper spinal cord injury; characterized by severe hypertension and headache, bradycardia, nasal stuffiness, and flushing; caused by a noxious stimulus, usually a distended bladder or constipation. This is a neurologic emergency and must be promptly treated to prevent a hypertensive brain attack.

**autonomic nervous system (ANS)** The part of the nervous system that is not under conscious control; consists of the sympathetic nervous system and the parasympathetic nervous system.

**autonomy** Ethical principle that implies a person's self-determination and self-management.

**autosome** Any of the 22 pairs of human chromosomes containing genes that code for all the structures and regulatory proteins needed for normal function but do not code for the sexual differentiation of a person.

**axial loading** A mechanism of injury that involves vertical compression. An example is a diving accident, in which the blow to the top of the head causes the vertebrae to shatter and pieces of bone enter the spinal canal and damage the cord.

**azoospermia** The absence of living sperm in the semen.

**azotemia** An excess of nitrogenous wastes (urea) in the blood.

## B

**Babinski's sign** Dorsiflexion of the great toe and fanning of the other toes, which is an abnormal reflex in response to testing the plantar reflex with a pointed (but not sharp) object; indicates the presence of central nervous system disease. The normal response is plantar flexion of all toes.

**bacteremia** The presence of bacteria in the bloodstream.

**bacteriuria** Bacteria in the urine.

**bad death** A death embodied by pain, not having one's wishes followed at the end of one's life, isolation, abandonment, and constant agonizing about losses associated with death.

**Baker's cyst** Enlarged popliteal bursa.

**banding** See *endoscopic variceal ligation*.

**barbiturate coma** The use of drugs such as pentobarbital sodium or sodium thiopental at dosages to maintain complete unresponsiveness; used for patients whose increased intracranial pressure cannot be controlled by other means. These drugs decrease the metabolic demands of the brain and cerebral blood flow, stabilize cell membranes, decrease the formation of vasogenic edema, and produce a more uniform blood supply. The patient in a barbiturate coma requires mechanical ventilation, sophisticated hemodynamic monitoring, and intracranial pressure monitoring.

**bariatrics** Branch of medicine that manages obesity and its related diseases.

**baroreceptors** Sensory receptors in the arch of the aorta and at the origin of the internal carotid arteries that are stimulated when the arterial walls are stretched by an increased blood pressure.

**barotrauma** Damage to the lungs by positive pressure.

**Barrett's epithelium** Columnar epithelium (instead of the normal squamous cell epithelium) that develops in the lower esophagus during the process of healing from gastroesophageal reflux disease. It is considered premalignant and is associated with an increased risk of cancer in patients with prolonged disease.

**Barrett's esophagus** Ulceration of the lower esophagus caused by exposure to acid and pepsin, leading to the replacement of normal distal squamous mucosa with columnar epithelium as a response to tissue injury.

**base** A substance that binds (reduces) free hydrogen ions in solution. Strong bases bind hydrogen ions easily; weak bases bind less readily.

**Basic Cardiac Life Support (BCLS)** Procedure that involves ventilating the patient who has stopped breathing, as well as giving chest compressions in the absence of a carotid pulse. Also known as *cardiopulmonary resuscitation (CPR)*.

**Bell's palsy** Acute paralysis of cranial nerve VII; characterized by a drawing sensation and paralysis of all facial muscles on the affected side. The patient cannot close the eye, wrinkle the forehead, smile, whistle, or grimace. The face appears masklike and sags. Also called *facial paralysis*.

**beneficence** The ethical principle of preventing harm and ensuring the patient's well-being.

**benign tumor cells** Normal cells growing in the wrong place or at the wrong time.

**benign** Altered cell growth that is harmless and does not require intervention.

**bereavement** Grief and mourning experienced by the survivor before and after a death.

**bicaval technique** Surgical technique in heart transplantation in which the intact right atrium of the donor heart is preserved by anastomoses at the recipient's superior and inferior vena cavae.

**bifurcation** The point of division of a single structure into two branches.

**bigeminy** A type of premature complex that exists when normal complexes and premature complexes occur alternately in a repetitive two-beat pattern, with a pause occurring after each premature complex so that complexes occur in pairs.

**bilateral orchiectomy** The surgical removal of both testes, typically performed as palliative surgery in patients with prostate cancer. It is not intended to cure the prostate cancer but to arrest its spread by removing testosterone.

**bilateral salpingo-oophorectomy (BSO)** Surgical removal of both fallopian tubes and both ovaries.

**biliary colic** Intense pain due to obstruction of the cystic duct of the gallbladder from a stone moving through or lodged within the duct. Tissue spasm occurs in an effort to mobilize the stone through the small duct.

**biliary stent** A plastic or metal device that is placed percutaneously to keep a duct of the biliary system open in patients experiencing biliary obstruction.

**biofilm** A complex group of microorganisms that functions within a "slimy" gel coating on medical devices.

**biological response modifiers (BRMs)** A class of immunomodulating drugs that attempt to modify the course of disease. Also called *biologics*.

**biologics** See *biological response modifiers*.

**biomedical technician** Member of the health care team who maintains the safety of adaptive and electronic devices by monitoring their function and making repairs as needed.

**biotrauma** Inflammatory response-mediated damage to alveoli.

**bivalve** To cut a cast lengthwise into two equal pieces.

**black box warning** A governmental designation indicating that a drug has at least one serious side effect and must be used with caution.

**bladder ultrasound** Less invasive test to determine postvoiding residual urine volumes for the patient with a reflex (upper motor neuron) or uninhibited bladder; often used to measure residual urine in the bladder of patients with spinal cord injury.

**blanch** To whiten or lighten.

**blast effect** The damage sustained by the force of an explosion.

**blast phase cell** Immature cell that divides.

**blood pressure (BP)** The force of blood exerted against the vessel walls.

**blood stem cells** Immature, unspecialized (undifferentiated) cells that are capable of becoming any type of blood cell, depending on the body's needs.

**bloodborne metastasis** The release of tumor cells into the blood; the most common cause of cancer spread.

**Blumberg's sign** Pain felt on abrupt release of steady pressure (rebound tenderness) over the site of abdominal pain.

**blunt trauma** A type of trauma resulting from impact forces (e.g., motor vehicle accident, fall, assault).

**body mass index (BMI)** A measure of nutritional status that does not depend on frame size; indirectly estimates total fat stores within the body by the relationship of weight to height.

**bolus feeding** A method of tube feeding that involves intermittent feeding of a specified amount of enteral product at specified times during a 24-hour period, typically every 4 hours.

**bone biopsy** Procedure in which the physician extracts a specimen of bone tissue for microscopic examination to confirm the presence of infection or neoplasm; not commonly done today.

**bone mineral density (BMD)** The quality of bone that determines bone strength. It peaks between 30 and 35 years of age, when both bone resorption activity and bone-building activity occur at a constant rate. When bone resorption activity exceeds bone-building activity, bone density decreases.

**bone reduction** Realignment of fractured bone ends for proper healing.

**bone remodeling** A process in which bone is constantly undergoing changes.

**bone resorption** Loss of bone density due to demineralization resulting from the release of calcium from storage areas in bones.

**bone scan** A radionuclide test in which radioactive material is injected for visualization of the entire skeleton; used to detect tumors, arthritis, osteomyelitis, osteoporosis, vertebral compression fractures, and unexplained bone pain.

**borborygmus (borborygmi)** Bowel sounds, especially loud gurgling sounds, resulting from hypermotility of the bowel.

**boring** In pain, the type of intense pain that feels as if it is going through the body.

**Bouchard's nodes** Swelling at the proximal interphalangeal joints in osteoarthritis involving the hands.

**bowel retraining** A program for patients with neurologic problems that is designed to include a combination of suppository use and a consistent toileting schedule.

**bradycardia** Slowness of the heart rate; characterized as a pulse rate less than 50 to 60 beats/min.

**bradydysrhythmia** An abnormal heart rhythm characterized by a heart rate less than 60 beats/min.

**bradykinesia** Slow or no movement, as seen in a patient with Parkinson disease. Also called *akinesia*.

**brain abscess** A collection of pus that forms in the extradural, subdural, or intracerebral area of the brain as a result of a purulent infection, usually due to bacteria invading the brain directly or indirectly.

**brain attack** Stroke; disruption in the normal blood supply to the brain, either as an interruption in blood flow (ischemic stroke) or as bleeding within or around the brain (hemorrhagic stroke). A medical emergency that occurs suddenly, a stroke should be treated immediately to prevent neurologic deficit and permanent disability. Formerly called *cerebrovascular accident*, the National Stroke Association now uses the term *brain attack* to describe stroke.

**brain herniation syndrome** In the patient with untreated increased intracranial pressure, protrusion (herniation) of the brain downward toward the brainstem or laterally from a unilateral lesion within one cerebral hemisphere, causing irreversible brain damage and possibly death.

**breakthrough pain** Additional pain that “breaks through” the pain that is being managed by mainstay analgesic drugs.

**breast augmentation** Cosmetic surgical procedure to enhance the size, shape, or symmetry of the breasts.

**breast-conserving surgery** Surgical method for breast cancer that removes the bulk of the tumor rather than the entire breast.

**Broca's aphasia** See *expressive aphasia*.

**Broca's area** An important speech area of the cerebrum. It is located in the frontal lobe and is composed of neurons responsible for the formation of words, or speech.

**bronchoscopy** Insertion of a tube in the airway, usually as far as the secondary bronchi, for the purpose of visualizing airway structures and obtaining tissue samples for biopsy or culture.

**bruit** Swishing sound in the larger arteries (carotid, aortic, femoral, and popliteal) that can be heard with a stethoscope or Doppler probe; may indicate narrowing of the artery and is usually associated with atherosclerotic disease.

**B-type natriuretic peptide (BNP)** A peptide produced and released by the ventricles when the patient has fluid overload as a result of heart failure (HF).

**bulbar** Pertaining to the muscles involved in facial expression, chewing, and speech.

**bulimia nervosa** An eating disorder that is characterized by episodes of binge eating in which the patient ingests a large amount of food in a short time, followed by purging behavior such as self-induced vomiting or excessive use of laxatives and diuretics.

**bunion** Hallux valgus deformity of the foot in which lateral deviation of the great toe causes the first metatarsal head to become enlarged.

**bunionectomy** Surgical removal of the hallux valgus deformity (bunion) of the foot.

**butterfly rash** A dry, scaly raised rash on the face; the major skin manifestation of systemic lupus erythematosus.

## C

**C. difficile–associated disease (CDAD)** Clinical manifestations that are caused by *Clostridium difficile* as a potential result of antibiotic therapy use, especially in older adults.

**cachexia** Extreme body wasting and malnutrition that develop from an imbalance between food intake and energy use.

**calciphylaxis** A condition of thrombosis and skin necrosis that can occur in stage 5 chronic kidney disease.

**calculi** Abnormal formations of a mass of mineral salts that can occur in the body; forms in the kidney when excess calcium precipitates out of solution. Also called *stones*.

**calculous cholecystitis** Inflammation of the gallbladder usually following and created by obstruction of the cystic duct by a stone (calculus).

**callus** The loose, fibrous vascular tissue that forms at the site of a fracture as the first phase of healing and is normally replaced by hard bone as healing continues.

**calyx** The anatomic term for a cuplike structure.

**Canadian Triage Acuity Scale (CTAS)** A standardized model for triage in which lists of descriptors are used to establish the triage level.

**cancellous** The softer tissue inside bones that contains large spaces, or trabeculae, that are filled with red and yellow marrow.

**candidiasis** An infection caused by the fungus *Candida albicans*.

**canthus** The place where the upper and lower eyelids meet at the corner of either side of the eye.

**capillary closing pressure** The amount of pressure needed to occlude skin capillary blood flow.

**capillary leak syndrome** The response of capillaries to the presence of biologic chemicals (mediators) that change blood vessel integrity and allow fluid to shift from the blood in the vascular space into the interstitial tissues.

**Caplan's syndrome** The presence of pneumoconiosis and rheumatoid nodules in the lungs; noted primarily in coal miners and asbestos workers.

**capnography** An end-tidal carbon dioxide (EtCO<sub>2</sub>) monitor.

**capsule** The layer of fibrous tissue on the outer surface of the kidney, which provides protection and support. The renal capsule itself is surrounded by layers of fat and connective tissue.

**carboxyhemoglobin** Carbon monoxide on oxygen-binding sites of the hemoglobin molecule.

**carcinoembryonic antigen (CEA)** An oncofetal antigen that may be elevated in 70% of people with colorectal cancer. CEA is not specifically associated with the colorectal cancer and may be elevated in the presence of other benign or malignant diseases and in smokers. CEA is often used to monitor the effectiveness of treatment and to identify disease recurrence.

**carcinogen** Any substance that changes the activity of the genes in a cell so that the cell becomes a cancer cell.

**carcinogenesis** Cancer development.

**cardiac axis** In electrocardiography (ECG), the direction of electrical current flow in the heart. The relationship between the cardiac axis and the lead axis is responsible for the deflections seen on the ECG pattern.

**cardiac catheterization** The most definitive but most invasive test in the diagnosis of heart disease; involves passing a small catheter into the heart and injecting contrast medium.

**cardiac index** A calculation of cardiac output requirements to account for differences in body size; determined by dividing the cardiac output by the body surface area.

**cardiac markers** Serum studies that include troponin, creatine kinase-MB, and myoglobin.

**cardiac output (CO)** The volume of blood ejected by the heart each minute; normal range in adults is 4 to 7 L/min.

**cardiac rehabilitation** The process of actively assisting the patient with cardiac disease to achieve and maintain a productive life while remaining within the limits of the heart's ability to respond to increases in activity and stress. *Phase 1* begins with the acute illness and ends with discharge from the hospital. *Phase 2* begins after discharge and continues through convalescence at home. *Phase 3* refers to long-term conditioning.

**cardiac resynchronization therapy (CRT)** In patients with some types of heart failure, the use of a permanent pacemaker alone or in combination with an implantable cardioverter-defibrillator to provide biventricular pacing.

**cardiac tamponade** Compression of the myocardium by fluid that has accumulated around the heart; this compresses the atria and ventricles, prevents them from filling adequately, and reduces cardiac output.

**cardiogenic shock** Post-myocardial infarction heart failure in which necrosis of more than 40% of the left ventricle has occurred. Also called *class IV heart failure*.

**cardiomegaly** Enlarged heart.

**cardiomyopathy** A subacute or chronic disease of cardiac muscle; classified into four categories based on abnormalities in structure and function: dilated, hypertrophic, restrictive, and arrhythmogenic.

**cardiopulmonary bypass (CPB)** Diversion of the blood from the heart to a bypass machine, where it is heparinized, oxygenated, and returned to the circulation through a cannula placed in the ascending aortic arch or femoral artery to provide oxygenation, circulation, and hypothermia during induced cardiac arrest for coronary artery bypass surgery. This process ensures a motionless operative field and prevents myocardial ischemia.

**cardioversion** A synchronized countershock that may be performed in emergencies for hemodynamically unstable ventricular or supraventricular tachydysrhythmias or electively for stable tachydysrhythmias that are resistant to medical therapies. The shock depolarizes a critical mass of myocardium simultaneously during intrinsic depolarization and is intended to stop the re-entry circuit and allow the sinus node to regain control of the heart.

**care coordination** The deliberate organization of and communication about patient care activities among members of the health care team (including the patient) to facilitate continuous health care to meet patient needs.

**carina** The point at which the trachea branches into the right and left mainstem bronchi.

**carpal tunnel syndrome (CTS)** A common condition in which the median nerve in the wrist becomes compressed, causing pain and numbness.

**carrier** (1) A person who harbors an infectious agent without symptoms of active disease; (2) in genetics, a person who has one mutated allele for a recessive genetic disorder. A carrier does not usually have any manifestations of the disorder but can pass the mutated allele to his or her children.

**case management** The process of assessment, planning, implementation, evaluation, and interaction for patients who have complex health problems and incur a high cost to the health care system. Goals include promoting quality of life, decreasing fragmentation and duplication of care across health care settings, and maintaining cost-effectiveness.

**caseation necrosis** A type of necrosis in which tissue is turned into a granular mass.

**cast** A rigid device that immobilizes the affected body part while allowing other body parts to move. It is most commonly used for fractures but may also be applied to correct deformities (e.g., clubfoot) or to prevent deformities (e.g., those seen in some patients with rheumatoid arthritis).

**cataract** A lens opacity that distorts the image projected onto the retina.

**catechol-O-methyltransferases (COMTs)** Enzymes that inactivate dopamine.

**catecholamines** Hormones (dopamine, epinephrine, and norepinephrine) released by the adrenal medulla in response to stimulation of the sympathetic nervous system.

**catheter-related bloodstream infection (CR-BSI)** Health care–acquired bloodstream infection caused by the presence of any type of intravenous catheter.

**catheter-related bloodstream infection (CRBSI) prevention bundle** An nationally recognized set of evidence-based interventions to prevent CR-BSIs.

**cation** Ion that has a positive charge.

**cell saver system** A technique that allows for collection of the person's own red blood cells during surgery, which is then reinfused directly back to the patient via a closed system.

**cell-mediated immunity** Microbial resistance that is mediated by the action of specifically sensitized T-lymphocytes.

**cellular regulation** The physiologic processes used to control cellular growth, replication, and differentiation (maturation into a specific cell type) to maintain homeostasis.

**cellulitis** An acute, spreading, edematous inflammation of the deep subcutaneous tissues; usually

caused by infection of a wound or burn.

**central IV therapy** IV therapy in which a vascular access device (VAD) is placed in a central blood vessel, such as the superior vena cava.

**central line–associated bloodstream infection (CLA-BSI)** Health care–acquired bloodstream infection caused by the presence of a central intravenous line.

**cerebral angiography (arteriography)** Visualization of the cerebral circulation (carotid and vertebral arteries) after injecting a contrast medium into an artery (usually the femoral).

**cerebral blood flow (CBF)** Useful in evaluating cerebral vasospasm; can be measured in many areas of the brain with the use of radioactive substances.

**cerebral perfusion pressure (CPP)** The pressure gradient over which the brain is perfused. It is influenced by oxygenation, cerebral blood volume, blood pressure, cerebral edema, and intracranial pressure (ICP) and is determined by subtracting the mean ICP from the mean arterial pressure. A cerebral perfusion pressure above 70 mm Hg is generally accepted as an appropriate goal of therapy.

**cerebral salt wasting (CSW)** The primary cause of hyponatremia in the neurosurgical population; characterized by hyponatremia, decreased serum osmolality, and decreased blood volume. It is thought to result from the extrarenal influence of atrial natriuretic factor.

**cerumen** The wax produced by glands within the external ear canal; helps protect and lubricate the ear canal.

**cervical polyp** Tumor that arises from the mucosa and extends to the opening of the cervical os. Polyps result from hyperplasia of the endocervical epithelium, inflammation, or an abnormal local response to hormonal stimulation or localized vascular congestion of the cervical blood vessels. Polyps are the most common benign growth of the cervix.

**CHADS<sub>2</sub> scoring system** Acronym for Congestive heart failure, Hypertension, Age  $\geq 75$  years, Diabetes mellitus, Stroke. Determines whether a patient with atrial fibrillation needs preventive anticoagulant therapy.

**chalazion** An inflammation of a sebaceous gland in the eyelid.

**chancre** The ulcer that is the first sign of syphilis. It develops at the site of entry (inoculation) of the organism, usually 3 weeks after exposure. The lesion may be found on any area of the skin or mucous membranes but occurs most often on the genitalia, lips, nipples, and hands and in the oral cavity, anus, and rectum.

**chemotherapy** The treatment of cancer with chemical agents that have systemic effects; used to cure and to increase survival time.

**chemotherapy-induced peripheral neuropathy (CIPN)** The loss of sensory or motor function of peripheral nerves associated with exposure to certain anticancer drugs.

**chest tube** A drain placed in the pleural space to allow closed–chest drainage, which restores intrapleural pressure and allows re-expansion of the lung after surgery in patients who have undergone thoracotomy (incision of the chest wall).

**Cheyne-Stokes respirations** Common sign of nearing death in which apnea alternates with periods of rapid breathing.

**choked disc** See *papilledema*.

**cholecystectomy** The surgical removal of the gallbladder.

**cholecystitis** Inflammation of the gallbladder.

**cholecystokinin** A hormone that stimulates digestive juices and that may work with leptin to

increase or decrease appetite.

**choledochojejunostomy** Surgical anastomosis of the common bile duct with the jejunum.

**cholelithiasis** The presence of gallstones.

**cholesteatoma** A benign overgrowth of squamous cell epithelium.

**cholesterol** Serum lipid that includes high-density lipoproteins and low-density lipoproteins.

**cholinergic crisis** Overmedication with cholinesterase inhibitors.

**cholinesterase inhibitors** Drugs that improve cholinergic neurotransmission in the central nervous system by delaying the destruction of acetylcholine by acetylcholinesterase, thus delaying the onset of cognitive decline. These are approved for symptomatic treatment of Alzheimer's disease but do not affect the course of the disease.

**chondroitin** A supplement that may play a role in strengthening cartilage.

**choreiform movement** Rapid, jerky movement.

**chronic** Having a slow onset and symptoms that persist for an extended period.

**chronic calcifying pancreatitis (CCP)** Alcohol-induced chronic pancreatitis that is characterized by protein precipitates that plug the ducts and lead to ductal obstruction, atrophy, and dilation. The epithelium of the ducts undergoes histologic changes, resulting in metaplasia (cell replacement) and ulceration. This inflammatory process causes fibrosis of the pancreatic tissue.

**chronic constrictive pericarditis** A fibrous thickening of the pericardium that prevents adequate filling of the ventricles and eventually results in cardiac failure; caused by chronic pericardial inflammation due to tuberculosis, radiation therapy, trauma, kidney failure, or metastatic cancer.

**chronic fatigue syndrome (CFS)** A chronic illness characterized by severe fatigue for 6 months or longer, usually following flu-like symptoms. At least four of the following criteria are required for diagnosis: sore throat; substantial impairment in short-term memory or concentration; tender lymph nodes; muscle pain; multiple joint pain with redness or swelling; headaches of a new type, pattern, or severity; unrefreshing sleep; and postexertional malaise lasting more than 24 hours.

**chronic gastritis** A patchy, diffuse inflammation of the mucosal lining of the stomach. Chronic gastritis usually heals without scarring but can progress to hemorrhage and ulcer formation.

**chronic health condition** A condition that has existed for at least 3 months.

**chronic hepatitis** Chronic liver inflammation that usually occurs as a result of hepatitis B or C. Superimposed infection with hepatitis D virus (HDV) in patients with chronic hepatitis B may also result in chronic hepatitis. Can lead to cirrhosis and liver cancer.

**chronic kidney disease (CKD)** A condition characterized by loss of kidney function over time.

**chronic obstructive pancreatitis** Pancreatitis that develops from inflammation, spasm, and obstruction of the sphincter of Oddi. Inflammatory and sclerotic lesions occur in the head of the pancreas and around the ducts, causing obstruction and backflow of pancreatic secretions.

**chronic osteomyelitis** Bone infection that persists over a long time due to misdiagnosis or inadequate treatment. Also called *subchronic osteomyelitis*.

**chronic pain** Pain that persists or recurs for indefinite periods (usually more than 3 months), often involves deep body structures, is poorly localized, and is difficult to describe. Also called *persistent pain*.

**chronic pancreatitis** A progressive, destructive disease of the pancreas characterized by remissions and exacerbations. Inflammation and fibrosis of the tissue contribute to pancreatic insufficiency

and diminished function of the organ.

**chronic paronychia** Inflammation of the skin around the nail that persists for months. People at risk for chronic paronychia are those with frequent exposure to water, such as homemakers, bartenders, and laundry workers.

**chronic pyelonephritis** A kidney disorder that results from repeated or continued upper urinary tract infections or the effects of such infections.

**chronic stable angina (CSA)** Type of angina characterized by chest discomfort that occurs with moderate to prolonged exertion and in a pattern that is familiar to the patient.

**chyme** The liquid formed when food is transformed during the digestion process in the gastrointestinal tract.

**circle of Willis** At the base of the brain, the ring formed by the anterior, middle, and posterior cerebral arteries where they are joined together by small communicating arteries.

**circumcision** The surgical removal of the prepuce or foreskin of the penis.

**circumferential** Referring to something that completely surrounds an extremity or the thorax.

**cirrhosis** Liver disease that is characterized by extensive scarring of the liver and that is usually caused by a chronic irreversible reaction to hepatic inflammation and necrosis; disease typically develops insidiously and has a prolonged, destructive course.

**classic heat stroke** A form of heat stroke in which the body's ability to dissipate heat is significantly impaired; occurs over time as a result of long-term exposure to a hot, humid environment such as a home without air-conditioning in the high heat of the summer.

**clinical practice guideline** An "official recommendation" based on evidence to diagnose and/or manage a health problem (e.g., pain management).

**clinical psychologist** Member of the health care team who counsels patients and families on their psychological problems and on strategies to cope with disability.

**clinically competent** The condition of being legally competent and having decisional capacity.

**clonic (rhythmic)** Pertaining to a state of alternating muscle stiffness followed by rhythmic jerking motions, as in a tonic-clonic seizure.

**clonus** The sudden, brief, jerking contraction of a muscle or muscle group often seen in seizures. Also called *myoclonus*.

**closed fracture** A fracture that does not extend through the skin and therefore has no visible wound. Also called *simple fracture*.

**closed reduction** A nonsurgical method for managing a simple fracture. While applying a manual pull, or traction, on the bone, the health care provider manipulates the bone ends so that they realign.

**closed traumatic brain injury** A type of traumatic primary brain injury that occurs as the result of blunt trauma; the integrity of the skull is not violated, and damage to brain tissue depends on the degree and mechanisms of injury.

**clotting** A complex, multi-step process by which blood forms a protein-based structure (clot) in an appropriate area of tissue injury to prevent excessive bleeding while maintaining whole-body blood flow (perfusion).

**clubbing** Changes in the tissue beds of the fingers and toes, with the base of the nail becoming spongy; results from chronic oxygen deprivation in the tissue beds.

**cluster headache** A type of oculotemporal or oculofrontal headache marked by unilateral, excruciating, nonthrobbing pain that is felt deep in and around the eye and may radiate to the

forehead, temple, cheek, ear, occiput, or neck. Average duration is 10 to 45 minutes. Headaches occur every 8 to 12 hours and up to 24 hours daily at the same time for about 6 to 8 weeks (hence the term *cluster*), followed by remission for 9 months to a year. Cause and mechanism are unknown but have been attributed to vasoreactivity and oxyhemoglobin desaturation.

**clysis** See *hypodermoclysis*.

**coagulopathy** Clotting abnormalities.

**cognition** The ability of the brain to process, store, retrieve, and manipulate information.

**cognitive rehabilitation** A way of helping brain-injured patients regain function in areas that are essential for a return to independence and a reasonable quality of life.

**cognitive therapist** A member of the rehabilitative health care team, usually a neuropsychologist, who works primarily with patients who have experienced head injuries and have cognitive impairments.

**cohorting** The practice of grouping patients who are colonized or infected with the same pathogen.

**cold antibody anemia** A form of immunohemolytic anemia (in which the immune system attacks a person's own red blood cells for unknown reasons) that occurs with complement protein fixation on immunoglobulin M (IgM). In this condition, the arteries in the hands and feet constrict profoundly in response to cold temperatures or stress.

**cold phase** A phase after peripheral nerve trauma resulting in complete denervation in which the skin appears cyanotic, mottled, or reddish blue and feels cool compared with the contralateral unaffected extremity. The cold phase follows the warm phase, which lasts 2 to 3 weeks after injury.

**colectomy** Surgical removal of part or all of the colon.

**collaboration** The planning, implementing, and evaluation of patient care using an interdisciplinary (ID) plan of care.

**collateral circulation** Circulation that provides blood to an area with altered tissue perfusion through smaller vessels that develop and compensate for the occluded vessels.

**colon interposition** A surgical procedure that may be performed in patients with an esophageal tumor when the tumor involves the stomach or the stomach is otherwise unsuitable for anastomosis. In colon interposition, a section of right or left colon is removed and brought up into the thorax to substitute for the esophagus.

**colon resection** Surgery performed for colorectal cancer in which the tumor and regional lymph nodes are removed.

**colonoscopy** The endoscopic examination of the entire large bowel.

**colostomy** The surgical creation of an opening between the colon and the surface of the abdomen.

**colposcopy** Examination of the cervix and vagina using a colposcope, which allows three-dimensional magnification and intense illumination of epithelium with suspected disease. This procedure can locate the exact site of precancerous and malignant lesions for biopsy.

**comatose** Unconscious and cannot be aroused despite vigorous or noxious stimulation.

**comfort** A state of physical well-being, pleasure, and absence of pain or stress.

**command center** See *emergency operations center*.

**commando procedure** Mnemonic for combined neck dissection, mandibulectomy, and oropharyngeal resection—a procedure in which the surgeon removes a segment of the mandible with the oral lesion and performs a radical neck dissection.

**communicable** The ability of an infection, such as influenza, to be transmitted from person to person.

**communicating hydrocephalus** Form of hydrocephalus that occurs when the flow of cerebrospinal fluid (CSF) is blocked after it exits the ventricles; this form is “communicating” because CSF can still flow between the ventricles, which remain open.

**compartment syndrome** A condition in which increased tissue pressure in a confined anatomic space causes decreased blood flow to the area, leading to hypoxia and pain.

**compensated cirrhosis** A form of cirrhosis in which the liver has significant scarring but is still able to perform essential functions without causing significant symptoms.

**compensatory mechanism** The means of producing compensation. Also called *adaptive mechanism*.

**complement activation and fixation** Actions triggered by some classes of antibodies that can remove or destroy antigen.

**complete spinal cord injury** An injury in which the spinal cord has been severed or damaged in a way that eliminates all innervation below the level of the injury.

**complex regional pain syndrome (CRPS)** A complex disorder that includes debilitating pain, atrophy, autonomic dysfunction (excessive sweating, vascular changes), and motor impairment (most notably muscle paresis), probably caused by an abnormally hyperactive sympathetic nervous system. This syndrome most often results from traumatic injury and commonly occurs in the feet and hands; formerly called *reflex sympathetic dystrophy (RSD)*.

**compliance** In respiratory physiology, a measure of elasticity within the lung. Also, a patient's fulfillment of a caregiver's prescribed course of treatment.

**compound fracture** See *open fracture*.

**compression fracture** A fracture that is produced by a loading force applied to the long axis of cancellous bone. These fractures commonly occur in the vertebrae of patients with osteoporosis.

**computed tomography coronary angiography (CTCA)** 64-slice diagnostic scan used to diagnose coronary artery disease in symptomatic patients.

**conductive hearing loss** Hearing loss that results from any physical obstruction of sound wave transmission (e.g., a foreign body in the external canal, a retracted or bulging tympanic membrane, or fused bony ossicles).

**conductivity** The ability of a cell to transmit an electrical stimulus from cell membrane to cell membrane.

**congestive heart failure (CHF)** Former term for *left-sided heart failure*. Categorized as either systolic heart failure or diastolic heart failure, which may be acute or chronic and mild to severe.

**conization** The removal of a cone-shaped sample of tissue from the cervix for cytologic study.

**conjunctivae** The mucous membranes of the eye that line the undersurface of the eyelids (palpebral conjunctiva) and cover the sclera (bulbar conjunctiva).

**connective tissue disease (CTD)** A group of diseases that are the major focus of rheumatology (the study of rheumatic diseases); most are musculoskeletal disorders.

**consensual response** In assessing pupillary reaction to light, a slight constriction of the pupil of the eye not being tested when a penlight is brought in from the side of the patient's head and shined into the eye being tested as soon as the patient opens his or her eyes.

**consolidation** Solidification; lack of air spaces in the lung, such as occurs in pneumonia.

**constipation** The passage of hard, dry stool fewer than 3 times a week (as defined by the

Association of Rehabilitation Nurses).

**contact laser prostatectomy (CLP)** Procedure for treating benign prostatic hyperplasia that uses laser energy to coagulate excess tissue. Also called *interstitial laser coagulation (ILC)*.

**Contact Precautions** Infection control guidelines from the U.S. Centers for Disease Control and Prevention; used for patients with infections spread by direct contact or contact with items in the patient's environment, such as pediculosis.

**contiguous** Something in direct contact with, or adjacent to, another area or structure.

**continence** The ability to voluntarily control emptying the bladder and colon. Continence is a learned behavior whereby a person can suppress the urge to urinate until a socially appropriate location is available.

**continuous feeding** A method of tube feeding in which small amounts of enteral product are continuously infused (by gravity drip or by a pump or controller device) over a specified time.

