## CONCEPTS FOR INTERPROFESSIONAL COLLABORATIVE CARE

9<sup>TH</sup> EDITION

### **Donna D. Ignatavicius, MS, RN, CNE, ANEF**

*Speaker and Curriculum Consultant for Academic Nursing Programs;  
Founder, Boot Camp for Nurse Educators;  
President, DI Associates, Inc.  
Littleton, Colorado*

### **M. Linda Workman, PhD, RN, FAAN**

*Author and Consultant  
Cincinnati, Ohio*

### **Cherie R. Rebar, PhD, MBA, RN, COI**

*Professor of Nursing  
Wittenberg University  
Springfield, Ohio  
**Section Editor:***

### **Nicole M. Heimgartner, MSN, RN, COI**

*Former Associate Professor of Nursing  
Kettering College;  
Subject Matter Expert, Author, and Consultant  
Louisville, Kentucky*

## Priority Concept Exemplars

Acid-Base Balance

Cellular Regulation

Clotting

Cognition

Comfort

Elimination

Fluid and Electrolyte Balance

Gas Exchange

Glucose Regulation

Immunity

Mobility

Nutrition

Perfusion

Sensory Perception

Sexuality

Tissue Integrity

Copyright

Consultants and Contributors

Reviewers

Preface

Key Themes for the 9th Edition

Clinical Currency and Accuracy

Outstanding Readability

Ease of Access

A Patient-Centered, Interprofessional Collaborative Care Approach

Organization

Multinational, Multicultural, Multigenerational Focus

Additional Learning Aids

An Integrated Multimedia Resource Based on Proven Strategies for Student Engagement and Learning

Dedication

About the Authors

Acknowledgments

Guide to Special Features

Best Practice for Patient Safety and Quality Care

Common Examples of Drug Therapy

Concept Map

Key Features

Evidence-Based Practice

Focused Assessment

Home Care Assessment

Laboratory Profile

Nursing Focus on the Older Adult

Patient and Family Education: Preparing for Self-Management

Quality Improvement

## **Unit I Foundations for Medical-Surgical Nursing**

Chapter 1 Overview of Professional Nursing Concepts for Medical-Surgical Nursing

Quality and Safety Education for Nurses Core Competencies

Patient-Centered Care

Safety

Teamwork and Interprofessional Collaboration

Evidence-Based Practice

Quality Improvement

Informatics and Technology

Clinical Judgment

Ethics

Health Care Organizations

Health Care Disparities

Get Ready for the NCLEX® Examination!

Selected Bibliography

Chapter 2 Overview of Health Concepts for Medical-Surgical Nursing

Acid-Base Balance

Cellular Regulation

Clotting

Cognition  
Comfort  
Elimination  
Fluid and Electrolyte Balance  
Glucose Regulation  
Gas Exchange  
Immunity  
Mobility  
Nutrition  
Perfusion  
Sensory Perception  
Sexuality  
Tissue Integrity  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 3 Common Health Problems of Older Adults

Overview  
Health Issues for Older Adults in Community-Based Settings  
Health Issues for Older Adults in Hospitals and Long-Term Care Settings  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 4 Assessment and Care of Patients With Pain

Overview of Comfort Concept Exemplar Pain  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 5 Principles of Genetics and Genomics for Medical-Surgical Nursing

Genetic Biology Review  
Patterns of Inheritance  
Genetic Testing  
The Role of the Medical-Surgical Nurse in Genetic Counseling  
Get Ready for the NCLEX® Examination!  
Bibliography

### Chapter 6 Rehabilitation Concepts for Chronic and Disabling Health Problems

Overview  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 7 End-of-Life Care Concepts

Overview of Death, Dying, and End of Life  
Pathophysiology of Dying  
Comfort Concept Exemplar End of Life  
Postmortem Care  
Ethics and Dying  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## **Unit II Principles of Emergency Care and Disaster Preparedness**

### Chapter 8 Principles of Emergency and Trauma Nursing

The Emergency Department Environment of Care  
Staff and Patient Safety Considerations  
Scope of Emergency Nursing Practice  
Emergency Nursing Principles  
The Impact of Homelessness  
Trauma Nursing Principles  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 9 Care of Patients With Common Environmental Emergencies

Heat-Related Illnesses  
Snakebites and Arthropod Bites and Stings  
Lightning Injuries  
Cold-Related Injuries  
Altitude-Related Illnesses  
Drowning  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 10 Principles of Emergency and Disaster Preparedness

Types of Disasters  
Impact of External Disasters  
Emergency Preparedness and Response  
Event Resolution and Debriefing  
Role of Nursing in Community Emergency Preparedness and Response  
Psychosocial Response of Survivors to Mass Casualty Events  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## **Unit III Interprofessional Collaboration for Patients With Problems of Fluid, Electrolyte, and Acid-Base Balance**

## Chapter 11 Assessment and Care of Patients With Problems of Fluid and Electrolyte Balance

Anatomy and Physiology Review

Fluid Balance

Disturbances of Fluid and Electrolyte Balance

Electrolyte Balance and Imbalances

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 12 Assessment and Care of Patients With Problems of Acid-Base Balance

Maintaining Acid-Base Balance

Acid-Base Imbalances

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 13 Concepts of Infusion Therapy

Overview

Peripheral Intravenous Therapy

Central Intravenous Therapy

Infusion Systems

Nursing Care for Patients Receiving Intravenous Therapy

Complications of Intravenous Therapy

Intravenous Therapy and Care of the Older Adult

Subcutaneous Infusion Therapy

Intraosseous Infusion Therapy

Intra-Arterial Infusion Therapy

Intraperitoneal Infusion Therapy

Intraspinal Infusion Therapy

Get Ready for the NCLEX® Examination!

Selected Bibliography

# Unit IV Interprofessional Collaboration for Perioperative Patients

## Chapter 14 Care of Preoperative Patients

Overview

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 15 Care of Intraoperative Patients

Overview

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 16 Care of Postoperative Patients

Overview

Get Ready for NCLEX® Examination

Selected Bibliography

# Unit V Interprofessional Collaboration for Patients With Problems of Immunity

## Chapter 17 Principles of Inflammation and Immunity

Overview

General Immunity: Inflammation

Specific Immunity

Age-Related Changes in Immunity

Transplant Rejection

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 18 Care of Patients With Arthritis and Other Connective Tissue Diseases

Mobility Concept Exemplar Osteoarthritis

Immunity Concept Exemplar Rheumatoid Arthritis

Lupus Erythematosus

Systemic Sclerosis

Gout

Lyme Disease

Disease-Associated Arthritis

Fibromyalgia Syndrome

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 19 Care of Patients With Problems of HIV Disease

Immunity Concept Exemplar HIV Infection and AIDS

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 20 Care of Patients With Hypersensitivity (Allergy) and Autoimmunity

Hypersensitivities/Allergies

Autoimmunity

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 21 Principles of Cancer Development

Pathophysiology

Cancer Development  
Cancer Prevention  
Get Ready for the NCLEX® Examination  
Selected Bibliography

## Chapter 22 Care of Patients With Cancer

Impact of Cancer on Physical Function  
Cancer Management  
Oncologic Emergencies  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 23 Care of Patients With Infection

Immunity Exemplar Infection  
Multidrug-Resistant Organism Infections and Colonizations  
Occupational and Environmental Exposure to Sources of Infection  
Problems Resulting From Inadequate Antimicrobial Therapy  
Critical Issues: Emerging Infections and Global Bioterrorism  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

# **Unit VI Interprofessional Collaboration for Patients With Problems of the Skin, Hair, and Nails**

## Chapter 24 Assessment of the Skin, Hair, and Nails

Anatomy and Physiology Review  
Assessment: Noticing and Interpreting  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 25 Care of Patients With Skin Problems

Tissue Integrity Concept Exemplar Pressure Injuries  
Minor Skin Irritations  
Common Inflammations  
Psoriasis  
Skin Infections  
Parasitic Disorders  
Trauma  
Skin Cancer  
Other Skin Disorders  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 26 Care of Patients With Burns

Introduction to Burn Injury  
Health Promotion and Maintenance  
Resuscitation Phase of Burn Injury  
Acute Phase of Burn Injury  
Rehabilitative Phase of Burn Injury  
Get Ready for NCLEX® Examination!  
Selected Bibliography

# Unit VII Interprofessional Collaboration for Patients With Problems of the Respiratory System

## Chapter 27 Assessment of the Respiratory System

Anatomy and Physiology Review  
Assessment: Noticing and Interpreting  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 28 Care of Patients Requiring Oxygen Therapy or Tracheostomy

Oxygen Therapy  
Gas Exchange Concept Exemplar Tracheostomy  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 29 Care of Patients With Noninfectious Upper Respiratory Problems

Cellular Regulation Concept Exemplar Head and Neck Cancer  
Cancer of the Nose and Sinuses  
Fractures of the Nose  
Epistaxis  
Facial Trauma  
Obstructive Sleep Apnea  
Laryngeal Trauma  
Upper Airway Obstruction  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 30 Care of Patients With Noninfectious Lower Respiratory Problems

Asthma  
Gas Exchange Concept Exemplar Chronic Obstructive Pulmonary Disease  
Cystic Fibrosis  
Pulmonary Arterial Hypertension  
Idiopathic Pulmonary Fibrosis

Lung Cancer

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 31 Care of Patients With Infectious Respiratory Problems

Seasonal Influenza

Pandemic Influenza

Middle East Respiratory Syndrome (MERS)

Gas Exchange Concept Exemplar Pneumonia

Immunity Concept Exemplar Pulmonary Tuberculosis

Rhinosinusitis

Peritonsillar Abscess

Inhalation Anthrax

Pertussis

Coccidioidomycosis

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 32 Care of Critically Ill Patients With Respiratory Problems

Gas Exchange Concept Exemplar Pulmonary Embolism

Acute Respiratory Failure

Acute Respiratory Distress Syndrome

The Patient Requiring Intubation and Ventilation

Chest Trauma

Get Ready for the NCLEX® Examination!

Selected Bibliography

# Unit VIII Interprofessional Collaboration for Patients With Problems of the Cardiovascular System

## Chapter 33 Assessment of the Cardiovascular System

Anatomy and Physiology Review

Assessment: Noticing and Interpreting

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 34 Care of Patients With Dysrhythmias

Review of Cardiac Conduction System

Electrocardiography

Overview of Normal Cardiac Rhythms

Common Dysrhythmias

Sinus Dysrhythmias

Atrial Dysrhythmias  
Perfusion Concept Exemplar Atrial Fibrillation  
Ventricular Dysrhythmias  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 35 Care of Patients With Cardiac Problems

Perfusion Concept Exemplar Heart Failure  
Valvular Heart Disease  
Inflammations and Infections  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 36 Care of Patients With Vascular Problems

Peripheral Venous Disease  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 37 Care of Patients With Shock

Overview  
Perfusion Concept Exemplar Hypovolemic Shock  
Immunity Concept Exemplar Sepsis and Septic Shock  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 38 Care of Patients With Acute Coronary Syndromes

Chronic Stable Angina Pectoris  
Perfusion Concept Exemplar Acute Coronary Syndrome  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

# **Unit IX Interprofessional Collaboration for Patients With Problems of the Hematologic System**

## Chapter 39 Assessment of the Hematologic System

Anatomy and Physiology Review  
Assessment: Noticing and Interpreting  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 40 Care of Patients With Hematologic Problems

Perfusion Concept Exemplar Sickle Cell Disease

Anemia  
Polycythemia Vera  
Hereditary Hemochromatosis  
Myelodysplastic Syndromes  
Immunity Concept Exemplar Leukemia  
Malignant Lymphomas  
Multiple Myeloma  
Autoimmune Thrombocytopenic Purpura  
Thrombotic Thrombocytopenic Purpura  
Hemophilia  
Heparin-Induced Thrombocytopenia  
Transfusion Therapy  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## **Unit X Interprofessional Collaboration for Patients With Problems of the Nervous System**

### Chapter 41 Assessment of the Nervous System

Anatomy and Physiology Review  
Assessment: Noticing and Interpreting  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 42 Care of Patients With Problems of the Central Nervous System

Cognition Concept Exemplar Alzheimer's Disease  
Mobility Concept Exemplar Parkinson Disease  
Migraine Headache  
Seizures and Epilepsy  
Meningitis  
Encephalitis  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 43 Care of Patients With Problems of the Central Nervous System

Immunity Concept Exemplar Multiple Sclerosis  
Mobility Concept Exemplar Spinal Cord Injury  
Back Pain  
Get Ready for the nclex® Examination!  
Selected Bibliography

### Chapter 44 Care of Patients With Problems of the Peripheral Nervous System

Immunity Concept Exemplar Guillain-Barré Syndrome

Myasthenia Gravis

Restless Legs Syndrome

Trigeminal Neuralgia

Facial Paralysis

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 45 Care of Critically Ill Patients With Neurologic Problems

Transient Ischemic Attack

Perfusion Concept Exemplar Stroke (Brain Attack)

Cognition Concept Exemplar Traumatic Brain Injury

Brain Tumors

Get Ready for the NCLEX® Examination!

Selected Bibliography

# Unit XI Interprofessional Collaboration for Patients With Problems of the Sensory System

## Chapter 46 Assessment of the Eye and Vision

Anatomy and Physiology Review

Assessment: Noticing and Interpreting

Get ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 47 Care of Patients With Eye and Vision Problems

Sensory Perception Concept Exemplar Cataract

Sensory Perception Concept Exemplar Glaucoma

Corneal Disorders

Retinal Disorders

Refractive Errors

Trauma

Get Ready for the NCLEX® Examination

Selected Bibliography

## Chapter 48 Assessment and Care of Patients With Ear and Hearing Problems

Anatomy and Physiology Review

Assessment: Noticing and Interpreting

Sensory Perception Concept Exemplar Otitis Media

External Otitis

Cerumen or Foreign Bodies

Mastoiditis

Trauma  
Tinnitus  
Ménière's Disease  
Acoustic Neuroma  
Sensory Perception Concept Exemplar Hearing Loss  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## **Unit XII Interprofessional Collaboration for Patients With Problems of the Musculoskeletal System**

### Chapter 49 Assessment of the Musculoskeletal System

Anatomy and Physiology Review  
Assessment: Noticing and Interpreting  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 50 Care of Patients With Musculoskeletal Problems

Cellular Regulation Concept Exemplar Osteoporosis  
Osteomyelitis  
Bone Tumors  
Disorders of the Hand  
Disorders of the Foot  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

### Chapter 51 Care of Patients With Musculoskeletal Trauma

Mobility Concept Exemplar Fractures  
Selected Fractures of Specific Sites  
Perfusion Concept Exemplar Amputations  
Knee Injuries  
Carpal Tunnel Syndrome  
Rotator Cuff Injuries  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## **Unit XII Interprofessional Collaboration for Patients With Problems of the Gastrointestinal System**

### Chapter 52 Assessment of the Gastrointestinal System

Anatomy and Physiology Review  
Assessment: Noticing and Interpreting  
Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 53 Care of Patients With Oral Cavity Problems

Tissue Integrity Concept Exemplar Stomatitis

Oral Cavity Disorders

Disorders of the Salivary Glands

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 54 Care of Patients With Esophageal Problems

Nutrition Concept Exemplar Gastroesophageal Reflux Disease (GERD)

Hiatal Hernias

Nutrition Concept Exemplar Esophageal Tumors

Esophageal Diverticula

Esophageal Trauma

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 55 Care of Patients With Stomach Disorders

Gastritis

Immunity Concept Exemplar Peptic Ulcer Disease (PUD)

Gastric Cancer

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 56 Care of Patients With Noninflammatory Intestinal Disorders

Elimination Concept Exemplar Intestinal Obstruction

Polyps

Cellular Regulation Concept Exemplar Colorectal Cancer

Irritable Bowel Syndrome

Herniation

Hemorrhoids

Malabsorption Syndrome

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 57 Care of Patients With Inflammatory Intestinal Disorders

Acute Inflammatory Bowel Disorders

Chronic Inflammatory Bowel Disease

Anal Disorders

Parasitic Infection

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 58 Care of Patients With Liver Problems

Cellular Regulation Concept Exemplar Cirrhosis

Immunity Concept Exemplar Hepatitis

Fatty Liver (Steatosis)

Liver Trauma

Cancer of the Liver

Liver Transplantation

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 59 Care of Patients With Problems of the Biliary System and Pancreas

Nutrition Concept Exemplar Cholecystitis

Immunity Concept Exemplar Acute Pancreatitis

Chronic Pancreatitis

Pancreatic Abscess

Pancreatic Pseudocyst

Pancreatic Cancer

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 60 Care of Patients With Malnutrition

Nutrition Standards for Health Promotion and Maintenance

Nutrition Assessment

Nutrition Concept Exemplar Malnutrition

Nutrition Concept Exemplar Obesity

Get Ready for the NCLEX® Examination!

Selected Bibliography

# Unit XIV Interprofessional Collaboration for Patients With Problems of the Endocrine System

## Chapter 61 Assessment of the Endocrine System

Anatomy and Physiology Review

Assessment: Noticing and Interpreting

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 62 Care of Patients With Pituitary and Adrenal Gland Problems

Disorders of the ANTERIOR Pituitary Gland

Disorders of the Posterior Pituitary Gland

Disorders of the Adrenal Gland

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 63 Care of Patients With Problems of the Thyroid and Parathyroid Glands

Thyroid Disorders

Parathyroid Disorders

Get Ready for the NCLEX® Examination

Selected Bibliography

## Chapter 64 Care of Patients With Diabetes Mellitus

Glucose Regulation Concept Exemplar Diabetes Mellitus

Get Ready for the NCLEX® Examination!

Selected Bibliography

# Unit XV Interprofessional Collaboration for Patients With Problems of the Renal/Urinary System

## Chapter 65 Assessment of the Renal/Urinary System

Anatomy and Physiology Review

Assessment: Noticing and Interpreting

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 66 Care of Patients With Urinary Problems

Elimination Concept Exemplar Urinary Incontinence

Cystitis

Urethritis

Urolithiasis

Urothelial Cancer

Bladder Trauma

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 67 Care of Patients With Kidney Disorders

Elimination Concept Exemplar Pyelonephritis

Acute Glomerulonephritis

Chronic Glomerulonephritis

Nephrotic Syndrome

Nephrosclerosis

Polycystic Kidney Disease

Hydronephrosis and Hydroureter

Renovascular Disease

Diabetic Nephropathy

Renal Cell Carcinoma

Kidney Trauma

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 68 Care of Patients With Acute Kidney Injury and Chronic Kidney Disease

Acute Kidney Injury

Elimination Concept Exemplar Chronic Kidney Disease

Get Ready for the NCLEX® Examination!

Selected Bibliography

# Unit XVI Interprofessional Collaboration for Patients With Problems of the Reproductive System

## Chapter 69 Assessment of the Reproductive System

Anatomy and Physiology Review

Assessment: Noticing and Interpreting

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 70 Care of Patients With Breast Disorders

Cellular Regulation Concept Exemplar Breast Cancer

Benign Breast Disorders

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 71 Care of Patients With Gynecologic Problems

Sexuality Concept Exemplar Uterine Leiomyoma

Pelvic Organ Prolapse

Endometrial (Uterine) Cancer

Ovarian Cancer

Cervical Cancer

Vulvovaginitis

Toxic Shock Syndrome

Get Ready for the NCLEX® Examination!

Selected Bibliography

## Chapter 72 Care of Patients With Male Reproductive Problems

Elimination Concept Exemplar Benign Prostatic Hyperplasia

Cellular Regulation Concept Exemplar Prostate Cancer

Testicular Cancer  
Erectile Dysfunction  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 73 Care of Transgender Patients

Patient-Centered Terminology  
Transgender Health Issues  
Stress and Transgender Health  
The Need to Improve Transgender Health Care  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

## Chapter 74 Care of Patients With Sexually Transmitted Infections

Overview  
Health Promotion and Maintenance  
Genital Herpes  
Syphilis  
Condylomata Acuminata (Genital Warts)  
Chlamydia Infection  
Gonorrhea  
Sexuality Concept Exemplar Pelvic Inflammatory Disease  
Get Ready for the NCLEX® Examination!  
Selected Bibliography

# Acid-Base Balance

Acidosis, 190

## **Cellular Regulation**

Breast Cancer, 1440

Cirrhosis, 1169

Colorectal Cancer, 1126

Head and Neck Cancer, 547

Hypothyroidism, 1270

Osteoporosis, 1015

Prostate Cancer, 1481

## Clotting

Venous Thromboembolism, 742

## **Cognition**

Alzheimer's Disease, 857

Traumatic Brain Injury, 940

## **Comfort**

End of Life, 104

Pain, 45

## **Elimination**

Benign Prostatic Hyperplasia, 1474

Chronic Kidney Disease, 1398

Intestinal Obstruction, 1121

Pyelonephritis, 1372

Ulcerative Colitis, 1150

Urinary Incontinence, 1343

## **Fluid and Electrolyte Balance**

Dehydration, 167

Hypercortisolism (Cushing's Disease), 1255

## **Gas Exchange**

Chronic Obstructive Pulmonary Disease, 572

Pneumonia, 598

Pulmonary Embolism, 616

Tracheostomy, 537

# Glucose Regulation

Diabetes Mellitus, 1280

## Immunity

Acute Pancreatitis, 1197

Angioedema, 361

Guillain-Barré Syndrome, 912

Hepatitis, 1180

HIV Infection and AIDS, 337

Infection, 413

Leukemia, 817

Multiple Sclerosis, 888

Peptic Ulcer Disease (PUD), 1107

Peritonitis, 1144

Pulmonary Tuberculosis, 605

Rheumatoid Arthritis, 318

Sepsis and Septic Shock, 760

## **Mobility**

Fractures, 1032

Osteoarthritis, 305

Parkinson Disease, 868

Spinal Cord Injury, 894

## **Nutrition**

Cholecystitis, 1191

Esophageal Tumors, 1095

Gastroesophageal Reflux Disease (GERD), 1087

Malnutrition, 1215

Obesity, 1225

## **Perfusion**

Acute Coronary Syndrome, 769

Amputations, 1050

Atrial Fibrillation, 678

Heart Failure, 691

Hypertension, 720

Hypovolemic Shock, 754

## CONSULTANTS

### **Deanne A. Blach MSN, RN**

President  
DB Productions of NW AR, Inc.  
Green Forest, Arkansas

### **Richard Lintner RT (R), (CV), (MR), (CT)**

Program Director, School of Interventional Radiology  
The University of Kansas Health System  
Kansas City, Kansas

## CONTRIBUTORS

### **Jeanette Spain Adams PhD, RN, CRNI, ACNS, BC**

Consultant  
University of Phoenix  
Coconut Grove, Florida

### **Meg Blair PhD, MSN, RN, CEN**

Professor  
Nursing Division  
Nebraska Methodist College  
Omaha, Nebraska

### **Andrea A. Borchers PhD, RN**

Assistant Professor  
Northern Arizona University  
Flagstaff, Arizona

### **Samuel A. Borchers OD**

Optometrist  
Vision Clinic  
Northern Arizona VA Healthcare System  
Prescott, Arizona

### **Katherine L. Byar MSN, APN, BC, BMTCN®**

Nurse Practitioner  
Nebraska Medicine  
Omaha, Nebraska

### **Michelle Camicia PhD(c), MSN, CRRN, CCM, FAHA**

Director of Operations  
Kaiser Foundation Rehabilitation Center  
Kaiser Permanente  
Vallejo, California;  
PhD Candidate  
The Betty Irene Moore School of Nursing  
University of California, Davis  
Davis, California

### **Lara Carver PhD, RN, CNE**

Professor  
Department of Nursing  
National University  
Las Vegas, Nevada

**Tammy Coffee MSN, RN, ACNP**

Nurse  
MetroHealth Medical Center  
Cleveland, Ohio

**Keelin Cromar MSN, RN**

# Preface

---

The first edition of this textbook, entitled *Medical-Surgical Nursing: A Nursing Process Approach*, was a groundbreaking work in many ways. The following eight editions built on that achievement and further solidified the book's position as a major trendsetter for the practice of adult health nursing. Now, in its ninth edition, "Iggy" charts the cutting-edge approach for the future of adult nursing practice—an approach reflected in its current title: *Medical-Surgical Nursing: Concepts for Interprofessional Collaborative Care*. The focus of this new edition continues to help students learn how to provide safe, quality nursing care that is patient-centered, evidence-based, and interprofessionally collaborative. In addition to print formats as single- and two-volume texts, this edition is now available in a variety of electronic formats.

The subtitle for this ninth edition was carefully chosen to emphasize the interprofessional nature of today's care, in which the nurse serves as a central role in collaboration with the patient, family, and members of the interprofessional health care team in acute care, community-based, and home settings. This approach reflects the National Academy of Medicine, The Joint Commission, the Quality and Safety Education for Nurses (QSEN) Institute, and the 2010 *Future of Nursing* report that unanimously have called for all health professionals to coordinate and deliver safe, evidence-based, patient-centered care as a collaborative team.

## Key Themes for the 9th Edition

The key themes for this edition strengthen this text's conceptual focus on safety, quality care, patient-centeredness, and clinical judgment to best prepare the student for interprofessional practice in medical-surgical health settings. Each theme is outlined and described below.

- **Enhanced Focus on Professional Nursing and Health Concepts.** This edition uniquely balances a focus on concepts, and a conceptual approach to teaching and learning, with important underpinnings of content. Prelicensure programs that embrace concept-based nursing curriculum, system-focused curriculum, or a hybrid approach will find this edition easy to use. To help students connect previously learned concepts with new information in the text, [Chapters 1 and 2](#) addresses the main concepts used in this edition, giving a working definition upon which the students will reflect and build as they learn new material. These unique features build on basic concepts learned in nursing fundamentals courses, such as gas exchange and safety, to help students make connections between foundational concepts and interprofessional patient care for medical-surgical conditions. For continuity and reinforcement, a list of specific Priority and Interrelated Nursing Concepts is highlighted at the beginning of each chapter. This placement is specifically designed to help students better understand the priority and associated needs that the nurse will address when providing safe, evidence-based, patient-centered care for individuals with selected health problems. When these concepts are discussed in the body of each chapter, they are presented in small capital letters (e.g., IMMUNITY) to help students relate and apply essential concepts to provide more focused nursing care.
- **Emphasis on Key Exemplars.** For each priority concept listed in selected chapters, the authors have identified key exemplars. The nursing and interprofessional collaborative care for patients experiencing these exemplar diseases and illnesses is discussed through the lens of the priority and interrelated concepts. In addition, patient problems are presented as a collaborative problem list rather than merely presenting nursing diagnoses.
- **Prioritized Focus on the Core Body of Knowledge and QSEN Competencies.** This edition not only continues to emphasize need-to-know content for the RN level of practice but also includes a continuing emphasis on Quality and Safety Education for Nurses (QSEN) Institute core competencies. Clinical practice settings emphasize the critical need for safe practices and quality improvement to provide interprofessional patient-centered care that is evidence-based. Many hospitals and other health care agencies have formally adopted these QSEN competencies as core values and goals for patient care, and many nursing programs have used these same competencies to build prelicensure nursing curriculum. To help prepare students for the work environment as new graduates, as well as to highlight the foundational underpinning of safety and quality into all nursing actions, this edition prioritizes a focus on these competencies.
- **Emphasis on Patient Safety.** Patient safety is emphasized throughout this edition, not only in the narrative but also in **Nursing Safety Priority boxes** that enable students to immediately identify the most important care needed for patients with specific health problems. These highlighted features are further classified as an Action Alert, Drug Alert, or Critical Rescue. We also continue to include our leading-edge Best Practice for Patient Safety & Quality Care charts to emphasize the most important nursing care. **Highlighted yellow text** also demonstrates the application of The Joint Commission's National Patient Safety Goals initiatives ([http://www.jointcommission.org/standards\\_information/npsgs.aspx](http://www.jointcommission.org/standards_information/npsgs.aspx)) and Core Measures content into everyday nursing practice. The Joint Commission's National Patient Safety Goals initiatives are also set in **boldface type** for further emphasis.
- **Focus on Patient-Centered Care.** Patient-centered care is enhanced in the ninth edition in several ways. The ninth edition continues to use the term “patient” instead of “client” throughout. Although the use of these terms remains a subject of discussion among nursing educators and health care organizations, we have not defined the patient as a dependent person. Rather, the patient can be an individual, a family, or a group—all of whom have rights that are respected in a mutually trusting nurse-patient relationship. Most health care agencies and professional organizations use “patient” in their practice and publications, and most professional nursing organizations support the term.
- **Focus on Gender Considerations.** To increase our emphasis on patient-centered care, **Gender**

**Health Considerations** focus on important gender-associated information that impacts nursing care. Differences in patient values, preferences, and beliefs are addressed in **Chapter 73, Care of Transgender Patients**. Along with other individuals in the LGBTQ population, the health needs of transgender patients have gained national attention through their inclusion in *Healthy People 2020* and The Joint Commission's standards. This chapter, first introduced in the eighth edition, continues to provide tools to help prepare students and faculty to provide safe, evidence-based, patient-centered care for transgender patients who are considering or who have undergone the gender transition process.

- **Emphasis on Evidence-Based Practice.** The ninth edition focuses again on the importance of *using best current evidence in nursing practice* and how to locate and use this evidence to improve patient care. **Evidence-Based Practice boxes** offer a solid foundation in this essential component of nursing practice. Each box summarizes a useful research article and explains the implications of its findings for practice and further research, as well as a rating of the level of evidence based on a well-respected scale.
- **Focus on Quality Improvement.** The QSEN Institute emphasizes, and clinical practice agencies require, that all nurses have *quality improvement* knowledge, skills, and attitudes. To help prepare students for that role, this edition includes unique **Quality Improvement boxes**. Each box summarizes a quality improvement project published in the literature and discusses the implications of the project's success in improving nursing care. The inclusion of these boxes disseminates information and research and helps students understand that quality improvement begins at the bedside as the nurse identifies potential evidence-based solutions to practice problems.
- **Emphasis on Clinical Judgment.** Stressing the importance of clinical judgment skills via prioritization and delegation helps to best prepare students for practice and the NCLEX® Examination. As in the eighth edition, the ninth edition emphasizes the importance of nursing clinical judgment to make timely and appropriate decisions and prioritize care. To help achieve that focus, all-new case-based **Clinical Judgment Challenges** based primarily on QSEN core competencies are integrated throughout the text. Selected Clinical Judgment Challenges highlight ethical dilemmas, as well as delegation and supervision issues. These exercises provide clinical situations in which students can use evolving nursing clinical judgment to help prepare them for the fast-paced world of medical-surgical nursing. Suggested answer guidelines for these Clinical Judgment Challenges are provided on the companion Evolve website (<http://evolve.elsevier.com/Iggy/>).  
Dr. Christine Tanner's clinical judgment framework (Tanner, 2006) is integrated more deeply in this edition to help students apply selected concepts in the Disorders chapters. The components of this model match Tanner's terminology to each nursing process heading, thereby helping students use nursing judgment to provide safe, quality care by:

- Assessment: Noticing
- Analysis: Interpreting
- Planning: Implementation and Responding
- Evaluation: Reflecting
- **Emphasis on Preparation for the NCLEX® Examination.** An enhanced emphasis on the NCLEX Examination and consistency with the 2016 NCLEX-RN® test plan has been refined in this edition. The ninth edition emphasizes “readiness” — readiness for the NCLEX Examination, readiness for disaster and mass casualty events, readiness for safe drug administration, and readiness for the continually evolving world of genetics and genomics. An increased number of new **NCLEX Examination Challenges** are interspersed throughout the text to allow students the opportunity to practice test-taking and decision making. Answers to these Challenges are provided in the back of the book, and their rationales are provided on the Evolve website

(<http://evolve.elsevier.com/Iggy>). In a world that needs more nurses than ever before, it is more critical than ever that students be ready to pass the licensure examination on the first try. To help students and faculty achieve that outcome, **Learning Outcomes** at the beginning of each chapter continue to be consistent with the competencies outlined in the detailed 2016 NCLEX-RN® Test Plan. The ninth edition continues to include an innovative end-of-chapter feature called **Get Ready for the NCLEX® Examination!** This unique and effective learning aid consists of a list of **Key Points** *organized by Client Needs Category* as found in the NCLEX-RN Test Plan. Relevant QSEN and Nurse of the Future competency categories are identified for selected Key Points.

- **New Focus on Care Coordination and Transition Management.** This edition includes a priority focus on continuity of care via a Care Coordination and Transition Management section in each Disorders chapter. Literature continues to emphasize the importance of care coordination and transition management between acute care and community-based care (Lattavo, 2014). To help students prepare for this role, the ninth edition of our text provides coverage focusing on Home Care Management, Self-Management Education, and Health Care Resources.

## Clinical Currency and Accuracy

To ensure currency and accuracy, we listened to students and faculty who have used the previous editions, focusing on their impressions of and experiences with the book. A thorough literature search of current best evidence regarding nursing education and clinical practice helped us validate best practices and national health care trends to shape the focus of the ninth edition.

In-depth reviews of every chapter were commissioned and conducted by a dedicated panel of instructors and clinicians across the United States and Canada. A well-respected interventional radiologist ensured the accuracy of diagnostic testing procedures and associated patient care. The input from these experts guided us in revising chapters into their final format.

The results of these efforts are reflected in the ninth edition's:

- Strong, consistent focus on NCLEX-RN® Examination preparation, clinical judgment, safe patient-centered interprofessional care, pathophysiology, drug therapy, quality improvement, evidence-based clinical practice, and care coordination and transition management
- Foundation of relevant research and best practice guidelines
- Emphasis on critical “need to know” information that entry-level nurses must master to provide safe patient care

With the amount of information that continues to evolve in health care practice and education, it is easy for a book to become larger with each new edition. The reality is that today's nursing students have a limited time to absorb and begin to apply essential information to provide safe medical-surgical nursing care. Materials in this edition were carefully scrutinized to determine what the essential information was that students will actively *use* when providing safe, patient-centered, interprofessional, quality nursing care for adults.

## **Outstanding Readability**

Today's students must maximize their study time to read information and quickly understand it. The average reading level of today's learner is 10th to 11th grade. To achieve this level of readability without reducing the quality or depth of material that students need to know, this text uses a direct-address style (where appropriate) that speaks directly to the reader, and sentences are as short as possible without sacrificing essential content. The new edition has improved consistency of difficulty level from chapter to chapter. The result of our efforts is a medical-surgical text of consistently outstanding readability in which content is clear, focused, and accessible.

## Ease of Access

To make this text as easy to use as possible, we have maintained our approach of having smaller chapters of more uniform length. Consistent with our focus on “need to know” material, we chose exemplars to illustrate concepts of care versus detailing every health disorder. The focused ninth edition contains 74 chapters.

The overall presentation of the ninth edition has been updated, including more current, high-quality photographs for realism, as well as design changes to improve accessibility of material. The design of the ninth edition includes appropriate placement of display elements (e.g., figures, tables, and charts) for a chapter flow that enhances text reading without splintering content or confusing the reader. Additional ease-of-access features for this edition include tabbed markings for the answer key, glossary, and index for quick reference. To increase the smoothness of flow and reader concentration, side-turned tables and charts or tables and charts that span multiple pages are infrequently used. Drug tables have been reformatted for consistency and ease of use.

We have maintained the unit structure of previous editions, with vital body systems (cardiovascular, respiratory, and neurologic) appearing earlier in the book. In these three units we continue to provide complex care content in separate chapters that discuss managing critically ill patients with coronary artery disease, respiratory health problems, and neurologic health problems.

To break up long blocks of text and highlight key information, we continue to include streamlined yet eye-catching headings, bulleted lists, tables, charts, and in-text highlights. Key terms are in boldface color type and are defined in the text to foster the learning of need-to-know vocabulary. A glossary is located in the back of the book. Current bibliographic resources at the end of each chapter include research articles, nationally accepted clinical guidelines, and other sources of evidence when available for each chapter. Classic sources from before 2011 are noted with an asterisk (\*).

## A Patient-Centered, Interprofessional Collaborative Care Approach

As in previous editions, we maintain in this edition a collaborative, interprofessional care approach to patient care. In the real world of health care, nurses, patients, and all other providers who are part of the interprofessional team *share* responsibility for the management of patient problems. Thus we present information in a collaborative framework with an increased emphasis on the interprofessional nature of care. In this framework we make no *artificial* distinctions between medical treatment and nursing care. Instead, under each Interprofessional Collaborative Care heading we discuss how the nurse coordinates care and transition management while interacting with members of the interprofessional team.

This edition includes newly redesigned patient-centered Concept Maps that underscore the interprofessional care approach. Each Concept Map contains a case scenario. It then shows how a selected complex health problem is addressed. Each Concept Map spells out the steps of the nursing process and related concepts to illustrate the relationships among disease processes, priority patient problems, collaborative management, and more.

Although our approach has a focus on interprofessional care, the text is first and foremost a *nursing* text. We therefore use a nursing process approach as a tool to organize discussions of patient health problems and their management. Discussions of *major* health problems follow a full nursing process format using this structure:

[Health problem]

Pathophysiology

Etiology (and Genetic Risk when appropriate)

Incidence and Prevalence

Health Promotion and Maintenance (when appropriate)

Interprofessional Collaborative Care

Assessment: Noticing

Analysis: Interpreting

Planning and Implementation: Responding

[Collaborative Intervention Statement (based on priority patient problems)]

Planning: Expected Outcomes

Interventions

Care Coordination and Transition Management

Home Care Management

## Self-Management Education

### Health Care Resources

### Evaluation: Reflecting

The Analysis sections list the priority patient problems associated with major health problems and disorders. The ninth edition identifies priority collaborative patient problems or needs as the basis for the interprofessional plan of care. These collaborative patient problems pair more clearly with the title's focus than the previous use of NANDA-I language, which addresses primarily nursing-oriented patient problems. With its concentration on collaborative patient problems or needs, the ninth edition aligns with the language of clinical practice.

Discussions of less common or less complex disorders follow a similar, yet abbreviated, format: a discussion of the problem itself (including pertinent information on pathophysiology) followed by a section on interprofessional collaborative care of patients with the disorder. To demonstrate our commitment to providing the content foundational to nursing education, and consistent with the recommendations of Benner and colleagues through the Carnegie Foundation for the Future of Nursing Education, we highlight essential pathophysiologic concepts that are key to understanding the basis for collaborative management.

Integral to the interprofessional care approach is a narrative of who on the health care team is involved in the care of the patient. When a responsibility is primarily the nurse's, the text says so. When a decision must be made jointly by various members of the team (e.g., by the patient, nurse, health care provider, and physical therapist), this is clearly stated. When health care practitioners in different care settings are involved in the patient's care, this is stated.

## Organization

The 74 chapters of *Medical-Surgical Nursing: Concepts for Interprofessional Collaborative Care* are grouped into 16 units. Unit 1, Foundations for Medical-Surgical Nursing, provides fundamental information for the health care concepts incorporated throughout the text. Unit 2 consists of three chapters on concepts of emergency and trauma care and disaster preparedness.

Unit 3 consists of three chapters on the management of patients with fluid, electrolyte, and acid-base imbalances. Chapters 11 and 12 review key assessments associated with fluid and electrolyte balance, acid-base balance, and related patient care in a clear, concise discussion. The chapter on infusion therapy (Chapter 13) is supplemented with an online Fluids & Electrolytes Tutorial on the companion Evolve website.

Unit 4 presents the perioperative nursing content that medical-surgical nurses need to know. This content provides a solid foundation to help the student better understand the interprofessional care required for the surgical patient regardless of setting. Emphasis is placed on continuous assessment during the perioperative period to prevent complications and improve outcomes as we continue to see an increase in ambulatory care.

Unit 5 provides core content on health problems related to immunity. This material includes information on inflammation and the immune response, altered cell growth and cancer development, and interventions for patients with connective tissue disease, HIV infection, and other immunologic disorders, cancers, and infections.

The remaining 11 units cover medical-surgical content by body system. Each of these units begins with an Assessment chapter and continues with one or more Nursing Care chapters for patients with selected health problems, highlighted via exemplars, in that body system. This framework is familiar to students who learn the body systems in preclinical foundational science courses such as anatomy and physiology.

## Multinational, Multicultural, Multigenerational Focus

To reflect the increasing diversity of our society, *Medical-Surgical Nursing: Concepts for Interprofessional Collaborative Care* takes a multinational, multicultural, and multigenerational focus. Addressing the needs of both U.S. and Canadian readers, we have included examples of trade names of drugs available in the United States and in Canada. Drugs that are available only in Canada are designated with the Canadian maple leaf symbol(♣). When appropriate, we identify specific Canadian health care resources, including their websites. In many areas, Canadian health statistics are combined with those of the United States to provide an accurate “North American” picture.

To help nurses provide quality care for patients whose preferences, beliefs, and values may differ from their own, numerous **Cultural/Spiritual Considerations** and **Gender Health Considerations boxes** highlight important aspects of culturally competent care. [Chapter 73](#) is dedicated to the special health care needs of transgender patients.

Increases in life expectancy and aging of the baby-boom generation contribute to a steadily increasing older adult population. To help nurses care for this population, the ninth edition continues to provide thorough coverage of the care of older adults. [Chapter 3](#) offers content on the role of the nurse and interprofessional team in promoting health for older adults, with coverage of common health problems that older adults may experience, such as falls and inadequate nutrition. The text includes many **Nursing Focus on the Older Adult** charts. Laboratory values and drug considerations for older patients are also included throughout the book. Charts specifying normal physiologic changes to expect in the older population are found in each Assessment chapter, and **Considerations for Older Adults boxes** emphasize key points for the student to consider when caring for these patients. A new feature for the ninth edition is **Veterans' Health Considerations**. An increasing number of veterans of wars have multiple physical and mental health problems and require special attention in today's health care environment.

## Additional Learning Aids

The ninth edition continues to include a rich array of learning aids geared toward adult learners that help students quickly identify and understand key information while serving as study aids.

- Written in “patient-friendly” language, **Patient and Family Education: Preparing for Self-Management charts** provide teaching information that nurses must know to safely transition patients and their families back to the community environment of care.
- **Laboratory Profile charts** summarize important laboratory test information commonly used to evaluate health status. Information typically includes the normal ranges of laboratory values (including differences for older adults, when appropriate) and the significance of abnormal findings.
- The streamlined **Common Examples of Drug Therapy charts** summarize important information about commonly used drugs. Charts include U.S. and Canadian trade names for typically used drugs along with nursing implications and rationales (rationales are indicated by italic type).
- **Key Features charts** highlight the clinical signs and symptoms of important health problems based on pathophysiologic concepts.
- **Evidence-Based Practice boxes**, provided in many chapters, give synopses of recent nursing research articles and other scientific articles applicable to nursing. Each box provides a summary of the research, its level of evidence (LOE), and a brief commentary with implications for nursing practice and future research. This feature helps students identify strengths and weaknesses of evidence while seeing how research guides nursing practice.
- **Quality Improvement boxes** offer anecdotes of recent nursing articles that focus on this important QSEN competency and how nurses at the bedside have an active hand in shaping best practice. Similar to the Evidence-Based Practice boxes, these features provide a brief summary of the research with commentary on the implications for practice.
- As in the previous editions, **Home Care Assessment charts** serve as a convenient summary of essential assessment points for patients who need follow-up home health nursing care.
- Subtypes of **Clinical Judgment Challenges** (CJCs) emphasize the six QSEN core competencies: Patient-Centered Care, Teamwork and Collaboration, Evidence-Based Practice, Quality Improvement, Safety, and Informatics.

# An Integrated Multimedia Resource Based on Proven Strategies for Student Engagement and Learning

*Medical-Surgical Nursing: Concepts for Interprofessional Collaborative Care*, 9th edition, is the centerpiece of a comprehensive package of electronic and print learning resources that break new ground in the application of proven strategies for student engagement, learning, and evidence-based educational practice. This integrated multimedia resource actively engages the student in problem solving and practicing clinical decision-making skills.

## Resources for Instructors

For the convenience of faculty, all Instructor Resources are available on a streamlined, secure instructor area of the Evolve website (<http://evolve.elsevier.com/Iggy/>). Included among these Instructor Resources are the **TEACH for Nurses Lesson Plans**. These Lesson Plans focus on the most important content from each chapter and provide innovative strategies for student engagement and learning. This ninth edition *TEACH for Nurses* product incorporates numerous interprofessional activities that give students an opportunity to practice as an integral part of the health care team. Lesson Plans are provided for each chapter and are categorized into several parts:

Learning Outcomes

Teaching Focus

Key Terms

Nursing Curriculum Standards

QSEN

Concepts

BSN Essentials

Student Chapter Resources

Instructor Chapter Resources

Teaching Strategies

Additional Instructor Resources provided on the Evolve website include:

- A completely revised, updated, high-quality **Test Bank** consisting of more than 1750 items, both traditional multiple-choice and NCLEX-RN® “alternate-item” types. Each question is coded for correct answer, rationale, cognitive level, NCLEX Integrated Process, NCLEX Client Needs Category, and new key words to facilitate question searches. Page references are provided for Remembering (Knowledge)-level and Understanding (Comprehension)-level questions. (Questions at the Applying [Application] and above cognitive level require the student to draw on understanding of multiple or broader concepts not limited to a single textbook page, so page cross references are not provided for these higher-level critical thinking questions.) The Test Bank is provided in the Evolve Assessment Manager and in ExamView and ParTest formats.
- An electronic **Image Collection** containing all images from the book (approximately 550 images), delivered in a format that makes incorporation into lectures, presentations, and online courses easier than ever.
- **PowerPoint Presentations**—a completely revised collection of more than 2000 slides corresponding to each chapter in the text and highlighting key materials with integrated images

and Unfolding Case Studies. Audience Response System Questions (three discussion-oriented questions per chapter for use with iClicker and other audience response systems) are included in these slide presentations. Answers and rationales to the Audience Response System Questions and Unfolding Case Studies are found in the “Notes” section of each slide.

Also available for adoption and separate purchase:

- Corresponding chapter-by-chapter to the textbook, *Elsevier Adaptive Quizzing (EAQ)* integrates seamlessly into your course to help students of all skill levels focus their study time and effectively prepare for class, course exams, and the NCLEX® certification exam. *EAQ* is comprised of a bank of high-quality practice questions that allows students to advance at their own pace—based on their performance—through multiple mastery levels for each chapter. A comprehensive dashboard allows students to view their progress and stay motivated. The educator dashboard, grade book, and reporting capabilities enable faculty to monitor the activity of individual students, assess overall class performance, and identify areas of strength and weakness, ultimately helping to achieve improved learning outcomes.
- *Simulation Learning System (SLS) for Medical-Surgical Nursing* is an online toolkit designed to help you effectively incorporate simulation into your nursing curriculum, with scenarios that promote and enhance the clinical decision-making skills of students at all levels. It offers detailed instructions for preparation and implementation of the simulation experience, debriefing questions that encourage critical thinking, and learning resources to reinforce student comprehension. Modularized simulation scenarios correspond to Elsevier's leading medical-surgical nursing texts, reinforcing students' classroom knowledge base, synthesizing lecture and clinicals, and offering the remediation content that is critical to debriefing.

## Resources for Students

Resources for students include a revised, updated, and retitled Study Guide, a Clinical Companion, Elsevier Adaptive Learning (EAL), Virtual Clinical Excursions (VCE), and Evolve Learning Resources.

The *Study Guide* has been completely revised and updated and features a fresh emphasis on clinical decision making, priorities of delegation, management of care, and pharmacology.

The pocket-sized *Clinical Companion* is a handy clinical resource that retains its easy-to-use alphabetical organization and streamlined format. It includes “Critical Rescue,” “Drug Alert,” and “Action Alert” highlights throughout based on the Nursing Safety Priority features in the textbook. National Patient Safety Goals highlights have been expanded as a QSEN feature, focusing on one of six QSEN core competencies while still underscoring the importance of observing vital patient safety standards. This “pocket-sized Iggy” has been tailored to the special needs of students preparing for clinicals and clinical practice.

Corresponding chapter-by-chapter to the textbook, *Elsevier Adaptive Learning (EAL)* combines the power of brain science with sophisticated, patented Cerego algorithms to help students to learn faster and remember longer. It's fun, it's engaging, and it constantly tracks and adapts to student performance to deliver content precisely when it's needed to ensure core information is transformed into lasting knowledge.

*Virtual Clinical Excursions*, featuring an updated and easy-to-navigate “virtual” clinical setting, is once again available for the eighth edition. This unique learning tool guides students through a virtual clinical environment and helps them “learn by doing” in the safety of a “virtual” hospital.

Also available for students is a dynamic collection of Evolve Student Resources, available at <http://evolve.elsevier.com/Iggy/>. The Evolve Student Resources include the following:

- Review Questions for the NCLEX® Examination
- Answer Guidelines for NCLEX® Examination and Clinical Judgment Challenges
- Interactive Case Studies
- Concept Maps (digital versions of the 12 Concept Maps from the text)
- Concept Map Creator (a handy tool for creating customized Concept Maps)
- Fluid & Electrolyte Tutorial (a complete self-paced tutorial on this perennially difficult content)
- Key Points (downloadable expanded chapter reviews for each chapter)
- Audio Glossary

- Audio Clips and Video Clips
- Content Updates

In summary, *Medical-Surgical Nursing: Concepts for Interprofessional Collaborative Care*, 9th edition, together with its fully integrated multimedia ancillary package, provides the tools you will need to equip nursing students to meet the opportunities and challenges of nursing practice both now and in an evolving health care environment. The only elements that remain to be added to this package are those that you uniquely provide—your passion, your commitment, your innovation, *your nursing expertise*.

*Donna D. Ignatavicius*

*M. Linda Workman*

*Cherie R. Rebar*

---

## Dedication

---

*To all the nursing educators who are passionate about teaching, and to all the nursing students who are passionate about learning.*

*To my husband, Charles, who has endured countless hours of loneliness while I've worked on this project, and to Stephanie, my daughter, who has educated me about the special needs of the LGBTQ community. Thank you!*

### **DONNA**

*To students everywhere.*

*To John, still my one.*

### **LINDA**

*To Michael...you are my everything.*

*To Gillian...all I do is for you, my beautiful girl.*

*To Mom and Dad...thank you for roots and wings.*

*To Donna and Linda...thank you for believing in me!*

*To our Elsevier team...thank you for your dedication!*

*To Carolyn, Laura, Nicole, Tracy, and Tracie...my kindred spirits.*

*To all who study, teach, and practice nursing...you are my heroes.*

### **CHERIE**

---

## About the Authors

---

**Donna D. Ignatavicius** received her diploma in nursing from the Peninsula General School of Nursing in Salisbury, Maryland. After working as a charge nurse in medical-surgical nursing, she became an instructor in staff development at the University of Maryland Medical Center. She then received her BSN from the University of Maryland School of Nursing. For 5 years she taught in several schools of nursing while working toward her MS in Nursing, which she received in 1981. Donna then taught in the BSN program at the University of Maryland, after which she continued to pursue her interest in gerontology and accepted the position of Director of Nursing of a major skilled-nursing facility in her home state of Maryland. Since that time, she has served as an instructor in several associate degree nursing programs. Through her consulting activities, faculty development workshops, and international nursing education conferences (such as Boot Camp for Nurse Educators<sup>®</sup>), Donna is nationally recognized as an expert in nursing education. She is currently the President of DI Associates, Inc. (<http://www.diassociates.com/>), a company dedicated to improving health care through education and consultation for faculty. In recognition of her contributions to the field, she was inducted as a charter Fellow of the prestigious Academy of Nursing Education in 2007 and received her Certified Nurse Educator credential in 2016.

**M. Linda Workman**, a native of Canada, received her BSN from the University of Cincinnati College of Nursing and Health. After serving in the U.S. Army Nurse Corps and working as an Assistant Head Nurse and Head Nurse in civilian hospitals, Linda earned her MSN from the University of Cincinnati College of Nursing and a PhD in Developmental Biology from the

University of Cincinnati College of Arts and Sciences. Linda's 30-plus years of academic experience include teaching at the diploma, associate degree, baccalaureate, master's, and doctoral levels. Her areas of teaching expertise include medical-surgical nursing, physiology, pathophysiology, genetics, oncology, and immunology. Linda has been recognized nationally for her teaching expertise and was inducted as a Fellow into the American Academy of Nursing in 1992. She received Excellence in Teaching awards at the University of Cincinnati and at Case Western Reserve University. She is a former American Cancer Society Professor of Oncology Nursing and held an endowed chair in oncology for 5 years. She has authored several additional textbooks and serves a consultant for major universities.

**Cherie R. Rebar** earned her first degree in education from Morehead State University in Morehead, Kentucky. She returned to school shortly thereafter to earn an Associate of Science degree in Nursing from Kettering College. Cherie's years of clinical practice includes medical-surgical, acute care, ear/nose/throat surgery and allergy, community, and psychiatric-mental health nursing. After earning her MSN and MBA from the University of Phoenix, Cherie combined her love of nursing and education and began teaching Associate and Baccalaureate Completion nursing students at Kettering College while pursuing her Family Nurse Practitioner post-Masters certificate from the University of Massachusetts Boston. Over a decade, Cherie served in numerous leadership positions at Kettering College, including Chair of AS, BSN Completion, and BSN Prelicensure Nursing Programs, as well as Director of the Division of Nursing. She currently is a Professor of Nursing at Wittenberg University, an Affiliate Faculty Member at Indiana Wesleyan University, a Psychiatric-Mental Health Nurse Practitioner Intern through the University of Cincinnati College of Nursing, and a frequent presenter at national nursing conferences. Cherie serves as a consultant with nursing programs and faculty, contributes regularly to professional publications, and holds student success at the heart of all she does.

---

# Acknowledgments

---

Publishing a textbook and ancillary package of this magnitude would not be possible without the combined efforts of many people. With that in mind, we would like to extend our deepest gratitude to many people who were such an integral part of this journey.

For the ninth edition, we welcomed section editor Nicole M. Heimgartner to assist in our revision process. Nicole has worked with our team in contributor and ancillary roles over the past editions. Within this edition, she updated and reviewed selected chapters of the text to provide her expertise.

Our contributing authors once again provided excellent manuscripts to underscore the clinical relevancy of this publication. We give special gratitude to Deanne Blach, who revised our Concept Maps, and to Dr. Richard Lintner, who provided expertise in interventional radiologic procedures and associated care. Our reviewers—expert clinicians and instructors from around the United States and Canada—provided invaluable suggestions and encouragement throughout the development of book.

The staff of Elsevier has, as always, provided us with meaningful guidance and support throughout every step of the planning, writing, revision, and production of the ninth edition. Executive Content Strategist Lee Henderson worked closely with us from the early stages of this edition to help us hone and focus our revision plan while coordinating the project from start to finish. Senior Content Development Specialist Laura Goodrich then worked with us to bring the logistics of the ninth edition from vision to publication. Laura also held the reins of our complex ancillary package and worked with a gifted group of writers and content experts to provide an outstanding library of resources to complement and enhance the text.

Senior Project Manager Jodi Willard was, as always, an absolute joy with whom to work. If the mark of a good editor is that his or her work is invisible to the reader, then Jodi is the consummate editor. Her unwavering attention to detail, flexibility, and conscientiousness helped to make the ninth edition consistently readable, while making the production process incredibly smooth. Also, a special thanks to Publishing Services Manager Jeff Patterson.

Designer Brian Salisbury is responsible for the beautiful cover and the new interior design of the ninth edition. Brian's work on this edition has cast important features in exactly the right light, contributing to the readability and colorful beauty of this edition.

Our acknowledgments would not be complete without recognizing our dedicated team of Educational Solutions Consultants and other key members of the Sales and Marketing staff who helped to put this book into your hands.

# Guide to Special Features

---

## **Best Practice for Patient Safety and Quality Care**

Acute Adrenal Insufficiency, 1253

AIDS, Infection Control for Home Care, 357

Alteplase, Nursing Interventions During and After Administration, 936

Altitude-Related Illnesses, 146

Alzheimer's Disease, Promoting Communication, 863

Anaphylaxis, 365

Anesthesia, Spinal and Epidural, Recognizing Serious Complications, 275

Anticoagulant Therapy, 744

Anticoagulant, Fibrinolytic, or Antiplatelet Therapy and Prevention of Injury, 623

Arteriovenous Fistula or Arteriovenous Graft, 1415

Artificial Airway Suctioning, 541

Aspiration Prevention During Swallowing, 543

Autologous Blood Salvage and Transfusion, Intraoperative, 264

Autonomic Dysreflexia: Immediate Interventions, 898

Benzodiazepine Overdose, 281

Breast Mass Assessment, 1445

Breast Reconstruction, Postoperative Care, 1451

Breast Self-Examination, 1444

Burn Patient and Fluid Resuscitation, 495

Burns, Emergency Management, 489

Cancer Pain Management with Intrathecal Pump, 62

Carpal Tunnel Syndrome Prevention, 1058

Catheter-Associated Urinary Tract Infections (CAUTI), 1356

Cervical Discectomy and Fusion, 910

Chest Discomfort, 775

Chest Tube Drainage System Management, 592

Chronic Diarrhea, Special Skin Care, 1142

Cognition Assessment, 847

Colonoscopy, 1073

Colorectal Cancer Screening Recommendations, 1128

Communicating With Patients Unable To Speak, 550

Continuous Passive Motion (CPM) Machine, 316

Contractures, Positioning to Prevent, 503

Dark Skin, Assessing Changes, 444

Death Pronouncement, 114

Dehydration, 169

Diagnostic Testing, Precautions for Use of Iodine-Based or Gadolinium Contrast, 852

Diarrhea, 19

Driver Safety Improvement in Older Adults, 34

Dysrhythmias, 672

Ear Irrigation, 994

Eardrops Instillation, 993

Emergency Department and Patient and Staff Safety, 120

Endocrine Testing, 1243

Energy Conservation, 826

Esophageal Surgery and Nasogastric Tube, 1100

Extremity Fracture, 1038

Eyedrops Instillation, 966

Fall Prevention in Older Adults, 41

Feeding Tube Maintenance, 1222

Fires in Health Care Facility, 150

Fluid Volume Management, 1405

Fundoplication Procedures and Postoperative Complications, 1094

Gait Training, 95

Gastrointestinal Health History, 1065

Thrombocytopenia, 825

Thyroid Storm, 1270

Total Parenteral Nutrition, Care and Maintenance, 1224

Tracheostomy Care, 542

Transfusion in Older Adults, 834

Transfusion Therapy, 833

Transurethral Resection of the Prostate, 1480

Tube-Feeding Care and Maintenance, 1221

Urinary Incontinence, Bladder Training and Habit Training to Reduce, 1351

Venous Catheters, Placement of Short Peripheral, 203

Vertebroplasty and Kyphoplasty, 1050

Viral Hepatitis Prevention in Health Care Workers, 1182

Vision Reduction, 975

Wandering, Prevention in Hospitalized Patients, 864

Wound Care, Perineal, 1133

Wound Monitoring, 460

## Common Examples of Drug Therapy

Acute Coronary Syndrome (Nitrates, Beta Blockers, Antiplatelets), 776

Adrenal Gland Hypofunction, 1255

Antidysrhythmic Medication, 677

Asthma, 569

Biologic Disease-Modifying Antirheumatic Drugs (DMARDs), 370

Biological Response Modifiers for Rheumatoid Arthritis and Other Connective Tissue Diseases, 323

Burn Wounds, 501

Diabetes Mellitus, 1292

Glaucoma, 976

HIV Infection, 351

Hypertension Management, 725

Hyperthyroidism, 1268

Hypovolemic Shock, 759

Inhalation Anthrax, Prophylaxis and Treatment, 612

Intravenous Vasodilators and Inotropes, 783

Kidney Disease, 1410

Nausea and Vomiting, Chemotherapy-Induced, 399

Osteoporosis, 1021

Pain, Postoperative, 284

Peptic Ulcer Disease, 1106

Plaque Psoriasis, 466

Pulmonary Embolism, 621

Transplant Rejection, 302

Tuberculosis, First-Line Treatment, 608

Urinary Incontinence, 1350

Urinary Tract Infections, 1360

## Concept Map

Benign Prostatic Hyperplasia, 1478

Chronic Kidney Disease, 1406

Chronic Obstructive Pulmonary Disease, 575

Cirrhosis, 1176

Community-Acquired Pneumonia (CAP), 602

Diabetes Mellitus Type 2, 1290

Hypertension, 724

Hypovolemic Shock, 757

Multiple Sclerosis, 893

Pressure Injury, 456

Primary Open-Angle Glaucoma, 973

## Key Features

Acidosis, 193

Acute Leukemia, 819

Adrenal Insufficiency, 1254

AIDS, 346

Alkalosis, 196

Alzheimer's Disease, 860

Anaphylaxis, 364

Anemia, 814

Angina and Myocardial Infarction, 773

Asthma Control Levels, 566

Asthma Control, Step System for Medication Use, 566

Autonomic Dysreflexia, 896

Bowel Obstructions, Small and Large, 1123

Brain Tumors, Common, 951

Celiac Disease, 1164

Cervical Discectomy and Fusion Complications, 910

Cholecystitis, 1193

Compartment Syndrome, 1034

Cor Pulmonale, 574

Diabetes Insipidus, 1250

Esophageal Tumors, 1096

Fluid Overload, 172

Gastric Cancer, Early Versus Advanced, 1116

Gastritis, 1105

Gastroesophageal Reflux Disease, 1088

Gastrointestinal Bleeding, Upper, 1109

Guillain-Barré Syndrome, 914

Heat Stroke, 134

Hiatal Hernias, 1093

Hypercortisolism (Cushing's Disease/Syndrome), 1257  
Hyperthyroidism, 1265  
Hypothermia, 143  
Hypothyroidism, 1271  
Infective Endocarditis, 711  
Inhalation Anthrax, 612  
Intracranial Pressure (ICP), Increased, 936  
Kidney Disease, Severe Chronic and End-Stage, 1403  
Liver Trauma, 1186  
Meningitis, 881  
Migraine Headaches, 874  
Multiple Sclerosis, 889  
Myasthenia Gravis, 917  
Nephrotic Syndrome, 1379  
Oral Cancer, 1080  
Osteomyelitis, Acute and Chronic, 1023  
Pancreatic Cancer, 1206  
Pancreatitis, Chronic, 1203  
Peripheral Arterial Disease, Chronic, 732  
Peritonitis, 1145  
Pituitary Hyperfunction, 1248  
Pituitary Hypofunction, 1246  
Polycystic Kidney Disease, 1381  
Pressure Injuries, 452  
Pulmonary Edema, 702  
Pulmonary Emboli: Fat Embolism Versus Blood Clot Embolism, 1034  
Pulmonary Embolism, 618  
Pyelonephritis, Acute, 1374  
Pyelonephritis, Chronic, 1374  
Renovascular Disease, 1384  
Rheumatoid Arthritis, 318

Shock, 752

Skin Conditions, Inflammatory, 463

Skin Infections, Common, 467

Stroke Syndromes, 933

Strokes, Left and Right Hemisphere, 933

Sustained Tachydysrhythmias and Bradydysrhythmias, 672

Systemic Lupus Erythematosus (SLE) and Systemic Sclerosis (SSc), 326

Transient Ischemic Attack, 928

Traumatic Brain Injury, Mild, 945

Ulcers, Lower-Extremity, 734

Uremia, 1398

Urinary Tract Infection, 1358

Valvular Heart Disease, 706

Ventricular Failure, Left, 695

Ventricular Failure, Right, 696

## Evidence-Based Practice

- Ambulation and Ambulation Protocol Effectiveness, 24
- Benign Prostatic Hyperplasia Surgery and Quality of Life, 1481
- Bone Loss, Risk Factors in Men, 1017
- Central Venous Access Device, Best Method for Securing, 213
- Chronic Pain Management in Older Adults, 56
- Dementia Caregivers and Telephone Support, 867
- End-of-Life Care for Prisoners, 106
- Hearing Loss in Combat, 997
- Heat Stroke and On-Site Treatment, 135
- Hepatitis C, Care of Military Veterans, 1183
- Hip Fracture, Resources for Caregivers, 1049
- HIV Self-Management and mHealth Technology Among African-American Women, 345
- Hysterectomy and Sexuality, 1462
- Noninvasive Ventilation (NIV) Effectiveness, 535
- Opioid Usage, 279
- Oral Care, Preoperative and Postsurgical Outcomes, 1082
- Preoperative Assessment, 239
- Pressure Injury Reduction Using Skin Integrity Care Bundle, 449
- Sickle Cell Disease and Self-Care in Young Adults, 813
- Traumatic Brain Injury (TBI) and Mannitol to Reduce Mortality, 948
- Veterans with Dementia, Reducing Hospital Admissions and Emergency Department Visits, 126

## **Focused Assessment**

AIDS, 356

Diabetic Foot, 1306

Diabetic Patient, Home or Clinic Visit, 1318

Hearing, 998

Hypophysectomy for Hyperpituitarism, 1249

Infection Risk, 821

Kidney Transplant, 1425

Oral Cancer and the Postoperative Older Adult, 1082

Pneumonia Recovery, 605

Postanesthesia Care Unit Discharge to Medical-Surgical Unit, 272

Preoperative Patient, 238

Pressure Injuries, 461

Seizures, Nursing Observations and Documentation, 878

Sexually Transmitted Infection, 1507

Thyroid Dysfunction, 1274

Total Abdominal Hysterectomy, Postoperative Care, 1462

Tracheostomy, 542

Urinary Incontinence, 1346

## Home Care Assessment

Amputation, Lower-Extremity, 1056  
Breast Cancer Surgery Recovery, 1453  
Cataract Surgery, 971  
Chronic Obstructive Pulmonary Disease, 581  
Colostomy, 1134  
Heart Failure, 704  
Inflammatory Bowel Disease, 1158  
Laryngectomy, 554  
Myocardial Infarction, 790  
Peripheral Vascular Disease, 737  
Pulmonary Embolism, 624  
Sepsis Risk, 766  
Ulcer Disease, 1115

## Laboratory Profile

Acid-Base Assessment, 188

Acid-Base Imbalances (Uncompensated), 193

Adrenal Gland Assessment, 1255

## UNIT I

# Foundations for Medical-Surgical Nursing

### OUTLINE

---

Chapter 1 Overview of Professional Nursing Concepts for Medical-Surgical Nursing

Chapter 2 Overview of Health Concepts for Medical-Surgical Nursing

Chapter 3 Common Health Problems of Older Adults

Chapter 4 Assessment and Care of Patients With Pain

Chapter 5 Principles of Genetics and Genomics for Medical-Surgical Nursing

Chapter 6 Rehabilitation Concepts for Chronic and Disabling Health Problems

Chapter 7 End-of-Life Care Concepts

## CHAPTER 1

# Overview of Professional Nursing Concepts for Medical-Surgical Nursing

Donna D. Ignatavicius

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- PATIENT-CENTERED CARE
- SAFETY
- TEAMWORK AND INTERPROFESSIONAL COLLABORATION
- EVIDENCE-BASED PRACTICE
- QUALITY IMPROVEMENT
- INFORMATICS AND TECHNOLOGY
- CLINICAL JUDGMENT
- ETHICS
- HEALTH CARE ORGANIZATIONS
- HEALTH CARE DISPARITIES

## LEARNING OUTCOMES

### **Safe and Effective Care Environment**

1. Briefly describe the scope of medical-surgical nursing.
  2. Explain the current priority focus on patient SAFETY and quality of care.
  3. Identify the purpose and function of the Rapid Response Team (RRT).
  4. Differentiate the six core Quality and Safety Education for Nurses (QSEN) competencies that interprofessional health care team members need to provide safe, PATIENT-CENTERED CARE.
  5. Identify six major ETHICS principles that help guide decision making and CLINICAL JUDGMENT.
  6. Communicate patient values, preferences, and expressed needs to other members of the INTERPROFESSIONAL health care team for effective COLLABORATION.
  7. Outline the five rights of the delegation and supervision process.
  8. Describe the SBAR procedure for successful hand-off communication in health care agencies.
  9. Describe the nurse's role in the systematic QUALITY IMPROVEMENT process.
0. Identify three ways that INFORMATICS AND TECHNOLOGY are used in health care.
1. Outline the major differences in types of HEALTH CARE ORGANIZATIONS.

### **Psychosocial Integrity**

2. Explain why many minority populations such as members of the LGBTQ community are at risk for HEALTH CARE DISPARITIES.
3. Identify the role of the nurse when communicating with LGBTQ patients.

Medical-surgical nursing, sometimes called *adult health nursing*, is a specialty practice area in which nurses promote, restore, or maintain optimal health for patients from 18 to older than 100 years of age (Academy of Medical-Surgical Nurses [AMSN], 2012). A separate chapter on care of older adults is part of this textbook because the majority of medical-surgical patients in most health care settings are older than 65 years (see [Chapter 3](#)). In addition, special features throughout the book highlight the unique needs of older adults.

To be consistent with the most recent health care literature, the authors use the term *patient* rather than *client* (except in NCLEX Examination Challenge questions where *client* is used to reflect that licensure examination). To be patient-centered, be sure to refer to individuals according to the policy of the health care organization and the individual's preference. The *family* refers to the patient's relatives and significant others in the patient's life whom the patient identifies and values as important.

Medical-surgical nursing is practiced in many types of settings, such as acute care agencies, skilled nursing facilities, ambulatory care clinics, and the patient's home, which could be either a single residence or group setting such as an assisted living facility. The role of the nurse in these settings includes care coordinator and transition manager, caregiver, patient educator, leader, and patient and family advocate. To function in these various roles, nurses need to have the knowledge, skills, attitudes, and abilities (KSAs) to keep patients and their families safe.

This chapter reviews 10 nursing concepts needed for effective professional practice. Six of the 10 concepts are Quality and Safety Education for Nurses core competencies. The additional four concepts are also essential to nursing practice and are typically introduced in foundations or fundamentals of nursing courses. For more information about these concepts, see your foundations or fundamentals of nursing textbook.

## Quality and Safety Education for Nurses Core Competencies

The Institute of Medicine (IOM, now the National Academy of Medicine [NAM]), a highly respected U.S. organization that monitors health care and recommends health policy, published many reports during the past 20 years suggesting ways to improve patient safety and quality care. One of its reports, *Health Professions Education: A Bridge to Quality*, identified five broad core competencies for health care professionals to ensure patient safety and quality care (Institute of Medicine [IOM], 2003). All of these competencies are interrelated and include:

- Provide *patient-centered care*.
- *Collaborate* with the interdisciplinary health care team.
- Implement *evidence-based practice*.
- Use *quality improvement* in patient care.
- Use *informatics* in patient care.

Several years later, the QSEN initiative, now called the *QSEN Institute*, validated the IOM (NAM) competencies for nursing practice and added *safety* as a sixth competency to emphasize its importance. More information about the QSEN Institute can be found on its website at [www.qsen.org](http://www.qsen.org).

In addition to emphasizing these six QSEN competency concepts, the authors selected four professional nursing concepts to integrate throughout the text. This chapter reviews these 10 nursing concepts, and includes the concept definition, scope, and attributes (characteristics) for each one. Each concept review then ends with examples of how the concept is used in practice. The 10 concepts reviewed in this chapter are:

- Patient-centered care
- Safety
- Teamwork and interprofessional collaboration
- Evidence-based practice
- Quality improvement
- Informatics and technology
- Clinical judgment
- Ethics
- Health care organizations
- Health care disparities

## Patient-Centered Care

### Definition of Patient-Centered Care

To be competent in patient-centered, the nurse recognizes “the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for [the] patient's preferences, values, and needs” (Quality and Safety Education for Nurses [QSEN], 2011). Implied in this widely used definition is the need for the nurse to be culturally competent when caring for diverse patients and their families. The Joint Commission, a major accrediting organization for health care agencies, uses the term *family-centered care* to emphasize the importance of including the patient's support system as part of interprofessional collaboration.

### Scope of Patient-Centered Care

Patient-centered care has been a focus of health professions' education and research for several decades. Prior to this period of time, patients in inpatient facilities and their families often had little to no input into their health care. Many health care professionals believed that they were better-prepared than patients to make care decisions and did not consistently include the patient and family in this process. The Joint Commission and other organizations called for the rights of patients or their designees (e.g., family members, guardians) to make their own informed decisions. The IOM (now NAM) further emphasized the need for all health care agencies to place patients and their families at the center of the interprofessional team to make mutual decisions based on patient preferences and values.

### Attributes of Patient-Centered Care

The attributes, or characteristics, of patient-centered care were identified by researchers as a result of a classic medical study (Frampton, et al., 2008). These attributes include:

- Respect for patients' values, preferences, and expressed needs
- Coordination and integration of care
- Information, communication, and education
- Physical comfort
- Emotional support and alleviation of fear and anxiety
- Involvement of family and friends
- Transition and continuity
- Access to care

Showing respect for the patient and family's preferences and needs is essential to ensure a holistic or “whole person” approach to care. To help illustrate the importance of culture and spirituality, and prepare nursing students for a multicultural society, this text includes *Cultural/Spiritual Considerations* features to highlight this important information. Additional features that focus on the culture and needs of special populations include:

- *Considerations for Older Adults*
- *Gender Health Considerations*
- *Veterans' Health Considerations*

Canadian nursing practice includes culture from a safety perspective. Promoting safety requires nursing practice that respects and nurtures the unique and dynamic characteristics of patients and families to meet their needs, preferences, values, and rights (Doane & Varcoe, 2015). Cultural safety is part of relational inquiry and practice and is valued in Canada as a major attribute in professional nursing.

## Examples of Context of Patient-Centered Care to Nursing and Health Care

Patient-centered care is a major emphasis in all health care settings. For example, many health care organizations integrate complementary and alternative medicine (CAM) as a supplement to traditional health care to meet the preferences of patients and their families. This *integrative care* model is in response to the increasing use of these therapies by consumers to maintain health and help manage chronic health issues, such as joint pain, back pain, and anxiety or depression (Halm & Katseres, 2015). Integrative care reflects nursing theories of caring, compassion, and holism to *respect the diverse preferences and needs* of patients and their families. Examples of these therapies are listed in Table 1-1. Specific complementary and integrative therapies are highlighted throughout this text as appropriate.

**TABLE 1-1**  
**Examples of Integrative (Complementary and Alternative) Therapies Used in Health Care Organizations**

<ul style="list-style-type: none"> <li>• Pet therapy</li> <li>• Massage therapy</li> <li>• Guided imagery</li> <li>• Biofeedback</li> <li>• Exercise and fitness programs</li> <li>• Nutritional supplements</li> </ul>	<ul style="list-style-type: none"> <li>• Massage therapy</li> <li>• Health-focused television</li> <li>• Music therapy</li> <li>• Acupuncture</li> <li>• Acupressure</li> <li>• Disease management programs</li> </ul>
---	--

Patients want to have their *basic physical care and comfort needs* met. For example, patients in a variety of settings often experience acute and/or chronic pain. Nurses continually assess the patient's pain management needs and implement interventions to relieve or reduce pain in a timely manner. Chapter 4 describes pain assessment and interventions in detail.

After discharge from a hospital or other inpatient setting, patients also have a need for individualized coordinated care. Many patients discharged from a hospital, especially older adults, are readmitted within 30 days at a cost of more than \$4 billion due to lack of coordinated care (Polster, 2015; Stubenrauch, 2015). **Care coordination** is the deliberate organization of and communication about patient care activities between two or more members of the health care team (including the patient) to facilitate appropriate and continuous health care to meet that patient's needs (Lamb, 2014). One of the most important members of the health care team who assists with care coordination is the case manager (CM) or discharge planner, who is typically a nurse or social worker in health care agencies.

The purpose of the **case management** process is to provide quality and cost-effective services and resources to achieve positive patient outcomes. In collaboration with the nurse, the CM coordinates inpatient and community-based care before discharge from a hospital or other facility. Part of that process may involve communicating with other CMs who are employed by third-party health care payers (e.g., Medicare) to keep patients from being readmitted to the hospital.

In addition to coordination and access of care following hospital discharge, transitions of care (also called transition management) are essential to prevent adverse events and hospital readmissions. **Transition management** involves safe and seamless movement of patients among health care settings, health care providers, and the community for ongoing care to meet patient needs. The Joint Commission (2013) recommends these components for effective care coordination and transition management:

- Understandable discharge instructions for the patient and family
- Explanation of self-care activities
- Ongoing or emergency care information
- List of community and outpatient (ambulatory care) resources and referrals
- Knowledge of the patient's language, culture, and health literacy
- Medication reconciliation (also a Joint Commission National Patient Safety Goal)

**Medication reconciliation** is a formal evaluative process in which the patient's actual current medications are compared to his or her prescribed medications at time of admission, transfer, or discharge to identify and resolve discrepancies. The types of information that clinicians use to reconcile medications include drug name, dose, frequency, route, and purpose. This comparison addresses duplications, omissions, and interactions and the need to continue current medications.

Medication discrepancies can cause negative patient outcomes, including rehospitalizations for medical complications. A quality improvement project by [Ruggerio et al. \(2015\)](#) demonstrated the effectiveness of a medication reconciliation process by increasing the accuracy of information provided to patients at discharge in a large metropolitan hospital system (see the [Quality Improvement](#) box).

## Quality Improvement QSEN

### Improving Medication Reconciliation With a Nurse-Led Protocol

Ruggerio, J., Smith, J., Copeland, J., & Boxer, B. (2015). Discharge time out: An innovative nurse-driven protocol for medication reconciliation. *MEDSURG Nursing*, 24(3), 165–172.

Medication reconciliation is a requirement for agencies accredited by The Joint Commission to ensure consistency between admission medications and those prescribed at discharge. A retrospective medical record review by nurse leaders at a large East Coast metropolitan hospital found a 77.9% discrepancy rate between admission and discharge medication reconciliation forms. Physician staff, most often residents, completed these forms before patient discharge. Three problem areas were identified: medication omissions, changes in doses at discharge without prescriptions, and omission of core measures requirements.

An oversight interprofessional team was formed to decrease these problems; the Define Measure Analyze Improve Control (DMAIC) methodology was used to guide the improvement process. A decision was made to transfer the responsibility of medication reconciliation from physician staff to nursing staff. All nurses on the pilot unit were educated on how to complete the reconciliation forms accurately during a patient discharge time-out. As a result of implementation and follow-up for 20 months, the discharge discrepancies decreased from 77.9% to 21.2%. These data showed the benefit of the new nurse-led protocol for discharge medication reconciliation.

#### Commentary: Implications for Practice and Research

In 2011 the Institute of Medicine (now the National Academy of Medicine) called on nurses to lead and coordinate collaborative improvement initiatives to transform their practice and the health care systems in which they work. This project was consistent with this goal by empowering nurses to identify and improve problems that affect patient safety. But the limitation of this project is that it is unknown whether the decrease in errors was the result of awareness of the issue or if using nurses rather than medical residents improved accuracy. More research is needed to answer this question.

In this text the authors use the heading *Care Coordination and Transition Management* to describe the specific activities, including medication reconciliation and discharge health teaching that are essential for patients with selected health problems and their families. Nurses play a major role in coordinating this care with the interprofessional team to promote safe, quality care.

## Safety

### Definition of Safety

Safety is the ability to keep the patient and staff free from harm and minimize errors in care. Health care errors by providers, nurses, and other professionals have been widely reported for the past 20 years. Many of these errors resulted in patient injuries or deaths, and increased health care costs. A number of national and international organizations implemented new programs and standards to combat this growing problem.

### Scope of Safety

Safety is essential for patients, staff members, and health care organizations. Although most literature discusses safety for patients, safety for members of the staff and interprofessional team is equally important. The scope of safety can be described as *unsafe*, possibly causing harm or even death, or *safe* to prevent harm or negative outcomes. Nurses have accountability for and play a key role in promoting safety and preventing errors, including “missed nursing care,” the necessary care that should have been provided by one or more nurses.

*Patient harm and errors* generally occur as a result of (Benner et al., 2010):

- Lack of clear or adequate communication among patient, family, and members of the interprofessional health care team
- Lack of attentiveness and patient monitoring
- Lack of clinical judgment
- Inadequate measures to prevent health complications
- Errors in medication administration
- Errors in interpreting authorized provider prescriptions
- Lack of professional accountability and patient advocacy
- Inability to carry out interventions in an appropriate and timely manner
- Lack of mandatory reporting

### Attributes of Safety

Patient and staff safety is a major priority for professional nurses. Best safety practices reduce error and harm through established protocols, memory checklists, and systems such as bar-code medication administration (BCMA) (Fig. 1-1). Maintaining safety requires that nurses and other health care professionals use these systems and practices consistently and as specified to achieve positive outcomes. Working around these systems (often called *work-arounds*) is not acceptable and can increase the risk of error to patients and/or staff.

FIG. 1-1 Example of a bar-code medication administration (BCMA) system.

Three types of *Nursing Safety Priority* boxes are found throughout this text to emphasize its importance in daily practice. These features delineate safety based on patient and/or staff need. For example, *Nursing Safety Priority: Critical Rescue* emphasizes the need for action for potential or actual life-threatening problems. *Nursing Safety Priority: Action Alert* boxes focus on the need for action but not necessarily for life-threatening situations. But safety alerts are essential to ensure optimal outcomes. As the name implies, *Nursing Safety Priority: Drug Alert* boxes specify actions needed to ensure safety related to drug administration, monitoring, or related patient and family education.

## Examples of Context of Safety to Nursing and Health Care

In 2002 The Joint Commission (TJC) published its first annual **National Patient Safety Goals (NPSGs)**. These goals require health care organizations to focus on specific priority safety practices, many of which involve establishing nursing and health system approaches to safe care. Since that time, TJC continues to add new goals each year. NPSGs address high-risk issues such as safe drug administration, prevention of health care–associated infections, and communication effectiveness among the interprofessional team. When appropriate, this textbook highlights related NPSGs. A complete list of the latest goals can be found on the TJC website at [www.jointcommission.org](http://www.jointcommission.org).

The Joint Commission (TJC) requires that health care organizations create a culture of safety. A **culture of safety** provides a blame-free approach to improving care in high-risk, error-prone health care organizations using interprofessional collaboration. Patients and families are encouraged to become safety partners in protecting patients from harm. In this environment, nurses and other interprofessional health team members should not hesitate to report and document errors or missed care using appropriate internal organizational documents for risk management, quality improvement, and staff education purposes. These variations in the standard of care are often referred to as **adverse events**. The Joint Commission requires that health care organizations report serious adverse events, known as *sentinel events*. A sentinel event is a severe variation in the standard of care that is caused by human or system error and results in an avoidable patient death or major harm.

# Teamwork and Interprofessional Collaboration

## Definition of Teamwork and Interprofessional Collaboration

To provide patient- and family-centered care, the nurse “functions effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision-making to achieve quality patient care” (QSEN, 2011). Therefore the knowledge and skills needed for this competency are effective communication and team functioning. Communication is an essential process for evaluating patient care together using an interprofessional (IP) plan of care. To help meet this purpose, health care organizations have frequent and regular IP meetings and conduct IP patient care rounds.

## Scope of Teamwork and Interprofessional Collaboration

In this textbook the interprofessional health care team includes the patient, family, nurses, unlicensed assistive personnel (UAP such as nursing assistants), and other health professionals and their assistants needed to provide appropriate and safe, evidence-based care. Other older terms used for these members include the *interdisciplinary* or multidisciplinary team, depending on health care organization, context, or setting. Although there are many health care team members, some health care professionals work more closely with nurses than others. For example, the physician or other health care provider and medical-surgical nurse collaborate frequently in a given day regarding patient care. The occupational therapist may not work as closely with the nurse unless the patient is receiving rehabilitation services. Collaboration with the rehabilitation team is discussed in [Chapter 6](#).

## Attributes of Teamwork and Interprofessional Collaboration

In 2011 the Interprofessional Education Collaborative (IPEC) Expert Panel published competencies to guide health professionals in education and practice; these competencies were updated in 2016. The four general competencies include:

- *Values/Ethics for Interprofessional Practice:* Work with individuals of other professions to maintain a climate of mutual respect and shared values.
- *Role-Responsibilities:* Use the knowledge of one's own role and those of other professions to appropriately assess and address the health care needs of patients and populations served.
- *Interprofessional Communication:* Communicate with patients, families, communities, and other health professionals in a responsive and responsible manner that supports a team approach to the maintenance of health and the treatment of disease.
- *Teams and Teamwork:* Apply relationship-building values and the principles of team dynamics to perform effectively in different team roles to plan and deliver patient-/population-centered care that is safe, timely, efficient, effective, and equitable.

Specific competencies for each of these general statements are delineated in the IPEC report. Examples of *Interprofessional Communication* are listed in [Table 1-2](#).

**TABLE 1-2**

### Interprofessional Communication Competencies

CC1. Choose effective communication tools and techniques, including information systems and communication technologies, to facilitate discussions and interactions that enhance team function. CC2. Organize and communicate information with patients, families, and health care team members in a form that is understandable, avoiding discipline-specific terminology when possible. CC3. Express one's knowledge and opinions to team members involved in patient care with confidence, clarity, and respect, working to ensure common understanding of information and treatment and care decisions. CC4. Listen actively and encourage ideas and opinions of other team members. CC5. Give timely, sensitive, instructive feedback to others about their performance on the team, responding respectfully as a team member to feedback from others. CC6. Use respectful language appropriate for a given difficult situation, crucial conversation, or interprofessional conflict. CC7. Recognize how one's own uniqueness, including experience level, expertise, culture, power, and hierarchy within the health care team, contributes to effective communication, conflict resolution, and positive interprofessional working relationships. CC8. Communicate consistently the importance of teamwork in patient-centered and community focused care.
---

Data from Interprofessional Education Collaborative Expert Panel. (2016). *Core competencies for interprofessional collaborative practice: Report of an expert panel* (2nd ed.). Washington, D.C.: Interprofessional Education Collaborative.

## Examples of Context of Teamwork and Interprofessional Collaboration to Nursing and Health Care

Electronic mail (e-mail) allows for quick communication among health care professionals to enhance collaboration and coordination of care. *However, it should not replace face-to-face and phone communication.*

### Communication

Poor communication between professional caregivers and health care agencies causes many medical errors and patient safety risks. **In 2006 The Joint Commission began to require systematic strategies for improving communication. Two years later, another National Patient Safety Goal mandated that nurses communicate continuing patient care needs such as pain management or respiratory support to post-discharge caregivers for safe transition management.**

To improve communication between staff members and health care agencies, procedures for hand-off communication were established. An effective procedure used in many agencies today is called *SBAR* (pronounced S-Bar) or similar method. **SBAR** is a formal method of communication between two or more members of the health care team. The SBAR process includes these four steps:

- **Situation:** Describe what is happening at the time to require this communication.
- **Background:** Explain any relevant background information that relates to the situation.
- **Assessment:** Provide an analysis of the problem or patient need based on assessment data.
- **Recommendation/Request:** State what is needed or what the desired outcome is.

Several modifications of SBAR include I-SBAR, I-SBAR-R, and SBARQ. In these methods the “I” reminds the individual to *identify* himself or herself. The last “R” stands for the *response* that the receiver provides based on the information given. The “Q” represents any additional questions that need to be answered. Be sure to follow the established documentation and reporting protocols in your health care organization.

TeamSTEPPS is also a systematic communication approach for interprofessional teams that was designed to improve safety and quality. STEPPS stands for **S**trategies and **T**ools to **E**nhance **P**erformance and **P**atient **S**afety. Adapted from the aviation industry, this model reminds professionals that mistakes can cause negative outcomes, including death (Haynes & Strickler, 2014). In addition to SBAR, these common communication tools as part of TeamSTEPPS are very effective for promoting patient safety and teamwork:

- **CUS words:** State “I’m concerned; I’m uncomfortable; I don’t feel like this is safe.”
- **Check backs:** Restate what a person said to verify understanding by all team members.
- **Call outs:** Shout out important information (such as vital signs) for all team members to hear at one time.
- **Two-challenge rule:** State a concern twice as needed; if ignored, follow the chain of command to get the concern addressed.

### Delegation and Supervision

As a nursing leader you will delegate certain nursing tasks and activities to unlicensed assistive personnel (UAP) such as patient care technicians (PCTs) or nursing assistants (NAs). **Delegation** is the process of transferring to a competent person the authority to perform a selected nursing task or activity in a selected patient care situation. This process requires precise and accurate communication. *The nurse is always accountable for the task or activity that is delegated!*

An important process that is sometimes not consistently performed by busy medical-surgical nurses is supervision of the UAP to whom the task or activity has been delegated. **Supervision** is guidance or direction, evaluation, and follow-up by the nurse to ensure that the task or activity is performed appropriately. Examples of delegated tasks are turning and positioning, vital signs, and intake and output measurements.

Be sure to follow these five rights when you delegate and supervise a nursing task or activity to a UAP:

- **Right task:** The task is within the UAP’s scope of practice and competence.
- **Right circumstances:** The patient care setting and resources are appropriate for the delegation.

- *Right person:* The UAP is competent to perform the delegated task or activity.
- *Right communication:* The nurse provides a clear and concise explanation of the task or activity, including limits and expectations.
- *Right supervision:* The nurse appropriately monitors, evaluates, intervenes, and provides feedback on the delegation process as needed.

Other activities or patient care responsibilities may be assigned by a registered nurse (RN) to another RN or to a licensed practical or vocational nurse (LPN/LVN). Each state designates which tasks may be safely delegated and assigned to nursing team members. Interventions that you can typically delegate or assign in any state are indicated throughout this text. Some of the *Clinical Judgment and NCLEX Examination Challenges* throughout this book will test your understanding of the delegation and supervision process.

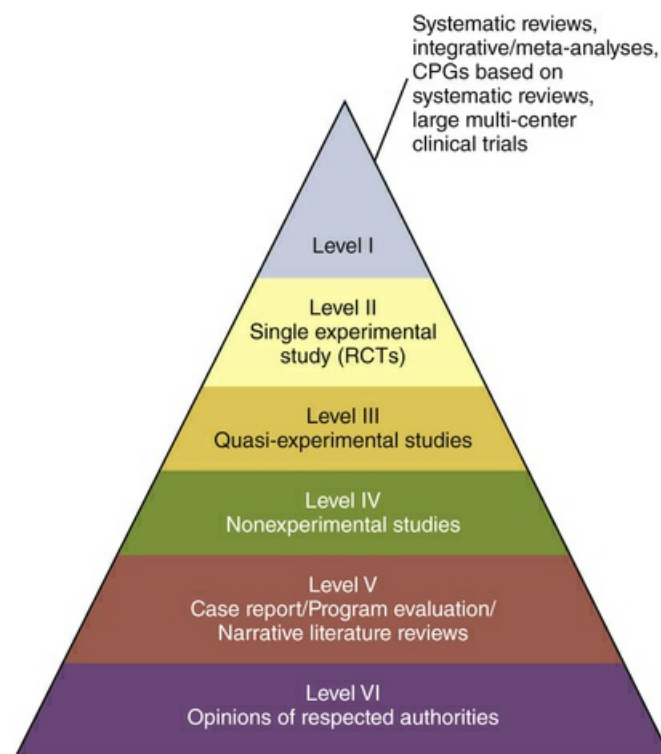

# Evidence-Based Practice

## Definition of Evidence-Based Practice

Evidence-based practice (EBP) is the integration of the best current evidence and practices to make decisions about patient care. It considers the patient's preferences and values and one's own clinical expertise for the delivery of optimal health care (Melnyk & Fineout-Overholt, 2015; QSEN, 2011).

## Scope of Evidence-Based Practice

The best source of evidence is research. Fig. 1-2 shows the level of evidence (LOE) pyramid that is commonly used to rate the quality (strength) or scope of available evidence. The highest levels of evidence are systematic reviews and integrative or meta-analysis studies. In these studies the researcher conducts a thorough literature search for appropriate studies and then analyzes findings of those studies to determine which best practices answer the research question. The types of research in nursing may be limited in some areas and may not reflect the highest or best level of evidence. Some nursing research is designed as small, descriptive studies to explore new concepts. The findings of these studies cannot be generalized, but they provide a basis for future larger and better-designed research.

**FIG. 1-2** Levels (strength) of evidence. Level 1 is the strongest evidence. (©2010. Rona F. Levin & Jeffrey M. Keefer.)

*Evidence-Based Practice* boxes are found throughout the text to provide the most current research that serves as a basis for nursing practice. Each of these features presents a brief summary of the research, identifies the LOE using the scale in Fig. 1-2, and concludes with a “Commentary: Implications for Practice and Research” discussion to help you apply the findings of the study to daily nursing practice.

## Attributes of Evidence-Based Practice

EBP promotes safety for patients, families, staff, and health care systems because it is based on

reliable studies, guidelines, consensus, and expert opinion. However, recall that a best practice identified through research or clinical practice guideline may not be consistent with the patient's or family's personal preferences or beliefs. Nurses must respect the values of the patient or designee at all times even if those values differ from their own or those of the interprofessional health care team.

## **Examples of Context of Evidence-Based Practice to Nursing and Health Care**

Health care organizations receiving Medicare and/or Medicaid funding are obligated to follow the evidence-based interprofessional Core Measures to ensure that best practices are followed for selected health problems. Examples of Core Measures are highlighted throughout this textbook, such as those related to heart failure, stroke, venous thromboembolism, and acute myocardial infarction.

In addition to complying with federal mandates and those outlined by The Joint Commission (TJC), many hospitals have achieved or are on the path to achieve the American Nurses Credentialing Center's Magnet Recognition. This highly desired recognition requires nurses to demonstrate how best current evidence guides their practice. Many hospitals have nursing research departments with experts to facilitate this process. Using research to guide practice is a way to continuously improve the quality of care, as described as part of the following concept.

# Quality Improvement

## Definition of Quality Improvement

Quality improvement (QI), sometimes referred to as *continuous quality improvement (CQI)*, is a process in which nurses and the interprofessional health care team use indicators (data) to monitor care outcomes and develop solutions to change and improve care. This process is also sometimes called the *evidence-based practice improvement (EBPI)* process because the best sources of evidence are used to support the improvement or change in practice.

## Scope of Quality Improvement

When a patient care or system issue is identified as needing improvement, specific systematic QI models such as the **Plan-Do-Study-Act (PDSO)** or the FOCUS-PDCA are typically used. The steps of the PDSO model include (Sutton & Suhayda, 2015):

1. Identify and analyze the problem (Plan).
2. Develop and test an evidence-based solution (Do).
3. Analyze the effectiveness of the test solution, including possible further improvement (Study).
4. Implement the improved solution to positively impact care (Act).

The steps of the more specific FOCUS-PDCA model are:

- Find a process to improve.
- Organize a team.
- Clarify the current process.
- Understand variations in current process.
- Select the process to improve.
- Plan the improvement.
- Do the improvement.
- Check for results.
- Act to hold the gain.

A QI project using the FOCUS-PDCA model was successfully conducted by a group of nurses to improve communication during morning rounds on a medical-surgical unit. The QI team developed a written communication tool for each patient that included a place for the staff nurse to list primary concerns for the patient. The physicians and other primary health care providers used the same tool to outline the goals and plan of care for the day. The results of this project improved daily communication between nurses and physicians, which led to improved patient care and safety (Perry et al., 2016).

Another method called the DMAIC model is gaining popularity as it more clearly delineates each QI step and includes the need to continue the new intervention or change over time. The steps of this model are:

1. **D**efine the issue or problem.
2. **M**easure the key aspects of the current process for the issue (collect data).
3. **A**nalyze the collected data.
4. **I**mprove or optimize the current process by implementing an evidence-based intervention/solution.
5. **C**ontrol the future state of the intervention to ensure continuity of the process.

## Attributes of Quality Improvement

As a medical-surgical nurse, you will be expected to be involved in the QI process on your unit or in your agency. You will need the knowledge and skills to:

- Identify indicators to monitor quality and effectiveness of health care.
- Access and evaluate data to monitor quality and effectiveness of health care.
- Recommend ways to improve care processes.
- Implement activities to improve care processes.

## Examples of Context of Quality Improvement to Nursing and Health Care

This textbook features *Quality Improvement* boxes that summarize articles on QI projects and end with a “Commentary: Implications for Practice and Research” discussion. These features will help you learn how nurses get involved in QI and the benefits to patients, staff, and health care systems or patient care units. An example of how one hospital unit improved practice using the DMAIC model to improve medication reconciliation is summarized in the *Quality Improvement* box in this chapter. Additional information about the QI process can be found in nursing leadership and management resources.

# Informatics and Technology

## Definition of Informatics and Technology

Informatics and technology are the access and use of information and electronic technology to communicate, manage knowledge, prevent error, and support decision making (QSEN, 2011).

## Scope of Informatics and Technology

Most health care settings have information technology (IT) departments. The largest application of health care informatics is use of the electronic health record (EHR) (also called *electronic patient record [EPR]* or *electronic medical record [EMR]*) for documenting nursing and interprofessional care. Computers may be located at the nurses' work station, at the patient's bedside (point of care [POC]), or near the nurses' station. Handheld mobile devices or laptops are also popular because of their ease of use and portability.

## Attributes of Informatics and Technology

Although safety and quality of health care are the major purposes of informatics and technology, patient and family privacy may be at risk unless precautions are implemented. For example, staff and students may take photos of patients to show their family and friends about the health problems for which they care. In some cases these photos are posted on social media such as Facebook. *This action is a violation of patient privacy and confidentiality.*

## Examples of Context of Informatics and Technology for Nursing and Health Care

Another major purpose of informatics is for retrieval of data for evidence-based practice and quality improvement. The Internet provides ways to search for multiple sources of information very efficiently. However, all data sources must be evaluated for their credibility and reliability.

New technologies for patient, staff, and resource (inventory) management are used in health care agencies to promote patient safety and improve efficiency. An example of these technologies is radiofrequency identification (RFID). RFID allows any person or object to be tracked electronically. Bar-code medication administration (BCMA) systems (see Fig. 1-1) and Smart IV pumps are other examples of systems used to ensure safety through technology.

Nurses need to be involved in decisions about introducing new or advanced health care technologies into the health care agency. They should also be included in designing technology that improves the effectiveness and efficiency of health care while providing for patient and staff privacy.

# Clinical Judgment

## Definition of Clinical Judgment

Clinical judgment is the process that nurses and other members of the interprofessional team use to make decisions based on interpretation of the patient's needs or problems. The nursing process, critical thinking, and a variety of reasoning patterns help the medical-surgical nurse make clinical decisions while being respectful of the patient's and family's cultural diversity, age, gender, and lifestyle choices. This textbook presents many *Clinical Judgment Challenges* and *NCLEX Examination Challenges* to help you practice how to use clinical judgment to make appropriate decisions based on current evidence as available.

## Scope of Clinical Judgment

Appropriate or “sound” clinical judgment (also referred to as *sound judgment*) leads to positive patient or staff outcomes. By contrast, inappropriate or “poor” judgment results in negative outcomes that can pose a risk to patient or staff safety. In her classic systematic review, [Tanner \(2006\)](#) concluded that sound clinical judgment is influenced by how well the nurse knows the patient's typical response pattern and the situational context or culture of the nursing care unit. Reflection on nursing practice is often triggered by poor clinical judgment and is essential for developing knowledge and improving reasoning.

The worst result of poor judgment is a growing health care crisis referred to as *failure to rescue*. **Failure to rescue** is the inability of nurses or other interprofessional health team members to save a patient's life in a timely manner when a health care issue or medical complication occurs. Patients often have beginning or subtle signs and symptoms 2 to 3 days before cardiopulmonary arrest or multiple organ failure. Failure to rescue occurs when those signs and symptoms are not noticed or accurately interpreted and therefore action to improve the patient's condition is not implemented ([Garvey, 2015](#)).

## Attributes of Clinical Judgment

According to Tanner, clinical judgment involves specific reasoning and critical thinking skills. In this edition of the text, each of these skills is paired with the steps of the nursing process for all exemplar health problems as follows:

- Assessment: Noticing
- Analysis: Interpreting
- Planning and Implementation: Responding
- Evaluation: Reflecting

## Examples of Context of Clinical Judgment to Nursing and Health Care

To improve patient safety and prevent failure to rescue, most hospitals have a Rapid Response Team (RRT), also called the *Medical Emergency Team (MET)*. **Rapid Response Teams** save lives and decrease the risk for harm by providing care *before* a medical emergency occurs by intervening rapidly when needed for patients who are *beginning* to clinically decline. Members of an RRT are critical care experts who are on-site and available at any time. Although membership varies among agencies, the team may consist of an intensive care unit (ICU) nurse, respiratory therapist, **intensivist** (physician who specializes in critical care), and/or **hospitalist** (family practice physician or internist employed by the hospital). In other hospitals acute care nurse practitioners or medical residents may be part of the team. The team responds to emergency calls, usually from clinical nurses, according to established agency protocols and policies ([Allen et al., 2015](#)). Patient families may also activate the RRT.

The Joint Commission's National Patient Safety Goals also include the need for early intervention for patients who are clinically changing. They require each health care organization to establish criteria for patients, families, or staff to call for additional assistance in response to an actual or

perceived change in the patient's condition.

# Ethics

## Definition of Ethics

According to the American Nurses Association (ANA), ethics is “a theoretical and reflective domain of human knowledge that addresses issues and questions about morality in human choices, actions, character, and ends (ANA, 2015, p. xii). *Applied* professional nursing ethics is about considering what is right and wrong when using clinical judgment to make clinical decisions.

## Scope of Ethics

Clinical decisions are either ethical or not ethical and are based on one or more of six principles described under Attributes of Ethics. Ethics is also described by the type of ethics or setting in which these decisions are made. For example, *organizational* ethics refers to the ethical practices of health care organizations. Applied nursing ethics is a type of *professional* ethics that are used in practice by individual nurses. Examples of the provisions of the ANA Code of Ethics are listed in Table 1-3.

**TABLE 1-3**  
**Examples of Provisions of the ANA Code of Ethics**

<ul style="list-style-type: none"><li>• The nurse practices with compassion and respect for the inherent dignity, worth, and unique attributes of every person.</li><li>• The nurse promotes, advocates for, and protects the rights, health, and safety of the patient.</li><li>• The nurse has authority, accountability, and responsibility for nursing practice; makes decisions; and takes action consistent with the obligation to promote health and to provide optimal care.</li><li>• The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth.</li><li>• The nurse collaborates with other health professionals and the public to protect human rights, promote health diplomacy, and reduce health disparities.</li></ul>
---

## Attributes of Ethics

Respect for people is the basis for six essential *ethical principles* that nurses and other health care professionals should use as a guide for clinical decision making. Respect implies that patients are treated as autonomous individuals capable of making informed decisions about their care. This patient **autonomy** is also referred to as *self-determination* or *self-management*. When the patient is not capable of self-determination, you are ethically obligated to protect him or her as an advocate within the professional scope of practice, according to the American Nurses Association (ANA) Code of Ethics for Nurses (ANA, 2015).

The second ethical principle is **beneficence**, which promotes positive actions to help others. In other words, it encourages the nurse to do good for the patient. **Nonmaleficence** emphasizes the importance of preventing harm and ensuring the patient's well-being. Harm can be avoided only if its causes or possible causes are identified. As described earlier in this chapter, patient safety is currently a major national focus to prevent deaths and injuries.

**Fidelity** refers to the agreement that nurses will keep their obligations or promises to patients to follow through with care. **Veracity** is a related principle in which the nurse is obligated to tell the truth to the best of his or her knowledge. If you are not truthful with a patient, his or her respect for you will diminish, and your credibility as a health care professional will be damaged.

**Social justice**, the last principle, refers to equality and fairness; that is, all patients should be treated equally and fairly, regardless of age, gender identity, sexual orientation, religion, race, ethnicity, or education. For example, a patient who cannot afford health care receives the same quality and level of care as one who has extensive insurance coverage. An older patient with dementia is shown the same respect as a younger patient who can communicate. A Hispanic patient who can communicate only in Spanish receives the same level of care as a Euro-American patient whose primary language is English. More information on ethics and ethical principles can be found in your fundamentals textbook.

## Examples of Context of Ethics to Nursing and Health Care

Nurses and other members of the interprofessional team are involved in many ethical decisions and

dilemmas in daily practice. Examples of these dilemmas include issues surrounding advance directives and aggressive treatment options. Some of the *Clinical Judgment Challenges* in this book relate to common ethical issues in medical-surgical nursing.

# Health Care Organizations

## Definition of Health Care Organizations

Health care organizations (HCOs) are purposely designed and structured systems in which health care is provided by members of nursing and interprofessional teams (Giddens, 2016).

## Scope of Health Care Organizations

HCOs are classified by their ownership (e.g., private versus public), financial purpose, and mission. For example, public HCOs are owned by county, state, provincial, and federal governments; they are usually nonprofit and supported by tax revenue. Private institutions are typically owned by companies or organizations. Many of these agencies are for-profit HCOs, but others are nonprofit or not-for-profit. Some HCOs are large research and teaching institutions such as Johns Hopkins in Baltimore, MD. Others are rural or small community hospitals.

HCOs can be single institutions or part of larger systems. For example, a single nursing home or assisted-living facility may be privately owned and not part of a network. By contrast, a large hospital system may house acute care, chronic care, rehabilitative care, ambulatory care, and skilled care in one or multiple locations.

HCOs also vary by mission or purpose; some offer generalized services, whereas others offer more specialized services. For example, free-standing rehabilitation facilities limit their services to care of patients with rehabilitative needs. Critical Care Access Hospitals (CAHs) are specially designated HCOs that must meet the following criteria:

- Be located in a rural area at least 35 miles away from any other hospital
- Have no more than 25 inpatient beds
- Maintain an annual average patient length of stay of no more than 96 acute inpatient hours
- Offer 24-hour, 7 day-a-week emergency care

Patients served by a CAH either have common stable health problems or are referred to larger hospitals once their conditions are stabilized.

In some cases HCOs restrict the population they serve based on mission or purpose. For example, Veterans Administration (VA) hospital systems provide services only for active or retired military patients. U.S. Indian Health Services HCOs provide care for American Indians.

## Attributes of Health Care Organizations

An HCO is characterized by its:

- Mission and philosophy
- Organizational structure
- Workforce (health care and ancillary)
- Patients
- Services provided

These characteristics allow the agency to provide safe, quality patient care that the public or local community can trust.

## Examples of Context of Health Care Organizations to Nursing and Health Care

Nurses often choose to work in an HCO based on its characteristics. For example, if a nurse prefers working with specialized populations such as veterans, he or she usually seeks employment in the VA system. If the nurse desires to work in a large teaching institution, he or she would need to work in an urban area where these HCOs are located. Opportunities for career advancement and continuing education may also be more readily available in larger institutions.

# Health Care Disparities

## Definition of Health Care Disparities

Health care disparities are differences in patient access to or availability of appropriate health care services.

## Scope of Health Care Disparities

A major focus of the U.S. *Healthy People 2020* initiative is to decrease health care disparities caused by poor communication, health care access, health literacy, and health care provider biases and discrimination. Although progress has been made over the past few decades, many minority populations have a high incidence of chronic disease and mortality as a result of health care disparities (Neumayer & Plumper, 2016). The National Center on Minority Health and Health Disparities of the National Institutes of Health leads and coordinates the efforts to reduce these disparities in the United States. Similar organizations in other countries exist for this same purpose.

## Attributes of Health Care Disparities

Many factors affect patient access to quality health care services, including geographic location, cultural variables, and resources. For instance, some individuals live in very rural areas that do not have quality health care services. In other cases the care is available, but the individual may not have transportation to get to the provider or value the need for regular preventive health care. Language barriers may also prevent the individual from accessing services. For example, many older individuals in Hispanic communities do not speak English, and most health care professionals do not speak Spanish. This communication barrier and possible mistrust of primary care providers can prevent access to needed health services.

Some individuals remain uninsured or underinsured and cannot afford health care services. “Working poor” patients may have health insurance but their copayments are too high to seek services. Copayments for a health care provider office visit may be as high as \$50 or more. Medication copayments can range from \$5 to over \$100 per prescription, depending on which type of insurance the patient has. These expenses are usually not a priority over other personal financial needs such as food and rent.

## Examples of Context of Health Care Disparities to Nursing and Health Care

Entire groups of people are vulnerable or likely to experience an inability to access available health care for a variety of reasons. Health care professionals may have biases and beliefs about certain cultures and groups that prevent them from being effective in developing an appropriate individualized plan of care. Examples of these groups include older adults, ethnic minorities, and the lesbian, gay, bisexual, transgender, and queer and/or questioning (LGBTQ) population.

### Special Needs of Older Adults

Older adults are a growing subset of the adult population as the baby boomers turn 60 to 70. This group of young older adults is different from previous generations as they aged. Many are working well past 65 years of age and have very active social lives. [Chapter 3](#) in this text is dedicated to the special health care needs of older adults, especially those between 70 and over 100 years old.

### Special Needs of Ethnic Minorities

Early health care research focused on promoting health or managing health problems among affluent Euro-Americans. More recent research has included implications for or differences in care based on ethnicity or gender. Health care disparities have been identified as they affect various groups and populations. As mentioned earlier in this chapter, many *Cultural/Spiritual Considerations* features are integrated throughout this textbook to highlight differences in care needed to meet the special health needs of individuals from a variety of racial and ethnic groups.

## Special Needs of the LGBTQ Population

Nurses today have been made aware of cultural variations and learned how to incorporate these differences to individualize patient care. However, one group that is seldom addressed in the nursing literature is the LGBTQ population (Pettinato, 2012). This terminology is widely accepted by the LGBTQ community and is commonly used, although *LGBT* may be seen more often in health care literature. Queer and/or questioning individuals prefer not having strict labels on their sexualities or genders. Another term that may also be used is *LGBTQI* to include intersex individuals. Intersex individuals have sexual or reproductive organs that are not clearly male or female or may have a combination of both male and female organs.

Many studies provide evidence that LGBTQ individuals do not feel comfortable with or trust health care professionals because of previous discrimination (IOM, 2011). The *Healthy People 2020* initiative added a category for these individuals because of health disparities in this population and the need to improve LGBTQ health. The complete document can be found on [www.healthypeople.gov/2020](http://www.healthypeople.gov/2020). This textbook includes special health needs of this population as part of its *Gender Health Considerations* features. A separate chapter in this book on transgender health helps students learn about the special needs of transgender patients.

The health care system, like other facets of society, often overlooks sexualities and genders that are alternative to the standard of heterosexuality and clearly delineated maleness or femaleness. As a health care professional, it is essential to not be restricted by rigid standards of identity. A good way of rethinking concepts of sexuality and gender is to think of each as existing along a spectrum rather than categorizing people into heterosexual/homosexual and male/female.

To begin to gain trust and show respect for the LGBTQ patient, health care professionals need to know their patient's sexual orientation and gender identity. Do not assume that every patient is heterosexual or clearly gendered. *Include questions about gender identity and sexual activity as part of your patient's health assessment.* Table 1-4 lists recommended patient interview questions about sexual orientation, gender identity, and health care.

---

**TABLE 1-4**

### Recommended Patient Interview Questions About Sexual Orientation, Gender Identity, and Health Care

---

- |  |
|--|
| <ul style="list-style-type: none"><li>• Do you have sex with men, women, both, or neither?</li><li>• Does anyone live with you in your household?</li><li>• Are you in a relationship with someone who does not live with you?</li><li>• If you have a sexual partner, have you or your partner been evaluated about the possibility of transmitting infections to each other?</li><li>• If you have more than one sexual partner, how are you protecting both of you from infections such as hepatitis B, hepatitis C, or HIV?</li><li>• Have you disclosed your gender identity and sexual orientation to your health care provider?</li><li>• If you have not, may I have your permission to provide that information to members of the health care team who are involved in your care?</li><li>• Whom do you consider to be your closest family members?</li></ul> |
|--|

*HIV*, Human immune deficiency virus.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Medical-surgical nursing is a specialty practice that requires a broad knowledge base and clinical skills to meet the needs of adult patients in a variety of settings.
- Medical-surgical nurses help meet human needs of adult patients such as mobility and gas exchange in a caring, respectful relationship.
- **The Joint Commission requires that health care organizations create a culture of safety by following the National Patient Safety Goals (NPSGs).**
- Rapid Response Teams (RRTs) save lives and decrease the risk for patient harm before a respiratory or cardiac arrest occurs. **QSEN: Safety**
- Remember to always observe for slow and sudden changes in patient condition, especially changes in vital signs and mental status.
- A vital role of the nurse is as an advocate to empower patients and their families to have control over their health care and function as safety partners. **QSEN: Safety**
- Examples of the provisions of the ANA Code of Ethics for Nurses are listed in [Table 1-3](#).
- Six essential ethical principles to consider when making clinical decisions are autonomy, beneficence, nonmaleficence, fidelity, veracity, and social justice. **Ethics**
- Nurses collaborate by communicating patient's needs and preferences with members of the interprofessional health care team to establish an individualized approach to care. **QSEN: Teamwork and Collaboration**
- The SBAR procedure or similar established method is used for successful hand-off communication between caregivers and between health care agencies.
- When delegating a nursing task to unlicensed assistive personnel (UAP), the nurse is always accountable to ensure that the task was performed safely and accurately. **QSEN: Safety**
- Evidence-based practice (EBP) is the integration of best current evidence to make decisions about patient care. It considers the patient's preferences and values and one's own clinical expertise.
- Nurses are active participants in the systematic quality improvement (QI) process in their health care agency and used one of several QI models to improve care and promote patient safety. **QSEN: Quality Improvement**
- Informatics and technology are used for patient documentation, electronic data access, and health care resource tracking. **QSEN: Informatics**
- Health care organizations vary by size, mission, financial goal, and purpose; some are single agencies and others are part of large networks in multiple locations. **Health Care Organizations**

### Psychosocial Integrity

- Nurses must show respect and compassion for the uniqueness of every individual to ensure patient-centered and family-centered care.
- Health care disparities are differences in the access or availability of health care; members of minority groups and other vulnerable populations are particularly at risk for health disparities. **Health Care Disparities**
- The lesbian, gay, bisexual, transgender, queer and/or questioning (LGBTQ) population typically does not trust health care professionals; use sensitive questioning about sexual orientation and gender identity as part of your interview with patients in this group (see [Table 1-4](#)). **QSEN: Patient-Centered Care**

## CHAPTER 2

# Overview of Health Concepts for Medical-Surgical Nursing

---

Donna D. Ignatavicius, Kristin Oneil

## PRIORITY AND INTERRELATED CONCEPTS

---

***The priority concepts for this chapter are:***

- ACID-BASE BALANCE
- CELLULAR REGULATION
- CLOTTING
- COGNITION
- COMFORT
- ELIMINATION
- FLUID AND ELECTROLYTE BALANCE
- GAS EXCHANGE
- GLUCOSE REGULATION
- IMMUNITY
- MOBILITY
- NUTRITION
- PERFUSION
- SENSORY PERCEPTION
- SEXUALITY
- TISSUE INTEGRITY

## LEARNING OUTCOMES

---

### **Safe and Effective Care Environment**

1. Collaborate with the nursing and interprofessional team to help patients meet selected physiologic health needs.

### **Health Promotion and Maintenance**

2. Develop an evidence-based teaching plan to enable adults to meet selected health needs and promote health.
3. Assess unsafe or unhealthy behaviors that could prevent the patient from meeting physiologic health needs.
4. Plan health promotion strategies to promote sensory perception in adults and maintain safety.

### **Psychosocial Integrity**

5. Differentiate delirium and dementia as common cognitive impairments.

### **Physiological Integrity**

6. Review the definition and scope of selected physiologic health needs of adults.
7. Describe common physiologic consequences when basic health needs are not met.
8. Document essential assessments to determine if basic health needs are met.
9. Plan patient-centered nursing interventions to help patients meet selected physiologic health needs.

Nurses care for adults in a variety of settings to help them meet a multitude of biopsychosocial needs. When these needs are not met, the nurse plans and implements care in collaboration with the interprofessional health team. This chapter reviews the 15 health concepts that are emphasized and built on in this text, and are presented alphabetically for easy access. For more information about these basic concepts, see your foundations or fundamentals of nursing textbook. Each chapter in the body systems units applies appropriate health concepts to patient assessment or interventions for selected health problems, identified as **exemplars**.

## Acid-Base Balance

### Definition of Acid-Base Balance

**Acid-base balance** is the maintenance of arterial blood pH between 7.35 and 7.45 through control of hydrogen ion production and elimination. Blood pH represents a delicate balance between hydrogen ions (acid) and bicarbonate (base) and is largely controlled by the lungs and kidneys.

### Scope of Acid-Base Balance

If the arterial blood pH is either below 7.35 or above 7.45, the patient has a type of acid-base *imbalance* (Fig. 2-1). *Acidosis* occurs if the arterial blood pH level falls below 7.35 and is caused by either too many hydrogen ions in the body (respiratory acidosis) or too little bicarbonate (metabolic acidosis). Conversely, *alkalosis* occurs if the pH is greater than 7.45 and is caused by either too few hydrogen ions in the body (respiratory alkalosis) or too much bicarbonate (metabolic alkalosis). Both severe acidosis and alkalosis can lead to death if the patient is not diagnosed accurately and treated quickly.

FIG. 2-1 Scope of acid-base balance.

### Common Risk Factors for Acid-Base Imbalance

Any individual is at risk for an acid-base imbalance, but it occurs most commonly as a complication of many acute and chronic health problems. The most common risk factors include poisoning such as excessive salicylate ingestion; medical conditions such as chronic obstructive pulmonary disease (COPD), uncontrolled diabetes mellitus (especially type 1), and chronic kidney disease; excessive emesis, diarrhea, or intravenous (IV) infusions; and fluid and electrolyte imbalances. A more thorough discussion of acid-base imbalances by specific type may be found in [Chapter 12](#) of this text.

### Physiologic Consequences of Acid-Base Imbalance

When the body has an impaired acid-base balance, several mechanisms are activated in an attempt to correct the imbalance, a process referred to as *compensation*. For example, if the patient is acidotic (pH lower than 7.35), the kidneys typically decrease the amount of bicarbonate ions (base) that is excreted through the urine. The lungs may try to rid the body of carbon dioxide (source of carbonic acid) through increased and deeper respirations. In this case, both compensatory mechanisms aim to restore acid-base balance by increasing the blood pH to greater than 7.35. These actions can only occur if the individual has healthy lungs and kidneys.

### Assessment of Acid-Base Balance

Take a patient health history for chronic illnesses such as diabetes mellitus or COPD and any past experiences of acid-base imbalance. Ask about the presence or recent history of signs and symptoms that could predispose the patient to acidosis or alkalosis such as excessive vomiting or diarrhea. The patient's current or recent use of medications, including over-the-counter drugs and herbal supplements, should be reviewed to determine if they could cause acid-base imbalance.

Arterial blood gas monitoring gives the health care team an understanding of the type of acid-base imbalance the patient is experiencing. Assessing the pH determines whether the patient has an imbalance and, if so, how severe it is. The PaCO<sub>2</sub> level (normal value is 35-45 mm Hg), or partial pressure of carbon dioxide, indicates how well the lungs are functioning in blowing off or retaining

carbon dioxide as needed to help correct the acid-base imbalance. The bicarbonate level, or  $\text{HCO}_3$  (normal value is 21-28 mEq/L [21-28 mmol/L \*]), indicates how well the kidneys are excreting or reabsorbing base as needed.

## Interventions to Promote Acid-Base Balance and Prevent Acid-Base Imbalance

The best way for an individual to maintain acid-base balance is to practice health promotion measures, including living a healthy lifestyle. For example, most cases of COPD can be prevented by avoiding or quitting smoking. Regular exercise and a healthy diet can decrease the incidence of type 2 diabetes mellitus and help control blood glucose in all types of diabetes.

Teach patients who are at risk for acute or chronic vomiting or diarrhea to be monitored carefully by a primary health care provider to assess for fluid, electrolyte, and acid-base imbalances. (See discussion of [fluid and electrolyte balance](#) later in this chapter.)

## Interventions for Patients With Acid-Base Imbalances

Managing a patient with an acid-base imbalance depends on which type of imbalance is present. When possible, the health care team aims to diagnose and treat the underlying cause(s) of the imbalance. [Chapter 12](#) describes the pathophysiology and management of common types of acid-base imbalance in detail.

# Cellular Regulation

## Definition of Cellular Regulation

**Cellular regulation** is the process to control cellular growth, replication, and differentiation to maintain homeostasis. Cellular *growth* refers to division and continued growth of the original cell. Cell *replication* refers to making a copy of a specific cell. Cell *differentiation* refers to the process of the cell becoming specialized to accomplish a specific task.

## Scope of Cellular Regulation

Cellular function can have both positive and negative effects within the body. Positive aspects of cellular function include cell development and reproduction of healthy cells, whereas negative aspects include cell replication and growth of unhealthy cells that represent tumors or neoplasms.

## Common Risk Factors for Impaired Cellular Regulation

Risk factors that increase the probability of impaired cellular regulation include:

- Older age (55 years and older, with significant potential for abnormal cell development at ages >70)
- Smoking
- Poor nutrition
- Physical inactivity
- Environmental pollutants (such as air, water, soil)
- Radiation
- Selected medications (such as chemotherapy)
- Genetic predisposition or risk

## Physiologic Consequences of Impaired Cellular Regulation

It is important to differentiate benign and malignant cell growth. *Benign* cell growth mirrors the original cell, but excessive cells are present. Benign cells do not have the capability to spread to other tissues or organs. However, benign masses can cause health risks because of the ability to obstruct or compress organs in the body, causing significant discomfort or high risk to the individual. For example, a meningioma (benign mass) can compress the brain and lead to increased intracranial pressure (ICP), a potentially fatal complication.

Malignant (cancerous) cells, over time, have no comparison to the original cells from which they are derived. Replication of abnormal cells leads to significant invasion of healthy cells, tissues, and organs through tumor formation and invasion.

## Assessment of Cellular Regulation

Perform a thorough patient history, extensive family history, and a psychosocial history. Completing a thorough and detailed physical examination may identify any visible or palpable masses, pain, or difficulty breathing. Diagnostic tests such as radiographic examination, computed tomography (CT), or magnetic resonance imaging (MRI) may identify the location of any mass. More invasive tests such as a colonoscopy or endoscopy give the primary health care provider an opportunity to actually see the mass. Laboratory tests can provide additional information regarding the overall health of the patient and the composition of any mass. For example, tissue biopsies and cell cytology are essential to identify the type of abnormal cell that is present. Grading and staging to identify the extent and severity of the growth are a necessity to diagnose, treat, and offer a prognosis for the patient.

## Interventions to Promote Cellular Regulation and Prevent

## Impaired Cellular Regulation

Interventions include primary and secondary prevention techniques. *Primary prevention* includes minimizing the risk of developing impaired cellular regulation. Teach patients to:

- Minimize exposure to sunlight or other source of ultraviolet light such as tanning beds (to prevent skin cancers).
- Stop smoking or other tobacco use if applicable (to prevent many cancer types, including lung, oral, and bladder cancers).
- Consume a diet low in saturated fat and high in fiber (to prevent breast and colon cancer).
- Increase physical activity and regular exercise (to prevent all cancer types).
- Avoid exposure to environmental hazards (to prevent all cancer types).

Healthy People 2020 addresses goals for reducing cancer risk and includes maintaining a healthy weight, managing proper oral health, and being aware of one's family history or genetic makeup.

*Secondary prevention* includes proper and regular screening to identify early any risks or hazards that could be present. Screening also enables the primary health care provider to diagnose cancer early, which often increases the patient's chance for a cure or long-term survival.

## Interventions for Patients With Impaired Cellular Regulation

Collaborative interventions for the patient with impaired cellular regulation can include surgery, radiation therapy, chemotherapy, hormonal therapy, targeted therapy, biologic therapy, and bone marrow or hemapoietic stem cell transplants. The type and course of interprofessional management depends on the type and severity of cellular regulation impairment. The two chapters on cancer in this textbook discuss the pathogenesis of cancer and its patient-centered management.

## Clotting

### Definition of Clotting

**Clotting** is a complex, multi-step process by which blood forms a protein-based structure (clot) in an appropriate area of tissue injury to prevent excessive bleeding while maintaining whole body blood flow (perfusion). A major component of this process involves specialized cells called *platelets* (thrombocytes) that circulate in the blood until they are needed. When injury occurs, platelets are activated to become sticky, causing them to aggregate (clump together) to form a temporary semi-solid plug. The platelet aggregation triggers a rapid complex process, known as the *clotting cascade*, in which multiple clotting factors (enzymes and plasma proteins) work together to create a fibrin clot and local blood coagulation (clotting). Another pathway, known as the *fibrinolytic system*, is triggered to cause clot lysis (breakdown) (McCance et al., 2014). Chapter 40 describes these processes in more detail.

### Scope of Clotting

An inability to form adequate clots can result in bleeding and threaten a person's life. In some cases an excess of platelets or excessive platelet stickiness can lead to **hypercoagulability** (increased clotting ability), which can impair blood flow. Therefore the scope of clotting can range from increased or excessive clotting to an inability to adequately clot, either locally at the site of an injury or systemically. Fig. 2-2 illustrates the potential scope of clotting.

FIG. 2-2 Scope of clotting.

### Common Risk Factors for Inadequate Clotting

When taking a patient and family history, be aware that impaired clotting may result in either excessive or inadequate clotting. Common risk factors for *increased* clotting include immobility or decreased mobility, health problems such as polycythemia, and smoking. Immobility slows venous blood flow to the heart and can result in venous stasis and venous thromboembolism (VTE), described later in this text. Certain chronic health problems such as diabetes mellitus are also associated with decreased blood flow, making patients more likely than healthy adults to develop VTE. Polycythemia causes an excessive production of red blood cells, which can lead to multiple clots. Atrial fibrillation causes pooling of blood in the atria (stasis) and often leads to embolic stroke. As people age and smoke, platelets typically become stickier and therefore tend to aggregate more easily. In addition, venous valves that normally prevent the backflow of blood become weak and often inadequate as adults age. The result is venous stasis and an increased risk for VTE.

*Decreased* clotting most often occurs when there is an inadequate number of circulating platelets (**thrombocytopenia**). For example, chemotherapeutic drugs and corticosteroids cause bone marrow suppression where platelets and other blood cells are produced. Patients with cirrhosis of the liver also have a decreased production of clotting factors, including prothrombin, causing them to be at an increased risk for bleeding. Some rare genetic diseases such as recessive sex-linked hemophilia A and B are the result of defective clotting factors that also increase the risk for bleeding.

### Physiologic Consequences of Inadequate Clotting

For patients at risk for *increased* or excessive clotting, recognize that clots can occur in either venous or arterial blood vessels. Venous **thrombosis** is a clot formation in either superficial or deep (most often) veins, usually in the leg. If a thrombus becomes dislodged, it is known as an **embolus**. Emboli may travel to the brain (causing a stroke) or lung (pulmonary embolus).

For patients with a *decreased* ability to clot, prolonged internal (systemic) or external (localized) bleeding may occur. Internal bleeding may occur in the brain (hemorrhagic stroke), gastrointestinal (GI) tract (frank or occult blood in the stool), and/or urinary tract (hematuria). It may also occur under the skin (purpura). External bleeding often manifests as epistaxis (nose bleeds) or prolonged bleeding at the site of soft tissue trauma.

## Assessment of Clotting

Observe patients for signs and symptoms of *decreased* clotting, especially purpurial lesions such as ecchymosis (bruising) and petechiae (pinpoint purpura). Notice if bleeding is prolonged as a result of injury or trauma. Check urine and stool for the presence of occult or frank blood. Observe for frank bleeding from the gums or nose.

For patients with *increased* risk for clotting or excessive clotting, observe for signs and symptoms of *venous* thrombosis such as localized redness, swelling, and warmth.

## Nursing Safety Priority QSEN

### Critical Rescue

An *arterial* thrombosis is not locally observable and is typically manifested by decreased blood flow (PERFUSION) to a distal extremity or internal organ. For example, a femoral arterial clot causes an occlusion (blockage) of blood to the leg. In this case the distal leg becomes pale and cool; distal pulses may be weak or absent; *this is an emergent problem requiring immediate intervention*. If these changes are present, notify the primary health care provider or Rapid Response Team immediately. If this condition continues, the leg may become gangrenous and require amputation. A mesenteric artery thrombosis can cause small bowel ileus and gangrene if not treated in a timely manner. A renal artery thrombosis can cause acute kidney injury.

A number of serum laboratory tests are available to measure clotting factor levels and bleeding time. The most common tests are prothrombin time (PT) and activated partial thromboplastin time (aPTT). An international normalized ratio (INR) indicating a derived measure of prothrombin is used to monitor the effectiveness of warfarin (Coumadin, Warfilone .

## Interventions to Promote Adequate Clotting and Prevent Inadequate Clotting

Teach patients with *decreased* clotting ability to report unusual bleeding or bruising immediately.

Be sure to teach patients at risk for *increased* clotting to:

- Drink adequate fluids to prevent dehydration.
- Avoid crossing the legs.
- Ambulate frequently and avoid prolonged sitting.
- Refer patients for smoking cessation programs as needed.
- Call a health care provider if redness, swelling, and warmth occur in a lower extremity.

## Interventions for Patients With Inadequate Clotting

In addition to the previous interventions, for many adults at increased risk for clotting, *anticoagulants* or *antiplatelet drugs* (also called *blood thinners* by many patients) are prescribed either in community or inpatient settings. Examples of medications that require frequent laboratory testing are sodium heparin and warfarin. *Teach adults the importance of obtaining these tests and monitor results to ensure that they are within the desired range to ensure patient safety.*

Newer anticoagulants called *direct thrombin inhibitors* may be given to decrease the risk of stroke in patients with atrial fibrillation. Monitor patients receiving any of these drugs for signs of bleeding, including bruising and blood in the urine or stool. Continued bleeding can lead to anemia or hemorrhage.

# Cognition

## Definition of Cognition

**Cognition** is the complex integration of mental processes and intellectual function for the purposes of reasoning, learning, memory, and personality. *Reasoning* is a high-level thinking process that allows an individual to make decisions and judgments. *Memory* is the ability of an individual to retain and recall information for learning or recall of past experiences. *Personality* refers to the way an individual feels and behaves, often based on how he or she thinks.

## Scope of Cognition

An adult may have either intact or adequate cognitive functioning or inadequate cognitive functioning. Examples of inadequate cognition include **delirium** (acute fluctuating confusion) and **dementia** (chronic confusion). [Table 2-1](#) compares these two major cognitive disorders that are most common in older adults. [Chapter 3](#) describes these health problems in detail. Adults may also have delayed intellectual functioning or amnesia (loss of memory) caused by brain trauma, congenital disorders, or acute health problems such as a stroke.

**TABLE 2-1**  
**Differences in the Characteristics of Delirium and Dementia**

VARIABLE	DEMENTIA	DELIRIUM
Description	A chronic, progressive cognitive decline	An acute, fluctuating confusional state
Onset	Slow	Fast
Duration	Months to years	Hours to less than 1 month
Cause	Unknown, possibly familial, chemical	Multiple, such as surgery, infection, drugs
Reversibility	None	May be possible
Management	Treat signs and symptoms	Remove or treat the cause
Nursing interventions	Reorientation is not effective in the late stages; use validation therapy (acknowledge the patient's feelings and do not argue); provide a safe environment; observe for associated behaviors such as delusions and hallucinations	Reorient the patient to reality; provide a safe environment

## Common Risk Factors for Inadequate Cognition

Inadequate cognition is complex and includes a variety of signs and symptoms. They may be short term and reversible or long term and not reversible. Common risk factors include:

- Advanced age (although dementia is *not* a normal physiologic change of aging)
- Brain trauma at any age, including at birth
- Disease or disorder such as brain tumor, hypoxia, or stroke (infarction)
- Environmental exposure to toxins such as lead
- Substance use disorder
- Genetic diseases such as Down syndrome
- Depression
- Opioids, steroids, psychoactive drugs, and general anesthesia, especially in older adults
- Fluid and electrolyte imbalances

## Physiologic Consequences of Inadequate Cognition

Common signs and symptoms of inadequate cognition include:

- Loss of short- and/or long-term memory
- Disorientation to person, place, and/or time
- Impaired reasoning and decision-making ability
- Impaired language skills
- Uncontrollable or inappropriate emotions such as severe agitation and aggression
- Delusions and hallucinations

These manifestations often result in patient safety and communication issues. For example, an adult with impaired short-term memory may forget to turn off a stove burner that could result in a fire. A person who has impaired reasoning and decision-making ability may decide to drive a motor vehicle or operate machinery. Communication with a patient who is disoriented, aggressive, and/or delusional may not be possible.

## Assessment of Cognition

Taking a thorough history is essential to determine potential or actual cognitive impairment. Conduct a mental status assessment using one of several available mental health/behavioral health screening tools such as the Confusion Assessment Method (CAM). Other tools also assess memory, speech and language, judgment, thought processes, calculation, and abstract reasoning. Discussion of assessment tools to screen for specific cognitive problems may be found throughout this text and in mental health textbooks.

Diagnostic testing includes brain imaging procedures such as magnetic resonance imaging (MRI) to determine the presence of brain abnormalities such as trauma, tumors, and infarction. Neuropsychological testing by a licensed clinical psychologist may be performed to diagnose the cause and severity of specific changes associated with cognitive problems.

## Interventions to Promote Cognition and Prevent Inadequate Cognition

Teach adults to avoid risk factors such as substance use and lifestyle behaviors such as motorcycle driving without protective headgear. Teach older adults to stimulate the intellectual part of their brain through new learning activities such as taking music lessons, mastering a new language, or completing crossword puzzles or other “brain teasers.”

## Interventions for Patients With Inadequate Cognition

Nursing interventions focus on *safety* to prevent injury and foster communication. For adults with delirium or mild dementia, provide orientation to person, time, and place. Collaborate with the interprofessional team to determine the underlying cause of delirium, such as psychoactive drugs or hypoxia. Patients with moderate or severe dementia cannot be oriented to reality because they have chronic confusion.

### Nursing Safety Priority QSEN

#### Action Alert

Teach families and caregivers to provide a safe environment for the individual with cognitive impairment living in the community! Adults who are confused or cannot follow instructions may be injured by operating machinery or driving a motor vehicle. For those in inpatient facilities, provide a safe environment, depending on the patient's specific cognitive deficit. For example, implement fall precautions for those who need help getting out of bed. Adults with delirium or dementia may wander outside and be injured. Be sure they wear an alarm and identification bracelet.

In some cases the primary health care provider may prescribe psychoactive drug therapy for specific cognitive disorders. Some of these drugs are described later in this text but are discussed in more detail in mental health/behavioral health textbooks.

# Comfort

## Definition of Comfort

**Comfort** is a state of physical well-being, pleasure, and absence of pain or stress. This definition implies that comfort has physical and emotional dimensions. A primary role of the nurse is to promote basic care and comfort.

## Scope of Comfort

The desired outcome for optimal health and well-being of any individual is to have comfort or be comfortable. Many health problems can cause decreased comfort, also called *discomfort*. Most often patients report pain or other sensation that disrupts their ability to function, either physically or mentally.

## Common Risk Factors for Decreased Comfort

Risk factors can be divided into physical causes and emotional, or psychosocial, causes. In some cases patients have risk factors for both physical and emotional discomfort. For example, patients who are having surgery are often anxious and feel stressed about the procedure. They may worry about who will care for them or their family after the surgery. This emotional stress is uncomfortable and can affect the outcomes of surgery. In addition, patients who have surgery typically have acute pain. This unpleasant sensation causes more emotional stress and discomfort. Some postoperative patients also have nausea or light-headedness as a result of the anesthesia used during the surgical procedure. All of these symptoms are causes of discomfort.

## Physiologic Consequences of Decreased Comfort

Physical causes of decreased comfort (discomfort) such as pain, nausea, and itching can result in emotional stress and discomfort. The body's "fight or flight" mechanism helps the individual cope with the source and manifestations of the discomfort. If this response is not successful in reducing stress, the individual may develop chronic pain and anxiety.

## Assessment of Comfort

Ask patients if they are comfortable. If pain is the source of discomfort, assess the level of pain and plan interventions to manage it. See [Chapter 4](#) of this text for pain assessment. If emotional stress is the source of discomfort, be sure to help the patient describe the nature and cause of stress. Once the underlying cause(s) of discomfort is identified, coordinate with the interprofessional health care team to treat or remove it if possible.

## Interventions to Prevent Impaired Comfort

Pain and emotional stress are the most common sources of decreased comfort. To prevent these sensations, anticipate which patient may experience them and provide preplanned interventions. For example, for postoperative pain control, ensure that the patient receives a basal dose of patient-controlled analgesia for continuous pain control.

## Interventions for Patients With Decreased Comfort

Assess patients at risk for discomfort and plan interventions to alleviate it, depending on its source and cause. Collaborate care with members of the interprofessional health care team as needed. For example, refer the patient to a counselor, social worker, or other qualified mental health professional to manage emotional stress. Consult with the primary health care provider and pharmacist to manage acute and chronic pain.

# Elimination

## Definition of Elimination

**Elimination** is the excretion of waste from the body by the gastrointestinal (GI) tract (as feces) and by the urinary system (as urine). *Bowel* elimination occurs as a result of food and fluid intake and ends with passage of feces (stool) or solid waste products from food into the rectum of the colon. The fecal material remains in the rectum until the urge to defecate occurs. Bowel elimination control depends on multiple factors, including muscle strength and nerve function.

*Urinary* elimination occurs as a result of multiple kidney processes and ends with the passage of urine through the urinary tract. When the urge to void occurs, urine is passed from the bladder through the urinary sphincter, urethra, and meatus. Urine consists of water and waste products (toxins) from many chemical processes in the body. Urinary elimination control also depends on multiple factors, including muscle strength and nerve function.

## Scope of Elimination

Adults desire voluntary control of both bowel and urinary elimination, a normal condition called *continence*. However, a number of factors can cause *incontinence* (lack of bowel or bladder control) or *retention* (an inability to expel stool or excrete urine).

Bowel elimination may also be categorized by the consistency of fecal material, which is shown in Fig. 2-3. At one end of the continuum the stool can be watery and without solid form, a condition called **diarrhea**. At the other end of the continuum, the stool can be hard, dry, and difficult to pass through the rectum, a condition called **constipation**. The inability to pass stool is known as **obstipation**.

FIG. 2-3 Scope of bowel elimination.

## Common Risk Factors for Changes in Elimination

*Incontinence* of either the bowel or bladder can occur as a result of aging when pelvic floor muscles become weaker. It may also occur in adults who have neurologic disorders such as stroke, dementia, and multiple sclerosis. Excessive use of laxatives may also cause fecal (diarrheal) incontinence. *Diarrhea* also results from acute GI infections such as gastroenteritis and chronic inflammatory bowel diseases such as Crohn's disease. Irritable bowel syndrome causes frequent diarrhea, constipation, or intermittent episodes of diarrhea and constipation.