**continuous femoral nerve blockade** A method used to administer anesthesia using an IV moderate sedation agent is used in addition to the neuraxial or PNB drug. PNB may be either a single injection or continuous infusion by a portable pump.

**continuous positive airway pressure (CPAP)** A respiratory treatment that improves obstructive sleep apnea in patients with heart failure.

**contractility** The ability of a cell to contract in response to an impulse. In cardiac electrophysiology, the ability of atrial and ventricular muscle cells to shorten their fiber length in response to electrical stimulation, generating sufficient pressure to propel blood forward. Contractility is the mechanical activity of the heart.

**contraction** The closure of a wound as new collagen replaces damaged tissue, pulling the wound edges inward along the path of least resistance.

**contralateral** Pertaining to the opposite side.

**contrecoup injury** Bruising of the brain tissue, with damage occurring on the side opposite the site of impact.

**control therapy drugs** Drugs used every day, regardless of symptoms, to reduce airway responsiveness to prevent asthma attacks from occurring.

**contusion** A bruise; when referring to closed head injury, a bruising of brain tissue usually found at the site of impact (coup injury). Compare with *contrecoup injury*.

**cor pulmonale** Right-sided heart failure caused by pulmonary disease.

**cordectomy** Excision of a vocal cord in surgery for laryngeal cancer.

**cornea** The clear layer that forms the external coat on the front of the eye.

**corneal abrasion** Scrape or scratch of the cornea that disrupts its integrity.

**corneal ulceration** Deep disruption of the corneal epithelium that extends into the stromal layer and is caused by bacteria, protozoa, or fungi.

**coronary artery bypass graft (CABG)** A surgical procedure in which occluded coronary arteries are bypassed with the patient's own venous or arterial blood vessels or synthetic grafts.

**coronary artery disease (CAD)** Disease affecting the arteries that provide blood, oxygen, and nutrients to the myocardium; partial or complete blockage of the blood flow through the coronary arteries, causing ischemia and infarction of the myocardium, angina pectoris, and acute coronary syndromes. Also known as *coronary heart disease* or simply *heart disease*.

**coronary artery vasculopathy (CAV)** A form of coronary artery disease that presents as diffuse

plaque in the arteries of the donor heart in patients who have received a heart transplant.

**cortisol** The main glucocorticoid produced by the adrenal cortex.

**coryza** The common cold, or acute viral rhinitis.

**cough assist** A technique for assisting the tetraplegic patient to cough. Place his or her hands on either side of the rib cage or upper abdomen below the diaphragm; then, as the patient inhales, push upward to help expand the lungs and cough.

**craniotomy** Surgical incision into the cranium.

**creatine kinase (CK)** An enzyme specific to cells of the brain, myocardium, and skeletal muscle. Its appearance in the blood indicates tissue necrosis or injury, with levels following a predictable rise and fall during a specified period.

**Credé maneuver** A technique used to assist in urination in which a patient places his or her hand in a cupped position directly over the bladder area and pushes inward and downward gently as if massaging the bladder to empty.

**crepitus** A continuous grating sensation caused when irregular cartilage or bone fragments rub together and which may be felt or heard as a joint is put through passive range of motion; also, a crackling sensation that can be felt on a patient's chest, indicating that air is trapped within the tissues.

**CREST syndrome** In patients with systemic sclerosis, the combination of **calc**cinosis (calcium deposits), **R**aynaud's phenomenon, **es**ophageal dysmotility, **s**clerodactyly (scleroderma of the digits), and **t**elangiectasia (spider-like hemangiomas).

**cricothyroidotomy** Surgical procedure in which an opening is made between the thyroid cartilage and cricoid cartilage ring and results in a tracheostomy. Also called *cricothyrotomy*. The procedure is used in an emergency for access to the lower airways.

**crises** In the patient with sickle cell disease, periodic episodes of extensive cellular sickling that have a sudden onset and can occur as often as weekly or as seldom as once a year.

**critical access hospital** A small rural facility of 15 or fewer inpatient beds that provides around-the-clock emergency care services 7 days per week. Considered a necessary provider of health care to community residents who are not close to other hospitals in a given region.

**cross-contamination** A type of contamination in which organisms from another person or from the environment are transmitted to the patient.

**cryotherapy** (1) A way of decreasing muscle pain by “cooling down” the area with a local, short-acting gel or cream, such as after physical therapy; (2) in ophthalmologic surgery, use of a freezing probe to repair retinal detachment.

**cryptorchidism** Failure of the testes to descend into the scrotum.

**culture of safety** A blame-free approach to improving care in high-risk, error-prone health care organizations using interprofessional collaboration. Patients and families are encouraged to become safety partners in protecting patients from harm.

**culture** A procedure for identifying a microorganism by cultivating and isolating it in tissue cultures or artificial media.

**Curling's ulcer** Acute ulcerative gastroduodenal disease, which may develop within 24 hours of a severe burn injury because of reduced gastrointestinal blood flow and mucosal damage.

**Cushing's disease (Cushing's syndrome)** Hypercortisolism caused by oversecretion of hormones by the adrenal cortex.

**Cushing's triad** A classic yet late sign of increased intracranial pressure (ICP) manifested by severe

hypertension with a widened pulse pressure and bradycardia. As ICP increases, the pulse becomes thready, irregular, and rapid. Cerebral blood flow increases in response to hypertension.

**Cushing's ulcer** Acute ulcerative gastroduodenal disease that may develop as a result of increased intracranial pressure.

**cutaneous (superficial) reflexes** Superficial reflexes. Usually the plantar and abdominal reflexes are tested.

**cyanosis** Bluish or darkened discoloration of the skin and mucous membranes; results from an increased amount of deoxygenated hemoglobin.

**cyclic feeding** A method of tube feeding similar to continuous feeding (see definition of *continuous feeding*) except the infusion is stopped for a specified time in each 24-hour period ("down time"); the down time typically occurs in the morning to allow bathing, treatments, and other activities.

**cystitis** Inflammation of the bladder.

**cystocele** Herniation of the bladder into the vagina.

**cytokines** Small protein hormones produced by white blood cells.

**cytotoxic** Having cell-damaging effects.

## D

**dandruff** An accumulation of patchy or diffuse white or gray scales on the surface of the scalp.

**death rattle** Loud, wet respirations caused by secretions in the respiratory tract and oral cavity of a patient who is near death.

**death** When illness or trauma overwhelms the compensatory mechanisms of the body and the lungs and heart cease to function.

**débridement** The removal of infected tissue from a healing wound.

**debriefing** After a mass casualty incident or disaster, (1) the provision of sessions for small groups of staff in which teams are brought in to discuss effective coping strategies (critical incident stress debriefing), and (2) the administrative review of staff and system performance during the event to determine opportunities for improvement in the emergency management plan.

**debris** Dead cells and tissues in a wound.

**decerebrate posturing** Abnormal posturing and rigidity characterized by extension of the arms and legs, pronation of the arms, plantar flexion, and opisthotonos; usually associated with dysfunction in the brainstem area. Also called *decerebration*.

**decerebration** See *decerebrate posturing*.

**decompensated cirrhosis** A form of cirrhosis in which liver function is significantly impaired with obvious manifestations of liver failure.

**decompressive craniectomy** Removal of a section of the skull in the patient with uncontrolled intracranial pressure (ICP); allows for additional space for edema without increasing ICP.

**decorticate posturing** Abnormal posturing seen in the patient with lesions that interrupt the corticospinal pathways. The arms, wrists, and fingers are flexed with internal rotation and plantar flexion of the legs. Also called *decortication*.

**decortication** See *decorticate posturing*.

**deep tendon reflexes** Tested as part of the neurologic assessment. An intact reflex arc is indicated

when the muscle contracts in response to the tendon being struck with a reflex hammer.

**deep vein thrombophlebitis** Presence of a thrombus associated with inflammation in the deep veins, usually in the legs. Compared with superficial thrombophlebitis, it presents a greater risk for pulmonary embolism. Also called *deep vein thrombosis*.

**deep vein thrombosis (DVT)** Common term for *deep vein thrombophlebitis*.

**defibrillation** An asynchronous countershock that depolarizes a critical mass of myocardium simultaneously to stop the re-entry circuit, allowing the sinus node to regain control of the heart.

**dehiscence** A partial or complete separation of the outer layers of a wound, sometimes described as a “splitting open” of the wound.

**dehydration** Fluid intake less than what is needed to meet the body's fluid needs.

**delayed union** Term describing a fracture that has not healed within 6 months of injury.

**delegation** The process of transferring to a competent person the authority to perform a selected nursing task or activity in a selected patient care situation.

**delirium** An acute state of confusion, usually short-term and reversible within 3 weeks. Often seen among older adults in a hospital or other unfamiliar setting.

**dementia** A syndrome of slowly progressive cognitive decline with global impairment of intellectual function. The most common type is Alzheimer's disease.

**demyelination** Destruction of myelin between the nodes of Ranvier; a major pathologic finding in multiple sclerosis or Guillain-Barré syndrome.

**depolarization** The ability of a cell to respond to a stimulus by initiating an impulse. Also called *excitability*.

**depression** A response to multiple life stresses, a single situation, a primary disorder, or a problem associated with dementia; this response can range from mild, transient feelings of sadness to a severe sense of helplessness and hopelessness.

**dermal papillae** Fingerlike projections of dermal tissue that anchor the epidermis to the dermis.

**dermatomes** Specific areas of the skin that receive sensory input from spinal nerves.

**descending tracts** Groups of nerves that begin in the brain and end in the spinal cord.

**desquamation** The shedding or peeling of skin.

**diabetic nephropathy** A vascular complication of diabetes mellitus that causes permanent damage to kidney tissue and is a leading cause of end-stage kidney disease.

**diabetic peripheral neuropathy (DPN)** A progressive deterioration of nerves that results in loss of nerve function (sensory perception). A common complication of diabetes, it often involves all parts of the body.

**diagnostic peritoneal lavage (DPL)** Test that determines the presence of internal bleeding following abdominal trauma.

**dialysate** The solution used in dialysis. It is composed of water, glucose, sodium chloride, potassium, magnesium, calcium, and bicarbonate; dialysate composition may be altered according to the patient's needs for treatment of electrolyte imbalances.

**dialyzer** The apparatus used to perform hemodialysis. Also known as the “artificial kidney,” it has four parts: a blood compartment, a dialysate compartment, a semipermeable membrane, and an enclosed structure to support the membrane.

**diaphragmatic pacing** A pacemaker for the phrenic nerve to cause the diaphragm to contract

(leading to inhalation). Also known as *phrenic nerve pacing*.

**diarrhea** A condition in which the stool can be watery and without solid form.

**diastole** The phase of the cardiac cycle that consists of relaxation and filling of the atria and ventricles; normally about two thirds of the cardiac cycle.

**diastolic blood pressure** The amount of pressure/force against the arterial walls during the relaxation phase of the heart.

**diastolic heart failure** Heart failure that occurs when the left ventricle is unable to relax adequately during diastole, which prevents the ventricle from filling with sufficient blood to ensure adequate cardiac output.

**Dietary Guidelines for Americans** Recommendations made by the USDA and U.S. Department of Health and Human Services to help people maintain nutritional health; updated every 5 years.

**Dietary Reference Intakes (DRIs)** Nutrition guide developed by the Institute of Medicine of the National Academies that provides a scientific basis for food guidelines in the United States and Canada.

**diffuse axonal injury (DAI)** A type of closed head injury that is usually related to high-speed acceleration/deceleration, as with motor vehicle crashes. There is significant damage to axons in the white matter, and there are lesions in the corpus callosum, midbrain, cerebellum, and upper brainstem. Patients with severe injury may present with immediate coma, and most survivors require long-term care.

**diffuse cutaneous systemic sclerosis** Skin thickening on the trunk, face, and proximal and distal extremities in patients with systemic sclerosis.

**diffuse light reflex** A description of a light reflex that is spotty or multiple because of a changed eardrum shape from either retraction or bulging.

**diffusion** The spontaneous, free movement of particles (solute) across a permeable membrane down a concentration gradient; that is, from an area of higher concentration to an area of lower concentration.

**digestion** The mechanical and chemical process in which complex foodstuffs are broken down into simpler forms that can be used by the body.

**digital 3D mammography** Breast imaging procedure that allows the radiologist to visualize through layers or "slices" of breast tissue, similar to a CT scan.

**digoxin toxicity** A reaction to therapy with digitalis derivatives (digoxin) that is identified by monitoring serum digoxin and potassium levels (hypokalemia potentiates digitalis toxicity). Signs of toxicity are nonspecific (anorexia, fatigue, changes in mental status). Toxicity may cause dysrhythmia, most commonly premature ventricular contractions.

**dilated cardiomyopathy (DCM)** A type of cardiomyopathy that involves extensive damage to the myofibrils and interference with myocardial metabolism. There is normal ventricular wall thickness but dilation of both ventricles and impairment of systolic function.

**dilation** Increase in the diameter of blood vessels.

**diplopia** Double vision.

**direct current stimulation (DCS)** The placement of an implantable device to promote bone fusion; used as an adjunct for patients for whom spinal fusion may be difficult.

**direct inguinal hernia** A sac formed from the peritoneum that contains a portion of the intestine and passes through a weak point in the abdominal wall.

**direct response** Pupil constriction in response to bringing a penlight in from the side of the patient's

head and shining the light in the eye being tested as soon as the patient opens his or her eyes.

**directly observed therapy (DOT)** A technique in which a health care professional watches the patient swallow prescribed drugs.

**disabling health condition** Any physical or mental health problem that can cause disability.

**disaster triage tag system** A system that categorizes triage priority by colored and numbered tags.

**disaster** A mass casualty incident in which the number of casualties exceeds the resource capabilities of a particular community or hospital facility.

**discoid lesion** Round lesion in patients who have discoid lupus erythematosus; evident when exposed to sunlight or ultraviolet light.

**disease-modifying antirheumatic drugs (DMARDs)** Drugs prescribed to slow the progression of mild rheumatoid disease before it worsens, such as hydroxychloroquine, sulfasalazine, or minocycline.

**disequilibrium** A condition in which the hydrostatic pressure is not the same in the two fluid spaces on either side of a permeable membrane.

**disinfection** A method of infection control in which the level of disease-causing organisms is reduced but the organisms are not killed; adequate when an item is entering a body area that has resident bacteria or normal flora, such as the respiratory tract.

**diskitis** Disk inflammation.

**dislocation of a joint** Occurrence of the articulating surfaces of two or more bones moving away from each other.

**dissociate** The act of separating and releasing ions.

**diverticula** Sacs resulting from the herniation of the mucosa and submucosa of a tubular organ into surrounding tissue.

**diverticulitis** The inflammation of one or more diverticula.

**diverticulosis** The presence of many abnormal pouchlike herniations (diverticula) in the wall of the intestine.

**dizziness** A disturbed sense of a person's relationship to space.

**DNR** Do not resuscitate; order from a physician or other authorized health care provider who instructs that CPR not be attempted in the event of cardiac or respiratory arrest.

**dopamine agonist** A class of drugs that mimic dopamine. Dopamine agonists stimulate dopamine receptors and are typically the most effective during the first 3 to 5 years of use. Prescribed for the patient with Parkinson disease to reduce dyskinesias (problems with movement).

**dose-dense chemotherapy** Chemotherapy that uses higher doses more often for aggressive cancer treatment, especially breast cancer.

**double-barrel stoma** The least common type of colostomy, which is created by dividing the bowel and bringing both the proximal and distal portions to the abdominal surface to create two stomas.

**double-contrast barium enema** A type of contrast radiography (x-rays) in which the patient's colon and rectum are visualized after a liquid containing barium, and then air, is placed into the colon.

**doubling time** The amount of time it takes for a tumor to double in size.

**Droplet Precautions** Infection control guidelines from the U.S. Centers for Disease Control and Prevention; used for patients with infections spread by the droplet transmission route, such as

influenza.

**drug holiday** Period of time lasting up to 10 days in which the patient with Parkinson disease receives no drug therapy.

**dual x-ray absorptiometry (DXA or DEXA)** A type of radiographic scan that measures bone mineral density in the hip, wrist, or vertebral column; used as a screening and diagnostic tool for diagnosis and for follow-up evaluation of treatment of osteoporosis.

**ductal carcinoma in situ (DCIS)** An early, noninvasive form of breast cancer in which cancer cells are located within the duct and have not invaded the surrounding fatty breast tissue.

**ductal ectasia** A benign breast disease caused by dilation and thickening of the collecting ducts in the subareolar area. The ducts become distended and filled with cellular debris, which activates an inflammatory response. It is usually seen in women approaching menopause.

**dumping syndrome** A constellation of vasomotor symptoms that typically occur within 30 minutes after eating; believed to occur as a result of the rapid emptying of gastric contents into the small intestine, which shifts fluid into the gut and causes abdominal distention. Early manifestations include vertigo, tachycardia, syncope, sweating, pallor, and palpitations.

**Dupuytren's contracture** A slowly progressive contracture of the palmar fascia that results in flexion of the fourth or fifth digit of the hand and occasionally affects the third digit. Although a fairly common problem, the cause is unknown. It usually occurs in older men, tends to occur in families, and can be bilateral.

**durable power of attorney for health care (DPOAHC)** A legal document in which a person appoints someone else to make health care decisions in the event he or she becomes incapable of making decisions.

**dysarthria** Slurred speech.

**dysfunctional uterine bleeding (DUB)** A nonspecific term to describe bleeding that is excessive or abnormal in amount or frequency without predisposing anatomic or systemic conditions. Such bleeding occurs most often at either end of the span of a woman's reproductive years, when ovulation is becoming established or when it is becoming irregular at menopause.

**dyskinesia** Difficulty with movement.

**dyslexia** Problems understanding written language; caused by brain injury or disease.

**dysmetria** The inability to direct or limit movement.

**dyspareunia** Painful sexual intercourse.

**dyspepsia** Indigestion or heartburn following meals.

**dysphagia** Difficulty in swallowing.

**dysphasia** Slurred speech.

**dyspnea on exertion (DOE)** Dyspnea that is associated with activity, such as climbing stairs.

**dyspnea** Difficulty in breathing or breathlessness.

**dysrhythmia** A disorder of the heartbeat involving a disturbance in cardiac rhythm; irregular heartbeat.

**dystrophic** Pertaining to or characterized by dystrophy; abnormal.

**dystrophin** A muscle protein that maintains muscle integrity by sending signals to coordinate smooth, synchronous muscle fiber contraction. Faulty action of this protein causes muscular dystrophy.

**dysuria** Painful urination.

## E

**Eaton-Lambert syndrome** A form of myasthenia gravis that affects the muscles of the trunk and the pelvic and shoulder girdles; often observed in combination with small cell carcinoma of the lung. Although weakness increases after exertion, there may be a temporary increase in muscle strength during the first few contractions, followed by a rapid decline.

**ecchymoses** Large purple, blue, or yellow bruises of the skin resulting from small hemorrhages; these bruises are larger than petechiae.

**ecchymotic** Pertaining to a bruise.

**ECG caliper** A measurement tool used in analysis of an electrocardiographic (ECG) rhythm strip.

**echocardiography** In cardiovascular assessment, the use of ultrasound waves to assess cardiac structure and mobility, particularly of the valves; a noninvasive, risk-free test that is easily performed at the bedside or on an ambulatory care basis.

**echolalia** Automatic repetition of what another person says.

**ectopic** Out of place.

**ectropion** A turning outward and sagging of the eyelid, which is caused by relaxation of the orbicular muscle.

**edema** Tissue swelling as a result of the accumulation of excessive fluid in the interstitial spaces.

**edentulous** Without teeth.

**efferent arterioles** The extremely small blood vessels that carry the remaining blood out of the glomerulus (once the glomerulus has filtered the blood to make urine) and into one of two additional capillary systems (the peritubular capillaries or the vasa recta).

**effluent** Drainage.

**effusion** An accumulation of fluid, such as in a joint (where it may limit movement).

**ejection fraction** The percentage of blood ejected from the heart during systole.

**electrical bone stimulation** The use of an electronic device (e.g., magnetic coils applied on the skin or over a cast to deliver a pulsed magnetic field) to promote bone union after a fracture. The exact mechanism of action is unknown, but this procedure is based on research showing that bone has inherent electrical properties that are used in healing.

**electrocardiogram (ECG)** A graphic recording of the electrical current generated by the heart. The ECG provides information about cardiac dysrhythmias, myocardial ischemia, site and extent of myocardial infarction, cardiac hypertrophy, electrolyte imbalances, and effectiveness of cardiac drugs. It is a routine part of cardiovascular evaluation and is a valuable diagnostic test.

**electroencephalography (EEG)** A recording of the electrical activity of the cerebral hemispheres; it represents the voltage changes in various areas of the brain as determined by recording the difference between two electrodes.

**electrolyte** A substance in body fluids that carries an electrical charge. Also called an *ion*.

**electromyography (EMG)** A recording of the electrical activity of peripheral nerves by testing muscle activity.

**electrophysiologic study (EPS)** In cardiovascular assessment, an invasive procedure performed in a catheterization laboratory during which programmed electrical stimulation of the heart is used

to induce and evaluate lethal dysrhythmias and conduction abnormalities to permit accurate diagnosis and effective treatment. The study is used in patients who have survived cardiac arrest, have recurrent tachydysrhythmias, or experience unexplained syncopal episodes.

**electrovaporization of the prostate (EVAP)** Procedure for treating benign prostatic hyperplasia with high-frequency electrical current to cut and vaporize excess tissue.

**elimination** The excretion of waste from the body by the GI tract (as feces) and by the kidneys (as urine).

**embolectomy** Removal of a blood clot.

**embolic stroke** Damage to the brain when a blood clot forms somewhere in the body (usually the heart) and travels through the bloodstream to block one or more of the arteries supplying the brain.

**embolus** The occurrence of inflammation and thickening of the vein wall around a clot (thrombus).

**emergence** Recovery from anesthesia.

**emergency medical technician (EMT)** Prehospital care provider who supplies basic life-support interventions such as oxygen, basic wound care, splinting, spinal immobilization, and monitoring of vital signs.

**emergency medicine physician** A member of the emergency health care team with education and training in the specialty of emergency patient management.

**emergency operations center (EOC)** A designated location in the Hospital Incident Command System (HICS) with accessible communication technology. Also called the *command center*.

**emergency preparedness** A goal or plan to meet an extraordinary need for hospital beds, staff, drugs, personal protective equipment, supplies, and medical devices such as mechanical ventilators.

**Emergency Severity Index (ESI)** A standardized model for triage that categorizes both patient acuity and resource utilization into five levels, from most urgent to least urgent.

**emergent triage** In a three-tiered triage scheme, the category that includes any condition or injury that poses an immediate threat to life or limb, such as crushing chest pain or active hemorrhage.

**emetogenic** A substance that induces nausea and vomiting.

**emmetropia** The state of perfect refraction of the eye; with the lens at rest, light rays from a distant source are focused into a sharp image on the retina.

**emotional abuse** The intentional use of threats, humiliation, intimidation, and isolation to another person.

**emotional lability** Having uncontrollable emotions; for example, the patient laughs and then cries unexpectedly for no apparent reason.

**empyema** A collection of pus in the pleural space.

**encephalitis** An inflammation of the brain parenchyma (brain tissue) and meninges that affects the cerebrum, brainstem, and cerebellum; usually caused by a virus.

**endogenous** An infection in which organisms are carried by the bloodstream from other areas of infection in the body.

**endometrial ablation** Procedure for dysfunctional uterine bleeding that removes a built-up uterine lining using a laser, roller ball, or balloon.

**endometrial cancer** Cancer of the inner uterine lining.

**endometriosis** The abnormal occurrence of endometrial tissue outside the uterine cavity.

**endometritis** An infection of the endometrium.

**endoscope** A tube that allows viewing and manipulation of internal body areas.

**endoscopic retrograde cholangiopancreatography (ERCP)** The visual and radiographic examination of the liver, gallbladder, bile ducts, and pancreas by means of an endoscope and the injection of radiopaque dye to identify the cause and location of obstruction.

**endoscopic variceal ligation (EVL)** The application of small "O" bands around the base of esophageal varices to cut off their blood supply. Also called *banding*.

**endoscopy** The direct visualization of the gastrointestinal tract by means of a flexible fiberoptic endoscope.

**endothelin** A secretion produced by the endothelial cells when they are stretched.

**endovascular stent graft** The repair of an abdominal aortic aneurysm using a stent made of flexible material; the stent is inserted through a skin incision into the femoral artery by way of a catheter-based system.

**end-stage kidney disease (ESKD)** Acute renal failure combined with chronic renal insufficiency, resulting in the inability of the kidney to excrete waste products normally. The patient may need hemodialysis or a kidney transplant.

**energy conservation** Strategies to reduce the fatigue associated with chronic and disabling conditions, such as allowing rest periods and setting priorities.

**engraftment** The successful transplantation of cells in the patient's bone marrow.

**enophthalmos** Backward displacement of the eyeball into the orbit so that the eye appears sunken.

**enteroscopy** Visualization of the small intestine.

**enterostomal feeding tube** A tube used for patients who need long-term enteral feeding; the physician directly accesses the gastrointestinal tract using surgical, endoscopic, or laparoscopic techniques.

**entropion** The turning inward of the eyelid, causing the eyelashes to rub against the eye.

**enucleation** The surgical removal of the entire eyeball.

**envenomation** Venom injection from a snakebite.

**epididymitis** Inflammation of the epididymis.

**epidural hematoma** An accumulation of clotted blood resulting from arterial bleeding into the space between the dura and the skull; a neurosurgical emergency.

**epidural** Term for the space between the dura mater and vertebrae; it consists of fat, connective tissue, and blood vessels.

**epiglottis** A leaf-shaped, elastic structure that is attached along one edge to the top of the larynx; it closes over the glottis during swallowing to prevent food from entering the trachea and opens during breathing and coughing.

**epiglottitis** Infection or inflammation of the epiglottis and supraglottic structures that results in swelling. If swelling is great enough, the airway can be obstructed.

**epilepsy** A chronic disorder characterized by recurrent, unprovoked seizure activity; may be caused by an abnormality in electrical neuronal activity, an imbalance of neurotransmitters, or a combination of both.

**epistaxis** Nosebleed.

**erectile dysfunction (ED)** The inability to achieve or maintain a penile erection sufficient for sexual intercourse.

**ergonomics** An applied science in which the workplace is designed to increase worker comfort (thus reducing injury) while increasing efficiency and productivity.

**erosion** Ulceration.

**eructation** The act of belching.

**erythema migrans** A round or oval flat or slightly raised rash.

**erythema** Redness of the skin.

**erythrocyte** A red blood cell (RBC). Red blood cells are the major cells in the blood and are responsible for tissue oxygenation.

**erythroplakia** A velvety red mucosal lesion, most often occurring in the oral cavity.

**erythropoiesis** The selective maturation of stem cells into mature erythrocytes.

**eschar** The crust of dead tissue that forms from coagulated particles of destroyed dermis in a patient with a full-thickness burn injury.

**escharotomy** Incision made through tight eschar to relieve pressure and allow normal blood flow and breathing.

**esophageal stricture** Narrowing of the esophageal opening.

**esophageal varices** The distention of fragile, thin-walled esophageal veins due to increased pressure; the increased pressure is a result of portal hypertension, in which the blood backs up from the liver and enters the esophageal and gastric vessels that carry it into the systemic circulation.

**esophagectomy** The surgical removal of all or part of the esophagus.

**esophagitis** Inflammation of the esophagus.

**esophagogastroduodenoscopy (EGD)** The visual examination of the esophagus, stomach, and duodenum by means of a fiberoptic endoscope.

**esophagogastrostomy** The surgical creation of a communication between the stomach and the esophagus; it involves the removal of part of the esophagus and proximal stomach.

**essential hypertension** Elevated blood pressure that is not caused by a specific disease. The major risk factor is a family history of hypertension. Also called *primary hypertension*.

**euploid** Having the correct number of chromosome pairs for the species.

**euploidy** The normal diploid number for a cell.

**eustachian tube** Tube that connects the nasopharynx with the middle ear and opens during swallowing to equalize pressure within the middle ear.

**euthyroid** Having normal thyroid function.

**euvolemia** A state of balanced fluid intake and output.

**evidence-based practice (EBP)** A QSEN competency in which the nurse integrates best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care.

**evisceration** The total separation of all layers of a wound and the protrusion of internal organs

through the open wound.

**evoked potentials** Tests to measure the electrical signals to the brain generated by hearing, touch, or sight. Also called *evoked response*.

**exacerbation** An increase in severity of a disease. Also called *flare-up*.

**excitability** The ability of a cell to respond to a stimulus by initiating an impulse. Also called *depolarization*. In cardiac electrophysiology, it is the ability of non-pacemaker myocardial cells to respond to an electrical impulse generated from pacemaker cells and to depolarize.

**exemplars** Selected health problems and issues that are associated with health and professional nursing concepts.

**exercise electrocardiography** In cardiovascular assessment, a test that assesses cardiovascular response to an increased workload. Also called *exercise tolerance* or a *stress test*. Exercise electrocardiography helps determine the functional capacity of the heart, screens for coronary artery disease, and identifies dysrhythmias that develop during exercise. It also aids in evaluating the effectiveness of antidysrhythmic drugs.

**exercise tolerance** See *exercise electrocardiography*.

**exertional dyspnea** Breathlessness or difficulty breathing that develops during activity or exertion.

**exertional heat stroke** A form of heat stroke with a sudden onset, typically due to strenuous physical activity in hot, humid conditions. Lack of acclimatization to hot weather and wearing clothing too heavy for the environment are common contributing factors.

**exogenous hyperthyroidism** Hyperthyroidism caused by excessive use of thyroid replacement hormones.

**exogenous** Originating outside the body.

**exophthalmos** Abnormal protrusion of the eyeball (proptosis).

**expedited partner therapy (EPT)** Therapy used to treat chlamydia in which patients are given a drug or prescription with specific instructions for administration to their partners without direct evaluation by a health care provider. Also called *patient-delivered partner therapy*.

**exploratory laparotomy** A surgical opening of the abdominal cavity to investigate the cause of an obstruction or peritonitis.

**exposure** (1) The final component of the primary survey that allows for thorough assessment of the trauma patient; (2) in radiation therapy, the amount of radiation that is delivered to a tissue.

**expressed gene** When a particular gene has been “turned on.”

**expressed** Turned on or activated.

**expressive aphasia** A type of aphasia resulting from damage in Broca's area of the frontal lobe of the brain. A motor speech problem in which the patient understands what is said but is unable to communicate verbally and has difficulty writing; rote speech and automatic speech, such as responses to a greeting, are often intact. The patient is aware of the deficit and may become frustrated and angry. Also called *Broca's aphasia* or *motor aphasia*.

**expressivity** In genetics, the degree of expression a person has when a specific autosomal dominant gene is present. The gene is always expressed, but some people have more severe results.

**external fixation** A system in which pins or wires are passed through skin and bone and connected to a rigid external frame to immobilize a fracture during healing.

**external fixator** See *external fixation*.

**external hemorrhoid** A hemorrhoid that lies below the anal sphincter and can be seen on inspection

of the anal region.

**external otitis** A painful irritation or infection of the skin of the external ear, with resulting allergic response or inflammation. When it occurs in patients who participate in water sports, external otitis is called *swimmer's ear*.

**external urethral sphincter** The sphincter composed of the skeletal muscle that surrounds the urethra.

**extracapsular** Located outside the joint capsule.

**extracellular fluid (ECF)** The portion of total body water (about one third) that is in the space outside the cells. This space also includes interstitial fluid, blood, lymph, bone, and connective tissue water, and the transcellular fluids.

**extracranial-intracranial bypass** A surgical procedure in which the surgeon performs a craniotomy and bypasses the blocked artery by making a graft (bypass) from the first artery to the second artery to establish blood flow around the blocked artery and re-establish blood flow to the involved areas.

**extramedullary tumor** A tumor found within the spinal dura but outside the cord.

**extrapulmonary** Involving nonpulmonary tissues.

**extravasation** Escape of fluids or drugs into the subcutaneous tissue; a complication of intravenous infusion.

**extrinsic factor** In hematology, an event (e.g., trauma) that occurs outside the blood to cause platelet plugs to form.

**extubation** The removal of an endotracheal tube.

## F

**facial paralysis** See *Bell's palsy*.

**facilitated diffusion** Diffusion across a cell membrane that requires the assistance of a transport system or membrane-altering system. Also called *facilitated transport*.

**facilitated transport** See *facilitated diffusion*.

**failed back surgery syndrome (FBSS)** A combination of organic, psychological, and socioeconomic factors in patients for whom back surgery is not successful. Discouraged by repeated surgical procedures, these patients must continue long-term nonsurgical management of pain, including nerve blocks.

**failure to rescue** The inability of nurses or other interprofessional health team members to save a patient's life in a timely manner when a health care issue or medical complication occurs.

**fall** An unintentional change in body position that results in the patient's body coming to rest on the floor or ground.

**fallophobia** In some older adults, the fear of falling and sustaining a serious injury.

**far point (of vision)** The farthest point at which the eye can see an object.

**fascia** An inelastic tissue that surrounds groups of muscles, blood vessels, and nerves in the body.

**fasciculation** Abnormal, involuntary twitching of a muscle.

**fasciotomy** A surgical procedure in which an incision is made through the skin and subcutaneous tissues into the fascia of the affected compartment to relieve the pressure in and restore circulation to the affected area in the patient with acute compartment syndrome.

**fat embolism syndrome (FES)** A serious complication, usually resulting from a fracture, in which fat globules are released from the yellow bone marrow into the bloodstream. This syndrome usually occurs within 48 hours of the fracture and can result in respiratory failure or death, often from pulmonary edema.

**fatigue (stress) fracture** A fracture that results from excessive or repeated strain and stress on a bone.

**fatty liver** Caused by the accumulation of fats in and around the hepatic cells. It may be caused by alcohol abuse or other factors. Also known as *steatosis*.

**fecal microbiota transplantation (FMT)** A procedure in which healthy normal flora is placed into the lower GI system of the infected patient who does not respond to antibiotic therapy or has recurrent disease .

**fecal occult blood test (FOBT)** A diagnostic test that measures the presence of blood in the stool from gastrointestinal bleeding; this is a common finding associated with colorectal cancer.

**Felty's syndrome** The combination of rheumatoid arthritis, hepatosplenomegaly (enlarged liver and spleen), and leukopenia.

**femoral hernia** A hernia that protrudes through the femoral ring.

**fetor hepaticus** The distinctive fruity or musty breath odor of chronic liver disease and portal-systemic encephalopathy.

**fibrinolysis** The breakdown of a clot.

**fibrinolytic** Drug that targets the fibrin component of the coronary thrombosis; used to dissolve thrombi in the coronary arteries and restore myocardial blood flow; examples include tissue plasminogen activator, anisoylated plasminogen-streptokinase activator complex, and reteplase.

**fibroadenoma** A solid, slowly enlarging benign mass of connective tissue that is unattached to the surrounding breast tissue and is typically discovered by the patient herself. The mass is usually round, firm, easily movable, nontender, and clearly delineated from the surrounding tissue.

**fibrocystic breast condition (FBC)** Physiologic nodularity of the breast that is thought to be caused by an imbalance in the normal estrogen-to-progesterone ratio. It is the most common breast problem of women between 20 and 30 years of age.

**fibroids** See *leiomyomas*.

**fibromyalgia syndrome (FMS)** A chronic pain syndrome characterized by pain and tenderness at specific sites in the back of the neck, upper chest, trunk, low back, and extremities along with fatigue, sleep disturbances, and headache.

**fibrosis** Replacement of normal cells with connective tissue and collagen (scar tissue).

**fidelity** Ethical principle that refers to the agreement that nurses will keep their obligations or promises to patients to follow through with care.

**filter** The movement of fluid from the space with higher hydrostatic pressure through the membrane into the space with lower hydrostatic pressure.

**filtration** The movement of fluid through a cell or blood vessel membrane because of hydrostatic pressure differences on both sides of the membrane.

**financial abuse** Mismanagement or misuse of the patient's property or resources.

**first heart sound (S<sub>1</sub>)** Sound created by the closure of the mitral and tricuspid valves (atrioventricular valves).

**first intention** Healing in which the wound can be easily closed and dead space eliminated without

granulation, which thus shortens the phases of tissue repair. Inflammation resolves quickly, and connective tissue repair is minimal, resulting in a thin scar.

**fistula** An abnormal opening between two adjacent organs or structures.

**five cardinal manifestations of inflammation** Warmth, redness, swelling, pain, and decreased function.

**fixed occlusion** Wiring the jaws together in the mouth closed position.

**flaccid bladder** See *areflexic bladder*.

**flaccid paralysis** Paralysis of a part of the body that is characterized by loss of muscle tone due to hypotonia; may be seen in the patient who has experienced a brain attack.

**flail chest** Inward movement of the thorax during inspiration, with outward movement during expiration; results from multiple rib fractures caused by blunt chest trauma that leaves a segment of the chest wall loose.

**flat bone** Bone that protects vital organs and often contains blood-forming cells, such as the scapula.

**flatulence** The presence of an excessive amount of gas in the stomach or intestines.

**fluid and electrolyte balance** The regulation of body fluid, fluid osmolality, and electrolytes by processes such as filtration, diffusion, and osmosis.

**fluid overload** An excess of body fluid. Also called *overhydration*.

**folliculitis** A superficial bacterial infection involving only the upper portion of the hair follicle.

**forensic nurse examiner (RN-FNE)** Emergency department specialist who is trained to recognize evidence of abuse and to intervene on the patient's behalf and who obtains patient histories, collects forensic evidence, and offers counseling and follow-up care for victims of rape, child abuse, and domestic violence.

**fracture** A break or disruption in the continuity of a bone.

**fremitus** Vibrations felt on the chest or back when the patient talks.

**fremitus** Vibration.

**frequency** (1) The highness or lowness of tones (expressed in hertz). The greater the number of vibrations per second, the higher the frequency (pitch) of the sound; the fewer the number of vibrations per second, the lower the pitch; (2) an urge to urinate frequently in small amounts.

**fresh frozen plasma (FFP)** Plasma that is frozen immediately after donation so that the clotting factors are preserved.

**friable** Easily crumbled or damaged.

**frostbite** A cold injury characterized by the degree of tissue freezing and the resultant damage it produces. Frostbite injuries can be superficial, partial, or full thickness.

**frostnip** A form of superficial frostbite (typically on the face, fingers, or toes) that produces pain, numbness, and pallor but is easily remedied with the application of warmth and does not induce tissue injury.

**Fulmer SPICES** A framework that identifies six serious "marker conditions" that can lead to longer hospital stays for patients, higher medical costs, and deaths.

**fulminant hepatitis** A severe acute and often fatal form of hepatitis caused by failure of the liver cells to regenerate, with progression to necrosis.

**furuncle** A localized inflammation of the skin caused by bacterial infection, usually *Staphylococcus*, of a hair follicle. Also called a *boil*.

## G

**gallium scan** A test that is similar to a bone scan but that uses the radioisotope *gallium citrate* and is more specific and sensitive in detecting bone problems. This substance also migrates to brain, liver, and breast tissue and therefore is used to examine these structures when disease is suspected.

**gamma globulin** See *immunoglobulin*.

**ganglion** A round, cystlike lesion, often overlying a wrist joint or tendon.

**gas exchange** The process of oxygen transport to the cells and carbon dioxide transport away from the cells through ventilation and diffusion.

**gastrectomy** The surgical removal of part or all of the stomach.

**gastric bypass** A type of gastric restriction surgery in which gastric resection is combined with malabsorption surgery. The patient's stomach, duodenum, and part of the jejunum are bypassed so that fewer calories can be absorbed. Also known as a *Roux-en-Y gastric bypass*, or *RNYGB*.

**gastric lavage** Procedure of irrigating the stomach in which a large-bore nasogastric tube is inserted into the stomach and room-temperature solution is instilled in volumes of 200 to 300 mL. The solution and blood are repeatedly withdrawn manually until returns are clear or light pink and without clots.

**gastritis** An inflammation of the gastric mucosa (stomach lining).

**gastroenteritis** An increase in the frequency and water content of stools or vomiting as a result of inflammation of the mucous membranes of the stomach and intestinal tract. It affects primarily the small bowel and can be of either viral or bacterial origin.

**gastroesophageal reflux (GER)** Condition that occurs as a result of backward flow of stomach contents into the esophagus.

**gastroesophageal reflux disease (GERD)** An upper gastrointestinal disease caused by the backward flow (reflux) of gastrointestinal contents into the esophagus.

**gastrojejunostomy** Surgical anastomosis of the stomach to the jejunum.

**gastroparesis** Delay in gastric emptying.

**gastrostomy** A stoma created from the abdominal wall into the stomach.

**gel phenomenon** In patients with rheumatoid arthritis, morning stiffness that lasts between 45 minutes and several hours after awakening.

**gender dysphoria** Discomfort with one's natal sex.

**gender identity** A person's inner sense of maleness or femaleness not related to reproductive anatomy.

**gender reassignment surgery** See *sex reassignment surgery*.

**gene** The deoxyribonucleic acid (DNA) in the form of chromosomes within the nucleus of each cell that contains the instructions for making all the different proteins any organism makes. Every human cell with a nucleus contains the entire set of human genes.

**general anesthesia** A reversible loss of consciousness induced by inhibiting neuronal impulses in the central nervous system.

**generalized seizure** One of the three broad categories of seizure disorders along with partial seizures and unclassified seizures. There are six types: tonic-clonic, tonic, clonic, absence, myoclonic, and atonic (akinetic).

**genetics** The science concerned with the general mechanisms of heredity and the variation of inherited traits.

**genital herpes (GH)** An acute, recurring incurable viral disease of the genitalia caused by the herpes simplex virus and transmitted through contact with an infected person. An outbreak typically is preceded by a tingling sensation of the skin followed by the appearance of vesicles (blisters) on the penis, scrotum, vulva, perineum, vagina, cervix, or perianal region. The blisters rupture spontaneously, leaving painful erosions. After the lesions heal, the virus remains dormant, periodically reactivating with a recurrence of symptoms.

**genome** The complete set of human genes. Each human cell with a nucleus contains the entire set of human genes. The human genome contains about 35,000 individual genes.

**genomic health care** The application of known genetic variation to enhance health care to individuals and their families.

**genomics** The science focusing on the function of all of the human DNA, including genes and noncoding DNA regions.

**genotype** The actual alleles for a genetic trait, not just what can be observed.

**genu valgum** A deformity in which the knees are abnormally close together and the space between the ankles is increased. Also called *knock-knee*.

**genu varum** A deformity in which the knees are abnormally separated and the lower extremities are bowed inward. Also called *bowleg*.

**Geriatric Depression Scale—Short Form (GDS-SF)** A valid and reliable screening tool to help determine if an older patient has clinical depression.

**geriatric failure to thrive (GFTT)** A complex syndrome including under-nutrition, impaired physical functioning, depression, and cognitive impairment.

**geriatric syndromes** Major health issues that are associated with late adulthood in community and inpatient settings.

**ghrelin** The “hunger hormone” that is secreted in the stomach; increases in a fasting state and decreases after a meal.

**Glasgow Coma Scale (GCS)** An objective and widely accepted tool for neurologic assessment and documentation of level of consciousness. It establishes baseline data for eye opening, motor response, and verbal response. The patient is assessed and assigned a numeric score for each of these areas. A score of 15 represents normal neurologic functioning, and a score of 3 represents a deep coma state.

**glaucoma** A group of ocular diseases resulting in increased intraocular pressure, causing reduced blood flow to the optic nerve and retina and followed by tissue damage.

**glomerulus** A series of specialized capillary loops that receive blood from the afferent arteriole and then filter water and small particles from the blood to make urine. The remaining blood leaves the glomerulus via the efferent arteriole.

**glossectomy** The partial or total surgical removal of the tongue.

**glossitis** A smooth, beefy red tongue.

**glottis** The opening between the true vocal cords inside the larynx.

**glucagon** A hormone secreted by the pancreas that increases blood glucose levels. It is a

“counterregulatory” hormone that has actions opposite those of insulin. It causes the release of glucose from cell storage sites whenever blood glucose levels are low.

**gluconeogenesis** The conversion of proteins and amino acids to glucose in the body.

**glucosamine** A supplement that may decrease inflammation.

**glycemic** A term referring to blood glucose.

**glycogenesis** The production of glycogen in the body.

**glycogenolysis** The breakdown of glycogen into glucose.

**glycoprotein (GP) IIb/IIIa inhibitors** Drugs that target the platelet component of the thrombus. They are administered intravenously to prevent fibrinogen from attaching to activated platelets at the site of a thrombus and are given to patients with acute coronary syndromes (especially unstable angina and non-Q-wave myocardial infarction). Examples include abciximab, eptifibatide, and tirofiban.

**glycosylated hemoglobin (A1C)** A standardized test that measures how much glucose permanently attaches to the hemoglobin molecule. A1C levels greater than 6.5% are diagnostic of diabetes mellitus.

**“go bag”** See *personal readiness supplies*.

**goiter** Enlargement of the thyroid gland.

**gonadotropins** Hormones that stimulate the ovaries and testes to produce sex hormones.

**gonads** The male and female reproductive endocrine glands. Male gonads are the testes, and female gonads are the ovaries.

**goniometer** An instrument for measuring angles; also refers to a tool used to measure joint range of motion.

**good death** A death that is free from avoidable distress and suffering for patients, families, and caregivers; in agreement with patients' and families' wishes; and consistent with clinical practice standards.

**gout** A systemic disease in which urate crystals deposit in the joints and other body tissues, causing inflammation.

**grading** System of classifying cellular aspects of a cancer tumor.

**granulation** The formation of scar tissue for wound healing to occur.

**granuloma** Growth that develops in the lungs of patients with sarcoidosis and contains lymphocytes, macrophages, epithelioid cells, and giant cells; scar tissue.

**Graves' disease** Toxic diffuse goiter characterized by hyperthyroidism, enlargement of the thyroid gland, abnormal protrusion of the eyes, and dry, waxy swelling of the front surfaces of the lower legs.

**gray (gy)** Unit of measurement for an absorbed radiation dose.

**gray matter** In the spinal cord, neuron cell bodies.

**grief** The emotional feeling related to the perception of loss.

**grommet** A polyethylene tube that is surgically placed through the tympanic membrane to allow continuous drainage of middle-ear fluids in the patient with otitis media.

**ground substance** A lubricant composed of protein and sugar groups that surrounds the dermal cells and fibers and contributes to the skin's normal suppleness and turgor.

**guardian** A person appointed to make health care decisions for a patient who is determined to not be legally competent.

**Guillain-Barré syndrome (GBS)** An acute autoimmune disorder characterized by varying degrees of motor weakness and paralysis. It may be referred to by a variety of other names, such as *acute idiopathic polyneuritis* and *polyradiculoneuropathy*.

**gynecomastia** Abnormal enlargement of the breasts in men.

## H

**H<sub>2</sub>-receptor antagonists** A group of drugs that inhibit gastric acid secretion by blocking the effects of histamine on parietal cell receptors in the stomach.

**half-life** Time it takes for the amount of drug in the body to be reduced by 50%.

**halitosis** A foul odor of the mouth.

**hallux valgus** A common deformity of the foot that occurs when the great toe deviates laterally at the metatarsophalangeal joint; sometimes referred to as a *bunion*.

**halo fixator** A static traction device used for immobilization of the cervical spine. Four pins or screws are inserted into the skull, and a metal halo ring is attached to a plastic vest or cast when the spine is stable, allowing increased patient mobility.

**“halo” sign** A clear or yellowish ring surrounding a spot of blood.

**hammertoe** The dorsiflexion of any metatarsophalangeal joint with plantar flexion of the adjacent proximal interphalangeal joint. The second toe is most often affected.

**hand hygiene** Infection control protocol that refers to both handwashing and alcohol-based hand rubs.

**hantavirus pulmonary syndrome** A severe and potentially lethal respiratory disease that is a complication of hantavirus infection carried by mice and rats.

**health care–associated infection (HAI)** Infections associated with the provision of health care; for example, microorganisms can enter the body through the genitourinary tract in patients with indwelling urinary catheters.

**heart failure** A general term for the inadequacy of the heart to pump blood throughout the body, causing insufficient perfusion of body tissues with vital nutrients and oxygen. Also called *pump failure*.

**heart rate (HR)** Term referring to the number of times the ventricles contract each minute.

**heart transplantation** A surgical procedure in which a heart from a donor with a comparable body weight and ABO compatibility is transplanted into a recipient less than 6 hours after procurement. It is the treatment of choice for patients with severe dilated cardiomyopathy and may be considered for patients with restrictive cardiomyopathy.

**heat exhaustion** A syndrome primarily caused by dehydration from heavy perspiration and inadequate fluid and electrolyte consumption during heat exposure over hours to days; if left untreated, can be a precursor to heat stroke.

**heat stroke** A true medical emergency in which the victim's heat regulatory mechanisms fail and are unable to compensate for a critical elevation in body temperature; if uncorrected, organ dysfunction and death will ensue.

**Heberden's nodes** Swelling at the distal interphalangeal joints in osteoarthritis that involves the hands.

**hematemesis** The vomiting of blood.

**hematochezia** The passage of red blood via the rectum.

**hematocrit** The percentage of packed red blood cells per deciliter of blood.

**hematogenous** See *endogenous*.

**hematogenous tuberculosis** A form of tuberculosis that spreads throughout the body when a large number of organisms enter the blood. Also called *miliary tuberculosis*.

**hematopoiesis** The production of blood cells, which occurs in the red marrow of bones.

**hematuria** Blood in the urine.

**hemianopsia** Blindness in half of the visual field of one or both eyes. Also called *hemianopia*.

**hemiarthroplasty** Surgical replacement of part of the shoulder joint, typically the humeral component, as an alternative to total shoulder arthroplasty.

**hemiparesis** Weakness on one side of the body.

**hemiplegia** Paralysis on one side of the body.

**hemoconcentration** Elevated plasma levels of hemoglobin, hematocrit, serum osmolarity, glucose, protein, blood urea nitrogen, and electrolytes that occur when only the water is lost and other substances remain.

**hemodilution** Excessive water in the vascular space.

**hemoglobin A (HbA)** Normal adult hemoglobin. The molecule has two alpha chains and two beta chains of amino acids.

**hemoglobin S (HbS)** An abnormal beta chain of hemoglobin associated with sickle cell disease that is sensitive to low oxygen content of red blood cells.

**hemolytic anemia** Anemia caused by the destruction of red blood cells.

**hemolytic** The characteristic of destroying red blood cells.

**hemoptysis** Coughing up blood or blood-stained sputum.

**hemorrhoid** Unnaturally swollen or distended vein in the anorectal region.

**hemorrhoidectomy** The excision of a hemorrhoid.

**hemostasis** The multistep process of controlled blood clotting.

**hemothorax** Bleeding into the chest cavity.

**heparin-induced thrombocytopenia (HIT)** The aggregation of platelets into “white clots” that can cause thrombosis, usually in the form of an acute arterial occlusion; occurs with heparin administration. Also called *white clot syndrome*.

**hepatic encephalopathy** See *portal-systemic encephalopathy*.

**hepatitis A** Hepatitis that is caused by the hepatitis A virus (HAV) and is characterized by a mild course similar to that of a typical viral syndrome and often goes unrecognized. It is spread via the fecal-oral route by oral ingestion of fecal contaminants. Sources of infection include contaminated water, shellfish caught in contaminated water, and food contaminated by infected food handlers. The virus may also be spread by oral-anal sexual activity. The incubation period is usually 15 to 50 days. The disease is usually not life threatening but may be more severe in people older than 40 years. It can also complicate pre-existing liver disease.

**hepatitis B** A form of hepatitis that is caused by the hepatitis B virus (HBV), which is shed in the

body fluids of infected people and asymptomatic carriers. It is spread through unprotected sexual intercourse with an infected partner, needle sharing, blood transfusions, and other modes. Symptoms usually occur within 25 to 180 days of exposure and include nausea, fever, fatigue, joint pain, and jaundice. Most adults who get hepatitis B recover, clear the virus from their bodies, and develop immunity; however, up to 10% of patients with the disease do not develop immunity and become carriers.

**hepatitis C** Hepatitis that is caused by the hepatitis C virus (HCV). Transmission is blood to blood, most commonly by needle sharing or needlestick injury with contaminated blood. The rate of sexual transmission is very low; it is not spread by casual contact and is rarely transmitted from mother to fetus. The average incubation period is 7 weeks. Most people are asymptomatic and are not diagnosed until long after the initial exposure when an abnormality is detected during a routine laboratory evaluation or when symptoms of liver impairment appear. Hepatitis C causes chronic inflammation in the liver that eventually causes the hepatocytes to scar and may progress to cirrhosis.

**hepatitis carrier** Person who has had hepatitis B but has not developed immunity. Hepatitis carriers can infect others even though they are not sick and demonstrate no obvious signs of disease. Chronic carriers are at high risk for cirrhosis and liver cancer.

**hepatitis D** The hepatitis D virus (HDV) co-infects with hepatitis B virus (HBV) and needs the presence of HBV for viral replication. HDV can co-infect a patient with HBV or can occur as a superinfection in a patient with chronic HBV. Superinfection usually develops into chronic HDV infection. The incubation period is 14 to 56 days. As with HBV, the disease is transmitted primarily by parenteral routes.

**hepatitis E** Hepatitis E virus (HEV) was originally identified by its association with waterborne epidemics of hepatitis in the Indian subcontinent. Since then, it has occurred in epidemics in Asia, Africa, the Middle East, Mexico, and Central and South America, typically after heavy rains and flooding. In the United States, hepatitis E has been found only in travelers returning from endemic areas. The virus is transmitted via the fecal-oral route, and the clinical course resembles that of hepatitis A. HEV has an incubation period of 15 to 64 days. There is no evidence at this time of a chronic form of hepatitis E.

**hepatitis** The widespread inflammation of liver cells.

**hepatocyte** Liver cell.

**hepatomegaly** Enlargement of the liver.

**hepatorenal syndrome (HRS)** A state of progressive oliguric renal failure associated with hepatic failure, resulting in functional impairment of kidneys with normal anatomic and morphologic features. It indicates a poor prognosis for the patient with hepatic failure and is often the cause of death in patients with cirrhosis.

**hereditary chronic pancreatitis** Pancreatitis that may be associated with *SPINK1* and *CFTR* gene mutations.

**heritability** The risk that a disorder can be transmitted to one's children in a recognizable pattern.

**hernia** A weakness in the abdominal muscle wall through which a segment of the bowel or other abdominal structure protrudes.

**herniated nucleus pulposus (HNP)** The protrusion (herniation) of the pulpy material from the center of a vertebral disk; herniated disks occur most often between the fourth and fifth lumbar vertebrae (L4-5) but may occur at other levels. A herniation in the lumbosacral area can press on the adjacent spinal nerve (usually the sciatic nerve), causing severe burning or stabbing pain into the leg or foot, or it may press on the spinal cord itself, causing leg weakness and bowel and bladder dysfunction. The specific area of pain depends on the level of herniation.

**hernioplasty** Surgical repair of a hernia in which the surgeon reinforces the weakened outside

- muscle wall with a mesh patch.
- herniorrhaphy** The surgical repair of a hernia.
- heterotopic ossification** Abnormal bony overgrowth, often into muscle; seen as a complication of prolonged immobility in patients with spinal cord injury.
- hiatal hernia** Protrusion of the stomach through the esophageal hiatus of the diaphragm and into the thorax. Also called *diaphragmatic hernia*.
- high altitude disease (HAD)** See *high altitude illnesses*.
- high altitude illnesses** Pathophysiologic responses in the body caused by exposure to low partial pressure of oxygen at high elevations.
- high altitude pulmonary edema (HAPE)** A form of acute mountain sickness often seen with high altitude cerebral edema. Clinical indicators include persistent dry cough, cyanosis of the lips and nail beds, tachycardia and tachypnea at rest, and rales auscultated in one or both lungs. Pink, frothy sputum is a late sign.
- high-alert drug** A drug that has an increased risk for causing patient harm if given in error.
- high-density lipoproteins (HDLs)** Part of the total cholesterol value that should be more than 45 mg/dL for men and more than 55 mg/dL for women; “good” cholesterol.
- highly sensitive C-reactive protein (hsCRP)** A serum marker of inflammation and a common and critical component to the development of atherothrombosis.
- high-output heart failure** Heart failure that occurs when cardiac output remains normal or above normal. It is usually caused by increased metabolic needs or hyperkinetic conditions such as septicemia (fever), anemia, and hyperthyroidism. This type of heart failure is different from left- and right-sided heart failure, which are typically low-output states, and is not as common as other types.
- hilum** The area of the kidney in which the renal artery and nerve plexus enter and the renal vein and ureter exit. This area is not covered by the renal capsule.
- hirsutism** Abnormal growth of body hair, especially on the face, chest, and the linea alba of the abdomen of women.
- homeostasis** The narrow range of normal conditions (e.g., body temperature, blood electrolyte values, blood pH, blood volume) in the human body; the tendency to maintain a constant balance in normal body states.
- homeostatic mechanism** A safeguard or control mechanism within the human body that prevents dangerous changes.
- homocysteine** An essential sulfur-containing amino acid that is produced when dietary protein breaks down; elevated values (greater than 15 mmol/L) may be a risk factor for the development of cardiovascular disease.
- homonymous hemianopsia** Condition in which there is blindness in the same side of both eyes.
- hordeolum** An infection of the sweat glands in the eyelid.
- hormone** Chemical produced in the body that exerts its effects on specific tissues known as *target tissues*.
- hospice** An interdisciplinary approach to facilitate quality of life and a “good” death for patients near the end of their lives, with care provided in a variety of settings.
- Hospital Incident Command System (HICS)** An organizational model for disaster management in which roles are formally structured under the hospital or long-term care facility incident commander, with clear lines of authority and accountability for specific resources.

**hospital incident commander** As defined in a hospital's emergency response plan, the person (either an emergency physician or administrator) who assumes overall leadership for implementing the institutional plan at the onset of a mass casualty incident. The hospital incident commander has a global view of the entire situation, facilitates patient movement through the system, and brings in resources to meet patient needs.

**hospitalist** Family practitioner or internist employed by a hospital.

**human leukocyte antigen (HLA)** Antigen that is present on the surfaces of nearly all body cells as a normal part of the person and acts as an antigen only if it enters another person's body.

**human papilloma virus (HPV) test** A test that can identify many high-risk types of HPV associated with the development of cervical cancer.

**humoral immunity** A type of immunity provided by antibodies circulating in body fluids.

**Huntington disease (HD)** A hereditary disorder transmitted as an autosomal dominant trait at the time of conception (formerly called *Huntington chorea*). Men and women between 35 and 50 years of age are affected; clinical onset is gradual. The two main symptoms are progressive mental status changes (leading to dementia) and choreiform movements (rapid, jerky movements) in the limbs, trunk, and facial muscles.

**hydrocephalus** The abnormal accumulation of cerebrospinal fluid within the skull.

**hydronephrosis** Abnormal enlargement of the kidney caused by a blockage of urine lower in the tract and filling of the kidney with urine.

**hydrophilic** Tending to absorb water readily.

**hydrophobic** Not readily absorbing water; waterproof.

**hydrostatic pressure** The force of the weight of water molecules pressing against the confining walls of a space.

**hydrotherapy** The application of water for treatment of injury or disease.

**hydroureter** Abnormal distention of the ureter.

**hyperacusis** An intolerance for sound levels that do not bother other people.

**hyperaldosteronism** Excessive mineralocorticoid production.

**hypercalcemia** A total serum calcium level above 10.5 mg/dL or 2.75 mmol/L, which can cause fatigue, anorexia, nausea and vomiting, constipation, polyuria, and serious damage to the urinary system.

**hypercapnia** Increased arterial carbon dioxide levels.

**hypercarbia** Increased partial pressure of arterial carbon dioxide (PaCO<sub>2</sub>) levels.

**hypercellularity** An abnormal number of cells.

**hypercoagulability** Increased clotting ability.

**hyperemia** Increased blood flow to an area.

**hyperesthesia** Abnormally increased sensation.

**hyperextension** A mechanism of injury that occurs when a part of the body is suddenly accelerated and then decelerated, causing extreme extension.

**hyperflexion** A mechanism of injury that occurs when a part of the body is suddenly and forcefully accelerated forward, causing extreme flexion.

**hyperglycemia** Abnormally high levels of blood glucose.

**hyperinsulinemia** Chronic high blood insulin levels.

**hyperkalemia** An elevated level of potassium in the blood.

**hyperlipidemia** An elevation of serum lipid (fat) levels in the blood.

**hypermagnesemia** A serum magnesium level above 2.1 mEq/L.

**hyponatremia** An excessive amount of sodium in the blood.

**hyperopia** An error of refraction that occurs when the eye does not refract light enough, causing images to fall (converge) behind the retina and resulting in poor near vision. Also called *farsightedness*.

**hyperosmotic** Describes fluids with osmolarities (solute concentrations) greater than 300 mOsm/L; hyperosmotic fluids have a greater osmotic pressure than do isosmotic fluids and tend to pull water from the isosmotic fluid space into the hyperosmotic fluid space until an osmotic balance occurs. Also called *hypertonic*.

**hyperpharmacy** See *polypharmacy*.

**hyperphosphatemia** A serum phosphorus level above 4.5 mg/dL.

**hyperpituitarism** Hormone oversecretion that occurs with pituitary tumors or hyperplasia.

**hyperplasia** Growth that causes tissue to increase in size by increasing the number of cells; abnormal overgrowth of tissue.

**hyperpnea** An abnormal increase in the depth of respiratory movements.

**hypersensitivity** An overreaction to a foreign substance.

**hypertension** A cardiovascular condition pertaining to people who have a systolic blood pressure of 140 mm Hg or higher or a diastolic blood pressure of 90 mm Hg or higher or who take medication to control blood pressure; approximately 1 of every 5 Americans has hypertension.

**hypertensive crisis** A severe elevation in blood pressure (greater than 180/120 mm Hg) that can cause damage to organs such as the kidneys or heart.

**hyperthermia** Elevated body temperature; fever.

**hyperthyroidism** A condition caused by excessive production of thyroid hormone.

**hypertonia** A condition of excessive muscle tone, which tends to cause fixed positions or contractures of the involved extremities and restricted range of motion of the joints.

**hypertonic** See *hyperosmotic*.

**hypertriglyceridemia** Elevated levels (150 mg/dL or above) of triglyceride in the blood.

**hypertrophic cardiomyopathy (HCM)** A type of cardiomyopathy that involves disarray of the myocardial fibers and asymmetric ventricular hypertrophy; leads to a stiff left ventricle that results in diastolic filling abnormalities.

**hypertrophy** The enlargement or overgrowth of an organ; tissue increases in size by the enlargement of each cell.

**hyperuricemia** An excess of uric acid in the blood.

**hyperventilation** A state of increased rate and depth of breathing.

**hyperviscous** The quality of being thicker than normal.

**hypervolemia** Increased plasma volume; or fluid excess.

**hypocalcemia** A total serum calcium level below 9.0 mg/dL or 2.25 mmol/L.

**hypocapnia** Decreased arterial carbon dioxide levels.

**hypocarbica** PaCO<sub>2</sub> less than 40 to 45 mm Hg or decreased partial pressure of carbon dioxide in arterial blood.

**hypodermoclysis** The slow infusion of isotonic fluids into subcutaneous tissue.

**hyposesthesia** Abnormally decreased sensation.

**hypoglycemia** Abnormally low levels of glucose in the blood.

**hypokalemia** A decreased serum potassium level; a common electrolyte imbalance.

**hypomagnesemia** A low serum magnesium level, usually lower than 1.8 mEq/L or 0.74 mmol/L.

**hyponatremia** A serum sodium level below 136 mEq/L (mmol/L).

**hypo-osmotic** Describes fluids with osmolarities of less than 270 mOsm/L. Hypo-osmolar fluids have a lower osmotic pressure than isosmotic fluids, and water tends to be pulled from the hypo-osmotic fluid space into the isosmotic fluid space until an osmotic balance occurs. Also called *hypotonic*.

**hypophonia** Soft voice.

**hypophosphatemia** Inadequate levels of phosphate in the blood (below 3.0 mg/dL).

**hypophysectomy** Surgical removal of the pituitary gland.

**hypoproteinemia** A decrease in serum proteins.

**hypothalamic-hypophysial portal system** The small, closed circulatory system that the hypothalamus shares with the anterior pituitary gland; it allows hormones produced in the hypothalamus to travel directly to the anterior pituitary gland.

**hypothalamus** A structure within the brain; an integral part of autonomic nervous system control (controlling temperature and other functions) that is essential in intellectual function.

**hypothermia** A core body temperature less than 95° F (35° C).

**hypotonia** An abnormal condition of inadequate muscle tone, with an inability to maintain balance.

**hypotonic** See *hypo-osmotic*.

**hypoventilation** A state in which gas exchange at the alveolar-capillary membrane is inadequate so that too little oxygen reaches the blood and carbon dioxide is retained.

**hypovolemia** Abnormally decreased volume of circulating fluid in the body; fluid deficit.

**hypoxemia (hypoxemic)** Decreased blood oxygen levels; hypoxia.

**hypoxia** A reduction of oxygen supply to the tissues.

**hysterosalpingogram** An x-ray of the cervix, uterus, and fallopian tubes that is performed after injection of a contrast medium. This test is used in infertility workups to evaluate tubal anatomy and patency and uterine problems such as fibroids, tumors, and fistulas.