*Urinary retention* is often a problem in older men who have benign prostatic hyperplasia (overgrowth). This overgrowth blocks the bladder neck and prevents urination or complete bladder emptying. *Retention of stool*, or constipation, is also common in older adults who have decreased peristalsis and/or lack of adequate dietary fiber and fluids to promote fecal passage. Lack of exercise and use of certain medications such as opioids, diuretics, and psychoactive drugs can contribute to constipation in adults of any age. Spinal cord and brain injuries or diseases often cause involuntary control or retention of both bowel and bladder.

Renal and urinary health problems can alter urinary elimination, depending on the type of disease or disorder. For example, urinary tract obstructions such as ureteral stones may prevent urine from reaching the bladder. Chronic kidney disease can cause changes in the amount of urinary output, depending on the stage of the disease. In the end stage the patient experiences oliguria (scant urine) or anuria (absence of urine) because the kidneys have lost their ability to make urine.

## Physiologic Consequences of Changes in Elimination

Adults who have urinary or bowel *incontinence* are at risk for damage to tissue integrity. If not removed promptly from the skin, stool and urine can cause skin irritation, fungal infection, and/or skin breakdown, which are very uncomfortable. Loss of bladder and bowel control can also lead to depression and anxiety. Older adults in both health care and community settings may wear undergarments or briefs to prevent soiling their clothes. Many older adults perceive these protective garments as “diapers” and are embarrassed or feel humiliated when wearing them.

If not treated, patients with prolonged *diarrhea* may develop fluid and electrolyte imbalances, especially dehydration and hypokalemia (decreased serum potassium). These problems are serious and can be life-threatening because hypokalemia often causes cardiac rhythm abnormalities (dysrhythmias).

Urinary or bowel *retention* can result in a buildup of toxins and waste products in the body. Although not common, a large amount of retained urine can cause rupture of the bladder. A large amount of stool can lead to bowel impaction and result in partial or total intestinal obstruction. These conditions can be life threatening.

## Assessment of Elimination

Take a patient history to determine risk factors or the underlying cause for impaired or altered elimination. Ask the patient or designated family member if incontinence or retention is or has been a problem. Assess the perineal area and buttocks for skin breakdown, redness, and fungal infection in patients who have incontinence.

Monitor the frequency, amount, consistency, and characteristics of urine and stool. Listen to bowel sounds in all four quadrants for presence of adequate bowel sounds. Expect overactive bowel sounds in a patient who has diarrhea; anticipate hypoactive bowel sounds in patients who have constipation. Palpate the bladder and bowel for distention.

For some patients laboratory testing of urine or stool may be useful in determining the cause of elimination changes. For example, a urinalysis and culture and sensitivity are appropriate for the patient with suspected urinary stones, retention, and infection. Radiologic testing and ultrasonography for stones or other structural abnormalities may also be performed.

A stool culture and sensitivity may be done for patients suspected of have methicillin-resistant *Staphylococcus aureus* (MRSA) infection. This infection often causes severe diarrhea in older adults who have received antibiotic therapy.

## Interventions to Prevent Changes in Elimination

Maintaining normal elimination requires adequate nutrition and hydration. Teach adults to ensure a diet high in fiber, including eating fruits, vegetables, and whole grains, and drinking 8 to 12 glasses of water each day unless medically contraindicated. Remind them to promptly toilet or void when the urge occurs. Patients at risk for *constipation* may need to take bulk-forming agents or stool softeners in addition to a high-fiber diet and fluids. Remind adults who have or are at risk for constipation to exercise frequently to stimulate peristalsis.

## Interventions for Patients With Changes in Elimination

Adults with *diarrhea* need medical attention to determine the underlying cause of the problem. Monitor the patient for signs and symptoms of fluid and electrolyte imbalances. These problems can be treated to help the patient return to more normal elimination patterns and restore lost fluids and electrolytes. [Chart 2-1](#) outlines nursing best practices for care of the patient experiencing diarrhea.

### Chart 2-1

## Best Practice for Patient Safety and Quality Care QSEN

### Patient With Diarrhea

- Protect the perineal and buttock area with zinc oxide or other barrier cream to prevent skin irritation and excoriation, especially for patients who are incontinent.
- Wash and dry skin where stool and urine have made contact, especially for patients who are incontinent.
- Encourage fluid intake and ensure that the patient consumes foods high in potassium such as oranges and potatoes.
- Document food and fluid intake and urinary/stool output.
- Check the patient's weight each day for weight loss.
- Collaborate with the primary health care provider for prescribing an antifungal cream if needed.

Nursing care for patients with *constipation* includes health teaching and collaboration with the interprofessional health care team. In addition to teaching about measures to prevent worsening of constipation as described previously, recommend that the patient take stool softeners, bulk-forming agents, and/or mild laxatives as needed to restore normal elimination patterns. In some cases enemas are needed to stimulate peristalsis and empty the rectum.

Adults who experience urinary *incontinence* need frequent toileting every 1 to 2 hours. This routine can prevent incontinence and train the bladder to empty at more regular intervals. A similar toileting schedule, especially after a meal, can help train the bowel to evacuate at about the same time each day.

Patients with short-term urinary *retention* require one or more straight urinary catheterizations to empty the bladder until the usual voiding pattern returns. For those with long-term retention, especially retention caused by lack of nerve stimuli, teach the patient or family/caregiver how to perform catheterizations on a daily routine schedule.

# Fluid and Electrolyte Balance

## Definition of Fluid and Electrolyte Balance

**Fluid and electrolyte balance** is the regulation of body fluid, fluid osmolality, and electrolytes by processes such as filtration, diffusion, and osmosis. To maintain balance or homeostasis in the body, fluid and electrolyte balance must be as close to normal as possible. Water makes up 55% to 60% of total body weight. Older adults have less body fluid than younger adults.

*Fluid* occupies the inside of the cell (intracellular fluid) and the outside of the cell (extracellular fluid). Extracellular fluid is found in the vascular space (plasma) and interstitial space (fluid between cells, often referred to as *third space fluid*). *Electrolytes* are chemicals in the body needed for normal body functioning, especially the heart and brain. Examples of electrolytes are sodium, potassium, calcium, and magnesium.

## Scope of Fluid and Electrolyte Balance

*Fluid imbalances* range from decreased fluid (deficit), often causing dehydration, to excessive fluid (overload), often causing edema. *Electrolyte imbalances* may also occur as deficits such as hypokalemia (low serum potassium) and excesses such as hyperkalemia (high serum potassium). [Table 2-2](#) lists common fluid and electrolyte imbalances.

**TABLE 2-2**

**Common Fluid and Electrolyte Imbalances**

Common Fluid Imbalances	Common Electrolyte Imbalances
Fluid volume deficit (dehydration)	Hyponatremia (low serum sodium)
Fluid volume excess (overload)	Hypernatremia (high serum sodium)
	Hypokalemia (low serum potassium)
	Hyperkalemia (high serum potassium)
	Hypocalcemia (low serum calcium)
	Hypercalcemia (high serum calcium)
	Hypomagnesemia (low serum magnesium)
	Hypermagnesemia (high serum magnesium)

## Common Risk Factors for Fluid and Electrolyte Imbalance

Risk factors that can alter a person's fluid and electrolyte balance include acute illnesses (e.g., vomiting and diarrhea), severe burns, serious injury or trauma, chronic kidney disease, surgery, and poor nutritional intake. Older adults are especially at risk for imbalances in fluids and electrolytes because they have less body water and are most likely to experience acute and chronic illnesses.

## Physiologic Consequences of Fluid and Electrolyte Imbalance

Physiologic consequences of *fluid deficit* are the result of lack of blood flow and oxygen to all parts of the body. A decrease in blood volume leads to hypotension (low blood pressure). In an attempt to compensate for hypotension and perfuse major organs, the heart rate increases (tachycardia). Peripheral pulses become weak and thready. For patients with severe dehydration, fever may occur due to inadequate body water. Older adults may also experience delirium due to lack of blood flow to the brain. If fluid deficit is not adequately managed, the kidney function diminishes, as evidenced by a decrease in urinary output. Recall that the minimum hourly urinary output should be at least 30 mL per hour.

Patients with *fluid excess* (overload) usually have an increase in blood pressure due to increased blood volume. Peripheral pulses are often strong and bounding. Many patients experience peripheral edema due to fluid excess. Fluid from the vascular space shifts to the interstitial space (third spacing).

The physiologic consequences of *electrolyte deficit* depend on which electrolyte is decreased. For example, a decrease in serum potassium level (hypokalemia) can result in cardiac dysrhythmias (abnormal heart rhythms) and muscle weakness. A decreased sodium level (hyponatremia) can result in changes in mental status and generalized weakness.

The consequences of *electrolyte excess* also depend on which electrolyte is increased. For example, an increase in serum potassium (hyperkalemia) or calcium (hypercalcemia) can cause cardiac dysrhythmias. In addition, skeletal muscle spasms are likely. An increased calcium level can also result in kidney or urinary tract calculi (stones). [Chapter 11](#) describes specific fluid and electrolyte imbalances in detail.

## Assessment of Fluid and Electrolyte Balance

Take a complete health history for past experiences of fluid and electrolyte imbalance and for any risk factors that can lead to an imbalance. Ask about any current episodes of nausea, vomiting, or diarrhea. Inquire about the current use of medications, including over-the-counter and herbal supplements.

Monitor vital signs, especially blood pressure and pulse rate and quality, fluid intake and output, and weight. *Changes in weight are the best indicator of fluid volume changes in the body.* Assess skin and mucous membranes for dryness and decreased skin turgor. Monitor and interpret laboratory tests to determine fluid or electrolyte imbalance. Examples of common tests are measurements of serum electrolyte concentration, blood urea nitrogen (BUN), and serum osmolality. [Chapter 11](#) discusses each of these assessments in detail.

## Interventions to Promote Fluid and Electrolyte Balance and Prevent Fluid and Electrolyte Imbalance

Maintaining fluid and electrolyte balance in the body is essential for normal body functioning. Teach patients to drink adequate fluids to remain hydrated. Eight glasses or more of water a day are often recommended unless medically contraindicated. Older adults may not feel thirsty or want to limit their fluid intake to prevent urinary incontinence. Teach them the importance of drinking adequate fluids to prevent dehydration and potential urinary tract infection.

Remind all adults about the need to eat a well-balanced diet that promotes electrolyte balance. Certain foods contain high concentrations of essential vitamins, minerals, and electrolytes. For instance, milk and other dairy products are a good source of calcium. Bananas and potatoes are good sources of potassium.

## Interventions for Fluid and Electrolyte Imbalances

Priority nursing interventions include maintenance of patient safety and comfort measures when managing fluid or electrolyte imbalances. For patients with a *fluid deficit*, the primary collaborative intervention is fluid replacement, either orally or parenterally. Depending on the cause of *fluid overload*, patients may require a fluid restriction (e.g., for those with chronic kidney disease). Diuretic therapy is often used for patients with fluid overload caused by chronic heart failure to prevent pulmonary edema, a potentially life-threatening complication. If lower extremity edema is present, teach patients the importance of elevating the legs above the heart to promote venous return.

Interprofessional collaborative management of electrolyte imbalance depends on which electrolyte balance is impaired. In general, electrolyte deficits are treated by replacing them, usually parenterally as intravenous (IV) fluids. Electrolyte excesses are managed by restricting additional electrolytes or using a medication or fluids that can help eliminate the excess. For example, sodium polystyrene sulfonate (Kayexalate) may be used for patients with hyperkalemia to eliminate excess potassium via the GI system.

## Glucose Regulation

GLUCOSE REGULATION is the process of maintaining optimal blood glucose levels. Though this concept is not a primary concept of this title, it is discussed in connection to multiple interrelated concepts with the GLUCOSE REGULATION concept exemplar Diabetes Mellitus in [Chapter 64](#).

# Gas Exchange

## Definition of Gas Exchange

**Gas exchange** is the process of oxygen transport to the cells and carbon dioxide transport away from the cells through ventilation and diffusion. This process begins with ventilation triggered by neurons in the brain sensing the need for gas exchange. These neurons stimulate contraction of skeletal muscles that expand the chest cavity, causing inhalation of oxygen-containing air into the airways and lungs. From the lung alveoli, oxygen diffuses into blood and red blood cells, and the waste gas carbon dioxide diffuses from the blood into the alveoli. Once in the alveoli, carbon dioxide is exhaled from the body as a result of recoil of lung elastic tissues and contraction of skeletal muscles that constrict the chest cavity. The oxygen in red blood cells bound to hemoglobin is transported through the blood by cardiac effort to tissue cells (perfusion), where low oxygen concentration allows release of oxygen from hemoglobin and diffusion or cell metabolism. The high concentration of carbon dioxide waste resulting from cellular metabolism allows diffusion of this gas into the blood and red blood cells. The waste gas is then transported back to the lungs to diffuse into the alveoli for removal during exhalation.

## Scope of Gas Exchange

Gas exchange is either normal to allow for adequate perfusion and removal of waste gas (carbon dioxide) or decreased. Decreased gas exchange can range from minimal to severe.

## Common Risk Factors for Decreased Gas Exchange

Adequate ventilation requires normal functioning central (brain and spinal cord) neurons, normal diaphragm function, adequate skeletal muscle contractility (especially the intercostal muscles between the ribs), and an intact chest thorax. Any acute or chronic problems that affect these functions can result in decreased ventilation, which impairs gas exchange. For example, pneumonia or lung abscess prevents adequate ventilation and gas exchange. A patient who experienced a cervical spinal cord injury often has decreased ventilation ability due to damage to spinal nerves that control the diaphragm.

As adults age, pulmonary alveoli lose some of their elasticity, causing a decrease in gas exchange. Health problems can also affect lung functioning. Any condition that decreases ventilation such as asthma can impair gas exchange. Asthma causes bronchospasm and narrowed airways, which diminishes the amount of oxygen available for gas exchange. Other lung diseases such as chronic obstructive pulmonary disease (COPD) directly damage the alveoli, decreasing both oxygen and/or carbon dioxide diffusion (Fig. 2-4). Risk factors for developing these diseases include smoking and environmental pollutants. In addition, prolonged immobility can decrease gas exchange as a result of inadequate pulmonary ventilation.

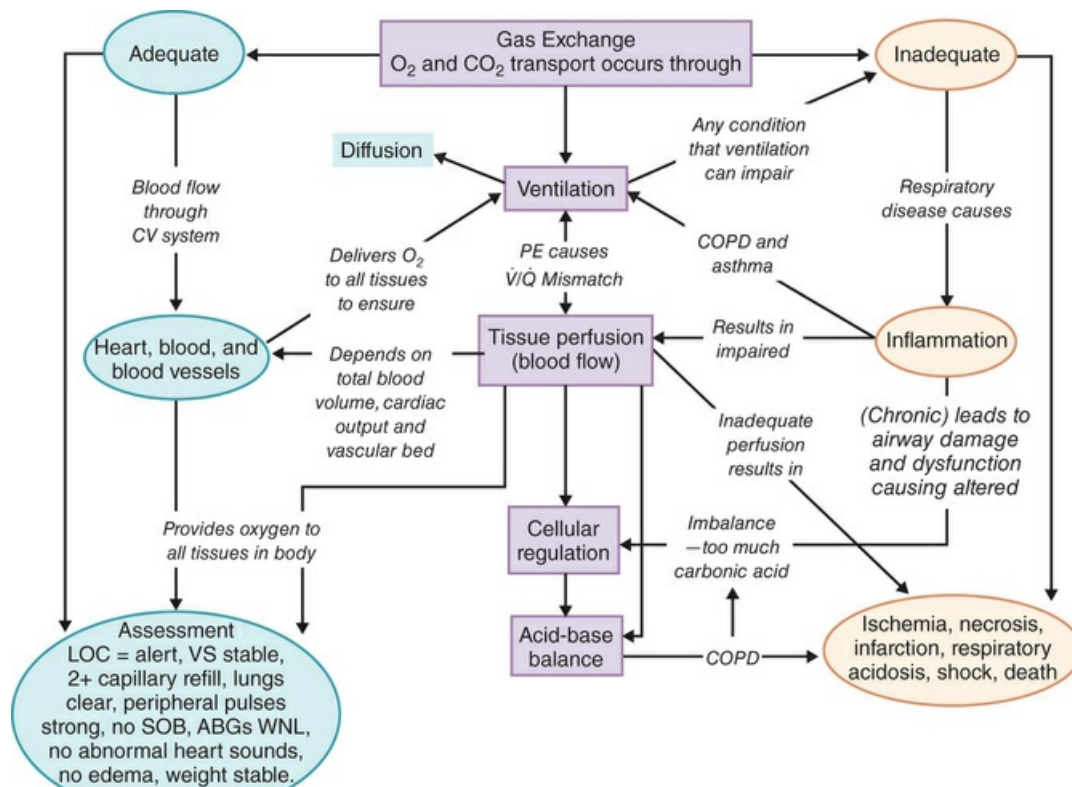

**FIG. 2-4** Damaged inelastic alveoli common in patients with COPD cause decreases in oxygen and carbon dioxide diffusion.

## Physiologic Consequences of Decreased Gas Exchange

Decreased gas exchange results in (1) inadequate transportation of oxygen to body cells and organs; and/or (2) retention of carbon dioxide. Inadequate oxygen results in cell dysfunction (ischemia) and possible cell death (necrosis or infarction) (Fig. 2-5). An excessive buildup of carbon dioxide combines with water to produce carbonic acid. This increase in acid causes respiratory acidosis and lowers the pH of blood. See the previous discussion of acid-base imbalance earlier in this chapter and in [Chapter 12](#).

**FIG. 2-5** Concept map showing comparison of adequate and inadequate gas exchange with consequences of impaired gas exchange. (ABG, Arterial blood gas; COPD, chronic obstructive pulmonary disease; CV, cardiovascular; LOC, level of consciousness; PE, pulmonary embolism; SOB, shortness of breath;  $\dot{V}/\dot{Q}$ , ventilation-perfusion; VS, vital signs; WNL, within normal limits.)

## Assessment of Gas Exchange

Take a complete health history and perform a focused respiratory assessment. Ask the patient about current or history of lung disease or trauma. Assess the patient's breathing effort, oxygen saturation, capillary refill, thoracic expansion, and lung sounds anteriorly and posteriorly. Monitor for the presence of a cough; sputum; report of shortness of breath; dizziness; chest pain; presence of cyanosis; or adventitious lung sounds such as wheezing, rhonchi, or crackles. Interpret associated laboratory results, including arterial blood gases (ABGs) and complete blood count (CBC). When necessary, a chest x-ray, chest computerized tomography (CT), or  $\dot{V}/\dot{Q}$  scan may be performed to determine the presence and severity of lung disease. Pulmonary function tests can determine the extent of airway disease in the small and large airways of the lungs and their structures. Bronchoscopy can provide direct visualization into the bronchus and its extending structures.

## Interventions to Promote Gas Exchange and Prevent Decreased Gas Exchange

Teach patients the importance of using infection control measures (primarily proper handwashing), smoking cessation to prevent COPD, and getting vaccinations as recommended to prevent influenza and pneumonia. Instruct them to be aware of exposure to specific respiratory conditions, including tuberculosis and influenza.

## Interventions for Decreased Gas Exchange

Managing decreased gas exchange requires finding the underlying cause and treating it, often with drug therapy. Examples of drugs used to treat respiratory health problems include antihistamines, decongestants, glucocorticoids, bronchodilators, mucolytics, and antimicrobials.

Chest expansion is improved when the patient is sitting or is in a semi-Fowlers position. Teach

the patient about the need for deep breathing and coughing to further enhance lung expansion and decrease breathing effort. Teach him or her how to correctly use incentive spirometry and inhalers if indicated. Administer oxygen therapy and monitor pulse oximetry to determine its effectiveness.

# Immunity

## Definition of Immunity

**Immunity** is protection from illness or disease that is maintained by the body's physiologic defense mechanisms. *Natural active* immunity occurs when an antigen enters the body and the body creates antibodies to fight off the antigen. *Artificial active* immunity occurs via a vaccination or immunization. *Natural passive* immunity occurs when antibodies are passed from a mother to the fetus through the placenta or using colostrum or the breast milk; *artificial passive* immunity occurs via a specific transfusion such as immunoglobulins.

Multiple organs and cells in the body are involved in the immune response. *Antibody-mediated immunity* (humoral immunity) includes the antigens and antibodies interacting in an attempt to slow down or destroy the foreign body. B-cells play a major role in this activity, together with the macrophages, T-lymphocytes (T-cells), and spleen. *Cell-mediated immunity* involves the functions of numerous cells to fight off the antigen, including white blood cells (WBCs), T-cells, natural killer (NK) cells, and multiple cytokines. The thymus and lymph nodes also play a role in this immune process.

## Scope of Immunity

Immunity has the potential to be decreased (suppressed or weakened) or excessive (exaggerated or heightened).

## Common Risk Factors for Changes in Immunity

Adult populations at risk for impaired immunity include but are not limited to:

- Older adults (diminished immunity due to normal aging changes)
- Low socioeconomic groups (inability to obtain proper immunizations)
- Nonimmunized adults
- Adults with chronic illnesses that weaken the immune system
- Adults on chronic drug therapy such as corticosteroids and chemotherapeutic agents
- Adults experiencing substance use disorder
- Adults who have a genetic risk for decreased or excessive immunity

## Physiologic Consequences of Changes in Immunity

An individual with a decreased immune response is susceptible to multiple types of infections because of the inability to “fight off” particular antigens. An individual with an excessive immune response has allergies or autoimmune reactions or diseases. Reactions are graded types I to IV and have varying degrees of urgency. These types are discussed in detail in [Chapter 20](#).

## Assessment of Immunity

A thorough history of the individual and the family is necessary to determine any of the previous risks associated with an immune problem. Identify any patient allergies, current medications, and history of environmental exposures. Ask the patient about an immunization history.

Assess weight, adequate wound healing, cognitive function, allergic responses (red, watery eyes; nasal congestion; swelling or rashes), and potential or actual organ dysfunction (cardiovascular, respiratory, renal or musculoskeletal). Monitor laboratory tests such as complete blood count (CBC) with differential, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and allergy testing to identify any susceptibilities that may exist. Specific tests such as the enzyme-linked immunosorbent assay (ELISA) and Western blot tests may be performed to identify the presence of human immune deficiency virus (HIV) antibodies. A complete immune panel, including antinuclear antibody (ANA) and rheumatoid factor (RF) testing, helps to detect autoimmune disease.

## Interventions to Promote Immunity and Prevent Changes in Immunity

Avoiding infections, handwashing, and having recommended immunizations are essential for promoting healthy immune function. Teach patients to practice a healthy lifestyle, including eating a well-balanced diet to ensure adequate vitamins and minerals, getting at least 7 to 8 hours of sleep each day, and having regular primary health care provider physical examinations. Remind them to avoid environmental hazards such as potential allergens (if sensitive) and people with contagious infections such as influenza.

## Interventions for Changes in Immunity

Patients with a *decreased* immune system for any reason are very prone to infection. Teach them to avoid large crowds or anyone with a transmittable infectious disease or illness. Remind them to wash their hands frequently and use hand sanitizer when water and soap are not available.

Patients with an *excessive* immune function have hypersensitivity reactions. Interprofessional collaborative management of these adults depends on the type and severity of the reaction. The expected outcome of treatment is to decrease symptoms and promote a quality of life. In some cases remission of the health problem can be achieved, but not a cure. Examples of autoimmune diseases that typically have remissions and exacerbations (flare-ups) are rheumatoid arthritis and lupus erythematosus (see [Chapter 18](#)).

# Mobility

## Definition of Mobility

**Mobility** is the ability of an individual to perform purposeful physical movement of the body. When a person is able to move, he or she is usually able to perform activities of daily living (ADLs) such as eating, dressing, and walking. This ability depends primarily on the function of the central and peripheral nervous system and the musculoskeletal system and is sometimes referred to as *functional ability*.

## Scope of Mobility

The scope of mobility can be best understood as continuum of a person's ability to move, with high-level (normal) mobility on one end of the continuum and total immobility on the other end. Many patients have varying degrees of impaired or altered physical mobility. *Decreased* physical mobility is the inability to move purposefully within the environment because of multiple factors, such as severe fatigue, decreased muscle strength, pain, or advanced dementia.

## Common Risk Factors for Decreased Mobility

Patients who have dysfunction of the musculoskeletal or nervous system are most at risk for decreased mobility or immobility. For example, a patient with a fractured hip is not able to walk because of pain and hip joint instability until the hip is surgically repaired and healed. Patients who have severe brain or spinal cord injuries have decreased mobility or total immobility caused by lack of neuronal communication or damaged nerve tissues that enable body movement. Any person who is bedridden or on prolonged bedrest is at risk for immobility issues, regardless of health problem or medical diagnosis (Crawford & Harris, 2016).

## Physiologic Consequences of Decreased Mobility

Decreases in mobility or total immobility for even a few days can cause serious and often life-threatening complications (Teodoro et al., 2016). Table 2-3 lists the most common complications seen in adult patients.

**TABLE 2-3**  
**Common Complications of Decreased Mobility and Causes**

<b>Physiologic Complications (Occur Most Often in Older Adults)</b>
<ul style="list-style-type: none"><li>• Pressure injuries (pressure on skin over bony prominences)</li><li>• Disuse osteoporosis (increased bone resorption)</li><li>• Constipation (decreased gastrointestinal [GI] motility)</li><li>• Weight loss or gain (decreased appetite and movement)</li><li>• Muscle atrophy (catabolism)</li><li>• Atelectasis/hyostatic pneumonia (decreased lung expansion)</li><li>• Venous thromboembolism (e.g., deep venous thrombosis and pulmonary embolus [decreased blood circulation])</li><li>• Urinary system calculi (stones) (urinary stasis)</li></ul>
<b>Psychosocial Complications</b>
<ul style="list-style-type: none"><li>• Depression (isolation, inability to provide self-care)</li><li>• Changes in sleep-wake cycle (especially if confined to bed)</li><li>• Sensory deprivation (especially if confined to bed)</li></ul>

## Assessment of Mobility

Observe patients within the environment to determine their mobility level. The mobility level of the patient is adequate if he or she can move purposely to walk with an erect posture and coordinated gait and perform ADLs without assistance. Several functional assessment tools are available to measure the level at which a patient can perform ADLs (see Chapter 6). Assessment of muscle strength and joint range of motion (ROM) can also be measured using a scale of 0 to 5, with 5 being normal and 0 indicating no muscle contractility.

## Interventions to Prevent Decreased Mobility

The nurse has a major role in promoting mobility and preventing immobility. First assess the patients who are most at risk for decreased mobility. In general, to maintain a high level of mobility or prevent decreased mobility in high-risk patients, perform these priority interventions for the patient at home or in a health care facility:

- Teach patients to do active ROM exercises every 2 hours. Assess and manage pain to promote more comfortable movement.
- Teach patients to perform “heel pump” activities and drink adequate fluids to help prevent venous thromboembolism (VTE) such as deep vein thrombosis (DVT).
- In collaboration with the occupational therapist, evaluate the patient's need for assistive devices to promote ADL independence such as a plate guard or splint; encourage self-care.
- Evaluate the patient's need for ambulatory aids such as a cane or walker; encourage ambulation; collaborate with the physical therapist if needed.

A study by [Teodoro et al. \(2016\)](#) found that a practical nurse–led ambulation program designed for hospitalized patients significantly improved mobility (see the [Evidence-Based Practice](#) box).

## Evidence-Based Practice OSEN

### Is a Nurse-Initiated Ambulation Protocol Effective in Promoting Patient Ambulation?

Teodoro, C. R., Breault, K., Garvey, C., Klick, C., O'Briend, J., Purdue, T., et al. (2016). STEP-UP: Study of the effectiveness of a patient ambulation protocol. *MEDSURG Nursing*, 25(2), 111–116.

Impaired mobility or immobility in hospitalized patients can cause multiple complications, many of which are life-threatening (e.g., deep vein thrombosis, hospital-acquired pneumonia). The authors assigned 48 patients on a 30-bed medical-surgical unit in a community hospital to one of two randomly assigned matched groups: 22 patients participated in the formal ambulation protocol (STEP-UP group), and 26 patients received usual care. All patients in the study sample were in the hospital for at least 3 days and had orders for ambulation. All patients were alert and oriented and able to be ambulated with the assistance of one or two staff members. Each patient in the sample viewed a short educational video on the importance of ambulation. Each participant wore a pedometer to track the number of steps taken for 2 consecutive study days. The participants in the STEP-UP group had significantly higher numbers of steps when compared to the group who received usual care.

#### Level of Evidence: 3

The study used a quasi-experimental design.

#### Commentary: Implications for Practice and Research

This study illustrates the need for staff nurses to ensure that hospitalized patients who are able continue to ambulate using a systematic approach or protocol to prevent impaired mobility and its associated complications. Complications of immobility are often life threatening and costly. In addition, third-party payers such as Medicare do not pay for acquired complications resulting from inadequate care.

More research is needed to follow a larger group of patients for a longer period of time in multiple settings to increase the generalizability of the findings this study. Additional studies are also needed to compare the incidence of complications from impaired mobility in both groups of patients.

## Interventions for Patients With Decreased Mobility

For patients who are immobile or have decreased mobility, perform these nursing interventions in collaboration with the interprofessional team at home or in a health care agency:

- Perform passive ROM exercises for patients who are immobile or have severe impaired mobility.
- Turn and reposition the patient every 1 to 2 hours; assess for skin redness and intactness.
- Keep the patient's skin clean and dry; use pressure-relieving or pressure-reducing devices as indicated.
- In collaboration with the registered dietitian, teach the patient and family the need for adequate

nutrition, including high-fiber and protein-rich foods to promote elimination and slow muscle loss.

- Teach the patient to eat high-calcium foods to help prevent bone loss; avoid excessive high-calorie foods to prevent obesity.
- Encourage deep-breathing and coughing exercises; teach the patient how and when to use incentive spirometry.
- Teach the patient and family the need for adequate hydration to prevent renal calculi (stones) and constipation.
- Teach the patient and family to report signs and symptoms of complications of immobility such as pressure injuries; swollen, reddened lower leg; and excessive respiratory secretions.
- Collaborate with the physical therapist to ambulate the patient with mobility aids (e.g., walker, cane) if needed.

# Nutrition

## Definition of Nutrition

**Nutrition** is the process of ingesting and using food and fluids to grow, repair, and maintain optimal body functions. Nutrients from food and fluids are used for optimal cellular metabolism and health promotion. Examples of nutrient groups are proteins, carbohydrates, fats, vitamins, and minerals.

## Scope of Nutrition

An optimal nutritional status means that the individual has adequate nutrients for body functioning. However, some adults have decreased or poor nutritional status because of lack of available nutrients or inadequate use of nutrients. *Malnutrition* occurs in adults who are underweight or overweight/obese. Some individuals have *generalized* malnutrition; others have specific nutrient deficiencies such as lack of vitamin D, iron, or protein.

## Common Risk Factors for Decreased Nutrition

Older adults are the largest population at risk for malnutrition as a result of acute and chronic diseases, poor oral health, and social isolation. Obesity is a common problem in people who have type 2 diabetes mellitus and metabolic syndrome.

In addition to these high-risk populations, other common risk factors for decreased nutrition in adults include lack of money to purchase healthy food and substance use. Adults with anorexia or bulimia nervosa are also malnourished. These disorders are discussed in textbooks on mental and behavioral health. [Table 2-4](#) summarizes common risk factors for decreased nutrition.

---

**TABLE 2-4**

**Risk Factors for Decreased Nutrition**

---

<ul style="list-style-type: none"><li>• Familial predisposition or genetic risk</li><li>• High stress level</li><li>• Depression and social isolation, especially among older adults</li><li>• Consuming fad diets that do not provide adequate nutrients</li><li>• Obesity</li><li>• Substance use</li><li>• Lack of money to purchase food</li><li>• Impaired food intake caused by dysphagia, poor appetite, or poor oral health</li><li>• Thyroid disorders</li><li>• Chronic diseases such as chronic obstructive pulmonary disease (COPD) and cancer</li><li>• Gastrointestinal (GI) distress such as excessive diarrhea or vomiting</li><li>• Anorexia or bulimia nervosa</li></ul>
--

## Physiologic Consequences of Decreased Nutrition

The physiologic changes that occur as a result of decreased nutrition depend on whether the individual has generalized malnutrition or a lack of specific nutrients such as vitamin D, iron, and protein. For example, an individual who is lactose intolerant may not ingest adequate amounts of vitamin D in the diet. This deficit can cause bone demineralization such as osteoporosis. An adult who does not eat meat or other sources of iron can develop iron-deficiency anemia. Most of these patients have low serum protein, especially albumin and prealbumin, resulting in generalized edema. Serum proteins exert an osmotic pull to keep fluid within the vascular space. When they are decreased, fluid leaves the vascular system and moves into the interstitial space (third spacing).

## Assessment of Nutrition

Conduct a complete patient and family history for risk factors that could cause impaired nutrition. Ask about current or recent GI symptoms such as nausea, vomiting, constipation, and diarrhea. Obtain the patient's height and weight and calculate body mass index (BMI). Assess the patient's skin, hair, and nails. Malnutrition often causes very dry skin and brittle hair and nails.

Serum laboratory testing depends on which nutrients are inadequate. For example, older women often have vitamin D and calcium testing to determine risk for bone demineralization risk. Low

serum iron levels and anemia indicate an iron deficiency. The most common assessment for generalized malnutrition is prealbumin and albumin measurement. Albumin is a major serum protein that is below normal in patients who have had inadequate nutrition for weeks. Prealbumin assessment is preferred because it decreases more quickly when nutrition is not adequate. Monitor and interpret these laboratory data to assess the patient's nutritional status.

## Interventions to Promote Nutrition and Prevent Decreased Nutrition

Teach adults to follow a healthy lifestyle that includes regular exercise and adequate nutrients to promote optimal nutrition and a BMI between 19 and 24.9. Remind them to avoid high-calorie, high-fat foods with no nutritive value. For patients at risk for decreased nutrition, collaborate with the interprofessional team to implement the appropriate interventions discussed in the following section.

## Interventions for Patients With Decreased Nutrition

Collaborative interventions to improve nutrition depend on the cause of decreased nutrition. For those with weight loss or low weight, common interventions include high-protein oral supplements, enteral supplements (either oral or by feeding tube), or parenteral nutrition. Collaborate with the registered dietitian for specific instructions regarding enteral feedings; consult with the pharmacist to administer parenteral therapy. Drug therapy such as iron or vitamin D to replace selected nutrients may also be given. To determine effectiveness of these interventions, weigh the patient at least once a week or as prescribed, using the same scale at the same time of day and preferably before breakfast.

Patients experiencing obesity may be prescribed drug therapy to help them lose weight. In some cases bariatric surgical procedures are needed to restrict the volume of food that can be ingested and/or decrease the absorptive area for nutrients. These procedures have the potential to cause multiple complications and require an interprofessional team approach for success. [Chapter 60](#) describes these surgeries in detail and their associated nursing and interprofessional collaborative care.

# Perfusion

## Definition of Perfusion

**Perfusion** is adequate arterial blood flow through the peripheral tissues (*peripheral* perfusion) and blood that is pumped by the heart to oxygenate major body organs (*central* perfusion). Perfusion is a normal physiologic process of the body; without adequate perfusion, cell death can occur.

## Scope of Perfusion

The scope of perfusion can best be understood as a continuum of the heart's ability to adequately supply blood to the body and the patency of arteries to adequately supply blood to peripheral tissues. *Ischemia* refers to impaired perfusion, whereas *infarction* is complete tissue death (Fig. 2-6).

## Common Risk Factors for Decreased Perfusion

Risk factors for decreased perfusion can be either modifiable (can be changed) or nonmodifiable (cannot be changed). *Nonmodifiable* factors include age, gender, and family history (genetics). Older adults are at the most risk for impaired perfusion. Examples of *modifiable* risk factors are smoking, lack of physical activity, and obesity. Patients with hyperlipidemia, diabetes mellitus, peripheral vascular disease, and arteriosclerosis are at a very high risk for both decreased central and peripheral perfusion.

## Physiologic Consequences of Decreased Perfusion

Decreased *peripheral* perfusion most often occurs in the lower extremities. The distal legs become cool and pale or cyanotic. Pedal pulses may be diminished or absent. If not treated, inadequate perfusion can result in skin ulcers (see [tissue integrity](#) later in this chapter) or cell death such as gangrene. Decreased *central* perfusion can result in life-threatening systemic events such as acute myocardial infarction, stroke, and shock as a result of decreased blood flow to major organs.

## Assessment of Perfusion

Conduct a complete patient and family history for risk factors and existing problems with perfusion. Assess for signs and symptoms of inadequate central perfusion, including dyspnea, dizziness or syncope, and chest pain. Signs and symptoms of decreased cardiac output include hypotension, tachycardia, diaphoresis, anxiety, decrease in cognitive function, and dysrhythmias. Assess for signs and symptoms of decreased *peripheral* perfusion, including decreased hair distribution, pallor, coolness, and/or cyanosis of the extremities. Document the presence and quality of distal peripheral pulses.

## Interventions to Promote Perfusion and Prevent Decreased Perfusion

The nurse plays a vital role in promoting adequate perfusion and preventing any impairment. Help the patient identify modifiable risk factors such as poor nutrition and smoking. Teach the importance of a heart-healthy lifestyle that includes a well-balanced diet, regular exercise, and smoking cessation. Encourage the patient to obtain frequent screening and monitoring of blood pressure and relevant laboratory work to detect early signs of decreased perfusion.

## **Interventions for Decreased Perfusion**

Inadequate perfusion can cause serious and life-threatening consequences. For patients who have decreased perfusion, the primary health care provider may prescribe vasodilating drugs to promote blood flow. However, for many patients a vascular intervention to open the occluded or narrowed artery is performed. This type of procedure can be done to open coronary arteries (central perfusion) or peripheral arteries such as the femoral or pelvic arteries in the leg.

# Sensory Perception

## Definition of Sensory Perception

**Sensory perception** is the ability to perceive and interpret sensory input into one or more meaningful responses. Sensory input is usually received through the five major senses of vision, hearing, smell, taste, and touch.

## Scope of Sensory Perception

The most likely cause of changes in smell and taste for adults is a dry mouth, which is a common side effect of drug therapy. Examples of drugs that can cause dry mouth include antidepressants, chemotherapeutic agents, antihistamines, and antiepileptic drugs (AEDs). When the causative drug is discontinued, the problem typically subsides. Touch (peripheral sensation loss) is most often affected in patients who have acute and chronic neurologic problems such as stroke, traumatic brain injury, or spinal cord injury. For many patients this sensory deficit is permanent. These health problems are discussed elsewhere in this text.

Problems of sensory perception that occur in the adult population largely affect vision and hearing. Therefore the following discussion is limited to these two sensory functions.

Vision and hearing abilities (acuity) vary from person to person, depending on a number of factors. Acuity of vision and hearing ranges from optimum through a continuum to complete blindness (vision) and deafness (hearing). Many adults have visual or hearing deficits but are able to function independently.

## Common Risk Factors for Changes in Sensory Perception

As adults age, they are at an increased risk for decreased visual and hearing acuity. Older adults typically have *presbyopia* (far-sightedness) and *presbycusis* (sensorineural type) caused by the aging process. Chronic diseases such as diabetes mellitus and hypertension can lead to decreased visual acuity. Although these health problems can occur in any age-group, they most commonly occur in older adults. The older population is also more at risk for glaucoma, cataracts, and macular degeneration, all of which can cause loss of vision.

Other causes for changes in or loss of vision include direct mechanical or chemical trauma, genetic risk, cranial nerve II (optic) damage, and drug therapy such as antihistamines and antihypertensives. Hearing loss may be caused by direct physical trauma, cranial nerve VIII (acoustic, or auditory) damage, occupational factors (e.g., consistent loud noises), genetic risk, and drugs that are ototoxic. Examples of drugs that can cause ototoxicity are salicylates, diuretics, AEDs, and antibiotics, especially aminoglycosides.

## Physiologic Consequences of Changes in Sensory Perception

Adults with visual and hearing acuity loss that cannot be corrected are at risk for physical injury, including falls and other accidents. They may not be able to perform ADLs or ambulate independently and may require assistance. Those with hearing loss may not be able to rely solely on verbal communication. Visually impaired adults may not be able to use written communication.

## Assessment of Sensory Perception

Conduct a thorough patient and family history to determine risk factors for vision or hearing loss. Ask the patient about the use of eyeglasses, contacts, or a magnifier to improve vision. Inquire if he or she uses one or more hearing aids or amplifier. If any of these corrective aids are used, determine their effectiveness.

Ask the patient to read from a written text source such as a newspaper. Assess the patient to determine reading ability before requesting this screening. In the community setting a Snellen chart is often used to assess visual acuity. Use a whisper test to determine if the patient can hear. More extensive testing of the eyes and ears, including physical assessment, is performed by the health care provider or other qualified health professional.

## Interventions to Promote Sensory Perception and Prevent Changes in Sensory Perception

Primary and secondary preventive interventions are used to promote vision and hearing and prevent sensory deficits. *Primary* measures focus on avoiding risk factors that cause vision and hearing loss or using protective devices to minimize risk. For example, safety goggles help prevent eye injury when working with materials that can get into the eye. Ear plugs or other ear protective devices can minimize the exposure to loud noises such as that caused by machinery. A healthy lifestyle can help prevent the risk for diseases such as diabetes mellitus and hypertension, thus reducing the chance for decreased visual acuity from chronic disease.

The purpose of secondary prevention is to perform screening and diagnostic tests for early detection of beginning sensory loss. Examples of these strategies include regular eye examinations (annually for older adults) and physical examinations to diagnose and manage any chronic diseases early.

## Interventions for Patients With Changes in Sensory Perception

For patients who have glaucoma, drug therapy (local or systemic) may decrease intraocular pressure and prevent loss of vision. For some patients, corrective lenses or eye surgery (LASIK) can improve refractory vision problems. Adults with visual changes may have correction with eyeglasses or contact lenses; those with hearing loss may benefit from one or two hearing aids (Fig. 2-7). Adults who are totally blind may use guide dogs and/or braille. Those who are deaf may use closed-caption television, assistive listening devices, and sign language.

**FIG. 2-7** Example of a hearing aid. (From Touhy, T. A., & Jett, K. (2012). *Ebersole & Hess' toward healthy aging* (8th ed.). St. Louis: Mosby. Courtesy Kathleen Jett.)

Assess patients with vision and hearing loss for self-image and anxiety, especially those with a new onset of one of these deficits. Consult with or refer those who are having psychological distress to a qualified member of the interprofessional health team.

# Sexuality

## Definition of Sexuality

**Sexuality** is a complex integration of physiologic, emotional, and social aspects of well-being related to intimacy, self-concept, and role relationships. It is not the same as *reproduction*, which is the process of conceiving and having a child. Sexuality involves sex, sexual acts, and sexual orientation; these terms are *not* the same as gender identity, which is discussed later in [Chapter 73](#).

## Scope of Sexuality

The concept of sexuality ranges from positive sexual health and function to negative sexual health, impairment, or dysfunction ([Giddens, 2016](#)). Men and women often define sexuality, sex, and sexual health differently. Women usually view sexuality as defined previously; men often associate the term sexuality only with the act of sexual intercourse ([Giddens, 2016](#)). Therefore the concept of sexuality may be perceived differently by different individuals.

## Common Risk Factors for Changes in Sexuality

For some adults, changes in sexuality may be equated with poor sexual health or lack of sexual intercourse. During menopause some women perceive more positive sexuality, but others feel that changes such as vaginal atrophy and moodiness cause a more negative sexual experience. Men who have problems with erection or deal with prostate problems often feel sexually inadequate and have a poor self-concept when they are unable to satisfy their partners. As men get older, the risk of erectile dysfunction (ED) increases.

## Physiologic Consequences of Changes in Sexuality

Depending on the individual, the major consequence of sexuality changes or sexual dysfunction may not be physiologic. Rather, the adult experiencing changes in sexuality often has a poor self-image and self-concept. Being able to be intimate with another person is an important human need for most people. Sexual intimacy shows a deep sense of caring for another person.

## Assessment of Sexuality

Discussing sexuality, sexual health, and sexual intercourse is often difficult for both the patient and nurse. Ask patients about their perception of their sexuality, including both sexual activity and intimacy behaviors. Determine if they have sex and/or intimacy with one or more partners. Ask about protection measures and any history of sexually transmitted infections (STIs) or problems during sexual intercourse.

## Interventions to Promote Sexuality and Prevent Changes in Sexuality

Interventions include STI screening and physical examinations to determine any physical cause of changes in sexuality. For example, a man may have ED, and a woman may have decreased libido due to menopause. Assess patients for self-concept related to these issues or other intimacy concerns. Encourage patients at risk for STIs to be evaluated for their occurrence.

## Interventions for Patients With Changes in Sexuality

Interventions depend on the cause of the sexual impairment. Physical causes such as ED or STIs can be managed by drug therapy and other measures. Refer the patient whose impaired sexuality is caused by emotional or psychological factors to a qualified health care provider.

## Tissue Integrity

### Definition of Tissue Integrity

**Tissue integrity** is the intactness of the structure and function of the integument (skin and subcutaneous tissue) and mucous membranes. The skin is the largest organ of the body and has multiple functions, including protection from infection, fluid preservation, and temperature control.

### Scope of Tissue Integrity

Tissue integrity can vary from intact (normal) to impaired tissue integrity, often referred to as a wound or ulcer, depending on its cause. Tissue integrity changes can occur as a result of infections, burns, local skin reactions, injury/trauma, growths or lesions, and inadequate peripheral perfusion (decrease in oxygenated blood to a specific area of the body). The degree of tissue damage is referred to as partial- or full-thickness loss. A *partial-thickness* wound extends through the epidermis and dermis. *Full-thickness* wounds extend into the subcutaneous tissue and can expose muscle or bone.

### Common Risk Factors for Tissue Integrity Changes

Changes in tissue integrity can occur at any age, but older adults are at an increased risk. The skin and underlying tissues of older adults become thinner, drier, and more likely to bruise because of increased capillary fragility. Arterial blood flow is often decreased. Certain medical conditions also increase the risk of impaired tissue integrity and include malnutrition, neurologic disorders, diabetes mellitus, peripheral vascular disease, urinary and bowel incontinence, and immune suppression. The most common tissue impairment is *pressure injuries*, which account for a significant number of hospital and long-term care admissions.

### Physiologic Consequences of Tissue Integrity Changes

Alterations in tissue integrity can lead to localized (cellulitis) or systemic (sepsis) infection. Both partial- and full-thickness wounds can be very painful and difficult to heal, especially for patients with diabetes and other diseases in which arterial perfusion is diminished.

### Assessment of Tissue Integrity

Take a thorough health history of previous and current chronic health problems and current medications (prescribed and over-the-counter [OTC]). Assess for change in skin color, moles or lesions, excessive skin dryness, bruising, and hair loss or brittle nails (indicating decreased tissue perfusion). Document any existing tissue impairment in detail, including wound size, color, depth, and drainage. Monitor serum albumin and prealbumin levels to ensure that the patient has adequate protein for preventing tissue impairment or healing any existing wounds.

### Interventions to Promote Tissue Integrity and Prevent Tissue Integrity Changes

The primary health promotion focus is on proper hygiene and nutrition to enhance tissue health. Teach patients at risk for impaired tissue integrity to inspect the skin every day. Keep the skin clean and dry; when needed, moisturize the skin to prevent excessive dryness. For patients who are confined to a bed or chair, ensure that pressure is relieved by changing body position every 1 to 2 hours. Be sure that patients sit or lie on pressure-reducing surfaces such as mattress overlays or chair gel pads. Assess patients at risk for pressure injuries with evidence-based screening tools such as the Braden Scale, discussed elsewhere in this text.

### Interventions for Tissue Integrity Changes

Provide preventive interventions as described previously to prevent further skin and tissue

breakdown. Ensure that patients eat an adequate diet and receive supplements as needed for healing. Protein and vitamin C are especially important for preventing skin breakdown and promoting healing of existing wounds. Protein shakes and powders can be added to the daily diet.

Interprofessional collaborative management of any tissue integrity alteration may include drug therapy (e.g., antibiotics, topical steroids, and creams). Chemical and/or surgical wound débridement for necrotic tissue is essential to allow healing. In some cases, the primary health care provider may need to perform an interventional procedure to open arteries that are narrowed or obstructed to increase blood flow and promote wound healing.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Collaborate with members of the interprofessional health care team as needed to meet the patient's physiologic needs. For example, consult with the registered dietitian for patients who have impaired nutrition; consult with the physical therapist for patients with impaired mobility. **QSEN: Teamwork and Collaboration**

### Health Promotion and Maintenance

- Provide patient education/health teaching to promote physiologic health, including nutrition, mobility, and gas exchange.
- Assess patient lifestyle behaviors and other factors to determine risks for impairments in basic physiologic needs such as mobility, gas exchange, and perfusion (see [Tables 2-3](#) and [2-4](#)). **Clinical Judgment**

### Psychosocial Integrity

- Differentiate the assessment findings associated with dementia versus delirium (see [Table 2-1](#)).
- Plan interventions to promote sensory perception, especially in older adults. **QSEN: Patient-Centered Care**

### Physiological Integrity

- Provide evidence-based nursing interventions to manage impairments in physiologic needs such as impaired nutrition and mobility to maintain patient safety (see [Chart 2-1](#)). **QSEN: Evidence-Based Practice; Safety**

## CHAPTER 3

# Common Health Problems of Older Adults

Donna D. Ignatavicius

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- MOBILITY
- NUTRITION
- COGNITION

**The interrelated concepts for this chapter are:**

- ELIMINATION
- SENSORY PERCEPTION
- TISSUE INTEGRITY

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with the interprofessional team to help the patient, family, and caregivers achieve positive health outcomes.
2. Identify risk factors for falls and impaired driving ability, including decreased MOBILITY and SENSORY PERCEPTION, in older adults who live in the community or are hospitalized.
3. Explain evidence-based falls risk and prevention interventions for older adults in the hospital and community.
4. Summarize best practices to promote patient safety when using restraints.

### Health Promotion and Maintenance

5. Teach selected evidence-based lifestyle practices to promote health in older adults.
6. Identify health disparities for subgroups within the older-adult population.
7. Conduct a medication assessment for potential risks for adverse drug events in older adults.

### Psychosocial Integrity

8. Assess the older patient's risk for and signs of neglect and abuse.
9. Select valid and reliable assessment tools to document inadequate COGNITION in the older adult.
0. Compare characteristics of common problems of COGNITION: depression, delirium, and dementia.
1. Develop interprofessional collaborative interventions to assist the older adult to cope with relocation stress syndrome.

### Physiological Integrity

2. Identify the four major subgroups of older adults.
3. Explain factors that contribute to decreased NUTRITION and ELIMINATION changes among older adults in the community and inpatient facilities.
4. Describe the effects of drugs on the older adult.
5. Identify key interventions to prevent TISSUE INTEGRITY changes in older adults.

About 13% of the people in the United States are currently older than 65 years, but this number is expected to grow to 20% by 2030 and 25% by 2050 (Ortman et al., 2014). Although Euro-Caucasians are the majority of the current older population, the ethnic and racial makeup of this group is expected to change over the next few decades. In general, women live longer than men, although the exact reason for this difference is not known. Most patients on adult acute care and nursing home units are older than 65 years; many of these patients are discharged for home health services. Therefore nurses and other interprofessional team members need to know about the special needs of older adults to care for them in a variety of settings.

This chapter describes the major health issues, sometimes referred to as **geriatric syndromes**, associated with late adulthood in community and inpatient settings (Brown-O'Hara, 2013). The care of older adults (sometimes referred to as *elders*) with specific acute and chronic health problems is discussed as appropriate throughout this text. *Nursing Focus on the Older Adult* charts and *Considerations for Older Adults* boxes highlight the most important information. A brief review of major physiologic changes of aging is listed in the Assessment chapter of each body system unit. A number of gerontologic nursing textbooks and journals are available for additional information about older adult care.

## Overview

Late adulthood can be divided into four major subgroups:

- 65 to 74 years of age: the young old
- 75 to 84 years of age: the middle old
- 85 to 99 years of age: the old old
- 100 years of age or older: the elite old

*The fastest growing subgroup is the old old, sometimes referred to as the advanced older-adult population.* Members of this subgroup are sometimes referred to as the *frail elderly*, although a number of 85- to 95-year-olds are very healthy and do not meet the criteria for being frail. *Frailty* is actually a geriatric syndrome in which the older adult has unintentional weight loss; weakness and exhaustion; and slowed physical activity, including walking. Frail older adults are also at high risk for adverse outcomes (Brown-O'Hara, 2013).

The vast majority of older adults live in the community at home, in assisted-living facilities, or in retirement or independent living complexes. Of all older adults, only about 5% live in long-term care (LTC) facilities (mostly nursing homes), and another 10% to 15% are ill but are cared for at home. Older adults from any setting usually experience one or more hospitalizations in their lifetime. Many older adults will likely be admitted at some time during their life for short-term stays in a skilled unit of a LTC facility, usually for rehabilitation or complex medical-surgical follow-up care.

Other institutions also have an increase in aging adults. For example, men older than 50 years are the fastest growing group of prisoners today. Like the rest of the older population, older prisoners have multiple chronic health problems. However, these problems are often complicated by a history of substance use and poor NUTRITION that require specific management strategies. Nurses who work in these settings must have expertise in care of older adults.

*The number of homeless people older than 60 years is also growing.* The inability to pay for housing and family/partner relationship problems are primary factors that contribute to this trend. Most homeless adults have one or more chronic health problems, including mental health/behavioral health disorders (Gerber, 2013). A growing number are veterans of recent wars.

## Health Issues for Older Adults in Community-Based Settings

Health is a major concern for many older adults. Health status can affect the ability to perform ADLs and to participate in social activities. A failure to perform these activities may increase dependence on others and may have a negative effect on morale and life satisfaction. If older adults lose the ability to function independently, they often feel empty, bored, and worthless. Loss of autonomy is a painful event related to the physical and mental changes of aging and/or illness.

Older adults may also experience a number of losses that can affect a sense of control over their lives such as the death of a spouse and friends or the loss of social and work roles. Nurses need to support older adults' self-esteem and feelings of independence by encouraging them to maintain as much control as possible over their lives, to participate in decision making, and to perform as many tasks as possible.

Like younger and middle-age adults, older adults need to practice health promotion and illness prevention to maintain or achieve a high level of wellness. Teach them the importance of promoting wellness and strategies for meeting this outcome ([Chart 3-1](#)).

### Chart 3-1

## Patient and Family Education: Preparing for Self-Management

### Lifestyles and Practices to Promote Wellness

#### Health-Protecting Behaviors

- Have yearly influenza vaccinations (preferably after October 1).
- Obtain a pneumococcal vaccination.
- Obtain a shingles vaccination.
- Have a tetanus immunization and get a booster every 10 years.
- Wear seat belts when you are in an automobile.
- Use alcohol in moderation or not at all.
- Avoid smoking; if you do smoke, do not smoke in bed.
- Install and maintain working smoke detectors and/or sprinklers.
- Create a hazard-free environment to prevent falls; eliminate hazards such as scatter rugs and waxed floors.
- Use medications, herbs, and nutritional supplements according to your primary health care provider's prescription.
- Avoid over-the-counter medications unless your primary health care provider directs you to use them.

#### Health-Enhancing Behaviors

- Have a yearly physical examination; see your primary health care provider more often if health problems occur.
- Reduce dietary fat to not more than 30% of calories; saturated fat should provide less than 10% of

your calories.

- Increase your daily dietary intake of complex carbohydrate- and fiber-containing food to five or more servings of fruits and vegetables and six or more servings of grain products.
- Increase calcium intake to between 1000 and 1500 mg daily; take a vitamin D supplement every day if not exposed daily to sunlight.
- Allow at least 10 to 15 minutes of sun exposure two or three times weekly for vitamin D intake; avoid prolonged sun exposure.
- Exercise regularly three to five times a week.
- Manage stress through coping mechanisms that have been successful in the past.
- Get together with people in different settings to socialize.
- Reminisce about your life through reflective discussions or journaling.

Common health issues and geriatric syndromes that often affect older adults in the community include:

- Decreased NUTRITION and hydration
- Decreased MOBILITY
- Stress, loss, and coping
- Accidents
- Drug use and misuse
- Inadequate COGNITION
- Substance use
- Elder neglect and abuse

## Decreased Nutrition and Hydration

Chapter 2 includes a concept review of NUTRITION. The minimum nutritional requirements of the human body remain consistent from youth through old age, with a few exceptions. Older adults need an increased dietary intake of calcium and vitamins D, C, and A because aging changes disrupt the ability to store, use, and absorb these substances. For older adults who have a sedentary lifestyle and decreased metabolic rate, a reduction in total caloric intake to maintain an ideal body weight is needed. Decreased NUTRITION, either underweight or overweight/obesity, can occur in older adults when these needs are not met.

Many physical aging changes influence nutritional status or the ability to consume needed nutrients. For example, diminished senses of taste and smell often result in a loss of desire for food. Older adults often have less ability to taste sweet and salt than to taste bitter and sour. This aging change may result in an overuse of table sugar and salt to compensate. Some older adults consume numerous desserts and other sweet foods, which can cause them to become overweight or obese. Teach older adults how to balance their diets with healthy food selections. Remind them to substitute herbs and spices to season food and vary the textures of food substances to feel satisfied.

Tooth loss and poorly fitting dentures from inadequate dental care or calcium loss can also cause the older adult to avoid important nutritious foods. Unlike today, dental preventive programs were not readily available or stressed as being important when today's older adults were younger. Older people with dentition problems may eat soft, high-calorie foods such as ice cream and mashed potatoes, which lack roughage and fiber. Unless the person carefully chooses more nutritious soft foods, vitamin deficiencies, constipation, and other problems can result. The extensive use of prescribed and over-the-counter (OTC) drugs, including herbal supplements, may decrease appetite, affect food tolerances and absorption, and cause constipation.

Constipation can reduce quality of life for older adults and cause pain, depression, anxiety, and decreased social activities. In some cases it leads to a small or large bowel obstruction, a potentially life-threatening event. Constipation is common among older adults and can be caused by multiple

risk factors, including foods, drugs, and diseases.

## Nursing Safety Priority QSEN

### Action Alert

Teach older adults to increase fiber and fluid intake, exercise regularly, and avoid risk factors that contribute to constipation. Older adults should consume 35 to 50 g of fiber each day and drink at least 2 liters a day unless medically contraindicated. Some people may also add a “colon cocktail” of equal parts of prune juice, applesauce, and psyllium (e.g., Metamucil) to their daily diet. Remind older adults to take 1 to 2 tablespoons of the mixture daily. If these measures do not prevent constipation, teach them to take a stool softener. For opioid-induced constipation (OIC), drug therapy may be prescribed.

Reduced income, chronic disease, fatigue, and decreased ability to perform ADLs are other factors that contribute to decreased NUTRITION and constipation among older adults. “Fast food” is often inexpensive and requires no preparation. However, it is usually high in fat, carbohydrates, and calories but lacking in healthy nutrients. Older adults can become overweight or obese when they consume a diet high in fast food.

Other older adults may reduce their intake of food to near-starvation levels, even with the availability of programs such as food stamps (Supplemental Nutritional Assistance Program [SNAP]), community food banks, and Meals on Wheels. Many senior centers and homeless shelters offer meals and group social activities. The lack of transportation, the necessity of traveling to obtain such services, and the inability to carry large or heavy groceries prevent some older adults from taking advantage of food programs. Others are too proud to accept free services.

Decreased NUTRITION may also be related to loneliness. Older adults may respond to loneliness, depression, and boredom by not eating, which can lead to weight loss. Many who live alone lose the incentive to prepare or eat balanced diets, especially if they do not “feel well.” Men who live at home alone are especially at risk for undernutrition.

## Nursing Safety Priority QSEN

### Action Alert

Perform nutritional screening for older adults in the community who are at risk for decreased NUTRITION—either weight loss or obesity. Ask the person about unintentional weight loss or gain, eating habits, appetite, prescribed and OTC drugs, and current health problems. Determine contributing factors for older adults who have or are at risk for poor NUTRITION such as transportation issues or loneliness. Based on these assessment data, develop and implement a plan of care in collaboration with the registered dietitian, pharmacist, and/or case manager to manage these problems. Chapter 60 describes nutritional assessment and management of NUTRITION problems in more detail.

Some older adults are at risk for **geriatric failure to thrive (GFTT)**—a complex syndrome including under-nutrition, impaired physical functioning, depression, and cognitive impairment (Rocchiccioli & Sanford, 2009). However, drug therapy, chronic diseases, major losses, and poor socioeconomic status can cause these same health problems. Be sure to consider these factors when screening for GFTT. For those at risk for or who have GFTT, collaborate with the older adult and family to plan referral to his or her primary health care provider for extensive evaluation. Early supportive intervention can help prevent advanced levels of deterioration.

People older than 65 years are also at risk for dehydration because they have less body water content than younger adults. In severe cases they require emergency department visits or hospital stays.

## Nursing Safety Priority QSEN

## Action Alert

Older adults sometimes limit their fluid intake, especially in the evening, because of decreased MOBILITY, prescribed diuretics, and urinary incontinence. *Teach older adults that fluid restrictions make them likely to develop dehydration and electrolyte imbalances (especially sodium and potassium) that can cause serious illness or death.*

Incontinence may actually increase because the urine becomes more concentrated and irritating to the bladder and urinary sphincter. Teach older adults the importance of drinking 2 liters of water a day plus other fluids as desired. Remind them to avoid excessive caffeine and alcohol because they can cause dehydration. [Chapter 11](#) discusses fluid and electrolyte imbalances in detail.

## NCLEX Examination Challenge 3-1

### Health Promotion and Maintenance

Which statement by the older adult indicates a need for further teaching about meeting nutrition and hydration needs?

- A. "I will make sure I eat plenty of fruits and vegetables and avoid red meat."
- B. "I will stop drinking liquids after dinner to prevent getting up at night."
- C. "I'm going to check if I can get food stamps to help me afford better food."
- D. "I've got to increase more fiber in my diet to help my bowels work better."

## Decreased Mobility

[Chapter 2](#) provides a concept review of MOBILITY. Exercise and activity are important for older adults as a means of promoting and maintaining mobility and overall health ([Fig. 3-1](#)). Physical activity can help keep the body in shape and maintain an optimal level of functioning. Regular exercise has many benefits for older adults in community-based settings. The major advantages of maintaining appropriate levels of physical activity include:

**FIG. 3-1** Exercise is important to older adults for health promotion and maintenance.

- Decreased risk for falls
- Increased muscle strength and balance
- Increased MOBILITY

- Increased sleep
- Reduced or maintained weight
- Improved sense of well-being and self-esteem
- Improved longevity
- Reduced risks for diabetes, coronary artery disease, and dementia

Assess older adults in any setting regarding their history of exercise and any health concerns they may have. For independent older adults, remind them to check with their health care provider to implement a supervised plan for regular physical activity. Teach older adults about the value of physical activity.

For people who are homebound, focus on functional ability such as performing ADLs. For those who are not homebound, teach the importance of exercise. For example, resistance exercise maintains muscle mass. Aerobic exercise such as walking improves strength and endurance. One of the best exercises is walking at least 30 minutes, 3 to 5 times a week. During the winter indoor shopping centers and other public places can be used. In addition, many senior centers and community centers offer exercise programs for older adults. For those who have limited MOBILITY, chair exercises are provided.

Swimming is also a good way to exercise but does not offer the weight-bearing advantage of walking. Weight bearing helps build bone, an especially important advantage for older women to prevent osteoporosis (see [Chapter 50](#)). Teach older adults who have been sedentary to start their exercise programs slowly and gradually increase the frequency and duration of activity over time under the direction of their primary health care provider.

## Stress, Loss, and Coping

Stress can speed up the aging process over time, or it can lead to diseases that increase the rate of degeneration. It can also impair the reserve capacity of older adults and lessen their ability to respond and adapt to changes in their environment.

Although no period of the life cycle is free from stress, the later years can be a time of especially high risk. Frequent sources of stress and anxiety for the older population include:

- Rapid environmental changes that require immediate reaction
- Changes in lifestyle resulting from retirement or physical incapacity
- Acute or chronic illness
- Loss of significant others
- Financial hardships
- Relocation

How people react to these stresses depends on their personal coping skills and support networks. For instance, losses leave many older adults without friends for support and help. As a result, many must rely solely on their personal resources to maintain their mental health/behavioral health. A combination of poor physical health and social problems can leave older adults susceptible to stress overload, which can result in illness and premature death.

The ways in which people adapt to old age depend largely on the personality traits and coping strategies that have characterized them throughout their lives. Establishing and maintaining relationships with others throughout life are especially important to the older person's happiness. Even more important than having friends is the nature of the friendships. People who have close, intimate, stable relationships with others in whom they confide are often more likely to cope with crisis.

Some older adults choose to return to work at least on a part-time basis to increase their income and socialize with other people. If a person retired between the ages of 55 and 65 years and lives into his or her 80s, retirement funds can deplete. As one ages, additional income is needed to meet basic needs, including money for prescription drugs. Although US government Medicare Part A pays for inpatient hospital care, older adults pay for Medicare Part B to reimburse for 80% of most ambulatory care services, Medicare Part D for prescription drugs, and a private Medi-Gap insurance (e.g., United Health or Blue Cross/Blue Shield) to cover the costs not paid for by Medicare. The premiums for these insurances are very expensive and may still require that older adults pay out-of-pocket copayments for health care services and prescription drugs.

In other developed countries part of or all older-adult care is provided for publicly by the federal government. For example, in Canada all acute and primary health care provider care is paid for publicly. In Germany all older-adult care, including long-term care, is paid for by the government.

*Fortunately most older adults are relatively healthy and live in and own their own homes.* Physical and/or mental health/behavioral health problems may force some to relocate to a retirement center or an assisted-living facility, although these facilities can be very expensive. Others move in with family members or to apartment buildings funded and designated for seniors. Older adults usually have more difficulty adjusting to major change when compared with younger and middle-age adults. Being admitted to a hospital or nursing home is a particularly traumatic experience. Older adults often suffer from relocation stress syndrome, also known as *relocation trauma*. **Relocation stress syndrome** is the physical and emotional distress that occurs after the person moves from one setting to another. Examples of physiologic behaviors are sleep disturbance and increased physical symptoms such as GI distress. Examples of emotional manifestations are withdrawal, anxiety, anger, and depression. [Chart 3-2](#) lists nursing interventions that may help decrease the effects of relocation.

### **Chart 3-2**

## **Best Practice for Patient Safety & Quality Care** QSEN

### **Minimizing the Effects of Relocation Stress in Older Adults**

- Provide opportunities for the patient to assist in decision making.
- Carefully explain all procedures and routines to the patient before they occur.
- Ask the family or significant other to provide familiar or special keepsakes to keep at the patient's bedside (e.g., family picture, favorite hairbrush).
- Reorient the patient frequently to his or her location.
- Ask the patient about his or her expectations during hospitalization or assisted-living or nursing home stay.
- Encourage the patient's family and friends to visit often.
- Establish a trusting relationship with the patient as early as possible.
- Assess the patient's usual lifestyle and daily activities, including food likes and dislikes and preferred time for bathing.
- Avoid unnecessary room changes.
- If possible, have a family member, significant other, staff member, or volunteer accompany the patient when leaving the unit for special procedures or therapies.

Family members and facility staff need to be aware that older adults need personal space in their new surroundings. Older adults need to participate in deciding how the space will be arranged and what they can keep in their new home to help offset potential feelings of powerlessness. Suggest that the patient or family bring in personal items such as pictures of relatives and friends, favorite clothing, and valued knickknacks to help make the new setting seem more familiar and comfortable. This same intervention can be carried out in a hospital setting.

## **Accidents**

Accidents are very common among older adults; falls are the most common. Motor vehicle crashes increase as well because of physiologic changes of aging or chronic diseases such as Alzheimer's disease or peripheral neuropathy.

## Fall Prevention

Most accidents occur at home. Teach older adults about the need to be aware of safety precautions to prevent accidents such as falls. Incapacitating accidents are a primary cause of decreased MOBILITY and chronic pain in old age. Some people develop **fallophobia** (fear of falling) and avoid leaving their homes. This reaction is particularly common for those who have previously fallen and/or have osteoporosis (bone tissue loss). Osteoporosis is especially common in older thin Euro-Caucasian women who typically have a stooped posture (kyphosis), which can cause problems with balance (see Ch. 50).

Home modifications may help prevent falls (Saccomano & Ferrara, 2015). Collaborate with the older adult, family, and significant others when recommending useful changes to prevent injury. Safeguards such as handrails, slip-proof pads for rugs, and adequate lighting are essential in the home. Avoiding scatter rugs, slippery floors, and clutter is also important to prevent falls. Installing grab bars and using nonslip bathmats can help prevent falls in the bathroom. Raised toilet seats are also important, especially for those who have hip and knee arthritis. Remind older adults to avoid going out on days when steps are wet or icy and to ask for help when ambulating. To minimize sensory overload, advise the older adult to concentrate on one activity at a time.

Changes in SENSORY PERCEPTION and MOBILITY can create challenges for older adults in any environment. For example, **presbyopia** (farsightedness that worsens with aging) may make walking more difficult; the person is less aware of the location of each step. In addition, the older adult may have disorders that affect visual acuity such as macular degeneration, cataracts, glaucoma, or diabetic retinopathy. Teach the person to look down at where he or she is walking and have frequent eye examinations to update glasses or contact lenses to improve vision. Drug therapy or surgery may be needed to correct glaucoma or cataracts.