**hysteroscopy** Examination of the interior of the uterus and cervical canal using an endoscope.

## I

**icterus** Yellow discoloration of the sclerae.

**idiopathic chronic pancreatitis** Pancreatitis that may be associated with *SPINK1* and *CFTR* gene mutations.

**idiopathic seizure** See *unclassified seizure*.

**ileostomy** The surgical creation of an opening into the ileum, usually by bringing the end of the terminal ileum through the abdominal wall and forming a stoma, or ostomy.

**immediate memory** Short-term or new memory. Test by asking the patient to repeat two or three unrelated words to make sure they were heard; after about 5 minutes, while continuing the examination, ask the patient to repeat the words.

**immunity** Resistance to infection; usually associated with the presence of antibodies or cells that act on specific microorganisms.

**immunocompetent** Having proper functioning of the body's ability to maintain itself and defend against disease.

**immunoglobulin** Antibody. Also called *gamma globulin*.

**impermeable** Not porous.

**implanted port** A device used for long-term or frequent infusion therapy; consists of a portal body, a dense septum over a reservoir, and a catheter that is surgically implanted on the upper chest or upper extremity.

**inactivation** The process of binding an antibody to an antigen to cover the antigen's active site and to make the antigen harmless without destroying it. Also called *neutralization*.

**incisional hernia** Protrusion of the intestine at the site of a previous surgical incision resulting from inadequate healing. Most often caused by postoperative wound infections, inadequate nutrition, and obesity. Also called *ventral hernia*.

**incomplete spinal cord injury** An injury in which the spinal cord has been damaged in a way that allows some function or movement below the level of the injury.

**incontinence** Involuntary loss of urine or stool severe enough to cause social or hygienic problems.

**independent living skills** See *instrumental activities of daily living (IADLs)*.

**indirect inguinal hernia** A sac formed from the peritoneum that contains a portion of the intestine or omentum. The hernia pushes downward at an angle into the inguinal canal. In males, indirect inguinal hernias can become large and often descend into the scrotum.

**indolent** Slow-growing.

**induration** Hardening.

**infarction** Necrosis, or cell death.

**infective endocarditis** A microbial infection (e.g., viruses, bacteria, fungi) involving the endocardium; previously called *bacterial endocarditis*.

**inferior vena cava filtration** Surgical procedure in which the surgeon inserts a filter device percutaneously into the inferior vena cava of a patient with recurrent deep vein thrombosis (to prevent pulmonary emboli) or pulmonary emboli that do not respond to medical treatment. The device is meant to trap emboli in the inferior vena cava before they progress to the lungs. Holes in the device allow blood to pass through, thus not significantly interfering with the return of blood to the heart.

**inferior wall myocardial infarction** A type of myocardial infarction that occurs in patients with

obstruction of the right coronary artery, causing significant damage to the right ventricle.

**infiltrating ductal carcinoma** The most common type of breast cancer; it originates in the mammary ducts and grows in the epithelial cells lining these ducts.

**infiltration** The leakage of IV solution into the tissues around the vein.

**inflammatory breast cancer** A rare but highly aggressive form of invasive breast cancer. Symptoms include swelling, skin redness, and pain in the breasts.

**inflammatory cytokines** Proteins produced primarily by white blood cells that assist in the inflammatory and immune responses of the body (e.g., tumor necrosis factor, interleukins).

**inflow disease** Chronic peripheral arterial disease with obstruction at or above the common iliac artery, abdominal aorta, or profunda femoris artery. The patient experiences discomfort in the lower back, buttocks, or thighs after walking a certain distance. The pain usually subsides with rest.

**informatics** A QSEN competency in which the nurse uses information and technology to communicate, manage knowledge, mitigate error, and support decision making.

**infratentorial** Located below the tentorium of the cerebellum.

**infusate** A solution that is infused into the body.

**infusion therapy** The delivery of parenteral medications and fluids through a variety of catheter types and locations using multiple techniques and procedures, such as intravenous and intra-arterial therapy to deliver solutions into the vascular system.

**inpatient rehabilitation facilities (IRFs)** Freestanding rehabilitation hospitals, rehabilitation or skilled units within hospitals (e.g., transitional care units), and skilled nursing facilities to which the patient is typically admitted for 1 to 3 weeks or longer.

**inpatient** A patient who is admitted to a hospital.

**insensible water loss** Water loss from the skin, lungs, and stool that cannot be controlled.

**instrumental activities of daily living (IADLs)** Special activities performed in the course of a day such as using the telephone, shopping, preparing food, and housekeeping. Also called *independent living skills*.

**insufflation** The practice of injecting gas or air into a cavity before surgery to separate organs and improve visualization.

**intensity** A quality of sound that is expressed in decibels; generally, having a high degree of energy or activity.

**intensivist** A physician who specializes in critical care.

**intention tremor** A tremor that occurs when performing an activity.

**interbody cage fusion** Cagelike spinal device that is implanted into the space where a disk was removed. Bone graft tissue grows into and around the cage and creates a stable spine at that level.

**intercostally** Located between the ribs.

**intermittent claudication** A characteristic leg pain experienced by patients with chronic peripheral arterial disease. Typically, patients can walk only a certain distance before a cramping muscle pain forces them to stop. As the disease progresses, the patient can walk only shorter and shorter distances before pain recurs. Ultimately, pain may occur even at rest.

**internal derangement** A broad term for disturbances of an injured knee joint.

**internal fixation** The use of metal pins, screws, rods, plates, or prostheses to immobilize a fracture during healing. The surgeon makes an incision (open reduction) to gain access to the broken bone and implants one or more devices.

**internal hemorrhoid** A hemorrhoid that is located above the anal sphincter and cannot be seen on inspection of the perineal area.

**internal urethral sphincter** The smooth detrusor muscle that lines the interior of the bladder neck.

**interstitial cystitis** A bladder inflammation of unknown etiology that occurs predominantly in women and is characterized by urinary frequency and pain on bladder filling.

**interstitial fluid** A portion of the extracellular fluid that is between cells, sometimes called the *third space*.

**interstitial laser coagulation (ILC)** Procedure for treating benign prostatic hyperplasia that uses laser energy to coagulate excess tissue. Also called *contact laser prostatectomy (CLP)*.

**intra-abdominal hypertension (IAH)** Condition of sustained or repeated intra-abdominal pressure of 12 mm Hg or higher.

**intra-abdominal pressure** Pressure contained within the abdominal cavity.

**intra-aortic balloon pump (IABP)** An intra-aortic counterpulsation device. It may be used as an invasive intervention to improve myocardial perfusion during an acute myocardial infarction, to reduce preload and afterload, and to facilitate left ventricular ejection. It is also used when patients do not respond to drug therapy with improved tissue perfusion, decreased workload of the heart, and increased cardiac contractility.

**intra-arterial infusion therapy** The use of catheters placed into arteries to obtain repeated arterial blood samples, to monitor various hemodynamic pressures continuously, and to infuse chemotherapy agents or fibrinolytics.

**intracapsular** Located within the joint capsule.

**intracellular fluid (ICF)** The portion of total body water (about two thirds) that is found inside the cells.

**intracerebral hemorrhage** Bleeding within the brain tissue caused by the tearing of small arteries and veins in the subcortical white matter.

**intracorporeal** Situated or occurring inside the body.

**intramedullary tumor** Tumor originating within the spinal cord in the central gray matter and anterior commissure. It is often malignant.

**intraocular pressure (IOP)** Pressure of the fluid within the eye; may be measured by methods that involve direct contact with the eye or by noncontact techniques.

**intraoperative** During surgery.

**intraosseous (IO) therapy** Infusion therapy that is delivered to the vascular network in the long bones.

**intraperitoneal (IP) infusion therapy** The administration of antineoplastic agents into the peritoneal cavity.

**intrapulmonary** Within the respiratory tract.

**intrarenal/intrinsic renal failure** Decreased renal function resulting from damage to the glomeruli, interstitial tissue, or tubules. It can contribute to acute renal failure.

**intrathecal** Referring to the spine.

**intravascular ultrasonography (IVUS)** In cardiac catheterization, the use of a flexible catheter with a miniature transducer that emits sound waves. Sound waves are reflected off the plaque and the arterial wall, creating an image of the blood vessel; used as an alternative to injecting a contrast medium into the coronary arteries.

**intravenous (systemic) fibrinolytic therapy** The intravenous administration of thrombolytic agents to dissolve a thrombus.

**intravesical** Situated inside the bladder.

**intrinsic factor** A substance normally secreted by the gastric mucosa and needed for intestinal absorption of vitamin B<sub>12</sub>. A deficiency of intrinsic factor and the resulting failure to absorb vitamin B<sub>12</sub> lead to pernicious anemia.

**intussusception** The telescoping of a segment of the intestine within itself.

**invasive hemodynamic monitoring** System used in critical care areas to provide quantitative information about vascular capacity, blood volume, pump effectiveness, and tissue perfusion. It directly measures pressures in the heart and great vessels.

**ion** A substance found in body fluids that carries an electrical charge. Also called *electrolyte*.

**iontophoresis** A treatment for lower back pain in which a small electrical current and dexamethasone are typically used.

**ipsilateral** Occurring on the same side.

**iris** The colored portion of the external eye; its center opening is the pupil. Muscles of the iris contract and relax to control pupil size and the amount of light entering the eye.

**irreducible hernia** A hernia that cannot be reduced or placed back into the abdominal cavity; requires immediate surgical evaluation.

**irregular bone** Bone that has a unique shape, such as the carpal bones of the wrist.

**irritability** An overresponse to stimuli.

**irritable bowel syndrome (IBS)** A chronic gastrointestinal disorder characterized by chronic or recurrent diarrhea, constipation, and/or abdominal pain and bloating. Also called *spastic colon*, *mucous colon*, or *nervous colon*.

**ischemia** Blockage of blood flow through a blood vessel resulting in a lack of oxygen. Prolonged severe ischemia can cause irreversible damage to tissue.

**ischemic stroke** A type of brain attack caused by occlusion of a cerebral artery by either a thrombus or an embolus. About 80% of all brain attacks are ischemic.

**ischemic** Cell dysfunction or death from a lack of oxygen resulting from decreased blood flow in a body part.

**isoelectric** Having equal electric potentials, such as in the heart.

**isosmotic** Having the same osmotic pressures. Also called *isotonic* or *normotonic*.

**isotonic** See *isosmotic*.

## J

**jaundice** A syndrome characterized by excessive circulating bilirubin levels. Liver cells cannot effectively excrete bilirubin, and skin and mucous membranes become characterized by a yellow coloration.

**jejunostomy** The surgical creation of an opening between the jejunum and the surface of the abdominal wall.

**joint** The place at which two or more bones come together. Also referred to as “articulation” of the joint. The primary function is to provide movement and flexibility in the body.

**jugular venous distention (JVD)** Enlargement of the jugular vein of the neck; caused by an increase in jugular venous pressure.

**juxtaglomerular complex** Specialized cells that produce and store renin in the afferent arteriole, efferent arteriole, and distal collecting tubule; taken together, the juxtaglomerular cells and the macula densa.

## K

**karyotype** Technique used to make an organized arrangement of all the chromosomes within one cell during the metaphase section of mitosis.

**keratin** The protein produced by keratinocytes; makes the outermost skin layer waterproof.

**keratinocytes** Basal skin cells attached to the basement membrane of the epidermis that undergo cell division and differentiation to continuously renew skin tissue integrity and maintain optimal barrier function. As basal cells divide, keratinocytes are pushed upward and flattened to form the stratified layers of the epithelium (Malpighian layers).

**keratoconjunctivitis sicca** A condition of the eyes that results from changes in tear composition, lacrimal gland malfunction, or altered tear distribution. Also called *dry eye syndrome*.

**keratoconus** The degeneration of the corneal tissue resulting in abnormal corneal shape.

**keratoplasty** Corneal transplant. The surgical removal of diseased corneal tissue and replacement with tissue from a human donor cornea.

**ketogenesis** The conversion of fats to acids in the body.

**ketone bodies** Substances, including acetone, that are produced as by-products of the incomplete metabolism of fatty acids. When insulin is not available (as in uncontrolled diabetes mellitus), they accumulate in the blood and cause metabolic acidosis. Also called *ketones*.

**knee height caliper** Device that uses the distance between the patella and heel to estimate height.

**Kupffer cells** Phagocytic cells that are part of the body's reticuloendothelial system and that are involved in the protective function of the liver. Kupffer cells engulf harmful bacteria and anemic red blood cells.

**Kussmaul respiration** A type of breathing that occurs when excess acids caused by the absence of insulin increase hydrogen ion and carbon dioxide levels in the blood. This state triggers an increase in the rate and depth of respiration in an attempt to excrete more carbon dioxide and acid.

**kwashiorkor** Lack of protein quantity and quality in the presence of adequate calories. Body weight is somewhat normal, and serum proteins are low.

**kyphoplasty** A minimally invasive surgery for managing vertebral fractures in patients with

osteoporosis. Bone cement is injected into the fracture site to provide pain relief, and an inflated balloon is used to restore height to the vertebra.

## L

**labyrinthectomy** Surgical removal of the labyrinth; used as a radical treatment of Ménière's disease when medical therapy is ineffective and the patient already has significant hearing loss.

**labyrinthitis** An infection of the labyrinth of the ear; may occur as a complication of acute or chronic otitis media.

**laceration** A type of wound characterized by tearing or mangling and usually caused by sharp objects and projectiles.

**lacrimal gland** A small gland that produces tears; located in the upper outer part of each ocular orbit.

**lacto-ovo-vegetarian** A vegetarian diet pattern in which milk, cheese, eggs, and dairy foods are eaten but meat, fish, and poultry are avoided.

**lactose intolerance** The inability to convert lactose (found in milk and dairy products) to glucose and galactose in the body.

**lacto-vegetarian** A vegetarian diet pattern in which milk, cheese, and dairy foods are eaten but meat, fish, poultry, and eggs are avoided.

**laparoscopy** A minimally invasive procedure in which the surgeon makes several small incisions near the umbilicus through which a small endoscope is placed to examine the abdomen; direct examination of the pelvic cavity through an endoscope.

**laparotomy** An open surgical approach in which a large abdominal incision is made.

**laryngectomee** A person who has had a laryngectomy.

**laryngopharynx** The area behind the larynx that extends from the base of the tongue to the esophagus. It is the critical dividing point at which solid foods and fluids are separated from air.

**larynx** The "voice box"; it is composed of several cartilages and is located above the trachea and just below the throat at the base of the tongue; part of the upper respiratory tract.

**laser** An acronym for **l**ight **a**mplification by **s**timulated **e**mission of **r**adiation. As a surgical tool, a laser emits a high-powered beam of light that cuts tissue more cleanly than do scalpel blades. A laser creates intense heat, rapidly clots blood vessels or tissue, and turns target tissue (e.g., a tumor) into vapor.

**latency period** The time between the initiation of a cell and the development of an overt tumor.

**latex allergy** Reactions to exposure to latex in gloves and other medical products; reactions include rashes, nasal or eye symptoms, and asthma.

**latroductism** A syndrome caused by the venom of a black widow spider bite in which neurotransmitter releases from nerve terminals to cause severe abdominal pain, muscle rigidity and spasm, hypertension, and nausea and vomiting.

**lead axis** In electrocardiography, the imaginary line that joins the positive and negative poles of the lead systems.

**lead** In an ECG, the provider of one view of the heart's electrical activity.

**left shift** An increase in the band cells (immature neutrophils) in the white blood cell differential count; an early indication of infection.

**left-sided heart (ventricular) failure** Inadequacy of the left ventricle of the heart to pump

adequately; results in decreased tissue perfusion from poor cardiac output and pulmonary congestion from increased pressure in the pulmonary vessels; typical causes include hypertensive, coronary artery, or valvular disease involving the mitral or aortic valve. Most heart failure begins with failure of the left ventricle and progresses to failure of both ventricles.

**legally competent** A legal term used to describe a person 18 years of age or older, a pregnant or a married minor, a legally emancipated (free) minor who is self-supporting, or a person not declared incompetent by a court of law.

**leiomyomas** Benign, slow-growing solid tumors of the uterine myometrium (muscle layer). These are the most commonly occurring pelvic tumors. Also called *myomas* and *fibroids*.

**lens** The circular, convex structure of the eye that lies behind the iris and in front of the vitreous body. Normally transparent, the lens bends the rays of light entering through the pupil so that they focus on the retina. The curve of the lens changes to focus on near or distant objects.

**leptin** A hormone that is released by fat cells and possibly by gastric cells; it also acts on the hypothalamus to control appetite.

**lethargic** Drowsy but easily awakened.

**leukemia** A type of cancer with uncontrolled production of immature white blood cells in the bone marrow; the bone marrow becomes overcrowded with immature, nonfunctional cells, and the production of normal blood cells is greatly decreased.

**leukocyte** White blood cell (WBC); this immune system cell protects the body from the effects of invasion by organisms.

**leukopenia** A reduction in the number of white blood cells.

**leukoplakia** White, patchy lesions on a mucous membrane.

**level of consciousness (LOC)** The degree of alertness or the amount of stimulation needed to engage a patient's attention and can range from *alert* to *coma*.

**levels of evidence** Term used to refer to the status, rank, or strength of evidence.

**LGBTQ** Acronym for "lesbian, gay, bisexual, transgender, and queer/questioning" culture.

**libido** Sexual desire.

**lichenified** An abnormal thickening of the skin to a leathery appearance; can occur in patients with chronic dermatitis because of their continual rubbing of the area to relieve itching.

**Lichtenberg figures** Branching or ferning marks that appear on the skin as a result of a lightning strike. Also called *keratographic markings* or *erythematous arborization*.

**life review** A structured process of reflecting on one's life that is often facilitated by an interviewer.

**ligament** Connective tissue that attaches bones to other bones at joints.

**light reflex** The reflection of the otoscope's light off the eardrum in the form of a clearly demarcated triangle of light in the normal ear.

**limited cutaneous systemic sclerosis** Thick skin that is usually limited to sites distal to the elbow and knee but also involves the face and neck.

**lipid** Fat, including cholesterol and triglycerides, that can be measured in the blood.

**lipolysis** The decomposition or splitting up of fat to provide fuel for energy when liver glucose is unavailable.

**liposuction** A cosmetic procedure to reduce the amount of adipose tissue in selected areas of the body.

- literacy challenged** An individual who has a low reading level ability.
- lithotripsy** The use of sound, laser, or dry shock wave energy to break a kidney stone into small fragments. Also called *extracorporeal shock wave lithotripsy*.
- living will** A legal document that instructs physicians and family members about what life-sustaining treatment is wanted (or not wanted) if the patient becomes unable to make decisions.
- lobectomy** Surgical removal of an entire lung lobe.
- lobular carcinoma in situ (LCIS)** A noninvasive form of breast cancer that does not show up as a calcified cluster on a mammogram and is therefore most often diagnosed incidentally during a biopsy for another problem.
- local anesthesia** Anesthesia that is delivered by applying it to the skin or mucous membranes of the area to be anesthetized or by injecting it directly into the tissue around an incision, wound, or lesion.
- locus** The specific chromosome location for a gene.
- log rolling** Turning technique in which the patient turns all at once while his or her back is kept as straight as possible.
- long bone** Bone that is cylindrical with rounded ends and often bears weight, such as the femur.
- loop electrosurgical excision procedure (LEEP)** Diagnostic procedure/treatment in which a thin loop-wire electrode that transmits a painless electrical current is used to cut away affected cervical cancer tissue.
- lordosis** The anterior concavity in the curvature of the lumbar and cervical spine when viewed from the side; a common finding in pregnancy and abdominal obesity.
- Lou Gehrig's disease** See *amyotrophic lateral sclerosis (ALS)*.
- low back pain (LBP)** Pain in the lumbosacral region of the back caused by muscle strain or spasm, ligament sprain, disk degeneration, or herniation of the nucleus pulposus from the center of the disk. Herniated disks occur most often between the fourth and fifth lumbar vertebrae (L4-5) but may occur at other levels.
- low-density lipoproteins (LDLs)** Part of the total cholesterol value that should be less than 130 mg/dL; "bad" cholesterol.
- lower esophageal sphincter (LES)** The portion of the esophagus proximal to the gastroesophageal junction; when at rest, the sphincter is closed to prevent reflux of gastric contents into the esophagus.
- lower urinary tract symptoms (LUTS)** Symptoms that occur as a result from prostatic hyperplasia, such as urinary retention and overflow incontinence, or urinary leaking.
- low-intensity pulsed ultrasound** A method using ultrasonic waves to promote bone union in slow-healing fractures or for new fractures as an alternative to surgery.
- low-profile gastrostomy device (LPGD)** A gastrostomy device that uses a firm or balloon-style internal bumper or retention disk; an antireflux valve keeps gastric contents from leaking onto the skin.
- loxoscelism** Systemic effects from the injected toxin of a spider bite.
- lumbar puncture (spinal tap)** The insertion of a spinal needle into the subarachnoid space between the third and fourth (sometimes the fourth and fifth) lumbar vertebrae to withdraw spinal fluid for analysis.
- lumen** The inside cavity of a tube or tubular organ, such as a blood vessel or airway.

**lung compliance** The quality of elasticity of the lungs.

**lunula** The white crescent-shaped portion of the nail at the lower end of the nail plate.

**lurch** An abnormality in the swing phase of gait; occurs when the muscles in the buttocks or legs are too weak to allow the person to change weight from one foot to the other.

**Lyme disease** A systemic infectious disease that is caused by the spirochete *Borrelia burgdorferi* and results from the bite of an infected deer tick. Signs and symptoms include a large "bull's-eye" circular rash, malaise, fever, headache, and muscle or joint aches.

**lymphadenopathy** Persistently enlarged lymph nodes.

**lymphedema** Abnormal accumulation of protein fluid in the subcutaneous tissue of the affected limb after a mastectomy.

**lymphoblastic** Pertaining to abnormal leukemic cells that come from the lymphoid pathways and develop into lymphocytes.

**lymphocytic** Pertaining to abnormal leukemic cells that come from the lymphoid pathways.

**lymphokine** Cytokine produced by T-cells.

**lysis** Breakage, for example, of a cell membrane.

## M

**macrocytic anemia** A form of vitamin B<sub>12</sub> deficiency anemia characterized by abnormally large precursor cells.

**macrovascular** Referring to large blood vessels.

**macular degeneration** The deterioration of the macula, the area of central vision.

**macular** Referring to a macula, a discolored spot on the skin that is not raised above the surface.

**magnesium (Mg<sup>2+</sup>)** A mineral that forms a cation when dissolved in water.

**magnetoencephalography (MEG)** A noninvasive imaging technique that measures the magnetic fields produced by electrical activity in the brain via extremely sensitive devices such as superconducting quantum interference devices (SQUIDS).

**malabsorption** A syndrome associated with a variety of disorders and intestinal surgical procedures and characterized by impaired intestinal absorption of nutrients.

**malignant cell growth** Altered cell growth that is serious and, without intervention, leads to death; cancer.

**malignant hypertension** A severe type of elevated blood pressure that rapidly progresses, with systolic blood pressure greater than 200 mm Hg and diastolic blood pressure greater than 150 mm Hg (greater than 130 mm Hg when there are pre-existing complications).

**malignant transformation** The process of changing a normal cell into a cancer cell.

**malignant** Referring to cancer.

**mammography** An x-ray of the soft tissue of the breast.

**mandibulectomy** Surgical removal of the jaw.

**marasmic-kwashiorkor** A combined protein and energy malnutrition that often presents clinically when metabolic stress is imposed on a chronically starved patient.

**marasmus** A calorie malnutrition in which body fat and protein are wasted but serum proteins are often preserved.

**marsupialization** Surgical formation of a pouch that is a new duct opening.

**mass casualty event** A situation affecting the public health that is defined based on the resource availability of a particular community or hospital facility. When the number of casualties exceeds the resource capabilities, a disaster situation is recognized to exist.

**mastication** The process of chewing.

**mastoiditis** An acute or chronic infection of the mastoid air cells caused by untreated or inadequately treated otitis media.

**maze procedure** An open chest surgical technique often performed with coronary artery bypass grafting for patients in atrial fibrillation with decompensation.

**mean arterial pressure (MAP)** The arterial blood pressure (between 60 and 70 mm Hg) necessary to maintain perfusion of major body organs, such as the kidneys and brain.

**mechanical débridement** Method of débriding a wound by mechanical entrapment and detachment of dead tissue.

**mechanical obstruction** The physical obstruction of the bowel by disorders outside the intestine (e.g., adhesions or hernias) or by blockages in the lumen of the intestine (e.g., tumors, inflammation, strictures, or fecal impactions).

**mechanism of injury (MOI)** The method by which a traumatic event occurred.

**mediastinal shift** A shift of central thoracic structures toward one side; seen on chest x-ray.

**mediastinitis** Infection of the mediastinum.

**medical command physician** As defined in a hospital's emergency response plan, the person responsible for determining the number, acuity, and medical resource needs of victims arriving from the incident scene and for organizing the emergency health care team response to injured or ill patients.

**medical harm** Physician incidents and all errors caused by members of the health care team or system that lead to patient injury or death.

**medical nutrition supplements (MNSs)** Enteral products taken by patients who cannot consume enough nutrients in their usual diet (e.g., Ensure, Boost).

**medication overuse headache** See *rebound headache*.

**medication reconciliation** A formal evaluative process in which the patient's actual current medications are compared with his or her prescribed medications at time of admission, transfer, or discharge to identify and resolve discrepancies.

**medulla** A general term for the most interior portion of an organ or structure.

**melena** Blood in the stool, with the appearance of black tarry stools.

**memory cell** A type of B-lymphocyte that remains sensitized but does not start to produce antibodies until the next exposure to the same antigen.

**Ménière's disease** Tinnitus, one-sided sensorineural hearing loss, and vertigo that is related to overproduction or decreased reabsorption of endolymphatic fluid and causes a distortion of the entire inner canal system.

**meninges** The immediate protective covering of the brain and the spinal cord.

**meningioma** A type of benign brain tumor that arises from the coverings of the brain (the

meninges) and causes compression and displacement of adjacent brain tissue.

**meningitis** Inflammation, usually bacterial or viral, of the arachnoid and pia mater of the brain and spinal cord and the cerebrospinal fluid. May be caused by bacteria or viruses; symptoms are the same regardless of the causative organism.

**meniscectomy** Surgical excision of a meniscus, as in a knee joint.

**menses** The monthly flow of blood from the genital tract of women.

**metabolic syndrome** A collection of related health problems with insulin resistance as a main feature. Other features include obesity, low levels of physical activity, hypertension, high blood levels of cholesterol, and elevated triglyceride levels. Metabolic syndrome increases the risk for coronary heart disease. Also called *syndrome X*.

**metastasis** The growth and spread of cancer.

**metastasize** To spread cancer from the main tumor site to many other body sites.

**metastatic** Referring to disease, such as cancer, that transfers from one organ to another organ or part not directly connected; pertains to additional tumors that form after cancer cells move from the primary location by breaking off from the original group and establishing remote colonies.

**methemoglobinemia** The conversion of normal hemoglobin to methemoglobin.

**microalbuminuria** The presence of very small amounts of albumin in the urine that are not measurable by a urine dipstick or usual urinalysis procedures. Specialized assays are used to analyze a freshly voided urine specimen for microscopic levels of albumin.

**microbiome** The genomes of all the microorganisms that coexist in and on an adult and can affect cellular regulation.

**microcytic** Abnormally small in size, such as an abnormally small red blood cell.

**microvascular decompression** A surgical procedure to relieve the pain of trigeminal neuralgia by relocating a small artery that compresses the trigeminal nerve as it enters the pons. The surgeon carefully lifts the loop of the artery off the nerve and places a small silicone sponge between the vessel and the nerve.

**microvascular** Referring to small blood vessels.

**midline catheter** A type of catheter that is 6 to 8 inches long and inserted through the veins of the antecubital fossa; used in therapies lasting from 1 to 4 weeks.

**migraine headache** An episodic familial disorder manifested by a unilateral, frontotemporal, throbbing pain that is often worse behind one eye or ear. It is often accompanied by a sensitive scalp, anorexia, photophobia, and nausea with or without vomiting. Three categories of migraine headache are migraines with aura, migraines without aura, and atypical migraines.

**migratory arthritis** In the early stage of rheumatoid arthritis, symptoms that are migrating or involve more joints.

**miliary tuberculosis** See *hematogenous tuberculosis*.

**minimally invasive direct coronary artery bypass (MIDCAB)** Surgical procedure that does not require cardiopulmonary bypass and may be used for patients with a lesion of the left anterior descending artery. Also known as “keyhole” surgery.

**minimally invasive esophagectomy (MIE)** A laparoscopic surgical procedure to remove part of the esophagus; may be performed in patients with early-stage cancer.

**minimally invasive inguinal hernia repair (MIIHR)** Surgical repair of an inguinal hernia through a laparoscope, which is the treatment of choice.

**minimally invasive surgery (MIS)** A general term for any surgery performed using laparoscopic technique.

**Minimum Data Set (MDS) 3.0** Interdisciplinary tool required by the U.S. Centers for Medicare and Medicaid Services (CMS) to assess patients (residents) in nursing homes.

**miosis** Constriction of the pupil of the eye.

**mitosis** Cell division.

**mitotic index** The percentage of actively dividing cells within a tumor.

**mitral regurgitation** Inability of the mitral valve to close completely during systole, which allows the backflow of blood into the left atrium when the left ventricle contracts; usually due to fibrosis and calcification caused by rheumatic disease. Also called *mitral insufficiency*.

**mitral stenosis** Thickening of the mitral valve due to fibrosis and calcification and usually caused by rheumatic fever. The valve leaflets fuse and become stiff, the chordae tendineae contract, and the valve opening narrows, preventing normal blood flow from the left atrium to the left ventricle. As a result, left atrial pressure rises, the left atrium dilates, pulmonary artery pressures increase, and the right ventricle hypertrophies.

**mitral valve prolapse (MVP)** Dysfunction of the mitral valve that occurs because the valvular leaflets enlarge and prolapse into the left atrium during systole; usually benign but may progress to pronounced mitral regurgitation.

**mixed conductive-sensorineural hearing loss** A profound hearing loss that results from a combination of both conductive and sensorineural types of hearing loss.

**mobility** The ability of an individual to perform purposeful physical movement of the body.

**modifiable risk factor** A factor in disease development that can be altered or controlled by the patient. Examples include elevated serum cholesterol levels, cigarette smoking, hypertension, impaired glucose tolerance, obesity, physical inactivity, and stress.

**monokine** Cytokine made by macrophages, neutrophils, eosinophils, and monocytes.

**morbid obesity** A weight that has a severely negative effect on health; usually more than 100% above ideal body weight or a body mass index greater than 40.

**morbidity** An illness or an abnormal condition or quality.

**mortality** Death.

**Morton's neuroma** Plantar digital neuritis, a condition in which a small tumor grows in a digital nerve of the foot. The patient usually describes the pain as an acute, burning sensation in the web space that involves the entire surface of the third and fourth toes.

**motor aphasia** See *expressive aphasia*.

**motor cortex** Area in the frontal lobe of the brain that controls voluntary movement.

**motor end plate** The junction of a peripheral motor nerve and the muscle cells that it supplies.

**motor** Facilitating movement.

**mourning** The outward social expression of loss.

**MR elastography** A noninvasive diagnostic procedure that provides information about tissue stiffness by assessing qualities of shear waves generated into the tissue.

**mucositis** Open sores on mucous membranes.

**multi-casualty event** A disaster event in which a limited number of victims or casualties are

involved and can be managed by a hospital using local resources.

**multigated blood pool scanning** In nuclear cardiology, cardiac blood pool imaging is a noninvasive test to evaluate cardiac motion and calculate ejection fraction by using a computer to synchronize the patient's electrocardiogram with pictures obtained by a gamma-scintillation camera. In multigated blood pool scanning, the computer breaks the time between R waves into fractions of a second, called "gates." The camera records blood flow through the heart during each gate. By analyzing information from multiple gates, the computer can evaluate ventricular wall motion and calculate ejection fraction (percentage of the left ventricular volume that is ejected with each contraction) and ejection velocity.

**multiple organ dysfunction syndrome (MODS)** The sequence of inadequate blood flow to body tissues, which deprives cells of oxygen and leads to anaerobic metabolism with acidosis, hyperkalemia, and tissue ischemia; this is followed by dramatic changes in vital organs and leads to the release of toxic metabolites and destructive enzymes.

**multiple sclerosis (MS)** A chronic autoimmune disease that affects the myelin sheath and conduction pathway of the central nervous system. It is one of the leading causes of neurologic disability in persons 20 to 40 years of age.

**murmur** Abnormal heart sound that reflects turbulent blood flow through normal or abnormal valves; murmurs are classified according to their timing in the cardiac cycle (systolic or diastolic) and their intensity depending on their level of loudness.

**muscle biopsy** The extraction of a muscle specimen for the diagnosis of atrophy (as in muscular dystrophy) and inflammation (as in polymyositis).

**muscular dystrophy (MD)** A group of degenerative myopathies characterized by weakness and atrophy of muscle without nervous system involvement. At least nine types have been clinically identified and can be broadly categorized as slowly progressive or rapidly progressive.

**mutation** A change in deoxyribonucleic acid (DNA) that is passed from one generation to another.

**myalgia** Muscle aches/muscle pain.

**myasthenia gravis (MG)** A chronic autoimmune disease of the neuromuscular junction. It is characterized by remissions and exacerbations, with fatigue and weakness primarily in the muscles innervated by the cranial nerves and in the skeletal and respiratory muscles. It ranges from mild disturbances of the ocular muscles to a rapidly developing, generalized weakness that may lead to death from respiratory failure.

**myasthenic crisis** Undermedication with cholinesterase inhibitors.

**mydriasis** Dilation of the pupil of the eye.

**myelin sheath** A white, lipid covering of the axon.

**myelocytic** Pertaining to leukemias in which the abnormal cells come from the myeloid pathways.

**myelogenous** Pertaining to leukemias in which the abnormal cells come from the myeloid pathways.

**myelography** Radiography of the spine after injection of contrast medium into the subarachnoid space of the spine; used to visualize the vertebral column, intervertebral disks, spinal nerve roots, and blood vessels.

**myocardial hypertrophy** Enlargement of the myocardium.

**myocardial infarction (MI)** Injury and necrosis of myocardial tissue that occurs when the tissue is abruptly and severely deprived of oxygen; usually caused by atherosclerosis of a coronary artery, rupture of the plaque, subsequent thrombosis, and occlusion of blood flow.

**myocardial nuclear perfusion imaging (MNPI)** The use of radionuclide techniques in which

radioactive tracer substances are used to view, record, and evaluate cardiovascular abnormalities; useful for detecting myocardial infarction and decreased myocardial blood flow and for evaluating left ventricular ejection.

**myocardium** The heart muscle.

**myoglobin** A low-molecular-weight heme protein found in cardiac and skeletal muscle; an early marker of myocardial infarction.

**myoglobinuria** The release of muscle myoglobin into the urine.

**myomas** See *leiomyomas*.

**myomectomy** The surgical removal of leiomyomas with preservation of the uterus.

**myopathy** A problem in muscle tissue.

**myopia** An error of refraction that occurs when the eye over-refracts or over-bends the light and focuses images in front of the retina; this results in normal near vision but poor distance vision. Also called *nearsightedness*.

**myositis** Inflammation of a muscle.

**myosplint** Electrical stimulation of tension splints in the heart to help the ventricle change to a more normal shape in the patient with heart failure; under investigation in Europe and the United States.

**myringoplasty** Surgical reconstruction of the eardrum.

**myringotomy** The surgical creation of a hole in the eardrum; performed to drain middle-ear fluids and relieve pain in the patient with otitis media (middle-ear infection).

**myxedema coma** A rare, serious complication of untreated or poorly treated hypothyroidism in which decreased metabolism causes the heart muscle to become flabby and the chamber size to increase, resulting in decreased cardiac output and decreased perfusion to the brain and other vital organs.

**myxedema** Dry, waxy swelling of the skin that is accompanied by nonpitting edema (especially around the eyes, in the hands and feet, and between the shoulder blades) and is associated with primary hypothyroidism.

## N

**nadir** In cancer treatment therapy, the period of greatest bone marrow suppression, when the patient's platelet count may be very low.

**nasoduodenal tube (NDT)** A tube that is inserted through a nostril and into the small intestine.

**nasoenteric tube (NET)** Any feeding tube that is inserted nasally and then advanced into the gastrointestinal tract.

**nasogastric (NG) tube** A tube that is inserted through a nostril and into the stomach for liquid feeding or for withdrawing gastric contents.

**nasotracheal** The route for inserting a tube into the trachea via the nose.

**natal sex** A person's genital anatomy present at birth. Also known as *biological sex*.

**National Patient Safety Goals (NPSGs)** Goals published by The Joint Commission that require health care organizations to focus on specific priority safety practices.

**natural chemical débridement** Method of débriding a wound by creating an environment that promotes self-digestion of dead tissues by bacterial enzymes.

**near point of vision** The closest distance at which the eye can see an object clearly.

**near-drowning** Recovery after submersion in a liquid medium (usually water); this term is no longer used because language that describes drowning incidents has been standardized.

**near-syncope** Dizziness with an inability to remain in an upright position.

**necrotizing hemorrhagic pancreatitis (NHP)** Inflammation of the pancreas that is characterized by diffusely bleeding pancreatic tissue with fibrosis and tissue death. This form affects about 20% of patients with pancreatitis.

**needle thoracostomy** A quick, temporary method of chest decompression in which a large-bore needle is used to vent trapped air pending chest tube insertion.

**negative deflection** In electrocardiography, the flow of electrical current in the heart (cardiac axis) away from the positive pole and toward the negative pole.

**negative feedback control mechanism** The condition of maintaining a constant output of a system by exerting an inhibitory control on a key step by a product of that system. Used in a series of reactions that control hormone secretion and cellular activity based on responses to correct any movement away from normal function. An example of a simple negative feedback hormone response is the control of insulin secretion in which the action of insulin (decreasing blood glucose levels) is the opposite of the condition that stimulated insulin secretion (elevated blood glucose levels).

**negative nitrogen balance** A net loss of protein that occurs when the breakdown (degradation) of protein exceeds buildup (synthesis).

**neglect** In nursing, failure to provide for a patient's basic needs.

**neoadjuvant therapy** Treatment of a cancerous tumor with chemotherapy to shrink the tumor before it is surgically removed.

**neoplasia** Any new or continued cell growth not needed for normal development or replacement of dead and damaged tissues.

**nephrectomy** The surgical removal of the kidney.

**nephrolithiasis** The formation of stones in the kidney.

**nephron** The "working" unit of the kidney where urine is formed from blood. Each kidney consists of about 1 million nephrons, and each nephron separately makes urine. There are two types of nephrons: cortical and juxtamedullary.

**nephropathy** Pathologic change in the kidney that reduces kidney function and leads to renal failure.

**nephrosclerosis** Thickening in the nephron blood vessels that results in narrowing of the vessel lumen, with decreased renal blood flow and chronically hypoxic kidney tissue.

**nephrostomy** The surgical creation of an opening directly into the kidney; performed to divert urine externally and prevent further damage to the kidney when a stricture is causing hydronephrosis and cannot be corrected with urologic procedures.

**nephrotic syndrome (NS)** A condition of increased glomerular permeability that allows larger molecules to pass through the membrane into the urine and be removed from the blood. This process causes massive loss of protein into the urine, edema formation, and decreased plasma albumin levels.

**neuraxial** Referring to the epidural or spinal area.

**neuritic plaques** Degenerating nerve terminals found particularly in the hippocampus, an important part of the limbic system, and marked by increased amounts of an abnormal protein

called *beta amyloid*; a characteristic change of the brain found in patients with Alzheimer's disease.

**neurofibrillary tangles** Tangled masses of fibrous elements throughout the neurons; a classic finding at autopsy in the brains of patients with Alzheimer's disease.

**neurogenic shock** Hypotension and bradycardia associated with cervical spinal injuries and caused by a loss of autonomic function. The patient is at greatest risk in the first 24 hours after injury.

**neuroglia cells** Cells of varying size and shape that provide protection, structure, and nutrition for the neurons.

**neurohypophysis** The posterior lobe of the pituitary gland that stores hormones produced in the hypothalamus.

**neuroma** A sensitive tumor consisting of nerve cells and nerve fibers.

**neuron** Excitable nerve cell that processes and transmits information through electrical and chemical signals.

**neuropathic pain** A type of chronic noncancer pain that results from a nerve injury. Examples of causes include diabetic neuropathy, postherpetic neuralgia, radiculopathy (spinal nerve damage), and trigeminal neuralgia. Neuropathic pain is described as burning, shooting, stabbing, and the sensation of "pins and needles."

**neuropathy** A problem in nerve tissue that can cause muscle weakness.

**neurotransmitter** Regulatory chemical that exerts inhibitory (slowing down) or excitatory (speeding up) activity at postsynaptic nerve cell membranes. Acetylcholine, norepinephrine, epinephrine, dopamine, and serotonin are neurotransmitters.

**neurovascular assessment** Assessment of the neuromuscular system that includes inspection of skin color, temperature, and capillary refill distal to an injury, surgical procedure, or cast. Palpation of pulses in the extremities below level of injury and assessment of sensation, movement, and pain in the injured part give a complete assessment.

**neutralization** See *inactivation*.

**neutropenia** Decreased numbers of leukocytes, especially neutrophils, which causes immunosuppression.

**neutrophilia** Increased number of circulating neutrophils.

**nevus** A mole; a benign skin growth of the pigment-forming cells.

**new-onset angina** Cardiac chest pain that occurs for the first time.

**nitroglycerin (NTG)** A drug prescribed for patients with angina. It increases collateral blood flow, redistributes blood flow toward the subendocardium, and causes dilation of the coronary arteries.

**nits** Lice eggs.

**N-methyl-D-aspartate (NMDA) receptor antagonist** A group of drugs that block excess amounts of glutamate, which damages nerve cells in the brain; used to treat Alzheimer's disease.

**nociception** Term used to describe how pain becomes a conscious experience.

**nociceptive pain** Pain related to the skin, musculoskeletal structures, or body organs.

**nociceptors** Sensory neurons that respond to pain or other noxious stimuli.

**nocturia** The need to urinate excessively at night. Also called *nocturnal polyuria*.

**nocturnal polyuria** See *nocturia*.

**nonadherence** In health care, accidental failure by a patient to take medication.

**noncompliance** In health care, deliberate failure by a patient to take medication.

**nonmaleficence** Ethical principle that emphasizes the importance of preventing harm and ensuring the patient's well-being.

**nonmechanical obstruction** Intestinal obstruction that does not involve a physical obstruction in or outside the intestine. Instead, decreased or absent peristalsis results in a slowing of the movement or a backup of intestinal contents. This is also known as *paralytic ileus* or *adynamic ileus* because it is a result of neuromuscular disturbance.

**nonmodifiable risk factor** Factor in disease development that cannot be altered or controlled by the patient. Examples include age, gender, family history, and ethnic background.

**non-ST-segment elevation myocardial infarction (NSTEMI)** Myocardial infarction in which the patient typically has ST and T-wave changes on a 12-lead ECG; this indicates myocardial ischemia.

**nonsustained ventricular tachycardia (NSVT)** Occurrence of three or more successive premature ventricular complexes.

**nontunneled percutaneous central venous catheter (CVC)** A type of catheter, usually 15 to 20 cm long and with dual or triple lumens, that is inserted through the subclavian vein in the upper chest or through the jugular veins in the neck using sterile technique.

**nonurgent** In a three-tiered triage scheme, the category that includes patients who can generally tolerate waiting several hours for health care services without a significant risk of clinical deterioration, such as those with sprains, strains, or simple fractures.

**normal flora** The microorganisms living in or on the human host without causing disease; the bacteria that are characteristic of each body location. Normal flora often compete with and prevent infection from unfamiliar microorganisms attempting to invade a body site.

**normal sinus rhythm (NSR)** The rhythm originating from the sinoatrial node (dominant pacemaker), with atrial and ventricular rates of 60 to 100 beats/min and regular atrial and ventricular rhythms.

**normotonic** See *isosmotic*.

**North American pit vipers** The Crotalidae, one of two families of indigenous poisonous snakes in North America; named for the characteristic depression between each eye and nostril. They include rattlesnakes, copperheads, and water moccasins and account for most poisonous snakebites in the United States.

**nosocomial (infection)** Acquired in an inpatient health care setting; for example, infections that were not present at hospital admission. Also called *hospital-acquired infections* and *health care-associated infections*.

**nothing by mouth (NPO)** No eating, drinking (including water), or smoking.

**nuchal rigidity** Stiff neck, which can be a sign of cerebrospinal fluid leak; nuchal rigidity is not checked until a spinal cord injury has been ruled out.

**nucleotide** The final form of a base that actually gets put into the strand of deoxyribonucleic acid. A nucleoside becomes a complete nucleotide by the attachment of phosphate groups.

**nursing assistant** A member of the rehabilitative health care team who assists the registered nurse in the care of patients.

**nursing technician** See *nursing assistant*.

**nutrition** The process of ingesting and using food and fluids to grow, repair, and maintain optimal body functions.

**nutritional screening** A screening by the health care provider that includes visual inspection, measured height and weight, weight history, usual eating habits, ability to chew and swallow, and any recent changes in appetite or food intake. The screening is a way to determine which patients need more extensive nutritional assessment.

**nutritional status** Reflects the balance between nutrient requirements and intake.

**nystagmus** Involuntary rapid eye movements.

## O

**obesity** An increase in body weight at least 20% above the upper limit of the normal range for ideal body weight, with an excess amount of body fat; in an adult, a body mass index greater than 30.

**obligatory urine output** The minimum amount of urine per day needed to dissolve and excrete toxic waste products.

**obstipation** The inability to pass stool; intractable constipation.

**obstruction** Blockage.

**obstructive jaundice** Jaundice caused by an impediment to the flow of bile from the liver to the duodenum; may be caused by edema of the ducts or gallstones.

**obstructive sleep apnea** A breathing disruption during sleep that lasts at least 10 seconds and occurs a minimum of 5 times in an hour.

**Occupational Safety and Health Administration (OSHA)** A federal agency that protects workers from injury or illness at their place of employment.

**occupational therapist (OT, OTR)** A member of the rehabilitation health care team who works to develop the patient's fine motor skills used for activities of daily living and the skills related to coordination and cognitive retraining.

**odynophagia** Pain on swallowing.

**oligomenorrhea** Scant or infrequent menses.

**oligospermia** Low sperm count.

**oliguria** Scant urine output. Usually less than 400 mL per day.

**oliguria** Decreased excretion of urine in relation to amount of fluid intake; usually defined as urine output less than 400 mL/day.

**oncogene** Proto-oncogene that has been "turned on" and can cause cells to change from normal cells to cancer cells.

**oncogenesis** Cancer development.

**oncovirus** Virus that causes cancer.

**oophorectomy** Surgical removal of the ovary.

**open fracture** A fracture in which the skin surface over the broken bone is disrupted, causing an external wound. Also called *compound fracture*.

**open reduction** The reduction of a fracture after surgical incision into the site to allow direct visualization of the fracture. See *internal fixation*.

**open traumatic brain injury** A type of traumatic primary brain injury that occurs with a skull fracture or when the skull is pierced by a penetrating object. The integrity of the brain and the dura is violated, and there is exposure to outside contaminants, with damage to the underlying vessels, dural sinus, brain, and cranial nerves.

**opportunistic infection** Infection caused by organisms that are present as part of the normal environment and would be kept in check by normal immune function.

**optic disc** The point at the inside back of the eye where the optic nerve enters the eyeball. It appears as a creamy pink to white depressed area in the retina and contains only nerve fibers and no photoreceptor cells.

**optic fundus** The area at the inside back of the eye that can be seen with an ophthalmoscope.

**optic nerve** The nerve of sight; connects the optic disc to the brain.

**orbit** The bony socket of the skull that surrounds and protects the eye along with the attached muscles, nerves, vessels, and tear-producing glands.

**orchiectomy** The surgical removal of one or both testes.

**orchitis** An acute testicular inflammation resulting from trauma or infection.

**orexin** Neuropeptide that is an appetite stimulant.

**organ donor** An individual who has consented to donating one or more organs when he or she dies.

**orotracheal** The route for inserting a tube into the trachea via the mouth.

**orthopnea** Shortness of breath that occurs when lying down but is relieved by sitting up.

**orthostatic hypotension** A decrease in blood pressure (20 mm Hg systolic and/or 10 mm Hg diastolic) that occurs during the first few seconds to minutes after changing from a sitting or lying position to a standing position. Also called *postural hypotension*.

**orthostatic** Pertaining to or caused by standing erect.

**orthotopic** The most common type of transplantation procedure in which a diseased organ is removed and a donor organ is grafted in its place. For example, during heart transplantation, the surgeon removes the diseased heart and leaves the posterior walls of the patient's atria, which serve as the anchor for the donor heart; anastomoses are made between the recipient and donor atria, aorta, and pulmonary arteries.

**osmolality** The number of milliosmoles in a kilogram of solution.

**osmolarity** The number of milliosmoles in a liter of solution.

**osmosis** The movement of a solvent across a semipermeable membrane (a membrane that allows the solvent but not the solute to pass through) from a lesser to a greater concentration.

**ossiculoplasty** Replacement of the ossicles within the middle ear.

**osteitis deformans** See *Paget's disease*.

**osteoarthritis** Noninflammatory form of arthritis characterized by the progressive deterioration and loss of cartilage in one or more joints; most common form of arthritis.

**osteoblast** Cell associated with formation of bone.

**osteoclast** Cell associated with destruction or resorption of bone.

**osteocyte** Bone cell.

**osteomalacia** Abnormal softening of the bone tissue characterized by inadequate mineralization of osteoid. It is the adult equivalent of rickets (vitamin D deficiency) in children.

**osteomyelitis** An inflammation of bone tissue caused by pathogenic microorganisms; produces an increased vascularity and edema often involving the surrounding soft tissues.

**osteonecrosis** The death of bone tissue, usually because the blood supply to the bone is disrupted. Usually a complication of a hip fracture or any fracture in which there is displacement of bone.

**osteopenia** A condition of low bone mass that occurs when there is a disruption in the bone remodeling process.

**osteophyte** Bone spur.

**osteoporosis** A metabolic disease in which bone demineralization results in decreased density and subsequent fractures.

**osteotomy** Surgical resection of bone.

**ostomate** A patient with an ostomy.

**ostomy** The surgical creation of an opening, usually referring to an opening in the abdominal wall; stoma.

**otorrhea** Ear discharge.

**otosclerosis** Irregular bone growth around the ossicles.

**otoscope** An instrument used to examine the ear; consists of a light, a handle, a magnifying lens, and a pneumatic bulb for injecting air into the external canal to test mobility of the eardrum.

**ototoxic** Having a toxic effect on the inner ear structures.

**outflow disease** Chronic peripheral arterial disease with obstruction at or below the superficial femoral or popliteal artery. The patient experiences burning or cramping in the calves, ankles, feet, and toes after walking a certain distance; the pain usually subsides with rest.

**outpatient** A patient who goes to the hospital for treatment and returns home on the same day.

**overflow urinary incontinence** The involuntary loss of urine when the bladder is overdistended.

**overweight** An increase in body weight for height compared with a reference standard (e.g., the Metropolitan Life height and weight tables) or 10% greater than ideal body weight. However, this weight may not reflect excess body fat, which in an adult is a body mass index of 25 to 30.

**ovoid pupil** In evaluating pupils for size and reaction to light, the midstage between a normal-size pupil and a dilated pupil; indicates the development of increased intracranial pressure.

**oxygen concentrator** A machine that removes nitrogen, water vapor, and hydrocarbons from room air. Also known as *oxygen extractor*.

**oxygen dissociation** The transfer of oxygen from hemoglobin to tissues.

## P

**P wave** In the electrocardiogram, the deflection representing atrial depolarization.

**pack-years** The number of packs of cigarettes per day multiplied by the number of years the patient has smoked; used in recording a patient's smoking history.

**Paget's disease** A metabolic disorder of bone remodeling, or turnover, in which increased resorption or loss results in bone deposits that are weak, enlarged, and disorganized. Also known as *osteitis deformans*.

**pain** An unpleasant sensory and emotional experience associated with actual or potential tissue damage; the most reliable indication of pain is the patient's self-report.

**palliation** Relieving symptoms.

**palliative care** A compassionate and supportive approach to patients and families who are living with life-threatening illnesses; involves a holistic approach that provides relief of symptoms experienced by the dying patient.

**palpitations** A feeling of fluttering in the chest, an unpleasant awareness of the heartbeat, or an irregular heartbeat; may result from a change in heart rate or rhythm or from an increase in the force of heart contractions.

**pancreatic abscess** A collection of purulent material that results from extensive inflammatory necrosis of the pancreas after infection by organisms such as *Escherichia coli*; the most serious complication of pancreatitis. It is fatal if left untreated.

**pancreatic pseudocyst** A false cyst, so named because, unlike a true cyst, it does not have an epithelial lining. It is an encapsulated saclike structure that forms on or surrounds the pancreas and develops as a complication of acute or chronic pancreatitis. It may contain up to several liters of straw-colored or dark-brown viscous fluid, the enzymatic exudate of the pancreas.

**pancreaticojejunostomy** Surgical anastomosis of the pancreatic duct with the jejunum.

**pancytopenia** A deficiency of all three cell types (red blood cells, white blood cells, and platelets) of the blood.

**pandemic** A general epidemic spread over a wide geographic area and affecting a large proportion of the population.

**panniculectomy** The surgical removal of any panniculus, most often the abdominal apron; usually done as a follow-up to bariatric surgery in an obese patient.

**panniculitis** Infection of the panniculus.

**panniculus** A layer of membrane; also used to refer to skinfold areas in the obese patient.

**pannus** Vascular granulation tissue composed of inflammatory cells that forms in a joint space; erodes articular cartilage and eventually destroys bone.

**Papanicolaou test (Pap smear)** A cytologic study that is effective in detecting precancerous and cancerous cells obtained from the cervix.

**papilla** The anatomic term for a small, nipple-shaped projection or structure.

**papilledema** Edema and hyperemia of the optic disc; a sign of increased intracranial pressure found on ophthalmoscopic examination. Also called a *choked disc*.

**papilloma** A pedunculated outgrowth of tissue.

**papillotomy** An incision of a papilla, a small nipple-shaped projection or structure.

**papular** Referring to a papule, a small, solid elevation of the skin.

**paracentesis** A procedure in which the physician inserts a trocar catheter into the abdomen to remove and drain ascitic fluid from the peritoneal cavity.

**paradoxical blood pressure** An exaggerated decrease in systolic pressure by more than 10 mm Hg during the inspiratory phase of the respiratory cycle (normal is 3 to 10 mm Hg); clinical conditions that may produce a paradoxical blood pressure include pericardial tamponade, constrictive pericarditis, and pulmonary hypertension. Also known as *paradoxical pulse* and *pulsus paradoxus*.

**paradoxical chest wall movement** The “sucking inward” of the loose chest area during inspiration and a “puffing out” of the same area during expiration in a patient with a flail chest.

**paradoxical pulse** See *paradoxical blood pressure*.

**paradoxical splitting** Abnormal splitting of the S<sub>2</sub> heart sound heard in patients with severe myocardial depression; causes early closure of the pulmonic valve or a delay in aortic valve closure.

**paralysis** Absence of movement.

**paralytic ileus** Absence of peristalsis.

**paramedic** Prehospital care provider for patients who require care that exceeds basic life support resources. Advanced life support (ALS) may include cardiac monitoring, advanced airway management and intubation, establishing IV access, and administering drugs en route to the emergency department.

**paranasal sinuses** The air-filled cavities within the bones that surround the nasal passages. Lined with ciliated membrane, the sinuses provide resonance during speech and decrease the weight of the skull.

**paraparesis** Weakness that involves only the lower extremities, as seen in lower thoracic and lumbosacral injuries or lesions.

**paraplegia** Paralysis that involves only the lower extremities, as seen in lower thoracic and lumbosacral injuries or lesions.

**paresis** Weakness.

**paresthesia** Abnormal or unusual nerve sensations of touch, such as tingling and burning.

**parietal cells** Cells lining the wall of the stomach that secrete hydrochloric acid and produce intrinsic factor.

**Parkinson disease (PD)** A debilitating neurologic disease that affects motor ability and is characterized by four cardinal symptoms: tremor, rigidity, akinesia (slow movement), and postural instability. It is the third most common neurologic disorder of older adults. Also called *paralysis agitans*.

**parotidectomy** The surgical removal of the parotid glands.

**paroxysmal nocturnal dyspnea (PND)** In the patient with heart disease, difficulty breathing that develops after lying down for several hours and causes the patient to awaken abruptly with a feeling of suffocation and panic. Occurs because the heart is unable to compensate for the increased volume when blood from the lower extremities is redistributed to the venous system, which increases venous return to the heart. A diseased heart is ineffective in pumping the additional fluid into the circulatory system, and pulmonary congestion results.

**paroxysmal supraventricular tachycardia (PSVT)** A form of supraventricular tachycardia that occurs when the rhythm is intermittent; it is initiated suddenly by a premature complex, such as a premature atrial complex, and terminated suddenly with or without intervention.

**partial left ventriculectomy (PLV)** A ventricular reconstructive procedure that involves removing a triangle-shaped section of the weakened heart in the left lateral ventricle to reduce the ventricle's diameter and decrease wall tension. Also known as *heart reduction surgery* and *Batista procedure*.

**partial seizure** One of the three broad categories of seizure disorders along with generalized seizure and unclassified seizure. Partial seizures are of two types: complex and simple. Partial seizures begin in a part of one cerebral hemisphere; some can evolve into generalized tonic-clonic, tonic, or clonic seizures. They are most often seen in adults and in general are less responsive to medical treatment. Also called *focal seizures* or *local seizures*.

**passive euthanasia** See *withdrawing or withholding life-sustaining therapy*.

**passive immunity** Resistance to infection that is of short duration (days or months) and either natural by transplacental transfer from the mother or artificial by injection of antibodies (e.g., immunoglobulin).

**patellofemoral pain syndrome (PFPS)** A health problem that occurs most often in people who are runners or who overuse their knee joints. For that reason, it is sometimes referred to as “runner's knee.” These patients describe pain as being behind or around their patella (knee cap) in one or both knees.

**pathogen** Any microorganism capable of producing disease.

**pathogenicity** The ability to cause disease.

**pathologic (spontaneous) fracture** A fracture that occurs after minimal trauma to a bone that has been weakened by a disease such as bone cancer or osteoporosis.

**patient-centered care** A QSEN competency in which the nurse recognizes the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for the patient's preferences, values, and needs.

**patient-controlled analgesia** A method that allows the patient to control the dosage of opioid analgesic received by using an infusion pump to deliver the desired amount of medication through a conventional IV route.

**PDSA** Acronym for plan, do, study, act, which is one of the steps of the evidence-based practice improvement (EBPI) model.

**peaceful death** A death that is free from avoidable distress and suffering for patients and families, is in agreement with patients' and families' wishes, and is consistent with clinical practice standards.

**pedal** Pertaining to the feet.

**pediculosis** An infestation by human lice.

**pedigree** A graph of a family history for a specific trait or health problem over several generations.

**pelvic inflammatory disease (PID)** Any infection of the pelvis involving the upper genital tract beyond the cervix in women. It occurs when organisms from the lower genital tract migrate from the endocervix upward through the uterine cavity into the fallopian tubes.

**pelvic organ prolapse (POP)** Condition in which the sling of muscles and tendons that support the pelvic organs becomes weak and is no longer able to hold them in place.

**penetrance** In genetics, how often or how well a gene is expressed when it is present within a population.

**penetrating trauma** Injuries caused by piercing; classified by the velocity of the vehicle (e.g., knife or bullet) causing the injury. Low-velocity injuries from knife wounds cause damage directly at the site; high-velocity injuries from gunshot wounds cause both direct and indirect damage. Also called *penetrating injury*.

**peptic ulcer disease (PUD)** The impairment of gastric mucosal defenses so that they no longer protect the epithelium from the effects of acid and pepsin.

**peptic ulcer** A mucosal lesion of the stomach or duodenum.

**percutaneous alcohol septal ablation** Surgical procedure for hypertrophic cardiomyopathy (HCM) in which alcohol is injected into a target septal branch of the left anterior descending coronary artery to produce a small septal infarction. This procedure also widens the left ventricular outflow tract.

**percutaneous coronary intervention (PCI)** See *percutaneous transluminal coronary angioplasty (PTCA)*.

**percutaneous endoscopic gastrostomy (PEG)** A stoma created from the abdominal wall into the stomach for insertion of a short feeding tube.

**percutaneous stereotactic rhizotomy (PSR)** Procedure performed under general anesthesia to treat trigeminal neuralgia; a hollow needle is passed through the inside of the patient's cheek into the trigeminal nerve fibers, and a heating current (radiofrequency thermocoagulation) goes through the needle to destroy some of the fibers.

**percutaneous transhepatic cholangiography (PTC)** The radiographic study of the biliary duct system using an iodinated dye instilled via a percutaneous needle inserted through the liver into the intrahepatic ducts. It may be performed when a patient has jaundice or persistent upper abdominal pain, even after cholecystectomy, but it is rarely performed as a diagnostic procedure.

**percutaneous transluminal coronary angioplasty (PTCA)** A nonsurgical method of improving arterial flow by opening the vessel lumen and creating a smooth inner vessel surface. One or more arteries are dilated with a balloon catheter advanced through a cannula, which is inserted into or above an occluded or stenosed artery. Also called *percutaneous vascular intervention* and *percutaneous coronary intervention (PCI)*.

**percutaneous vascular intervention** See *percutaneous transluminal coronary angioplasty*.

**percutaneous** Performed through the skin and other tissues.

**perfusion** Adequate arterial blood flow to the peripheral tissues (peripheral perfusion) and blood that is pumped by the heart to oxygenate major body organs (central perfusion).

**pericardial effusion** Complication of pericarditis that occurs when the space between the parietal and visceral layers of the pericardium fills with fluid.

**pericardial friction rub** An abnormal sound that originates from the pericardial sac and occurs with the movements of the heart during the cardiac cycle; usually transient and a sign of inflammation, infection, or infiltration; may be heard in patients with pericarditis resulting from myocardial infarction, cardiac tamponade, or post-thoracotomy.

**pericardiectomy** Surgical excision of the pericardium (the sac around the heart).

**pericardiocentesis** Withdrawal of pericardial fluid through a catheter inserted into the pericardial space to relieve the pressure on the heart.

**pericarditis** An inflammation of the tissue (pericardium) surrounding the heart.

**perichondrium** A tough, fibrous tissue layer that surrounds the ear cartilage and gives shape to the pinna.

**periodontal disease** Gum disease in which mandibular bone loss has occurred.

**perioperative** The operative experience consisting of the preoperative, intraoperative, and postoperative time periods.

**peripheral blood stem cells (PBSCs)** Stem cells that are collected from peripheral blood for transplantation into the patient.

**peripheral chemoreceptors** Several 1- to 2-mm collections of tissue identified in the carotid arteries and along the aortic arch.

**peripheral IV therapy** IV therapy in which a vascular access device (VAD) is placed in a peripheral vein, usually in the arm.

**peripheral vascular disease (PVD)** Any disorder that alters the natural flow of blood through the

arteries and veins of the peripheral circulation.

**peripherally inserted central catheter (PICC)** A long catheter inserted through a vein of the antecubital fossa (inner aspect of the bend of the arm) or the middle of the upper arm.

**peritonitis** Acute inflammation of the visceral/parietal peritoneum and endothelial lining of the abdominal cavity, or peritoneum.

**peritonsillar abscess (PTA)** A complication of acute tonsillitis. The infection spreads from the tonsil to the surrounding tissue, which forms an abscess.

**periungual lesion** Skin lesion around the nail bed.

**permeable** The quality of being porous.

**pernicious anemia** A form of megaloblastic anemia caused by failure to absorb vitamin B<sub>12</sub> because of a deficiency of intrinsic factor (normally secreted by the gastric mucosa) needed for intestinal absorption of vitamin B<sub>12</sub>.

**PERRLA** An acronym that stands for the phrase “Pupils should be *e*qual in size, *r*ound and *r*egular in shape, and react to *l*ight and *a*ccommodation.”

**personal emergency preparedness plan** An individual plan that outlines specific arrangements in the event of disaster, such as childcare, pet care, and older adult care.

**personal protective equipment (PPE)** Infection control protocol that refers to the use of gloves, isolation gowns, face protection, and respirators with N95 or higher filtration.

**personal readiness supplies** A preassembled disaster supply kit for the home and/or automobile that contains clothing and basic survival supplies. Also called a “*go bag*.”

**petechiae** Pinpoint red spots on the mucous membranes, palate, conjunctivae, or skin.

**pH monitoring examination** The most accurate testing method of diagnosing GERD, accomplished by placing a small catheter into the distal esophagus or esophageal wall (depending on the specific technique). The patient then records a diary of activities and symptoms over a 24- to 48-hour period while pH is continuously monitored.