A reduced sense of touch decreases the awareness of body orientation (e.g., whether the foot is squarely on the step). The decreased reaction time that commonly results from age-related changes in the neurologic system may also impair the ability to recognize or move from a dangerous setting. Chronic diseases such as peripheral neuropathy and arthritis can affect MOBILITY and SENSORY PERCEPTION in the older adult as well. If needed, encourage the use of visual, hearing, or ambulatory assistive devices. High costs and a fear of appearing old sometimes prevent older adults from obtaining or using hearing aids, eyeglasses, walkers, or canes.

Once an older person has been identified as being at high risk for falls, choose interventions that help prevent falls and possible serious injury. For example, for those in the community, tai chi exercise or yoga for seniors is very helpful to improve balance and MOBILITY and decrease the fear of falling, especially among older women (Saccomano & Ferrara, 2015).

## NCLEX Examination Challenge 3-2

### Safe and Effective Care Environment

The nurse performs an initial assessment for an older adult being admitted to an assisted-living facility. Which nursing findings indicate that the client is at risk for falls? **Select all that apply.**

- A. Uses a roller walker
- B. Has had arthritis for 20 years
- C. Is oriented to person, place, and time
- D. Wears eyeglasses
- E. Has bilateral cataracts
- F. Has severe osteoporosis

## Driving Safety

*Motor vehicle crashes are a major cause of accidents and death among the older-adult population. Increased national concerns about this growing problem have prompted many states to require more frequent*

testing for older drivers. As one ages, reaction time and the ability to multitask decrease. Sleep disturbances, especially insomnia, are also common in older adults but are *not* part of normal aging. Some crashes occur because the person falls asleep while driving.

The older the person, the more likely that he or she will have chronic diseases and the drugs needed to manage them. These health problems and treatments can contribute to motor vehicle crashes. For instance, peripheral neuropathy may prevent a driver from feeling whether his or her foot is on the brake or accelerator. Drugs used for hypertension can cause orthostatic hypotension (low blood pressure when changing body position from a supine to sitting or standing position).

Primary health care providers play a major role in identifying driver safety issues. Yet many are reluctant to intervene because older patients think they will lose their independence if they cannot drive. They may also be angry and resistant to the idea of giving up perhaps their only means of transportation. As an alternative, health care professionals can recommend driving refresher courses and suggest that high-risk driving conditions such as wet roads be avoided. Newer vehicles have safety features to help older adults such as large-print digital readouts for speed and rear cameras to see behind the vehicle. [Chart 3-3](#) lists additional ways to improve older-adult driver safety.

### **Chart 3-3**

## **Best Practice for Patient Safety & Quality Care**

### **Recommendations for Improving Older Adult Driver Safety**

- Discuss driving ability with the patient to assess his or her perception.
- Assess physical and mental deficits that could affect driving ability.
- Consult with appropriate primary health care providers to treat health problems that could interfere with driving.
- Suggest community-based transportation options, if available, instead of driving.
- Discuss driving concerns with patients and their families.
- Remind the patient to wear glasses and hearing aids if prescribed.
- Encourage driver-refresher classes, often offered by AARP (formerly the American Association of Retired Persons).
- Consult a certified driving specialist for an on-road driving assessment.
- Encourage avoiding high-risk driving locations or conditions such as busy urban interstates and wet or icy weather conditions.
- Report unsafe drivers to the state department of motor vehicles if they continue to drive.

## **Drug Use and Misuse**

Drug therapy for the older population can be another major health issue. Because of the multiple chronic and acute health problems that occur in this age-group, drugs for older adults account for about one third of all prescription drug costs. The term **polymedicine** has been used to describe the use of many drugs to treat multiple health problems for older adults. **Polypharmacy** is the use of multiple drugs, duplicative drug therapy, high-dosage medications, and drugs prescribed for too long a period of time.

Older adults commonly take multiple nonprescription or over-the-counter (OTC) drugs such as analgesics, antacids, cold and cough preparations, laxatives, and herbal/nutritional supplements, often without consulting a health care provider. Therefore this population is at high risk for adverse drug events (ADEs) directly related to the number of drugs taken and the frequency with which they are taken. Drug-drug, food-drug, drug-herb, and drug-disease interactions are common ADEs

that often lead to hospital admission.

## Effects of Drugs on Older Adults

Older adults often do not tolerate the standard dosage of drugs traditionally prescribed for younger adults. The physiologic changes related to aging make drug therapy more complex and challenging. These changes affect the absorption, distribution, metabolism, and excretion of drugs from the body. Even common antibiotics can lead to temporary memory loss or acute confusion. More commonly, antibiotic therapy can cause a *Clostridium difficile* infection, as discussed in [Chapter 23](#).

Age-related changes that can potentially affect drug *absorption* from an oral route include an increase in gastric pH, a decrease in gastric blood flow, and a decrease in GI motility. Despite these changes, older adults do not have major absorption difficulties because of age-related changes alone.

Age-related changes that affect drug *distribution* include smaller amounts of total body water, an increased ratio of adipose tissue to lean body mass, a decreased albumin level, and a decreased cardiac output. Increased adipose tissue in proportion to lean body mass can cause increased storage of lipid-soluble drugs. This leads to a decreased concentration of the drug in plasma but an increased concentration in tissue.

Drug *metabolism* often occurs in the liver. Age-related changes affecting metabolism include a decrease in liver size, a decrease in liver blood flow, and a decrease in serum liver enzyme activity. These changes can result in increased plasma concentrations of a drug. Monitor liver function studies and teach older adults to have regular physical examinations.

Changes in the kidneys can also result in high plasma concentrations of drugs. The *excretion* of drugs usually involves the renal system. Age-related changes of the renal system include decreased renal blood flow and reduced glomerular filtration rate. These changes result in a decreased creatinine clearance and thus a slower excretion time for medications. Consequently serum drug levels can become toxic, and the patient can become extremely ill or die. *Monitor renal studies, especially serum creatinine and creatinine clearance, when giving drugs to older adults!*

A creatinine clearance test measures the glomerular filtration rate of the kidneys. A commonly used formula for calculating creatinine clearance for men rather than directly measuring it is:

$$\frac{(140 - \text{Age in years}) \times \text{Lean body weight in kg}}{\text{Serum creatinine in mg/dL}} \times 72$$

For women, use this formula and multiply the answer by 0.85. A normal creatinine clearance for men is 107 to 139 mL/min and for women 87 to 107 mL/min. Values decrease as a person ages.

When chronic disease is added to the physiologic changes of aging, drug reactions have a more dramatic effect and take longer to correct. Often a lower dose of a drug is necessary to prevent ADEs. The policy of “start low, go slow” is essential when health care providers prescribe drugs for older adults. The physiologic changes of aging are highly individual. Alterations in drug therapy should always be individualized according to the actual physiologic changes present and the occurrence and severity of chronic disease. Common ADEs are listed in [Table 3-1](#).

---

**TABLE 3-1**

### Common Adverse Drug Events (ADEs) in Older Adults

---

- Edema
- Severe nausea and vomiting
- Anorexia
- Dehydration
- Dysrhythmias
- Fatigue
- Weakness
- Dizziness
- Syncope
- Urinary retention
- Diarrhea
- Constipation/impaction
- Hypotension
- Acute confusion

Data from Berryman, S. N., Jennings, J., Ragsdale, S., Lofton, T., Huff, D. C., & Rooker, J. S. (2012). Beers criteria for potentially inappropriate medication use in older adults. *MEDSURG Nursing*, 21(3), 129-133.

## Self-Administration of Drugs

Most people older than 65 years take their own medications. Because the risk for drug toxicity is considerably increased in the older population, help patients assume this task responsibly. Teach patients and their caregivers, providing clear and concise directions and developing ways to help them overcome difficulties with self-administration.

Older adults may make errors in self-administration or do not adhere to the drug regimen for several reasons. First they may simply forget. In the rush of daily activities, they may not take their drugs or may take them too often because they cannot remember when or whether they have taken the medications. It is often helpful if they associate pill taking with daily events (e.g., meals) or keep a simple chart or calendar. Pill boxes are available for a daily, weekly, or monthly supply of medicine that can be placed in small compartments (Fig. 3-2). Egg cartons can be very cost-effective pill boxes. Large print on the drug label helps patients who have poor vision. Writing the drug regimen on the top of the bottle with large letters and numbers is helpful for some older adults. Colored labels or dots can also be applied. Easy-open bottle caps help older adults with limited hand mobility or strength.

FIG. 3-2 A medication system for safe self-administration.

A second reason for drug errors is poor communication with health care professionals. These problems result from poor explanations that are not understood because of educational limitations, language barriers, or difficulty with hearing and vision. Health care professionals often presume that their patients have learned the information if they have taught them about the drugs. Help older adults plan their drug therapy schedules as needed.

A third reason for errors is the varying ways that older adults take their medications. Many people older than 65 years use a multitude of complementary and integrative therapies. Some add to their drug regimen by taking OTC drugs, which can interact with prescription drugs and cause serious problems. For example, a patient receiving warfarin (Coumadin, Warfilone) for anticoagulation may take ibuprofen (Motrin) regularly for arthritis or garlic for hypertension. Because ibuprofen and garlic can inhibit clotting, this combination can cause serious bleeding. When obtaining a drug history, ask patients about all OTC drugs, including herbal and food supplements.

Some older adults avoid taking their prescribed drugs. The fear of dependency or the cost of the drugs may cause many to discontinue their drug therapy too soon or not begin taking the drug. In addition, the actions or side effects of some drugs may not be desirable. For example, diuretics may cause incontinence when patients cannot get to the bathroom quickly enough. Others may think that two pills are twice as effective and therefore it is better to take two rather than just one. Some older adults take drugs that are left over from a previous illness or one that is borrowed from someone else. Teach patients to take their medications exactly as prescribed by their health care providers.

## Medication Assessment and Health Teaching

The *Healthy People 2020* initiative recommends that older adults be interviewed regarding their medication use and include these questions:

- Do you take five or more prescription medications?
- Do you take herbs, vitamins, other dietary supplements, or OTC medications?

- Do you have your prescriptions filled at more than one pharmacy?
- Is more than one health care practitioner prescribing your medications?
- Do you take your medications more than once a day?
- Do you have trouble opening your medication bottles?
- Do you have poor eyesight or hearing?
- Do you live alone?
- Do you have a hard time remembering to take your medications?

The Beers Criteria for Potentially Inappropriate Medication Use in Older Adults assessment tool, simply known as the *Beers criteria*, is also very useful in screening for medication-related risks in older adults who have chronic health problems (Berryman et al., 2012). The tool lists multiple medications and related concerns. Examples of these “at-risk” drugs are listed in [Table 3-2](#).

**TABLE 3-2**

**Examples of Beers Criteria for Potentially Inappropriate Medication Use in Older Adults**

- meperidine (Demerol)
- cyclobenzaprine (Flexeril)
- digoxin (Lanoxin) (Should not exceed 0.125 mg daily except for atrial fibrillation)
- ticlopidine (Ticlid)
- fluoxetine (Prozac)
- amitriptyline (Elavil)
- diazepam (Valium)
- promethazine (Phenergan)
- ketorolac (Toradol)
- short-acting nifedipine (e.g., Procardia)
- ferrous sulfate (Iron) (Should not exceed 325 mg daily)
- chlorpropamide (Diabinese)
- diphenhydramine (Benadryl)

Data from Berryman, S. N., Jennings, J., Ragsdale, S., Lofton, T., Huff, D. C., & Rooker, J. S. (2012). Beers criteria for potentially inappropriate medication use in older adults. *MEDSURG Nursing*, 21(3), 129-133.

**Nursing Safety Priority** QSEN

**Drug Alert**

To reduce drug-related risks in older adults, perform a medication assessment every 6 months or more often if an acute illness or exacerbation of a chronic disease occurs. Be sure to:

- Obtain a list of all medications taken on a regular and as-needed basis; include OTC and prescribed drugs, herbs, and nutritional supplements. If a list is not available, ask the older adult or family to gather all ointments, pills, lotions, eyedrops, inhalers, injectable solutions, vitamins, minerals, herbs, and other OTC medications and place into a bag for review.
- Highlight all medications that are part of the Beers criteria; highlight any medication for which the indication for its use is not clear, is inappropriate, or could be discontinued (e.g., duplicative drug).
- Collaborate with the older adult, family, pharmacist, and primary health care provider if appropriate to determine the need for medication changes. Suggest once-a-day dosing if possible.
- Give older adults verbal and written information (at the appropriate reading level) regarding any change or new medication prescribed.
- Promote adherence to the drug therapy regimen exactly as prescribed; remind older adults to check with their primary care provider if they want to change their regimen or add an OTC medication or natural product (nutritional or herbal supplement, or probiotic).
- Encourage lifestyle changes and other nonpharmacologic interventions to help manage or prevent health problems.
- Remind older adults not to share or borrow medications.

## NCLEX Examination Challenge 3-3

### Physiological Integrity

A nurse conducts an assessment of an older adult's medications and herbal/nutritional supplements. Which supplement is **most** likely to cause an interaction with prescribed medications?

- A. Probiotics
- B. Echinacea
- C. Vitamin D
- D. Vitamin C

### Inadequate Cognition

Chapter 2 reviews the concept of cognition. Older adults are usually mentally sound and competent. Some changes in COGNITION have been identified as age related and are linked to specific cognitive functions rather than intellectual capacity. These changes include a decreased reaction time to stimuli and an impaired memory for recent events. *However, severe cognitive impairment and psychosis are not common.*

Two forms of competence exist: legal competence and clinical competence. A person is **legally competent** if he or she is:

- 18 years of age or older
- Pregnant or a married minor
- A legally emancipated (free) minor who is self-supporting
- Not declared incompetent by a court of law

If a court determines that an older adult is not legally competent, a **guardian** is appointed to make health care decisions. Guardians may be family members or a person who is not related to the patient. When no one is available, a guardian may be appointed from a local Area Agency on Aging, an organization with comprehensive services and resources for older adults.

A person is **clinically competent** if he or she is legally competent and can make clinical decisions. Decisional capacity is determined by a person's ability to identify problems, recognize options, make decisions, and provide the rationale supporting the decisions. Selected behavioral/mental illnesses often affect both legal and clinical competence.

Nurses are in a unique position to teach older adults about ways to promote cognitive health. Cognitive training (e.g., learning a new skill), physical activity, social engagement, and NUTRITION are the most helpful interventions to prevent cognitive changes in older adults. In some communities online cognitive training is playing a role in helping to improve memory in older adults (Haesner et al., 2015).

As older adults age, they are at increasing risk for cognitive impairments—depression, delirium, and dementia, often referred to as the 3Ds. The 3Ds are discussed briefly here; more comprehensive discussions can be found in mental health/behavioral health textbooks.

## Veterans' Health Considerations

### Patient-Centered Care QSEN

Many older veterans of the Korean and Vietnam wars also suffer from chronic pain, depression, post-traumatic stress disorder (PTSD), and severe anxiety. Substance use, especially alcoholism, is common among young and older veterans. Alcoholism can contribute to cognitive decline and may be used as a coping mechanism for loss. As a result, many of today's homeless population are veterans of previous and more recent wars.

## Depression

Depression is the most common mental health/behavioral health problem among older adults in the community. It increases in incidence when older adults are admitted to the hospital or nursing home. **Depression** is broadly defined as a mood disorder that can have cognitive, affective, and physical manifestations. It can be primary or secondary and can range from mild to severe or major. As a *primary* problem, depression is thought to result from a lack of the neurotransmitters *norepinephrine* and *serotonin* in the brain. *Secondary* depression, sometimes called *situational* depression, can result when there is a sudden change in the person's life such as an illness or loss. Common illnesses that can cause secondary depression include stroke, arthritis, and cardiac disease. It is often underdiagnosed by primary health care providers and is therefore undertreated.

Families and nurses are in the best position to suspect depression in an older adult. Several screening tools are available to help determine if the patient has clinical depression. The **Geriatric Depression Scale—Short Form (GDS-SF)** is a valid and reliable screening tool and is available in multiple languages. The patient selects "yes" or "no" to 15 questions, or a nurse or other health care professional can ask the patient the questions. A score of 10 or greater is consistent with a possible diagnosis of clinical depression (Fig. 3-3). These patients are then evaluated more thoroughly by the health care provider for treatment. Without diagnosis and treatment, depression can result in:

**Geriatric Depression Scale—Short Form**

Choose the best answer for how you have felt over the past week:

1. Are you basically satisfied with your life? YES / **NO**
2. Have you dropped many of your activities and interests? **YES** / NO
3. Do you feel that your life is empty? **YES** / NO
4. Do you often get bored? **YES** / NO
5. Are you in good spirits most of the time? YES / **NO**
6. Are you afraid that something bad is going to happen to you? **YES** / NO
7. Do you feel happy most of the time? YES / **NO**
8. Do you often feel helpless? **YES** / NO
9. Do you prefer to stay at home, rather than going out and doing new things? **YES** / NO
10. Do you feel you have more problems with memory than most? **YES** / NO
11. Do you think it is wonderful to be alive now? YES / **NO**
12. Do you feel pretty worthless the way you are now? **YES** / NO
13. Do you feel full of energy? YES / **NO**
14. Do you feel that your situation is hopeless? **YES** / NO
15. Do you think that most people are better off than you are? **YES** / NO

Answers in bold indicate depression. Score 1 point for each bolded answer.

A score > 5 points is suggestive of depression.  
A score ≥ 10 points is almost always indicative of depression.  
A score > 5 points should warrant a follow-up comprehensive assessment.

**FIG. 3-3** The Geriatric Depression Scale—Short Form. (From the Aging Clinical Research Center (ACRC), a joint project of Stanford University and the VA Palo Alto Health Care System, Palo Alto, CA, funded by the National Institute of Aging and the Department of Veterans Affairs.)

- Worsening of medical conditions
- Risk for physical illness
- Alcoholism and drug use

- Increased pain and disability
- Delayed recovery from illness
- Suicide (especially in Euro-Caucasian men between 75 and 85 years of age)

Older adults with depression may have early-morning insomnia, excessive daytime sleeping, poor appetite, a lack of energy, and an unwillingness to participate in social and recreational activities. The primary treatment for depression usually includes drug therapy and psychotherapy, depending on the severity of the problem. Selective serotonin reuptake inhibitors (SSRIs) are the first choice for drug therapy but take 2 to 3 weeks to work. They act by increasing the amount of serotonin and norepinephrine at nerve synapses in the brain.

## Nursing Safety Priority QSEN

### Drug Alert

Tricyclic antidepressants should not be used for older adults because they have anticholinergic properties that can cause acute confusion, severe constipation, and urinary incontinence. For older adults who may be prescribed this group of drugs, question the primary health care provider and request an SSRI or other treatment.

Reminiscence or reflective therapies also help older adults overcome feelings of depression and despair. More information about depression, including strategies for preventing depression, is available in mental health/behavioral health nursing textbooks.

### Dementia

**Dementia** is a broad term used for a syndrome that involves a slowly progressive cognitive decline, sometimes referred to as *chronic confusion*. This syndrome represents a global impairment of intellectual function and is generally chronic and progressive. There are many types of dementia, the most common being Alzheimer's disease. Multi-infarct dementia, the second most common dementia, results from a vascular disorder. [Chapter 42](#) discusses dementias in detail, with a focus on Alzheimer's disease.

### Delirium

Whereas dementia is a chronic, progressive disorder, delirium has an *acute* and fluctuating onset. It is often seen among older adults in a setting with which they are unfamiliar, including both acute and long-term care (Kalish et al., 2014). **Delirium** is characterized by the patient's inattentiveness, disorganized thinking, and altered level of consciousness (either hypoalert or hyperalert). In addition to cognitive changes, some patients have physical and emotional manifestations and may become psychotic.

The types of delirium are *hyperactive*, *hypoactive*, and *mixed*. *Hyperactive* patients may try to climb out of bed or become agitated, restless, and aggressive. *Hypoactive* patients are quiet, apathetic, lethargic, unaware, and withdrawn. They often move very slowly and stare. Patients with hypoactive dementia are often not diagnosed. *Mixed* delirium patients have a combination of hyperactive and hypoactive manifestations.

Identify patients who are at risk for delirium; high-risk patients are usually the late old and those with alcoholism and/or disorders of major body organs. Some hospitals offer programs to prevent delirium and loss of function in high-risk patients such as the Hospital Elder Life Program (HELP) (Kalish et al., 2014).

Some of the many factors that can cause delirium are:

- Drug therapy (especially anticholinergics, opioids, and psychoactive drugs)
- Fluid and electrolyte imbalances
- Infections, especially urinary tract, pneumonia, and sepsis
- Fecal impaction or severe diarrhea
- Surgery (especially fracture hip repair and post-transplant)
- Metabolic problems such as hypoglycemia

- Neurologic disorders such as tumors
- Circulatory, renal, and pulmonary disorders
- Nutritional deficiencies
- Hypoxemia (decreased arterial oxygen level)
- Mechanical ventilation
- Relocation
- Major loss
- Critical care setting

Many patients have more than one of these factors as causes for their delirium.

## Nursing Safety Priority QSEN

### Action Alert

Delirium is a major predictor of morbidity and mortality (Kalish et al., 2014). For example, acutely confused patients who are discharged from the hospital are at an increased risk for functional decline, falls, and incontinence at home. Therefore carefully assess older patients in any setting for acute confusion so it can be managed.

A number of tools have been developed for point-of-care screening for delirium, including the Confusion Assessment Method (CAM), Delirium Index (DI), NEECHAM Confusion Scale, and Mini-Cog. The CAM is a short and easy-to-use tool that consists of nine open-ended questions and a diagnostic algorithm for determining delirium (Table 3-3). This screening tool is easily adaptable for computerized point-of-care charting.

**TABLE 3-3**

### The Confusion Assessment Method (CAM)

1. Acute onset and fluctuating course (e.g., Is there evidence of an acute change in mental status from the patient's baseline?)
2. Inattention (e.g., Does the patient have difficulty focusing attention or keeping track of what is being said?)
3. Disorganized thinking (e.g., Is the patient's thinking and conversation disorganized or incoherent?)
4. Altered level of consciousness (e.g., Is the patient lethargic, hyperalert, or difficult to arouse?)
The diagnosis of delirium by the CAM is the presence of features 1 and 2 <i>and</i> either 3 or 4.

Data from Sendelbach, S., & Guthrie, P. F. (2009). Evidence-based guideline—Acute confusion/delirium: Identification, assessment, treatment, and prevention. *Journal of Gerontological Nursing*, 35(11), 11-17.

Collaborate with the interprofessional health care team to remove or treat risk or causative factors for acute confusion. For example, if the patient has a low oxygen saturation level, provide supplemental oxygen therapy to increase oxygen to the brain. If the patient has a urinary tract infection (UTI), it is treated. The primary sign of a UTI in older adults is acute confusion.

To help prevent and manage delirium, use a calm voice to frequently reorient the patient. For example, playing tapes of soothing music may have a calming effect. Providing a doll or stuffed animal with which to “fidget” may prevent the patient from removing important medical tubes or equipment. Some nurses believe that providing dolls and stuffed animals is treating the adult like a child, but this intervention can sometimes be very effective when used for therapeutic purposes. If the patient has a favorite item such as an afghan blanket or a picture, ask the family or significant others to provide it for the same purpose.

Table 2-1 in Chapter 2 highlights the major differences between delirium and dementia and lists the major nursing considerations for each. The most difficult challenge is caring for a patient who is experiencing both problems at the same time.

## Substance Use

Excessive substance use (both alcohol and illicit drugs) increases the risk for falls and other accidents; affects mood and COGNITION; and leads to complications of chronic diseases such as diabetes mellitus, hypertension, and heart disease. Isolation, depression, and delirium can result from substance use. The National Institute on Aging (NIA) recommends that people older than 65 years have no more than one alcoholic drink a day or seven drinks in a week (NIA, 2012). Illicit

drugs such as cannabis (marijuana) should be avoided unless they are needed for therapeutic use.

The Short Michigan Alcoholism Screening Test—Geriatric Version (SMAST-G) is often used by nurses and other health care professionals in ambulatory care settings to detect alcohol use or alcoholism. The 10 yes/no question test is available in English and Spanish and can be either self-administered or administered by a clinician. Examples of questions on the tool are:

- Do you drink to take your mind off your problems?
- When you feel lonely, does having a drink help?

A “yes” answer is worth one point. A total score of two or more points indicates that the person has a problem with alcohol.

Other screening tools for alcohol use in older adults include the CAGE questionnaire, the Alcohol-Related Problems Survey (ARPS), and the Short ARPS (shARPS). The acronym *CAGE* comes from four questions:

- Have you ever tried to **cut** down on your drinking?
- Have people **annoyed** you by criticizing your drinking?
- Have you ever felt bad or **guilty** about your drinking?
- Have you ever had a drink first thing in the morning to settle your nerves to get rid of a hangover (**eye-opener**)?

## Elder Neglect and Abuse

Another problem for some older adults is neglect and abuse, both verbal and physical. Some older adults are more vulnerable to these problems than others, especially widows who may have difficulty being assertive. Elder abuse and neglect is a serious problem that affects many older adults each year. Older people who are neglected or abused are often physically dependent from one or more disabilities. The abuser is often a family member who becomes frustrated or distraught over the burden of caring for the older adult. Unfortunately only a few cases of elder abuse are reported.

Prolonged caregiving by a family member is a common new role for adult children, usually women. This new role may result in role fatigue, conflict, and strain. As a result, **neglect** can occur when a caregiver fails to provide for an older adult's basic needs such as food, clothing, medications, or assistance with ADLs. The caregiver refuses to let other people such as nursing assistants or home care nurses into the home. Whether intentional or unintentional, neglect accounts for almost half of all cases of actual elder abuse.

**Physical abuse** is the use of physical force that results in bodily injury, especially in the “bathing suit” zone (abdomen, buttocks, genital area, upper thighs). Examples of physical abuse are hitting, burning, pushing, and molesting the patient. Sedating the older adult is also abusive. **Financial abuse** occurs when the older adult's property or resources are mismanaged or misused; this is more common than physical abuse. **Emotional abuse** is the intentional use of threats, humiliation, intimidation, and isolation toward older adults.

Carefully assess the patient for signs of abuse such as bruises in clusters or regular patterns; burns, commonly to the buttocks or the soles of the feet; unusual hair loss; or multiple injuries, especially fractures. If the older adult is too weak or has no other resources or support systems, he or she may not admit that abuse is occurring. Neglect may be manifested by pressure injuries, contractures, dehydration or malnutrition, urine burns, excessive body odor, and listlessness. Depression and dementia are common in community older adults who are abused or neglected.

Be sure to screen for abuse and neglect of older adults using an appropriate assessment tool. [Table 3-4](#) lists tools that can be used by nurses and other health care professionals to screen for elder abuse and neglect. The older adult should be referred to the appropriate service when there is:

---

**TABLE 3-4**

### Examples of Elder Abuse Screening Tools

---

- |   |
|---|
| <ul style="list-style-type: none"><li>• Elder Abuse Suspicion Index</li><li>• Elder Assessment Instrument</li><li>• Indicators of Abuse Screen</li><li>• Questions to Elicit Elder Abuse</li><li>• Hwalek-Sengstock Elder Abuse Screening Tool</li><li>• Caregiver Abuse Screen</li><li>• Brief Abuse Screen for the Elderly</li><li>• Vulnerability to Abuse Screening Scale</li></ul> |
|---|

- Evidence of mistreatment without sufficient clinical explanation
- Report by an older adult of being abused or neglected
- A belief by the health care professional that there is a high risk for or probable abuse, neglect, abandonment, or exploitation

All states in the United States and other Western countries have laws requiring health care professionals to report suspected elder abuse. In the community, if physical abuse or neglect is suspected, notify the local Adult Protective Services agency or other advocate organization. In a hospital or nursing home, notify the social worker or ombudsman, who then will investigate the case and report the problem to the appropriate agency.

## Health Issues for Older Adults in Hospitals and Long-Term Care Settings

Forty percent of adults in critical care settings are over 65 years of age; 60% of medical-surgical patients in hospitals are also over 65 (Ellison et al., 2015). Older adults who are admitted to hospitals and long-term care settings such as nursing homes have special needs and potential health problems. Many of these problems are similar to those seen among community older adults as discussed in this chapter. Since 1996 the Hartford Institute for Gerontological Nursing has worked to ensure that all hospitalized patients 65 years of age and older be given quality care.

### Cultural/Spiritual Considerations

#### Patient-Centered Care QSEN

The health of Hispanic older adults continues to lag behind that for non-Hispanic whites due to a number of factors such as language barriers, inadequate health insurance, and lack of health care access. To add to this health disparity, most nurses and other health care professionals are not educated in the language or culture of Hispanic older adults. Some older Hispanic patients may have beliefs and values that conflict with traditional Western health care views. Many have strong religious and spiritual beliefs. For example, traditional Catholicism is practiced among most Hispanic elders in the Southwestern United States. Be respectful of these differences and incorporate them into your patient's plan of care. Become educated about the Hispanic culture and learn to speak basic medical Spanish to foster communication and trust (Strunk et al., 2013).

### Gender Health Considerations

#### Patient-Centered Care QSEN

Significant health disparities are also associated with the lesbian, gay, bisexual, transgender, and questioning (LGBTQ) older-adult population. Compared with heterosexual adults, LGBTQ older adults are at an elevated risk for disability from chronic disease and mental distress (Fredriksen-Goldsen, 2011). When admitted to the hospital or nursing home, they may hide their gender identity and/or sexual orientation from the nurse and primary health care providers because of fear of rejection or discrimination or lack of adequate health care.

Do not assume that your older patients or visitors are heterosexual. Establish a safe and trusting relationship with the patient and discuss sexual orientation and gender identity in a private setting to emphasize confidentiality. Do not force patients to answer any questions with which they feel uncomfortable. Teach direct caregivers such as nursing assistants that they may observe patients with sexual organs that conflict with the patient's gender identity. If this situation occurs, remind them not to be offensive or judgmental but, rather, to carry out the task as planned. Chapter 73 in this text describes care of transgender patients in detail.

Nurses may not be aware that the needs of older adults differ from those of younger adults. Some health care systems have designated Acute Care of the Elderly (ACE) units with geriatric resources nurses and geriatric clinical nurse specialists. The patients are cared for by geriatricians who specialize in the care of older adults.

Other hospitals have developed interprofessional health programs system-wide to meet the special needs of older patients. The incentive for these new programs is the Nurses Improving Care for Healthsystem Elders (NICHE) project, which continues to generate evidence-based practice guidelines for older adult care.

The purpose of all of these programs and units is to focus on the special health care issues or geriatric syndromes seen in the older population (Brown-O'Hara, 2013). The **Fulmer SPICES** framework was developed as part of the NICHE project and identifies six serious "marker conditions" that can lead to longer hospital stays, higher medical costs, and even deaths. These

conditions are:

- Sleep disorders
- Problems with eating or feeding
- Incontinence
- Confusion
- Evidence of falls
- Skin breakdown

Each of these problems is described briefly here and also is discussed in more detail in other parts of this chapter and the textbook. Other problems such as depression and constipation are also common in older hospitalized patients. Rather than being fully comprehensive, this classic, well-known SPICES framework is intended to be an easy tool that has been called *geriatric vital signs* (Fulmer, 2007).

## Problems of Sleep, Nutrition, and Continence

*Sleep disorders* are common in hospitalized patients, especially older adults. Adequate rest is important for healing and for physical and mental functioning. Pain, chronic disease, environmental noise and lighting, and staff conversations are a few of the many contributing factors to insomnia in the acute and long-term care setting. Assess the patient and ask how he or she is sleeping. If the patient is not able to answer, observe for restlessness and other behaviors that could indicate lack of adequate rest. Manage the patient's pain by giving pain medication before bedtime. Attempt to keep patients awake during the day to prevent insomnia. Keep staff conversations as quiet as possible and away from patients' rooms. Dim the lights to make the patient area as dark as possible. Avoid making loud noises such as slamming doors. Postpone treatments until waking hours or early morning if they can be delayed safely. If possible, place a "Do Not Disturb" sign on the patient's door to avoid unnecessary interruptions in sleep.

*Problems with eating and feeding* prevent the older patient from receiving adequate NUTRITION. Malnutrition is common among older adults and is associated with poor clinical outcomes, including death. Nurses need to perform nutritional screenings on the first day of patient admission, including a thorough nutritional history and weight, height, and body mass index (BMI) calculation. [Chapter 60](#) describes nutritional screening in more detail.

Collaborate with the registered dietitian about the patient's nutritional status as needed to achieve health goals. Consider cultural preferences and determine which foods the patient likes. Manage symptoms such as pain, nausea, and vomiting. If the patient has difficulty chewing or swallowing, coordinate a plan of care with the speech-language pathologist and dietitian. If there are no dietary restrictions, encourage family members or friends to bring in food that the patient might enjoy. Additional interventions to prevent nutrition-related problems are discussed in [Chapter 60](#).

*Urinary and bowel ELIMINATION issues* vary in type and severity and may be caused by many factors, including acute or chronic disease, ADL ability, and available staff. Assess the patient to identify causes for incontinence or retention. *These problems are not physiologic changes of aging but are very common in both the hospital and long-term care setting.* Place the patient on a toileting schedule or a bowel or bladder training program, if appropriate. Delegate this activity to unlicensed assistive personnel and supervise them. [Chapter 6](#) discusses bowel and bladder training in detail; constipation was described earlier in this chapter.

## Confusion, Falls, and Skin Breakdown

*Acute and chronic confusion* affect many older patients in both the hospital and nursing home. Whereas chronic confusion states such as dementia are not reversible, acute confusion, or delirium, may be avoidable and is often reversible when the causes are resolved or removed (see [Table 2-1](#)). For example, avoiding multiple drugs and promoting adequate sleep can help prevent acute confusion. Help the patient by reorienting him or her to reality as much as needed. Keep the patient as comfortable as possible (e.g., provide interventions to control pain). Delirium is discussed earlier in this chapter. [Chapter 42](#) describes dementia in detail.

## NCLEX Examination Challenge 3-4

### Physiological Integrity

An older adult has been taking furosemide 20 mg daily for the past 6 months. The family reports that the client suddenly became confused, weak, and very agitated. What is the nurse's **best** action?

- A. Begin intravenous fluid therapy.
- B. Draw blood to assess electrolyte levels.
- C. Start oxygen via mask at 6 L/min.
- D. Place the patient on strict intake and output.

The most common accident among older patients in a hospital or nursing home setting is falling. A **fall** is an unintentional change in body position that results in the patient's body coming to rest on the floor or ground. Some falls result in serious injuries such as fractures and head trauma. **The Joint Commission's National Patient Safety Goals (NPSGs) require that all inpatient health care settings use admission and daily fall risk assessment tools and a fall reduction program for patients who are at high risk.**

Assess all older patients for risk for falls. Many evidence-based assessment tools such as the Morse Fall Scale, STRATIFY, and the Hendrich II Fall Risk Model (HIIFRM) have been developed to help the nurse focus on factors that increase an older person's risk for falling. Some of these tools also recommend selected interventions, depending on the patient's fall risk score (Swartzell et al., 2013). [Chart 3-4](#) lists some of the common risk factors that should be assessed and evidence-based, collaborative interventions for preventing falls in high-risk patients. *A recent history of falling is the single most important predictor for falls.*

### Chart 3-4

## Best Practice for Patient Safety & Quality Care QSEN

### Assessing Risk Factors and Preventing Falls in Older Adults

**Assess for the presence of these risk factors:**

- History of falls
- Advanced age (>80 years)
- Multiple illnesses
- Generalized weakness or decreased mobility
- Gait and postural instability
- Disorientation or confusion
- Use of drugs that can cause increased confusion, mobility limitations, or orthostatic hypotension
- Urinary incontinence
- Communication impairments
- Major visual impairment or visual impairment without correction
- Alcohol or other substance use

- Location of patient's room away from the nurses' station (in the hospital or nursing home)
- Change of shift or mealtime (in the hospital or nursing home)

**Implement these nursing interventions for all patients, regardless of risk:**

- Monitor the patient's activities and behavior as often as possible, preferably every 30 to 60 minutes.
- Teach the patient and family about the fall prevention program to become safety partners.
- Remind the patient to call for help before getting out of bed or a chair.
- Help the patient get out of bed or a chair if needed; lock all equipment such as beds and wheelchairs before transferring patients.
- Teach patients to use the grab bars when walking in the hall without assistive devices or when using the bathroom.
- Provide or remind the patient to use a walker or cane for ambulating if needed; teach him or her how to use these devices.
- Remind the patient to wear eyeglasses or a hearing aid if needed.
- Help the incontinent patient to toilet every 1 to 2 hours.
- Clean up spills immediately.
- Arrange the furniture in the patient's room or hallway to eliminate clutter or obstacles that could contribute to a fall.
- Provide adequate lighting at all times, especially at night.
- Observe for side effects and toxic effects of drug therapy.
- Orient the patient to the environment.
- Keep the call light and patient care articles within reach; ensure that the patient can use the call light.
- Place the bed in the lowest position with the brakes locked.
- Place objects that the patient needs within reach.
- Ensure that adequate handrails are present in the patient's room, bathroom, and hall.
- Have the physical therapist assess the patient for mobility and safety.

**For patients at a high risk for falls:**

- Implement all assessments and interventions listed previously.
- Relocate the patient for best visibility and supervision.
- Encourage family members or significant other to stay with the patient.
- Collaborate with other members of the health care team, especially the rehabilitative services.
- Use technologic devices such as mattress sensor pads and chair alarms to alert staff to patients getting out of bed.
- Use low beds or futon-type beds to prevent injury if the patient is at risk for falling out of bed.

Toileting-related falls are very common, especially at night. Older patients often have **nocturia** (urination at night) and get out of bed to go to the bathroom. They may forget to ask for assistance and may subsequently fall as a result of disorientation in the darkness in an unfamiliar environment. In some cases they may crawl over the side rail, which can make the fall more serious. Because of this, side rails are used far less often in both hospitals and nursing homes. In both settings side rails are classified as restraints unless the use of rails helps patients increase mobility.

A **restraint** is any device or drug that prevents the patient from moving freely and must be prescribed by a health care provider. In 1990 the US government enforced a law that gives nursing home residents the right to be restraint free. Removing physical restraints from nursing home residents has reduced serious injuries, although falls and minor injuries have increased in some cases. Mattresses placed on floors next to patient beds or “low beds” have helped reduce injury.

Hospitals have also reduced the use of physical restraints. The Joint Commission has specific standards that limit the use of physical restraints in hospitals and nursing homes. Although not appropriate, chemical restraints (psychoactive drugs) such as haloperidol (Haldol) have sometimes been used in place of physical restraints.

Experts agree that older adults should not be placed in a physical restraint or sedated just because they are old. Use alternatives before applying any type of restraint (**Chart 3-5**). However, if all other interventions (e.g., reminding patients to call for assistance when needed; asking a family member to stay with patients) are not effective in fall prevention, a physical restraint may be required for a limited period. Applying a restraint is a serious intervention and should be analyzed for its risk versus its benefit. Check the patient in a restraint every 30 to 60 minutes and release the restraint at least every 2 hours for turning, repositioning, and toileting. Physical restraints such as vests have caused serious injury and even death. *If restraint is needed, use the least restrictive device first. Be sure to follow your facility policy and procedure for using restraints.*

### **Chart 3-5**

## **Best Practice for Patient Safety & Quality Care**

### **Using Restraint Alternatives**

- If the patient is acutely confused, reorient him or her to reality as often as possible.
- If the patient has dementia, use validation to reaffirm his or her feelings and concerns.
- Check the patient often, at least every hour.
- If the patient pulls tubes and lines, cover them with roller gauze or another protective device; be sure that IV insertion sites are visible for assessment.
- Keep the patient busy with an activity, pillow or apron, puzzle, or art project.
- Provide soft, calming music.
- Place the patient in an area where he or she can be supervised. (If the patient is agitated, do not place him or her in a noisy area.)
- Turn off the television if the patient is agitated.
- Ask a family member or friend to stay with the patient at night.
- Help the patient to toilet every 2 to 3 hours, including during the night.
- Be sure that the patient's needs for food, fluids, and comfort are met.
- If agency policy allows, provide the patient with a pet visit.
- Provide familiar objects or cherished items that the patient can touch.

- Document the use of all alternative interventions.
- If a restraint is applied, use the least restrictive device (e.g., mitts rather than wrist restraints, a roller belt rather than a vest).

Chemical restraints are often overused in hospital settings. Examples include:

- Antipsychotic drugs
- Antianxiety drugs
- Antidepressant drugs
- Sedative-hypnotic drugs

The most potent group of psychoactive drugs is the antipsychotics. These drugs are appropriate only for the control of certain behavioral problems such as delusions, acute psychosis, and schizophrenia. Typical antipsychotic drugs include haloperidol (Haldol, Peridol) and thiothixene (Navane). These drugs should not be used to treat anxiety or induce sedation.

## Nursing Safety Priority QSEN

### Drug Alert

Closely monitor older adults receiving antipsychotics for adverse drug events (ADEs). Assess patients for:

- Anticholinergic effects, the most common problem, causing constipation, dry mouth, and urinary retention
- Orthostatic hypotension, which increases the patient's risk for falls and fractures
- Parkinsonism, including tremors, bradycardia, and a shuffling gait
- Restlessness and the inability to stay still in any one position
- Hyperglycemia and diabetes mellitus, which occur more with drugs such as risperidone (Risperdal) and quetiapine (Seroquel)

If any of these ADEs occur, notify the primary health care provider immediately.

*Skin breakdown*, especially pressure injuries, is a major TISSUE INTEGRITY problem among older adults in hospitals and nursing homes. In some cases these wounds cause death from infection. Therefore prevention is the best approach. **The Joint Commission's NPSGs require that all health care agencies have a program to prevent agency-associated pressure injuries. The program should include these evidence-based interventions:**

- **Nutritional support**
- **Avoidance of skin injury from friction or shearing forces**
- **Repositioning and support surfaces**
- **A plan to increase MOBILITY and activity level when appropriate**
- **Skin cleaning and use of moisture barriers**

Assess older adults for their risk for pressure injuries, using an assessment tool such as the Braden Scale for Predicting Pressure Sore Risk (see [Chapter 25](#)). Implement evidence-based interventions to prevent agency-acquired pressure injuries and maintain TISSUE INTEGRITY. Coordinate these interventions with members of the interprofessional health care team, including the dietitian and wound care specialist.

## Nursing Safety Priority QSEN

### Action Alert

Supervise unlicensed assistive personnel (UAP) for frequent turning and repositioning for the patient who is immobile. Assess the skin every 8 hours for reddened areas that do not blanch. Remind UAP to keep the skin clean and dry. Use pressure-relieving mattresses and avoid briefs or absorbent pads that can cause skin irritation and excess moisture. Chapter 25 describes in detail additional interventions for prevention and management of pressure injuries.

*Skin tears are also common in older adults, especially the old-old group and those who are on chronic steroid therapy. Teach UAP to use extreme caution when handling these patients. Use a gentle touch and report any open areas. Avoid bruising because older adults have increased capillary fragility.*

## Care Coordination and Transition Management

Some older adults and their families experience a breakdown in communication and coordination of care when transitioning from the hospital or long-term care (LTC) setting (nursing home) to the home setting. If the transition is not optimal, older adults experience high readmission rates and an increase in visits to the emergency department or primary health care provider's office.

A qualitative study by Dossa et al. (2012) showed that health care professionals, especially nurses, did not communicate effectively when they prepared for the discharge of older adults. Care was not coordinated among health care professionals, which led to confusion for the older adult and family caregivers. To help prevent these problems, the authors recommended that a system be in place to address patients' communication needs. The system should include follow-up phone calls after discharge to home and having one case manager to coordinate care during and after the transition from the inpatient agency to home. A home care nurse or other health care professional can serve as a "health coach" to ensure understanding of discharge instructions, consistent follow-up appointments, and a designated emergency contact for the patient and family. Discharge instructions should be easy to read, in large print, and accurate. Continuity of care for high-quality transition between settings is essential to achieve positive outcomes for older adults.

# Get Ready for the NCLEX<sup>®</sup> Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Collaborate with the interprofessional team when providing care to older adults in the community or inpatient setting. For example, consult with the registered dietitian for problems with NUTRITION; consult with the pharmacist to discuss the patient's drug regimen. **Health Care Organizations; QSEN: Teamwork and Collaboration**
- Assess all older adults for risk factors for impaired driving ability such as decreased MOBILITY, SENSORY PERCEPTION, and COGNITION (see [Chart 3-3](#)).
- Assess older adults in the community and inpatient settings for falls risk factors (e.g., cognitive decline and vision impairment) and implement interventions as delineated in [Chart 3-4](#). **QSEN: Safety**
- Physical and chemical restraints should not be used for older adults until all other alternatives have been tried (see [Chart 3-5](#)). **QSEN: Evidence-Based Practice**
- **Follow The Joint Commission's National Patient Safety Goals and federal/state standards when using patient restraints to maintain patient safety. QSEN: Safety**

### Health Promotion and Maintenance

- Teach older adults about the benefits of regular physical exercise.
- Provide information regarding community resources for older adults to help them meet their basic needs. **Clinical Judgment**
- Be aware that nonwhite subgroups such as Hispanics and elders who identify as LGBTQ often are afraid or unable to obtain adequate health services. **Health Care Disparities**
- Teach health promotion practices as listed in [Chart 3-1](#).
- Conduct a medication assessment for potential risks in older adults using the Beers criteria. **QSEN: Safety**

### Psychosocial Integrity

- Depression is the most common yet most underdiagnosed and undertreated mental health/behavioral health disorder among older adults.
- Delirium is acute confusion that has a sudden onset and fluctuating course; dementia is chronic confusion (see [Table 2-1](#)). Confusion is not part of the normal aging process.
- Screen older adults for alcohol abuse or alcoholism and refer those with identified problems to appropriate resources. **QSEN: Evidence-Based Practice**
- Screen older adults for neglect and abuse, which are serious problems; family caregivers are usually the abusers (see [Table 3-4](#)). **QSEN: Safety**
- Relocation stress syndrome is the reaction of an older adult when transferred to a different environment; ways to minimize this problem are listed in [Chart 3-2](#).

### Physiological Integrity

- The four subgroups of the older-adult population are the young old, middle old, old old, and elite old.
- The biggest concern regarding accidents among older adults in both the community and inpatient setting is falls. **QSEN: Safety**
- Physiologic changes of aging predispose older adults to toxic effects of medication; drugs are

absorbed, metabolized, and distributed more slowly than in younger people. They are also excreted more slowly by the kidneys. **QSEN: Safety**

- Medication use in older adults is often a problem when they commit errors when self-medicating, avoid needed medications, or have problems understanding their medication regimen. **QSEN: Evidence-Based Practice**
- **Follow The Joint Commission's National Patient Safety Goals and best practice guidelines to prevent agency-acquired pressure injuries.**
- Promote sleep and rest for older adults to decrease the incidence of delirium and to prevent falls. **QSEN: Evidence-Based Practice**
- Use the SPICES assessment tool for identifying serious health problems that can be prevented or managed early.

## CHAPTER 4

# Assessment and Care of Patients With Pain

Melanie H. Simpson, Donna D. Ignatavicius

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concept for this chapter is COMFORT.**

✚ The COMFORT concept exemplar for this chapter is Pain, below.

**The interrelated concepts for this chapter are:**

- COGNITION
- SENSORY PERCEPTION

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Identify the role of the nurse as an advocate for patients with acute pain or chronic cancer or noncancer pain.
2. Collaborate with members of the interprofessional team to develop the pain management plan of care.

### Health Promotion and Maintenance

3. Develop a teaching plan for patients to include complementary and integrative therapies for pain management and promotion of COMFORT.
4. Incorporate special considerations for older adults and veterans of war related to pain assessment and management.
5. Describe how to provide patient-centered care by respecting patients' preferences, values, and beliefs regarding pain and COMFORT management.

### Psychosocial Integrity

6. Discuss the attitudes and knowledge of patients and their families regarding pain assessment and management.

### Physiological Integrity

7. Document a complete pain assessment per agency policy.
8. Compare and contrast the characteristics of the major types of pain and give examples of each.
9. Explain the role of the three analgesic groups in pain management.
0. Prioritize evidence-based nursing interventions to prevent common side effects of opioid analgesics, including the effects on COGNITION and SENSORY PERCEPTION.
  1. Compare the advantages and disadvantages of drug administration routes.
  2. Describe the benefits and limitations of selected safety-enhancing technologies used in pain management.
  3. Use clinical judgment to prioritize care for the patient receiving patient-controlled analgesia.
  4. Outline care for a patient receiving epidural analgesia.
  5. Incorporate nonpharmacologic interventions into the patient's plan of care as needed to control pain and promote COMFORT.

## Overview of Comfort Concept Exemplar Pain

Pain is a universal, complex, and personal experience that everyone has at some point in life. It is the most common reason people seek medical care and the number-one reason people take medication. Pain causes impaired COMFORT and can lead to poor health for many millions of people. Unrelieved pain can alter or diminish quality of life more than any other single health-related problem. Despite more than 30 years of education and dissemination of guideline recommendations, the failure to adequately manage pain remains a major health problem worldwide.

In response to mandates by multiple organizations and The Joint Commission (TJC), many hospitals and other health care agencies have implemented interprofessional pain initiatives to help ensure that patients receive the best possible treatment. Some hospitals address this mandate by establishing pain resource nurse (PRN) programs. As the name implies, one or more nurses per clinical unit are educated to serve as a resource to other members of the health care team in managing pain and promoting COMFORT. Other hospitals have a formal team or pain service consisting of one or more nurses, pharmacists, case managers, and/or primary health care providers. In larger facilities, pain services may specialize by type of pain (e.g., acute pain service or pain and palliative care team). Although a large part of the interprofessional team's plan may center on drug therapy, these groups also recommend nonpharmacologic measures when appropriate.

### Scope of the Problem

Pain is a major economic problem and a leading cause of disability that changes the lives of many people, especially older adults. Chronic noncancer pain such as osteoarthritis, rheumatoid arthritis, and diabetic neuropathy is the most common cause of long-term disability, affecting millions of Americans and others throughout the world.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Pain is treated inadequately in almost all health care settings. Populations at the highest risk in medical-surgical nursing are older adults, patients with substance use disorder, and those whose primary language differs from that of the health care professional. Older adults in nursing homes are at especially high risk because many residents are unable to report their pain. In addition, there often is a lack of staff members who have been educated to manage pain in the older-adult population.

Inadequate pain management can lead to many adverse consequences affecting the patient and family members (Table 4-1). Therefore nurses have a legal and ethical responsibility to promote COMFORT and ensure that patients receive adequate pain control. Many professional organizations, including the American Society for Pain Management Nursing (ASPMN), the American Pain Society (APS), and TJC state that patients in all health care settings, including home care, have a right to effective pain management.

**TABLE 4-1**  
**Impact of Unrelieved Pain**

Physiologic Impact	Quality-of-Life Impact
<ul style="list-style-type: none"> <li>• Prolongs stress response</li> <li>• Increases heart rate, blood pressure, and oxygen demand</li> <li>• Decreases GI motility</li> <li>• Causes immobility</li> <li>• Decreases immune response</li> <li>• Delays healing</li> <li>• Poorly managed acute pain increases risk for development of chronic pain</li> </ul>	<ul style="list-style-type: none"> <li>• Interferes with ADLs</li> <li>• Causes anxiety, depression, hopelessness, fear, anger, and sleeplessness</li> <li>• Impairs family, work, and social relationships</li> </ul>
	Financial Impact
	<ul style="list-style-type: none"> <li>• Costs Americans billions of dollars per year</li> <li>• Increases length of hospital stay</li> <li>• Leads to lost income and productivity</li> </ul>

Patients rely on nurses and other health care professionals to adequately assess and manage their pain. As the coordinator of patient care, be sure to accurately document your assessments and

actions, including patient and caregiver teaching. Communication and collaboration among the patient and members of the interprofessional health team about the patient's pain, expectations, and progress toward control are equally important.

## Definitions of Pain

**Pain** is defined as an unpleasant sensory and emotional experience associated with actual or potential tissue damage. **McCaffery (1968)** offered the more classic and personal definition when she stated that pain is whatever the experiencing person says it is and exists whenever he or she says it exists. This has become the clinical definition of pain worldwide and reflects an understanding that the patient is the authority and the *only* one who can describe the pain experience. *In other words, self-report is always the most reliable indication of pain.* Nurses who approach pain from this perspective can help the patient achieve effective management by advocating for proper control. If the patient cannot provide self-report, a variety of other methods such as observation of behavioral indicators are used for pain assessment (see later in this chapter).

## Categorization of Pain by Duration

Pain is often described as being acute or chronic based on its duration (**Table 4-2**). *Acute pain* is usually short-lived, whereas *chronic pain* can last a person's lifetime. *Acute pain* often results from sudden, accidental trauma (e.g., fractures, burns, lacerations) or from surgery, ischemia, or acute inflammation. *Chronic pain* or *persistent pain* is further divided into two subtypes. *Chronic cancer pain* is pain associated with cancer and is usually the result of tissue changes from tumor growth. *Chronic noncancer pain* is associated with past or ongoing tissue damage such as chronic back or neck pain or osteoarthritis pain. *Noncancer pain is the most common type of chronic pain.*

**TABLE 4-2**  
**Characteristics of Acute Pain and Chronic Pain**

ACUTE	CHRONIC* (OR PERSISTENT)
<ul style="list-style-type: none"> <li>• Has short duration</li> <li>• Usually has a well-defined cause</li> <li>• Decreases with healing</li> <li>• Is usually reversible</li> <li>• Initially serves a biologic purpose (warning sign to withdraw from painful stimuli or seek help)</li> <li>• When prolonged, serves no useful purpose</li> <li>• Ranges from mild-to-severe intensity</li> <li>• May be accompanied by anxiety and restlessness</li> <li>• When unrelieved can increase morbidity and mortality and prolong length of hospital stay</li> </ul>	<ul style="list-style-type: none"> <li>• Usually lasts longer than 3 months</li> <li>• May or may not have well-defined cause</li> <li>• Usually begins gradually and persists</li> <li>• Serves no useful purpose</li> <li>• Ranges from mild-to-severe intensity</li> <li>• Often accompanied by multiple quality-of-life and functional adverse effects, including depression; fatigue; financial burden; and increased dependence on family, friends, and the health care system</li> <li>• Can impact the quality of life of family members and friends</li> </ul>

\*Includes chronic cancer pain and chronic noncancer pain.

## Acute Pain

Almost everyone experiences acute pain at some time. Brief **acute pain** serves a biologic purpose in that it acts as a warning signal by activating the sympathetic nervous system and causing various physiologic responses. Although not consistent in all people, when acute pain is severe, you may see responses similar to those found in “fight-or-flight” reactions such as increased vital signs, sweating, and dilated pupils. Most people protect themselves by drawing away from the painful stimulus. Behavioral signs may include restlessness (especially among cognitively impaired older adults who sometimes fidget and pick at clothing), an inability to concentrate, apprehension, and overall distress of varying degrees. These heightened physiologic and behavioral responses are often referred to as the *acute pain model*. It is important to remember that the response to pain is highly individual and that humans quickly adapt physiologically and behaviorally to pain. Be careful not to expect certain responses when assessing any type of pain. *The absence of the physiologic and behavioral responses does not mean the absence of pain.*

Acute pain is usually temporary, has a sudden onset, and is easily localized. The pain is typically confined to the injured area and may subside with or without treatment. As the injured area heals, the **SENSORY PERCEPTION** of pain changes and, in most cases, diminishes and resolves. Both the caregiver and the patient can see an end to the pain, which usually makes coping somewhat easier.

Pain that accompanies surgery is one of the most common examples of acute pain, but it is not always well managed. *The response to pain after surgery is highly individual and variable.* There is no

evidence that shows that one type of surgery is consistently more or less painful than another. Usually poorly managed postoperative pain is a result of inadequate drug (analgesic) therapy. Poorly managed and prolonged acute pain serves no useful purpose and has many adverse effects, including inability of the patient to participate in the recovery process with subsequent increased disability. The severity of early postoperative pain may be a predictor of long-term pain. Those who experience unrelieved severe postoperative pain are at high risk for the development of chronic persistent postsurgical pain (Wright, 2015).

## Chronic Pain

**Chronic pain** (also called *persistent pain*) is often defined as pain that lasts or recurs for an indefinite period, usually for more than 3 months. The onset is gradual, and the character and quality of the pain often change over time. *Chronic pain serves no biologic purpose.* Because it persists for an extended period, it can interfere with personal relationships and performance of ADLs. Chronic pain can also result in emotional and financial burdens, depression, and hopelessness for patients and their families. It is important to remember that the body adapts to persistent pain; thus vital signs such as pulse and blood pressure may actually be lower than normal in people with chronic pain. *Although many characteristics of chronic pain are similar in different patients, be aware that each patient is unique and requires a highly individualized plan of care.*

## Chronic Cancer Pain.

Many patients with cancer report pain at the time of diagnosis, which increases in advanced stages of the disease. Most cancer pain can be managed successfully by giving adequate amounts of oral opioids around the clock, yet patients with cancer are often treated inadequately for what can be persistent, excruciating pain and suffering.

Most cancer pain is the result of tumor growth, including nerve compression; invasion of tissue; and/or bone metastasis, an extremely painful condition. Cancer treatments also can cause *acute pain* (e.g., from repetitive blood draws and other procedures, surgery, and toxicities from chemotherapy and radiation therapy).

Patients with cancer pain generally have pain in two or more areas of the body but usually talk about only the primary area. Be sure to perform a complete pain assessment to ensure an effective plan of care.

## Chronic Noncancer Pain.

Chronic noncancer pain is a global health problem, occurring most often in people older than 65 years. This type of pain was formerly called *chronic nonmalignant* pain. However, most experts, and certainly patients who suffer daily, believe that all pain is malignant. There are many sources and types of chronic noncancer pain. Among the most common are neck, shoulder, and low back pain following injury. Chronic conditions such as diabetes, rheumatoid arthritis, Crohn's disease, and interstitial cystitis often are associated with chronic pain. People who have had a stroke or trauma or are paralyzed may report persistent pain as a result of central nervous system (CNS) damage. Sometimes the exact cause of the pain is unclear, as with fibromyalgia.

## ▼ Veterans' Health Considerations

### Patient-Centered Care QSEN

Over half of the veterans of recent wars such as those in Iraq and Afghanistan have chronic noncancer pain, mostly due to musculoskeletal disorders (MSDs) from either trauma or arthritis. Research shows that pain-related MSD causes or exacerbates depression, post-traumatic stress disorder (PTSD), and a decreased sense of well-being in this young to middle-age population (Matthias et al., 2014). Some of these patients are managed through Veterans Administration Medical Centers in ambulatory care clinics in the United States. Unfortunately others are jobless and homeless and therefore receive no care to manage their physical or psychological health problems.

## Categorization of Pain by Underlying Mechanisms

Pain is more commonly categorized as either nociceptive (normal pain processing) or neuropathic (abnormal pain processing) (Table 4-3). The duration of nociceptive and neuropathic pain can be either acute (short lived) or chronic (persistent), and a person can have both types.

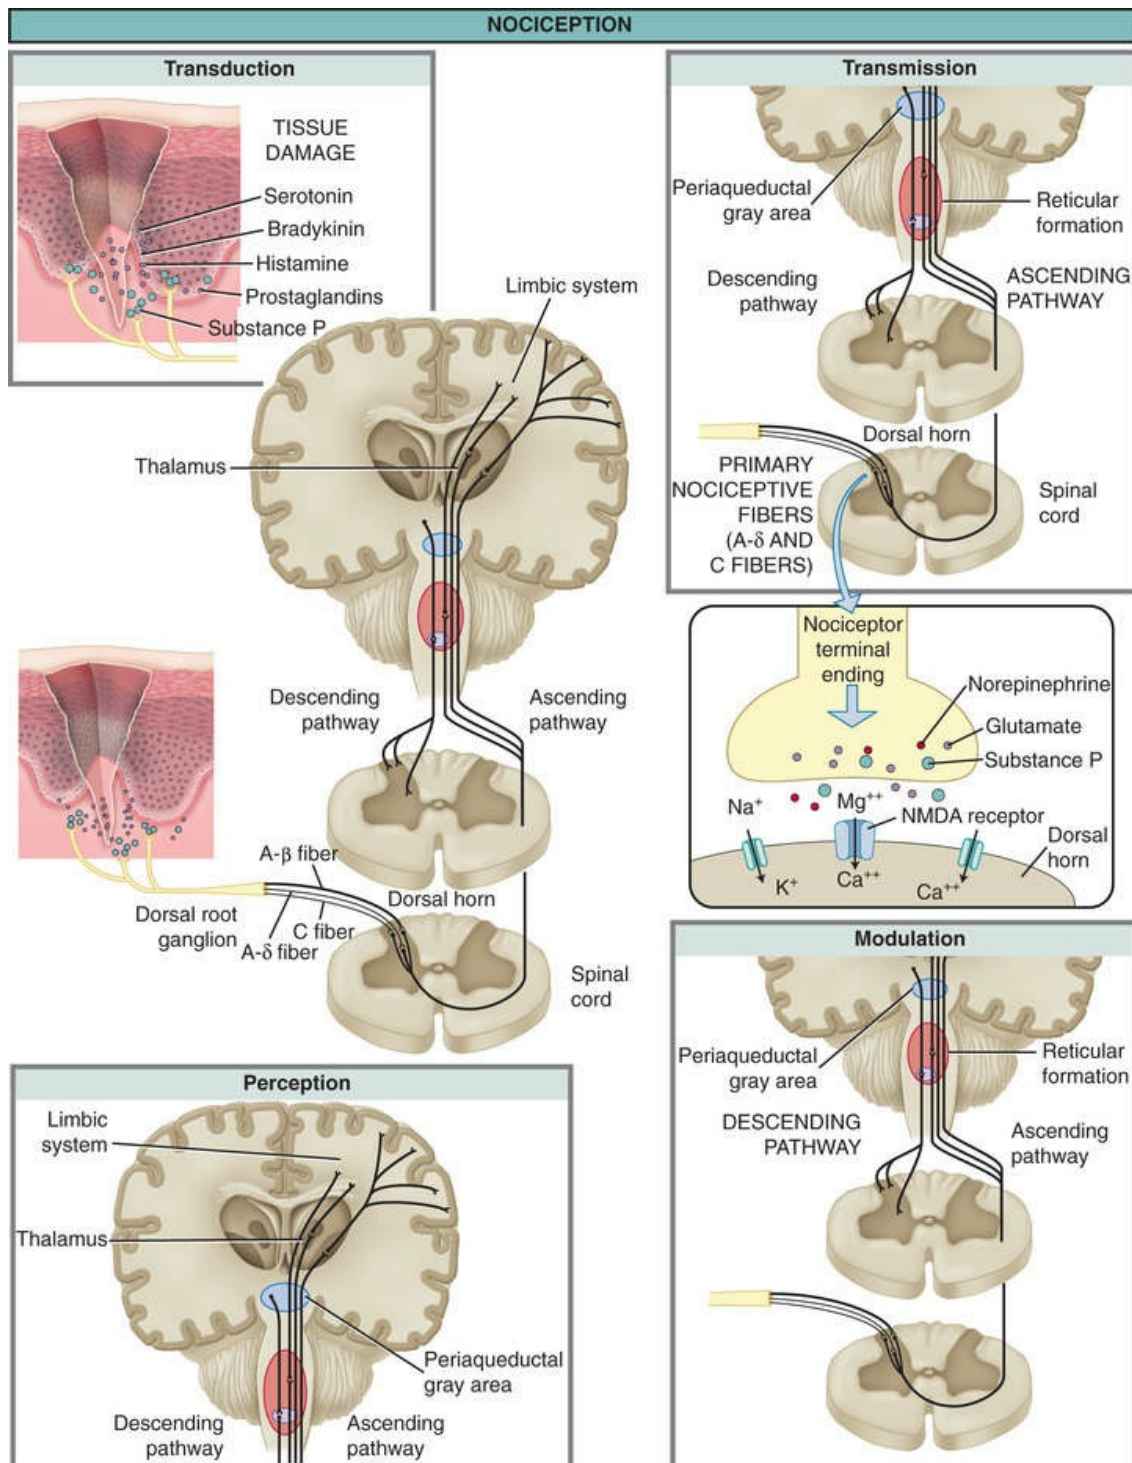

**TABLE 4-3**  
**Physiologic Sources of Nociceptive Pain and Neuropathic Pain**

PHYSIOLOGIC STRUCTURE	CHARACTERISTICS OF PAIN	SOURCES OF ACUTE POSTOPERATIVE PAIN	SOURCES OF CHRONIC PAIN SYNDROMES
<b>Nociceptive Pain (Normal Pain Processing)</b>			
<b>Somatic Pain</b>			
Cutaneous or superficial: skin and subcutaneous tissues	Well localized Sharp, throbbing	Incisional pain, pain at insertion sites of tubes and drains, wound complications, orthopedic procedures, skeletal muscle spasms	Bony metastases, osteoarthritis and rheumatoid arthritis, low back pain, peripheral vascular diseases
Deep somatic: bone, muscle, blood vessels, connective tissues	Dull, aching, cramping		
<b>Visceral Pain</b>			
Organs and the linings of the body cavities	Poorly localized Diffuse, deep cramping or pressure, sharp, stabbing	Chest tubes, abdominal tubes and drains, bladder distention or spasms, intestinal distention	Pancreatitis, liver metastases, colitis, appendicitis
<b>Neuropathic Pain (Abnormal Pain Processing)</b>			
Peripheral or central nervous system: nerve fibers, spinal cord, and higher central nervous system	Poorly localized Shooting, burning, fiery, shocklike, tingling, painful numbness	Phantom limb pain, postmastectomy pain, nerve compression	HIV-related pain, diabetic neuropathy, postherpetic neuralgia, chemotherapy-induced neuropathies, cancer-related nerve injury, radiculopathies

*HIV*, Human immune deficiency virus.

## Nociceptive Pain

**Nociception** is the term that is used to describe how pain becomes a conscious experience. It involves the *normal functioning of physiologic systems* that process noxious stimuli, with the ultimate result being that the stimuli are perceived to be painful. In short, nociception means “normal” pain transmission and is generally discussed in terms of four processes: transduction, transmission, perception, and modulation (Fig. 4-1). Although it is helpful to consider nociception in the context of these four processes, it is important to understand that they do not occur as four separate and distinct entities. They are continuous, and the processes overlap as they flow from one to another.

**FIG. 4-1** Nociception. Modified from Pasero, C., & McCaffery, M. (2011). Pain assessment and pharmacologic management. St. Louis: Mosby.

*Transduction* is the first process of nociception and refers to the means by which noxious events activate neurons that exist throughout the body (skin, subcutaneous tissue, and visceral [or somatic] structures) and have the ability to respond selectively to specific noxious stimuli. These neurons are called *nociceptors*. When they are stimulated directly, a number of excitatory compounds (e.g., serotonin, bradykinin, histamine, substance P, and prostaglandins) are released that further activate more nociceptors (see Fig. 4-1).

*Transmission* is the second process involved in nociception. Nociceptors have small-diameter axons—either A-delta or C fibers (see Fig. 4-1). Effective transduction generates an electric signal (action potential) that is transmitted in these nerve fibers from the periphery toward the CNS. A-

*delta fibers* are lightly myelinated and conduct faster than unmyelinated C fibers. The endings of A-delta fibers detect thermal and mechanical injury. The SENSORY PERCEPTION accompanying A-delta fiber activation is sharp and well localized and leads to an appropriately rapid protective response such as reflex withdrawal from the painful stimuli. *C fibers* are unmyelinated or poorly myelinated slow conductors and respond to mechanical, thermal, and chemical stimuli. Activation after acute injury yields a poorly localized (more widely distributed) typically aching or burning pain. In contrast to the intermittent nature of A-delta sensations, C fibers usually produce more continuous pain.

*Perception* is the third broad process involved in nociception. Perception, which may be viewed as the end result of the neural activity associated with transmission of information about noxious events, involves the conscious awareness of pain (see Fig. 4-1). It requires the activation of higher brain structures, including the cortex, and involves both awareness and the occurrence of emotions and drives associated with pain. The physiology of pain perception is very poorly understood but presumably can be targeted by therapies that activate higher cortical functions and COGNITION to achieve pain control or coping. Cognitive-behavioral therapy and specific approaches such as distraction and imagery (discussed later in the chapter) have been developed based on evidence that brain processes can strongly influence pain perception.

*Modulation* of afferent input generated in response to noxious stimuli happens at every level from the periphery to the cortex (see Fig. 4-1). The neurochemistry of modulation is complex and not yet fully understood, but it is known that multiple peripheral and central systems and dozens of neurochemicals are involved. For example, the endogenous opioids (endorphins) are found throughout the peripheral nervous system (PNS) and CNS and, like the exogenous opioids administered therapeutically, they inhibit neuronal activity by binding to opioid receptors. Other central inhibitory neurotransmitters important in the modulation of pain include serotonin and norepinephrine, which are released in the spinal cord and brainstem by the descending fibers of the modulatory system to inhibit pain.

**Nociceptive pain** is the result of actual or potential tissue damage or inflammation and is often categorized as being somatic or visceral. *Somatic pain* arises from the skin and musculoskeletal structures, and *visceral pain* arises from organs. Examples include pain-associated trauma, surgery, burns, and tumor growth.