**pH** A measure of the free hydrogen ion level in body fluid.

**phagocytosis** The process of engulfing, ingesting, killing, and disposing of an invading organism by neutrophils and macrophages; a key process of inflammation.

**Phalen's maneuver** Test to determine the presence of carpal tunnel syndrome (CTS); a positive test for CTS causes paresthesia in the medial nerve distribution of the palm of the hand in 60 seconds.

**phantom limb pain (PLP)** A frequent complication of amputation in which the patient perceives sensation in the absent (amputated) foot or hand. This sensation usually diminishes over time.

**pharmacist** Member of the health care team who oversees the prescription and preparation of medications and provides the team with essential information regarding drug safety.

**pharmacologic stress echocardiogram** A form of echocardiography in which either dobutamine (increases heart's contractility) or adenosine (dilates coronary arteries) is given to the patient; usually used when patients cannot tolerate exercise.

**phenotype** Any genetic characteristic that can actually be observed or, in some cases, determined by laboratory test.

**pheochromocytoma** A tumor of the adrenal medulla, which can cause excessive secretion of catecholamines.

**phlebitis** Inflammation of a vein, which can predispose patients to thrombosis.

**phlebothrombosis** Presence of a thrombus in a vein without inflammation.

**phonophobia** Abnormal sensitivity to sound.

**phonophoresis** Treatment for back pain in which a topical drug (e.g., lidocaine, hydrocortisone) is applied followed by continuous ultrasound for 10 minutes.

**photophobia** Abnormal sensitivity to light.

**photopsia** The appearance of bright flashes of light due to the onset of retinal detachment.

**physiatrist** A physician who specializes in rehabilitative medicine.

**physical abuse** The use of a physical force, such as hitting, burning, pushing, and molesting the patient, that results in bodily injury.

**physical therapist (PT, RPT)** A member of the rehabilitation health care team who helps the patient achieve mobility and who teaches techniques for performing certain activities of daily living.

**piggyback set** See *secondary administration set*.

**pitting** Indentation of the skin; often occurs with edema.

**pituitary Cushing's disease** Oversecretion of ACTH by the anterior pituitary gland, which causes hyperplasia of the adrenal cortex in both adrenal glands and an excess of most hormones secreted by the adrenal cortex.

**placebo** Any medication or procedure, including surgery, that produces an effect in a patient because of its implicit or explicit intent and not because of its specific physical or chemical properties.

**Plan-Do-Study-Act (PDSA)** A specific systematic model of quality improvement.

**plantar fasciitis** An inflammation of the plantar fascia, which is located in the area of the arch of the foot. It is often seen in athletes, especially runners.

**plasma cell** A short-lived B-lymphocyte that begins to function immediately to produce antibodies against sensitizing antigens.

**plasmapheresis** The separation of plasma from whole blood, after which the blood cells are returned to the patient without the plasma to eliminate antibodies.

**plethoric** A flushed appearance of the skin.

**pleura** The continuous smooth membrane composed of two surfaces that totally enclose the lungs.

**pleural effusion** Fluid in the pleural space.

**pleuritic chest pain** A stabbing pain on taking a deep breath.

**plexus** Cluster of nerves.

**ploidy** The number and appearance of chromosomes; used to describe cancer cells.

**pluripotent stem cell** The precursor cell involved in the production of red blood cells.

**pneumonectomy** Removal of an entire lung, including all blood vessels.

**pneumonia** Excess fluid in the lungs resulting from an inflammatory process that can include infection.

**pneumothorax** Air in the pleural (chest) cavity.

**podagra** Inflammation of the metatarsophalangeal joint of the great toe.

**point of maximal impulse (PMI)** See *apical impulse*.

**polycystic kidney disease (PKD)** An inherited disorder in which fluid-filled cysts develop in the kidneys.

**polycythemia vera (PV)** A disease that involves massive production of red blood cells, leukocytes, and platelets.

**polydipsia** Excessive intake of water.

**polymedicine** The use of many drugs to treat multiple health problems for older adults.

**polymorphism** A variation in form.

**polyp** An abnormal outgrowth from a mucous membrane.

**polyphagia** Excessive eating.

**polypharmacy** The use of many drugs to treat multiple health problems for older adults. Also known as *hyperpharmacy*.

**polyuria** Frequent and excessive urination.

**pores** Openings or spaces.

**portal hypertension** An abnormal persistent increase in pressure within the portal vein; a major complication of cirrhosis.

**portal hypertensive gastropathy** A complication that can occur in patients with portal hypertension, with or without esophageal varices. Slow gastric mucosal bleeding may result in chronic slow blood loss, occult positive stools, and anemia.

**portal-systemic encephalopathy (PSE)** A clinical disorder seen in hepatic failure and cirrhosis; it is manifested by neurologic symptoms and is characterized by an altered level of consciousness, impaired thinking processes, and neuromuscular disturbances. Also called *hepatic encephalopathy* and *hepatic coma*.

**positive deflection** In electrocardiography, the flow of electrical current in the heart (cardiac axis) toward the positive pole.

**positive inotropic agents** Drugs that increase myocardial contractility; such drugs are prescribed to improve cardiac output.

**postanesthesia care unit (PACU)** Recovery room.

**postcholecystectomy syndrome (PCS)** The occurrence of the clinical manifestations of biliary tract disease following cholecystectomy; caused by residual or recurring calculi, inflammation, or stricture of the common bile duct.

**post-concussion syndrome** A group of clinical manifestations following a concussion that consist of personality changes, irritability, headaches, dizziness, restlessness, nervousness, insomnia, memory loss, and depression. The prolonged pattern is classified as post-trauma syndrome.

**posterior colporrhaphy** The surgical procedure to repair a rectocele by strengthening pelvic supports and reducing the bulging.

**posteroanterior** Back to front; position for standard chest x-rays.

**postherpetic neuralgia** Pain that persists after herpes zoster lesions have resolved.

**postictal stage** Referring to the time immediately after a seizure.

**postoperative period** After surgery.

**postpericardiotomy syndrome** Symptoms, including pericardial and pleural pain, pericarditis, friction rub, elevated temperature and white blood cell count, and dysrhythmias, that occur in patients after cardiac surgery; may occur days to weeks after surgery and seems to be associated with blood that remains in the pericardial sac.

**postrenal failure** Decrease in renal function related to an obstruction in the flow of urine. It can progress to acute renal failure.

**postural hypotension** See *orthostatic hypotension*.

**posture** A person's body build and alignment when standing and walking.

**post-void residual (PVR)** The amount of urine remaining in the bladder within 20 minutes after voiding.

**power air purifying respirator (PAPR)** Device with a high efficiency particulate air (HEPA) filter and battery to promote positive pressure air flow; more effective than an N95 respirator.

**PQRST** A mnemonic (memory device) that may help in the current problem assessment of patients with gastrointestinal tract disorders. The letters represent these areas: P, precipitating or palliative (What brings it on? What makes it better or worse?); Q, quality or quantity (How does it look, feel, or sound?); R, region or radiation (Where is it? Does it spread anywhere?); S, severity scale (How bad is it [on a scale of 0 to 10]? Is it getting better, worse, or staying the same?); T, timing (Onset, duration, and frequency?).

**PR interval** In the electrocardiogram, the interval measured from the beginning of the P wave to the end of the PR segment; represents the time required for atrial depolarization as well as impulse delay in the atrioventricular node and travel time to the Purkinje fibers.

**PR segment** In the electrocardiogram, the isoelectric line from the end of the P wave to the beginning of the QRS complex, when the electrical impulse is traveling through the atrioventricular node, where it is delayed.

**Prader-Willi syndrome (PWS)** A complex neurodevelopmental genetic disorder that results from a hypothalamic-pituitary dysfunction that prevents appetite control. Patients with this syndrome are typically morbidly obese.

**prandial (insulin secretion)** The increased levels of insulin that are secreted after eating. Within 10 minutes of eating, an early burst of insulin secretion occurs, which is followed by an increasing insulin release that lasts as long as hyperglycemia is present.

**prealbumin (PAB)** A protein secreted by the liver that binds thyroxine.

**precipitation** The formation of large, insoluble antigen-antibody complexes during the antibody-binding process.

**prediabetes** An impaired fasting glucose (IFG) or impaired glucose tolerance (IGT).

**prehospital care provider** Typically, any of the first caregivers encountered by the patient if he or she is transported to the emergency department by an ambulance or helicopter.

**preictal phase** Referring to events that a patient experiences before a seizure, such as the presence of an aura.

**pre-infarction angina** Chest pain that occurs in the days or weeks before a myocardial infarction.

**preload** The degree of myocardial fiber stretch at the end of diastole and just before contraction; determined by the amount of blood returning to the heart from both the venous system (right heart) and the pulmonary system (left heart).

**premature atrial complex (contraction) (PAC)** In the electrocardiogram, an early complex that occurs when atrial tissue becomes irritable. This ectopic focus fires an impulse before the next sinus impulse is due, thus usurping the sinus pacemaker. The premature P wave from the atrial

focus is early and has a shape different from that of the P wave generated from the sinus node.

**premature complex** In the electrocardiogram, an early complex that occurs when a cardiac cell or cell group other than the sinoatrial node becomes irritable and fires an impulse before the next sinus impulse is generated. After the premature complex, there is a pause before the next normal complex, which creates an irregularity in the rhythm.

**premature ventricular complex (PVC)** In the electrocardiogram, an early ventricular complex is followed by a pause that results from increased irritability of ventricular cells. The QRS complexes may be unifocal or uniform (of the same shape), or multifocal or multiform (of different shapes).

**preoperative** Before surgery.

**prerenal failure** Condition that causes inadequate kidney perfusion; can progress to acute renal failure.

**presbycusis** The loss of hearing, especially for high-pitched sounds; occurs as a result of aging.

**presbyopia** An age-related impairment of vision characterized by a loss of lens elasticity and the ability of the eye to accommodate. The near point of vision increases, and near objects must be placed farther from the eye to be seen clearly.

**presence** A type of communication that consists of listening and acknowledging the legitimacy of the patient's and/or family's pain.

**pressure ulcer** Tissue damage caused when the skin and underlying soft tissue are compressed between a bony prominence and an external surface for an extended period; commonly occurs over the sacrum, hips, and ankles.

**pretibial myxedema** Dry, waxy swelling of the front surfaces of the lower legs.

**pretibial** Pertaining to the front of the leg below the knee.

**primary angle-closure glaucoma** A form of glaucoma characterized by a narrowed angle and forward displacement of the iris so that movement of the iris against the cornea narrows or closes the chamber angle, obstructing the outflow of aqueous humor. It can have a sudden onset and is an emergency. Also called *closed-angle glaucoma*, *narrow-angle glaucoma*, or *acute glaucoma*.

**primary arthroplasty** A total joint arthroplasty procedure that has been performed for the first time.

**primary gout** The most common type of gout; results from one of several inborn errors of purine metabolism.

**primary lesions** In describing skin disease, the initial reaction to a problem that alters one of the structural components of the skin.

**primary open-angle glaucoma (POAG)** The most common form of primary glaucoma; characterized by reduced outflow of aqueous humor through the chamber angle. Because the fluid cannot leave the eye at the same rate it is produced, intraocular pressure gradually increases.

**primary prevention** Strategies used to avoid or delay the actual occurrence of a specific disease.

**primary progressive multiple sclerosis (PPMS)** A type of multiple sclerosis (MS) that involves a steady and gradual neurologic deterioration without remission of symptoms. Patients with this type of MS are usually between 40 and 60 years of age at onset of the disease and experience progressive disability with no acute attacks.

**primary survey** Priorities of care addressed in order of immediate threats to life as part of the initial assessment in the emergency department. Survey is based on an "ABC" mnemonic with "D" and "E" added for trauma patients: airway/cervical spine (A), breathing (B), circulation (C),

disability (D), and exposure (E).

**primary tumor** The original tumor, usually identified by the tissue from which it arose (parent tissue), such as in breast cancer or lung cancer.

**progressive multifocal leukoencephalopathy (PML)** Rare disease affecting the white matter of the brain caused by a virus that attacks the cells that make myelin; occurs most often in patients who are immunosuppressed.

**progressive-relapsing multiple sclerosis (PRMS)** A type of multiple sclerosis (MS) that occurs in only 5% of patients with MS. It is characterized by the absence of periods of remission, and the patient's condition does not return to baseline. Progressive cumulative symptoms and deterioration occur over several years.

**proliferative diabetic retinopathy** A form of retinopathy associated with diabetes mellitus in which a network of fragile new blood vessels develops, leaking blood and protein into surrounding tissue. The new blood vessels are stimulated by retinal hypoxia that results from poor capillary perfusion of the retinal tissues. New blood vessels grow in the retina, onto the iris, and into the back of the vitreous. The vitreous contracts and pulls away from the retina, causing blood vessels to break and bleed into the vitreous.

**promoter** In oncology, a substance that promotes or enhances growth of the initiated cancer cell; may be a hormone, drug, or chemical.

**pronator drift** Occurs in a patient with muscle weakness due to cerebral or brainstem reasons. The arm on the weak side tends to fall, or "drift," with the palm pronating (turning inward) after the patient has closed his or her eyes and held the arms perpendicular to the body with the palms up for 15 to 30 seconds; part of the neurologic assessment.

**prophylactic mastectomy** Highly controversial practice of surgically removing the breast in order to reduce the risk of breast cancer.

**proportionate palliative sedation** A care management approach involving the administration of drugs such as benzodiazepines for the purpose of lowering patient consciousness.

**proprioception (proprioceptive)** Awareness of body position and movement.

**prosopagnosia** The inability to recognize oneself and other familiar faces; occurs in patients in the later stages of Alzheimer's disease.

**prostaglandins** Chemicals that are produced in the cells and cause inflammation and swelling.

**prostate artery embolization** A procedure in which the interventional radiologist threads a small vascular catheter into the prostate's arteries and injects particles blocking some of the blood flow to shrink the prostate gland.

**prostate-specific antigen (PSA)** A glycoprotein produced solely by the prostate. The normal blood level of PSA is less than 4 ng/mL; levels are higher in patients with increased prostatic tissue as a result of benign prostatic hyperplasia, prostatic infarction, prostatitis, and prostate cancer. Levels associated with prostate cancer are usually much higher than those occurring with other prostate tissue enlargement.

**prostatitis** Inflammation of the prostate.

**protein synthesis** The process by which genes are used to make the proteins needed for physiologic function.

**protein-calorie malnutrition (PCM)** A disorder of nutrition that may present in three forms: marasmus, kwashiorkor, and marasmic-kwashiorkor. Also called *protein-energy malnutrition*.

**protein-energy malnutrition (PEM)** See *protein-calorie malnutrition*.

**proteinuria** The presence of protein in the urine.

**proteolysis** The breakdown of proteins to provide fuel for energy when liver glucose is unavailable.

**proton pump inhibitor (PPI)** A group of drugs that inhibit the proton pump in the stomach to decrease gastric acid production.

**pruritus** An unpleasant itching sensation.

**psoriasis** A chronic autoimmune disorder of the skin with exacerbations and remissions. It results from overstimulation of the immune system (Langerhans' cells) in the skin that activates T-lymphocytes. The features include increased skin cell division in patchy areas forming scaly plaques.

**psoriatic arthritis (PsA)** A syndrome of inflammatory arthritis associated with psoriasis, the skin condition characterized by a scaly, itchy rash.

**psychiatric crisis nurse team** An emergency department specialty team whose nurses interact with patients and families in crisis.

**psychotropic drugs** Antipsychotic and neuroleptic drugs. These are appropriately given to patients with emotional and behavioral health problems (e.g., hallucinations and delusions) that accompany dementia but are sometimes inappropriately used for agitation, combativeness, or restlessness. They are considered chemical restraints because they decrease mobility and patients' ability to care for themselves.

**ptosis** Drooping of the eyelid.

**pulmonary artery occlusive pressure (PAOP)** See *pulmonary artery wedge pressure*.

**pulmonary artery wedge pressure (PAWP)** Measurement of pressure in the left atrium using a balloon-tipped catheter introduced into the pulmonary artery. When the balloon at the catheter tip is inflated, the catheter advances and wedges in a branch of the pulmonary artery. The tip of the catheter is able to sense pressures transmitted from the left atrium, which reflect left ventricular end-diastolic pressure. Also called *pulmonary artery occlusive pressure*.

**pulmonary autograph** The relocation of the patient's own pulmonary valve to the aortic position for aortic valve replacement (Ross procedure).

**pulmonary embolism (PE)** A collection of particulate matter, most commonly a blood clot, that enters venous circulation and lodges in the pulmonary vessels, obstructing pulmonary blood flow and leading to decreased systemic oxygenation, pulmonary tissue hypoxia, and potential death.

**pulmonary empyema** A collection of pus in the pleural space most commonly caused by a pulmonary infection.

**pulse deficit** The difference between the apical and peripheral pulses.

**pulse pressure** The difference between the systolic and diastolic pressures.

**pulse therapy** Any therapy given at a high dose for a short duration.

**pulsus alternans** A type of pulse in which a weak pulse alternates with a strong pulse despite a regular heart rhythm; seen in patients with severely depressed cardiac function.

**punctum** The opening through which tears drain; located at the nasal side of the eyelid edges.

**pupil** The opening through which light enters the eye; located in the center of the iris of the eye.

**Purkinje cells** In the cardiac conduction system, the cells that make up the bundle of His, bundle branches, and terminal Purkinje fibers. These cells are responsible for the rapid conduction of electrical impulses throughout the ventricles, leading to ventricular depolarization and subsequent ventricular muscle contraction.

**purpura** Purple patches on the skin that may be caused by blood disorders, vascular abnormalities, or trauma.

**pyelolithotomy** The surgical removal of a stone from the kidney.

**pyelonephritis** A bacterial infection in the kidney and renal pelvis (the upper urinary tract).

**pyloromyotomy** An incision through the serosa and muscularis of the pylorus, down to the mucosa; created to prevent gastric motility disturbances in patients who have undergone esophagectomy.

**pyuria** The presence of white blood cells (pus) in the urine.

## Q

**QRS complex** In the electrocardiogram, the portion consisting of the Q, R, and S waves, representing ventricular depolarization.

**QRS duration** In the electrocardiogram, the time required for depolarization of both ventricles; measured from the beginning of the QRS complex to the J point (the junction at which the QRS complex ends and the ST segment begins).

**QT interval** In the electrocardiogram, the time from the beginning of the QRS complex to the end of the T wave. It represents the total time required for ventricular depolarization and repolarization.

**quadriceps-setting exercise** Postoperative leg exercise performed by straightening the legs and pushing the back of the knees into the bed.

**quadrigeminy** A type of premature complex consisting of a repetitive four-beat pattern; usually occurs as three sequential normal complexes followed by a premature complex and a pause, with the same pattern repeating itself in a four-beat pattern.

**quadriparesis** Weakness that involves all four extremities; seen with cervical spinal cord injury.

**qualitative question** A clinical question that focuses on the meanings and interpretations of human phenomena or experience of people and usually analyzes the content of what a person says during an interview or what a researcher observes.

**quality improvement** A QSEN competency in which the nurse uses data to monitor the outcomes of care processes and uses improvement methods to design and test changes to continuously improve the quality and safety of health care systems.

**quantitative question** A clinical question that asks about the relationship between or among defined, measurable phenomena and includes statistical analysis of information that is collected to answer a question.

## R

**radiation dose** The amount of radiation absorbed by the tissue.

**radiation proctitis** Rectal mucosa inflammation that results from external beam radiation therapy.

**radical cystectomy** Removal of the bladder and surrounding tissue with urinary diversion.

**radicular** Referring to a nerve root.

**radiculopathy** Referring to radicular pain; spinal nerve root involvement.

**radiofrequency catheter ablation** An invasive procedure that uses radiofrequency waves to abolish an irritable focus that is causing a supraventricular or ventricular tachydysrhythmia.

**Rapid Response Team** Team of critical care experts who save lives and decrease the risk for harm by providing care to patients before a respiratory or cardiac arrest occurs. Also called *Medical Emergency Team*.

**rapidly progressive glomerulonephritis** A primary inflammation of the glomeruli, nephrons, and kidney tissue that develops over several weeks to months.

**RBC** Red blood cell.

**rebound headache** Headache that occurs as a side effect of a drug that has relieved an initial migraine headache. Also called *medication overuse headache*.

**recall memory** Recent memory, which can be tested during the history taking by asking about items such as the dates of clinic or physician appointments.

**receptive aphasia** A type of aphasia caused by injury to Wernicke's area in the temporoparietal area of the brain and characterized by an inability to understand the spoken and written word; reading and writing ability are equally affected. Although the patient can talk, the language is often meaningless and neologisms (made-up words) are common parts of speech. Also called *Wernicke's aphasia* or *sensory aphasia*.

**reconstructive plastic surgery** Type of plastic surgery that corrects or improves functional defects that have occurred as a result of congenital problems, trauma and scarring, or other types of therapy.

**recreational therapist** A member of the health care team who works to help patients continue or develop hobbies or interests. Also called *activity therapist*.

**rectocele** A protrusion of the rectum through a weakened vaginal wall.

**red reflex** A reflection of light on the retina seen as a red glare during ophthalmoscopic examination. An absent red reflex may indicate a lens opacity or cloudiness of the vitreous.

**redirection** An intervention to help with communication problems in patients with dementia; consists of attracting the patient's attention before conversing, keeping the environment as free of distractions as possible, and speaking directly to the patient in a distinct manner using clear and short sentences.

**reducible hernia** A hernia that can be placed back into the abdominal cavity by gentle pressure.

**reduction mammoplasty** Breast reduction surgery in which the surgeon removes excess breast tissue and then repositions the nipple and remaining skin flaps to produce an optimal cosmetic effect.

**Reed-Sternberg cell** A specific cancer cell type, found in lymph nodes, that is a marker for Hodgkin's lymphoma.

**re-epithelialization** In partial-thickness (superficial) wounds involving damage to the epidermis and upper layers of the dermis, a form of healing by means of the production of new skin cells by undamaged epidermal cells in the basal layer of the dermis.

**refeeding syndrome** Life-threatening metabolic complication that can occur when nutrition is restarted for a patient who is in a starvation state.

**reflex arc** A closed circuit of spinal and peripheral nerves that requires no control by the brain.

**reflex sympathetic dystrophy (RSD)** See *complex regional pain syndrome*.

**reflux esophagitis** Damage to the esophageal mucosa, often with erosion and ulceration, in patients with gastroesophageal reflux disease.

**reflux** Reverse or backward flow.

**refraction** The bending of light rays.

**refractory hypoxemia** Low blood oxygen levels that persist even when 100% oxygen is given.

**regional anesthesia** A type of local anesthesia that blocks multiple peripheral nerves in a specific body region.

**registered dietitian (RD)** Member of the health care team who ensures that patients meet their nutritional needs. Also called *nutritionist*.

**regurgitation** Flowing in the opposite direction from normal, as the occurrence of warm fluid traveling up the throat, unaccompanied by nausea, in the patient with gastroesophageal reflux disease.

**rehabilitation assistants** Assistants to rehabilitation therapists.

**rehabilitation case manager** Nurse or other health care professional who coordinates health care for patients undergoing rehabilitation in home or acute care settings.

**rehabilitation nurse** Nurse who coordinates the efforts of health care team members for patients undergoing rehabilitation in the inpatient setting; may be designated as the patient's case manager.

**rehabilitation therapists** The collective group of physical therapists (PTs), occupational therapists (OTs), and speech-language pathologists (SLPs).

**rehabilitation** The process of learning to live with chronic and disabling conditions by returning the patient to the fullest possible physical, mental, social, vocational, and economic capacity.

**reinfusion system** A technique that allows for collection of red blood cells from a joint drain over a specific time frame, which then can be reinfused directly back into the patient's systemic circulation.

**relapsing-remitting multiple sclerosis (RRMS)** A type of multiple sclerosis that occurs in 85% of cases and is characterized by a mild or moderate course, depending on the degree of disability. Relapses develop over 1 to 2 weeks and resolve over 4 to 8 months, after which the patient returns to baseline.

**reliever drugs** Drugs used in asthma therapy to stop an asthma attack once it has started.

**religions** Formal belief systems that provide a framework for making sense of life, death, and suffering and responding to universal spiritual questions; a formal expression of spirituality.

**relocation stress syndrome** Physiologic or psychosocial distress following transfer from one environment to another, such as after admission to a hospital or nursing home. Also called *relocation trauma*.

**reminiscence** The process of randomly reflecting on memories of events in one's life.

**remote memory** Long-term memory of events; can be tested by asking patients about their birth date, schools attended, city of birth, or anything from the past that can be verified.

**renal colic** Severe pain associated with distention or spasm of the ureter, such as with an obstruction or the passing of a stone; the pain radiates into the perineal area, groin, scrotum, or labia. Pain may be intermittent or continuous and may be accompanied by pallor, diaphoresis, and hypotension.

**renal columns** Cortical tissue that dips into the interior of the kidney and separates the pyramids in the medulla. Also called *columns of Bertin*.

**renal cortex** The outermost layer of functional kidney tissue lying beneath the renal capsule.

**renal osteodystrophy** The problems in bone metabolism and structure caused by renal failure—

induced hypocalcemia and hyperphosphatemia.

**renal pelvis** The expansion from the upper end of the ureter into which the calices of the kidney open.

**renal threshold** The limit to the amount of glucose that the kidney can reabsorb as glucose is filtered from the blood. Also called the *transport maximum*.

**renin** A hormone that is produced in the juxtaglomerular complex of the kidney and that helps regulate blood flow, glomerular filtration rate, and blood pressure. Renin is secreted when sensing cells (macula densa) in the distal convoluted tubule sense changes in blood volume and pressure.

**repetitive stress injury (RSI)** Injury caused by repeated movements of the same part of the body (e.g., carpal tunnel syndrome).

**replication** The reproduction of DNA that occurs each time a cell divides.

**resident** An individual who lives in an inpatient facility and has all the rights of anyone living in his or her home.

**residuals** Amount of feeding that remains in the stomach after enteral nutrition.

**resistin** A hormone produced by fat cells that creates resistance to insulin activity.

**resorption** In referring to bone, the loss of bone minerals and density; the release of free calcium from bone storage sites directly into the extracellular fluid.

**restorative aide** A member of the health care team, often with the nursing department, who assists the therapists, especially in the long-term care setting.

**restraint** Any device (physical restraint) or drug (chemical restraint) that prevents the patient from moving freely.

**restrictive (lung disorder)** Any lung disorder that prevents good expansion and recoil of the gas exchange unit.

**restrictive cardiomyopathy** A form of cardiomyopathy that restricts the filling of the ventricles; a type of lung disease that prevents good expansion and recoil of the gas exchange unit.

**resurfacing** Regrowth of new skin cells across the open area of a wound as it heals.

**resuscitation phase** The first phase of a burn injury, beginning at the onset of injury and continuing to about 48 hours.

**rete pegs** The fingers of epidermal tissue that project into the dermis.

**reticular activating system (RAS)** Special cells throughout the brainstem that constitute the system that controls awareness and alertness.

**retina** The innermost layer of the eye, made up of sensory receptors that transmit impulses to the optic nerve. It contains blood vessels and two types of photoreceptors called *rods* and *cones*. Rods work at low light levels and provide peripheral vision; cones are active at bright light levels and provide color and central vision.

**retinal detachment** Separation of the retina from the epithelium.

**retinal hole** A break in the retina; can be caused by trauma or can occur with aging.

**retinal tear** Jagged and irregularly shaped break in the retina resulting from traction on the retina.

**retinopathy** Inflammation of the retina. Also used as a general term for vision problems.

**retrograde** Going against the normal direction of flow.

**retroviruses** The family of viruses that includes the human immune deficiency virus.

**revision arthroplasty** Surgical replacement of a prosthesis that has loosened and is causing pain.

**rhabdomyolysis** The breakdown or disintegration of muscle tissue; associated with excretion of myoglobin in the urine.

**rheumatic carditis** Inflammatory lesions in the heart due to a sensitivity response that develops after an upper respiratory tract infection with group A beta-hemolytic streptococci, which occurs in about 40% of patients with rheumatic fever. Inflammation results in impaired contractile function of the myocardium, thickening of the pericardium, and valvular damage. Also called *rheumatic endocarditis*.

**rheumatic disease** Any disease or condition involving the musculoskeletal system.

**rheumatoid arthritis (RA)** A chronic, progressive, systemic, inflammatory autoimmune disease process that primarily affects the synovial joints; one of the most common connective tissue diseases and the most destructive to the joints.

**rhinitis** An inflammation of the nasal mucosa.

**rhinoplasty** A surgical reconstruction of the nose done for cosmetic purposes and improvement of airflow.

**rhinorrhea** Watery drainage from the nose; a “runny” nose.

**rhinosinusitis** An inflammation of the mucous membranes of one or more of the sinuses; usually seen with rhinitis, especially the common cold (coryza).

**rickets** Vitamin D deficiency in children.

**right-sided heart (ventricular) failure** The inability of the right ventricle to empty completely, resulting in increased volume and pressure in the systemic veins and systemic venous congestion with peripheral edema.

**robotic technology** Technology that provides mechanical parts for extremities when they are not functional or have been amputated.

**Romberg sign** Swaying or falling when the patient is standing with arms at the sides, feet and knees close together, and eyes closed; a test of equilibrium in neurologic assessment.

**rotation** A mechanism of injury in which the head is turned excessively beyond the normal range.

**rubor** Dusky red discoloration of the skin.

**rugae** Folds, as of a mucous membrane.

## S

**S<sub>3</sub> gallop** The third heart sound; an early diastolic filling sound that indicates an increase in left ventricular pressure and may be heard on auscultation in patients with heart failure.

**safer sex practices** Interventions that reduce the risk of nonintact skin or mucous membranes coming in contact with infected body fluids and blood, such as using a condom.

**safety** A QSEN competency in which the nurse minimizes risk of harm to patients and providers through both system effectiveness and individual performance.

**Salem sump tube** Tube inserted through the nose and placed into the stomach that is attached to low continuous suction. It has a vent (“pigtail”) that prevents the stomach mucosa from being pulled away during suctioning.

**salpingitis** Infection of the fallopian tube.

**sanguineous** Having a bloody appearance.

**sarcoidosis** A granulomatous disorder of unknown cause that can affect any organ but most often involves the lung.

**SBAR** Acronym for a formal method of communication between two or more members of the health care team. It is used most often when there is an unmet patient need or problem but can also be used to communicate continuing care issues when a patient is discharged from one agency to another. It consists of four steps: **S**ituation, **B**ackground, **A**ssessment, **R**ecommendation.

**scabies** A contagious skin disease caused by mite infestations.

**sclera** The external white layer of the eye.

**scleroderma** See *systemic sclerosis*.

**sclerotherapy** The injection of a sclerosing agent via a catheter, usually in an endoscopic procedure, to stop variceal bleeding.

**sclerotic** Hard, or hardening.

**scoliosis** An abnormal lateral curve in the spine, which normally should be a straight vertical line.

**scotomas** Changes in peripheral vision.

**sebum** A mildly bacteriostatic, fat-containing substance produced by the sebaceous glands. Sebum lubricates the skin and reduces water loss from the skin surface.

**second intention** Healing of deep tissue injuries or wounds with tissue loss in which a cavity-like defect requires gradual filling of the dead space with connective tissue, which prolongs the repair process.

**secondary administration set** A short conduit that is attached to the primary administration set at a Y-injection site and is used to deliver intermittent medications. Also called a *piggyback set*.

**secondary gout** Gout involving hyperuricemia.

**secondary hypertension** Elevated blood pressure that is related to a specific disease (e.g., kidney disease) or medication (e.g., estrogen).

**secondary lesion** Describing skin disease in terms of changes in the appearance of the primary lesion. These changes occur with progression of an underlying disease or in response to a topical or systemic therapeutic intervention.

**secondary prevention** Early detection of a disease or condition, sometimes before signs and symptoms are evident, to prevent or limit permanent disability or death.

**secondary progressive multiple sclerosis (SPMS)** A type of multiple sclerosis that begins with a relapsing-remitting course and later becomes steadily progressive. Attacks and partial recoveries may continue to occur.

**secondary survey** In the emergency department, a more comprehensive head-to-toe assessment performed to identify other injuries or medical issues that need to be managed or that might impact the course of treatment.

**secondary tumor** Additional tumor that is established when cancer cells move from the primary location to another area in the body. Also called *metastatic tumor*.

**seizure** An abnormal, sudden, excessive, uncontrolled electrical discharge of neurons within the brain that may result in an alteration in consciousness, motor or sensory ability, and/or behavior.