## Neuropathic Pain

**Neuropathic pain** is a descriptive term used to refer to pain that is believed to be sustained by a set of mechanisms driven by damage to or dysfunction of the PNS and/or CNS. In contrast to nociceptive pain, which is sustained by ongoing activation of essentially *normal* neural systems, neuropathic pain is sustained by the *abnormal* processing of stimuli. Whereas nociceptive pain involves tissue damage or inflammation, neuropathic pain may occur in the absence of either.

It is not clear why noxious stimuli result in neuropathic pain in some people and not in others and why some treatments work in some and not in others. Neuropathic pain is difficult to treat and often resistant to first-line analgesics. Asking patients to describe it is the best way to identify the presence of neuropathic pain. Common distinctive descriptors include “burning,” “shooting,” “tingling,” and “feeling pins and needles.” Much is unknown about what causes and maintains neuropathic pain; it is the subject of intense ongoing research.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

All accepted guidelines identify the patient's self-report as the gold standard for assessing the existence and intensity of pain (Pasero & McCaffery, 2011). Because pain is such a private and personal experience, it may be difficult for the person to describe or explain it to others. However, subjective descriptions of the experience and measurement of pain intensity are more reliable and accurate than observable qualities of pain. The amount of pain and responses to it vary from person to person; therefore interpreting it solely on actions or behaviors can be misleading and is not recommended. Patients may report pain in the absence of any observable or documented physiologic changes.

Although nurses and other members of the interprofessional team are entitled to their doubts and opinions about a patient's pain, these doubts and opinions cannot be allowed to interfere with

appropriate patient care. The primary role in pain and COMFORT management is to advocate for patients by *accepting* their reports of pain and acting promptly to relieve it while respecting their preferences and values.

To be patient-centered, always respect the patient's verbal and nonverbal expressions of pain without making judgments or inferences about its reality. If patients perceive that health care professionals doubt the existence of their pain, mistrust and other negative feelings can arise and interfere with a therapeutic nurse-patient relationship.

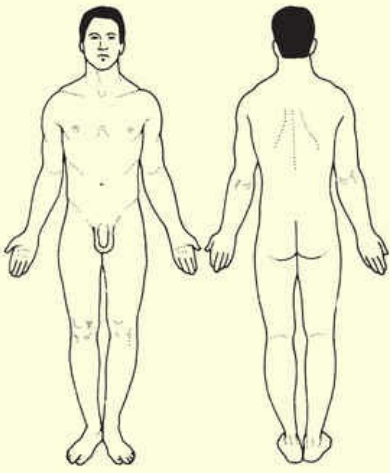

### **The Comprehensive Pain Assessment.**

A comprehensive pain assessment should be conducted during the initial interview with the patient, with each new report of pain, and whenever indicated by changes in the patient's condition or treatment plan during the course of care. Pain assessment at these intervals serves as the foundation for developing and evaluating the effectiveness of the treatment plan. Remember that patients' personal preferences and values affect how they report their history. *When culturally appropriate, be sure to make this information-gathering process family centered by including families and significant others.*

Components of a comprehensive pain assessment and tips on how to obtain the information from the patient include:

- *Location(s)*: Ask the patient to state or point to the area(s) of pain on the body. Sometimes allowing patients to make marks on a body diagram is helpful in gaining this information (Fig. 4-2). Patients may present with more than one specific painful site. Encourage those who cannot identify the painful areas and state that they “hurt all over” to focus on parts of the body that are not painful. Ask them to begin with the hand and fingers of one extremity and identify the presence or absence of pain. By focusing attention on selected areas of the body, the patient is assisted in better localizing painful areas. People who state that they hurt everywhere often begin to realize that some parts of the body are not painful. Identifying painful areas helps the patient understand the origin of the pain. This understanding is particularly important for those with cancer because every new pain often raises the suspicion of metastasis (spread of disease). The pain may have other causes such as immobility or constipation. Pain may be described as belonging to one of four categories related to its location:

<b>McGill-Melzack PAIN QUESTIONNAIRE</b>		<b>Part 2. What Does Your Pain Feel Like?</b>																																																																																														
Patient's name _____ Age _____ File No. _____ Date _____ Clinical category (e.g., cardiac, neurologic) Diagnosis: _____ _____ _____ Analgesic (if already administered): 1. Type _____ 2. Dosage _____ 3. Time given in relation to this test _____ Patient's intelligence: circle number that represents best estimate. 1 (low)    2    3    4    5 (high)	Some of the words below describe your <i>present</i> pain. Circle <i>ONLY</i> those words that best describe it. Leave out any category that is not suitable. Use only a single word in each appropriate category—the one that applies best.																																																																																															
This questionnaire has been designed to tell us more about your pain. Four major questions we ask are 1. Where is your pain? 2. What does it feel like? 3. How does it change with time? 4. How strong is it? It is important that you tell us how your pain feels now. Please follow the instructions at the beginning of each part.	<table style="width: 100%; border-collapse: collapse;"> <tr> <td style="width: 25%;">1 Flickering</td> <td style="width: 25%;">6 Tugging</td> <td style="width: 25%;">11 Tiring</td> <td style="width: 25%;">16 Annoying</td> </tr> <tr> <td>2 Quivering</td> <td>7 Pulling</td> <td>12 Exhausting</td> <td>17 Troublesome</td> </tr> <tr> <td>3 Pulsing</td> <td>8 Wrenching</td> <td>13 Sickening</td> <td>18 Miserable</td> </tr> <tr> <td>4 Throbbing</td> <td>9 Hot</td> <td>14 Suffocating</td> <td>19 Intense</td> </tr> <tr> <td>5 Beating</td> <td>10 Burning</td> <td>15 Fearful</td> <td>20 Unbearable</td> </tr> <tr> <td>6 Pounding</td> <td>11 Scalding</td> <td>16 Radiating</td> <td>17 Spreading</td> </tr> <tr> <td>7 Jumping</td> <td>12 Searing</td> <td>17 Frightful</td> <td>18 Penetrating</td> </tr> <tr> <td>8 Flashing</td> <td>13 Shooting</td> <td>18 Terrifying</td> <td>19 Piercing</td> </tr> <tr> <td>9 Shooting</td> <td>14 Tingling</td> <td>19 Punishing</td> <td>20 Tight</td> </tr> <tr> <td>10 Pricking</td> <td>15 Itchy</td> <td>20 Stinging</td> <td>1 Numb</td> </tr> <tr> <td>11 Boring</td> <td>16 Smarting</td> <td>1 Numbing</td> <td>2 Drawing</td> </tr> <tr> <td>12 Drilling</td> <td>17 Stinging</td> <td>2 Cruel</td> <td>3 Squeezing</td> </tr> <tr> <td>13 Stabbing</td> <td>18 Dull</td> <td>3 Vicious</td> <td>4 Tearing</td> </tr> <tr> <td>14 Lancinating</td> <td>19 Sore</td> <td>4 Killing</td> <td>5 Cool</td> </tr> <tr> <td>15 Sharp</td> <td>20 Hurting</td> <td>5 Wretched</td> <td>6 Cold</td> </tr> <tr> <td>16 Cutting</td> <td>1 Aching</td> <td>6 Blinding</td> <td>7 Freezing</td> </tr> <tr> <td>17 Cutting</td> <td>2 Heavy</td> <td>7 Tender</td> <td>8 Nagging</td> </tr> <tr> <td>18 Lacerating</td> <td>3 Tender</td> <td>8 Taut</td> <td>9 Nauseating</td> </tr> <tr> <td>19 Pinching</td> <td>4 Rasping</td> <td>9 Splitting</td> <td>10 Agonizing</td> </tr> <tr> <td>20 Pressing</td> <td>5 Rasping</td> <td>10 Crushing</td> <td>11 Dreadful</td> </tr> <tr> <td>1 Gnawing</td> <td>6 Splitting</td> <td></td> <td>12 Torturing</td> </tr> <tr> <td>2 Cramping</td> <td></td> <td></td> <td></td> </tr> <tr> <td>3 Crushing</td> <td></td> <td></td> <td></td> </tr> </table>				1 Flickering	6 Tugging	11 Tiring	16 Annoying	2 Quivering	7 Pulling	12 Exhausting	17 Troublesome	3 Pulsing	8 Wrenching	13 Sickening	18 Miserable	4 Throbbing	9 Hot	14 Suffocating	19 Intense	5 Beating	10 Burning	15 Fearful	20 Unbearable	6 Pounding	11 Scalding	16 Radiating	17 Spreading	7 Jumping	12 Searing	17 Frightful	18 Penetrating	8 Flashing	13 Shooting	18 Terrifying	19 Piercing	9 Shooting	14 Tingling	19 Punishing	20 Tight	10 Pricking	15 Itchy	20 Stinging	1 Numb	11 Boring	16 Smarting	1 Numbing	2 Drawing	12 Drilling	17 Stinging	2 Cruel	3 Squeezing	13 Stabbing	18 Dull	3 Vicious	4 Tearing	14 Lancinating	19 Sore	4 Killing	5 Cool	15 Sharp	20 Hurting	5 Wretched	6 Cold	16 Cutting	1 Aching	6 Blinding	7 Freezing	17 Cutting	2 Heavy	7 Tender	8 Nagging	18 Lacerating	3 Tender	8 Taut	9 Nauseating	19 Pinching	4 Rasping	9 Splitting	10 Agonizing	20 Pressing	5 Rasping	10 Crushing	11 Dreadful	1 Gnawing	6 Splitting		12 Torturing	2 Cramping				3 Crushing

Which word describes the worst toothache you ever had? _____</li> <li>5. Which word describes the worst headache you ever had? _____</li> <li>6. Which word describes the worst stomachache you ever had? _____</li> </ol>																																																																																															

**FIG. 4-2** The McGill-Melzack Pain Questionnaire. (From Melzack, R. (1975). The McGill Pain Questionnaire: Major properties and scoring methods. *Pain*, 1, 272-281.)

- *Localized* pain is confined to the site of origin.

- *Projected* pain is diffuse around the site of origin and is not well localized.
- *Referred* pain is felt in an area distant from the site of painful stimuli.
- *Radiating* pain is felt along a specific nerve or nerves.
- *Intensity*: Ask the patient to rate the severity of the pain using a reliable and valid assessment tool. Various self-report scales have been developed to help patients communicate pain intensity. Once a scale is selected, be sure to use the *same* scale over time for that patient and assess intensity both with and without activity. See [Table 4-4](#) for strategies that can be used to teach patients and their families how to use a pain rating scale. The most common intensity rating scales are:

**TABLE 4-4**  
**Teaching Patients and Their Families How to Use a Pain Rating Scale\***

<p><b>Step 1.</b> Show the pain rating scale to the patient and family and explain its primary purpose.  <i>Example:</i> "This is a pain rating scale that many of our patients use to help us understand their pain and set goals for pain relief. We will ask you regularly about pain, but any time you have pain you must let us know so we can help control it. We don't always know when you hurt."</p> <p><b>Step 2.</b> Explain the parts of the pain rating scale. If the patient does not like it or understand it, switch to another scale (e.g., vertical presentation, VDS, or FACES).  <i>Example:</i> "On this pain rating scale 0 means no pain, and 10 means the worst possible pain. The middle of the scale, around 5, means moderate pain. A 2 or 3 would be mild pain, but 7 or higher means severe pain."</p> <p><b>Step 3.</b> Discuss pain as a broad concept that is not restricted to a severe and intolerable sensation.  <i>Example:</i> "Pain refers to any kind of discomfort anywhere in your body. Pain also means aching and hurting. Pain can include pulling, tightness, burning, knifelike feelings, and other unpleasant sensations."</p> <p><b>Step 4.</b> Verify that the patient understands the broad concept of pain. Ask the patient to mention two examples of pain that he or she has experienced. If the patient is already in pain that requires treatment, use the present situation as the example.  <i>Example:</i> "I want to be sure that I've explained this clearly; so would you give me two examples of pain you've had recently?" If the patient examples include various parts of the body and various pain characteristics, it indicates that he or she understands pain as a fairly broad concept. An example of what a patient might say is "I have a mild, sort of throbbing headache now, and yesterday my back was aching."</p> <p><b>Step 5.</b> Ask the patient to practice using the pain rating scale with the present pain or select one of the examples mentioned.  <i>Example:</i> "Using the scale, what is your pain right now? What is it at its worst?" OR "Using the pain rating scale and one of your examples of pain, what is that pain usually? What is it at its worst?"</p> <p><b>Step 6.</b> Set goals for comfort and function/recovery/quality of life. Ask patients which pain rating would be acceptable or satisfactory, considering the activities required for recovery or for maintaining a satisfactory quality of life.  <i>Example for a surgical patient:</i> "I have explained the importance of coughing and deep breathing to prevent pneumonia and other complications. Now we need to determine the pain rating that will not interfere with this so you may recover quickly."  <i>Example for patient with chronic pain or terminal illness:</i> "What do you want to do that pain keeps you from doing? Which pain rating would allow you to do this?"</p>
--

\*When a patient is obviously in pain or not focused enough to learn to use a pain rating scale, pain treatment should proceed without pain ratings. Teaching can be undertaken when pain is reduced to a level that facilitates understanding how to use a pain scale.

VDS, Verbal descriptor scale.

From Pasero, C., & McCaffery, M. (2011). *Pain assessment and pharmacologic management*. St. Louis: Mosby. Copyright 2011, McCaffery, M., & Pasero, C. Used with permission.

- **Numeric Rating Scale (NRS):** The NRS is usually presented as a horizontal 0-to-10 point scale, with word anchors of "no pain" at one end of the scale, "moderate pain" in the middle of the scale, and "worst possible pain" at the end of the scale. Some patients relate better to a vertical presentation of the scale.
- **Wong-Baker FACES® Pain Rating Scale:** The FACES scale consists of six cartoon faces with word descriptors, ranging from a smiling face on the left for "no pain (or hurt)" to a frowning, tearful face on the right for "worst pain (or hurt)." The faces are most commonly

numbered 0 to 10. Patients are asked to choose the face that best describes their pain. It is important to appreciate that faces scales are self-report tools; *clinicians should not attempt to match a face shown on a scale to the patient's facial expression to determine pain intensity.* Fig. 4-3 provides the Wong-Baker FACES scale combined with the NRS.

**FIG. 4-3** Wong-Baker FACES® pain rating scale. (From Wong-Baker FACES Foundation [2016]. Wong-Baker FACES® Pain Rating Scale. Retrieved March 12, 2017, with permission from <http://www.WongBakerFACES.org>.)

- **Faces Pain Scale—Revised (FPS-R):** The FPS-R has seven faces to make it consistent with other scales using the 0-to-10 metric. The faces range from a neutral facial expression to one of intense pain. As with the Wong-Baker FACES® scale, patients are asked to choose the face that best reflects their pain. Some research shows that the FPS-R is preferred by both cognitively intact and impaired older adults.
- **Verbal Descriptor Scale (VDS):** A VDS uses different words or phrases to describe the intensity of pain such as “no pain, mild pain, moderate pain, severe pain, very severe pain, and worst possible pain.” The patient is asked to select the phrase that best describes the pain intensity.
- **Quality:** Ask the patient to describe how the pain and discomfort feels. He or she may use one word or a group of words to convey the SENSORY PERCEPTION of the pain. *Avoid suggesting descriptive words for the pain; allow patients to use their own words to describe it.* Descriptors such as “sharp,” “shooting,” or “burning” may help identify the presence of neuropathic pain. Ask the patient whether the pain is superficial or deep. In general, those with pain involving superficial or cutaneous (skin) structures describe it as superficial and can often localize the pain to a specific area.

- *Onset and duration*: Ask the patient when the pain started and whether it is constant or intermittent.
- *Aggravating and relieving factors*: Ask the patient what makes the pain worse and what makes it better. Ask about strategies the patient has used before to manage pain.
- *Effect of pain on function and quality of life*: The effect of pain on the ability to perform recovery activities should be evaluated regularly. It is particularly important to ask patients with persistent pain about how it has affected their lives. Are they able to sleep? Ask what they could do before the pain began that they can no longer do and what they want to do but cannot do.
- *Comfort-function (pain intensity) outcomes*: For patients with *acute pain*, identify expected short-term functional outcomes. Reinforce to the patient that adequate pain control will lead to more successful achievement of those outcomes. For example, tell surgical patients that they will be expected to ambulate or participate in physical therapy after surgery. Ask patients to identify a level of pain that will allow accomplishment of the expected outcomes. A realistic outcome for most patients is 2 or 3 on a scale of 0 to 10. Pain intensity that is consistently above the desired level requires further evaluation and consideration of possible adjustment of the treatment plan.
- *Other information*: Consider the patient's culture, past pain experiences, and pertinent medical history such as comorbidities. Current treatments and diagnostic studies are considered when performing an assessment. For example, patients who are intubated may be awake and alert but unable to speak.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Pain is not a result of aging; however, the incidence is higher in older adults. Sensitivity to pain does not diminish with age. Many older adults, even those with mild-to-moderate dementia, are able to use a self-report assessment tool if nurses and other caregivers take the time to administer it. Many older adults are reluctant to report pain for a variety of reasons, including the belief that it is normal and that they are bothering the nurse. It is essential that attempts be made to obtain the patient's self-report and that pain be assessed frequently with a focus on functional and quality-of-life indicators in this vulnerable population.

### Psychosocial Assessment.

Pain holds unique meaning for the person experiencing it. Patients having *acute pain* from surgery may interpret it as necessary and expected. It may be viewed with relief as a sign that some greater problem has been resolved or alleviated by the surgery. Knowing that the duration of the pain is limited may be reassuring for a patient. In contrast, acute chest pain associated with angina may mark the beginning of a life of fear and uncertainty.

Various psychosocial factors influence *chronic pain*. Some factors are similar to those found in the acute pain experience such as anxiety or fear related to the meaning of the pain. Because chronic pain persists or is perhaps only partially relieved, the patient may feel powerless, angry, hostile, or desperate. He or she is also vulnerable to labels such as “chronic complainer” or “faker.” Remember that it is unprofessional and inappropriate to label or stereotype patients. *Remain objective and advocate for proper pain control for all patients.*

Assess the status of family and other close relationships, along with the range of social resources available to the patient with chronic pain. The existence of a pain-specific conflict with a spouse or significant other may affect or limit coping strategies. Other people may react to chronic pain with depression, social withdrawal, and preoccupation with physical symptoms. Refer the patient and family to self-help groups such as the American Chronic Pain Association (<http://theacpa.org>), which provides the “10-Step Program from Patient to Person.”

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

If the chronic pain is associated with a progressive disease such as cancer, rheumatoid arthritis, or peripheral vascular disease, the patient may have worries and concerns about the consequences of the illness. People with cancer-related pain may fear death or body mutilation. Some may think they are being punished for some wrongdoing in life. Others may attach a religious or spiritual significance to lingering pain.

Ask open-ended questions (e.g., “Tell me how your pain has affected your job or your role as a mother.”) to allow the patient to describe personal attitudes about pain and its influence on life. This opportunity can help someone whose life has been changed by pain. However, some patients choose not to share their private information or fears. As a patient-centered nurse, always respect patients' preferences and values.

## NCLEX Examination Challenge 4-1

### Physiological Integrity

A client who had a total knee replacement 2 weeks ago reports severe pain at the surgical site. Which responses by the nurse are **most** appropriate for the client at this time? **Select all that apply.**

- A. “Please rate your pain on a 0-10 scale, with 10 being the worst possible pain.”
- B. “Could you describe the pain in your knee?”
- C. “By now your pain should be a lot less than it was 2 weeks ago.”
- D. “Which positions make the pain feel worse or better?”
- E. “Having your joint replaced should have decreased your knee pain.”

### Assessment Challenges.

Patients who are unable to report their pain using the customary self-report assessment tools are at higher risk for undertreated pain than those who can report. These include patients who are cognitively impaired, critically ill (intubated, unresponsive), comatose, or imminently dying. Patients who are receiving neuromuscular blocking agents or are sedated from general anesthetics and other drugs given during surgery are also among this at-risk population.

The *Hierarchy of Pain Measures* is recommended by many professional organizations today as a

framework for assessing pain in patients who cannot self-report. The key components of the Hierarchy require the nurse to (1) attempt to obtain self-report; (2) consider underlying pathology or conditions and procedures that might be painful (e.g., surgery); (3) observe behaviors; (4) evaluate physiologic indicators; and (5) conduct an analgesic trial. See Table 4-5 for detailed information on each component of the Hierarchy of Pain Measures.

**TABLE 4-5**  
**Hierarchy of Pain Measures**

<p>1. Attempt to obtain the patient's self-report, the single most reliable indicator of pain. Do not assume that a patient cannot provide a report of pain; many cognitively impaired patients are able to use a self-report tool if simple actions are taken.</p> <ul style="list-style-type: none"> <li>• Try using a standard pain assessment tool (see Fig. 4-3).</li> <li>• Ensure that eyeglasses and hearing aids are functioning.</li> <li>• Increase the size of the font and other features of the scale.</li> <li>• Present the tool in vertical format (rather than the frequently used horizontal).</li> <li>• Try using alternative words such as "ache," "hurt," and "sore" when discussing pain.</li> <li>• Ask about pain in the present.</li> <li>• Repeat instructions and questions more than once.</li> <li>• Allow ample time to respond.</li> <li>• Remember that head nodding and eye blinking or squeezing the eyes tightly can also be used to signal presence of pain and sometimes to rate intensity.</li> <li>• Ask awake and oriented ventilated patients to point to a number on the numeric scale if they are able.</li> <li>• Repeat instructions and show the scale each time pain is assessed.</li> </ul> <p>2. Consider the patient's condition or exposure to a procedure that is thought to be painful. If appropriate, <i>assume pain is present</i> (APP) and document APP when approved by institution policy and procedure. As an example, pain should be assumed to be present in an unresponsive, mechanically ventilated, critically ill trauma patient. Nurses should assume that certain procedures are painful and premedicate based on that assumption.</p> <p>3. Observe behavioral signs (e.g., facial expressions, crying, restlessness, and changes in activity). A pain behavior in one patient may not be in another. Try to identify pain behaviors that are unique to the patient ("pain signature"). Many behavioral pain assessment tools are available that will yield a pain behavior score and may help determine if pain is present. However, it is important to remember that a behavioral score is not the same as a pain intensity score. Behavioral tools are used to help identify the presence of pain and whether an intervention is effective, but the pain intensity is unknown if the patient is unable to provide it.</p> <ul style="list-style-type: none"> <li>• A surrogate who knows the patient well (e.g., parent, spouse, or caregiver) may be able to provide information about underlying painful pathology or behaviors that may indicate pain.</li> <li>• Although surrogates may be helpful in identifying behaviors that may indicate pain, research has shown that they commonly underestimate or overestimate the intensity of the pain. Therefore they should not be asked to rate the patient's pain intensity.</li> </ul> <p>4. Evaluate physiologic indicators with the understanding that they are the <i>least</i> sensitive indicators of pain and may signal the existence of conditions other than pain or a lack of it (e.g., hypovolemia, blood loss). Patients quickly adapt physiologically despite pain and may have normal or below-normal vital signs in the presence of severe pain. The overriding principle is that the absence of an elevated blood pressure or heart rate does not mean the absence of pain.</p> <p>5. Conduct an analgesic trial to confirm the presence of pain and to establish a basis for developing a treatment plan if pain is thought to be present. An analgesic trial involves administering a low dose of analgesic and observing patient response. The initial low dose may not be enough to illicit a change in behavior and should be increased if the previous dose was tolerated, or another analgesic may be added. If behaviors continue despite optimal analgesic doses, other possible causes should be investigated.</p> <ul style="list-style-type: none"> <li>• In patients who are unresponsive, no change in behavior will be evident, and the optimized analgesic dose should be continued.</li> </ul>
---

From Pasero, C., & McCaffery, M. (2011). *Pain assessment and pharmacologic management*. St. Louis: Mosby.

Patients with problems of COGNITION are among those at highest risk for undertreated pain because they are unable to report or have difficulty reporting their pain. The Hierarchy of Pain Measures lists several strategies to use when obtaining self-report is a challenge. When these are ineffective, the Hierarchy suggests that a number of behaviors have been shown to be indicators of pain. Behavioral pain assessment tools are often used to systematically evaluate behaviors to help determine the presence of pain. Improvement in the behavioral pain score helps confirm suspicions that pain is present and provides a reference point for assessing the effectiveness of interventions.

It is important for nurses to remember that a *score obtained from the use of a behavioral tool is not the same as a self-reported pain intensity score*. Although it may seem logical to assume that the higher the behavioral score, the more intense the pain, this cannot be proven without the patient's report. Some patients remain nonverbal and lie completely still (which would yield a low behavioral score) despite having severe pain. The reality is that, if a patient cannot report the intensity of pain, the exact intensity is unknown. Two of the most commonly used behavioral assessment tools that are used for patients with problems of COGNITION such as delirium (acute confusion) or dementia (chronic confusion) are:

- Checklist of Nonverbal Pain Indicators (CNPI) has been tested in the acute care setting in patients with varying levels of cognitive impairment. The tool groups behavioral indicators of pain into six categories. Each category allows a score of 0 if the behavior is not observed and a 1 if the behavior occurred even briefly during activity or rest:
- Facial expression (e.g., grimacing, crying)
- Verbalizations or vocalizations (e.g., screaming)

- Body movements (e.g., restlessness)
- Changes in interpersonal interactions
- Changes in activity patterns or routines
- Mental status changes (e.g., confusion, increased confusion)
- Pain Assessment in Advanced Dementia (PAINAD) scale has been tested in patients with severe dementia (Herr et al., 2011). The tool groups behavioral indicators into five categories for scoring using a graduated scale of 0 (least intense behaviors) to 2 (most intense behaviors) per category for a maximum behavioral score of 10:
- Breathing (independent of vocalization)
- Negative vocalization
- Facial expression
- Body language
- Consolability (ability to calm the patient)

For patients who are mechanically ventilated or may not be able to use other tools for communication, try these interventions:

- Establish a reliable yes-no signal (e.g., thumbs up or down, head nods, or eye blinks) to determine the presence of pain.
- Use communication boards, alphabet boards, computer, or picture boards with word labels for patients with COGNITION problems.
- Correctly interpret lip reading by maintaining eye contact, encouraging the patient to speak slowly, and using dentures if required.

#### ◆ **Interventions: Responding**

Pain is managed using nonpharmacologic interventions, drug therapy, or both. Although nonpharmacologic interventions are commonly used, they are most often combined with drug therapy as complementary or supplemental therapies. Because drug therapy is the most often used approach to pain management, it is presented first in this chapter.

#### **Drug Therapy.**

Safe and effective use of analgesics requires the development of an individualized treatment plan based on a comprehensive assessment. This plan includes clarifying the desired outcomes of treatment and discussing options and preferences with the patient and family. Desired outcomes are periodically re-evaluated, and changes made, depending on patient response and in some cases disease progression.

#### **Multimodal Analgesia.**

Pain is complex, which explains why there is no single, universal treatment for it. Its complexity is also the basis for the widespread recommendation that a multimodal analgesic approach be used,

regardless of the type of pain (American Society of Anesthesiologists [ASA], 2012; Pasero & McCaffery, 2011). Multimodal treatment involves the use of two or more classes of analgesics or interventions to target different pain mechanisms in the PNS or CNS. It relies on the thoughtful and rational combination of analgesics to maximize relief and prevent analgesic gaps that may lead to worsening pain or unnecessary episodes of uncontrolled pain.

A multimodal approach may allow lower doses of each of the drugs in the treatment plan. Lower doses have the potential to produce fewer side effects. Further, multimodal analgesia can result in comparable or greater relief than can be achieved with any single analgesic. For postoperative pain the use of combination therapy to prevent both inflammatory and neuropathic pain is likely to yield the best immediate results. It also offers the promise of reducing the incidence of prolonged or persistent postsurgical pain.

The multimodal strategy also has a role in the management of persistent pain. The complex nature of the many chronic conditions indicates the need for appropriate combinations of analgesics such as anticonvulsants, antidepressants, and local anesthetics to target differing underlying mechanisms.

*Preemptive analgesia* involves the administration of local anesthetics, opioids, and other drugs (multimodal analgesia) in anticipation of pain along the continuum of care during the preoperative, intraoperative, and postoperative periods. This continuous approach is designed to decrease pain severity in the postoperative period, reduce analgesic dose requirements, prevent morbidity, shorten hospital stay, and avoid complications after discharge. Continuous multimodal analgesia may inhibit changes in the spinal cord that can lead to changes in the PNS and CNS that initiate and sustain chronic persistent postsurgical pain (see Nociception earlier in the chapter).

### Routes of Administration.

The oral route is the *preferred* route of analgesic administration. It should be used whenever feasible because it is generally the least expensive, best tolerated, easiest to administer, and replicable at home once the patient is discharged. Other routes of administration are used when the oral route is not possible such as in patients who are NPO, nauseated, or unable to swallow. For example, early postoperative pain and pain that is severe and escalating are managed with the IV route of administration. Then patients are transitioned to oral analgesics when they are able to tolerate oral intake.

### Around-the-Clock Dosing.

Two basic principles of providing effective interprofessional collaborative care are (1) preventing pain and (2) maintaining a level of pain control that allows the patient to function and have an acceptable quality of life. Accomplishment of these desired outcomes may require the mainstay analgesic to be administered on a scheduled around-the-clock (ATC) basis rather than PRN (“as needed”) to maintain stable analgesic levels. *ATC dosing regimens are designed to control pain for patients who report it being present 12 hours or more during a 24-hour period*, such as that associated with most chronic syndromes and pain during the first 24 to 48 hours after surgery or other tissue injury. PRN dosing of analgesics is appropriate for intermittent pain such as before painful procedures and **breakthrough pain** (additional pain that “breaks through” the pain being managed by the mainstay analgesic), for which supplemental doses of analgesic are provided.

### Patient-Controlled Analgesia.

**Patient-controlled analgesia** (PCA) is an interactive method of management that allows patients to treat their pain by self-administering doses of analgesics. It is used to manage all types of pain and given by multiple routes of administration, including IV, subcutaneous, epidural, and perineural. A PCA infusion device (“pump”) is used when PCA is delivered by invasive routes of administration and is programmed so the patient can press a button (“pendant”) to self-administer a set dose of analgesic (“PCA dose”) at a set time interval (“demand” or “lockout”) as needed. *Patients who use PCA must be able to understand the relationships among pain, pressing the PCA button and taking the analgesic, and pain relief. They must also be cognitively and physically able to use any equipment that is used to administer the therapy.*

PCA may be given with or without a basal rate (continuous infusion). The use of a basal rate is common when patient-controlled epidural analgesia (PCEA) is used. For IV PCA, a basal rate may be added for opioid-tolerant patients to replace their home analgesic regimen. Basal rates should be

used with great caution and only in special circumstances for opioid-naïve patients receiving IV PCA. Remember that the patient has no control over the delivery of a continuous infusion. Essential to the safe use of a basal rate is prompt discontinuation of the basal rate if increased sedation or respiratory depression occurs.

## Nursing Safety Priority QSEN

### Action Alert

Teach patients how to use the PCA device and to report side effects such as dizziness, nausea and vomiting, and excessive sedation. As with all opioids, monitor the patient's sedation level and respiratory status at least every 2 hours. Promptly decrease the opioid dose (i.e., discontinue basal rate) if increased sedation is detected.

The primary benefit of PCA is that it recognizes that only the patient can feel the pain and only the patient knows how much analgesic will relieve it. This fact reinforces that *PCA is for patient use only and that unauthorized activation of the PCA button (called "PCA by proxy") can be very dangerous*. Instruct staff, family, and other visitors to contact the nurse if they have concerns about pain control rather than pressing the PCA button for the patient.

### The Three Analgesic Groups.

Analgesics are categorized into three main groups: (1) nonopioid analgesics, which include acetaminophen and the NSAIDs; (2) opioid analgesics such as morphine, hydrocodone, hydromorphone, fentanyl, and oxycodone; and (3) adjuvant analgesics (sometimes referred to as *co-analgesics*), which make up the largest group and include a variety of agents with unique and widely differing mechanisms of action. Examples are local anesthetics, muscle relaxants, and some anticonvulsants and antidepressants.

### Nonopioid Analgesics.

Acetaminophen and NSAIDs make up the nonopioid analgesic group. *Acetaminophen* is thought to relieve pain by underlying mechanisms in the CNS. It has analgesic and antipyretic properties but is not effective for treating inflammation. In contrast, *NSAIDs* have analgesic, antipyretic, and anti-inflammatory properties. These drugs produce pain relief by blocking prostaglandins through inhibition of the enzyme *cyclooxygenase (COX)* in the peripheral nervous system (see Nociception and Fig. 4-1 earlier in the chapter).

Nonopioids are available in a variety of formulations and given by multiple routes of administration. They are also flexible analgesics used for a wide range of conditions. Nonopioid drugs are appropriate alone for mild-to-moderate nociceptive pain (e.g., from surgery, trauma, or osteoarthritis) or are added to opioids, local anesthetics, and/or anticonvulsants as part of a multimodal analgesic regimen for more severe nociceptive pain. *However, they have limited benefit for neuropathic pain.*

Acetaminophen and an NSAID may be given together, and there is no need for staggered doses. Unless contraindicated, all surgical patients should routinely be given acetaminophen and an NSAID in scheduled doses as the foundation of the pain treatment plan throughout the postoperative course, preferably initiated before surgery.

The nonopioids are often combined in a single tablet with opioids such as oxycodone (Percocet) or hydrocodone (Vicodin, Norco, Vicoprofen) and are very popular for the treatment of mild-to-moderate acute pain. Many people with persistent pain also take a combination nonopioid/opioid analgesic. However, it is important to remember that these combination drugs are not appropriate for severe pain of any type because the maximum daily dose of the nonopioid limits the escalation of the opioid dose.

Oral *acetaminophen* (Tylenol, Abenol) has a long history of safety in recommended doses in all age-groups and most patient populations. It is recommended as first line for musculoskeletal pain (e.g., osteoarthritis) in older adults but has no inflammatory properties. Therefore acetaminophen is less effective than NSAIDs for chronic inflammatory pain (e.g., rheumatoid arthritis). IV acetaminophen (Ofirmev) is approved for treatment of pain and fever in adults and is given by a 15-minute infusion in single or repeated doses. It can be given alone for mild-to-moderate pain or in

combination with opioid analgesics for more severe pain.

*The most serious complication of acetaminophen is hepatotoxicity (liver damage) as a result of overdose.* Patient's hepatic risk factors must always be considered before administration of acetaminophen. In the healthy adult a maximum daily dose below 4000 mg is rarely associated with liver toxicity. Many experts recommend reducing the daily dose (e.g., 2500 to 3000 mg daily) when used for *long-term* treatment in older adults. Acetaminophen does not increase bleeding time and has a low incidence of GI adverse effects, making it the analgesic of choice in many people in pain, especially older adults (see [Evidence-Based Practice](#) box).

## Evidence-Based Practice QSEN

### What Are the Best Practices for Managing Chronic Pain in Older Adults?

Makris, U. E., Adams, R. C., Gurland, B., & Reid, M. C. (2014). Management of persistent pain in the older patient: A clinical review. *JAMA*, 312(8), 825-836.

The researchers conducted an extensive review of 92 meta-analysis studies, Cochrane reviews, systematic reviews, consensus statements, and clinical guidelines to determine best practices for managing chronic (persistent) pain in older adults. Of the reviewed studies and reviews, 35 focused on drug therapy for pain control; 57 focused on nonpharmacologic strategies. Fifty of the 92 studies discussed pain management for older adults with osteoarthritis, the most common cause of chronic musculoskeletal pain in this population. The authors concluded that acetaminophen is the primary drug of choice, followed by a trial of topical NSAIDs or tramadol if acetaminophen is not effective. Further, the researchers found no support for long-term use of oral NSAIDs due to toxicities and common adverse effects of these drugs among the older-adult population. Nonpharmacologic measures should be used based on the patient's preference to supplement the drug therapy regimen.

#### Level of Evidence: 1

This research presents the results of an in-depth clinical review of multiple published meta-analyses and systematic reviews. In addition, the authors examined guidelines and consensus statements.

#### Commentary: Implications for Practice and Research

This study reinforced the need to teach older adults to avoid the long-term use of NSAIDs and use acetaminophen for pain control because it is a safer drug. In addition, teach patients about the value of topical NSAIDs and nonpharmacologic modalities that may supplement the drug therapy. More research is needed on which nonpharmacologic strategies are best practice measures for chronic pain associated with osteoarthritis in older adults.

## Nursing Safety Priority QSEN

### Drug Alert

Teach patients to tell their primary health care provider about the amounts of acetaminophen and NSAIDs they take each day. Remind patients of the importance of being alert to the adverse effects of the medications they take and to complete any prescribed laboratory tests (e.g., liver enzymes) to identify early indicators of adverse effects.

A benefit of the *NSAID* group is the availability of a wide variety of agents for administration via noninvasive routes. Ibuprofen (Motrin, Novo-Profen), naproxen (Naprosyn, Nu-Naprox), and celecoxib (Celebrex) are the most widely used oral NSAIDs in the United States and Canada. Diclofenac (Voltaren) is prescribed in patch and gel form for topical administration. An intranasal patient-controlled formulation of ketorolac (Sprix) has been approved for short-term treatment of acute pain. IV formulations of ketorolac (Toradol), ibuprofen (Caldolor), and diclofenac (Dyloject) are also used to manage acute pain. Each have been shown to produce excellent analgesia alone for mild-to-moderate nociceptive pain and significant opioid dose-sparing effects when administered as part of a multimodal analgesic plan for more severe pain.

NSAIDs have more adverse effects than acetaminophen, with gastric toxicity and ulceration being the most common. Risk factors for NSAID adverse effects include being older than 60 years or having a history of peptic ulcer or cardiovascular (CV) disease. An important principle of NSAID use is to administer the lowest dose for the shortest time necessary.

All NSAIDs carry a risk for CV adverse effects through prostaglandin inhibition. The US Food and Drug Administration (FDA) cautions against the use of any NSAIDs after high-risk open-heart surgery because of an elevated CV risk with NSAIDs in this population. Prostaglandins also affect renal function. Be sure that the patient is adequately hydrated when administering NSAIDs to prevent acute renal failure.

## Nursing Safety Priority QSEN

### Drug Alert

NSAIDs can cause GI disturbances and decrease platelet aggregation (clotting), which can result in bleeding. Therefore observe the patient for gastric discomfort or vomiting and for bleeding or bruising. Tell the patient and family to stop taking these drugs and report these effects to the primary health care provider immediately if any of these problems occur. Celecoxib has no effect on bleeding time and produces less GI toxicity compared with other NSAIDs.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Older adults are at increased risk for NSAID-induced GI toxicity. Acetaminophen should be used for mild pain. If an NSAID is needed for inflammatory pain or additional analgesia, the least ulcer-causing NSAID is recommended. The addition of a proton pump inhibitor (e.g., lansoprazole, omeprazole) to NSAID therapy or use of opioid analgesics rather than an NSAID is recommended for high-risk patients. Topical NSAIDs may be used as needed, especially for musculoskeletal disorder pain (Makris et al., 2014).

## NCLEX Examination Challenge 4-2

### Physiological Integrity

An older client takes ibuprofen 1600 mg daily for osteoarthritis. Which health teaching will the nurse provide for the client related to this medication? **Select all that apply.**

- A. "Be sure and take your medication with food to prevent stomach ulcers."
- B. "Take your medication only when you need it for chronic pain."
- C. "Avoid any over-the-counter medications that may contain ibuprofen."
- D. "Take your blood pressure often because ibuprofen can cause it to go up."
- E. "You might want to take acetaminophen because it has fewer side effects than ibuprofen."

### Opioid Analgesics.

Opioid analgesics are the mainstay in the management of moderate-to-severe nociceptive types of pain such as postoperative, surgical, trauma, and burn pain. Although it is often used, the term *narcotic* is considered obsolete and inaccurate when discussing the use of opioids for pain management. "Narcotic" is used loosely by law enforcement and the media to refer to a variety of substances of potential abuse. Legally controlled substances classified as narcotics include opioids, cocaine, and others. *The preferred term is "opioid analgesics" when discussing these agents in the context of pain management.* Some patients prefer the term *pain medications* or *pain medicine*.

## Genetic/Genomic Considerations

### Patient-Centered Care QSEN

It has long been known that the cytochrome (CY) *P450* enzyme system is important to the metabolism of some opioids. Interethnic variations in phenotypes of the *CYP450* enzymes are common, causing decreased metabolism of selected analgesics in a small percentage of Caucasians and Asians. These variations have clinical implications when the opioid *codeine*, which is metabolized by the *CYP450* enzyme system, is administered. Slow metabolizers may not respond well to codeine, and ultra-rapid metabolizers may have an exaggerated response. Current research is focused on other genetic variables that may explain an individual's response to opioids to manage pain (Wright, 2015).

Opioids produce their effects by interacting with opioid receptor sites located throughout the body, including in the peripheral tissues, the GI system, and the spinal cord and brain. When an opioid binds to the opioid receptor sites, it produces analgesia and unwanted effects such as constipation, nausea, sedation, and respiratory depression. There are three classifications of opioids:

- **Full or *mu* agonists** (“morphine-like”) bind primarily to the mu-type opioid receptors in the CNS and, among other actions, block the release of the neurotransmitter *substance P*, which prevents the opening of calcium channels and the transmission of pain (Wright, 2015). A major benefit of the mu opioid agonists is that they have no ceiling on analgesia. This means that increases in dose produce increases in pain relief and that there is no maximum dose (see Physical Tolerance later in the chapter). This property makes the mu opioid agonists the first-line opioid analgesics for moderate-to-severe nociceptive pain. Examples are morphine, fentanyl, hydromorphone, oxycodone, oxymorphone, and hydrocodone.
- **Mixed agonists/antagonists** bind to more than one type of opioid receptor. They bind as agonists to the kappa opioid receptors to produce analgesia and other effects and to the mu opioid receptors as antagonists. This antagonistic property explains why these drugs can trigger severe pain and opioid withdrawal syndrome characterized by rhinitis, abdominal cramping, nausea, agitation, and restlessness in patients who have been taking regular daily doses of a mu agonist opioid for several days. Another undesirable effect of these drugs is that they produce a dose-ceiling effect, which means that further increases in dose will not produce further relief. This latter property limits their usefulness in pain management. Occasionally these drugs are used in very low doses to antagonize (in hopes of relieving) opioid-induced side effects such as pruritus. However, this approach risks reversing analgesia; therefore patients must be assessed frequently to ensure that adequate pain control and COMFORT are maintained. Examples are butorphanol (Stadol) and nalbuphine (Nubain).
- **Partial agonists** have some kappa and mu opioid receptor activity but produce an analgesia plateau and are not easily reversed by opioid antagonists such as naloxone (Narcan). These properties limit their role in pain management. Buprenorphine is a partial agonist opioid, available in a transdermal patch (Butrans) for stable pain management. The drug has been formulated alone (Subutex) and with naloxone (Suboxone) for the treatment of the disease of addiction.

*Opioid antagonists* (e.g., naloxone [Narcan], naltrexone [Revia]) are drugs that also bind to opioid receptors but produce no analgesia. If an antagonist is present, it competes with opioid molecules for binding sites on the opioid receptors and has the potential to block analgesia and other effects. They are used most often to reverse opioid effects such as excessive sedation and respiratory depression.

### Key Principles of Opioid Administration.

Many factors are considered when determining the appropriate opioid analgesic for the patient with pain. These include the unique characteristics of the various opioids and patient factors such as type of pain, pain intensity, age, gender, coexisting disease, current drug regimen and potential drug interactions, prior treatment outcomes, and patient preference.

## Gender Health Considerations

## Patient-Centered Care QSEN

Research has identified differences between females and males in a number of factors that influence the pharmacokinetics (absorption, distribution, metabolism, and excretion) and pharmacodynamics (effects on the body) of drugs. Some of these factors are organ physiology, body composition, gastric emptying time, enzyme activity, and drug clearance (Wright, 2015). Research also shows that women are at substantially greater risk for more pain conditions than men and that they may experience more postoperative and procedural pain than men (Fillingim et al., 2009). In the immediate postoperative period women seem to have a higher opioid requirement, but men demonstrate higher opioid consumption after the initial recovery period. This difference may be partly explained by the faster recovery after general anesthesia in women. Side effects and complications associated with opioid and nonopioid analgesics appear to be more prevalent in women than in men. Creatinine clearance (drug excretion) is generally higher in men than in women because of increased muscle mass, and clearance varies with the menstrual cycle in women. Additional research is needed to better understand the effects of gender on the pain experience.

**Titration** (dose increases or decreases) of the opioid dose is usually required at the start and throughout the course of treatment when opioids are administered. Whereas patients with cancer pain most often are titrated upward over time for progressive pain, patients with acute pain, particularly postoperative pain, are eventually titrated downward as pain resolves. Although the dose and analgesic effect of mu agonist opioids have no ceiling, the dose may be limited by side effects. The absolute dose administered is unimportant as long as a balance between pain relief and side effects is favorable. *The desired outcome of titration is to use the smallest dose that provides satisfactory pain relief with the fewest side effects.*

When an increase in the opioid dose is necessary and safe, the increase can be titrated by percentages. When a slight improvement in analgesia is needed, a 25% increase in the opioid dose may be sufficient; a 50% increase for moderate improvement; and a 100% increase may be indicated for strong improvement such as when treating severe, escalating pain (Pasero & McCaffery, 2011). The time at which the dose can be increased is determined by the onset and peak effects of the opioid and its formulation. For example, the frequency of IV opioid doses during initial titration may be as often as every 5 to 15 minutes (see later discussion of specific opioids). In contrast, at least 24 hours should elapse before the dose of transdermal fentanyl is increased after the first patch application.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Although the patient's weight is not a good indicator of analgesic requirement, *age is considered an important factor to consider when selecting an opioid dose.* For older adults the guideline is to “start low and go slow” with all drug dosing. For example, the starting opioid dose may need to be reduced by 25% to 50% in older adults because they are more sensitive to opioid side effects than are younger adults. The subsequent doses are based on patient response, which should be evaluated frequently. Monitor sedation level and respiratory status and promptly reduce the drug dose if sedation occurs or the respiratory rate is markedly decreased, depending on agency policy. Chart 4-1 describes best practices for pain assessment and management in the older adult.

### Chart 4-1

## Nursing Focus on the Older Adult

### Pain

#### Prevalence of Pain

- Recognize that older adults are at high risk for undertreated pain and those with cognitive

impairment are at even higher risk.

- Common caregiver and health care team misconceptions such as that pain sensitivity decreases with aging and older adults cannot tolerate analgesics without significant adverse effects contribute to the undertreatment of pain in older adults.

### Beliefs About Pain

- Older adults tend to report pain less often than younger adults, which frequently results in members of the health care team administering suboptimal analgesics and doses. The failure of older adults to report pain may be related to common beliefs and concerns they have about pain and reporting it such as:
  - Pain is an inevitable consequence of aging and little can be done to relieve it.
  - Expressing pain is unacceptable or is a sign of weakness.
  - Reporting pain will result in being labeled as a “bad” patient or a “complainer.”
  - Nurses and physicians are too busy to listen to reports of pain.
  - Pain signifies a serious illness or impending death.
- Be aware of the common beliefs of older patients regarding pain and its management and correct misconceptions to help prevent barriers to achieving optimal pain relief.
- Nurses and other caregivers can overcome their reluctance to administer prescribed analgesics in adequate doses by following the principles of pain management in older people (see *Management of Pain* section).

### Assessment of Pain

- Ask the patient to provide his or her own report of pain; even mild to some moderate cognitively impaired older adults are able to provide self-report if nurses and caregivers take the time to obtain it.
- Offer various self-report pain tools.
- Always show tools in hard copy with large lettering, adequate space between lines, nonglossy paper, and color for increased visualization.
- Be sure that the patient is wearing glasses and hearing aids if needed and available.
- Provide adequate lighting and privacy to avoid distracting background noise.

- Repeat questions more than once and allow adequate time for response.
- Use verbal descriptions such as “ache,” “sore,” and “hurt” if the patient seems to have difficulty relating to the word “pain.”
- Ask about present pain only.
- If the patient is able to use a self-report tool, use the same tool and retest the tool each time pain is assessed.

#### Considerations for Cognitively Impaired Patients (also see Table 4-5)

- Remember to “assume that pain is present” in patients with diseases and conditions or procedures commonly associated with pain (see discussion below on *analgesic trial*).
- If the patient is unable to provide self-report, look for behaviors that may indicate the presence of pain.
- Someone who knows the patient well such as a family member or caregiver may be helpful in identifying behaviors that might indicate pain. Do not ask others to rate pain intensity and do not attempt to rate it yourself. Only the patient knows how severe the pain is; if he or she cannot rate or describe the intensity, the exact intensity is unknown.
- Assess using a reliable and valid behavioral pain assessment tool.
- Remember that behavioral tools tell us that pain might be present and provide a reference point to help determine the effectiveness of interventions, but the scores on behavioral tools have not been correlated with the ratings on pain intensity scales. A behavioral score is not a pain intensity rating.
- Use the same behavioral assessment tool each time pain is assessed.
- Consider an analgesic trial to help determine the presence of pain and to establish an ongoing treatment plan in patients who are thought to have pain. This involves the administration of a low-dose analgesic; changes or decreases in the intensity of behaviors indicate that pain may be the cause of the behaviors. Doses should be increased, or additional analgesics added as appropriate.

#### Management of Pain

- Use a multimodal approach that combines analgesics with different underlying mechanisms with the desired outcome of achieving optimal pain relief with lower doses than would be possible with a single analgesic; lower doses result in fewer side effects.
- Consider the type of pain and begin therapy with the first-line analgesics that are recommended

for that type of pain.

- Do not give meperidine to older adults because most have decreased renal function and are unable to efficiently eliminate its central nervous system (CNS)–toxic metabolite *normeperidine*.
- Use around-the-clock (ATC) dosing of analgesics for pain that is of a continuous nature (e.g., chronic osteoarthritis or cancer pain; chronic neuropathic pain, first 24 to 48 hours after surgery).
- Use as needed (PRN) dosing for intermittent pain and before painful activities such as before ambulation and physical therapy.
- Be aware of the main side effects of the analgesics that are administered and that they may be more likely to occur or be more severe in older than in younger adults.
- *Start low and go slow* with drug dosing; increase doses to achieve adequate analgesia based on patient's response to the previous dose.
- Teach the patient and family or other caregiver about the pain management plan (analgesics and nonpharmacologic strategies) and when to notify the primary health care provider for unrelieved pain or unmanageable or intolerable drug side effects.
- To promote adherence to the pain management plan in the home setting, suggest using a pillbox to organize each day's medications and keeping a diary to identify times of the day or activities that increase pain. The diary can be presented to the primary health care provider who can use it to make necessary adjustments in the treatment plan.

In some cases, needed drug therapy for older adults experiencing pain may not be provided. A study by [Platts-Mills et al. \(2013\)](#) found that among the prehospital population, older adults received analgesia less often than younger adults. Adults older than 85 years of age were the least likely to receive any analgesia. When reporting mild-to-moderate pain, they were less likely to be given analgesics than younger adults with the same pain intensity. However, older women reporting a pain level of 8 or greater (on a pain scale of 0 to 10) were treated for their pain more often than their younger counterparts reporting the same level of pain. Clearly a consistent pain assessment and management protocol is needed for all patients, starting with prehospital and emergency department (ED) care. Many older adults are admitted to the ED with fractures of the hip, pelvis, and spine, which are very painful and require prompt and adequate pain management to promote patient COMFORT.

### Physical Dependence, Tolerance, and Addiction.

The terms *physical dependence* and *tolerance* often are confused with *addiction*; thus clarification of definitions is important. The most widely accepted definitions of these terms are:

- *Physical dependence is a normal response* that occurs with repeated administration of an opioid for several days. It is manifested by the occurrence of withdrawal symptoms when the opioid is stopped suddenly or rapidly reduced or an antagonist such as naloxone is given. Withdrawal symptoms may be suppressed by the natural, gradual reduction of the opioid as pain decreases or by gradual, systematic reduction, referred to as *tapering*. *Physical dependence is not the same as addictive disease.*
- *Tolerance is also a normal response* that occurs with regular administration of an opioid and consists of a decrease in one or more effects of the opioid (e.g., decreased analgesia, sedation, or respiratory depression). Like physical dependence, *tolerance is not the same as addictive disease.* Tolerance to analgesia usually occurs in the first days to 2 weeks of opioid therapy but is uncommon after that. It may be treated with increases in dose or rotation to a different opioid. However, disease progression, not tolerance to analgesia, appears to be the reason for most dose escalations. Stable pain usually results in stable opioid doses. With the exception of constipation, tolerance to the opioid side effects develops with regular daily dosing of opioids over several days.
- *Opioid addiction is a chronic neurologic and biologic disease.* The development and characteristics of addiction are influenced by genetic, psychosocial, and environmental factors. No single cause of addiction such as taking an opioid for pain relief has been found. It is characterized by one or

more of these behaviors: impaired control over drug use, compulsive use, continued use despite harm, and craving. *The disease of addiction is a treatable disease; as for any other suspected disease, refer the patient to an expert for diagnosis and treatment.*

- *Pseudoaddiction* is a mistaken diagnosis of addictive disease. When a patient's pain is not well controlled, the patient may begin to manifest symptoms suggestive of addictive disease. For example, in an effort to obtain adequate pain relief, the patient may respond with demanding behavior, escalating demands for more or different medications, and repeated requests for opioids on time or before the prescribed interval between doses has elapsed. Pain relief typically eliminates these behaviors and is often accomplished by increasing opioid doses or decreasing intervals between doses.

### Opioid Naïve Versus Opioid Tolerant.

Patients are often characterized as being either opioid naïve or opioid tolerant. An *opioid-naïve* person has not recently taken enough opioid on a regular basis to become tolerant to the effects of an opioid. An *opioid-tolerant* person has taken an opioid long enough at doses high enough to develop tolerance to many of the effects, including analgesia and the undesirable effects such as nausea and sedation. There is no set time for the development of tolerance, with wide individual variation among people. Some patients do not develop tolerance at all. Opioid tolerance can be defined as regularly taking opioids for about 7 days or longer.

### Equianalgesia.

The term *equianalgesia* means approximately “equal analgesia.” An equianalgesic chart provides a list of analgesic doses, both oral and parenteral (IV, subcutaneous, and IM), that are approximately equal to one another in ability to provide pain relief (Table 4-6). Equianalgesic conversion of doses is used to help ensure that patients receive approximately the same pain relief when they are switched from one opioid or route of administration to another. It requires a series of calculations based on the daily dose of the current opioid to determine the equianalgesic dose of the opioid to which the patient is to be switched. Consult and collaborate with the pharmacist whenever equianalgesic conversion is indicated.

**TABLE 4-6**  
**Equianalgesic Dose Chart for Common Mu Opioid Analgesics**

OPIOID	ORAL	PARENTERAL	COMMENTS
Morphine	30 mg	10 mg	Standard for comparison; first-line opioid via multiple routes of administration; once-daily and twice-daily oral formulations; clinically significant metabolites
Fentanyl	No formulation	100 mcg IV 100 mcg/hr of transdermal fentanyl is approximately equal to 4 mg/hr of IV morphine; 1 mcg/hr of transdermal fentanyl is approximately equal to 2 mg/24 hr of oral morphine	First-line opioid via IV, transdermal, and intraspinal routes; available in oral transmucosal and buccal formulations for breakthrough pain in opioid-tolerant patients; no clinically relevant metabolites
Hydrocodone	30 mg	No formulation	Available in combination with nonopioid, short-acting, and twice-daily formulations
Hydromorphone (Dilaudid)	7.5 mg	1.5 mg	First-line opioid via multiple routes of administration; once-daily oral formulation; clinically significant metabolites noted with long-term, high-dose infusion
Oxycodone	20 mg	No formulation in the United States	Short-acting and twice-daily oral formulations
Oxymorphone	10 mg	1 mg	Parenteral, short-acting, and twice-daily oral formulations

Data from Pasero, C., & McCaffery, M. (2011). *Pain assessment and pharmacologic management*. St. Louis: Mosby.

Relative potency is the ratio of drug doses required to produce the same effect. For example, note in Table 4-6 that a single dose of 1.5 mg of parenteral hydromorphone produces approximately the same analgesia as 10 mg of parenteral morphine. This means that hydromorphone is more potent than morphine, but increased potency does not mean that the drug is therapeutically superior or that it provides any advantage. Safe and effective pain management requires nurses to appreciate the differences in the potencies of the various opioids and apply the principles of equianalgesia when administering opioids.

### Drug Formulation Terminology.

The terms *short acting*, *fast acting*, *immediate release (IR)*, and *normal release* have been used interchangeably to describe oral opioids that have an onset of action of about 30 minutes and a relatively short duration of 3 to 4 hours. The term *immediate release* is misleading because none of the oral analgesics have an immediate or even a fast onset of analgesia. The term *short acting* is

preferred to reflect the short duration of oral opioids. Oral transmucosal and intranasal formulations are appropriately referred to as *ultra-fast acting* because they have a peak effect of 5 to 15 minutes, depending on formulation.

The terms *modified release*, *extended release (ER)*, *sustained release (SR)*, and *controlled release (CR)* are used to describe opioids that are formulated to release over a prolonged period of time. For the purposes of this chapter, the term *modified release* will be used when discussing these opioid formulations. *Long acting* is applied to drugs with a long *half-life* such as methadone. The half-life of a drug provides an estimate of how fast the drug leaves the body. By definition, **half-life** is the time it takes for the amount of drug in the body to be reduced by 50%.

## Nursing Safety Priority QSEN

### Drug Alert

*Modified-release opioids should never be crushed, broken, or chewed because doing so alters the formulation of the drug and can result in adverse events, including death from respiratory depression if consumed. Teach the patient to swallow the drug whole and allow the “time-release” function of the drug to take effect. Intact modified-release tablets may be administered rectally in some patients who cannot swallow.*

### Selected Opioid Analgesics.

*Morphine* is the standard against which all other opioid drugs are compared. It is the most widely used opioid throughout the world, particularly for cancer pain, and its use is established by extensive research and clinical experience. Morphine is a *hydrophilic* drug (readily absorbed in aqueous solution), which accounts for its slow onset and long duration of action when compared with other opioid analgesics. It is available in a wide variety of short-acting and modified-release oral formulations and is given by multiple other routes of administration, including rectal, subcutaneous, and IV.

*Fentanyl* (Sublimaze) differs from morphine significantly in characteristics. It is a *lipophilic* (readily absorbed in fatty tissue) opioid and, as such, has a fast onset and short duration of action. These characteristics make it the most commonly used IV opioid when rapid analgesia is desired such as for the treatment of severe, escalating acute pain and for procedural pain when a short duration of action is desirable. Fentanyl is the recommended opioid for patients with end-organ failure because it has no clinically relevant metabolites. It also produces fewer hemodynamic adverse effects than other opioids; therefore it is often preferred in patients who are hemodynamically unstable such as the critically ill.

Its lipophilicity makes fentanyl ideal for drug delivery by transdermal patch (Duragesic) for long-term opioid therapy, and by the oral transmucosal (Actiq), sublingual (Subsys), and buccal (Fentora) routes for breakthrough pain treatment in opioid-tolerant patients. After application of the transdermal patch, a subcutaneous depot of fentanyl is established in the skin near the patch. After absorption from the depot into the systemic circulation, the drug distributes to fat and muscle. When the first patch is applied, 12 to 18 hours are required for clinically significant analgesia to be obtained. Be aware that the patient may need adequate supplemental analgesia during that time. Change the patch every 48 to 72 hours, depending on patient response.

## Nursing Safety Priority QSEN

### Drug Alert

Teach patients using transdermal fentanyl not to apply heat (e.g., hot packs, heating pads) directly over the patch because heat increases absorption of the drug and can result in adverse events, including death from fentanyl-induced respiratory depression. Ask patients about the presence of patches on admission and document and communicate this information to other members of the interdisciplinary health care team.

*Hydromorphone* (Dilaudid) is less hydrophilic than morphine but less lipophilic than fentanyl,

which contributes to an onset and duration of action that is intermediate between morphine and fentanyl. The drug is often used as an alternative to morphine, especially for acute pain, most likely because the two drugs produce similar analgesia and have comparable side effects. It is a first- or second-choice opioid (after morphine) for postoperative management via IV patient-controlled analgesia (PCA) and is available in a once-daily modified-release oral formulation (Exalgo) for long-term opioid treatment.

## NCLEX Examination Challenge 4-3

### Physiological Integrity

A client has a one-time prescription for morphine 1 mg IV push. The drug is available as 5 mg/mL. The nurse administers \_\_\_\_\_ mL of morphine for one dose.

*Oxycodone* is available in the United States for administration by the oral route only and is used to treat all types of pain. In combination with acetaminophen or ibuprofen, it is appropriate for mild-to-some moderate pain. Single-entity, short-acting (OxyIR) and modified-release (OxyContin) oxycodone formulations are used in patients with moderate-to-severe chronic pain. It has been used successfully as part of a multimodal treatment plan for postoperative pain as well. Like morphine, it is available in liquid form for patients who are unable to swallow tablets.

*Hydrocodone* in combination with nonopioids (Norco, Vicodin) limits its use to the treatment of mild-to-some moderate pain. It is the most commonly prescribed opioid analgesic in the United States and Canada, but its prescription for treatment of persistent pain (except for breakthrough dosing) should be evaluated carefully because of its ceiling on efficacy and safety related to the nonopioid constituent (ingredient). It is also available as a modified-release formulation (Zohydro, Hysingla) for chronic pain.

*Methadone* (Dolophine) is a unique opioid analgesic that may have advantages over other opioids in carefully selected patients. In addition to being a mu opioid, it is an antagonist at the NMDA (N-methyl-D-aspartate) receptor site and thus has the potential to produce analgesic effects as a second- or third-line option for some neuropathic pain states.

Although it has no active metabolites, methadone has a very long and highly variable half-life (5 to 100+ hours; average is 20 hours). Patients must be watched closely for excessive sedation—a sign of drug accumulation during the titration period. Other limitations are its tendency to interact with a large number of medications and prolong corrected QT (QTc) interval. Methadone should be prescribed only by providers who are familiar with its unique properties.

### Dual Mechanism Analgesics.

The dual mechanism analgesics *tramadol* (Ultram) and *tapentadol* (Nucynta) have been useful additions to the pain management arena. These drugs bind weakly to the mu opioid-receptor site and block the reuptake (resorption) of the inhibitory neurotransmitters *serotonin* and/or *norepinephrine* in the spinal cord and brainstem of the modulatory descending pain pathway (see Nociception earlier in this chapter). This makes these neurotransmitters more available to fight pain. Because they have the opioid receptor-binding property, they are discussed in the Opioid Analgesics section of this chapter. However, they are usually referred to as dual mechanism or mixed analgesics rather than opioid analgesics.

Tramadol is used for both acute and chronic pain and is available in oral short-acting (Ultram) and modified-release (Ultram ER) formulations, including a short-acting tablet in combination with acetaminophen (Ultracet). It is appropriate for acute pain and has been designated as a second-line analgesic for the treatment of neuropathic pain. Side effects are similar to those of opioids. The drug can lower seizure threshold and interact with other drugs that block the reuptake of serotonin such as the selective serotonin reuptake inhibitor (SSRI) antidepressants. Although rare, this combination can have an additive effect and result in serotonin syndrome, characterized by agitation, diarrhea, heart and blood pressure changes, and loss of coordination.

The newer dual-mechanism analgesic *tapentadol* is also available in short-acting (Nucynta) and modified-release (Nucynta ER) formulations and is appropriate for both acute and chronic pain. Major benefits of tapentadol are that it has no active metabolites and a significantly more favorable side effect profile (particularly GI effects) compared with opioid analgesics.

## Opioids to Avoid.

*Meperidine* (Demerol) was once the most widely used opioid analgesic in the inpatient setting. In recent years it has either been removed from or severely restricted on US hospital formularies for the treatment of pain in an effort to improve patient safety. A major drawback to the use of meperidine is its active metabolite, *normeperidine*, a CNS stimulant that can cause delirium, irritability, tremors, myoclonus, and generalized seizures. It is a particularly poor choice in older adults because they have decreased renal function, which prevents the elimination of the toxic metabolite. Meperidine has no advantages over any other opioid, and it has no place in the treatment of persistent pain or in delivery systems such as PCA. If prescribed, meperidine should not be used for more than 48 hours or at doses exceeding 600 mg/24 hours.

*Codeine* in combination with nonopioids (e.g., with acetaminophen in Tylenol No. 3) has been used for many years for the management of mild-to-moderate pain; however, it has largely been replaced by analgesics that are more efficacious and better tolerated (e.g., Percocet, Vicodin). Research has shown that codeine/acetaminophen is less effective and associated with more adverse effects than NSAIDs such as ibuprofen and naproxen for acute pain.

## Intraspinal Analgesia.

Intraspinal analgesia involves the administration of analgesics via a needle or catheter placed in the epidural space or the intrathecal (subarachnoid) space by an anesthesia provider (see Fig. 4-4). The intraspinal routes of administration are used to manage both acute pain such as postoperative pain and some chronic cancer and noncancer pain.

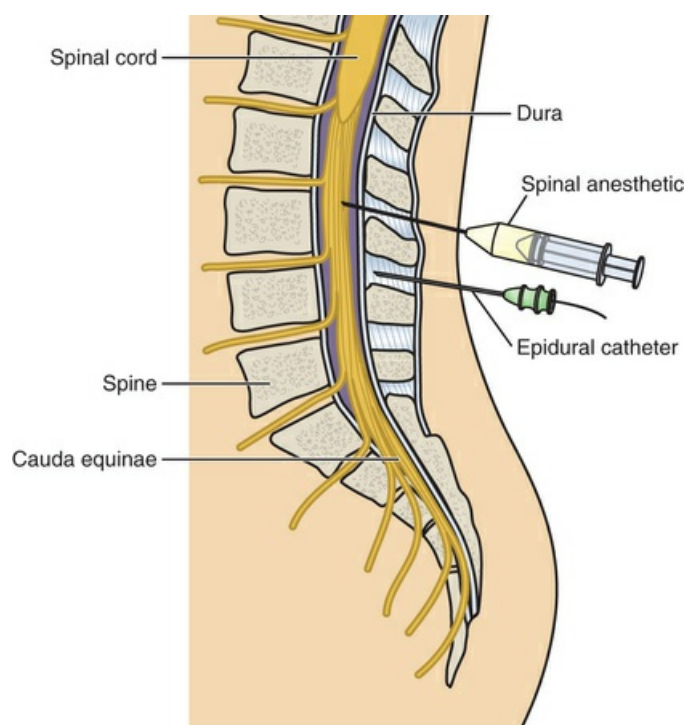

FIG. 4-4 Intraspinal analgesia.

Epidural analgesia can be delivered by intermittent bolus technique, continuous infusion, or patient-controlled epidural analgesia (PCEA) with or without continuous infusion. The most commonly administered analgesics by the epidural route are the opioids *morphine*, *hydromorphone*, and *fentanyl* in combination with a long-acting local anesthetic such as bupivacaine (Marcaine) or ropivacaine (Naropin). This multimodal approach allows lower doses of both the opioid and local anesthetic and produces fewer side effects. A single epidural injection of preservative-free morphine (Duramorph) is effective for about 24 hours. An extended-release formulation of preservative-free epidural morphine (DepoDur) is effective for 48 hours.

Intrathecal (spinal) analgesia is usually delivered via single bolus technique for patients with acute pain (e.g., hysterectomy) or continuous infusion via an implanted device (pump) for the

treatment of chronic pain. Because the drug is delivered directly into the aqueous cerebrospinal fluid (CSF), morphine with its hydrophilic nature is used most often for intrathecal analgesia. Extremely small amounts of drug are administered by the intrathecal route (about 10 times less than by the epidural route) because the drug is so close to the spinal action site.

The side effects of intraspinal analgesia depend on the type of drug administered. In other words, if opioids are administered, the same opioid-induced side effects that occur with other routes of administration can occur with intraspinal administration. If local anesthetics are administered, common side effects are urinary retention, hypotension, and numbness and weakness of lower extremities. The latter can occur on a continuum (mild and localized) to a complete block (undesirable and requires prompt anesthesia evaluation). In most cases the side effects that occur during continuous infusion or PCEA can be managed by decreasing the dose.

Complications of intraspinal analgesia are rare but can be life threatening. Complications from the intrathecal pump can be surgical, pump related, or catheter related (Textor, 2016). Chart 4-2 summarizes best practices needed when caring for a patient who has an intrathecal pump. Perform frequent neurologic assessments and promptly report abnormal findings to the anesthesiologist or nurse anesthetist.

#### Chart 4-2

### Best Practice for Patient Safety & Quality Care QSEN

#### Care of the Patient Who Has an Intrathecal Pump for Managing Cancer Pain

Provide postoperative care and health teaching to include:

- Carefully monitor respiratory status, including respiratory rate, oxygen saturation, and level of consciousness every 1 to 2 hours after surgery for at least 12 hours or as per surgeon or agency protocol.
- Apply an abdominal binder in place as prescribed to hold the pump in a flat position.
- Teach the patient that a burning sensation may occur around the pump area. Cold packs and topical lidocaine may provide COMFORT; do *not* use heat over the lumbar pump site.
- Teach the patient to avoid lifting more than 5 lb or twisting/bending at the waist for 6 weeks or as instructed by the surgeon.

Monitor for and teach the patient and family to report these potential complications:

- Surgical complications
- Infection: Observe for fever and localized redness or hematoma at the lumbar site.
- Cerebrospinal (CSF) fluid leak: Ask about headache; observe for swelling without redness at the lumbar site.

- Catheter-related complications
- Structural damage, including kinks, occlusion, or disconnection; note change in pain control or signs of opioid withdrawal.
- Pump-related complications (not common)
- Malfunction or displacement: Observe for opioid overdose or underdosing, causing a change in pain control or opioid withdrawal.

Keep these safety and care precautions in mind when caring for the patient:

- Be sure that the pump is shielded if the patient received external beam radiation.
- Be sure that the patient does not have an abrupt discontinuation of baclofen (can cause respiratory depression) or clonidine (can cause hypertension and stroke).

Data adapted from Textor, L. (2016). Intrathecal pumps for cancer pain. *AJN*, 116(5), 36-41.

## Nursing Safety Priority QSEN

### Drug Alert

Assess patients receiving epidural local anesthetic for their ability to bend their knees and lift their buttocks off the mattress (if not prohibited by surgical procedure). Ask them to point to any areas of numbness and tingling. Mild, transient lower-extremity motor weakness and orthostatic hypotension may be present, necessitating assistance with ambulation. Most undesirable effects can be managed with a reduction in local anesthetic dose. Promptly report areas of numbness outside of the surgical site, inability to bear weight, and severe hypotension to the anesthesia provider. *Do not delegate assessment of local anesthetic effects to unlicensed assistive personnel!*

SENSORY PERCEPTION manifestations (e.g., increasing numbness and tingling of extremities), decreasing ability to bear weight, and/or changes in bowel or bladder function can indicate the development of an epidural hematoma or abscess. If not detected, a hematoma or abscess can cause spinal cord compression and paralysis.

Nurses have an extensive role in the management and monitoring of intraspinal techniques, including infusion device operation, replacing empty drug reservoirs, checking and protecting infusion sites and systems, treating side effects, preventing complications, discontinuing therapy, and removing catheters.

### Adverse Effects of Opioid Analgesics.

The most common side effects of opioid analgesics are constipation, nausea, vomiting, pruritus, and sedation. Respiratory depression is less common but the most feared of the opioid side effects. *Most of the opioid side effects are dose related; therefore simply decreasing the opioid dose is sufficient to eliminate or make the most of the side effects tolerable for most patients.* Table 4-7 lists interventions to prevent and manage opioid-induced side effects.

**TABLE 4-7**

## Nursing Interventions to Prevent and Treat Selected Opioid Side Effects

<p><b>Constipation</b></p> <ul style="list-style-type: none"> <li>Assess previous bowel habits.</li> <li>Keep a record of bowel movements.</li> <li>Remind patients that tolerance to this side effect does not develop, so a <i>preventive approach must be used</i>; administer a stool softener plus mild stimulant laxative for duration of opioid therapy; do not give bulk laxatives because these can result in obstruction in some patients.</li> <li>Provide privacy, encourage adequate fluids and activity, and give foods high in roughage.</li> <li>If ineffective, try suppository or Fleet's enema.</li> <li>For long-term opioid-induced constipation (OIC) in patients with chronic pain, drug therapy may be used (e.g., lubiprostone [Amitiza], methylnaltrexone [Relistor]).</li> </ul>
<p><b>Nausea and Vomiting (N/V)</b></p> <ul style="list-style-type: none"> <li>Use a multimodal antiemetic preventive approach (e.g., dexamethasone plus ondansetron in moderate- to high-risk patients).</li> <li>Assess cause of nausea and eliminate contributing factors if possible.</li> <li>Reduce opioid dose if possible.</li> <li>Reassure patients taking long-term opioid therapy that tolerance to this side effect develops with regular daily opioid doses.</li> <li>Treat with antiemetic drug as prescribed.</li> <li>Consider switching to another opioid for unresolved N/V.</li> </ul>
<p><b>Sedation</b></p> <ul style="list-style-type: none"> <li>Remember that sedation precedes opioid-induced respiratory depression; identify patient and iatrogenic risk factors and monitor sedation level and respiratory status frequently during the first 24 hours of opioid therapy.</li> <li>Use a simple sedation scale to monitor for unwanted sedation (see Table 4-8).</li> <li>If excessive sedation is detected, reduce opioid dose to prevent respiratory depression.</li> <li>Eliminate unnecessary sedating drugs such as antihistamines, anxiolytics, muscle relaxants, and hypnotics. If it is necessary to administer these drugs during opioid therapy, monitor sedation and respiratory status closely.</li> <li>Reassure patients taking long-term opioid therapy that tolerance to this side effect develops with regular daily opioid doses.</li> <li>Be aware that stimulants such as caffeine may counteract opioid-induced sedation.</li> <li>Consider switching to another opioid for unresolved excessive sedation during long-term opioid therapy.</li> </ul>
<p><b>Respiratory Depression</b></p> <ul style="list-style-type: none"> <li>Be aware that counting respiratory rate alone does not constitute a comprehensive respiratory assessment. Proper assessment of respiratory status includes observing the rise and fall of the patient's chest to determine depth and quality in addition to counting respiratory rate for 60 seconds.</li> <li>Recognize that <i>snoring is respiratory obstruction</i> and an ominous sign (see text).</li> <li>Remember that sedation precedes opioid-induced respiratory depression; identify patient and iatrogenic risk factors and monitor sedation level and respiratory status frequently during the first 24 hours of opioid therapy (see Sedation section).</li> <li>Stop opioid administration immediately for clinically significant respiratory depression, stay with patient, continue attempts to arouse patient, support respirations, call for help (consider Rapid Response Team or Code Blue), and consider giving naloxone.</li> <li>Reassure patients taking long-term opioid therapy that tolerance to this side effect develops with regular daily opioid doses.</li> </ul>

Most patients experience sedation at the beginning of opioid therapy and whenever the opioid dose is increased significantly. *If undetected or left untreated, excessive sedation can progress to clinically significant respiratory depression.* Like most of the other opioid side effects, sedation and respiratory depression are dose related. Preventing clinically significant opioid-induced respiratory depression begins with administering the lowest effective opioid dose (multimodal analgesia with a nonopioid foundation), careful titration, and closely monitoring sedation and respiratory status throughout therapy. *Unless the patient is at the end of life, promptly reduce opioid dose or stop titration whenever increased sedation is detected to prevent respiratory depression.* In some patients (e.g., those with obstructive sleep apnea, pulmonary dysfunction, multiple comorbidities), mechanical monitoring such as capnography (to measure exhaled carbon dioxide) and pulse oximetry (to measure oxygen saturation) is needed.

Occasionally drugs that produce significant sedation are used to treat side effects and other conditions that accompany the pain experience. For example, *antianxiety agents* (anxiolytics) such as alprazolam (Xanax) and lorazepam (Ativan) are prescribed to reduce anxiety. Many of the drugs used to treat opioid side effects are sedating, such as the antihistamines (diphenhydramine) for pruritus and the antiemetics *promethazine* (Phenergan) and *hydroxyzine* (Vistaril) for nausea. It is important to recognize that administration of these drugs together has an additive sedating effect. If administered, closely monitor for sedation and assess respiratory status frequently.

To assess sedation, use a simple, easy-to-understand sedation scale developed for assessment of *unwanted* sedation that includes what should be done at each level of sedation. Table 4-8 presents a widely used sedation scale. The key to assessing sedation is to determine how easy it is to arouse the patient. Assess each person's response to the first dose of an opioid. If opioids are administered by bolus technique, assess sedation level and respiratory status at the opioid's peak time after each bolus.

**TABLE 4-8**

### Pasero Opioid-Induced Sedation Scale (POSS) With Interventions\*

<p>5 = Sleep, easy to arouse  <i>Acceptable; no action necessary; may increase opioid dose if needed.</i></p> <p>1 = Awake and alert  <i>Acceptable; no action necessary; may increase opioid dose if needed.</i></p> <p>2 = Slightly drowsy, easily aroused  <i>Acceptable; no action necessary; may increase opioid dose if needed.</i></p> <p>3 = Frequently drowsy, arousable, drifts off to sleep during conversation  <i>Unacceptable; monitor respiratory status and sedation level closely until sedation level is stable at less than 3 and respiratory status is satisfactory; decrease opioid dose 25% to 50%<sup>1</sup> or notify primary<sup>2</sup> or anesthesia provider for orders; consider administering a nonsedating, opioid-sparing nonopioid such as acetaminophen or a NSAID if not contraindicated; ask patient to take deep breaths every 15-30 minutes.</i></p> <p>4 = Somnolent; minimal or no response to verbal and physical stimulation  <i>Unacceptable; stop opioid; consider administering naloxone<sup>3,4</sup>; call Rapid Response Team (code blue); stay with patient, stimulate, and support respiration as indicated by patient status; notify primary<sup>2</sup> or anesthesia provider; monitor respiratory status and sedation level closely until sedation level is stable at less than 3 and respiratory status is satisfactory.</i></p>
--

\*Appropriate action is given in italics at each level of sedation.

<sup>1</sup>Opioid analgesic prescriptions or a hospital protocol should include the expectation that a nurse will decrease the opioid dose if a

patient is excessively sedated.

<sup>2</sup>For example, the physician, nurse practitioner, advanced practice nurse, or physician assistant responsible for the pain management prescription.

<sup>3</sup>For adults experiencing respiratory depression, administer dilute solution (0.4 mg of naloxone in 10 mL of normal saline) very slowly (0.5 mL over 2 minutes) while observing the patient's response (titrate to effect).

<sup>4</sup>Hospital protocols should include the expectation that a nurse will administer naloxone to any patient suspected of having life-threatening opioid-induced sedation and respiratory depression.

From Pasero, C., & McCaffery, M. (2011). *Pain assessment and pharmacologic management*. St. Louis: Mosby. Copyright 1994. Used with permission.

Respiratory depression is assessed on the basis of what is normal for a particular person and is usually described as clinically significant when there is a significant decrease in the rate, depth, and regularity of respirations from baseline, rather than just by a specific number of respirations per minute. Risk factors for opioid-induced respiratory depression include age 55 years or older, obesity, obstructive sleep apnea, and pre-existing pulmonary dysfunction or other comorbidities.

## Nursing Safety Priority QSEN

### Critical Rescue

Watch the rise and fall of the patient's chest to determine depth and regularity of respirations in addition to counting the respiratory rate for 60 seconds. For accuracy, respiratory assessment is done before arousing the sleeping patient. *If a patient is difficult to arouse, always stop the opioid, stay with the patient, continue vigorous attempts to arouse, and call for help!*

Listening to the sound of the patient's respiration is critical as well—*snoring indicates airway obstruction and must be attended to promptly* with repositioning, including placing the patient in a sitting position. Depending on severity, collaborate with the respiratory therapist for consultation and further evaluation.

## Nursing Safety Priority QSEN

### Drug Alert

Unless the patient is at the end of life, promptly administer the opioid antagonist naloxone (Narcan) IV to reverse clinically significant opioid-induced respiratory depression, usually when the respiratory rate is less than 8 breaths per minute or according to agency protocol. When giving the opioid antagonist naloxone, administer it slowly until the patient is more arousable and respirations increase to an acceptable rate. The desired outcome is to reverse just the sedative and respiratory depressant effects of the opioid but not the analgesic effects. Giving too much naloxone too fast not only can cause severe pain but also can lead to ventricular dysrhythmias, pulmonary edema, and even death. Continue to closely monitor the patient after giving naloxone because its duration is shorter than that of most opioids and respiratory depression can recur. Sometimes more than one dose of naloxone is needed.

## Considerations for Older Adults

### Patient-Centered Care QSEN

The incidence of opioid side effects in the older-adult population varies, depending on the side effect. Older adults are sensitive to the sedating effects of opioids, making them higher risk for respiratory depression than in younger adults.

## NCLEX Examination Challenge 4-4

### Physiological Integrity

A nursing technician reports that a client who is receiving IV PCA morphine is very drowsy,

unable to complete a sentence without falling asleep, and has a respiratory rate of 10 breaths per minute. What is the nurse's **priority** action at this time?

- A. Wake the client and raise the head of the bed to a 90-degree angle.
- B. Promptly call the primary health care provider to reduce the opioid dose.
- C. Document the assessment findings and take vital signs in an hour.
- D. Give naloxone according to agency protocol.

### Adjuvant Analgesics.

Adjuvant analgesics (sometimes called *co-analgesics*) are drugs that have a primary indication other than pain but are analgesic for some painful conditions (see [Table 4-6](#)). For example, the primary indication for antidepressants is depression, but some antidepressants help relieve some types of pain. The adjuvant analgesics are the largest and most diverse of the three analgesic groups. Drug selection and dosing are based on both experience and evidence-based practice guidelines.

### Anticonvulsants and Antidepressants.

*Anticonvulsants* (also called *antiepileptic drugs [AEDs]* when used for seizure management) produce analgesia by blocking sodium and calcium channels in the CNS, thereby diminishing the transmission of pain. The gabapentinoids *gabapentin (Neurontin)* and *pregabalin (Lyrica)* are recommended as first-line analgesics for persistent neuropathic pain. Gabapentin may also be administered as an epidural injection. These drugs are increasingly being added to postoperative treatment plans to address the neuropathic component of surgical pain. Primary side effects are sedation and dizziness, which are usually transient and most notable during the titration phase of treatment.

*Antidepressants* relieve pain on the descending modulatory pathway by blocking the body's reuptake of the inhibitory neurochemicals *norepinephrine* and *serotonin*. Antidepressant adjuvant analgesics are divided into two major groups: the *tricyclic antidepressants (TCAs)* and the newer *serotonin and norepinephrine reuptake inhibitors (SNRIs)*. Evidence-based guidelines recommend the TCAs *desipramine (Norpramin)* and *nortriptyline (Aventyl, Pamelor)* and the SNRIs *duloxetine (Cymbalta)* and *venlafaxine (Effexor)* as first-line options for neuropathic pain treatment (D'Arcy, 2014).

The most common side effects of the TCAs are dry mouth, sedation, dizziness, mental clouding, weight gain, and constipation. Orthostatic hypotension is a potentially serious TCA side effect, making TCAs a poor choice for older adults. The most serious adverse effect is cardiotoxicity, especially for patients with existing significant heart disease. The SNRIs have a more favorable side effect profile and are better tolerated than the TCAs. The most common SNRI side effects are nausea, headache, sedation, insomnia, weight gain, impaired memory, sweating, and tremors.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Older adults are often sensitive to the effects of the adjuvant analgesics that produce sedation and other CNS effects such as anticonvulsants and antidepressants. Therapy should be initiated with low doses, and titration should proceed slowly with systematic assessment of patient response. Caregivers in the home setting must be taught to take preventive measures to reduce the likelihood of falls and other accidents. A home safety assessment is highly recommended and can be arranged by social services before discharge.

### Local Anesthetics.

Local anesthetics relieve pain by blocking the generation and conduction of the nerve impulses necessary to transmit pain. The local anesthetic effect is dose related. A high enough dose of local anesthetic can produce complete anesthesia, and a low enough dose (subanesthetic) can produce analgesia.

Local anesthetics have a long history of safe and effective use for the treatment of all types of pain. Allergy to local anesthetics is rare, and side effects are dose-related. CNS signs of systemic toxicity include ringing in the ears, metallic taste, irritability, and seizures. Signs of cardiotoxicity include tingling and numbness, bradycardia, cardiac dysrhythmias, and cardiovascular collapse.

The *lidocaine patch 5%* (Lidoderm) is 10 cm by 14 cm and contains 700 mg of lidocaine. The patch is placed directly over or adjacent to the painful area for absorption into the tissues directly below. A major benefit of the drug is that it produces minimal systemic absorption and side effects. The patch is left in place for 12 hours and then removed for 12 hours (12-hours-on, 12-hours-off regimen). This application process is repeated as needed for continuous analgesia.

*Topical local anesthetic creams* for superficial procedures such as IV insertion include *EMLA* (eutectic mixture of local anesthetics) and *LMX-4*. *EMLA* contains a combination of lidocaine 2.5% and prilocaine 2.5% and is applied to intact skin for 60 to 120 minutes before the procedure. *LMX-4* contains 4% lidocaine and is applied 30 minutes before the procedure. *EMLA* has a longer duration of action (2 hours) than *LMX-4* (30 minutes) after cream removal. Topical local anesthetic side effects are rare and usually transient, with local skin reactions being the most common.

*Liposomal bupivacaine* (Exparel) for postoperative wound infiltration is a sustained-release formulation injected as a single dose into the surgical site by the surgeon. The sustained-release formulation has been shown to produce prolonged analgesia, which decreases the need for potent opioids.

For many years *regional anesthesia* has been administered by single-injection peripheral nerve blocks using a long-acting local anesthetic such as bupivacaine or ropivacaine to target a specific nerve or nerve plexus. This technique is highly effective in producing pain relief, but the effect is temporary (4-12 hours). *Continuous peripheral nerve block* (also called *perineural regional analgesia*) offers an alternative with longer-lasting analgesia. A continuous peripheral nerve block involves establishment by an anesthesia provider of an initial block followed by placement of a catheter through which an infusion of local anesthetic is administered continuously, with or without PCA capability. When PCA capability is added, this is referred to as patient-controlled regional analgesia (*PCRA*). Just as with epidural and intrathecal analgesia, nurses are responsible for monitoring and managing the therapy.

### Use of Placebos.

A **placebo** is defined as any medication or procedure, including surgery, which produces an effect in a patient because of its implicit or explicit intent, not because of its specific physical or chemical properties. A saline injection is one example of a placebo. Administration of a medication at a known subtherapeutic dose (e.g., 0.05 mg of morphine in an adult) is also considered a placebo.

Placebos are appropriately used as controls in research evaluating the effects of a new medication. Patients or volunteers who participate in placebo-controlled research must be able to give informed consent or have a guardian who can provide informed consent. Unfortunately occasionally placebos are used clinically in a deceitful manner and without informed consent. This is often done when the clinician does not accept the patient's report of pain. Pain relief resulting from a placebo, should it occur, is mistakenly believed to invalidate a patient's report of pain. This typically results in the patient being deprived of pain-relief measures despite research showing that many patients who have obvious physical stimuli for pain (e.g., abdominal surgery) report pain relief after placebo administration. The use of placebos has both ethical and legal implications, violates the nurse-patient relationship, and deprives patients of more appropriate methods of assessment or treatment.

## Nursing Safety Priority QSEN

### Drug Alert

Deceitful administration of a placebo violates informed consent law and jeopardizes the nurse-patient therapeutic relationship. Never administer a placebo to a patient. Promptly contact your nursing supervisor if you are given an order to do so.

### Nonpharmacologic Management.

Most people use self-management and nonpharmacologic strategies to deal with their health issues and promote well-being. Nonpharmacologic methods are appropriate alone for mild- and some moderate-intensity pain and should be used to complement, not replace, pharmacologic therapies for more severe pain. The effectiveness of nonpharmacologic methods can be unpredictable. Although not all have been shown to relieve pain, they offer many benefits to some patients of all ages. For example, research has shown that nonpharmacologic methods can facilitate relaxation and reduce anxiety, stress, and depression, which often accompany the pain experience (Bruckenthal, 2010; Wright, 2015). Many patients find that the use of nonpharmacologic methods helps them cope better and feel greater control over the pain experience. Nurses play an important role in providing and teaching their patients about nonpharmacologic strategies. Many of the methods are relatively easy for nurses to incorporate into daily clinical practice and may be used individually or in combination with other nonpharmacologic therapies.

Nonpharmacologic interventions are categorized as being body-based (physical) modalities; mind-body (cognitive-behavioral) methods; biologically based therapies; and energy therapies. Biologically based and energy therapies are used most often in the ambulatory care setting and are beyond the scope of this chapter. Body-based and mind-body therapies are often used by patients to self-manage their pain and enhance COMFORT.

### Physical Modalities.

In the acute care setting the physical modalities are used most often because of their ease in implementation and their role in postoperative recovery. In the ambulatory care setting or at home, sustained physical regimens such as regular low-impact exercise, in combination with analgesics and other interventions, improve outcomes for people with chronic pain. Many of the physical modalities require a prescription for use and reimbursement. Some require a trained expert to administer the technique (e.g., acupuncture). Among the most effective physical modalities used to manage or prevent pain are:

- Physical therapy
- Occupational therapy
- Aquatherapy
- Functional restoration (also has cognitive-behavioral components)
- Acupuncture
- Low-impact exercise programs such as slow walking and yoga

The physical modalities are often administered using an interprofessional collaborative approach. The assistance of physical and occupational therapists to help design and implement an individualized plan with realistic goal setting promotes effectiveness of these methods. Coordinate with the therapist to implement strategies to decrease pain before therapy sessions with the purpose of increasing function and preventing further deterioration. Teach patients to adhere to their drug regimen to maximize effectiveness of the treatment plan. Expected patient outcomes include an increase in the range of motion, strength, and function of the affected area and an improved quality of life. The occupational therapist may also help decrease pain by making one or more splints to rest severely inflamed joints.

A number of *cutaneous (skin) stimulation* strategies, which apply mild stimulation to the skin and subcutaneous tissues, have been used for many years to relieve pain. Examples of cutaneous stimulation include:

- Application of heat, cold, or pressure
- Therapeutic massage
- Vibration
- Transcutaneous electrical nerve stimulation (TENS)

Cold applications (ice) are especially helpful for inflamed areas such as for patients with rheumatoid arthritis and those who have knee surgery. Heat is appropriate when an increased blood flow is desired such as for patients with osteoarthritis pain. Paraffin dips for the hands can be helpful to increase movement for those patients as well. Warm showers and compresses that can be done at home are useful in reducing stiffness and promoting movement in patients with arthritis, especially after awakening. Local short-acting gels and creams may provide *cryotherapy (cold treatment)* to relieve muscle aches and pains. These products can often be bought over the counter

(OTC) (e.g., Bengay, Icy Hot). The effects of this type of application can last up to 2 hours. Discuss this information with the patient before the use of a cutaneous method.

The benefits of cutaneous stimulation are highly unpredictable and may vary from application to application. Despite these potential drawbacks, it can be effective in the management of both acute and chronic pain in selected patients. A major benefit of these methods is that many are easy for patients to self-administer.

TENS is used as an adjunctive treatment for pain. Although there are several types of **transcutaneous electrical nerve stimulation (TENS)** units, each involves the use of a battery-operated device capable of delivering small electrical currents through electrodes applied to the painful area (Fig. 4-5). The voltage or current is regulated by adjusting a dial to the point at which the patient perceives a prickly “pins-and-needles” SENSORY PERCEPTION rather than the pain. The current is adjusted based on the degree of desired relief. Newer, smaller, and less expensive TENS units are easy for anyone to apply and are often used at home or other community-based setting. The cost for a single unit usually ranges between \$100 to \$300 per unit, depending on the number of settings and leads.

**FIG. 4-5** TENS unit used in the home by the patient. (Courtesy Compass Health Brands, Middleburg Heights, Ohio.)

**Spinal cord stimulation** is an *invasive* stimulation technique that provides pain control by applying an electrical field over the spinal cord. A trial with a percutaneous epidural stimulator is conducted to determine whether permanent placement of the device is appropriate. If the trial is successful, electrodes are surgically placed in the epidural space and connected to an external or implanted programmable generator. The patient is taught to program and adjust the device to maximize comfort. Spinal cord stimulation can be extremely effective in selected patients but is reserved for intractable neuropathic pain syndromes that have been unresponsive to less invasive methods. Care for the patient with an implanted spinal cord stimulator is the same as that for anyone who has back surgery and epidural anesthesia.

#### **Cognitive-Behavioral Strategies.**

Cognitive-behavioral strategies, sometimes referred to as *cognitive-behavioral therapy (CBT)*, is facilitated by a licensed psychologist or other qualified mental health professional. These strategies are referred to by some psychologists as third-wave interventions or treatments (Morley & Williams, 2015). Cognitive-behavioral strategies are useful in reducing the patient's focus on pain but do not physiologically block pain transmission. Instead they help the patient adapt to challenges presented by the pain experience such as anxiety and distress (Morley & Williams, 2015). They are most appropriate as an adjunct to pharmacologic therapy.

Cognitive-behavioral methods range from simple (e.g., prayer, relaxation breathing, artwork, reading, and watching television) to more complex (e.g., mindfulness, meditation, guided imagery, hypnosis, biofeedback, and virtual reality). It is important to recognize that many of the methods require patient teaching and subsequent patient participation. Many patients use these methods as part of their self-management and COMFORT promotion. Not all patients are receptive to the use of these methods. To respect their wishes, values, and preferences as part of patient-centered care, do not insist that patients use any one particular method.

*Distraction* is probably the most commonly used cognitive-behavioral method. All of us use simple distraction measures in our daily life when we watch television or read a book. Nurses often observe that patients request less pain medication when family members are present and when talking on the phone. After visiting hours it is not unusual for patients to request pain medication because they are no longer distracted.

Visual distracters (e.g., looking at a picture, watching television, playing a video game) can divert the attention to something pleasant or interesting. Auditory distracters (e.g., listening to music or relaxation tapes) can have a calming effect. Changing the environment involves removing or reducing unpleasant stressors that can interfere with the patient's ability to cope with pain such as loud noise and bright lights.

*Imagery* is a more complex form of distraction in which the patient is encouraged to visualize or think about a pleasant or desirable feeling, sensation, or event. The person is encouraged to sustain a sequence of thoughts aimed at diverting attention away from the pain. Patients who practice this technique can mentally and vividly experience sights, sounds, smells, events, or other sensations. Intense concentration is required to visualize images; therefore patients must have fairly well-controlled pain to participate.

Before suggesting imagery, assess the patient's level of concentration to determine whether he or she can sustain a particular thought or thoughts for a desired time. The time interval for mental imagery can vary from 5 to 60 minutes. Behaviors that may be helpful in assessing whether a patient is a candidate for teaching guided imagery include that the patient is able to:

- Read and comprehend a newspaper or magazine article
- Tap to a rhythm or sing while listening to music
- Follow the logic and participate in sustained conversation
- Have an interest in environmental surroundings

When the patient has demonstrated ability to concentrate, help him or her identify a pleasant or favorable thought. Encourage the patient to focus on this thought to divert attention away from painful stimuli. CDs or other audio recordings, either commercial or created by the patient and family, may help form and maintain images. Internet-based technology can be used to help patients whose language differs from that of the facilitating practitioner (Morley & Williams, 2015; Wilson et al., 2015).

*Mindfulness* is similar to imagery except that the patient focuses on his or her actual environment rather than imagining it. For example, in the fall in an area where tree leaves change colors, the patient focuses on the beauty of the colors to appreciate them.

Patients may also use *relaxation techniques* to reduce anxiety, tension, and emotional stress, all of which can exacerbate pain. For example, before and during a painful procedure, patients can be reminded to breathe slowly, deeply, and rhythmically to divert attention and promote relaxation. Relaxation techniques can be both physical and psychological. Physical relaxation techniques include:

- Relaxation breathing
- Receiving a body massage, back rub, or warm bath
- Modifying the environment to reduce distractions
- Moving into a comfortable position

Psychological relaxation techniques include:

- Pleasant conversation
- Laughter and humor
- Music (provide a range of choices)
- Relaxation tapes

## Veterans' Health Considerations

### **Patient-Centered Care** QSEN

Veterans of recent wars with chronic pain can benefit from CBT strategies. A recent randomized clinical trial of veterans with chronic noncancer pain (musculoskeletal) evaluated a stepped-care pain management approach in a randomized clinical trial of 241 veterans (Bair et al., 2015). These young veterans were randomly assigned to one of two groups: 121 were assigned to the treatment group to receive 12 weeks of analgesia and self-management techniques followed by 12 weeks of CBT. The other 120 veterans were assigned to the usual chronic-care group for the same period of time. A 9-month follow-up showed that the treatment group receiving the drug therapy, self-management, and CBT had significantly lower pain-related disability, pain interference with daily life, and pain intensity when compared with the usual care group. All interventions were facilitated by nurse care managers.

This large study demonstrates the value of nonpharmacologic methods in managing pain in this vulnerable population. In addition, it shows that nurses play a key role in pain management as part of the interprofessional health care team.

## Clinical Judgment Challenge 4-1

### **Patient-Centered Care; Safety** QSEN

A 79-year-old woman had a femur fracture for which she had an open reduction with internal fixation (ORIF) surgery 6 weeks ago. She has been going to physical therapy (PT) but finds that her pain and anxiety prevent her from following the instructions provided by PT. She continues to take her oral opioid on an as-needed basis and believes that she cannot function without it. Her physical therapist suggests that she look into nonpharmacologic methods of pain management, including improving her spiritual health. Today she is having her follow-up with the orthopedic surgeon. She asks you, the office nurse, for advice on what she should do. The surgeon wants her to discontinue the opioid medication immediately.

1. Which questions will you ask the patient at this time in preparation for teaching?
2. What are the concerns about her current pain management regimen?
3. Which nonpharmacologic methods might benefit her? How will you determine if they are appropriate for her values and beliefs?
4. Who else on the interprofessional team might be able to help this patient and how?

## **Care Coordination and Transition Management**

Before patients are discharged from any health care setting, collaborate with members of the interprofessional health care team to optimize pain control. Before discharge or transfer ensure that the patient, especially one who will receive opioid analgesia, has appropriate prescriptions and enough doses to last at least until the first follow-up visit with the primary health care provider.

### **Home Care Management.**

Fatigue exacerbates pain. If physical modifications in the home (e.g., installing a downstairs bathroom) are unrealistic, suggest changes in schedules, role responsibilities, and daily routines to help prevent or reduce it.

At home, patients may require a referral for physical therapy, especially to start or continue exercise regimens, treatment with cutaneous stimulation, or heat or cold techniques. Patients may need a social worker to help them develop coping strategies or maintain adequate family dynamics. A hospice or palliative care referral (hospital- or community-based) can help maintain continuity of care in the management of terminally ill patients and those who require treatment of some chronic conditions.

Home infusion therapy programs provide a wide variety of services to patients who require technology-supported pain management at home. Many of these services depend on approval by the insurance carrier, usually before analgesic options are considered and therapy is started. Case managers can be helpful in answering insurance and other payment questions. Well-defined home agency practices and professional support at home are required if patients leave the hospital with infusion therapy for pain management. Often family members are taught to assume the responsibilities of home infusion therapy.

### **Self-Management Education.**

Teach the patient and family about analgesic regimens, including any technical skills needed to administer the analgesic; the purpose and action of various drugs, their side effects, and complications; and the importance of correct dosing and dosing intervals. Explain how to prevent or treat the constipation commonly associated with taking opioid analgesics and other medications. Inform the patient about what to do and who to contact if the prescribed management regimen is not controlling pain well or when side effects are intolerable or unmanageable.

Help the patient establish an analgesic regimen that does not interfere with sleep, rest, appetite, and level of physical mobility. Ensure that patients are aware of any dangers associated with driving or operating mechanical equipment. Tell patients to ask their primary health care provider when these activities are safe to perform. Older patients and others at risk for falls or accidents in the home setting may benefit from a home safety assessment.

In patients with pain from advanced cancer, all efforts are directed toward maximizing relief and symptom control at home and eliminating unnecessary hospital re-admissions. This may mean that the primary health care provider prescribes a flexible analgesic schedule that allows the patient to adjust analgesics according to the amount of pain. Teach the patient and family how to safely treat breakthrough pain and increase drug doses within the prescribed dosing guidelines. If painful ambulatory care treatments or procedures are expected, tell the patient how important it is to talk with his or her primary health care provider to determine available options for preventing procedural pain (e.g., premedicating).

Evaluate family support systems to help the patient adhere to and continue the proposed medical treatment and nursing plan of care. Inform and include family members in activities during and after hospitalization. To achieve a reasonable level of involvement in life activities for the patient, suggest ways to continue participation in household, social, sexual, and work-oriented activities after discharge. Help the patient identify important activities and plan to do them with adequate rest periods.

The patient with chronic pain needs continued support to cope with the anxiety, fear, and powerlessness that often accompany this type of pain. Help the patient and family or significant others identify coping strategies that have worked in the past. Outside support systems are often extremely helpful (e.g., organizations such as the *American Chronic Pain Association* [<http://theacpa.org>]). This organization has the "10-Step Program from Patient to Person," provides numerous educational materials, and facilitates the establishment of local support groups for people with chronic pain. Teach patients about the value of nonpharmacologic methods, including mindfulness as part of CBT.

### **Health Care Resources.**

Ask the prescriber for a home health care or hospice referral, as appropriate, for patients who require assistance or supervision with the pain management regimen at home. Important information to provide to the home health care nurse includes the patient's condition, level of sedation, weakness or fatigue, possible constipation or nutritional problem, sleep patterns, and functional status. Detailed information about the patient's current pain management regimen and how well it has been tolerated is essential. Use a structured procedure such as SBAR (situation, background, assessment, recommendations) to communicate this information.

In addition to explaining the patient's physical status to the home health care nurse, describe his or her level of anxiety and general expectations about pain after discharge. Close relationships and available support networks are important factors in providing ongoing support for effective pain intervention strategies.

Referral to an advanced practice nurse pain specialist, social worker, or psychologist may be necessary for some patients and families to provide continued support, reinforce instructions for

complex pharmacologic or nonpharmacologic strategies, or evaluate overall physical and emotional adaptation after discharge. When severe chronic or intractable pain exists, health care professionals should direct the patient and family to appropriate resources such as pain centers or primary health care providers who specialize in long-term pain management.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- The nurse is legally and ethically responsible for acting as an advocate for patients experiencing pain.
- Collaborate with the interprofessional team as needed to provide adequate analgesia and nonpharmacologic pain management methods. **QSEN: Teamwork and Collaboration**

### Health Promotion and Maintenance

- Provide information to the patient and family about nonpharmacologic physical modalities such as ice, heat, and the use of TENS units.
- Teach the value of cognitive-behavioral strategies such as mindfulness, distraction, and imagery. **QSEN: Evidence-Based Practice**
- Consider the special needs of older adults when assessing and managing their pain (see [Chart 4.1](#)). **QSEN: Patient-Centered Care**
- Recognize that many veterans of war have chronic pain caused by trauma; some are managed in Veterans Administration Medical Centers, whereas many others are homeless and do not receive care. **Health Care Disparities**
- Assess and meet the patient's need for pain management promptly to promote relief; be sensitive to the cultural preferences and values of the patient and family. **QSEN: Patient-Centered Care**

### Psychosocial Integrity

- Be aware that some nurses and physicians may have biases about pain assessment and management; be objective when caring for patients with pain. **Clinical Judgment**
- Assess and document the patient's and family's expectations for management of pain and promotion of COMFORT. **QSEN: Patient-Centered Care**
- Provide accurate information to patients who have misconceptions and misunderstandings about pain management to prevent these from becoming barriers. **Ethics**

### Physiological Integrity

- Remember that pain is what the patient says it is; self-report is always the most reliable indicator of pain. **QSEN: Patient-Centered Care**
- Perform and document a complete pain assessment, including duration, location, intensity, and quality of pain (see [Tables 4.4](#) and [4.5](#)). **QSEN: Informatics**
- Never use placebos to assess the presence of pain; their deceitful use is prohibited by state boards of nursing and numerous professional organizations. **Ethics**
- Factors that can affect pain and its management include age, gender, genetics, and culture. **QSEN: Patient-Centered Care**
- The two major types of pain are nociceptive pain and neuropathic pain. Pain is also classified by its duration as acute or chronic. Chronic pain is further classified as cancer or noncancer chronic pain (see [Tables 4-2](#) and [4-3](#)).
- Examples of causes for acute pain include surgery and trauma; arthritis and cancer are common causes of chronic pain.
- Multimodal analgesia is the evidence-based approach for the management of all types of pain. Multimodal analgesia combines different drugs with different underlying mechanisms of action

with the goal of producing better pain relief at lower analgesic doses than would be possible with any single analgesic alone. **QSEN: Evidence-Based Practice**

- Assess patients on acetaminophen for signs and symptoms of hepatotoxicity and nephrotoxicity; these adverse drug effects may occur when the medication is taken in higher than recommended daily doses. **QSEN: Safety**
- Recall that NSAIDs should be used with caution in older adults because of adverse effects such as GI toxicity, bleeding, and fluid retention, for which they are at higher risk than younger adults. **QSEN: Safety**
- The mu opioid agonists are first-line therapy for moderate-to-severe nociceptive pain. Morphine, fentanyl, hydromorphone, and oxycodone are the most commonly used mu opioid agonists and are available in a wide variety of formulations for administration by a variety of routes of administration for both acute and chronic pain. **QSEN: Evidence-Based Practice**
- Meperidine is not recommended for the treatment of any type of pain. Its toxic metabolite (normeperidine) can accumulate and cause confusion, seizures, and even death. **QSEN: Evidence-Based Practice**
- Physical dependence is a normal response that occurs with repeated administration of an opioid for several days. It is manifested by the occurrence of withdrawal symptoms when the opioid is suddenly stopped or rapidly reduced or an antagonist such as naloxone is given.
- Tolerance is a normal response that occurs with regular administration of an opioid and consists of a decrease in one or more effects of the opioid (e.g., decreased analgesia, sedation, or respiratory depression). It cannot be equated with addictive disease.
- Opioid addiction is a chronic neurologic and biologic disease. The development and characteristics of addiction are influenced by genetic, psychosocial, and environmental factors. It is characterized by one or more of these behaviors: impaired control over drug use, compulsive use, continued use despite harm, and craving.
- Use an equianalgesic chart (see [Table 4-6](#) when changing from one opioid or route of administration to another to help ensure that the patient receives about the same relief with the new opioid or route as with the previous. **QSEN: Evidence-Based Practice**
- Be aware of the advantages and disadvantages of the various routes of analgesic administration.
- Observe for and prevent common side effects of analgesics (see [Table 4-7](#)). Remember that the single most effective treatment of most side effects is to decrease the dose of the drug causing the side effect. **Clinical Judgment**
- Remember that sedation precedes opioid-induced respiratory depression; assess sedation using a sedation scale and decrease the opioid dose if excessive sedation is detected (see [Table 4-8](#)). **QSEN: Safety**
- The intraspinal routes include the intrathecal (also called *spinal*) and epidural routes of administration. Intrathecal analgesia is given by single injection of opioid (most often) into the subarachnoid space for acute pain or implanted device for chronic pain; epidural analgesia is given by single injection or continuous infusion with or without PCA capability for all types of pain and usually combines an opioid with a local anesthetic.
- Adjuvant analgesics are drugs that have a primary indication other than pain but are analgesic for some painful conditions. The most commonly used are antidepressants, anticonvulsants, and local anesthetics. Examples are listed in [Table 4-6](#).
- Nonpharmacologic therapies may be effective alone for mild pain and are used to complement, not replace, pharmacologic interventions for moderate-to-severe pain. **QSEN: Evidence-Based Practice**
- Pain can be managed in any setting, including the home. All patients require teaching with regard to their pain management regimen to ensure continuity of care. Patients or family members will require specialized training when infusion therapy is used in the home setting.
- Request referral or consultation with pain specialists and/or pain centers for patients with pain that cannot be managed with customary methods. **QSEN: Teamwork and Collaboration**

## CHAPTER 5

# Principles of Genetics and Genomics for Medical-Surgical Nursing

M. Linda Workman

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concept for this chapter is CELLULAR REGULATION.**

**The interrelated concepts for this chapter are:**

- ETHICS
- PATIENT-CENTERED CARE

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with the interprofessional team to coordinate high-quality PATIENT-CENTERED CARE to adults who may have a genetic-based increased risk for a health problem.
2. Ensure that appropriate informed consent procedures are followed before a patient undergoes genetic testing.

### Health Promotion and Maintenance

3. Teach the patient and family who are at increased genetic risk for a disease or disorder to implement environmental modifications to reduce the risk and to participate in early detection screening programs.
4. Identify resources for patients who have an increased genetic risk for a health problem.

### Psychosocial Integrity

5. Implement patient-centered nursing interventions to decrease the psychosocial impact caused by genetic assessment and genetic testing.

### Physiological Integrity

6. Apply knowledge of anatomy and physiology and genetic/genomic principles when performing an evidence-based genetic assessment and generating a three-generation pedigree for adult health problems that have a potential increased genetic risk.
7. Ensure the use of professional ETHICS when integrating genomic health into medical-surgical nursing practice.
8. Ensure PATIENT-CENTERED CARE by helping the patient and family who undergo genetic testing receive an appropriate level of genetic counseling to interpret the findings.

The purpose of genes and genetics is to provide cellular regulation in all cells throughout the lifespan. CELLULAR REGULATION are the processes that control cellular growth, replication, and differentiation to maintain homeostasis. Thus the turning on and off of specific genes determines everything that a cell does, including what it produces, how it functions within a group, when it reproduces, and even when it dies. [Chapter 2](#) provides a summary discussion of cellular regulation.

Genetic and genomic influences are part of today's comprehensive PATIENT-CENTERED CARE and form the basis for "precision health care" (precision medicine) in which therapies are tailored to an adult's specific genetic makeup. These influences have become especially important in determining the exact drug therapy for best patient responses. It is important for nurses to understand the

genetic basis of disease because most of the serious, common adult-onset disorders have a genetic component (Cheek and Howington, 2017; Paz De Jesus & Mitchel, 2016; Quigley, 2015).

Although the terms genetics and genomics often are used interchangeably, there are some differences. **Genetics** is concerned with the general mechanisms of heredity and the variation of inherited traits. Thus how genetic traits are transmitted from one generation to the next composes genetics. The definition of **genomics** is both broader and more specific, focusing on the *function* of all of the human DNA, including genes and noncoding DNA regions. Thus how a gene is expressed and its effects on CELLULAR REGULATION within a person or family constitute genomics.

Many adult-onset health problems have a genetic basis, meaning that variation of gene sequences and expression contributes to an adult's risk for disease development. Some of these health problems also demonstrate **heritability**, meaning that the risk for developing the disorder can be transmitted to one's children in a recognizable pattern. Some adult-onset disorders such as Huntington disease are unavoidable when a person inherits a specific genetic mutation that causes the disorder. For other health problems, the risk is increased but is not absolute, indicating a *predisposition* or *susceptibility* toward the problem when a specific genetic mutation is inherited, but such a disorder may never occur. For example, certain gene variations increase the risk for type 2 diabetes; however, the disease is more likely to develop only when the adult with the genetic variations has a sedentary lifestyle and is overweight. One outcome of genomic health care is to identify personal risk for disease development and help the adult reduce the risk by modifying his or her environment (Manuck & McCaffery, 2014).

Specific discoveries regarding each adult's genetic differences are being used to assess disease risk, enhance disease prevention strategies, and personalize disease management approaches (Bielinski et al., 2014). As a result, all health care professionals, including registered nurses, are expected to have at least a minimum knowledge of basic genetics to provide the best possible care for patients and families (Calzone et al., 2013). Table 5-1 lists selected genetic competencies important in medical-surgical nursing. Nurses are expected to know enough about basic genetics to recognize when a patient or family has a possible genetic risk for a health problem and to coordinate the attention of health care team members to ensure appropriate care.

## Genetic Biology Review

**Genes** are the coded instructions for the CELLULAR REGULATION of all the proteins the human body produces. For every hormone, enzyme, and other proteins the human body makes, it is the specific genes that tell each cell which protein to make, how to make it, when to make it, and how much to make. Think of each gene as a specific “recipe” for making a protein.

Every human somatic cell with a nucleus contains the entire set of human genes, known as the **genome**. The human genome contains between 20,000 and 25,000 genes. For example, all cells have the gene for insulin. However, the only cell type that allows the insulin gene to be **expressed** (turned on, activated) for CELLULAR REGULATION and make insulin is the beta cell of the pancreas. So although the insulin gene is present in skin cells, heart cells, brain cells, and other cells, only in the beta cells is this gene selectively expressed when insulin is needed.

Genes are composed of DNA, which is present as 46 separate large chunks within the nucleus (Fig. 5-1). During cell division each large chunk of DNA replicates and then organizes into a chromosome form to ensure precise delivery of the genetic information to each of the two new daughter cells. Thus DNA, chromosomes, and genes refer to different structures of the same materials.

**FIG. 5-1** The various forms of DNA from a loose double helix to coiled tightly into a chromosome. *bp*, Base pair.

Each chromosome has many genes within it. Humans have 23 pairs of chromosomes—46 individual chromosomes. The Y chromosome is small and has fewer than 100 genes. Larger chromosomes such as the number 1 chromosome contain thousands of genes.

One way to think of it is to consider all the DNA in the genome of any cell to be a giant “cookbook” containing all the recipes needed for total CELLULAR REGULATION to make all the proteins, hormones, enzymes, and other substances your body needs. The chromosome pairs are the different book chapters (so the human genome cookbook has 23 chapters), and the genes are the

individual recipes contained within the chapters.

There is a specific chromosome location (**locus**) for every gene. For example, the locus of the gene for blood type is on chromosome 9. The location and the exact DNA sequence for many, but not all, genes is now known.

## DNA

### DNA Structure

In humans DNA is a linear, double-stranded structure composed of multiple units of four different nitrogenous bases, each attached to a sugar molecule. The bases in each strand are linked together by phosphate groups. These two individual strands are held together loosely. This double-stranded DNA is arranged like a long set of railroad tracks. The “backbones” of the track are the two long steel rails. For DNA these backbones are the phosphate groups that hold the bases in place. The bases are the individual railroad ties. Think of each tie as having two pieces—one piece attached to the right rail and one piece attached to the left rail.

Fig. 5-2 shows a very small piece of double-stranded DNA on the left (containing only four base pairs) taken from the larger piece of DNA on the right. The phosphate groups that hold the nucleotides together as a strand are in the red box. The green box in the lower left section shows a whole nucleotide (a base with the sugar and the phosphate group) in place in the left DNA strand. The blue box in the middle of the two strands shows how the base from the left strand lines up with and pairs to a complementary base in the right strand.

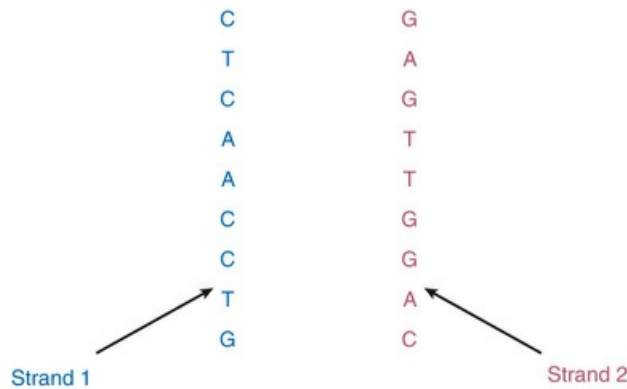

**FIG. 5-2** The structure of DNA. (Modified from Nussbaum, R., McInnes, R., & Willard, H. (2007). *Thompson & Thompson: Genetics in medicine* (7th ed.). Philadelphia: Saunders.)

*Bases* are the essential parts of DNA. Many trillions of bases in the DNA are found in the nucleus of just one cell. The four bases in DNA are adenine (A), guanine (G), cytosine (C), and thymine (T). Each base becomes a complete **nucleotide** when a five-sided sugar (known as a *deoxyribose sugar*) and a phosphate group are attached (see Fig. 5-2). Nucleotides form the DNA strands with the phosphate groups holding the bases in place.

*Base pairs* are the linked bases in the two opposite strands of DNA. The bases always link together across from each other in a very specific way. Thymine always forms a pair with adenine, and cytosine always forms a pair with guanine. Thus the bases of each pair are *complementary* to each other. Because these complementary base pairs in DNA are specific, if the base sequence of one strand of DNA is known, the opposite strand's sequence could be accurately predicted. For example, if the left section of DNA (strand 1 in Fig. 5-3) had the sequence C-T-C-A-A-C-C-T-G, the corresponding (complementary) right section (strand 2 in Fig. 5-3) of DNA would have the sequence G-A-G-T-T-G-G-A-C.

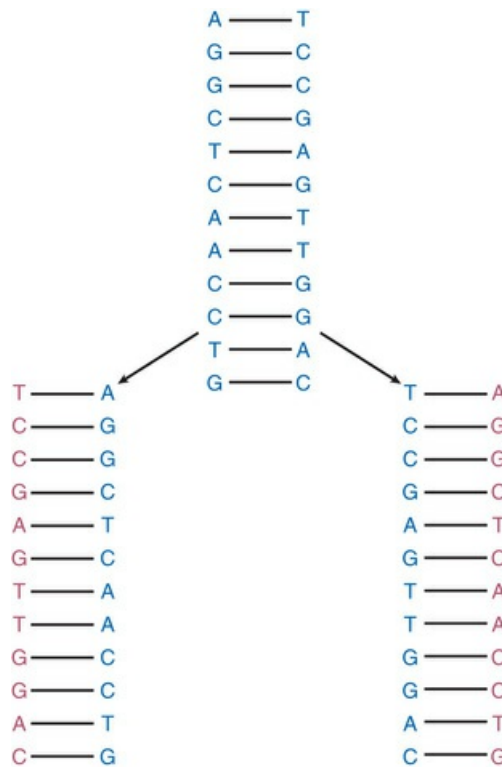

**FIG. 5-3** Complementary strands of DNA.

When the two strands of DNA are lined up properly, they twist into a loose helical shape (see Fig. 5-1). In this shape the DNA is so fine that it can be seen only with electron microscopes. Only when a cell undergoes mitosis does the DNA super-coil tightly into dense pieces called *chromosomes* (Fig. 5-1), which can be seen with standard microscopes.

### DNA Replication

DNA must reproduce itself (**replicate**) every time a cell divides (undergoes mitosis). The purpose of mitosis is for one cell to reproduce into two new daughter cells, each of which is identical to the parent cell that started mitosis. For each new cell to have exactly the right amount of DNA and genes, the DNA in the dividing cell must replicate exactly. This process involves having the double strands of DNA separate and then build two new strands that are perfectly complementary to the original strands (Fig. 5-4). The result is two sets of double-stranded DNA. At the time of actual cell division with the separation into two new cells, one set of DNA will move into one of the two new cells made during mitosis, and the second set will move into the other new cell. In this way every new cell ends up with exactly the right amount of DNA with all the genes for appropriate CELLULAR REGULATION.

**FIG. 5-4** DNA replication. *Blue type*, Original DNA; *red type*, newly replicated DNA.

## Chromosomes

As shown in Fig. 5-1, a chromosome is a specific large chunk of highly condensed double-stranded DNA, with each chunk containing billions of bases and hundreds (and sometimes thousands) of genes. Each chromosome forms and moves to the center of the cell that is about to divide. Just before the cell splits into two cells, each chromosome is pulled apart so half of each chromosome goes into one new cell and the other half goes into the other new cell. Thus chromosomes are temporary structures to ensure the precise delivery of DNA to the two new cells. Humans have 46 chromosomes divided into 23 pairs.

Some things about an adult can be known by examining his or her chromosomes, but limited information can be obtained by chromosomal analysis because each chromosome is composed of a large chunk of DNA. Only very large deletions, additions, or rearrangements of DNA show up at the level of the chromosome. Losses or gains of even tens of thousands of bases cannot be detected by chromosome analysis.

A **karyotype** is an organized arrangement of all of the chromosomes present in a cell during the metaphase section of mitosis (Fig. 5-5). A picture of the chromosomes is made. Chromosomes are first paired up and then arranged according to size (largest first) and centromere position. This gross organization of DNA can be used to determine missing or extra whole chromosomes and some large structural rearrangements. *A missing gene or a mutated gene would not show up at this level of analysis.* What can be learned about the adult from whom the karyotype in Fig. 5-7 was made is that she is human and **euploid** (has the correct number of chromosome pairs for the species). She is chromosomally “normal,” although she probably has some genes that are different (variant from or mutated) compared with the same gene in other people. If the karyotype is abnormal in any way (has more or less than the normal number or has broken chromosomes), the karyotype would be called **aneuploid**.

**FIG. 5-5** A karyotype of a chromosomally normal female. (The sex chromosomes are circled in red.)  
 (Modified from Jorde, L., Carey, J., Bamshad, M., & White, R. (2000). *Medical genetics* (2nd ed.). St. Louis: Mosby.)

**Autosomes** are the 22 pairs of human chromosomes (numbered 1 through 22) that do not code for the sexual differentiation of a human. **Sex chromosomes** are the pair of chromosomes that include the genes for the sexual differentiation of the human. Chromosomally normal males have an X and a Y as the sex chromosomes. Chromosomally normal females have two Xs (XX) as the sex chromosomes (see Fig. 5-5).

## Gene Structure and Function

A **gene** is a specific segment(s) of DNA that contains the code (recipe) for a specific protein (see Fig. 5-1) involved in CELLULAR REGULATION. Genes are the smallest functional unit of the DNA. Each chromosome is a large segment of DNA that contains hundreds of genes.

For many human traits, one gene controls the expression of that trait in any person. Such traits are known as *single gene traits* (*monogenic traits*). For each single gene we have two alleles. An **allele** (pronounced "ah-lee-el") is an alternate form (or variation) of a gene. For example, there is one gene for blood type but there are three possible gene alleles (A, B, and O). Each person has only two of the three specific gene alleles for blood type. One of these alleles is on one chromosome 9 of the pair; the other allele is located on the other number 9 chromosome. Because each person only has two number 9 chromosomes, he or she can have only two of the three possible alleles for blood type. One gene allele was inherited from the person's mother, and the other gene allele was inherited from the person's father. *Some traits have even more than three possible alleles, but each person has only two.* Which blood type-gene alleles are inherited from a person's parents determines which blood type he or she expresses.

If a person has inherited a blood-type A allele from his or her mother and a blood-type B allele from his or her father, he or she has the A and B alleles; the blood type expressed when the blood

bank determines type is type AB. Fig. 5-6 shows this concept. In Fig. 5-6 a woman is about to become pregnant with the help of a specific adult man. What are the possibilities for this baby to have a specific type of ear shape (pointy, rounded, square, triangular)? The gene for ear shape is trait 1, and it (for the purposes of this explanation) is on chromosome number 6.

**FIG. 5-6** Inheritance of four possible alleles for the single gene trait 1. (Any one person can have only two alleles for a single gene trait.)

Each of the father's sperm contains only one number 6 chromosome, and each of the mother's eggs contains only one number 6 chromosome (so when the sperm fertilizes the egg, the resulting person conceived will have only one pair of chromosome number 6 instead of two pairs of chromosome number 6).

Half the father's sperm have the 1a allele for ear shape, and the other half have allele 1b for ear shape. Half the mother's eggs have 1c for ear shape, and the other half have 1d. The baby can inherit only either a 1a or a 1b from the father, not both; and this same baby can inherit only a 1c or a 1d from the mother—again, not both. The lower part of Fig. 5-6 shows all the combinations possible for each ear shape gene alleles for any child these two adults have.

If a person has two identical alleles for a single gene trait, that person is said to be *homozygous* for that trait. Thus if a person has an A blood-type gene allele on one number 9 chromosome and an A blood-type gene allele on the other number 9 chromosome, he or she is homozygous for that trait and will express the A blood type.

If a person has two different alleles for a single gene trait, he or she is *heterozygous* for that trait. So if a person has an A blood-type gene allele on one number 9 chromosome and a B blood-type gene allele on the other number 9 chromosome, that person is heterozygous for that trait and will express the AB blood type. Because the A and B alleles are equally dominant (*co-dominant*), they will both be expressed in the actual blood type.

There are differences in expression of the alleles for a trait depending on whether an allele is dominant or recessive. If a person has an A blood-type gene allele on one number 9 chromosome and an O blood-type gene allele on the other number 9 chromosome, that person is heterozygous for that trait and expresses only the A blood type. Because the A allele is dominant and the O allele is recessive, they will not both be expressed in the actual blood type. Only the dominant allele is expressed, and the recessive allele is “silent.” More information about dominant, recessive, and co-dominant expression is presented later in the Patterns of Inheritance section.

## Phenotype

The **phenotype** of any gene for a person is which characteristic can actually be observed or, in some cases, determined by a laboratory test. For example, the person who has the AO gene alleles for blood type has the phenotype of type A blood. A person with curly hair has a curly-hair phenotype, regardless of whether he or she has two alleles for curly hair or one allele for curly hair and one allele for straight hair.

## Genotype

The **genotype** for a person's single gene trait is what the actual alleles are for that trait—not just what can be observed. A person with a phenotype of type A blood could have either an AA genotype or an AO genotype. The person who has type O blood would have an OO genotype. When a person has homozygous alleles for a trait, we would expect the genotype and phenotype to be the same. When a person has heterozygous alleles for a trait, the phenotype and the genotype are not always the same. *Recessive traits are expressed only when the person is homozygous for the alleles.* Thus for expressed recessive traits phenotype and genotype are the same. Dominant traits are expressed whether the person is homozygous for the gene alleles or heterozygous for the gene alleles. Thus for dominant traits phenotype and genotype can be the same but do not have to be the same.

## Gene Expression

Genes control CELLULAR REGULATION by coding for the making of a specific protein. For example, the hormone *insulin* is a protein. When an adult's blood glucose level starts to rise, the beta cells of the pancreas rapidly make insulin to maintain his or her blood glucose homeostasis.

To continue the cookbook analogy, each gene is the recipe needed to make a specific protein for CELLULAR REGULATION. All the hormones, enzymes, growth factors, and chemicals needed to keep an adult functioning are proteins. These proteins are *gene products* because they are produced when the right gene is *expressed*. Just a few examples of gene products are insulin, hemoglobin, erythropoietin, angiotensin, and estrogen.

## Protein Synthesis

**Protein synthesis** is the process by which genes are used to make the proteins needed for physiologic function and CELLULAR REGULATION. Proteins are made up of individual amino acids hooked together like beads on a string. There are 22 different amino acids. Every protein has a specific number of each of the amino acids and a specific order in which they are placed. *If even one amino acid is out of order or completely deleted from the sequence, the protein may be less functional or perhaps nonfunctional and unable to assist with cellular regulation.*

For example, the hormone *insulin* is a protein that contains 51 amino acids in a specific sequence. If some of the amino acids are missing or are in the wrong position, the protein made would be different from real insulin and could not reduce blood glucose levels. *Thus the actual order of the amino acids is critical for cellular regulation and the final function of any protein.*

Within the DNA there is a three-nucleotide (base) code for each amino acid. A gene for a specific protein contains all the amino acid codes in exactly the right order for that protein. For example, the final active form of the protein *insulin* has 51 amino acids. Thus the minimum number of bases needed in the gene for insulin would be 153 (three bases per amino acid × 51 amino acids). Fig. 5-7 shows an example of a short protein made up of only seven amino acids.

**FIG. 5-7** A sample protein composed of seven amino acids.

The key for making a functional protein is accurate placement of all the amino acids in the order specified by the gene. When problems exist in the base sequence of a gene, its expression may not result in a functional protein. In addition, the process of protein synthesis involves many steps. A problem at any step could cause failure to produce a functional protein.

## Mutations and Variations

Many human genes have been sequenced, meaning that their base sequence is known and so is the sequence of their amino acids in the expressed proteins. Most people have the same base sequence for a specific gene such as the gene for insulin. When this sequence is the most common one found in a large population of humans, it is referred to as the *wild-type* gene sequence. Think of the term wild-type as meaning “normal” or “expected.” When a person has a different sequence for a gene

compared with the known wild-type sequence, the gene has a variation or mutation. Mutations as small variations in gene sequences occur more often in very large genes, and the significance of some of these changes is not known. It is these variations in the sequences of some genes from the wild-type that are being examined more closely. Some variations can reduce the function of the protein produced, some can eliminate the function of the protein produced, and a few variations have been found that enhance the function of the produced protein compared with the function of the wild-type protein.

Mutations are DNA changes that are passed from one generation to another and thus are *inherited*. An inherited mutation does not have to mean that the mutation is passed from one human generation to another. It can mean that the mutation is passed from one *cell* generation to another and may affect only certain tissues within a person rather than be a problem within a family. Mutations that occur in general body cells (somatic cells) are known as *somatic mutations*. Because these mutations occur in a person's cells after conception, the adult cannot pass a somatic mutation on to his or her children. A possible outcome of somatic mutations is a loss of CELLULAR REGULATION with an increased risk for cancer in cells with such mutations.

When mutations occur in sex cells, they are called *germline mutations*. A germline mutation *can* be passed on to a person's children; and each of that child's cells, including his or her somatic cells and sex cells, will contain the mutated DNA.

When mutations resulting in sequence variation occur in a gene area of the DNA, the change can alter the expression of that gene, and an incorrect gene product (protein) might result. Mutations can have serious results, although some mutations may be beneficial. Gene mutations that increase the risk for a disorder are known as *susceptibility genes*. Gene mutations or variations that decrease the risk for a disorder are known as *protective* or *resistance genes*.

The gene sequences for most proteins are generally the same in all people. Sometimes a base in one person's gene for a specific protein is not the same as that in the wild-type. Either this difference can be a variation known as a *single nucleotide polymorphism*, or *SNP* ("snip"), or it can be a mutation. When a base difference allows the protein to be made but there are differences in how well the protein works, the difference is called a *gene variation* or a **polymorphism**. When a base difference causes a loss of protein function leading to impaired CELLULAR REGULATION, it is called a **mutation**.

Clinically many SNPs exist within different people in the genes of a large family of enzymes involved in drug metabolism. These enzymes are the cytochrome P-450 family, coded for by at least ten separate extremely large genes, with as many as 100 subsets of genes. Cytochrome p is abbreviated as CYP (pronounced "sip"). SNPs in these genes can make the resulting enzyme less active than normal or more active than normal. Either way, a change in activity of any one of these enzymes can affect a person's response to drug therapy. For example, the drug warfarin (Coumadin) is metabolized for elimination primarily by two enzymes from this system, CYP2C9 and CYP2C19. About 17% to 37% of white adults have an SNP variation in CYP2CP that slows the metabolism of warfarin. This means that warfarin remains in the patient's system longer, greatly increasing the risk for bleeding and other side effects. For adults who have this gene mutation, warfarin doses need to be much lower than those for the general population (Cheek et al., 2015).

Another example of changes in patient responses to drugs is codeine, an opioid analgesic. When taken orally or given parenterally, codeine is an inactive prodrug that must be metabolized by the CYP2D6 enzyme in the tissues to morphine, which is the active drug. Patients who have nonfunctional or poorly functional CYP2D6 because of a gene variation obtain no pain relief from codeine but do obtain pain relief from morphine (Kelly, 2013).

## NCLEX Examination Challenge 5-1

### Safe and Effective Care Environment

What therapy outcome does the nurse expect for a client receiving warfarin therapy who has a variant of the CYP2C9 that makes the enzyme have **greater** activity?

- A. Having an increased risk for drug side effects
- B. Having excessive bleeding from minor trauma
- C. Requiring a higher dose to achieve the desired anticoagulation level

D. Requiring a lower dose to achieve the desired anticoagulation level

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Many adults of Ethiopian heritage have a variation of the CYP2D6 gene that results in much higher levels of the enzyme produced and are known as “ultrametabolizers.” This enzyme deactivates and helps eliminate many drugs, including metoprolol, which is often used to control blood pressure. An adult who ultrametabolizes this drug does not achieve a high enough blood level of the drug for it to be effective. They eliminate the drug too quickly. Thus any adult of Ethiopian heritage who needs antihypertensive therapy is not likely to respond to metoprolol or any other beta blockers. When patients do not respond to beta-blocker therapy as expected, be sure to ask about their cultural and ethnic heritage.

The most devastating gene mutations are the ones that change the amino acid codes so a proper protein is not made or does not function at all. Other changes may impair CELLULAR REGULATION by altering how often or how well a group of cells divides. Gene mutations or variations may cause one adult to have a greater-than-normal risk for developing a disease. A different variation in the same gene may cause another adult to have a smaller-than-normal risk for developing the same disease.

## Microbiome

A current issue in precision health care and genomics is the microbiome. The **microbiome** for an adult is genomes of all the microorganisms that coexist in and on him or her and can affect CELLULAR REGULATION (Abbas et al., 2015). This includes the organisms that live in the mouth, the rest of the GI tract, the nose and sinuses, the vagina, and on the skin. The number of microbial cells in the body outnumber human cells by about ten to one. Most of these organisms are part of our “normal flora,” which differ somewhat from person to person. These organisms are mostly nonpathogenic (non-disease causing) when they remain confined to the expected area. However, when they manage to escape their normal human habitat and move elsewhere, they may be pathogenic in the new environment. For example, when gut organisms get into the urinary tract or the blood, serious infections can occur.

Adults start acquiring their microbiomes from birth, and their specific microbiome profiles change almost daily over time. The interaction between an adult and his or her microbiome is complex and represents all the lifelong experiences of the foods eaten, the drugs taken, and the touching of other people and animals, along with the specific human genes inherited. To a large extent an adult's microbiome is protective in nature and is important for good health such as helping with food digestion and keeping some pathogenic organisms in check (Abbas et al., 2015). Recent discoveries indicate that the types of gut organisms an adult has can even change how well he or she responds to immunotherapy for cancer.

When the types of organisms that compose the microbiome in an area change, health can suffer. For example, when natural “gut” organisms are reduced or eliminated by antibiotic therapy, *Clostridium difficile* (C. diff) can overgrow and cause chronic severe, bloody diarrhea. A very successful therapy for this problem is the reconstitution of the “healthy” microbiome through fecal transplantation or transfer from one person to another.

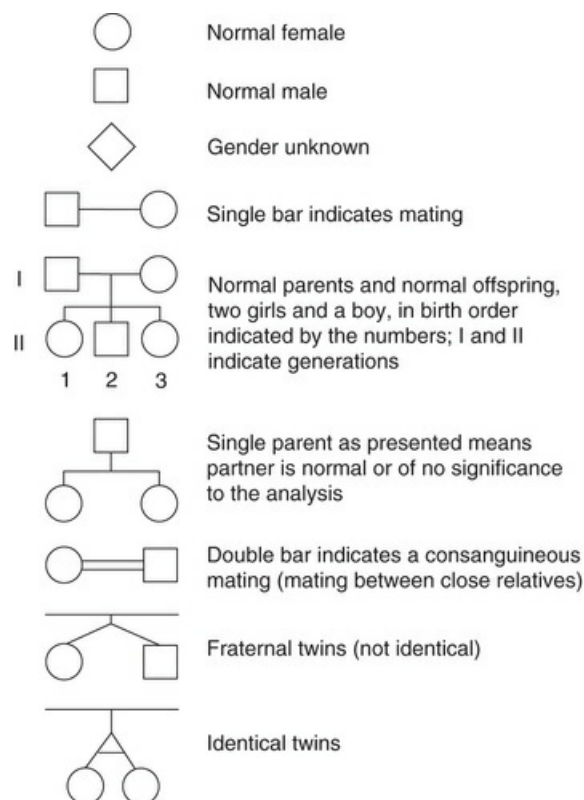

## Patterns of Inheritance

For every single gene trait, a person inherits one allele for that gene from his or her mother and one allele from his or her father. How these traits are expressed depends on whether one or both alleles are “dominant” or “recessive.” Expression also depends on whether the gene for the trait is located on an autosome or on a sex chromosome.

It is possible to determine how the gene for a specific trait is passed from one human generation to the next (*transmitted*). By looking at how that trait is expressed through several generations of a family, patterns emerge that indicate whether the gene for the trait is dominant or recessive and whether it is located on an autosomal chromosome or on one of the sex chromosomes. This information can be determined through *pedigree analysis*. Determining inheritance patterns for a specific trait makes it possible to predict the relative risk for any one person to have a trait or transmit that trait to his or her children.

## Pedigree

A **pedigree** is a graph of a family history for a specific trait or health problem over several generations. Its use by nurses is important for assessing certain PATIENT-CENTERED CARE needs (Lough & Seidel, 2015). Fig. 5-8 shows common symbols used when creating a pedigree. Fig. 5-9 shows a typical three-generation pedigree. Although the term *pedigree* is the correct genetic term, it can offend some patients. Use the term *family tree* in place of pedigree when talking with patients. Construct a pedigree that includes at least three generations when taking the family history. When analyzing a pedigree, note the answers to these:

**FIG. 5-8** Standard pedigree symbols. (Modified from Jorde, L., Carey, J., & Bamshad, M. (2010). *Medical genetics* (4th ed.). St. Louis: Mosby.)

**FIG. 5-9** A three-generation pedigree showing an autosomal dominant pattern of inheritance.

- Is any pattern of inheritance recognized, or does the trait appear sporadic?
- Is the trait expressed equally among male and female family members or unequally?
- Is the trait present in every generation, or does it skip one or more generations?
- Do only affected adults have children who are affected with the trait, or do unaffected adults also have children who express the trait?

The four types of inheritance patterns associated with single gene—controlled traits are autosomal dominant, autosomal recessive, sex-linked dominant, and sex-linked recessive. Each inheritance pattern has specific defining criteria. Table 5-2 lists the patterns of inheritance for some disorders that occur in adults or may be identified in children who live to adulthood.