A single seizure may occur for no known reason; however, seizures may be due to a pathologic condition of the brain, such as a tumor.

**self-tolerance** In immunology, the ability to recognize self cells versus non-self cells, which is necessary to prevent healthy body cells from being destroyed along with invading cells.

**Sengstaken-Blakemore tube** Tube similar to a nasogastric tube that is placed through the nose and into the stomach in which an attached balloon is inflated to apply pressure to bleeding variceal areas of the esophagus.

**sensitivity** The likelihood that infecting bacterial organisms will be killed or stopped by a particular antibiotic drug. Sensitivity is determined by testing different antibiotics against the organisms. Organisms are sensitive if the antibiotic is effective in stopping their growth; organisms are resistant if the antibiotic is not effective.

**sensorineural hearing loss** Hearing loss that results from a defect in the cochlea, the eighth cranial nerve, or the brain itself. Exposure to loud noises and music may cause this type of hearing loss as a result of damage to the cochlear hair cells.

**sensory aphasia** See *receptive aphasia*.

**sensory perception** The ability to perceive and interpret sensory input into one or more meaningful responses. Sensory input is usually received through the five major senses of vision, hearing, smell, taste, and touch.

**sensory** Facilitating sensation.

**sentinel event** As defined by The Joint Commission, an unexpected occurrence involving serious physical or psychological injury or the risk thereof and requiring an intense analysis of the contributing factors and corrective action.

**sepsis** Systemic infection.

**septic shock** The type of shock that occurs when large amounts of toxins and endotoxins produced by bacteria are released into the blood, causing a whole-body inflammatory reaction.

**septicemia** Systemic disease associated with sepsis; the presence of pathogens in the blood.

**sequestrum** A piece of necrotic bone that has separated from surrounding bone tissue; a common complication of osteomyelitis.

**serologic testing** Laboratory testing that is performed to identify pathogens by detecting antibodies to the organism.

**serositis** Inflammation of a serous membrane, such as the pleura or peritoneum.

**serous** Having a serum-like appearance, or yellow color.

**serum sickness** A type III hypersensitivity reaction that develops first as a skin rash and occurs within 3 to 21 days of the administration of antivenin (*Crotalidae*) polyvalent. This allergic response is often accompanied by other manifestations such as fever, arthralgias (joint pains), and pruritus (itching).

**severe acute respiratory syndrome (SARS)** An easily spread respiratory infection first identified in China in November 2002. At first appearing as an atypical pneumonia, it is caused by a new, more virulent form of coronavirus, and there is no known effective treatment.

**severe sepsis** The progression of sepsis with an amplified inflammatory response.

**sex chromosomes** The pair of chromosomes containing the genes for sexual differentiation in humans. In males, the sex chromosomes are an X and a Y; in females, the sex chromosomes are two Xs.

**sex reassignment surgery (SRS)** Surgery, particularly procedures that affect the external or internal

genitalia, that transitions an individual from one's natal sex to one's inner gender identity. Also known as *gender reassignment surgery*.

**sexuality** An integration of the physiologic, emotional, and social aspects of well-being related to intimacy, self-concept, and role relationships.

**sexually transmitted infections (STIs)** Any of a group of diseases caused by infectious organisms that have been passed from one person to another through intimate contact. Some organisms that cause these diseases are transmitted only through sexual contact. Other organisms are transmitted by parenteral exposure to infected blood, fecal-oral transmission, intrauterine transmission to the fetus, and perinatal transmission from mother to neonate. Also known as *sexually transmitted diseases (STDs)*.

**SHARE** Acronym standing for **S**tandardize critical content, **H**ardwire within your system, **A**llow opportunity to ask questions, **R**einforce quality and measurement, **E**ducate and coach.

**shift to the left** An increased number of immature neutrophils found on a differential count in patients with infections; can be characterized by changes in percentages of different types of leukocytes. Also known as *left shift*.

**shock** The whole-body response to poor tissue oxygenation. Any problem that impairs oxygen delivery to tissues and organs can start the syndrome of shock and lead to a life-threatening emergency.

**short bone** Bone that is small and bears little or no weight, such as the phalanges (fingers and toes).

**short peripheral catheter** A catheter that consists of a plastic cannula built around a sharp stylet for venipuncture, which extends slightly beyond the cannula and is advanced into the vein.

**sialagogue** An agent that stimulates the flow of saliva.

**simple fracture** See *closed fracture*.

**single-photon emission computed tomography (SPECT)** A diagnostic tool using a radiopharmaceutical (agent that enables radioisotopes to cross the blood-brain barrier) that is administered by IV injection, after which the patient is scanned.

**sinoatrial (SA) node** In the cardiac conduction system, the primary pacemaker of the heart; located close to the epicardial surface of the right atrium near its junction with the superior vena cava. It can spontaneously and rhythmically generate electrical impulses at a rate of 60 to 100 beats/min. Also called the *sinus node*.

**sinus arrhythmia** A variant of normal sinus rhythm that results from changes in intrathoracic pressure during breathing; heart rate increases slightly during inspiration and decreases slightly during exhalation. Atrial and ventricular rates are between 60 and 100 beats/min, and atrial and ventricular rhythms are irregular.

**sinus bradycardia** A cardiac dysrhythmia caused by a decreased rate of sinus node discharge, with a heart rate that is less than 60 beats/min.

**sinus tachycardia** A cardiac dysrhythmia caused by an increased rate of sinus node discharge, with a heart rate that is more than 100 beats/min.

**sinusitis** An inflammation of the mucous membranes of the sinuses.

**SIRS** Acronym for systemic inflammatory response syndrome, an inflammatory state affecting the whole body.

**Sjögren's syndrome** In patients with advanced rheumatoid arthritis, the triad of dry eyes, dry mouth, and dry vagina caused by the obstruction of secretory ducts and glands by inflammatory cells and immune complexes.

**skilled nursing facility (SNF)** Part of either a hospital or long-term care (nursing home) setting in

which care is reimbursed through Medicare Part A for the first 21 days after admission.

**skinfold measurement** Measurement that estimates body fat.

**smart pump** An infusion pump with dosage calculation software.

**social justice** Ethical principle that refers to equality and fairness—that all patients should be treated equally and fairly, regardless of age, gender, religion, race, ethnicity, or education.

**social worker** Member of the health care team who helps patients identify support services and resources and who coordinates transfers to or discharges from the rehabilitation setting.

**sodium (Na<sup>+</sup>)** A mineral that is the major cation in the extracellular fluid and maintains extracellular fluid (ECF) osmolarity.

**solute** A particle dissolved or suspended in the water portion (solvent) of body fluids; a solution consists of a solute and a solvent.

**solvent** The water portion of fluids.

**spastic bladder** Incontinence characterized by sudden, gushing voids, usually without completely emptying the bladder; caused by neurologic problems affecting the upper motor neuron, such as with spinal cord injuries above the twelfth thoracic vertebra.

**spastic paralysis** Paralysis of a part of the body that is characterized by spasticity of muscles due to hypertonia; may be seen in the patient who has experienced a brain attack.

**specialized nutrition support (SNS)** Total nutritional intake orally or intravenously with commercially prepared products (either total enteral nutrition or total parenteral nutrition).

**speech-language pathologist (SLP)** A member of the rehabilitation health care team who evaluates and retrains patients with speech, language, or swallowing problems.

**sphincter of Oddi** The sheath of muscle fibers surrounding the papillary opening of the duodenum.

**sphincterotomy** A procedure for opening a sphincter.

**spider angiomas** See *telangiectasias*.

**spinal cord stimulation** An invasive stimulation technique that provides pain control by applying an electrical field over the spinal cord.

**spinal fusion (arthrodesis)** A surgical procedure to stabilize the spine after repeated laminectomies have been unsuccessful. Chips of bone are removed (typically from the iliac crest) or are obtained from donor bone; the chips are grafted between the vertebrae for support and to strengthen the back.

**spinal shock syndrome** Loss of reflex activity below the level of a spinal lesion; occurs immediately after injury as a result of disruption in the communication pathways between the upper motor neurons and the lower motor neurons. Also called *spinal shock*.

**spinal shock** See *spinal shock syndrome*.

**spinal stenosis** Narrowing of the spinal canal; typically seen in people older than 60 years.

**spiritual counselor** Counselor who specializes in spiritual assessments and care, usually a member of the clergy.

**spirituality** The connection to self, others, the environment, and a “higher power.”

**splenectomy** Surgical removal of the spleen.

**splenomegaly** Enlargement of the spleen.

**splint** Any object or device that extends to the joints above and below a fracture to immobilize it.

**splinter hemorrhage** Black longitudinal line or small red streak on the distal third of the nail bed; seen in patients with infective endocarditis.

**spondee** Two-syllable words in which there is generally equal stress on each syllable, such as *airplane, railroad, and cowboy*; used in testing speech reception threshold.

**spondylolisthesis** Condition in which one vertebra slips forward on the one below it, often as a result of spondylolysis. This problem causes pressure on the nerve roots, leading to pain in the lower back and into the buttocks.

**spondylolysis** A defect in one of the vertebrae; usually found in the lumbar spine.

**spontaneous bacterial peritonitis (SBP)** Bacterial infection of the abdominal peritoneum caused by ascites; often seen in patients with cirrhosis of the liver.

**spore** An encapsulated inactive organism.

**sprain** Excessive stretching of a ligament.

**ST segment** In the electrocardiogram, the line (normally isoelectric) representing early ventricular repolarization. It occurs from the J point to the beginning of the T wave.

**staging** System of classifying clinical aspects of a cancer tumor.

**Standard Precautions** Infection control guidelines from the U.S. Centers for Disease Control and Prevention stating that all body excretions, secretions, and moist membranes and tissues are potentially infectious; combines protective measures from Universal Precautions and Body Substance Isolation.

**stasis dermatitis** In patients with venous insufficiency, discoloration of the skin along the ankles, which may extend up to the calf.

**stasis ulcer** In patients with long-term venous insufficiency, ulcer formed as a result of edema or minor injury to the limb; typically occurs over the malleolus.

**status epilepticus** Prolonged seizures lasting more than 5 minutes or repeated seizures over the course of 30 minutes; a potential complication of all types of seizures.

**steatorrhea** An excessive amount of fat in the stool.

**ST-elevation myocardial infarction (STEMI)** Myocardial infarction in which the patient typically has ST elevation in two contiguous leads on a 12-lead ECG; this indicates myocardial infarction/necrosis.

**stem cell** An immature, undifferentiated cell produced by the bone marrow.

**stent** A small tube that is placed in a tubular structure to dilate it; a wirelike device that may be used along with percutaneous transluminal angioplasty to help keep the vessel open.

**stereotactic pallidotomy** A surgical treatment for the patient with Parkinson disease when drugs are ineffective in symptom management. An electrode is used to create a lesion in a targeted area within the pallidum, with the goal of reducing tremor and rigidity.

**sterilization** A method of infection control in which all living organisms and bacterial spores are destroyed; used on items that invade human tissue where bacteria are not commonly found.

**stoma** The surgical creation of an opening; usually refers to an opening in the abdominal wall.

**stomatitis** Inflammation of the oral mucosa; characterized by painful single or multiple ulcerations that impair the protective lining of the mouth. The ulcerations are commonly referred to as "canker sores."

**strain** Excessive stretching of a muscle or tendon when it is weak or unstable; sometimes referred to as “muscle pulls.”

**strangulated hernia** A tightly constricted hernia that compromises the blood supply to the herniated segment of the bowel as a result of pressure from the hernial ring (the band of muscle around the hernia); leads to ischemia and obstruction of the bowel loop, with necrosis of the bowel and possibly bowel perforation.

**strangulated obstruction** Intestinal obstruction with compromised blood flow.

**stratum corneum** The outermost layer of the skin.

**stress test** See *exercise electrocardiography*.

**stress ulcers** Multiple shallow erosions of the proximal stomach and occasionally the duodenum.

**stress urinary incontinence (SUI)** Loss of urine during activities that increase intra-abdominal pressure, such as laughing, coughing, sneezing, or lifting heavy objects.

**striae** Reddish purple streaks on the skin. Also called *stretch marks*.

**stricture** Narrowing.

**stridor** A high-pitched crowing sound caused by laryngospasm or edema above or below the glottis; heard during respiration.

**stroke volume (SV)** The amount of blood ejected by the left ventricle during each heartbeat.

**stroke** See *brain attack*.

**stuporous** Arousable only with vigorous or painful stimulation.

**subarachnoid space** Term for the space between the arachnoid mater and pia mater of the spinal cord. Also called *subarachnoid*.

**subcutaneous emphysema** The presence of bubbles under the skin because of air trapping; an uncommon late complication of fracture.

**subcutaneous infusion therapy** Infusion therapy that is delivered under the skin when patients cannot tolerate oral medications, when intramuscular injections are too painful, or when vascular access is not available.

**subcutaneous nodule** Characteristic round, movable, nontender swelling under the skin of the arm or fingers in patients with severe rheumatoid arthritis.

**subdural hematoma (SDH)** The collection of clotted blood that typically results from venous bleeding into the space beneath the dura and above the arachnoid.

**subdural space** Term for the space between the dura mater and the middle layer (arachnoid).

**subluxation** Partial joint dislocation.

**submucous resection (SMR)** Surgical procedure to straighten a deviated septum when chronic symptoms or discomfort occur. Also called *nasoseptoplasty*.

**submucous resection** Surgical procedure to straighten a deviated septum.

**substernally** Located below the ribs.

**subtotal thyroidectomy** The surgical removal of part of the thyroid tissue.

**sundowning** In patients with Alzheimer's disease, increased confusion at night or when excessively fatigued.

**superinfection** Reinfection or a second infection of the same type.

**supervision** Guidance or direction, evaluation, and follow-up by the nurse to ensure that the task or activity is performed appropriately.

**supratentorial** Located within the cerebral hemispheres, in the area above the tentorium of the cerebellum; the tentlike fold of dura that surrounds the cerebellar hemisphere and supports the occipital lobe.

**supraventricular tachycardia (SVT)** A form of tachycardia that involves the rapid stimulation of atrial tissue at a rate of 100 to 280 beats/min. It is most often due to a re-entry mechanism in which one impulse circulates repeatedly throughout the atrial pathway, re-stimulating the atrial tissue at a rapid rate.

**surfactant** A fatty protein secreted by type II pneumocytes to reduce surface tension in the alveoli.

**surveillance** Term used to describe the tracking of infections by health care agencies.

**susceptibility** The risk of the host to infection; may be increased by the breakdown of host defenses against pathogens.

**swimmer's ear** See *external otitis*.

**sympathectomy** Surgical cutting of the sympathetic nerve branches via endoscopy through a small axillary incision.

**sympathetic tone** A state of partial blood vessel constriction caused when nerves from the sympathetic division of the autonomic nervous system continuously stimulate vascular smooth muscle.

**synapse** The area through which impulses are transmitted to their eventual destination.

**syncope** Transient loss of consciousness (blackouts), most commonly caused by decreased perfusion to the brain.

**syndrome of inappropriate antidiuretic hormone (SIADH)** Persistent hyponatremia, hypovolemia, and inappropriately elevated urine osmolality that occurs when vasopressin (antidiuretic hormone) is secreted even when plasma osmolality is low or normal.

**synovectomy** The surgical removal of synovium.

**synovial joint** Type of joint lined with synovium, a membrane that secretes synovial fluid for lubrication and shock absorption.

**synovitis** Inflammation of synovial membrane.

**syphilis** A complex sexually transmitted disease that can become systemic and cause serious complications and even death. It is caused by the spirochete *Treponema pallidum*, which is found in the mouth, intestinal tract, and genital areas of people and animals. The infection is usually transmitted by sexual contact, but transmission can occur through close body contact and kissing.

**syringe pump** Pump for infusion therapy that uses a battery-powered piston to push the plunger continuously at a selected mL/hr rate; limited to small-volume continuous or intermittent infusions.

**systemic lupus erythematosus (SLE)** A chronic, progressive inflammatory connective tissue disorder that can cause major body organs and systems to fail; characterized by spontaneous remissions and exacerbations.

**systemic sclerosis (SSc)** A chronic connective tissue disease characterized by inflammation, fibrosis, and sclerosis of the skin and vital organs. Also called *scleroderma* and formerly called *progressive systemic sclerosis*.

**systemic** Affecting the body system as a whole.

**systole** The phase of the cardiac cycle that consists of the contraction and emptying of the atria and ventricles.

**systolic blood pressure** The amount of pressure/force generated by the left ventricle to distribute blood into the aorta with each contraction of the heart.

**systolic heart failure (systolic ventricular dysfunction)** Heart failure that results when the heart is unable to contract forcefully enough during systole to eject adequate amounts of blood into the circulation.

## T

**T wave** In the electrocardiogram, the deflection that follows the ST segment and represents ventricular repolarization.

**tachycardia** An excessively fast heart rate; characterized as a pulse rate greater than 100 beats/min.

**tachydysrhythmia** An abnormal heart rhythm with a rate greater than 100 beats/min.

**tactile (vocal) fremitus** A vibration of the chest wall produced when the patient speaks; can be palpated on the chest wall.

**target tissues** The tissues that respond specifically to a given hormone.

**taut** Tightly stretched.

**teamwork and collaboration** A QSEN competency in which the nurse functions effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care.

**telangiectasias** Vascular lesions with a red center and radiating branches. Also called *spider angiomas*, *spider nevi*, or *vascular spiders*.

**telemetry** In electrocardiography (ECG), the use of a battery-powered transmitter system for monitoring an ambulatory patient; allows freedom of movement within a certain radius without losing transmission of the ECG.

**temporal field blindness** A decrease in lateral peripheral vision.

**temporary pacing** A nonsurgical intervention for cardiac dysrhythmia that provides a timed electrical stimulus to the heart when either the impulse initiation or the intrinsic conduction system of the heart is defective.

**tendon transplant** Removal of a tendon from one part of the body and transplantation into the affected area to replace a ruptured tendon that cannot be repaired surgically.

**tendon** Any one of many bands of tough, fibrous tissue that attach muscles to bones.

**tenesmus** Straining, especially painful straining to defecate.

**tension pneumothorax** A life-threatening complication of pneumothorax in which air continues to enter the pleural space during inspiration and does not exit during expiration.

**teratogenic** Tending to produce birth defects.

**tetany** Continuous contractions of muscle groups; hyperexcitability of nerves and muscles.

**tetraplegia** Another term for *quadriplegia* (paralysis that involves all four extremities).

**thalamotomy** An alternative to stereotactic pallidotomy as a surgical treatment for the patient with Parkinson disease; uses thermocoagulation of brain cells to reduce tremor. Usually only unilateral surgery is performed to benefit the side of the body most affected by the disease.

**thalamus** A structure within the brain; functions as the “central switchboard” for the central nervous system.

**thallium scan** A test that is similar to a bone scan but uses the radioisotope *thallium* and is more sensitive in diagnosing the extent of disease in patients with osteosarcoma.

**The Joint Commission** An organization that offers peer evaluation for accreditation every 3 years for all types of health care agencies that meet their standards. Formerly known as the *Joint Commission for Accreditation of Healthcare Organizations (JCAHO)*.

**therapeutic hypothermia** Treatment that lowers the body core temperature to reduce the risk of cell, tissue, and organ damage from a low or absent blood flow. Usually follows cardiac arrest.

**thermotherapy** Technique for treating benign prostatic hyperplasia that uses a variety of heat methods to destroy excess prostate tissue.

**third intention** Delayed primary closure of a wound with a high risk for infection. The wound is intentionally left open for several days until inflammation has subsided and is then closed by first intention.

**thoracentesis** The aspiration of pleural fluid or air from the pleural space.

**threshold** In evaluating hearing, the lowest level of intensity at which pure tones and speech are heard by a patient; in general, the lowest level at which a stimulus is perceived.

**thrombectomy** Removal of a clot (thrombus) from a blood vessel.

**thrombocytopenia** A reduction in the number of blood platelets below the level needed for normal coagulation, resulting in an increased tendency to bleed.

**thrombophlebitis** The presence of a thrombus associated with inflammation; usually occurs in the deep veins of the lower extremities.

**thrombosis** The formation of a blood clot (thrombus) within a blood vessel.

**thrombotic stroke** Damage to the brain when blood flow is impaired from a clot, resulting in blockage to one or more of the arteries supplying blood to the brain.

**thrombus** A blood clot believed to result from an endothelial injury, venous stasis, or hypercoagulability.

**thymectomy** Removal of the thymus gland.

**thymoma** An encapsulated tumor of the thymus gland.

**thyrocalcitonin (TCT)** A hormone produced and secreted by the parafollicular cells of the thyroid gland to help regulate serum calcium levels; secreted in response to excess plasma calcium.

**thyroid storm (thyroid crisis)** A life-threatening event that occurs in patients with uncontrolled hyperthyroidism and is usually caused by Graves' disease. Key manifestations include fever, tachycardia, and systolic hypertension.

**thyroiditis** Inflammation of the thyroid gland.

**thyrotoxicosis** The condition caused by excessive amounts of thyroid hormones.

**thyroxine (T<sub>4</sub>)** A hormone that is produced by the follicular cells of the thyroid gland and that increases metabolism.

**Tinel's sign** Test that confirms a diagnosis of carpal tunnel syndrome; a positive test causes palmar paresthesias when the area of the median nerve is tapped lightly.

**tinnitus** A continuous ringing or noise perception in the ears.

**tissue integrity** The intactness of the structure and function of the integument (skin and subcutaneous tissue) and mucous membranes.

**titration** Adjustment of IV fluid rate on the basis of the patient's urine output plus serum electrolyte values.

**TNM (tumor, node, metastasis)** System developed by the American Joint Committee on Cancer to describe the anatomic extent of cancers.

**toe brachial pressure index (TBPI)** Toe systolic pressure divided by brachial (arm) systolic pressure; may be performed instead of or in addition to ankle-brachial index to determine arterial perfusion in the feet and toes.

**toll-like receptors (TLRs)** Receptors on immune system cells of humans and other animals that interact with the surface of any invading organism and allow recognition of non-self so actions are taken to rid the body of this invader.

**tonic phase** Pertaining to a state of stiffening or rigidity of the muscles, particularly of the arms and legs, and immediate loss of consciousness of a tonic-clonic seizure.

**tonsillitis** An inflammation and infection of the tonsils and lymphatic tissues located on each side of the throat.

**tophi** A collection of uric acid crystals that form hard irregular, painless nodules on the ears, arms, and fingers of patients with gout.

**topical chemical débridement** Method of débriding a wound by applying topical enzyme preparations to loosen necrotic tissue.

**torn meniscus** Tear of the knee meniscus (medial or lateral) in which the patient typically has pain, swelling, and tenderness in the knee.

**torsades de pointes** A type of ventricular tachycardia that is related to a prolonged QT interval.

**total hysterectomy** Removal of the uterus and cervix; the procedure may be vaginal or abdominal.

**total joint arthroplasty (TJA)** Surgical creation of a joint, or total joint replacement; commonly performed in patients with osteoarthritis. Also called *total joint replacement (TJR)*.

**total joint replacement (TJR)** See *total joint arthroplasty*.

**total parenteral nutrition (TPN)** Provision of intensive nutritional support for an extended time; delivered to the patient through access to central veins, usually the subclavian or internal jugular veins.

**total thyroidectomy** The surgical removal of all of the thyroid tissue.

**touch discrimination** Part of the neurologic examination. The patient closes his or her eyes while the practitioner touches the patient with a finger and asks that the patient point to the area touched.

**toxic and drug-induced hepatitis** Liver inflammation resulting from exposure to hepatotoxins (e.g., industrial toxins, alcohol, and medications).

**toxic epidermal necrolysis (TEN)** A rare acute drug reaction of the skin that results in diffuse erythema and blister formation, with mucous membrane involvement and systemic toxicity.

**toxic megacolon** Acute enlargement of the colon along with fever, leukocytosis, and tachycardia; usually associated with ulcerative colitis.

**toxic multinodular goiter** Hyperthyroidism caused by multiple thyroid nodules, which may be enlarged thyroid tissues or adenomas, and a goiter that has been present for several years.

**toxic shock syndrome (TSS)** A severe illness caused by a toxin produced by certain strains of *Staphylococcus aureus*. It was first recognized in 1980 as related to menstruation and tampon use. It is characterized by abrupt onset of a high fever and headache, sore throat, vomiting, diarrhea, generalized rash, and hypotension. The most common manifestations are skin changes (initially a rash that resembles a severe sunburn and changes to a macular erythema similar to a drug-related rash).

**toxicodrome** A syndrome related to drug toxicity.

**toxin** Protein molecule released by bacteria that affects host cell at a distant site. Continued multiplication of a pathogen is sometimes accompanied by toxin production.

**trabeculation** An abnormal thickening of the bladder wall caused by urinary retention and obstruction.

**tracheostomy** The (tracheal) stoma, or opening, that results from a tracheotomy.

**tracheotomy** The surgical incision into the trachea for the purpose of establishing an airway.

**trachoma** A chronic conjunctivitis caused by *Chlamydia trachomatis*.

**traction** The application of a pulling force to a part of the body to provide reduction, alignment, and rest.

**transcellular fluid** Any of the fluids in special body spaces, including cerebrospinal fluid, synovial fluid, peritoneal fluid, and pleural fluid.

**transcutaneous electrical nerve stimulation (TENS)** A battery-operated device capable of delivering small electrical currents through electrodes applied to an area of the body to relieve pain.

**transcutaneous pacing** Temporary pacing that is accomplished through the application of two large external electrodes.

**transesophageal echocardiography (TEE)** A form of echocardiography performed transesophageally (through the esophagus); an ultrasound transducer is placed immediately behind the heart in the esophagus or stomach to examine cardiac structure and function.

**transferrin** An iron-transport protein that can be measured directly or calculated as an indirect measurement of total iron-binding capacity.

**transgender** Patients who self-identify as the opposite gender or a gender that does not match their natal sex.

**transient ischemic attack (TIA)** A brief attack (lasting a few minutes to less than 24 hours) of focal neurologic dysfunction caused by a brief interruption in cerebral blood flow, possibly resulting from cerebral vasospasm or transient systemic arterial hypertension. Repeated attacks may damage brain tissue; multiple attacks indicate significant increased risk for brain attack.

**transition manager** A role of the professional nurse to facilitate continuity of care for patients as they transfer among health care settings and the community.

**transmyocardial laser revascularization** A new surgical procedure for patients with unstable angina and inoperable coronary artery disease with areas of reversible myocardial ischemia. After a single-lung intubation, a left anterior thoracotomy is performed and the heart is visualized. A laser is used to create 20 to 24 long, narrow channels through the left ventricular muscle to the left ventricle. The channels eventually allow oxygenated blood to flow from the left ventricle during diastole to nourish the muscle.

**transport maximum** See *renal threshold*.

**transsexual** A person who has modified his or her natal body to match the appropriate gender identity, either through cosmetic, hormonal, or surgical means.

**transurethral microwave therapy (TUMT)** Procedure for treating benign prostatic hyperplasia using high temperatures to heat and destroy excess tissue.

**transurethral needle ablation (TUNA)** Procedure for treating benign prostatic hyperplasia using low radiofrequency energy to shrink the prostate.

**transurethral resection of the prostate (TURP)** The traditional “closed” surgical procedure for removal of the prostate. In this procedure, the surgeon inserts a resectoscope (an instrument similar to a cystoscope, but with a cutting and cauterizing loop) through the urethra. The enlarged portion of the prostate gland is then resected in small pieces.

**trauma center** Specialty care facility that provides competent and timely trauma services to patients depending on its designated level of capability.

**trauma system** An organized and integrated approach to trauma care designed to ensure that all critical elements of trauma care delivery are aligned to meet the injured patient's needs.

**trauma** Bodily injury.

**triage officer** In a hospital's emergency response plan, the person who rapidly evaluates each patient who arrives at the hospital. In a large hospital, this person is generally a physician who is assisted by triage nurses; however, a nurse may assume this role when physician resources are limited.

**triage** In the emergency department, sorting or classifying patients into priority levels depending on illness or injury severity, with the highest acuity needs receiving the quickest evaluation and treatment.

**trigeminy** A type of premature complex consisting of a repetitive three-beat pattern; usually occurs as two sequential normal complexes followed by a premature complex and a pause, with the same pattern repeating itself in triplets.

**trigger points** In patients with fibromyalgia syndrome, tender areas that can typically be palpated to elicit pain in a predictable, reproducible pattern.

**triglycerides** Serum lipid profile that includes the measurement of cholesterol and lipoproteins.

**triiodothyronine (T<sub>3</sub>)** A hormone produced by the follicular cells of the thyroid gland.

**troponin** A myocardial muscle protein released into the bloodstream after injury to myocardial muscle. Because it is not found in healthy patients, any rise in values indicates cardiac necrosis or acute myocardial infarction.

**truss** A device, usually a pad made with firm material, that is held in place over the hernia with a belt to keep the abdominal contents from protruding into the hernial sac.

**tuberculosis (TB)** A highly communicable disease caused by *Mycobacterium tuberculosis*. It is the most common bacterial infection worldwide.

**tumescence** The condition of being swollen.

**tunneled central venous catheter** A type of catheter used for long-term infusion therapy in which a portion of the catheter lies in a subcutaneous tunnel, separating the points where the catheter enters the vein from where it exits the skin.

**turbidity** Cloudiness of a solution.

**turbinates** Three bony projections that protrude into the nasal cavities from the walls of the internal portion of the nose.

**turgor** The condition of being swollen and congested; indicates the amount of skin elasticity; the normal resiliency of a pinched fold of skin.

**type A gastritis** A type of gastritis that refers to an inflammation of the glands, fundus, and body of the stomach.

**type B gastritis** A type of gastritis that affects the glands of the antrum and may involve the entire stomach.

**tyrosine kinase inhibitors (TKIs)** Drugs with the main action of inhibiting activation of tyrosine kinases. There are many different TKIs. Some are unique to the cell type; others may be present only in cancer cells that express a specific gene mutation. As a result, the different TKI drugs are effective in disrupting the growth of some cancer cell types and not others.

## U

**U wave** In the electrocardiogram, the deflection that follows the T wave and may result from slow repolarization of ventricular Purkinje fibers. When present, it is of the same polarity as the T wave, although generally smaller. Abnormal prominence of the U wave suggests an electrolyte abnormality or other disturbance.

**ulcerative colitis (UC)** A chronic inflammatory process that affects the mucosal lining of the colon or rectum; one of a group of bowel diseases of unknown etiology characterized by remissions and exacerbations. It can result in loose stools containing blood and mucus, poor absorption of vital nutrients, and thickening of the colon wall.

**umbilical hernia** Protrusion of the intestine at the umbilicus; can be congenital or acquired. Congenital umbilical hernias appear in infancy. Acquired umbilical hernias directly result from increased intra-abdominal pressure and are most commonly seen in obese people.

**unclassified seizure** One of the three broad categories of seizure disorders along with *partial seizure* and *generalized seizure*. They occur for no known reason, do not fit into the generalized or partial classifications, and account for about half of all seizure activity. Also called *idiopathic seizure*.

**uncus** The inner part of the temporal lobe of the brain that can move downward and cause pressure on the brainstem; the vital sign center.

**undermining** Separation of the skin layers at the wound margins from the underlying granulation tissue.

**unilateral body neglect syndrome** In the patient who has had a brain attack, an unawareness of the existence of the paralyzed side. For example, the patient may believe he or she is sitting up straight when actually he or she is leaning to one side. Another typical example is the patient who washes or dresses only one side of the body.

**Unna boot** A wound dressing constructed of gauze moistened with zinc oxide; used to promote venous return in the ambulatory patient with a stasis ulcer and to form a sterile environment for the ulcer. The boot is applied to the affected limb, from the toes to the knee, after the ulcer has been cleaned with normal saline solution and covered with an elastic wrap. The dressing hardens like a cast.

**upper endoscopy** See *esophagogastroduodenoscopy*.

**upper esophageal sphincter (UES)** The ringlike band of muscle fibers at the upper end of the esophagus. When at rest, the sphincter is closed to prevent air from entering into the esophagus during respiration.

**upper GI (gastrointestinal) radiographic series** The radiographic visualization of the gastrointestinal tract from the oral part of the pharynx to the duodenojejunal junction; used to detect disorders of structure or function of the esophagus (barium swallow), stomach, or duodenum.

**uremia** The accumulation of nitrogenous wastes in the blood (azotemia); a result of renal failure,

with clinical symptoms including nausea and vomiting.

**uremic frost** A layer of urea crystals from evaporated sweat; may appear on the face, eyebrows, axilla, and groin in patients with advanced uremic syndrome.

**uremic syndrome** The systemic clinical and laboratory manifestations of end-stage kidney disease.

**ureterolithiasis** Formation of stones in the ureter.

**ureteropelvic junction (UPJ)** The narrow area in the upper third of the ureter at the point at which the renal pelvis becomes the ureter.