**TABLE 5-2**  
**Patterns of Inheritance for Genetic Disorders Among Adults**

PATTERN OF INHERITANCE	DISORDER
Autosomal dominant	Breast cancer* (mutation of <i>BRCA1</i> or <i>BRCA2</i> genes) Diabetes mellitus type 2* Familial adenomatous polyposis Familial melanoma Familial hypercholesterolemia Hereditary nonpolyposis colon cancer (HNPCC) Huntington disease Long QT syndrome and sudden cardiac death Malignant hyperthermia (MH) Marfan syndrome Myotonic dystrophy Neurofibromatosis (types 1 and 2) Ovarian cancer* (mutation of <i>BRCA1</i> genes) Polycystic kidney disease† (types 1 and 2) Retinitis pigmentosa† von Willebrand's disease
Autosomal recessive	Albinism Alpha <sub>1</sub> -antitrypsin deficiency Beta thalassemia Bloom syndrome Cystic fibrosis Hereditary hemochromatosis Sickle cell disease Xeroderma pigmentosum
Sex-linked recessive	Glucose-6-phosphate dehydrogenase deficiency Hemophilia Red-green color blindness
Complex disorders/familial clustering	Alzheimer's disease Autoimmune disorders Bipolar disorder Parkinson disease Schizophrenia Hypertension Rheumatoid arthritis

\*Some disorders have both a genetic and nongenetic form.

†Some disorders have more than one genetic form and can also be autosomal recessive.

## Autosomal Dominant Pattern of Inheritance

Autosomal dominant (AD) single gene traits require that the gene alleles controlling the trait be located on an autosomal chromosome. A dominant gene allele is usually expressed, even when only one allele of the pair is dominant. Other criteria for AD inheritance include:

- The trait appears in every generation with no skipping.
- The risk for an affected adult to pass the trait to a child is 50% with each pregnancy.
- Unaffected adults do not have affected children; therefore their risk is essentially 0%.
- The trait is found about equally in males and females.

An example of an AD trait is blood type A. If a person is homozygous for the blood-type A allele, he or she will express type A blood (with genotype being identical to the phenotype). If a person is

heterozygous for the blood-type A allele with the other allele being type O (which is a recessive trait), he or she will also express type A blood. However, in this case the phenotype is **not** identical to the genotype. *When a dominant allele is paired with a recessive allele, only the dominant allele is expressed.* The blood-type B allele is a dominant allele. When a B allele is paired with an O allele, B blood type is expressed. However, when a person has one blood-type A allele and a blood-type B allele, both alleles are expressed because they are equally dominant (co-dominant), and the person has type AB blood.

Some health problems inherited as autosomal dominant (AD) single gene traits are not apparent at birth but develop as the person ages (see Table 5-2). Two factors that affect the expression of some AD single gene traits are penetrance and expressivity.

### Penetrance

**Penetrance** is how often or how well, within a population, a gene is expressed when it is present. Some genes are more penetrant than others. For example, the gene for Huntington disease (HD) has an autosomal dominant pattern of transmission. This gene is “highly penetrant” (sometimes called *fully penetrant*). This means that, if a person has the HD gene allele, his or her risk for expressing the gene and developing the disease is about 99.99%. Therefore a person who has one HD allele is at high risk for developing HD.

Some dominant gene alleles have “reduced” penetrance. So a person who has the gene mutation has a lower risk for this gene being expressed and actually developing the disorder.

Penetrance has been calculated by examining a population of people known to have the gene mutation and assessing the percentage that go on to express the gene by developing the disorder. For example, the *BRCA2* gene mutation increases a person's risk for breast cancer. This gene is not fully penetrant; so some women (and men) who have the gene do not develop breast cancer. The penetrance rate for this gene mutation is calculated to be between 60% and 80%, meaning that an adult who has the gene mutation has a 60% to 80% risk for developing breast cancer. Although this risk is far higher than among adults who do not have the mutated gene, the risk is not 100%. Having the gene mutation does not absolutely predict that the adult will develop breast cancer — just that the risk is high. However, the adult with the mutation can pass on this genetic mutation to his or her children, who will then have an increased risk for breast cancer development.

### Expressivity

**Expressivity** is the degree of expression a person has when a dominant gene is present. So it is a personal issue, not a population issue. The gene is *always* expressed, but some people have more severe problems than other people. For example, the gene mutation for one form of neurofibromatosis (NF1) is dominant. Some people with this gene mutation have only a few light brown skin tone areas known as *café au lait spots*. Other people with the same gene mutation develop hundreds of tumors (neurofibromas) that protrude through the skin. Expressivity accounts for some variation in genetic disease severity.

## Autosomal Recessive Pattern of Inheritance

Autosomal recessive (AR) single gene traits require that the gene controlling the trait be located on an autosomal chromosome. Normally the trait can be expressed *only* when both alleles are present. Table 5-2 lists some AR adult disorders. Fig. 5-10 shows a typical pedigree for an AR disorder. Criteria for AR patterns of inheritance include:

FIG. 5-10 A typical pedigree showing an autosomal recessive pattern of inheritance.

- The trait may not appear in all generations of any one branch of a family.
- The trait often first appears only in siblings rather than in parents and children.
- About 25% of a family will be affected and express the trait.
- The children of two affected parents will *always* be affected (risk is 100%).
- Unaffected adults who are carriers (heterozygous for the trait) and do not express the trait themselves *can* transmit the trait to their children if their partner either is also a carrier or is affected.
- The trait is found about equally in male and female members of the same family.

An example of an AR trait is type O blood. The blood-type O allele is recessive, and both alleles must be type O (homozygous) for the person to express type O blood. If only one allele is a type O allele and the other allele is either type A or type B, the dominant allele will be expressed, and the O allele, although present, is not expressed. For AR single gene traits, phenotype and genotype are always the same.

An adult who has one mutated allele for a recessive genetic disorder is a **carrier**. A carrier, even though he or she may have one mutated allele, may not have any signs or symptoms of the disorder but can pass this mutated allele on to his or her children. For some autosomal recessive disorders, a carrier may have mild symptoms. One example is sickle cell trait. A patient with two sickle cell alleles has the disease and many associated health problems. A carrier with one sickle cell allele (has “sickle cell trait”) may be healthy most of the time and have symptoms only under conditions of severe hypoxia.

## Sex-Linked Recessive Pattern of Inheritance

Some genes are present only on the sex chromosomes. The Y chromosome has only a few genes that are not also present on the X chromosome. These genes are important for male sexual development. The X chromosome has many single genes that are not present on the Y or elsewhere in the genome. Some of these genes are specific for female sexual development, but there are also several hundred genes on the X chromosome that code for other functions. Few disorders have X-linked dominant expression and are not discussed in this chapter.

Because the number of X chromosomes in males and females is not the same (1:2), the number of X-linked chromosome genes in the two genders is also unequal. Males have only one X chromosome. As a result, X-linked recessive genes have dominant expression in males and recessive expression in females. This difference in expression is because males do not have a second X chromosome to balance the presence of a recessive gene on the first X chromosome.

Sex-linked (X-linked) recessive single gene traits require that the gene allele be present on both of the X chromosomes for the trait to be expressed in females (homozygous) and on only one X chromosome for the trait to be expressed in males. Fig. 5-11 shows a typical pedigree for a sex-linked recessive disorder. Features of a sex-linked recessive pattern of inheritance are:

**FIG. 5-11** A typical pedigree showing a sex-linked (X-linked) recessive pattern of inheritance.

- The incidence of the trait is much higher among males in a family than among females.
- The trait cannot be passed down (transmitted) from father to son.

- Transmission of the trait is from father to all daughters (who will be carriers).
- Female carriers have a 50% risk (with each pregnancy) of passing the gene to their children.

## Complex Inheritance and Familial Clustering

Some health problems appear in families at a rate higher than normal and greater than can be accounted for by chance alone; however, no specific pattern occurs within a family. Although clusters suggest a genetic influence, it is likely that additional factors such as gender and the environment also influence disease development or severity. Such disorders include Alzheimer's disease, type 1 diabetes, and many others. These disorders are often called *complex* and *multifactorial*, because, although an increased genetic risk may be present, the risk is changed by diet, lifestyle, exposure to toxins, infectious agents, and other factors.

### NCLEX Examination Challenge 5-2

#### Health Promotion and Maintenance

Which type pattern of inheritance does the nurse determine is probably present when reviewing the pedigree of a client diagnosed with a health problem in which the problem is present in both males and females, unaffected parents have affected children, and the problem appears mostly in siblings in about 25% of the three familial generations?

- A. Autosomal dominant
- B. Autosomal recessive
- C. Sex-linked recessive
- D. Familial clustering

# Genetic Testing

## Purpose of Genetic Testing

Many adults are eager to have genetic testing but also are fearful of it. The lay public often believe that a single genetic test can “tell everything about you.” Although genetic testing has the potential to be that informative, this is not currently how testing is conducted. *It is important to remember that no single adult is genetically perfect.*

Genetic testing can be performed with many different techniques. Some genetic tests are specific for a disorder. Others may show a gene variation, but the significance of the variation may not be known. Unexpected information can be found during genetic testing. Some ordinary tests such as blood typing and tissue typing provide genetic information. Tests that measure the amount of an enzyme or protein also provide genetic information.

Testing for the purpose of assessing genetic information can be performed at many levels. Cellular or biochemical tests provide information about gene products made by a cell, tissue, or organ. Chromosomes and chromosome segments can be assessed for missing, extra, broken, or rearranged chromosomes. The sequence of a gene can be examined to determine variation or mutation. At present not all genes can be analyzed, and the analysis of even one gene may be limited by expense and availability. Specific base pairs can be evaluated for mutations (Conley et al., 2013). Many tests are expensive, and the results may not be conclusive (Fisco et al., 2015). Table 5-3 lists purposes of genetic testing for adults.

**TABLE 5-3**  
**Purposes of Genetic Testing for Adults**

PURPOSE/TYPE	DEFINITION
Carrier testing	Determining whether a patient without symptoms has an allele for a recessive disorder that could be transmitted to his or her children. Disorders for which carrier testing is common include sickle cell disease, hemophilia, hereditary hemochromatosis, cystic fibrosis, beta thalassemia, and Tay-Sachs disease.
Diagnostic testing	Determining whether a patient has or does not have a mutation that increases the risk for a specific disorder.
Symptomatic	Patient has symptoms; test results confirm a diagnosis.
Presymptomatic	Patient has no symptoms but is at high risk for inheriting a specific genetic disorder for which there is no known prevention or treatment. A disorder for which presymptomatic testing is commonly performed is Huntington disease.
Predisposition	Family history or genetic testing indicates that risk is high for a known genetic disorder. The patient does not have any symptoms but wants to know whether he or she has the specific mutation and what the chances are that it will be expressed. Disorders for which predisposition testing is often performed include hereditary breast/ovarian cancer and hereditary colorectal cancers. The advantage of predisposition testing is that the patient can then engage in heightened screening activities or medical and surgical interventions that reduce risk.

## Benefits and Risks of Genetic Testing

Genetic testing is different from any other type of testing. Informed consent is required before genetic testing is performed. The adult tested is the one who gives consent, even though genetic testing *always* gives information about family members—not just the patient (Badzek et al., 2013). Thus genetic testing is a unique and personal aspect of PATIENT-CENTERED CARE.

*Benefits* of genetic testing include the ability to confirm a diagnosis or to test adults who are at risk for a health problem but do not have any symptoms (presymptomatic testing). The information can help an adult, family, and their primary health care provider develop a specific plan for care or provide early detection (Fisco et al., 2015). For example, in the case of a strong genetic predisposition for colon cancer, identifying a patient before symptoms appear allows interventions to prevent the disease or to diagnosis it earlier, when cure is more likely.

*Risks* are associated with genetic testing that are not associated with other types of tests. Genetic testing results do not change. Thus a positive test result cannot be “taken back.” Other risks may include psychological or social risks, as well as a risk for family disruption. Often genetic tests are expensive and may not be covered by insurance. Some genetic tests have limited value for predicting future risk. Testing may identify a patient at great risk for the future development of a serious health problem that cannot be prevented or managed. Such a disorder is Huntington disease (HD), which currently has no treatment. Knowing positive test results in this case can lead to depression, blame, and guilt.

Another risk of genetic testing is that positive results may be used to discriminate against an adult or a family. Some protection is in place to prevent health insurance companies from failing to insure a person or dropping the coverage of a person who is at high risk for developing a serious

illness (e.g., breast or ovarian cancer). However, there are no protections against rate hikes or exclusions of specific treatments. Patients often fear workplace and personal discrimination if positive test results become known. This problem is less common since the 2008 passage of federal legislation in the Genetic Information and Nondiscrimination Act (GINA), which provides federal protection against employment and insurance discrimination.

## Genetic Counseling

Genetic testing is not a standard test that any adult should have performed without knowing the benefits and risks. Counseling patients before, during, and after testing is critical and required by the professional ETHICS governing genetic medicine. Entire families may be a part of the genetic evaluation and follow-up. For example, a 45-year-old woman has breast cancer. In her family her mother, grandmother, brother, and one sister have all had breast cancer. Genetic testing indicates that she has a *BRCA1* gene mutation. This woman's older daughter wonders whether she has a gene mutation for breast cancer and asks to be tested. When she and her younger sister are tested, the older daughter does not have the mutation, but the younger sister does. Even a negative test result requires PATIENT-CENTERED CARE considerations.

Genetic counseling is a process—not a single session or a single recommendation. This process should begin when the patient or family is first identified as potentially having a genetic problem. The process continues through actual testing if the decision to test is made, and it continues through interpretation of results and follow-up. [Chart 5-1](#) lists the steps in the process.

### Chart 5-1

## Best Practice for Patient Safety & Quality Care QSEN

### Steps for Genetic Testing and Counseling

#### Pretesting Assessment and Patient Education (May Take Multiple Sessions)

- Determining patient understanding and why testing or counseling is being sought
- Determining whether testing is reasonable (considering cost of the test, specificity, probable risk, accuracy of testing)
- Establishing a trusting professional relationship
- Ensuring privacy and confidentiality
- Reviewing informed consent procedures
- Assessing the patient's ability to communicate accurately (including language issues, cognitive function, sensory perception)
- Assessing the patient's psychosocial status and availability of social support
- Taking a detailed patient health history (including drugs, diet, exercise, hormonal history, lifestyle issues)
- Obtaining physical assessment data relevant to the at-risk disorder
- Taking a detailed family history and constructing a three-generation pedigree (minimum)
- Obtaining and verifying information obtained from:
  - Patient
  - Family members

- Medical records
- Pathology reports
- Death certificates
- Interpreting the family history
- Discussing the consequences of testing
- Discussing patient rights and obligations regarding disclosure of information
- Discussing testing options
- Assessing to determine whether coercion is occurring
- Obtaining material to be tested (usually blood)

### Test Result Presentation

- Re-assessing the patient's wish to know or not know the test results
- Respecting the patient's decision to not know the test results
- Ensuring privacy and confidentiality
- Presenting the test results
- Interpreting the test results
- Assessing the patient's perception of the test results

### Follow-Up

- Supporting the patient's decision to disclose or not disclose the information to other family members
- Discussing the potential risks for other family members
- Ensuring privacy and confidentiality
- Addressing the patient's concerns
- Discussing prevention, early detection, and treatment options
- Discussing family concerns
- Addressing psychosocial issues
- Discussing available resources for information, support, and further counseling
- Providing summary of results and consultation to the patient

Adapted from Beery, T., & Workman, M. L. (2012). *Genetics and genomics in nursing and health care*. Philadelphia: F.A. Davis.

As a nurse and patient advocate providing PATIENT-CENTERED CARE, it is your professional duty to determine whether the patient understands the consequences of testing. Often a patient may request genetic testing even when there is no indication of an increased risk for a genetic disorder. Counseling and evaluation can help patients understand whether any useful information could be

obtained from testing.

Counseling should be a collaborative effort performed by an interprofessional team with members who have defined expertise in interpretation of genetic testing results. Such professionals include advanced practice nurses with specialization in genetics, certified genetic counselors, clinical geneticists, and medical geneticists. Each profession has a different level of preparation in genetics and different skills or roles in the counseling process. For example, an advanced practice genetic nurse may counsel a patient about the Huntington disease gene mutation because this test is not ambiguous and the gene is highly penetrant. When a genetic test shows a variation or mutation in an unusual gene region or when penetrance is reduced, the patient may best be served by counseling from a certified genetic counselor or a clinical or medical geneticist.

No matter which professional is involved in genetic counseling, a key feature of this counseling is to be “nondirective” in ensuring PATIENT-CENTERED CARE. When using a nondirective approach, the counselor provides as much information as possible about the risks and benefits but does not influence the patient's decision to test or not to test. Once the patient has made the decision, the counselor supports the patient and the decision.

## Ethical Issues

ETHICS and ethical issues are involved at every level of genetic testing. Some of the most important issues focus on the patient's right to know versus the right to not know his or her gene status, confidentiality, coercion, and sharing of information.

*The right to know genetic risk versus the right to not know* is the individual patient's choice. Sometimes a patient's right to know has an impact on the right of another family member to not know.

*Confidentiality* is crucial to genetic counseling. *The results of a genetic test must remain confidential to the patient. The results cannot be given to a family member, other primary health care provider, or insurance carrier without the patient's permission.*

*Coercion* is possible by other family members and health care professionals. *The final decision to have genetic testing or not to have genetic testing rests with the patient.* Other people may believe it is important for the patient to have the test; however, the patient must make the decision without such pressures. As a patient advocate ensuring PATIENT-CENTERED CARE, professional ETHICS require you to assess whether the patient is freely making the decision to have genetic testing or whether someone else is urging him or her to test. This important issue can be difficult to assess. Ask the patient who in the family wants to know the results of testing.

*Sharing test result information*, negative or positive, can be stressful. The patient makes the final decision whether to share the information with family members. Some patients choose not to share this information, even when other family members may also be at risk. This can be difficult for the health care provider who knows that the patient has a positive test result for a serious inherited condition and that the patient chooses not to tell other family members who may be at risk (Berkman & Hull, 2014). For example, hereditary nonpolyposis colon cancer (HNPCC) has an autosomal dominant inheritance pattern, and each child of the patient has a 50% risk for having the gene. If the patient chooses not to tell his or her grown children, they then do not have the opportunity for increased screening to find the cancer at an early stage when cure is possible. Ethical dilemmas arise when the primary health care provider wants to inform the children of their risk.

## The Role of the Medical-Surgical Nurse in Genetic Counseling

Medical-surgical nurses providing **PATIENT-CENTERED CARE** help patients during the assessing, testing, and counseling processes, although they do not provide in-depth genetic counseling. Patients often feel most comfortable sharing information with nurses and asking nurses to clarify information.

Nurses may be the first health care professionals to identify a patient at specific genetic risk. Some of the “red flags” that a patient may have a genetic risk for a disease or disorder are:

- The disease or disorder occurs at a higher incidence within the family compared with the general population.
- The patient or close family members have another identified genetic problem.
- The incidence of a specific disease or disorder occurs in the patient or in family members at an unusually early age.
- A rare disease is present in two or more family members.
- More than one type of cancer is present in any one adult.
- The specific physical characteristic is associated with one or more genetic disorders (e.g., unusual freckling or skin pigmentation, bicuspid aortic valve, deafness).

The nurse may be the health care professional who first verifies information to bring a genetic problem to light. For example, during an assessment a patient reveals that her mother died of bone cancer when she was 40 years old. Bone cancer is quite rare among adults; thus the nurse might then ask, “Did your mother ever have any other type of cancer?” Often the patient may then reveal that her mother had breast cancer some years before (“bone cancer” was actually breast cancer that had spread to the bones). Breast cancer at an early age can indicate a genetic predisposition.

Patients may ask questions that indicate they have an interest in genetic testing. These are examples of questions that may be cues that the patient has genetic concerns:

- Will my children get this disease?
- Because my sister has this problem, what are the chances I might also develop it?
- Is there a way to test and see whether my chances of getting this disease or problem are high or low?

There are many areas of responsibility for any medical-surgical nurse providing **PATIENT-CENTERED CARE** when working with a patient who is considering or having genetic testing. These areas include communication, privacy and confidentiality, information accuracy, patient advocacy, and support.

### Communication

Using professional **ETHICS**, act as a patient advocate by ensuring that communication between the patient and whoever is providing the genetic information is clear. First assess the patient's ability to receive and process information. Can he or she see and hear clearly, or are assistive devices needed? Does the patient understand English, or will an interpreter be needed? Does the patient have adequate cognition at the time of meeting with the genetics professional, or is it impaired by medication, disease, anxiety, or fear?

If the patient appears not to understand terms or jargon during a discussion between him or her and a genetics professional, ask the professional to use common terms and examples for the patient. Verify with the patient that he or she understands or does not understand.

After any discussion about genetic risk or genetic testing, assess the patient's understanding of what was said. Ask the patient to explain, in his or her own words, what the issue means and what his or her expectations are.

### Privacy and Confidentiality

Professional **ETHICS** require that all conversations regarding potential diagnoses or genetic testing

need to occur in a private environment. The patient has the right to determine who may be a part of the discussion and can decide to exclude the primary physician and any family member from the discussion with a genetics professional. It is important that health care professionals who may be present during such discussion do not disclose information, formally or informally, without the patient's permission. It is the nurse's ethical duty and responsibility in providing PATIENT-CENTERED CARE to protect this information from improper disclosure to family members, other health care professionals, other patients, insurance providers, or anyone not specified by the patient.

## Information Accuracy

Correct myths about genetic disorders and teach patients about the nature of genetic testing. In addition, help patients find accurate and helpful resource materials or websites. Medical-surgical nurses are not genetics experts and would not be expected to be the final source of definitive information; however, with interprofessional collaboration they can help ensure that the patient is referred to the correct level of genetic counseling. If you are present during the patient's discussions with a genetics professional, assess whether he or she understands the issues regarding the health problem.

## Patient Advocacy and Support

Professional ETHICS require you to ensure that the patient's rights are not neglected or ignored. Ask the patient privately what his or her wishes are regarding genetic testing. Ask whether another adult or agency is insisting on the testing. Remind the patient that he or she does not have to agree to be tested. Verify that he or she has signed an informed consent statement for the test.

Considering or having genetic testing is a stressful experience. The patient and family require support and may need help with coping. Ethically genetic testing should be performed only after genetic counseling has occurred and should be followed with more counseling.

Patients may feel anger, depression, guilt, or hopelessness. Patients who have positive results (results indicating that a specific mutation is present) from genetic testing may have issues of risk for early death or disability and the possibility of having passed the risk for a health problem on to their children. Patients who have an ambiguous test result or one of unknown significance may believe that they have agonized over a decision and spent money and still have no clear answer. Even patients who have negative genetic test results (results indicating that a specific mutation is not present) need counseling and support as part of PATIENT-CENTERED CARE. Some patients may have an unrealistic view of what a negative result means for their general health. Others may feel guilty that they were "spared" when other family members were not.

Assess the patient's response to genetic test results. Determine which coping methods were used successfully in the past. If the patient has disclosed information to family members, assess whether they can help provide support or need support themselves. Assess whether the information about positive test results has strained family relationships. Refer the patient to appropriate support groups and interprofessional counseling services.

For some positive genetic test results such as having a *BRCA1* gene mutation, the risk for developing breast cancer is high but is not a certainty. With high risk the patient needs a plan for prevention and risk reduction. One form of prevention is early detection. Thus a patient who tests positive for a *BRCA1* mutation should have at least annual mammograms and ovarian ultrasounds to detect cancer at an early stage when it is more easily cured. Provide PATIENT-CENTERED CARE by teaching the patient who has positive test results that indicate an increased risk for a specific health problem about the types of screening procedures that are available and how often screening should occur. For example, some patients at known high genetic risk for breast cancer and ovarian cancer choose the primary prevention methods of bilateral prophylactic mastectomies (surgical removal of the breasts) and oophorectomies (surgical removal of the ovaries). Although these strategies are severe, they are effective, and the patient should be informed about their availability.

Teach patients at known high risk for a specific disorder how to modify the environment to reduce risk. For example, a patient who has a specific mutation in the *α1AT* (alpha<sub>1</sub>-antitrypsin) gene is at increased risk for early-onset emphysema. The onset of emphysema is even earlier when the patient smokes or is chronically exposed to inhalation irritants. By modifying his or her environment, the disease can be delayed, or the symptoms reduced.

## NCLEX Examination Challenge 5-3

### Psychosocial Integrity

Which action(s) performed by a nurse with a client who is at increased genetic risk for a health problem is/are consistent with a “nondirective manner?” **Select all that apply.**

- A. Providing only the information the client or family specifically requests
- B. Skillfully directing the client and family toward the best choice that is supported by evidence-based research.
- C. Being present (at the client's request) when the client discloses his or her specific status to other family members.
- D. Presenting all facts and available options in a manner that neither promotes nor excludes any legally permitted decision or action.
- E. Clarifying the client's misconception that being positive for the BRCA1 gene guarantees that the client will develop breast or ovarian cancer.
- F. Filtering management options and focusing on the information that will support the decision the nurse believes is right for the individual client and family.

## Clinical Judgment Challenge 5-1

### Ethical and Legal; Teamwork and Collaboration QSEN

You are caring for a patient who is 48 years old and dying from ovarian cancer. Her daughter tells you that she is afraid she may be at risk for ovarian cancer because her gynecologist told her that some forms of this disease are inherited. She would like to be tested but only if her mother is positive for a BRCA1 mutation, and her mother has not been tested. She does not want to ask her mother to be tested because her mother is already in pain and would worry that she has passed on a risk for cancer. The daughter asks you if you would obtain a cheek swab from her mother without her mother's knowledge so the daughter can take it and have it tested.

1. Is the daughter's concern that she may be at risk for ovarian cancer justified? If so, how? (You may need to look up information on BRCA1 and BRCA2 mutations and ovarian cancer risk and on cost of testing.)
2. How should you respond to this request? Provide a rationale for your response.
3. Review the ethical principles in Chapter 1. Which principle(s) are in play here, and are there any unique factors? Explain your choices.
4. Which other members of the interprofessional team would be helpful in this situation to the patient, the daughter, and to you? Explain your choices.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Ensure that an adult or family with indications of an increased genetic risk for a disease or disorder is referred to an appropriate genetics professional. **QSEN: Teamwork and Collaboration**
- Advocate for the patient with regard to whether or not to have genetic testing, informed consent before testing, and sharing of test results. **QSEN: Patient-Centered Care**
- Ensure that confidentiality of genetic test results is maintained by all health care team members. **QSEN: Safety**
- Determine whether an informed consent statement was obtained before any genetic test is performed. **QSEN: Safety**

### Health Promotion and Maintenance

- Identify patients and families at increased genetic risk for disease or disorder. **QSEN: Patient-Centered Care**
- Teach patients and families at known increased genetic risk for disease or disorder which types of screening procedures and schedules are most appropriate (check specific disorder chapters for the appropriate screening guidelines). **QSEN: Evidence-Based Practice**
- Teach patients and families at known increased genetic risk for disease or disorder which types of environmental modifications can reduce risk, delay disease onset, or reduce symptom severity (check specific disorder chapters for appropriate modifications). **QSEN: Evidence-Based Practice**

### Psychosocial Integrity

- Assess patients who have received results of genetic testing for responses such as anger, guilt, or depression. **QSEN: Patient-Centered Care**
- Allow the patient and family who have been identified as being at increased genetic risk for serious health problems to express concerns and feelings. **QSEN: Patient-Centered Care**
- Ensure that the patient who undergoes genetic testing is appropriately counseled before testing, while waiting for test results, and after test results are obtained. **QSEN: Teamwork and Collaboration**
- Support the decision of the patient and family to have or not to have genetic counseling or testing. **QSEN: Patient-Centered Care**
- When a serious health problem with a genetic basis is found, help the patient and family locate appropriate community or Internet support groups and resources. **QSEN: Patient-Centered Care**

### Physiological Integrity

- Be aware that mutations or variations in gene sequences can change the activity of a protein and have adverse effects on health.
- Keep in mind that many common adult diseases or disorders have a genetic basis (hypertension, diabetes, cancer), although some of these diseases also may occur among adults with no genetic risk.
- Remind the patient that having a gene variation that increases the risk for a disorder does not necessarily mean that the disorder will ever develop.
- Ensure that patients understand that genetic testing reveals information about their family members, as well as about themselves.

- Construct a three-generation pedigree from data obtained during the family history section of patient assessment.
- Remind patients that the results of genetic testing cannot be “taken back.”
- Be prepared to assume the accepted roles of the medical-surgical nurse in genetic counseling, which include examining assessment data for indications of genetic risk, acting as a patient advocate, correcting myths about genetic disorders and genetic testing, protecting the patient's privacy and rights, and helping to ensure that the patient and family at increased genetic risk are referred to a genetics professional.

## CHAPTER 6

# Rehabilitation Concepts for Chronic and Disabling Health Problems

Michelle Camicia, Donna D. Ignatavicius

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- MOBILITY
- ELIMINATION
- COGNITION

**The interrelated concepts for this chapter are:**

- TISSUE INTEGRITY
- NUTRITION
- SENSORY PERCEPTION
- HEALTH CARE ORGANIZATIONS

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Identify the roles of each member of the collaborative interprofessional rehabilitation team.
2. Identify HEALTH CARE ORGANIZATIONS where rehabilitation care is provided.
3. Delegate and supervise selected nursing tasks as part of care for the rehabilitation patient.
4. Coordinate recommendations for home modifications and care coordination/transition management with the patient, family, occupational therapist, and case manager.
5. Explain how to use safe patient handling practices based on current evidence to prevent self-injury.

### Health Promotion and Maintenance

6. Develop a teaching plan to prevent complications for the rehabilitation patient who has decreased MOBILITY, including impaired TISSUE INTEGRITY.

### Psychosocial Integrity

7. Assess the patient's response to chronic or disabling health problems.
8. Identify special considerations for older adults undergoing rehabilitative care, including assessment of cognition.

### Physiological Integrity

9. Interpret health assessment findings to plan appropriate collaborative care for the rehabilitation patient in the acute or long-term care setting.
0. Assess the ability of patients to use assistive/adaptive devices to promote MOBILITY and SENSORY PERCEPTION.
  1. Identify the role of NUTRITION in the care of the patient in a rehabilitation setting.
  2. Plan interventions to prevent impaired TISSUE INTEGRITY for rehabilitation patients.
  3. Differentiate retraining methods for a patient with a spastic versus flaccid bladder and bowel

to promote ELIMINATION.

Rehabilitation is a philosophy of practice and an attitude toward caring for people with disabilities and chronic health problems (Larsen, 2011). The practice of rehabilitation nursing is recognized as the specialty of managing the care of people with disabilities and chronic health conditions across the lifespan. A **disabling health condition** is any physical or mental health/behavioral health problem that can cause disability. A **chronic health condition** is one that has existed for at least 3 months. This text focuses primarily on physical health problems; psychosocial health problems are integrated throughout the text as needed to describe whole-person care. They are discussed in more detail in textbooks on mental health/behavioral health nursing.

Patients with chronic and disabling health conditions need the integration of rehabilitation nursing concepts into their care, regardless of setting, to prevent further disability, maintain function, and restore individuals to optimal functioning in their community. This desired outcome requires care coordination and collaboration with the interprofessional health care team.

## Overview

### Chronic and Disabling Health Conditions

Chronic diseases and conditions are among the most common, costly, and preventable of all health problems in the United States. Eighty-six percent of all health care spending in 2010 was for people with one or more chronic health conditions (Gerteis et al., 2014). The rate of chronic and disabling conditions is expected to increase as more “baby boomers” approach late adulthood.

Stroke, coronary artery disease, cancer, chronic obstructive pulmonary disease (COPD), asthma, and arthritis are common chronic diseases that can result in varying degrees of disability. Most occur in people older than 65 years. However, younger adults are living longer with potentially disabling genetic disorders that in the past would have shortened life expectancy. Some of these more common disorders are discussed throughout this text.

Chronic and disabling conditions are not always illnesses (e.g., heart disease); they may also result from accidents. Accidents are a leading cause of trauma and death among young and middle-age adults. Increasing numbers of people survive accidents with severe injuries because of advances in medical technology and safety equipment such as motor vehicle airbags. As a result, they are often faced with chronic, disabling neurologic conditions such as traumatic brain injury (TBI) and spinal cord injury (SCI). Because people are living longer with chronic and disabling health problems, the need for rehabilitation is increasing!

### ▼ Veterans' Health Considerations

#### Patient-Centered Care QSEN

Combat in war is another major source of major disability. Many military men and women who served in recent wars such as those in Iraq and Afghanistan have one or more physical or mental health/behavioral health disabilities, most commonly TBI, single or multiple limb amputations, and post-traumatic stress disorder (PTSD). There is also a large population of veterans living with disabilities from wars of the past. These disabilities require months to years of follow-up rehabilitation after returning to the community. *Physical* veteran disabilities are described in this text; PTSD is discussed in your mental health/behavioral health book.

### Rehabilitation Settings

Many people with chronic and disabling conditions live independently or with assistance in the community. For example, a new-onset illness such as a stroke may require post-acute care (PAC) following the initial hospitalization for rehabilitation. This continuing care can be in an acute inpatient rehabilitation facility (IRF), skilled nursing facility (SNF), long-term acute care (LTAC) facility, or home health agency (HHA). Rehabilitation in each of these HEALTH CARE ORGANIZATIONS seeks to maximize the function of the individual impacted by the injury or chronic condition. Each of these care settings varies in the amount and type of rehabilitation and the nursing, health care provider, and other services offered.

Individuals requiring rehabilitation are referred to as *clients*, *patients*, or *residents*, depending on the setting. For the purpose of consistency within this text, the term *patient* is used throughout this chapter. *However, be sure to refer to individuals in rehabilitation programs by the term that is consistent with the setting and according to patient preference to be patient centered.*

The determination of the right level of PAC for an individual must be based on the individual's biopsychosocial and ecological assessment (Camicia et al., 2014). Factors that are considered include biological, social, financial, environmental, and systems factors. Biological factors include the individual's medical needs, pre-injury or pre-illness level of function, and tolerance of rehabilitation. Social factors include psychological, informal, and formal community supports. Other important considerations are financial resources and stressors and the physical environment of the community living setting. Systems factors include the components of care and services, the intensity of service provision (e.g., number of hours of nursing care or therapy), and the structure and process of the program. The PAC setting must be matched to the patients' needs. The nurse

coordinates care from acute through community-based care to ensure the person's optimal function and participation in the community.

Rehabilitation care occurs on a continuum. The intensity of services decreases across the continuum from the inpatient rehabilitation facility (IRF) or skilled nursing facility (SNF) to home health to comprehensive ambulatory care (outpatient) programs. The most resource-intensive level of PAC is the IRF. These HEALTH CARE ORGANIZATIONS are freestanding rehabilitation hospitals or rehabilitation units within hospitals. **Skilled nursing facilities (SNFs)** are part of either a hospital or long-term care (nursing home) setting (Fig. 6-1). For older adults in the United States, rehabilitation services for the first 100 days of inpatient care are paid by Medicare A.

**FIG. 6-1** Patient (resident) in a skilled nursing facility rehabilitation unit. (From Kostelnick, C. [2015]. *Mosby's textbook for long-term care nursing assistants* [7th ed.]. St. Louis: Mosby.)

Individuals in skilled nursing facilities, custodial nursing homes, and assisted-living facilities are called *residents*. The term **resident** implies that the person lives in the facility and has all the rights of anyone living in his or her home. Residents wear street clothes rather than hospital gowns and have choices in what they eat and how they plan each day.

Ambulatory care rehabilitation departments and home rehabilitation programs may be needed for continuing less-intensive services. Some agencies have specialized clinics focused on rehabilitation of patients with specific health problems such as those that care for individuals with strokes; amputations; and large, chronic, and/or nonhealing wounds.

People who are able to rehabilitate to independence or who have a caregiver and a home without environmental barriers are able to return home following a disabling medical event. Home for older adults is often in senior citizens' housing units, their family's home, or assisted-living facilities. Part-time rehabilitation services may be provided in any of these home settings by a variety of health care professionals. These services may be reimbursed by Medicare B or other private health insurance.

Alternative living settings include a board-and-care facility or transitional living apartment. Group homes are facilities in which individuals live independently together with other people with disabilities. Each patient or group of patients has a care provider such as a personal care aide to assist with ADLs. The patients may or may not be actively employed. In some cases the care home offers employment opportunities to the residents. The purpose of these homes is to provide independent living arrangements outside an institution, especially for younger people with TBI or SCI.

The desired outcome of rehabilitation is that the patient will return to the best possible physical, mental, social, vocational, and economic capacity. Rehabilitation is not limited to the return of function in post-traumatic situations. It also includes education and therapy for any chronic conditions characterized by a change in a body system function or body structure. Rehabilitation programs related to respiratory, cardiac, and musculoskeletal health problems are common examples that do not involve trauma.

## The Rehabilitation Interprofessional Team

Successful rehabilitation depends on the coordinated team effort of the patient, family, and health care professionals in planning, implementing, and evaluating care. The focus of the interprofessional rehabilitation team is to restore and maintain the patient's function to the greatest extent possible.

In addition to the patient, family, and/or significant others, members of the interprofessional health care team in the rehabilitation setting may include:

- Nurses and nursing assistants
- Rehabilitation nurse case managers
- Physicians and physicians assistants
- Advanced practice nursing (APNs) such as nurse practitioners and clinical nurse specialists
- Physical therapists and assistants
- Occupational therapists and assistants
- Speech-language pathologists and assistants
- Rehabilitation assistants/restorative aides
- Recreational or activity therapists
- Cognitive therapists or neuropsychologists
- Social workers
- Clinical psychologists
- Vocational counselors
- Spiritual care counselors
- Registered dietitians (RDs)
- Pharmacists

Not all settings that offer rehabilitation services have all of these members on their team. Not all patients require the services of all health care team members. The team should be comprised of providers who are clinically indicated for each patient.

*Rehabilitation nurses* in the inpatient setting coordinate the collaborative plan of care and therefore function as the patient's case manager. Nurses also create a rehabilitation milieu, which includes:

- Allowing time for patients to practice self-management skills
- Encouraging patients and providing emotional support
- Protecting patients from embarrassment (e.g., bowel training)
- Making the inpatient unit a more homelike environment

Table 6-1 summarizes the nurse's role as part of the rehabilitation team. Because of an increase in the need for older-adult rehabilitation, some nurses specialize in gerontologic rehabilitation. Nurses and other health care professionals may be designated as *rehabilitation case managers*. *Advanced practice nurses (APNs)* are masters- and doctorate-prepared nurses who function independently or under the supervision of a physician, depending on the rules and regulations of the state or province.

Adapted from Association of Rehabilitation Nurses. (2008). *Standards and scope of rehabilitation nursing practice*, Glenview, IL: Author.

As their name implies, *nursing assistants* or *nursing technicians* assist in the physical care of patients. These members of the rehabilitation team function under the direct supervision of the registered nurse (RN) or licensed practical or vocational nurse (LPN or LVN).

A physician who specializes in rehabilitative medicine is called a **physiatrist**. Physiatrists oversee the rehabilitation medical plan of care from the emergency department, intensive care unit, telemetry unit, and medical surgical unit into the community. The physiatrist is the attending physician at the IRF with consultation from general practitioners. They may also provide consultation in the SNF. *Physician assistants (PAs)* work under the supervision of the physician.

Physical therapists (PTs), also called *physiotherapists*, intervene to help the patient achieve self-management by focusing on *gross MOBILITY* skills (e.g., by facilitating ambulation and teaching the patient to use an assistive device such as a walker) (Fig. 6-2). They may also teach techniques for performing activities such as transferring (e.g., moving into and out of bed), ambulating, and toileting. In some settings PTs play a major role in providing wound care and cognitive retraining. Physical therapy assistants (PTAs) may be employed to help the PT.

**FIG. 6-2** A physical therapist helping a patient ambulate with a walker.

*Occupational therapists (OTs)* work to develop the patient's *fine* motor skills used for ADL self-management such as those required for eating, hygiene, grooming, and dressing. They also teach patients how to perform independent living skills such as cooking and shopping. To accomplish these outcomes, OTs teach skills related to coordination (e.g., hand movements) and cognitive retraining (Fig. 6-3). Occupational therapy assistants (OTAs) may be available to help the OT.

**FIG. 6-3** A registered occupational therapist working with a patient on improving hand strength.

*Speech-language pathologists (SLPs)* evaluate and retrain patients with speech, language, or swallowing problems. *Speech* is the ability to say words, and *language* is the ability to understand and put words together in a meaningful way. Some patients, especially those who have experienced a head injury or stroke, have difficulty with both speech and language. Those who have had a stroke also may have dysphagia (difficulty with swallowing). SLPs provide screening and testing for dysphagia. If the patient has this problem, the SLP recommends appropriate foods and eating techniques. Speech-language pathology assistants (SLPAs) may be employed to help the SLP.

PTs, OTs, and SLPs are collectively referred to as **rehabilitation therapists**. Assistants to PTs, OTs, and SLPs are called **rehabilitation assistants**. In long-term care settings, *restorative aides* may enhance the therapy team to continue the rehabilitation therapy plan of care when therapists are not available.

*Recreational or activity therapists* work to help patients continue or develop hobbies or interests. These activities may also contribute to strengthening fine motor skills.

*Cognitive therapists*, usually neuropsychologists, work primarily with patients who have experienced a stroke, brain injury, brain tumor, or other condition resulting in cognitive impairment. Computer programs are often used to assist with cognitive retraining.

Various professionals promote community reintegration of the patient and acceptance of the disability or chronic conditions. For example, *social workers* help patients identify support services and resources, including financial assistance. *Clinical psychologists* assess and diagnose mental health/behavioral health or COGNITION issues resulting from the disability or chronic condition and help both the patient and family identify strategies to foster coping. *Spiritual counselors* specialize in spiritual assessments and care and are able to address the needs of a wide array of patient preferences and beliefs.

*Vocational counselors* help with job placement, training, or further education. Work-related skills are taught if the patient needs to change careers because of the disability. If the patient has not yet completed high school, tutors may help with completion of the requirements for graduation.

*Registered dietitians (RDs)* help ensure that patients meet their needs for NUTRITION. For example, for patients who need weight reduction, a restricted-calorie diet can be planned. For patients who need additional calories or other nutrients, including vitamins, dietitians can plan a patient-specific diet.

*Pharmacists* collaborate with the other members of the health care team to ensure that the patient receives the most appropriate drug therapy, if required. They oversee the prescription and preparation of medications and provide the interprofessional team with essential information regarding drug safety, interactions, and side effects.

Depending on the patient's health care needs, additional team members may be included in the rehabilitation program such as the geriatrician, respiratory therapist, and prosthetist. Interprofessional team conferences for planning care and evaluating the patient's progress are held regularly with the patient, family and significant others, and the health care team.

## NCLEX Examination Challenge 6-1

### Psychosocial Integrity

A client who can't move his right leg or arm tells the nurse: "Life is over for me. I don't want to live if I'm going to be a burden to everyone." What is the nurse's **best** action?

- A. Report the client's concern to the primary health care provider.
- B. Consult with the clinical psychologist or social worker.
- C. Share the client's feelings with the family.
- D. Refer the client to the vocational counselor.

## Interprofessional Collaborative Care

### Assessment: Noticing

#### History.

Collect the history of the patient's present condition, any current medications (prescribed and over the counter [OTC]), and any treatment programs in progress. Begin by obtaining general background data about the patient and family. This information includes cultural and spiritual practices and the patient's home environment and support system. In collaboration with the occupational therapist, the nurse or case manager assesses the physical layout of the home and determines whether the layout, including stairs or the width of doorways, will present architectural barriers for the patient after discharge.

Assess the patient's usual daily schedule and habits of everyday living. These data include hygiene practices, nutrition, elimination, sexual activity, and sleep. Ask about the patient's preferred method and time for bathing and hygiene. In assessing dietary patterns, note food likes and dislikes. Also obtain information about the patient's bowel and bladder function and the usual pattern of elimination.

In assessing sexuality patterns, ask about changes in sexual function since the onset of the disability. The patient's current and previous sleep habits, patterns, usual number of hours of sleep, and use of hypnotics are also determined. Question whether the patient feels well rested after sleep. Sleep patterns have a significant impact on activity patterns. The assessment of activity patterns focuses on work, exercise, and recreational activities.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Older adults who need rehabilitation often have other chronic diseases that need to be managed, including diabetes mellitus, coronary artery disease, osteoporosis, and arthritis. These health problems, added to the normal physiologic changes associated with aging, predispose older adults to secondary complications such as falls, pressure injuries, and pneumonia. When discharged from the acute care setting, some older patients are undernourished, which causes weakness and fatigue. The longer the hospital stay, the more debilitated the older adult can become. For some patients severe undernutrition results in decreased serum albumin and prealbumin, causing third spacing. Assess the older adult for generalized edema, especially in the lower extremities. Be sure to collaborate with the RD to improve the patient's nutritional status, with a focus on increasing protein intake that is needed for healing and decreasing edema.

Health teaching may be challenging because some older patients may have beginning changes in COGNITION, including short-term memory loss. Sensory loss, like vision and hearing, may also affect their ability to give an accurate history or grasp new information.

#### Physical Assessment/Signs and Symptoms.

On admission for baseline and at least daily (depending on agency policy and type of setting), collect physical assessment data systematically according to major body systems (Table 6-2). The primary focus of the assessment related to rehabilitation and chronic disease is the *functional* abilities of the patient.

**TABLE 6-2**  
**Assessment of Patients in Rehabilitation Settings**

BODY SYSTEM	RELEVANT DATA
Cardiovascular system	Chest pain Fatigue Fear of heart failure
Respiratory system	Shortness of breath or dyspnea Activity tolerance Fear of inability to breathe
Gastrointestinal system and nutrition	Oral intake, eating pattern Anorexia, nausea, and vomiting Dysphagia Laboratory data (e.g., serum prealbumin level) Weight loss or gain Bowel elimination pattern or habits Change in stool (constipation or diarrhea) Ability to get to toilet
Renal-urinary system	Urinary pattern Fluid intake Urinary incontinence or retention Urine culture and urinalysis
Neurologic system	Motor function Sensation Perceptual ability Cognitive abilities
Musculoskeletal system	Functional ability Range of motion Endurance Muscle strength
Integumentary system	Risk for skin breakdown Presence of skin lesions

### Cardiovascular and Respiratory Assessment.

An alteration in cardiac status may affect the patient's cardiac output or cause activity intolerance. Assess associated signs and symptoms of decreased cardiac output (e.g., chest pain, fatigue). If present, determine when the patient experiences these symptoms and what relieves them. The primary health care provider may prescribe a change in drug therapy or a prophylactic dose of nitroglycerin to be taken before the patient resumes activities. Collaborate with the primary health care provider and appropriate therapists to determine whether activities need to be modified.

For the patient showing fatigue, the nurse and patient plan methods for using limited energy resources. For instance, frequent rest periods can be taken throughout the day, especially before performing activities. Major tasks might be performed in the morning because most people have the most energy at that time. The nurse must communicate needs for breaks in the therapy schedule for rest as needed. Schedule nursing care according to the patient's need for rest.

Ask the patient whether he or she has shortness of breath, chest pain, or severe weakness and fatigue during or after activity. *Determine the level of activity that can be accomplished without these symptoms.* For example, can the patient climb one flight of stairs without shortness of breath, or does shortness of breath occur after climbing only two steps?

### Gastrointestinal and Nutritional Assessment.

Monitor the patient's oral intake and pattern of eating. Assess for the presence of anorexia, dysphagia, nausea, vomiting, or discomfort that may interfere with oral intake. Determine whether the patient wears dentures and, if so, assess the fit. Review the patient's height, weight, hemoglobin and hematocrit levels, serum prealbumin and albumin, and blood glucose levels. (See Chapter 60 for discussion of how to perform a screening for NUTRITION status and Chapter 2 for a description of basic nutritional assessments.) Weight loss or weight gain is particularly significant and may be related to an associated disease or to the conditions that caused the disability.

Bowel ELIMINATION habits vary from person to person. They are often related to daily job or activity schedules, dietary patterns, age, and family or cultural background. Ask about usual bowel patterns before the injury or the illness. Note any changes in the patient's bowel routine or stool consistency. The most common problem for rehabilitation patients is constipation.

If the patient reports any alteration in ELIMINATION pattern, try to determine whether it is caused by a change in diet, activity pattern, or medication use. Always assess bowel habits on what is normal for that person.

Ask whether the patient can manage bowel function independently. Independence in bowel elimination requires adequate cognition, manual dexterity, sensation, muscle control, and mobility. If the patient requires help, determine whether someone is available at home to provide it. Also assess the patient's and family's ability to cope with any dependency in bowel elimination. Assessment of ELIMINATION is summarized in [Chapter 2](#).

### Renal and Urinary Assessment.

Ask about the patient's baseline urinary ELIMINATION patterns, including the number of voidings. Determine whether he or she routinely awakens during the night to empty the bladder (**nocturia**) or sleeps through the night. Record fluid intake patterns and volume, including the type of fluids ingested and the time they were consumed.

Question whether the patient has ever had any problems with urinary incontinence or retention. Monitor laboratory reports, especially the results of the urinalysis and culture and sensitivity, if needed. *Urinary tract infections (UTIs) among older adults are often missed because acute confusion may be the only indicator of the infection.* Unfortunately some health care professionals expect older patients to be confused and may not detect this problem. If untreated, UTIs can lead to kidney infection and possible failure.

### Neurologic and Musculoskeletal Assessment.

The neurologic assessment includes motor function (MOBILITY), SENSORY PERCEPTION, and COGNITION. [Chapter 2](#) reviews general assessment of these concepts. Assess the patient's pre-existing problems, general physical condition, and communication abilities. Patients may have **dysphasia** (slurred speech) because of facial muscle weakness or **aphasia** (inability to speak or comprehend) because of brain damage commonly occurring in those with a stroke or traumatic brain injury (TBI). These communication problems are discussed in detail in the chapters on problems of the nervous system.

Determine if the patient has **paresis** (weakness) or **paralysis** (absence of movement). Observe the patient's gait. Identify changes in SENSORY PERCEPTION such as visual acuity that could contribute to risk for injury. Assess his or her response to light touch, hot or cold temperature, and position change in each extremity and on the trunk. For a perceptual assessment, evaluate the patient's ability to receive and understand what is heard and seen and the ability to express appropriate motor and verbal responses. During this part of the assessment, begin to assess short-term and long-term memory.

Assess the patient's cognitive abilities, especially if there is a head injury or stroke. Several tools are available to evaluate COGNITION. One of the most commonly used tools in rehabilitation and long-term care settings is the Brief Interview for Mental Status (BIMS), which is described in [Chapter 41](#). The Confusion Assessment Method (CAM) is used to determine if the patient has delirium, an acute confusional state. (See [Chapter 3](#) for description of the CAM tool.)

As with other body systems, nursing assessment of the musculoskeletal system focuses on function. Assess the patient's musculoskeletal status; response to the impairment; and demands of the home, work, or school environment. Determine his or her endurance level and measure active and passive joint range of motion (ROM). Review the results of manual muscle testing by physical therapy, which identifies the patient's ROM and resistance against gravity. In this procedure the therapist determines the degree of muscle strength present in each body segment.

### Skin and Tissue Integrity Assessment.

Identify actual or potential interruptions in skin and TISSUE INTEGRITY. [Chapter 2](#) reviews the general assessment of this concept. To maintain healthy skin, the body must have adequate food, water, and oxygen intake; intact waste-removal mechanisms; sensation; and functional MOBILITY. Changes in any of these variables can lead to rapid and extensive skin breakdown.

If a pressure injury or other change in TISSUE INTEGRITY develops, accurately assess the problem and its possible causes. In the inpatient setting inspect the skin every 8 to 12 hours. Teach the patient or caregiver to inspect the skin daily at home. Measure the depth and diameter of any open skin areas in inches or centimeters, depending on the policy of the facility or country. Assess the area around the open lesion to determine the presence of cellulitis or other tissue damage. [Chapter 25](#) includes several widely used classification systems for assessing skin breakdown. Determine the patient's knowledge about the cause and treatment of skin breakdown and his or her ability to inspect the skin and participate in maintaining TISSUE INTEGRITY.

In most health care agencies the skin assessment is documented on a special form or part of the electronic health record to keep track of each area of skin breakdown. A baseline assessment is conducted on admission and updated periodically, depending on organization policy, and more frequently as indicated. In most long-term care, acute care, and rehabilitation settings and with the patient's (or family's if the patient cannot communicate) permission, photographs of the skin are taken on admission and at various intervals to pictorially document the appearance of the wound.

## NCLEX Examination Challenge 6-2

### Physiological Integrity

The nurse performs an admission assessment for an older adult following a fractured hip repair. Which priority client assessment findings will require the nurse to collaborate with members of the interprofessional health team? **Select all that apply.**

- A. Mild dependent edema in both ankles when sitting
- B. Chest pain when ambulating with the walker
- C. Lack of appetite and weight loss
- D. Report of joint pain at a 8 on a 0-10 intensity scale
- E. Dry and itchy skin over legs and arms

### Assessment of Functional Ability.

*Functional ability* refers to the ability to perform **activities of daily living (ADLs)** such as bathing, dressing, eating, using the toilet, and ambulating. **Instrumental activities of daily living (IADLs)** refer to activities necessary for living in the community such as using the telephone, shopping, preparing food, and housekeeping. Functional assessment tools are used to assess a patient's abilities. Rehabilitation nurses, physiatrists, or rehabilitation therapists complete assessment tools to document functional levels. The Centers for Medicare and Medicaid (CMS) require cross-setting assessment measures to evaluate a patient's function, regardless of the post-acute care (PAC) setting where they receive rehabilitation. These tools include functional assessment items for self-care and mobility on the Inpatient Rehabilitation Facility Patient Assessment Instrument (IRF-PAI) used in the IRF, the Minimum Data Set (MDS) used in the SNF (Table 6-3), and the Outcome and Assessment Information Set (OASIS) used in home health agencies. These assessments are also used for reimbursement from the CMS in the United States.

**TABLE 6-3**

### Assessment Components of the Minimum Data Set (MDS) 3.0

--	---

Data from Centers for Medicare and Medicaid Services (CMS). *MDS 3.0 for nursing homes and swing bed providers*, 2013, <http://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/NursingHomeQualityInits/NHQIMDS30.html>.

Another commonly used classic assessment tool is the Functional Independence Measure (FIM) developed by Granger and Gresham (1984). This tool is intended to measure the burden of care for a patient, not what a person should do or how the person would perform under different circumstances. Categories for assessment are self-care, sphincter control, MOBILITY and locomotion, communication, and COGNITION. Scoring is a 1-to-7 scale, in which 1 is dependent and 7 is independent. Each score has a definition for every item. The patient is evaluated when he or she is admitted to and discharged from a rehabilitation provider and at other specified times to determine progress toward desired outcomes (also referred to as *goals*). The FIM system has also been adapted

for use in across-care settings, including acute care and home care, and is available in multiple languages.

### Psychosocial Assessment.

In addition to determining COGNITION, assess the patient's body image and self-esteem through verbal indicators and descriptions of self-care. Encourage the family to allow the patient to perform as many functions as possible independently to build feelings of self-worth.

Assess the patient's use of defense mechanisms and manifestations of anxiety. If indicated, ask him or her to describe feelings concerning the loss of a body part or function. Assess for the presence of any stress-related physical problem. Some patients have symptoms of depression such as fatigue, a change in appetite, or feelings of powerlessness. See [Chapter 7](#) for a thorough discussion of loss and grieving and [Chapter 3](#) for a brief discussion of depression among the older-adult population.

## Cultural/Spiritual Considerations

### Patient-Centered Care

Determine the availability of support systems for the patient. The major support system is typically the family or significant others; those who do not have these support systems are more likely to develop depression. Ask patients what is important to them and gives meaning to their lives. Identify the patient's cultural, spiritual, and/or religious needs and refer to an appropriate health care team member as needed. Assess sexuality and intimacy needs.

### Vocational Assessment.

Patients in the United States should be informed about the Americans with Disabilities Act, which was passed by Congress in 1991 to prevent employer discrimination against people with disabilities. The employer must offer *reasonable* assistance to an employee with a disability to allow him or her to perform the job. For example, if an employee has a severe hearing loss, the employer may need to hire a sign language interpreter.

The rehabilitation team assesses the cognitive and physical demands of the patient's job to determine whether he or she can return to the position or if retraining in another field is necessary. The physical demands of jobs range from light in sedentary occupations (0 to 10 lb [4.54 kg] often lifted) to heavy (more than 100 lb [45.45 kg] often lifted). The nurse must also consider other required aspects of the job such as MOBILITY or SENSORY PERCEPTION (e.g., hearing).

Job analysis also involves assessing the work environment of the patient's former or current job. Collaborate with the vocational counselor to determine whether the environment is conducive to the patient's return to work because job modifications may be needed. If an injured worker requires vocational rehabilitation, refer him or her to vocational rehabilitation personnel to evaluate skills and necessary skill development. In most states Workers' Compensation insurance helps support vocational rehabilitation.

### ◆Analysis: Interpreting

Regardless of age or specific disability, these priority patient problems are common. Additional problems depend on the patient's specific chronic condition or disability. The priority collaborative problems for patients with chronic and disabling health conditions typically include:

1. Decreased mobility due to neuromuscular impairment, sensory-perceptual impairment, and/or chronic pain
2. Decreased functional ability due to neuromuscular impairment and/or impairment in perception or cognition
3. Risk for pressure injury due to altered sensation and/or altered nutritional state
4. Urinary incontinence or urinary retention due to neurologic dysfunction and/or trauma or disease affecting spinal cord nerves

5. Constipation due to neurologic impairment, inadequate nutrition, or decreased mobility

### ◆ **Planning and Implementation: Responding**

#### **Increasing Mobility**

##### **Planning: Expected Outcomes.**

The patient with chronic conditions or a disability is expected to reach the highest level of physical MOBILITY that can be obtained with or without assistive devices. The patient is also expected to be free of complications of immobility.

##### **Interventions.**

Most problems requiring rehabilitation relate to decreased or impaired physical MOBILITY. For example, patients with neurologic disease or injury, amputations, arthritis, and cardiopulmonary disease usually experience some degree of mobility impairment. Coordinate care with physical and occupational therapists as the key rehabilitation team members in helping patients meet their mobility outcomes. Complications of decreased MOBILITY or immobility and how to help prevent them are described in [Chapter 2](#).

##### **Safe Patient Handling and Mobility Practices.**

Before they learn to become independent, patients with decreased MOBILITY in any health care setting or at home often need assistance with positioning in bed and transfers such as from a bed to a chair, commode, or wheelchair. Patients may not be able to bear full weight, may have inadequate balance, and/or may be very obese. For many years nurses relied on “body mechanics” to prevent staff injury when moving patients or helping them move. This traditional, but outdated, approach was based on the belief that correct body positioning by staff members would protect them from the force of lifting and moving.

Heavy lifting and dependent transfers by staff members have resulted in a very high incidence of [work-related musculoskeletal disorders \(MSDs\)](#), most often chronic back and shoulder injuries, which can be prevented (see the [Quality Improvement](#) box). As a response to this costly problem, the National Institute for Occupational Safety and Health (NIOSH) established evidence-based guidelines for safe patient handling. Based on this document, the American Nurses Association, in partnership with NIOSH and the Veterans Health Administration, developed a curriculum for all nursing students and practicing nurses on how to safely handle and move patients in any health care setting or home environment ([American Nurses Association, 2012](#)). In addition, the Association of Rehabilitation Nurses (ARN), in collaboration with the American Physical Therapy Association (APTA), the American Occupational Therapy Association (AOTA), and the Veteran's Health Administration, outlined strategies that improve patient and health care provider safety in patient handling and movement tasks. In collaboration with other interprofessional team members, nurses must assess patient mobility and use best practices for safe patient handling and mobility (SPHM).

## **Quality Improvement** QSEN

### **Do Safe Handling Practices Protect Health Care Staff from Personal Injury?**

Kennedy, B. & Kopp, T. (2015). Safe handling protects employees too. *Nursing*, 45(8), 65–67.

During clinical rounds the nursing leaders of a large southeastern acute care hospital identified problems related to employee injuries, patient falls, and hospital-acquired pressure injuries. An interprofessional team was formed to develop an improvement process to decrease these problems and reduce workers' compensation costs. Using the American Nurses Association's best practice guidelines, a proposal to purchase over \$1 million of equipment such as ceiling-mounted mechanical lifts and friction-reducing slides and aids was approved. The equipment vendor worked with the improvement team to create a culture of safety and establish transfer mobility coaches to support the culture change. All nursing staff members were educated on how to use the new equipment correctly, and ongoing continuing education was provided each month.

As a result of implementing these interventions, the average number of monthly employee injuries decreased from 4.58 to 1.9. The monthly cost for workers' compensation decreased by more

than \$2000. In addition, patient falls declined, and the number of pressure injuries was reduced by 50% in the first year of the new program as a result of less shearing and skin tears.

### **Commentary: Implications for Research and Practice**

This change project was very successful at improving patient outcomes and reducing staff injuries. Strong administrative, financial, and interprofessional support was essential in meeting the project's outcomes. This QI project needs to be implemented in other health care organizations for comparison with the reported positive outcomes.

Because each patient has unique needs and characteristics, assess his or her mobility level using a standardized tool to plan interventions for SPHM. An example of an appropriate assessment tool for this purpose is shown in [Fig. 6-4](#). Before moving the patient, assess his or her environment for potential hazards that could cause injury such as a slippery or uneven floor.

**Assessment Tool and Care Plan for Safe Patient Handling and Movement**

**I. Patient's Level of Assistance**

- Independent—Patient performs task safely, with or without staff assistance, with or without assistive devices.
- Partial Assist—Patient requires no more help than standby, cueing, or coaxing, or caregiver is required to lift no more than 35 lb of a patient's weight.
- Dependent—Patient requires nurse to lift more than 35 lb of the patient's weight, or patient is unpredictable in the amount of assistance offered. In this case, assistive devices should be used.

An assessment should be made before each task if the patient has a varying level of ability to assist because of medical reasons, fatigue, medications, etc. When in doubt, assume the patient cannot assist with the transfer/repositioning.

**II. Weight-Bearing Capability**

- Full
- Partial
- None

**III. Bilateral Upper-Extremity Strength**

- Yes
- No

**IV. Patient's Level of Cooperation and Comprehension**

- Cooperative—May need prompting; able to follow simple commands.
- Unpredictable or variable (patient whose behavior changes frequently should be considered unpredictable)—Not cooperative or unable to follow simple commands.

**V. Weight \_\_\_\_\_ Height \_\_\_\_\_**

Body Mass Index (BMI) (needed if patient's weight is over 300 lb)\*  
*If BMI exceeds 50, institute Bariatric Algorithms.*

The presence of the following conditions is likely to affect the transfer/repositioning process and should be considered when identifying equipment and techniques needed to move the patient.

**VI. Check Applicable Conditions Likely to Affect Transfer/Repositioning Techniques**

\*If patient weighs more than 300 lb, the BMI is needed. For online BMI table and calculator, see [http://www.nhlbi.nih.gov/guidelines/obesity/bmi\\_tbl.htm](http://www.nhlbi.nih.gov/guidelines/obesity/bmi_tbl.htm).

**FIG. 6-4** Example of a tool to assess physical mobility.

Use these general SPHM practices and teach staff members to:

- Maintain a wide, stable base with your feet
- Put the bed at the correct height—waist level while providing direct care and hip level when moving patients
- Keep the patient or work directly in front of you to prevent your spine from rotating

- Keep the patient as close to your body as possible to prevent reaching

The Veterans Health Administration and many other health care systems follow a no-lift or limited-lift policy for all of their facilities. This means that nurses and therapists either rely on the patient to independently move and transfer or use a powered, mechanical full-body lift that is either ceiling- or wall-mounted or portable (mobile) (Fig. 6-5). Most lifts use slings that are comfortable, safe, and easy to apply. Electric-powered, portable sit-to-stand devices are also available. Mechanical lifts are also available for home use.

**FIG. 6-5** Example of powered, mechanical full-body lift. (From Potter, P., Perry, A., Stockert, P., & Hall, A. [2017]. *Fundamentals of nursing* [9th ed.]. St. Louis: Mosby.)

For patients who are learning to become independent in transfer or bed MOBILITY skills, the physical or occupational therapist usually specifies the procedure for these maneuvers. For example, a patient with quadriplegia may use a sliding board for transfer, whereas a patient with paraplegia may be able to transfer when the wheelchair arms are removed. A patient may be taught to turn independently using the side rails. In any case, for safety always plan or teach the patient to plan the transfer technique before initiating it. The desired outcome is that the patient will eventually be able to transfer safely, providing their maximum effort while assistance is provided by equipment and caregivers as needed.

## **Nursing Safety Priority** QSEN

### **Action Alert**

Assess the patient and the situation before any transfer. Orthostatic, or postural, hypotension is a common problem and may contribute to falls. If the patient moves from a lying to a sitting or standing position too quickly, his or her blood pressure may drop; as a result, he or she can become dizzy or faint. This problem is worsened by antihypertensive drugs, especially in older adults. To prevent this situation, help the patient change positions slowly, with frequent pauses to allow the blood pressure to stabilize. If needed, measure blood pressure with the patient in the lying, sitting, and standing positions to examine the differences. **Orthostatic hypotension** is indicated by a drop of more than 20 mm Hg in systolic pressure or 10 mm Hg in diastolic pressure between positions. Notify the health care provider and the therapists about this change.

If the patient has problems maintaining blood pressure while out of bed, the physical therapist may start him or her on a tilt table to gradually increase tolerance. A low blood pressure is a particularly common problem for patients with quadriplegia because they have a delayed blood flow to the brain and upper part of the body.

Weight gain is another potential problem when rehabilitation patients have decreased MOBILITY. Excessive weight hinders transfers both for the nurse or the therapist who is assisting and for the patient who is learning to transfer independently. Weight is usually checked every week to monitor gains or losses. If needed, collaborate with the dietitian to plan a weight-reduction diet.

## Gait Training.

The physical therapist works with patients for gait training if ambulation is a realistic goal. While regaining the ability to ambulate, patients may need to use assistive devices such as a variety of canes or walkers (Fig. 6-6). The specific device selected for each patient depends on the amount of weight bearing that is allowed or tolerated. For example, a stroke patient who has problems with maintaining balance or a steady gait when walking might need a cane that provides greater steadying. Some patients use walkers with rollers made of tennis-ball materials; others who tire easily may need a walker with a built-in seat to rest at intervals (sometimes referred to as a *rollator*). A patient who had a total hip replacement 6 weeks ago may be able to use a straight (also called *single-point*) cane.

**FIG. 6-6** Assistive devices for ambulation. Assistive devices vary in the amount of support they provide. A straight (single-point) cane provides less support than a walker (A) or quadripod cane (B).

When working with patients who are using these devices, also known as **ambulatory aids**, the physical therapist ensures that there is a level surface on which to walk. The therapist or nurse should use a gait belt to guide him or her during ambulation to help prevent falls. Use of transfer belts is recommended as one of the best practices for safe patient handling (ANA, 2012).

Reinforce the physical therapist's instructions and encourage practice, with the outcome being optimal mobility for the individual. Chart 6-1 outlines best practices for patient safety when teaching patients how to use ambulatory aids.

### Chart 6-1

## Best Practice for Patient Safety & Quality Care QSEN

### Gait Training With Selected Ambulatory Aids

#### Walker-Assisted Procedure

- Apply a transfer belt around the patient's waist.
- Guide the patient to a standing position.
- Remind the patient to place both hands on the walker.
- Ensure that the patient's body is well balanced.
- Teach the patient repeatedly to perform this sequence:
- Lift the walker.

- Move the walker about 2 feet forward and set it down on all legs.
- While resting on the walker, take small steps.
- Check balance.
- Repeat the sequence.

### Cane-Assisted Procedure

- Apply a transfer belt around the patient's waist.
- Guide the patient to a standing position.
- Be sure the cane is at the height of the patient's wrist when the arm is placed at his or her side. (Many canes can be adjusted to the required height.)
- Remind the patient to place his or her strong hand on the cane.
- Ensure that the patient's body is well balanced.
- Teach the patient to perform this sequence repeatedly:
- Move the cane and weaker leg forward at the same time.
- Move the stronger leg one step forward.
- Check balance and repeat the sequence.

Some patients never regain the ability to walk because of their impairment such as advanced multiple sclerosis or complete high spinal cord injury. They may require the use of a wheelchair and need to learn wheelchair or motorized-scooter mobility skills. With the help of physical and occupational therapy, most patients can learn to move anywhere in a wheelchair or electric scooter. For example, patients with high cervical injuries resulting in quadriplegia may require a motorized wheelchair that can be directed and propelled by moving their head or blowing into a device. A patient with severe, advanced multiple sclerosis may use a scooter because of fatigue or mobility impairment.

One way to increase MOBILITY is through ROM exercises. ROM techniques are beneficial for any patient with decreased mobility. Specific ROM techniques are presented in your basic foundations nursing textbook.

### Increasing Functional Ability

#### Planning: Expected Outcomes.

The patient with chronic conditions or disability is expected to increase functional ability in self-care and other self-management skills with or without assistive/adaptive devices.

#### Interventions.

ADLs, or self-care activities, include eating, bathing, dressing, grooming, and toileting. Encourage the patient to perform as much self-care as possible. Allow time to complete the task as independently as possible. Collaborate with the occupational therapist (OT) to identify ways in which self-care activities can be modified so the patient can perform them as independently as possible and with minimal frustration. For example, teach a patient with hemiplegia to put on a shirt by first placing the affected arm in the sleeve, followed by the unaffected arm. Slip-on shoes or

shoes with Velcro straps may be recommended for some patients. Encourage patients to practice and allow them time to try to be independent in ADLs.