**ureteroplasty** Surgical repair of the ureter.

**ureterovesical junction (UVJ)** The point at which each ureter becomes narrow as it enters the bladder.

**urethral meatus** The opening at the endpoint of the urethra.

**urethral stricture** An obstruction that occurs low in the urinary tract due to decreased diameter of the urethra, causing bladder distention before hydroureter and hydronephrosis.

**urethritis** An inflammation of the urethra that causes symptoms similar to urinary tract infection.

**urethroplasty** Surgical treatment of the urethral stricture to remove the affected area with or without grafting to create a larger opening.

**urgency** The feeling that urination will occur immediately.

**urgent triage** In a three-tiered triage scheme, the category that includes patients who should be treated quickly but in whom an immediate threat to life does not currently exist, such as those with abdominal pain or displaced fractures or dislocations.

**urinary tract infection (UTI)** An infection in the normally sterile urinary system. The unobstructed and complete passage of urine from the renal and urinary systems is critical in maintaining a sterile urinary tract. When any structural abnormality is present, the risk for damage as a result of infection is greatly increased.

**urolithiasis** The presence of calculi (stones) in the urinary tract.

**urosepsis** The spread of an infection from the urinary tract to the bloodstream, resulting in systemic infection accompanied by fever, chills, hypotension, and altered mental status.

**urticaria** A transient vascular reaction of the skin marked by the development of wheals (hives).

**uterine artery embolization** Treatment for leiomyomas in which a radiologist uses a percutaneous catheter inserted through the femoral artery to inject polyvinyl alcohol pellets into the uterine artery. The resulting blockage starves the tumor of circulation, allowing it (or them) to shrink.

**uterine prolapse** Downward displacement of the uterus into the vagina.

**uvea** The middle layer of the eye, which consists of the choroid, ciliary body, and iris. The choroid has many blood vessels that supply nutrients to the retina.

## V

**vagal maneuver** Nonsurgical management of cardiac dysrhythmias that is intended to induce vagal stimulation of the cardiac conduction system, specifically the sinoatrial and atrioventricular nodes. Vagal maneuvers may be attempted to terminate supraventricular tachydysrhythmia.

**vaginoplasty** The construction of a new vagina in a male-to-female patient, usually with inverted penile tissue or a colon graft, and the creation of a clitoris and labia using scrotal or penile tissue and skin grafts.

**validation therapy** For the patient with moderate or severe Alzheimer's disease, the process of recognizing and acknowledging the patient's feelings and concerns without reinforcing an erroneous belief (e.g., if the patient is looking for his or her deceased mother).

**Valsalva maneuver** A form of vagal stimulation of the cardiac conduction system in which the health care provider instructs the patient to bear down as if straining to have a bowel movement.

**valvular regurgitation** Regurgitation of any heart valve. See also *mitral regurgitation*.

**variant (Prinzmetal's) angina** A type of angina caused by coronary vasospasm (vessel spasm); usually associated with elevation of the ST segment on an electrocardiogram obtained during anginal attacks.

**varicose veins** Distended, protruding veins that appear darkened and tortuous; common in patients older than 30 years whose occupations require prolonged standing. As the vein wall weakens and dilates, venous pressure increases and the valves become incompetent (defective). The incompetent valves enhance the vessel dilation, and the veins become tortuous and distended.

**vascular access device (VAD)** A catheter; a plastic tube placed in a blood vessel to deliver fluids and medications.

**vasculitis** Blood vessel inflammation.

**vasoconstriction** Decrease in diameter of blood vessels.

**vasopressin** Secretion of the posterior pituitary gland. Also known as *antidiuretic hormone* or *ADH*.

**vasospasm** A sudden and transient constriction of a blood vessel.

**Vaughn-Williams classification** System used to categorize antidysrhythmic agents according to their effects on the action potential of cardiac cells.

**vegan** A vegetarian diet pattern in which only foods of plant origin are eaten.

**venous beading** A complication of diabetes; the abnormal appearance of retinal veins in which areas of swelling and constriction along a segment of vein resemble links of sausage. Such bleeding occurs in areas of retinal ischemia and is a predictor of proliferative diabetic retinopathy.

**venous insufficiency** Alteration of venous efficiency by thrombosis or defective valves; caused by prolonged venous hypertension, which stretches the veins and damages the valves, resulting in further venous hypertension, edema, and, eventually, venous stasis ulcers, swelling, and cellulitis.

**venous thromboembolism (VTE)** A term that refers to both deep vein thrombosis and pulmonary embolism; obstruction by a thrombus.

**ventilator-associated events (VAEs)** Complications of ventilator therapy that result in a significant and sustained deterioration in oxygenation (greater than 20% increase in the daily minimum fraction of inspired oxygen or an increase of at least 3 cm H<sub>2</sub>O in the daily minimum positive end-expiratory pressure [PEEP] to maintain oxygenation).

**ventilator-associated lung injury (VALI)** Damage from prolonged ventilation causing loss of surfactant, increased inflammation, fluid leakage, and noncardiac pulmonary edema. Also known as *ventilator-induced lung injury*.

**ventilator-induced lung injury (VILI)** See *ventilator-associated lung injury*.

**ventral hernia** See *incisional hernia*.

**ventricular asystole** The complete absence of any ventricular rhythm. There are no electrical impulses in the ventricles and therefore no ventricular depolarization, no QRS complex, no

contraction, no cardiac output, and no pulse, respirations, or blood pressure. The patient is in full cardiac arrest.

**ventricular fibrillation (VF)** A cardiac dysrhythmia that results from electrical chaos in the ventricles; impulses from many irritable foci fire in a totally disorganized manner so that ventricular contraction cannot occur; there is no cardiac output or pulse and therefore no cerebral, myocardial, or systemic perfusion. This rhythm is rapidly fatal if not successfully terminated within 3 to 5 minutes.

**ventricular gallop** An abnormal third heart sound that arises from vibrations of the valves and supporting structures and is produced during the rapid passive filling phase of ventricular diastole when blood flows from the atrium to a noncompliant ventricle. In patients older than 35 years, it is an early sign of heart failure or ventricular septal defect.

**ventricular remodeling** (1) Progressive myocyte (myocardial cell) contractile dysfunction over time; results from activation of the renin-angiotensin system caused by reduced blood flow to the kidneys, a common occurrence in low-output states; (2) after a myocardial infarction, permanent changes in the size and shape of the left ventricle due to scar tissue; such remodeling may decrease left ventricular function, cause heart failure, and increase morbidity and mortality.

**ventricular tachycardia (VT)** An abnormal heart rhythm that occurs with repetitive firing of an irritable ventricular ectopic focus, usually at a rate of 140 to 180 beats/min or more.

**ventriculomyectomy** The surgical excision of a portion of the hypertrophied ventricular septum to create a widened outflow tract in patients with obstructive hypertrophic cardiomyopathy. Also called *ventricular septal myectomy*.

**veracity** Ethical principle that requires that the nurse is obligated to tell the truth to the best of his or her knowledge.

**vertebroplasty** A minimally invasive surgery for managing vertebral fractures in patients with osteoporosis. Bone cement is injected directly into the fracture site to provide immediate pain relief.

**vertigo** A sense of spinning movement that may result from diseases of the inner ear.

**vesicant medications** Drugs that cause severe tissue damage if they escape into the subcutaneous tissue; also referred to as vesicants.

**vesicants** Chemicals or drugs that cause tissue damage on direct contact or extravasation.

**vesicle** In health care, a small bladder or blister.

**vestibule** A longitudinal area between the labia minora, the clitoris, and the vagina that contains Bartholin glands and the openings of the urethra, Skene's glands (paraurethral glands), and vagina.

**viral hepatitis** Inflammation of the liver that results from an infection caused by one of five major categories of viruses (hepatitis A, B, C, D, or E). Viral hepatitis is the most common type and can be either acute or chronic.

**viral load testing** Test that measures the presence of human immune deficiency virus genetic material (ribonucleic acid) or other viral proteins in the patient's blood.

**Virchow's triad** The occurrence of stasis of blood flow, endothelial injury, or hypercoagulability; often associated with thrombus formation.

**viremia** The presence of viruses in the blood.

**virilization** The presence of male secondary sex characteristics.

**virtual colonoscopy** A noninvasive alternative to the colonoscopy procedure. A scanner is used to view the colon.

**virulence** A term used to describe the frequency with which a pathogen causes disease (degree of communicability) and its ability to invade and damage a host. Virulence can also indicate the severity of the disease; often used as a synonym for *pathogenicity*.

**visceral proteins** Proteins such as albumin that circulate in the bloodstream and may be produced by the liver.

**vitiligo** An abnormality of the skin characterized by patchy areas of pigment loss with increased pigmentation at the edges. It is seen with primary hypofunction of the adrenal glands and is due to autoimmune destruction of melanocytes in the skin.

**vitreous body** The clear, thick gel that fills the vitreous chamber of the eye (the space between the lens and the retina). This gel transmits light and shapes the eye.

**vocational counselor** A member of the rehabilitative health care team who assists the patient with job placement, training, or further education.

**volutrauma** Damage to the lung by excess volume delivered to one lung over the other.

**volvulus** Obstruction of the bowel caused by twisting of the bowel.

**vulva** The external female genitalia.

**vulvovaginitis** Inflammation of the lower genital tract resulting from a disturbance of the balance of hormones and flora in the vagina and vulva.

## W

**warm antibody anemia** A form of immunohemolytic anemia (in which the immune system attacks a person's own red blood cells for unknown reasons) that occurs with immunoglobulin G antibody excess and may be triggered by drugs, chemicals, or other autoimmune problems.

**warm phase** A phase lasting 2 to 3 weeks after peripheral nerve trauma resulting in complete denervation; the extremity is warm, and the skin appears flushed or rosy. The warm phase is gradually superseded by a cold phase.

**water brash** Reflex salivary hypersecretion that occurs in response to reflux in the patient with gastroesophageal reflux disease.

**WBC** White blood cell.

**weaning** The process of going from ventilatory dependence to spontaneous breathing.

**wedge resection** Removal of small, localized areas of disease.

**Wernicke's aphasia** See *receptive aphasia*.

**Wernicke's area** An important speech area of the cerebrum. It is located in the temporal lobe and plays a significant role in higher-level brain function. It enables the processing of words into coherent thought and recognition of the idea behind written or printed words (language).

**Whipple procedure (radical pancreaticoduodenectomy)** A surgical treatment for cancer of the head of the pancreas. The procedure entails removal of the proximal head of the pancreas, the duodenum, a portion of the jejunum, the stomach (partial or total gastrectomy), and the gallbladder, with anastomosis of the pancreatic duct (pancreaticojejunostomy), the common bile duct (choledochojejunostomy), and the stomach (gastrojejunostomy) to the jejunum.

**white matter** In the spinal cord, myelinated axons that surround the gray matter (neuron cell bodies).

**Williams position** A position in which the patient lies in the semi-Fowler's position and flexes the knees to relax the muscles of the lower back and relieve pressure on the spinal nerve root. This is

typically more comfortable and therapeutic for the patient with low back pain.

**withdrawing or withholding life-sustaining therapy** The withdrawal or withholding of one or more therapies that might prolong the life of a person who cannot be cured by the therapy; the withdrawal of therapy does not directly cause death. Formerly called *passive euthanasia*.

**work-related musculoskeletal disorders (MSDs)** Disorders caused by heavy lifting and dependent transfers by staff members.

## X

**xenograft** Tissue transplanted (grafted) from another species; for example, a heart valve transplanted from a pig to a human.

**xerosis** Abnormally dry skin.

**xerostomia** Abnormal dryness of the mouth caused by a severe reduction in the flow of saliva.

**x-ray** Radiation that is generated by machine.

## Z

**Zika virus** A virus carried by mosquitoes that has affected people in over a dozen countries, including the United States, and can cause microcephaly (abnormally small heads) in newborns and Guillain-Barré syndrome in adults.

#### Breast(s)

anatomy of, 1429–1430

biopsy of, 1438, 1446

clinical examination of, 1443, 1456

large-breasted women, 1456

lymphatic drainage of, 1430*f*

mammography of, 1435–1436

reduction mammoplasty of, 1456

small-breasted women, 1456

ultrasonography of, 1446

#### Breast augmentation

description of, 1456

in male-to-female transgender patients, 1499

Breast cancer, 376*t*

- adjuvant therapy for, 1450–1451
- aromatase inhibitors for, 1452
- assessment of, 1445–1455
- axillary lymph node dissection for, 1447
- BRCA1* gene, 81, 83, 1442*b*
- BRCA2* gene, 79, 1442*b*
- breast-conserving surgery for, 1447, 1448*f*
- care coordination for, 1452–1454
- chemotherapy for, 1451–1452
- complementary and integrative health for, 1446–1447, 1447*t*
- coping strategies for, 1452
- diagnostic assessment of, 1446
- drug therapy for, 1451–1452
- ductal carcinoma in situ, 1441
- early detection of, 83
- etiology of, 1442
- genetic risk of, 1442, 1442*b*
- health care resources for, 1454
- health promotion and maintenance for, 1443–1445
- in high-risk women, 1443–1445
- history-taking for, 1445
- home care management of, 1452–1453
- imaging assessment of, 1446
- incidence of, 1442–1443
- infiltrating ductal carcinoma, 1441
- inflammatory, 1441
- interventions for, 1446–1454
- invasive, 1440–1441, 1441*f*
- laboratory assessment of, 1445–1446
- in lesbian and bisexual women, 1446*b*
- lobular carcinoma in situ, 1441
- magnetic resonance imaging of, 1446
- mammographic screening for, 1443, 1446
- mastectomy for
  - adjuvant therapy after, 1450–1451
  - breast reconstruction after, 1449–1450, 1450*t*, 1451*b*
  - exercises after, 1451*b*
  - modified radical, 1448, 1448*f*
  - postoperative teaching for, 1453–1454

- prophylactic, 1444
- total, 1448*f*
- in men, 1441
- metastasis of, 1440–1441, 1446–1452
- noninvasive, 1440–1441
- nonsurgical management of, 1446–1447
- pathophysiology of, 1440–1443
- physical assessment of, 1445
- prevalence of, 1442–1443
- prophylactic mastectomy for, 1444
- psychosocial assessment of, 1445

Sympathomimetics

- acute coronary syndromes treated with, [783b](#)
- description of, [1228–1229](#)

Synapse, [840](#)  
Synaptic cleft, [840](#)  
Synaptic knob, [840](#)  
Synarthrodial joints, [1006](#)  
Synchronized intermittent mandatory ventilation, [631](#), [636t](#)  
Syncope  
    definition of, [650–651](#), [1285](#)  
    description of, [618](#), [706](#)  
Syndrome of inappropriate antidiuretic hormone  
    characteristics of, [1251–1253](#), [1252t](#)  
    as oncologic emergency, [407–408](#)  
    signs and symptoms of, [954](#)  
Syndrome X, [771](#)  
Syngeneic stem cells, [822](#)  
Synovial joint, [1006–1007](#)  
Synovitis, [1006–1007](#), [1057](#)  
Syphilis, [1508–1510](#), [1508f](#)  
Syringe pumps, [211](#)  
Systemic inflammatory response syndrome, [761–762](#), [761f](#), [762t](#), [763b](#), [881](#)  
Systemic lupus erythematosus  
    care coordination of, [328](#)  
    definition of, [326](#)  
    drug therapy for, [327–328](#)  
    features of, [326b](#)  
    laboratory assessment of, [327](#)  
    pathophysiology of, [326](#)  
    psychosocial assessment of, [327](#)  
    self-management education for, [328](#)  
    signs and symptoms of, [326–327](#), [327f](#)  
    skin manifestations of, [326–327](#), [327f](#)  
    skin protection in, [328](#), [328b](#)  
    transition management of, [328](#)  
Systemic necrotizing vasculitis, [334t](#)  
Systemic sclerosis, [326b](#), [329–330](#), [330b](#)  
Systole, [644](#), [706](#)  
Systolic blood pressure, [646](#)  
Systolic heart failure, [692](#)  
Systolic murmurs, [655](#)

## T

T<sub>3</sub>, [Triiodothyronine](#)

T<sub>4</sub>, [Thyroxine](#)

T cells

- differentiation of, [295f](#)
- subsets of, [299](#)

T wave, [669](#), [669f](#), [671](#)

Tachycardia

- heart rate in, [670](#)
- paroxysmal supraventricular, [676](#)
- sinus, [673](#), [673f](#)
- supraventricular, [676–678](#)
- ventricular, [684](#), [684f](#)

Tachydysrhythmias, [668b](#), [672](#)

Tacrolimus, [302b](#), [1303](#)

Tactile fremitus, [518–519](#)

Tactile stimulation, for pain management, [496](#)

Tadalafil, [146](#)

Tamponade effect, [1341](#)

Tapentadol, [61](#)

Tar preparations, [464](#)

Target tissues, [1234–1235](#)

Targeted therapy

- breast cancer treated with, [1452](#)
- esophageal tumors treated with, [1097–1098](#)
- oral cancer treated with, [1081](#)
- pancreatic cancer treated with, [1207](#)
- renal cell carcinoma treated with, [1386](#)

Taste sense

- age-related changes in, [31](#)
- oral cancer effects on, [1083](#)

Tattoos, [439](#)

Tbo-filgrastim, [402f](#)

TBPI, [Toe brachial pressure index](#)

TBSA, [Total body surface area](#)

TeamSTEPPS, [6](#)

Teamwork

- attributes of, [5](#)
- definition of, [5](#)
- scope of, [5](#)

Technetium scan, [661](#)

Technology

- attributes of, 8
- context of, 8
- definition of, 7
- scope of, 8

Telangiectasias, 748

Telaprevir, 1185*t*

Telehealth, 101

Telemetry, 667

Teleneurology, 935

Telerehabilitation, 101

Teletherapy, 388

Temporal arteritis, 334*t*

Temporal lobe, 841*t*

Temporary pacing, 674–675

Tendons

- definition of, 1007
- rupture of, 1057*t*

Tenesmus, 1150, 1166

Tenofovir, 1185*t*

TENS, [Transcutaneous electrical nerve stimulation](#)

Tension pneumothorax, 637–638

Tentorium, 840

Teriparatide, 1022

Terminal dehydration, 115

Terminal delirium, 111

Terminal knob, 840

Terminally ill patients, withholding food in, 1219

Tertiary syphilis, 1508–1509

Testes

- anatomy of, 1430, 1430*f*
- hormones produced by, 1235*t*
- palpation of, 1242
- self-examination of, 1486*b*

Testicular cancer

- assessment of, 1487
- chemotherapy for, 1488–1489
- classification of, 1486–1487, 1487*t*
- laboratory assessment of, 1487
- pathophysiology of, 1486–1487
- psychosocial assessment of, 1487
- surgical management of, 1488

Testicular self-examination, [1486b](#)  
Testicular tumors, [1486–1487](#), [1487t](#)  
Testosterone, [1430](#), [1481–1482](#), [1498](#)  
Tetanus, [145](#)  
Tetany, [1269](#)  
Thalamus, [840](#), [840f](#)  
Thalidomide, [369](#)  
Thallium imaging, [661](#)  
Thallium scan, [1011–1012](#)  
The Joint Commission  
    care coordination recommendations, [3](#)  
    emergency department metrics, [117–118](#)  
    emergency preparedness plan, [150](#)  
    family-centered care, [2](#)  
    interprofessional communication strategies, [5](#)  
    lesbian, gay, bisexual, transgender, and queer population, [1495](#), [1495b](#)  
    medication reconciliation requirements, [4b](#)  
National Patient Safety Goals  
    blood components, [200](#), [833](#)  
    blood donation, [235](#)  
    description of, [4–5](#), [8](#)  
    drug safety, [201](#)  
    for falls, [40–41](#), [1018](#), [1020](#)  
    hand-off communication, [120](#), [317](#)  
    hand-off report, [271](#)  
    handwashing, [882](#), [1100](#)  
    infection control, [417](#)  
    influenza vaccine, [596–597](#)  
    informed consent, [658](#)  
    nutrition screening, [1212](#)  
    patient identification, [247](#), [262–263](#), [262b](#)  
    preoperative requirements, [238–239](#)  
    pressure injuries, [448–449](#)  
    surgical communication, [229](#)  
    tracheostomy communication, [544](#)  
    transfusion therapy, [833](#)  
    warfarin monitoring, [745](#)  
restraints used by hospitals, [41](#)  
sentinel event reporting requirements, [4–5](#)  
tobacco use screening, [514–515](#)  
Therapeutic hypothermia, [947](#)

Therapeutic Touch, 109

Thermal burns, 488, 491

Thermoregulation, 135*b*

Thiazide diuretics, 699, 725*b*

Thiazolidinediones, 1291, 1292*b*–1293*b*

Third space fluid, 19

Third spacing, 485, 1145, 1170

Third-degree frostbite, 144

Thirst, 164

Thoracentesis, 526, 526*f*, 593

Thoracic aortic aneurysms, 738–739

Thoracic outlet syndrome, 741*t*

Thoracotomy, 638

Thorax assessments, 518–521

Threshold (hearing), 990

Thrombectomy, 736, 738, 745

Thrombocytopenia

- chemotherapy as cause of, 395, 397–398, 588
- definition of, 815, 817
- description of, 15
- heparin-induced, 832
- injury prevention in patients with, 398*b*
- management of, 825*b*
- platelet count in, 805

Thrombocytosis, 321

Thrombolytic therapy

- contraindications for, 778*t*
- deep vein thrombosis treated with, 745
- myocardial infarction treated with, 777–778, 778*t*

Thrombophlebitis

- definition of, 742
- intravenous therapy as cause of, 217*t*–219*t*
- management of, 743

Thrombopoietin, 300*t*, 797

Thrombosis

- arterial, 16*b*
- deep vein, [Deep vein thrombosis](#)
- definition of, 15–16
- intravenous therapy as cause of, 217*t*–219*t*
- mesenteric artery, 16*b*
- vascular stasis as cause of, 816

venous, 15–16

Thrombotic stroke, 928, 929*t*

Thrombotic thrombocytopenic purpura, 831

Thromboxane A<sub>2</sub>, 798

Thrombus, [Thrombosis](#)  
definition of, 742  
etiology of, 742  
stroke caused by, 928

Thrush, 347*f*, 468

Thymoma, 918

Thyrocalcitonin, 179, 1239

Thyroid cancer, 1275

Thyroid cartilage, 510

Thyroid crisis, 1270

Thyroid disorders  
hyperthyroidism, [Hyperthyroidism](#)  
hypothyroidism, [Hypothyroidism](#)  
in older adults, 1274*b*  
thyroiditis, 1275

Thyroid gland  
anatomy of, 1238–1239, 1239*f*  
hormones produced by, 1235*t*, 1239*t*, 1264–1265  
palpation of, 1242, 1242*b*

Thyroid storm, 1267, 1270, 1270*b*

Thyroidectomy, 1269, 1275

Thyroiditis, 1275

Thyroid-stimulating hormone  
deficiency of, 1246, 1246*b*  
description of, 1237*t*, 1239, 1271  
overproduction of, 1248*b*

Thyroid-stimulating hormone receptors, 1265

Thyroid-stimulating immunoglobulins, 1265

Thyrotoxic periodic paralysis, 1268*b*

Thyrotoxicosis, 918, 1264–1265, 1268*b*

Thyrotropin-releasing hormone, 1239

Thyroxine, 697*b*, 1006, 1238, 1247, 1266, 1272

TIBC, [Total iron-binding capacity](#)

Tibial fracture, 1048–1049

Tibial nerve, 267*b*

Tic douloureux, [Trigeminal neuralgia](#)

Tidal volume, 631

Time-cycled ventilators, 631

Time-out, 265, 266*f*

Tinea capitis, 468

Tinea corporis, 468

Tinea cruris, 468

Tinea manus, 468

Tinea pedis, 468

Tinel's sign, 1058

Tinnitus, 987, 995

TIPS, Transjugular intrahepatic portal-systemic shunt

Tirofiban, 736–737

Tissue integrity

- assessment of, before rehabilitation, 90*t*, 91
- description of, 27–28

Tissue mast cells, 294

Tissue perfusion

- after amputation, 1053
- hematologic system in, 796*f*

Tissue plasminogen activator, 736–738

Tissue thromboplastin, 798*t*

TJC, The Joint Commission

TLS, Tumor lysis syndrome

Tobacco, 379, Smoking

Tocilizumab, 323*b*, 369, 370*b*

Toe brachial pressure index, 653

Toe fracture, 1038

Tofacitinib, 369

Toileting-related falls, 41

Tolerance, 58

Toll-like receptors, 290, 300

Tolterodine, 98

Tolvaptan, 954, 1252, 1252*b*

Tongue, 1062

Tonic-clonic seizures, 876, 878*b*–879*b*

Tonometry, 965

Tono-Pen, 965, 966*f*

Tooth loss, 31

Topiramate, 875

Topoisomerase inhibitors, 391, 391*t*

Torsade de pointes, 657

Total abdominal hysterectomy, [1462](#), [1462b–1463b](#)

Total body irradiation, [387](#)

Total body surface area, [489](#), [492](#)

Total body water, [160](#), [161f](#)

Total enteral nutrition

- abdominal distention caused by, [1222](#)
- administration of, [1220–1221](#), [1220f](#)
- complications of, [1221–1223](#)
- description of, [1219–1223](#)
- diarrhea secondary to, [1223](#)
- electrolyte imbalances caused by, [1222–1223](#)
- enterostomal feeding tubes used in, [1220–1221](#)
- fluid imbalances caused by, [1222–1223](#)
- gastrostomy for, [1221](#)
- jejunostomy for, [1221](#)
- nasoduodenal tube delivery of, [1220](#)
- nasoenteric tube delivery of, [1220](#), [1220f](#)
- nasogastric tube delivery of, [1220](#)
- nausea and vomiting caused by, [1222](#)
- refeeding syndrome caused by, [1221–1222](#)
- tube misplacement and dislodgement, [1222](#)

Total hip arthroplasty

- anesthesia used in, [310](#)
- complications of, [311f](#), [312–313](#)
- components of, [310–311](#), [310f](#)
- hip dislocation after, [311–312](#)
- hip resurfacing versus, [310](#)
- low-molecular-weight heparin uses, [312](#)
- minimally invasive, [310](#)
- mobility after, [313–314](#), [313f](#)
- operative procedures, [310–311](#)
- pain management after, [312b](#), [313](#)
- patient positioning after, [311](#), [313f](#)
- postoperative care, [311–314](#), [311b](#)
- preoperative care, [309–310](#)
- primary, [309](#)
- quadriceps-setting exercises after, [312–313](#)
- rehabilitation, [314](#)
- revision, [309](#)
- self-management education, [312b](#), [314](#)
- venous thromboembolism risks after, [310](#), [312–313](#)

- weight-bearing restrictions, 313–314
- Total iron-binding capacity, 805
- Total joint arthroplasty
  - hip, [Total hip arthroplasty](#)
  - hospital length of stay after, 314*b*
  - osteoarthritis treated with, 309
- Total knee arthroplasty
  - complications of, 316
  - continuous passive motion machine, 315, 315*f*, 316*b*
  - cryotherapy after, 315
  - description of, 314–316
  - discharge instructions, 316
  - minimally invasive, 314
  - operative procedures, 315
  - pain management after, 315–316
  - postoperative care, 315–316, 315*f*
  - preoperative care, 314–315
  - rehabilitation after, 316
- Total laryngectomy, 551, 551*t*, 555
- Total lymphocyte count, 1217
- Total parenteral nutrition
  - complications of, 1224
  - fluid imbalance risks, 1224
  - malnutrition treated with, 1224
  - solutions for, 200
- Total proctocolectomy with permanent ileostomy for, 1154, 1155*f*
- Total shoulder arthroplasty, 316
- Total thyroidectomy, 1269
- Total vaginal hysterectomy, 1462, 1463*b*
- Touch discrimination assessments, 849
- Touch sense, 33
- Tourniquets, 129–130, 222
- Toxic diffuse goiter, 1265
- Toxic epidermal necrolysis, 478
- Toxic hepatitis, 1180
- Toxic megacolon, 1151*t*, 1153
- Toxic multinodular goiter, 1265
- Toxic shock syndrome, 1471, 1471*b*
- Toxicity
  - digoxin, 700*b*
  - oxygen, 530

Toxins, 414

*Toxoplasma gondii*, 346

Toxoplasmosis encephalitis, 346

T-piece, 534–535, 534t, 535f, 636t

Trabeculation, 1358

Trabeculectomy, 975

Trachea, 510, 511f

Trachea–innominate artery fistula, 538t

Tracheal stenosis, 538t

Tracheobronchial tree, 510

Tracheoesophageal fistula, 538t

Tracheoesophageal puncture, 552

Tracheomalacia, 538t

Tracheostomy

- air warming in, 540–541
- aspiration prevention during swallowing, 543b
- assessments in, 542b
- bronchial hygiene in, 543
- care coordination for, 544
- care issues for patients with, 539–544
- care of, 542–543, 542b
- caregiver anxiety in, 555b
- communication issues during, 543–544
- complications of, 537–539, 538t
- definition of, 537
- dressings for, 543, 543f
- health care resources for, 544
- home care management of, 544
- humidification in, 540–541
- in laryngeal cancer, 550
- minimal leak technique in, 540
- nutrition in, 543
- operative procedures for, 537, 538f
- oral hygiene in, 543
- overview of, 537
- psychosocial needs in, 544
- self-concept needs in, 544
- self-management education for, 544
- suctioning of, 541–542, 541b
- tissue damage in, 539–540, 541f
- transition management for, 544

tubes used in, [539](#), [540f](#), [543](#)  
weaning from, [544](#)

Tracheostomy button, [544](#)

Tracheotomy, [494](#), [553](#), [561](#)

Traction

- fractures treated with, [1040–1041](#), [1040t](#), [1041b](#), [1041f](#)
- lower-extremity, [1040t](#)
- skeletal, [1040](#)
- skin, [1040](#), [1041f](#)
- spinal cord injury treated with, [899](#)
- upper-extremity, [1040t](#)

Trafficking, human, [Human trafficking](#)

Training

- bladder, [1350–1351](#), [1351b](#)
- for emergency nursing, [120t](#), [123](#)
- gait, [95–96](#), [95b](#), [95f](#)
- habit, [1351](#), [1351b](#)

TRALI, [Transfusion-related acute lung injury](#)

TRAM flap, [1449–1450](#)

Tramadol, [61](#)

Transarterial chemoembolization, for liver cancer, [1187](#)

Transbronchial biopsy, [526](#)

Transbronchial needle aspiration, [526](#)

Transcatheter aortic valve replacement, [708–709](#), [708f](#)

Transcervical endometrial resection, [1461](#)

Transcranial Doppler ultrasonography, [855](#)

Transcutaneous electrical nerve stimulation, [66](#), [66f](#)

Transcutaneous oxygen pressure, [1052](#)

Transcutaneous pacing, [674](#), [674f](#)

Transesophageal echocardiography

- description of, [660](#)
- valvular heart disease evaluations, [707](#)

Transfer belts, [95](#)

Transferrin, [805](#), [1217](#)

Transfusion

- acute reactions to, [835–836](#)
- allergies to, [263](#), [836](#)
- autologous blood, [836](#)
- bacterial reactions to, [836](#)
- cell savers, [235](#), [310](#)
- febrile reactions to, [835](#)

- hemolytic reactions to, [835](#)
- indications for, [832t](#)
- infusion therapy for, [200](#)
- in older adults, [834b](#)
- plasma, [835](#)
- platelet
  - idiopathic thrombocytopenic purpura treated with, [831](#)
  - indications for, [832t](#), [835](#)
  - reaction to, [835](#)
- reactions to, [835–836](#)
- red blood cells, [834–835](#)
  - compatibility determinations for, [834](#), [834t](#)
  - indications for, [832t](#), [834–835](#)
  - sickle cell disease treated with, [812](#)
- reinfusion system, [310](#)
- responsibilities in, [832–834](#)
- safety in, [833b](#)
- setup for, [832](#), [834f](#)
- types of, [834–835](#)
- white blood cells, [832t](#), [835](#)

Transfusion-associated circulatory overload, [836](#)

Transfusion-associated graft-versus-host-disease, [836](#)

Transfusion-related acute lung injury, [626](#), [836](#)

Transgender patients/health

- assessment of, [1495–1497](#)
- care coordination for, [1501](#)
- communication therapy for, [1499](#)
- definition of, [1493](#)
- drug therapy for, [1497–1498](#)
- environment for, [1495b](#)
- estrogen for, [1497–1498](#)
- female-to-male
  - definition of, [1493–1494](#), [1493t](#)
  - drug therapy for, [1498](#)