In SNF settings federal regulations require that residents not lose their functional skills while they are in the facility. Most facilities have developed *restorative nursing* programs and have coordinated these programs with rehabilitation therapy and activities therapy. The focus of this coordinated effort includes:

- Bed mobility
- Walking
- Transfers
- Dressing
- Grooming
- Active range of motion
- Communication

A variety of devices are available for patients with chronic conditions and disability for *assisting with self-care*. An **assistive/adaptive device** is any item that enables the patient to perform all or part of an activity independently and safely. Examples include long-handled shoehorns and “reachers” to prevent bending and losing one's balance. [Table 6-4](#) identifies common devices and describes their use.

**TABLE 6-4**  
**Examples and Uses of Common Assistive/Adaptive Devices**

DEVICE	USE
Buttonhook	Threaded through the buttonhole to enable patients with weak finger mobility to button shirts Alternative uses include serving as pencil holder or cigarette holder
Extended shoehorn	Assists in the application of shoes for patients with decreased mobility Alternative uses include turning light switches off or on while patient is in a wheelchair
Plate guard and spork (spoon and fork in one utensil)	Applied to a plate to assist patients with weak hand and arm mobility to feed themselves; spork allows one utensil to serve two purposes
Gel pad	Placed under a plate or glass to prevent dishes from slipping and moving Alternative uses include placement under bathing and grooming items to prevent them from moving
Foam buildups	Applied to eating utensils to help patients with weak hand grasps feed themselves Alternative uses include application to pens and pencils to assist with writing or over a buttonhook to assist with grasping the device
Hook and loop fastener (Velcro) straps	Applied to utensils, a buttonhook, or a pencil to slip over the hand and provide a method of stabilizing the device when the patient's hand grasp is weak
Long-handled reacher	Assists in obtaining items located on high shelves or at ground level for patients who are unable to change positions easily
Elastic shoelaces or Velcro shoe closure	Eliminates the need for tying shoes

Many medical equipment stores and large pharmacies carry clothing and assistive/adaptive devices designed for patients with disabilities. The occupational therapist determines the specific needs for this equipment. Collaborate with the occupational therapist to look for creative and inexpensive alternatives to meeting these needs. For example, barbecue tongs may be used as “reachers” for pulling up pants or obtaining items on high shelves. A foam curler with the plastic insert removed may be placed over a pencil or eating utensil to make a built-up device. The patient might use an extended shoehorn to operate light switches from wheelchair height. Hook-and-loop fasteners (Velcro) sewn on clothes can prevent the frustrations caused by buttons and zippers.

**Assistive technology** has further increased the ability for people with disabilities to care for themselves. For example, mobile devices, telephones, and computer keyboards can be operated by voice-activation devices. **Robotic technology** provides mechanical parts for the extremities when they are not functional or have been amputated. However, the cost of these aids has prevented their widespread use.

Fatigue often occurs with chronic and disabling conditions. Therefore collaborate with the OT to assess the patient's self-care abilities and determine possible ways of *conserving energy*. Preparation for ADLs can help reduce effort and energy expenditure (e.g., gathering all necessary equipment before starting grooming routines). If a patient has high energy levels in the morning, he or she can be taught to schedule energy-intensive activities in the morning rather than later in the day or evening. Spacing activities is also helpful for conserving energy. In addition, allowing time to rest before and after eating and toileting decreases the strain on energy level.

## Clinical Judgment Challenge 6-1

Teamwork and Collaboration; Safety **QSEN**

An 81-year-old widow is admitted to a skilled nursing facility (SNF) for rehabilitation and reconditioning after emergent abdominal surgery as part of a 30-day acute care stay. After surgery she was out of bed only a few times in a chair and has not ambulated. Before her hospitalization she was able to walk independently with a walker and lived alone. The patient has a history of advanced rheumatoid arthritis, osteoarthritis, diabetes mellitus, and peripheral vascular disease. As her nurse you complete her admission assessment. She is alert and oriented and has no history of cognitive impairment.

1. What are this resident's priority problems? How might they affect the course of her rehabilitation?
2. With which health care team members will you need to collaborate and why?
3. Which safe patient handling practices would you need to use?
4. Which type of ambulatory assistive device would be most appropriate for her at this time?
5. What health teaching does the resident need regarding her mobility and functional ability?

## Preventing Pressure Injury

### Planning: Expected Outcomes.

The patient with chronic conditions or disability is expected to have intact skin and TISSUE INTEGRITY.

### Interventions.

*The best intervention to prevent pressure injury and maintain TISSUE INTEGRITY is frequent position changes in combination with adequate skin care and sufficient nutritional intake. Teach staff to assist with turning and repositioning at least every 2 hours if patients are unable to perform this activity independently. This time frame may not be sufficient for people who are frail and have thin skin, especially older adults. To determine the best turning schedule, assess the patient's skin condition during each turning and repositioning. For example, if the patient has been sleeping and the nursing assistant decides to postpone turning and repositioning, reddened areas over the bony prominences may be present. If reddened areas do not fade within 30 minutes after pressure relief or do not blanch, they may be classified as pre-pressure injury areas, or stage I pressure areas (see Chapter 25).*

*Patients who sit for prolonged periods in a wheelchair need to be repositioned at least every 1 to 2 hours. Each patient is evaluated by the physical or occupational therapist for the best seating pad or cushion that is comfortable yet reduces pressure on bony prominences. Patients who are able are taught to perform pressure relief by using their arms to lift their buttocks off the wheelchair seat for 20 seconds or longer every hour or more often if needed (sometimes referred to as *wheelchair push-ups*). The PT or OT helps them strengthen their arm muscles in preparation for performing pressure relief.*

Many patients with neurologic problems have decreased or absent sensation and may not be able to feel the discomfort of increased pressure. Check any areas where there may be pressure, including places such as the lower legs where the leg of the wheelchair could rub against the skin.

*Adequate skin care is an essential component of prevention. Perform or help patients complete skin care each time they are turned, repositioned, or bathed. Delegate and supervise skin care to unlicensed assistive personnel (UAP), including cleaning soiled areas, drying carefully, and applying a moisturizer. If a patient is incontinent, use topical barrier creams or ointments to help protect the skin from moisture, which can contribute to skin breakdown. To prevent damage to the already fragile capillary system, teach UAP to avoid rubbing reddened areas. Instead carefully observe the areas for further breakdown and relieve pressure on the areas as much as possible. Bed pillows are often good pressure-relieving devices. (See Chapter 25 for a complete discussion of skin care interventions.)*

*Sufficient NUTRITION is needed both to repair wounds and to prevent pressure injuries. Collaborate with the dietitian to assess the patient's food selection and ensure that it contains adequate protein and carbohydrates. Both the nurse and the dietitian closely monitor the patient's weight and serum prealbumin levels. If either of these indices decreases significantly, he or she may need high-protein, high-carbohydrate food supplements (e.g., milkshakes) or commercial preparations.*

Chapter 60 describes nutritional supplementation in detail.

*Pressure-relieving or pressure-reducing devices* include waterbeds, gel mattresses or pads, air mattresses, low-air loss overlays or beds, and air-fluidized beds. Mattress overlays such as air and gel types and replacement mattresses are often effective in reducing pressure. *The use of any mechanical device (except air-fluidized beds) does not eliminate the need for turning and repositioning.*

Specialty beds are categorized as either “low air loss” or “air fluidized.” Air-fluidized therapy provides the most effective pressure relief by distributing the patient's weight to prevent pressure in any one area. These beds are not often used to *prevent* skin breakdown because insurers may not reimburse the agency for the use of the bed. Therefore they are reserved for *severe skin problems* that have not healed with the use of a conventional bed or other mechanical device. The primary disadvantage of this therapy is its expense, which may exceed several hundred dollars for each day of use. Patients also report discomfort from the heat generated by the bed. Although air-fluidized beds are heavy to move, lighter and more portable versions are available for home use. The cost of air-fluidized therapy is reimbursed by some health insurance providers if the bed is deemed medically necessary to treat the patient's skin problem.

## Establishing Urinary Continence

### Planning: Expected Outcomes.

Most patients with chronic conditions or disability are expected to have normal patterns of urinary ELIMINATION without retention, infection, or incontinence.

### Interventions.

Neurologic disabilities often interfere with successful bladder control. These disabilities result in two basic functional types of neurogenic bladder: overactive (e.g., reflex or spastic bladder) and underactive (e.g., hypotonic or flaccid bladder).

An overactive **spastic** (upper motor neuron) **bladder** causes incontinence with sudden voiding. The bladder does not usually empty completely, and the patient is at risk for urinary tract infection. Neurologic problems affecting the upper motor neuron typically occur in patients with strokes or with high-level spinal cord injuries (cervical) or those above the mid-thoracic region. These injuries result in a failure of impulse transmission from the lower spinal cord areas to the cortex of the brain. When the bladder fills and transmits impulses to the spinal cord, the patient cannot perceive the sensation. Because there is no injury to the *lower* spinal cord and the voiding reflex arc is intact, the efferent (motor) impulse from a distended bladder is relayed, and the bladder contracts.

### Nonpharmacologic Management.

An underactive **flaccid** or **areflexic** (lower motor neuron) **bladder** results in urinary retention and overflow (dribbling). Injuries that damage the lower motor neuron at the spinal cord level of S2-4 (e.g., multiple sclerosis, spinal cord injury or tumor below T12) may directly interfere with the reflex arc or may result in inaccurate interpretation of impulses to the brain. The bladder fills, and afferent (sensory) impulses conduct the message via the spinal cord to the brain cortex. Because of the injury, the impulse is not interpreted correctly by the bladder center of the brain, and there is a failure to respond with a message for the bladder to contract.

Patients who cannot completely empty their bladder are at risk for post-void residual urine and subsequent possible urinary tract infection. **Post-void residual (PVR)** is the amount of urine remaining in the bladder after voiding. PVR assessments using a noninvasive ultrasound device called the *BladderScan* are performed by nurses at the bedside. The residual amount measured is accurate if the device is used correctly. Obesity may interfere with accuracy. The outcome of bladder ultrasonography is to prevent the unnecessary use of an indwelling urinary catheter. Long-term urinary catheters cause urinary tract infections that are often chronic. A picture of the *BladderScan* device is in Chapter 65.

The nurse can teach a variety of techniques to assist the patient in bladder management, including (Table 6-5):

---

**TABLE 6-5**  
**Management of Neurogenic Bladder**

---

FUNCTIONAL TYPE	NEUROLOGIC DISABILITY	DYSFUNCTION	RE-ESTABLISHING VOIDING PATTERNS
Reflex (spastic)	Upper motor neuron spinal cord injury above T12	Urinary frequency, incontinence but may not empty completely	Triggering or facilitating techniques Drug therapy, as appropriate Bedside bladder ultrasound Intermittent catheterization Consistent toileting schedule Indwelling urinary catheter (as last resort) Increased fluids
Flaccid	Lower motor neuron spinal cord injury below T12 (affects S2-4 reflex arc)	Urinary retention, overflow	Valsalva and Credé maneuvers Increased fluids Intermittent or indwelling urinary catheterization

- Facilitating, or triggering, techniques
- Intermittent catheterization
- Consistent scheduling of toileting routines (“timed void”)

These techniques may not be as effective in patients with physiologic changes associated with aging, including stress incontinence in women with weak pelvic floor muscles and overflow incontinence in men with enlarged prostate glands.

*Facilitating (triggering) techniques* are used to stimulate voiding. If there is an upper motor neuron problem but the reflex arc is intact (reflex bladder pattern), the voiding response can be initiated by any stimulus that sends the message to the spinal cord level S2-4 that the bladder might be full. Such techniques include stroking the medial aspect of the thigh, pinching the area above the groin, massaging the peno-scrotal area, pinching the posterior aspect of the glans penis, and providing digital anal stimulation.

When the patient has a lower motor neuron problem, the voiding reflex arc is not intact (flaccid bladder pattern), and additional stimulation may be needed to initiate voiding. Two techniques used to facilitate voiding are the Valsalva maneuver and the Credé maneuver. For the Valsalva maneuver, teach the patient to hold his or her breath and bear down as if trying to defecate. This technique should not be used by a spinal cord–injured patient who is at risk for bradycardia as a result of loss of vagus nerve control. Help the patient perform the **Credé maneuver** by placing his or her hand in a cupped position directly over the bladder area. Then instruct him or her to push inward and downward gently as if massaging the bladder to empty.

*Intermittent catheterization* may be needed for a flaccid or spastic bladder. Initially a urinary catheter is inserted to drain urine every few hours—after the patient has attempted voiding and has used the Valsalva and Credé maneuvers. If less than 100 to 150 mL of post-void residual is obtained, the nurse typically increases the interval between catheterizations. *The patient should not go beyond 8 hours between catheterizations.* If intermittent self-catheterization is needed at home after discharge from the rehabilitation facility, the patient may use a specialized appliance to help perform the procedure, especially if he or she has problems with manual dexterity. For those who cannot catheterize themselves, a family member or significant other may need to be taught how to perform the procedure.

Most patients who need intermittent catheterization have chronic bacteriuria (bacteria in the urine with a positive culture), especially those with spinal cord injury (SCI). Unless the patient has symptoms of a urinary tract infection (UTI) such as fever or burning when voiding, the infection is not treated. *Older adults may become acutely confused as the only indication of a UTI.*

*Consistent toileting routines* may be the best way to re-establish voiding continence when the patient has an overactive bladder. Assess the patient's previous voiding pattern and determine his or her daily routine. At a minimum the nurse or nursing staff helps the patient voiding after awakening in the morning, before and after meals, before and after physical activity, and at bedtime. *Remind the staff to toilet the patient every 2 hours during the day and every 3 to 4 hours at night.*

Consider the patient's bladder capacity, which may range from 100 to 500 mL, MOBILITY limitations, and restrictive clothing. Bladder capacity is determined by measuring urine output. Ensure that the patient is aware of nearby bathrooms at all times or has a call system to contact the nurse or unlicensed assistive personnel for assistance. **Chapter 66** also describes methods of achieving bladder control.

### Drug Therapy.

Drugs are not commonly used for urinary ELIMINATION problems. Mild overactive bladder problems may be treated with antispasmodics such as oxybutynin (Ditropan XL, Apo-Oxybutynin), solifenacin (VESIcare), or tolterodine (Detrol LA) to prevent incontinence on a short-term basis.

## Considerations for Older Adults

### Patient-Centered Care QSEN

When urinary antispasmodic drugs are used in older adults, observe for, document, and report hallucinations, delirium, or other acute cognitive changes caused by the anticholinergic effects of the drugs.

Patients with symptomatic UTIs are managed with short-term antibiotics such as trimethoprim (Trimpex) or trimethoprim/sulfamethoxazole (Septra, Bactrim). Patients who have frequent UTIs may be placed on pulse antibiotic therapy in which they alternate 1 week of antibiotic therapy with 3 weeks without antibiotics. Report progress in bladder training to the rehabilitation team so the best decision regarding drug therapy can be made.

### Establishing Bowel Continence

#### Planning: Expected Outcomes.

The patient with chronic conditions or disability is expected to have regular evacuation of stool without constipation. If possible, patients control their bowel ELIMINATION schedule.

#### Interventions.

Neurologic problems often affect the patient's bowel pattern by causing a reflex (spastic) bowel, a flaccid bowel, or an uninhibited bowel. Bowel retraining programs are designed for each patient to best meet the expected outcomes (Table 6-6). Pardee et al. (2012) found that establishing a successful bowel program can also enhance the quality of life for patients, especially those who have a spinal cord injury (SCI).

**TABLE 6-6**  
**Management of Neurogenic Bowel**

FUNCTIONAL TYPE	NEUROLOGIC DISABILITY	DYSFUNCTION	RE-ESTABLISHING DEFECTION PATTERNS
Reflex (spastic)	Upper motor neuron spinal cord injury above T12	Defecation without warning, but may not empty completely	Triggering mechanisms Facilitation techniques High-fiber diet Increased fluids Laxative use (for some patients) Consistent toileting schedule Manual disimpaction
Flaccid	Lower motor neuron spinal cord injury below T12 (affects S2-4 reflex arc)	Usually absent stools for patients with complete lesions	Triggering or facilitating techniques Increased fluids High-fiber diet Suppository use Consistent toileting schedule Manual disimpaction

*Upper motor neuron* diseases and injuries such as a cervical or mid-level spinal cord injury (e.g., quadriplegia) may result in a reflex (spastic) bowel pattern, with defecation occurring suddenly and without warning. With this intact reflex pattern, any facilitating or triggering mechanism may lead to defecation if the lower colon contains stool. An example of facilitating or triggering techniques is digital stimulation. For this technique, use a lubricated glove or finger cot and massage the anus in a circular motion for no less than 1 full minute.

## Nursing Safety Priority QSEN

### Action Alert

Do not use digital stimulation for patients with cardiac disease because of the risk for inducing a vagal nerve response. This response causes a rapid decrease in heart rate (bradycardia).

*Lower motor neuron* diseases and injuries (e.g., paraplegia) interfere with transmission of the nervous impulse across the reflex arc and may result in a flaccid bowel pattern, with defecation occurring infrequently and in small amounts. The use of manual disimpaction may get the best

results. Some patients also need oral laxatives and/or stool softeners. Digital stimulation or suppositories are usually unsuccessful because of loss of the reflex for elimination.

Neurologic injuries that affect the brain may cause an uninhibited bowel pattern, with frequent defecation, urgency, and reports of hard stool. Patients may manage uninhibited bowel patterns through a consistent toileting schedule, a high-fiber diet, and the use of stool softeners.

In some cases patients are not able to regain their previous level of control over their bowel function. The rehabilitation team assists in designing a bowel ELIMINATION program that accommodates the disability.

Collaborate with patients to schedule bowel ELIMINATION as close as possible to their previous routine. For example, a patient who had stools at noon every other day before the illness or injury should have the bowel program scheduled in the same way. An exception is the patient who prefers another time that best fits into his or her daily routine. If he or she is employed during the day, a time-consuming bowel elimination program in the morning may not work. The bowel protocol can then be changed to the evening when there is more time.

**Bowel retraining** programs for patients with neurologic problems are often designed to include a combination of methods. Although drug therapy should not be a first choice when formulating a bowel training program, consider the need for a suppository if the patient cannot re-establish defecation habits through a consistent toileting schedule, dietary modification, or digital stimulation.

Bisacodyl (Dulcolax), a commonly used laxative, may be prescribed either rectally or orally as part of a bowel training program. Suppositories must be placed against the bowel wall to stimulate the sacral reflex arc (if intact) and promote rectal emptying. Results occur in 15 to 30 minutes. Administer the suppository when the patient expects to defecate (e.g., after a meal) to coincide with the gastrocolic reflex. Using the suppository every second or third day is usually effective in re-establishing defecation patterns for patients with upper motor neuron problems where the reflex arc is not damaged.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Many rehabilitation patients are at high risk for constipation, especially older adults. Encourage fluids (at least eight glasses a day) and 20 to 35 g of fiber in the diet. Teach patients to eat two to three daily servings of whole grains, legumes, and bran cereals and five daily servings of fruits and vegetables. Do not offer a bedpan when toileting. Instead be sure that the patient sits upright on a bedside commode or bathroom toilet to facilitate defecation. Additional information regarding managing constipation can be found in Chapter 2.

## NCLEX Examination Challenge 6-3

### Physiological Integrity

Which statement by a patient with complete paraplegia indicates a need for the nurse to provide further teaching about bowel retraining?

- A. "I'll eat high-fiber foods each day to help prevent constipation."
- B. "I'll drink at least 8 to 10 glasses of water every day."
- C. "I'll do my daily bowel training routine after I eat breakfast."
- D. "I'll use a suppository to help empty my rectum."

### Care Coordination and Transition Management

Care coordination and transition management begin at the time of the patient's admission. If the patient is transferred from a hospital to an IRF or SNF, orient him or her to the change in routine and emphasize the importance of self-care. When the patient is admitted, a case manager and/or

OT/PT assess his or her current living situation at home. Together with the patient and family or significant others, they determine the adequacy of the current situation and the potential needs after discharge to home. The patient with chronic conditions and disability may require home care, assistance with ADLs, nursing care, or physical or occupational therapy after discharge.

Other health care professionals may be necessary to meet the patient's needs. For example, patients with traumatic brain injury (TBI) may benefit from life planning—a process that examines and plans to meet lifelong needs. External case managers specializing in life planning may be part of the interprofessional rehabilitation team.

### **Home Care Preparation.**

Before the patient returns home, the nurse assesses his or her readiness for discharge from the institutional setting. The home may be assessed in multiple ways and points in time.

#### **Predischarge Assessment.**

Before discharge the home must be assessed to ensure accessibility for the patient, given a new mobility impairment. This may be completed by having the family videotape or photograph the home and provide measurements to the PT or OT. Some facilities use live stream such as Skype or Face Time to “walk through” the home with the patient's family. Other programs provide a PT or OT visit to the home to assess its layout, accessibility, and potential barriers or environmental risks. For example, a patient with a fractured hip who is ambulating well with a walker may neglect to explain to the nurse that the bathroom in the home is accessible by stairway only. The patient may not consider that it is important to mention that throw rugs, which can cause falls, are scattered throughout the apartment. Fall prevention strategies in the home environment for older adults are discussed in [Chapter 3](#).

The accessibility of bathrooms, bedrooms, and kitchen is assessed. If the patient will use a wheelchair after discharge from the facility, home modifications such as ramps to replace steps may be needed. Doorways should be checked for adequate width. A doorway width of 36 to 38 inches (slightly less than 1 meter [m]) is usually sufficient for a standard-size wheelchair. Obese patients require bariatric wheelchairs and furniture and therefore need a wider door opening. Any room that the patient needs to use is assessed. The bedroom should have sufficient space for the patient to maneuver transfers to and from the wheelchair and the bed, if needed. The bathroom may need a toilet seat raised to at least 17 inches (43 cm).

Space requirements depend on the patient's need to use a wheelchair, walker, or cane. In the bathroom, grab bars may need to be installed before the patient comes home. Bathtub benches can provide support for the individual who has difficulty with mobility and, when used in combination with a handheld showerhead, can provide easily accessible bathing facilities. Assessment of the kitchen may or may not be critical, depending on whether the patient has help with cooking and preparing meals. If the patient will be cooking after discharge, the kitchen may need to be assessed for wheelchair or walker accessibility, appliance accessibility, and the need for adaptive equipment.

#### **Therapeutic Leave-of-Absence Visit.**

A second method of assessing the patient's home is through a brief home visit, also called a *leave-of-absence (LOA) visit*, before discharge. Explain the need for the trial home visit and assess the patient's comfort level with this idea. The patient who has been hospitalized for a lengthy period may feel intense anxiety about returning home. The nurse may allay such anxieties with careful preparation. Before the visit the rehabilitation nurse meets with the patient and family members or significant others to set goals for the visit and identify specific tasks to be attempted while at home. After the home visit interview the patient to determine the success of the visit and to assess additional education or training needs before final discharge and transition of care.

Going home may not be an option for everyone. Some patients may not have a support network of family members or significant others. For example, many older adults have no spouse or close friends living nearby. Children may live far away, which can make home care difficult. If no caregiver is available, the family must decide whether care can be provided in the home by an outside resource. The patient may need to be admitted to a 24-hour supervised health care setting such as a transitional living apartment, board and care facility, assisted-living facility, or nursing home. The least restrictive, least institutional discharge environment is the desired outcome for all patients.

## Self-Management Education.

The OT and PT teach the patient to perform ADLs and IADLs independently. The patient's learning potential and cognitive capacity are assessed. He or she is asked to perform or direct each skill or technique independently to verify understanding. Written material explaining the steps in the procedure is provided to the patient and family members to reinforce learning and provide support with the technique after discharge. Before distributing written material the rehabilitation team assesses the reading level of the material and determines whether it is appropriate for the patient's reading ability and language skills.

Any chronic conditions or disability necessitates changes in lifestyle and body image. Help the patient deal with such changes by encouraging verbalization of feelings and emotions. A focus on existing capabilities instead of disabilities is emphasized.

The patient may fail to relate psychologically to the disability during hospitalization. For example, he or she may display anger or frustration in attempting to perform self-care routines before discharge from the rehabilitation facility. Encourage the patient to be open about such feelings and to talk about ways to prevent worries from becoming realities after discharge. If needed, refer the patient to a mental health/behavior health care professional to help with adjustment and coping strategies.

The LOA home visit assists the patient and family members or significant others in psychosocial preparation for discharge. It allows the experience of the home situation while being able to return to the hospital environment after a few hours. Often the patient finds new problems in the home that must be addressed before discharge. Review this information in preparation for transition to the home.

## Health Care Resources.

After discharge to the home, various health care resources (e.g., physical therapy, home care nursing, vocational counseling) are available to the patient with chronic conditions and disabilities. Assess the need for additional care and support throughout the hospitalization and coordinate with the case manager and health care provider in arranging for home services. A newer process using technology called *telehealth* or *telerehabilitation* allows for care coordination in the home setting. Through the use of various electronic devices, phone, or computer software, a health care team member can monitor the patient's vital signs, weight, and other assessment data. Other programs such as Rehab@Home allow patients to perform therapeutic exercises at home using Wii, a webcam, and a computer.

### ◆Evaluation: Reflecting

The patient and rehabilitation team evaluate the effectiveness of interdisciplinary interventions based on the common patient problems. Expected outcomes may include that the patient will:

- Reach a level of mobility that allows him or her to function independently with or without assistive devices
- Prevent complications of decreased MOBILITY
- Perform self-care and other self-management skills independently or with minimal assistance, possibly using assistive/adaptive devices
- Have intact skin and underlying tissues.
- Establish urinary ELIMINATION without infection, incontinence, or retention
- Have regular evacuation of stool without constipation or incontinence

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Recall that rehabilitation is the process of learning to live with chronic and disabling conditions; the role of the rehabilitation nurse is outlined in [Table 6-1](#).
- Collaborate with members of the interprofessional rehabilitation team, including physicians, nurse practitioners, staff nurses, physiotherapists, occupational therapists, dietitians, and speech/language pathologists; the patient and family are the center of and members of the team. **QSEN: Teamwork and Collaboration**
- Know that acute (short-term) rehabilitation care occurs in a variety of settings, including inpatient rehabilitation facilities (IRFs) and skilled nursing facilities (SNFs) in either a nursing home or hospital. **Health Care Organizations**
- Delegate and supervise selected nursing tasks such as reporting reddened skin areas as part of quality care for the rehabilitation patient.
- After assessing the home environment, the case manager, OT, and/or rehabilitation nurse make recommendations to the patient and family about home modifications. **QSEN: Teamwork and Collaboration**
- Use evidence-based safe patient handling practices such as using mechanical lifts and working with other team members when assessing and moving patients to prevent injury and improve mobility. **QSEN: Evidence-Based Practice; Safety**
- Recall that the rehabilitation therapists teach patients transfer, bed mobility, and gait training techniques (see [Chart 6-1](#)).
- Encourage the patient to be as independent as possible when performing ADLs and safe mobility skills.

### Health Promotion and Maintenance

- In coordination with the PT and OT, assess the patient's ability to perform ADLs, IADLs, and MOBILITY skills using a functional assessment process. **QSEN: Teamwork and Collaboration**
- Prevent complications of immobility for clients, and teach them how to prevent complications by using interventions discussed in [Chapter 2](#). Examples include pressure injuries, urinary calculi, constipation, and venous thromboembolism. **QSEN: Evidence-Based Practice**

### Psychosocial Integrity

- Assess the patient's self-esteem and changes in body image caused by chronic or disabling health problems.
- Assess the patient's COGNITION to screen for depression, delirium, and dementia using tools such as the Confusion Assessment Method (CAM), especially for older adults. **QSEN: Safety**
- Assess the patient's and family's response to chronic and disabling conditions, including feelings of loss and grief.
- Assist patients in coping with their loss and assess the availability of support systems, especially for older adults. **QSEN: Patient-Centered Care**

### Physiological Integrity

- Assess rehabilitation patients as outlined in [Table 6-2](#) to help plan appropriate collaborative care.
- Review the Functional Independence Measure (FIM) system as one tool used to assess functional ability of the patient in rehabilitation, including the need for assistive/adaptive devices.

- Assess patients in rehabilitation for risk factors that make them likely to develop skin breakdown; interventions to prevent skin problems include repositioning and adequate NUTRITION. **QSEN: Quality Improvement**
- Patients with neurogenic bladder and bowel ELIMINATION problems are managed by training programs; overactive (spastic or reflex) and underactive (hypotonic or flaccid) elimination problems are managed differently (see [Tables 6-5](#) and [6-6](#)).
- In collaboration with the rehabilitation therapists, evaluate the ability of clients to use assistive/adaptive devices to promote independence. **QSEN: Teamwork and Collaboration**
- Determine patient and family needs regarding discharge to home or other community-based setting.

## CHAPTER 7

# End-of-Life Care Concepts

---

Mary K. Kazanowski

## PRIORITY AND INTERRELATED CONCEPTS

---

**The priority concept for this chapter is COMFORT.**

✚ The COMFORT concept exemplar for this chapter is End of Life, p. 104.

**The interrelated concepts for this chapter are:**

- COGNITION
- PERFUSION
- ETHICS

## LEARNING OUTCOMES

---

### **Safe and Effective Care Environment**

1. Collaborate with members of the interprofessional health care team when caring for the dying patient and family or other caregivers.
2. Discuss the legal and ETHICS obligations of the nurse with regard to end-of-life (EOL) care.

### **Health Promotion and Maintenance**

3. Explain to patients and their families the purpose and procedure for advance directives.

### **Psychosocial Integrity**

4. Assess the patient's and family's ability to cope with the dying process.
5. Assess and plan interventions to meet the dying patient's spiritual needs.
6. Incorporate the patient's cultural practices and beliefs when promoting COMFORT and providing care during the dying process and death.

### **Physiological Integrity**

7. Explain the difference between palliative care consultations and hospice.
8. Assess patients for signs and symptoms related to the end of life.
9. Explain how to promote COMFORT and provide evidence-based end-of-life care to the dying patient, including managing symptoms that may result from impaired COGNITION and PERFUSION.
0. Describe best practice guidelines for performing postmortem care.

## Overview of Death, Dying, and End of Life

Although dying is part of the normal life cycle, it is often feared as a time of pain and suffering. For the family, death of a member is a life-altering loss that can cause significant and prolonged suffering. As sad and difficult as the death may be, the experience of dying need not be physically painful for the patient or emotionally agonizing for the family. The dying process can be an opportunity to change a difficult situation into one that is tolerable, peaceful, comfortable, and meaningful for the patient and the family left behind.

Because nurses spend more time with patients than do any other members of the interprofessional health care team, it is the nurse who often has the greatest impact on an adult's experience with death. A nurse can affect the dying process to prevent death without dignity (sometimes referred to as a *bad death*) from occurring while striving to promote a peaceful and meaningful death (sometimes referred to as a *good death*). A **peaceful death** is one that is free from avoidable distress and suffering for patients and families, in agreement with patients' and families' wishes, and consistent with clinical practice standards.

Table 7-1 lists the most common causes of death in the United States. Of all people who die, only a small percentage of them die suddenly and unexpectedly. Most people die after a long period of illness (e.g., cardiac, renal, respiratory disease), with gradual deterioration until a significant decline preceding death. Most people who die are older than 65 years. In most countries family and other lay caregivers provide the majority of long-term home care. In some countries such as Canada, these caregivers may be compensated by the local or provincial government for the health care they provide.

---

**TABLE 7-1**  
**Leading Causes of Death in the United States**

---

- Heart disease
- Cancer (malignant neoplasms)
- Chronic lower respiratory disease
- Accidents (intentional injuries)
- Stroke
- Alzheimer's disease
- Diabetes mellitus
- Influenza and pneumonia
- Kidney disease (nephritis, nephrotic syndrome, and nephrosis)
- Suicide (intentional self-harm)

Data from National Vital Statistics Bureau. (2013). *10 Leading causes of death by age-group, United States—2013*. [www.cdc.gov/injury/wisqars/pdf/leading\\_causes\\_of\\_death\\_in\\_the\\_United\\_States\\_2013-a.pdf](http://www.cdc.gov/injury/wisqars/pdf/leading_causes_of_death_in_the_United_States_2013-a.pdf).

The U.S. health care system continues to be based on the acute care model, which is focused on prevention, early detection, and cure of disease. This focus and advances in survival rates for once deadly diseases have made it difficult for patients and providers to accept death as an outcome. Many health care providers view death as a failure. These views have led to a major deficiency in the quality of care provided to many at the end of life. In 1995 a landmark study highlighted the poor quality of dying experienced by hospitalized patients. The Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatment (SUPPORT) showed that more than 50% of a sample of 9105 hospitalized patients with a life-threatening disease had moderate-to-severe pain during the last days of their lives. It was also learned that they did not have their wishes met, even when their wishes were known.

Since the SUPPORT study, some progress has been made in improving the dying process in the United States. However, multiple barriers remain, often related to the reluctance of the patient, family, or health care provider to stop treatment when the end of life is near.

## Pathophysiology of Dying

**Death** is defined as the cessation of integrated tissue and organ function, manifested by lack of heartbeat, absence of spontaneous respirations, or irreversible brain dysfunction. It generally occurs as a result of an illness or trauma that overwhelms the compensatory mechanisms of the body, eventually leading to cardiopulmonary failure/arrest. Direct causes of death include:

- Heart failure secondary to cardiac dysrhythmias, myocardial infarction, or cardiogenic shock
- Respiratory failure secondary to pulmonary embolism, heart failure, pneumonia, lung disease, or respiratory arrest caused by increased intracranial pressure
- Shock secondary to infection, blood loss, or organ dysfunction, which leads to lack of blood flow (i.e., PERFUSION) to vital organs

Inadequate PERFUSION to body tissues deprives cells of their source of oxygen, which leads to anaerobic metabolism with acidosis, hyperkalemia, and tissue ischemia. Dramatic changes in vital organs lead to the release of toxic metabolites and destructive enzymes, referred to as *multiple organ dysfunction syndrome (MODS)*. As illness or organ damage progresses, the syndrome occurs with renal and liver failure. Renal or liver failure can also *start* the dying process.

When the body is hypoxic and acidotic, a lethal dysrhythmia such as ventricular fibrillation or asystole can occur, which ultimately leads to lack of cardiac output and PERFUSION. Shortly after cardiac arrest, respiratory arrest occurs. When respiratory arrest occurs first, cardiac arrest follows within minutes.

## Comfort Concept Exemplar End of Life

In 1991 the U.S. Congress passed the Patient Self-determination Act (PSDA), which granted Americans the right to determine the medical care they wanted if they became incapacitated. Documentation of self-determination is accomplished by completing an **advance directive (AD)**. The PSDA requires that a representative in every health care agency ask patients when admitted if they have written advance directives. Patients who do not have ADs should be provided with information on the value of having an AD in place and given the opportunity to complete the state-required forms. Ideally advance directives should be completed long before a medical crisis.

Advance directives vary from state to state but are readily available through Caring Connections, an online program of the National Hospice and Palliative Care Organization ([www.caringinfo.org](http://www.caringinfo.org)). Anyone can complete the forms without legal consultation. Titles for ADs vary from state to state. Generally speaking, most have a section in which one names a **durable power of attorney for health care (DPOAHC)** (Fig. 7-1). The DPOAHC is not the same as durable power of attorney for one's finances. It may or may not be the same person, depending on who the patient designates.

<p><b>INSTRUCTIONS</b></p> <p><b>PRINT YOUR NAME</b></p> <p><b>PRINT THE NAME AND ADDRESS OF YOUR AGENT</b></p> <p><b>INSTRUCTION STATEMENTS</b></p> <p><b>CIRCLE AND INITIAL THE RESPONSES THAT REFLECT YOUR WISHES</b></p> <p><b>TERMINAL ILLNESS</b></p> <p><b>PERMANENTLY UNCONSCIOUS</b></p> <p><b>ARTIFICIAL NUTRITION AND HYDRATION</b></p> <p><b>ADD PERSONAL INSTRUCTIONS (IF ANY)</b></p> <p><b>ALTERNATE AGENT</b></p> <p><b>PRINT THE NAME AND ADDRESS OF YOUR ALTERNATE AGENT</b></p> <p><b>LOCATION OF THE ORIGINAL AND COPIES</b></p> <p><b>DATE AND SIGN THE DOCUMENT HERE</b></p> <p><b>WITNESSING PROCEDURE</b></p> <p><b>WITNESSES MUST SIGN AND PRINT THEIR ADDRESSES</b></p> <p><b>AND A NOTARY PUBLIC OR JUSTICE OF THE PEACE MUST COMPLETE THIS SECTION</b></p> <p>©2005 National Hospice and Palliative Care Organization 2014 Revised</p>	<p style="text-align: center;"><b>NEW HAMPSHIRE ADVANCE DIRECTIVE</b> <b>PART I: NEW HAMPSHIRE DURABLE POWER OF ATTORNEY FOR HEALTH CARE</b></p> <p>I, _____, hereby appoint _____ (name) (name of agent)</p> <p>of _____ (address)</p> <p>as my agent to make any and all health care decisions for me, except to the extent I state otherwise in this directive or as prohibited by law. This durable power of attorney for health care shall take effect in the event I lack the capacity to make my own health care decisions.</p> <p>In the event the person I appoint above is unable, unwilling or unavailable, or ineligible to act as my health care agent, I hereby appoint _____ (name of an alternate agent) of _____ (address)</p> <p>as alternate agent.</p> <p>When making health care decisions for me, my agent should think about what action would be consistent with past conversations we have had, my treatment preferences as expressed in this advance directive, my religious and other beliefs and values, and how I have handled medical and other important issues in the past. If what I would decide is still unclear, then my health care agent should make decisions for me that my health care agent believes are in my best interest, considering the benefits, burdens, and risks of my current circumstances and treatment option.</p> <p><b>STATEMENT OF DESIRES, SPECIAL PROVISIONS, AND LIMITATIONS REGARDING HEALTH CARE DECISIONS.</b></p> <p>For your convenience in expressing your wishes, some general statements concerning the withholding or removal of life-sustaining treatment are set forth below. (Life-sustaining treatment is defined as procedures without which a person would die, such as but not limited to the following: mechanical respiration, kidney dialysis or the use of other external mechanical and technological devices, drugs to maintain blood pressure, blood transfusions, and antibiotics.) There is also a section which allows you to set forth specific directions for these or other matters. If you wish, you may indicate your agreement or disagreement with any of the following statements and give your agent power to act in those specific circumstances.</p> <p><b>A. LIFE-SUSTAINING TREATMENT.</b></p> <p>1. If I am near death and lack the capacity to make health care decisions, I authorize my agent to direct that: (Initial beside your choice of (a) or (b).) ____ (a) life-sustaining treatment not be started, or if started, be discontinued. OR ____ (b) life-sustaining treatment continue to be given to me.</p> <p>2. Whether near death or not, if I become permanently unconscious I authorize my agent to direct that: (Initial beside your choice of (a) or (b).) ____ (a) life-sustaining treatment not be started, or if started, be discontinued. OR ____ (b) life-sustaining treatment continue to be given to me.</p> <p><b>B. MEDICALLY ADMINISTERED NUTRITION AND HYDRATION.</b></p> <p>1. I realize that situations could arise in which the only way to allow me to die would be to not start or to discontinue medically administered nutrition and hydration. In carrying out any instructions I have given in this document, I authorize my agent to direct that: (Initial beside your choice of (a) or (b).) ____ (a) medically administered nutrition and hydration not be started or, if started, be discontinued. OR ____ (b) even if all other forms of life-sustaining treatment have been withdrawn, medically administered nutrition and hydration continue to be given to me.</p> <p><b>INITIAL THE RESPONSES THAT REFLECT YOUR WISHES</b></p> <p><b>C. ADDITIONAL INSTRUCTIONS.</b> Here you may include any specific desires or limitations you deem appropriate, such as when or what life-sustaining treatment you would want used or withheld, or instructions about refusing any specific types of treatment that are inconsistent with your religious beliefs or are unacceptable to you for any other reason. You may leave this question blank if you desire.</p> <p>_____ (attach additional pages as necessary)</p> <p>I hereby acknowledge that I have been provided with a disclosure statement explaining the effect of this directive. I have read and understand the information contained in the disclosure statement. The original of this document will be kept at: _____, and the following persons and institutions will have signed copies: _____ Name _____ Address _____ _____ Name _____ Address _____</p> <p><b>ADD OTHER INSTRUCTIONS, IF ANY, REGARDING YOUR ADVANCE CARE PLANS</b> <b>THESE INSTRUCTIONS CAN FURTHER ADDRESS YOUR HEALTH CARE PLANS, SUCH AS YOUR WISHES REGARDING HOSPICE TREATMENT, BUT CAN ALSO ADDRESS OTHER ADVANCE PLANNING ISSUES, SUCH AS YOUR BURIAL WISHES.</b></p> <p><b>PART II. NEW HAMPSHIRE DECLARATION</b></p> <p>Declaration made this _____ day of _____, (day) (month, year)</p> <p>I, _____, (name) being of sound mind, willfully and voluntarily make known my desire that my dying shall not be artificially prolonged under the circumstances set forth below, do hereby declare: If at any time I should have an incurable injury, disease or illness and I am certified to be near death or in a permanently unconscious condition by 2 physicians or a physician and an ARNP, and two physicians or a physician and an ARNP have determined that my death is imminent whether or not life-sustaining treatment is utilized and where the application of life-sustaining treatment would serve only to artificially prolong the dying process, or that I will remain in a permanently unconscious condition, I direct that such procedures be withheld or withdrawn, and that I be permitted to die naturally with only the administration of medication, the natural ingestion of food or fluids by eating or drinking, or the performance of any medical procedure deemed necessary to provide me with comfort care. I realize that situations could arise in which the only way to allow me to die would be to discontinue medically administered nutrition and hydration.</p> <p>In carrying out any instruction I have given under this section, I authorize that: (Initial beside your choice of (a) or (b).) ____ (a) medically administered nutrition and hydration not be started or, if started, be discontinued, OR ____ (b) even if other forms of life-sustaining treatment have been withdrawn, medically administered nutrition and hydration continue to be given to me.</p> <p>Other directions: _____</p>
--	---

FIG. 7-1 An example of a durable power of attorney for health care (DPOAHC). ©2005. National Hospice and

The DPOAHC, often referred to as a *health care proxy*, *health care agent*, or *surrogate decision maker*, does not make health care decisions until a physician states that the person lacks capacity to make his or her own health care decisions. This is usually the result of impairment in COGNITION.

To have decision-making ability, a person must be able to perform three tasks:

- Receive information (but not necessarily be totally oriented)
- Evaluate, deliberate, and mentally manipulate information
- Communicate a treatment preference

By definition, the comatose patient does not have decisional ability.

The second part of the advance directive is a **living will** (LW), which identifies what one would (or would not) want if he or she were near death. Treatments that are discussed include cardiopulmonary resuscitation (CPR), artificial ventilation, and artificial nutrition or hydration. The third type of advance directive is a do-not-resuscitate (DNR) or do-not-attempt-to-resuscitate (DNAR) order, signed by a physician or other authorized primary health care provider, which instructs that CPR not be attempted in the event of cardiac or respiratory arrest. DNRs/DNARs are intended for people with life-limiting conditions, for whom resuscitation is not prudent. Depending on the state of residence, people who have made the decision not to be resuscitated may have portable DNR documents and or bracelets to identify themselves as having directions not to resuscitate. Some states also have directives referred to as *POLST* (physician orders for life-sustaining treatment), which document additional instructions in case of cardiac or pulmonary arrest. Like portable DNRs/DNARs, POLST follow the patient across health care settings.

By law all primary health care providers in the United States must initiate CPR for a person who is not breathing or is pulseless unless that person has a DNR order. The problem with performing CPR is that it can be a violent and likely painful intervention that prevents a peaceful death. CPR may also be unsuccessful or result in the patient being more compromised than they were before the event, perhaps for life. Many patients and families do not understand the limitations of CPR and do not realize that it was never intended to be performed on patients with end-stage disease.

## Hospice and Palliative Care

The concept of hospice in the United States and other countries came about from a grassroots effort in response to the unmet needs of terminally ill people. As both a philosophy and a system of care, **hospice** is considered to be the model for quality, compassionate care for people facing a life-limiting illness or injury. Hospice uses a team-oriented approach to providing expert medical care, pain management, and emotional and spiritual support expressly tailored to the person's needs and wishes. Support is also provided to the person's loved ones. Hospice systems of care are provided in a variety of settings. They are often affiliated with home care agencies, providing services to patients at home or in a long-term care or assisted-living facility. Some communities also have hospice houses, which provide care to patients in the terminal phase of their lives.

Hospice services may also be provided in non-health-related institutions such as prisons. In their recent systematic review, Wion and Loeb (2016) described end-of-life and hospice care for prisoners who were older and/or had terminal illness (see [Evidence-Based Practice box](#)).

## Evidence-Based Practice QSEN

### Is End-of-Life Care Provided for Prisoners?

Wion, R. K., & Loeb, S. J. (2016). End-of-life care behind bars: A systematic review. *AJN*, 116(3), 24–36.

As the population ages, prisoners with long-term sentences are also aging and developing life-threatening and terminal health conditions. This study was conducted as a systematic review of the published research on end-of-life (EOL) care in prisons in the United States and the United Kingdom. Nineteen articles published between 2002 and 2014 met the inclusion criteria for review. While criteria varied across settings, hospice services were provided in many prisons, with a daily

average census of three hospice patients. Care was provided by prison staff, interprofessional health care team members, and inmates. In many cases the number and types of health care disciplines caring for prisoners were higher than those provided in community hospice settings. Inmate caregiving and training varied, but many inmates found that providing end-of-life care was a transformational experience.

**Level of Evidence: 1**

This research presents the results of an in-depth review of multiple research articles published in the United States (18 studies) and the United Kingdom (1 study).

**Commentary: Implications for Practice and Research**

Nurses who work in prisons are in a unique position to increase awareness of and information about available end-of-life care for inmates. Nurses in other settings often provide care for dying inmates and can facilitate care transition for follow-up when the inmate returns to the prison setting. All people deserve to have a dignified death regardless of their setting or circumstance.

The *Medicare Hospice Benefit* serves as a guide for hospice care in the United States. This benefit pays for hospice services for Medicare recipients who have a prognosis of 6 months or less to live and who agree to forego curative treatment for their terminal illness. Historically those with terminal cancer made up the majority of patients receiving hospice care. However, the proportion of patients with terminal cancer has decreased, with increases in numbers of patients with other terminal illnesses, (e.g., dementia, end-stage chronic obstructive pulmonary disease [COPD], cardiac disease, or neurologic disease).

Guidelines are available to help primary health care providers and families identify who is entitled to hospice care under Medicare. Patients who do not qualify for Medicare may have benefits through private insurance or government medical assistance programs (e.g., Medicaid).

**Considerations for Older Adults**

**Patient-Centered Care** QSEN

In the last 15 years, twice as many older adults died in hospice care as in a hospital or nursing home compared to the previous decade. Despite increase in use, hospice is often a last resort after aggressive critical care. Earlier referrals to hospice care would be a benefit for older adults and their families.

**Palliative care** is a philosophy of care for people with life-threatening disease that helps patients and families identify their outcomes for care, assists them with informed decision making, and facilitates quality symptom management. Unlike hospice, *palliation* is provided by a physician, nurse practitioner, or team of providers as a consultation visit, with one or more follow-up visits. Palliative care consultations are provided in a large number of hospitals and on an ambulatory care basis in some communities. [Table 7-2](#) compares palliative care to hospice care. Classic research has demonstrated the benefits of early initiation of palliative care consultation ([Campbell et al., 2012](#)). Despite these benefits, palliative care is often not implemented until late in the patient's illness ([Institute of Medicine \[IOM\], 2014](#)). Because of their proximity to patients, nurses are in an excellent position to identify individuals who would benefit from palliative consultation. To accomplish this desired outcome, nurses need to have knowledge of end-of-life (EOL) care, compassion, advocacy, and therapeutic communication skills.

**TABLE 7-2**  
**Comparison of Hospice and Palliative Care**

HOSPICE CARE	PALLIATIVE CARE
Patients have a prognosis of six (6) months or less to live.	Patients can be in any stage of serious illness.
Care is provided when curative treatment such as chemotherapy has been stopped.	A consultation is provided that is concurrent with curative therapies or therapies that prolong life.
Care is provided in 60- and 90-day periods with an opportunity to continue if eligibility criteria are met.	Care is not limited by specific time periods.
Ongoing care is provided by RNs, social workers, chaplains, and volunteers.	Care is in the form of a consult visit by a primary health care provider who makes recommendations; follow-up visits may be provided.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

Obtain information about the patient's diagnosis, past medical history, and recent state of health to identify the risks for symptoms of distress at the end of life. People with lung cancer, heart failure, or chronic respiratory disease are at high risk for respiratory distress and dyspnea as they decline. Those with brain tumors are at risk for seizure activity. Patients with tumors near major arteries (e.g., head and neck cancer) are at risk for hemorrhage. Those who have been experiencing pain often continue to have pain at the end of life, which may increase, decrease, or remain at the same level of intensity.

### Physical Assessment/Signs and Symptoms.

As death nears, patients often have signs and symptoms of decline in physical function, manifested as weakness; sleeping more; anorexia; and changes in cardiovascular function, breathing patterns, and genitourinary function. Level of consciousness often declines to lethargy, unresponsiveness, or coma. Cardiovascular dysfunction leads to decreases in peripheral circulation and poor tissue PERFUSION manifested as cold, mottled, and cyanotic extremities. Blood pressure decreases and often is only palpable. The dying person's heart rate may increase, become irregular, and gradually decrease before stopping. Changes in breathing pattern are common, with breaths becoming very shallow and rapid. Periods of apnea and **Cheyne-Stokes respirations** (apnea alternating with periods of rapid breathing) are also common. Death occurs when respirations and heartbeat stop.

As the patient's level of consciousness decreases, he or she may lose the ability to speak. When caring for those who are unable to communicate their distress or needs, identify alternative ways to assess symptoms of distress. Teach family caregivers to watch closely for objective signs of impaired COMFORT (e.g., restlessness, grimacing, moaning) and identify when these symptoms occur in relation to positioning, movement, medication, or other external stimuli. Teach them how to perform interventions that can help relieve discomfort and stress as described in [Chart 7-1](#).

#### 📄 Chart 7-1

### Patient and Family Education: Preparing for Self-Management

#### Common Physical Signs and Symptoms of Approaching Death With Recommended Comfort Measures

##### Coolness of Extremities

Circulation to the extremities is decreased; the skin may become mottled or discolored.

- Cover the person with a blanket.
- Do not use an electric blanket, hot water bottle, electric heating pad, or hair dryer to warm the person.

##### Increased Sleeping

Metabolism is decreased.

- Spend time sitting quietly with the person.
- Do not force the person to stay awake.
- Talk to the person as you normally would, even if he or she does not respond.

##### Fluid and Food Decrease

Metabolic needs have decreased.

- Do not force the person to eat or drink.
- Offer small sips of liquids or ice chips at frequent intervals if the person is alert and able to swallow.
- Use moist swabs to keep the mouth and lips moist and comfortable.
- Coat the lips with lip balm.

### Incontinence

The perineal muscles relax.

- Keep the perineal area clean and dry. Use disposable underpads (Chux) and disposable undergarments.
- Offer a Foley catheter for comfort.

### Congestion and Gurgling

The person is unable to cough up secretions effectively.

- Position the patient on his or her side. Use toothette to gently clean mouth of secretions.
- Administer medications to decrease the production of secretions.

### Breathing Pattern Change

Slowed circulation to the brain may cause the breathing pattern to become irregular, with brief periods of no breathing or shallow breathing.

- Elevate the person's head.
- Position the person on his or her side.

### Disorientation

Decreased metabolism and slowed circulation to the brain.

- Identify yourself whenever you communicate with the person.
- Reorient the patient as needed.
- Speak softly, clearly, and truthfully.

## Restlessness

Decreased metabolism and slowed circulation to the brain.

- Play soothing music and use aromatherapy.
- Do not restrain the person.
- Massage the person's forehead.
- Reduce the number of people in the room.
- Talk quietly.
- Keep the room dimly lit.
- Keep the noise level to a minimum.
- Consider sedation if other methods do not work.

Adapted from the Hospice of North Central Florida, Inc.

Although the patient's point of view is the most valid indicator of comfort or distress, the family's perception of symptoms and COMFORT level is also important. Family caregivers, health care providers, and dying patients may differ in their perceptions of symptoms in terms of intensity, significance, and meaning. Whereas primary health care providers are often able to identify symptoms of distress, families are often more knowledgeable about the patient's habits and preferences. Incorporate all pertinent information into the plan for symptom management and work with patients and families toward a common outcome.

Assess any symptom of distress in terms of intensity, frequency, duration, quality, exacerbating (worsening) and relieving factors, and effect on the patient's comfort when awake or asleep. A method for rating the intensity of symptoms should be used to facilitate ongoing assessments and evaluate treatment response. A rating scale of 0 to 10 is commonly used, with 0 indicating no distress and 10 indicating the worst possible distress. The intensity of the symptom before and after an intervention (e.g., medication) is documented by the nurse or the family caregiver and is used daily to evaluate the patient's overall COMFORT.

### Psychosocial Assessment.

People facing death may have fear and/or anxiety about their impending death with difficulty coping. Assess cultural considerations, values, and religious beliefs of the patient and family for their influence on the dying experience, control of symptoms, and family bereavement.

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Be aware that patients differ in their needs at the end of life, depending on their culture and spiritual beliefs. If possible, ask the patient what to tell the family about the patient's condition. In some cultures, families may not want to know about the terminal conditions of their loved ones. This decision may be based on respect for older family members. Ask the family what they want to know and if they desire the assistance of a language interpreter.

At the end of life adults may feel challenged about their spirituality or want spirituality to

become a bigger part of their lives (Finocchiaro, 2016). Many patients reaffirm their faith and/or spirituality with hope that they have a peaceful death and eternal hope and life. Other patients who do not believe in an afterlife may still experience hope for a cure and a comfortable death.

When assessing a patient's spirituality at the end of life, use this classic HOPE mnemonic as a guide. Determine the patient's:

H: Sources of hope and strength

O: Organized religion (if any) and role that it plays in one's life

P: Personal spirituality, rituals, and practices

E: Effects of religion and spirituality on care and end-of-life decisions (Finocchiaro, 2016)

Families of people near death often manifest fear, anxiety, and knowledge deficits regarding the process of death and their role in providing care. Assess the patient and family for fear and anxiety and their expectations of the death experience. Provide them with information about the process itself, emphasizing that symptoms of distress do not always occur and, if they occur, can be treated and controlled. Ask them if they want to talk to a **bereavement** (grief) counselor or want guidance from clergy. Explain the common emotional signs of approaching death as described in [Chart 7-2](#).

## Chart 7-2

# Patient and Family Education: Preparing for Self-Management

## Common Emotional Signs of Approaching Death

### Withdrawal

The person is preparing to “let go” from surroundings and relationships.

### Vision-Like Experiences

The person may talk to people you cannot see or hear and see objects and places not visible to you. These are not hallucinations or drug reactions.

- Do not deny or argue with what the person claims.
- Affirm the experience.

### Letting Go

The person may become agitated or continue to perform repetitive tasks. Often this indicates that something is unresolved or is preventing the person from letting go. As difficult as it may be to do or say, the dying person takes on a more peaceful demeanor when loved ones are able to say things such as, “It's okay to go. We'll be alright.”

### Saying Goodbye

When the person is ready to die and you are ready to let go, saying “goodbye” is important for both of you. Touching, hugging, crying, and saying “I love you,” “Thank you,” “I'm sorry,” or “I'll miss you so much” are all natural expressions of sadness and loss. Verbalizing these sentiments can bring comfort both to the dying person and to those left behind.

Adapted from the Hospice of North Central Florida, Inc.

## ◆ Interventions: Responding

The desired outcomes for a patient near the end of life (EOL) are that the patient will have:

- Needs and preferences met
- Control of symptoms of distress
- Meaningful interactions with family
- A peaceful death

Interventions are planned to meet the physical, psychological, social, and spiritual needs of patients using a coordinated interprofessional health team approach to end-of-life care. *Although the perception of hospice is that it provides care for the dying, the major focus of hospice care is on quality of life.*

When developing a plan of care for people nearing the end of their lives, consideration should be given for where the person wants to die. A large percentage of Americans would like to die at home. If this is the patient's preference, work with the patient, family, and health care provider to determine if this desired outcome is possible. Arrange for patients and families to meet with hospice representatives who are educated in end-of-life care in a variety of settings.

### Managing Symptoms of Distress.

The most common end-of-life symptoms that can cause the patient distress are:

- Pain
- Weakness
- Breathlessness/dyspnea
- Nausea and vomiting
- Agitation and delirium
- Seizures

Interventions to relieve symptoms of distress include positioning, administration of medications, and a variety of complementary and integrative therapies. When medications are used, they are often scheduled around the clock to maintain COMFORT and prevent recurrence of the symptom.

### Managing Pain.

*Pain is the symptom that dying patients fear the most.* Diseases such as cancer often cause tumor pain as a result of the infiltration of cancer cells into organs, nerves, and bones. Other causes of impaired COMFORT in dying patients include osteoarthritis, muscle spasms, and stiff joints secondary to immobility.

Both nonopioid and opioid analgesics play a role in pain management near the end of life. Patients who have had their pain controlled with either short- or long-acting opioids should continue their scheduled doses to prevent recurrence of the pain. However, as patients get closer to death, they often lose the ability to swallow. Long-acting oral opioids generally cannot be crushed; and rotation to rectal, transdermal, intravenous, or a subcutaneous route may be necessary. Short-acting nonopioids such as acetaminophen or opioids such as morphine sulfate oxycodone, or hydromorphone elixir can be given sublingually. They may also be given rectally if the patient and family are receptive to this route. Short-acting analgesics are quick acting; effective; and safe to administer, even to comatose patients.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Pain in older adults is often underreported and undertreated. Do not withhold opioid drugs from older adults at the end of their lives. Instead give low doses of opioids initially, with slow increases, monitoring for changes in mental status or excessive sedation.

Some experts in symptom management at the end of life (EOL) recommend discontinuing routine doses of opioids such as morphine when patients become oliguric or anuric. The rationale for this decision is to decrease the risk for delirium that may occur as the result of the inability of a failing kidney to excrete morphine metabolites from the body. If delirium is causing distress for the patient, consider changing the opioid to fentanyl, which does not have active metabolites. The delirium may improve. For patients with known renal failure, fentanyl should ideally be used from the start of opioid administration. When it cannot be easily obtained (i.e., when not available by sublingual or IV route), oxycodone may be a better choice than morphine. [Chapter 4](#) describes in detail the management of chronic pain.

### Complementary and Integrative Health.

Nonpharmacologic interventions are often integrated into the pain management plan. Some common approaches are presented here and in [Chapter 4](#).

*Massage* may decrease pain in people with cancer and is one of the most popular complementary interventions used for patients at the end of life. This technique involves manipulating the patient's muscles and soft tissue, which improves circulation and promotes relaxation. Patients who are severely weak, are arthritic, or have advanced age may not tolerate extensive massage but may benefit from a short treatment to sites of their choice. In working with patients with cancer, use light pressure and avoid deep or intense pressure. Massage should not be performed over the site of tissue damage (e.g., open wounds, tissue undergoing radiation therapy), in patients with bleeding disorders, and in those who are uncomfortable with touch ([Westman & Blaisdell, 2016](#)).

*Music therapy* is another complementary therapy used by people near the end of life that has been shown to decrease pain by promoting relaxation. Select music based on patient preferences and values.

*Therapeutic Touch* involves moving one's hands through the patient's energy field to relieve pain. Reiki therapy is another type of energy therapy being evaluated for its role in pain and symptom management. Use of Reiki requires a Reiki practitioner who is trained in the method.

*Aromatherapy* can be used in conjunction with other treatments to relieve pain near the end of life. It is thought to decrease pain by promoting relaxation and reducing anxiety. Lavender, capsicum, bergamot, chamomile, rose, ginger, rosemary, lemongrass, sage, and camphor have been used in end-of-life care ([Allard & Katseres, 2016](#)).

## NCLEX Examination Challenge 7-1

### Physiological Integrity

An older client with advanced dementia and severe osteoarthritis is unresponsive but grimaces and moans when repositioned. Which intervention is the **most** appropriate for the nurse to implement for this client?

- A. Administer acetaminophen 650 mg by mouth PRN.
- B. Start an intravenous with 5% D/W solution.
- C. Provide range of motion once a shift.
- D. Obtain an order for transdermal fentanyl.

### Managing Weakness.

Patients commonly experience weakness and fatigue as death nears. At this point they are generally advised to remain in bed to avoid falls and injuries. Mechanical or electric beds are often obtained to elevate the patient's head to promote air exchange and facilitate administration of medications, food, or fluids. Insertion of a long-term urinary (e.g., Foley) catheter to avoid the need for exertion with voiding should be offered as a COMFORT measure. Risk for infection should not be a consideration when a person is near death.

Weakness combined with decreased neurologic function may impair the ability to swallow (dysphagia). Once the patient has difficulty swallowing, oral intake should be limited to soft foods and sips of liquids, offered but not forced. Teach families about the risk for aspiration and reassure them that anorexia is normal at this stage. Families often have difficulty accepting that their loved ones are not being fed and may request that IV fluids be started. With great sensitivity, reinforce that having no appetite or desire for food or fluids is expected. Inform families that giving fluids can actually increase discomfort in a person with multisystem slowdown. Impaired COMFORT from fluid replacement could lead to respiratory secretions (and distress), increased GI secretions, nausea, vomiting, edema, and ascites. Most experts believe that dehydration in the last hours of life (i.e., terminal dehydration) does not cause distress and may stimulate endorphin release that promotes the patient's sense of well-being. To avoid a dry mouth and lips, moisten them with soft applicators and apply an emollient to lips.

**Drug Alert**

Dysphagia near death presents a problem for oral drug therapy. Although some tablets may be crushed, drugs such as sustained-release capsules should not be taken apart. Reassess the need for each medication. Collaborate with the prescriber about discontinuing drugs that are not needed to control pain, dyspnea, agitation, nausea, vomiting, cardiac workload, or seizures. In collaboration with a pharmacist experienced in palliation, identify alternative routes and/or alternative drugs to promote COMFORT and maintain control of symptoms. Choose the least invasive route such as oral, buccal mucosa (inside cheek), transdermal (via the skin), or rectal. Some oral drugs can be given rectally. Depending on patient needs, the subcutaneous or IV route may be used if access is available. The intramuscular (IM) route is almost never used at the end of life because it is considered painful and drug distribution varies among patients.

**Managing Breathlessness/Dyspnea.**

Dyspnea is a subjective experience in which the patient has an uncomfortable feeling of breathlessness, often described as terrifying. It is a common symptom of distress near the end of life, especially among older adults because of decreased oxygen reserves associated with aging. Patients, families, and health care providers often consider it the major cause of suffering at the end of life. Dyspnea can be:

- Directly related to the primary diagnosis (e.g., lung cancer, breast cancer, coronary artery disease, chronic obstructive pulmonary disease [COPD])
- Secondary to the primary diagnosis (e.g., pleural effusion)
- Related to treatment of the primary disease (e.g., heart failure caused by chemotherapy, pneumonitis, or constrictive pericarditis caused by radiation therapy, anemia related to chemotherapy)
- Unrelated to the primary disease (e.g., pneumonia or congestive heart failure [CHF]).

Depending on the cause, the pathophysiology of dyspnea can involve:

- Obstructive, restrictive, or vascular disturbances in the airways with tumor or lymph node involvement
- Pulmonary congestion secondary to fluid overload and/or cardiac dysfunction
- Bronchoconstriction and bronchospasm as seen with respiratory infection, COPD, or airway blockage by a tumor
- Decreased hemoglobin-carrying capacity as with anemia
- Hyperventilation secondary to neuromuscular disease with limited movement of the diaphragm

Perform a thorough assessment of the patient's dyspnea. Include onset, severity (e.g., 0-to-10 scale), and precipitating factors. Precipitating factors may include time of day, position, anxiety, pain, cough, or emotional distress. *Pharmacologic interventions should begin early in the course of dyspnea.* Nonpharmacologic interventions are used in conjunction with but not in place of drug therapy.

*Opioids such as morphine sulfate are the standard treatment for dyspnea near death.* They work by (1) altering the perception of air hunger, reducing anxiety and associated oxygen consumption, and (2) reducing pulmonary congestion. Patients who have not been receiving opioids are given starting doses of morphine 5 to 6 mg (or less for patients of advanced age) orally every 4 hours during the day and 10 mg at bedtime. If dyspnea occurs only with activity, give morphine before the activity up to every 2 hours. Those who are taking morphine or other opioids for pain may need higher doses for breathlessness, at times up to 50% more than their usual dose.

If a patient is having severe respiratory distress and poor oxygenation, morphine by mouth may need to be repeated as often as every 30 minutes and an IV or subcutaneous route may need to be established. Subcutaneous or IV doses of 1 to 2 mg of morphine may be given every 5 to 10 minutes until dyspnea is relieved.

*Oxygen therapy* for dyspnea near death has not been established as a standard of care for all patients. However, those who do not respond promptly to morphine or other drugs should be tried on oxygen (2 to 6 L by nasal cannula) to assess its effect. Patients often feel more comfortable when

the oxygen saturation is greater than 90%. If possible, provide oxygen by nasal cannula (NC) because masks can be frightening. If oxygen is not effective, discontinue it.

## Nursing Safety Priority QSEN

### Action Alert

Offer oxygen to any patient with dyspnea near death, regardless of his or her oxygen saturation, because COMFORT is the desired outcome. If the patient is feeling dyspneic even though the oxygen saturation is above 90%, be sure that he or she receives oxygen to relieve respiratory distress. In addition, offer an electric fan directed toward the patient's face. Some patients find the circulating air more helpful than oxygen therapy.

*Bronchodilators* such as albuterol (Proventil) or ipratropium bromide (Atrovent, Apo-Ipravent) via a metered-dose inhaler (MDI) or nebulizer may be given for symptoms of bronchospasm (heard as wheezes). *Corticosteroids* such as prednisone (Deltasone, Winpred) may also be given for bronchospasm and inflammatory problems within and outside the lung. Superior vena cava syndrome and cancer-related lymphangitis causing dyspnea may also respond to corticosteroids (also see [Chapter 22](#)).

People who have fluid overload with dyspnea, crackles on auscultation, peripheral edema, and other signs of chronic congestive heart failure (CHF) may be given a *diuretic* such as furosemide (Lasix, Uritol) to decrease blood volume, reduce vascular congestion, and reduce the workload of the heart. Furosemide can be administered by mouth, IV, or subcutaneously. IV push administration, which is effective within minutes, may be preferred for heart failure and pulmonary edema.

*Antibiotics* may be indicated for dyspnea related to a respiratory infection. A trial of an appropriate antibiotic may be considered to make the patient comfortable.

Secretions in the respiratory tract and oral cavity may also contribute to dyspnea near death. Loud, wet respirations (referred to as **death rattle**) are disturbing to family and caregivers even when they do not seem to cause dyspnea or respiratory distress. Reposition the patient onto one side to reduce gurgling and place a small towel under his or her mouth to collect secretions. *Anticholinergics* such as atropine (ophthalmic) solution 1% given sublingually every 4 hours as needed or hyoscyamine (Levsin) every 6 hours are commonly given to dry up secretions. Scopolamine may also be given transdermally to reduce secretion production. Oropharyngeal suctioning is not recommended for loud secretions in the bronchi or oropharynx because it is often not effective and may only agitate the patient.

Fear and anxiety may be components of respiratory distress at the end of life. For this reason benzodiazepines are commonly given when morphine does not fully control the person's dyspnea. Low-dose lorazepam (Ativan) is administered orally, sublingually, or IV every 4 hours as needed or around the clock.

Other nonpharmacologic interventions include:

- Limiting exertion to avoid exertional dyspnea
- Inserting a long-term urinary (Foley) catheter to avoid dyspnea on exertion
- Positioning the patient with the head of the bed up either in a hospital bed or a reclining chair to increase chest expansion
- Applying wet cloths to the patient's face
- Encouraging imagery and deep breathing

### Managing Nausea and Vomiting.

Although not as common a problem as pain or dyspnea, nausea and vomiting occur frequently among terminally ill patients during the last week of life. It is particularly common in patients with acquired immune deficiency syndrome (AIDS) and with breast, stomach, or gynecologic cancers.

Other causes of nausea and vomiting at the end of life include:

- Uremia (increased serum urea nitrogen)
- Hypercalcemia

- Increased intracranial pressure
- Constipation or impaction
- Bowel obstruction

If constipation is identified as the cause of nausea and vomiting, give the patient a biphosphate enema (e.g., Fleet) to remove stool quickly. If stool in the rectum cannot be evacuated, a mineral oil enema followed by gentle disimpaction may relieve the patient's distress. Nausea and vomiting related to other causes can be controlled by one or more antiemetic agents such as prochlorperazine (Compazine), ondansetron (Zofran), dexamethasone (Decadron, Deronil, Dexasone), or metoclopramide (Reglan, Maxeran). Based on a patient's response, one or more of these drugs may be combined and compounded into rectal suppositories or oral troches. In addition to providing medications, be sure to remove sources of odors and keep the room temperature at a level that the patient desires.

### Complementary and Integrative Health.

Aromatherapy using chamomile, camphor, fennel, lavender, peppermint, and rose may reduce or relieve vomiting. However, some patients may have worse nausea with aroma. Ask the patient and family about their preferences and respect culturally established practices.

### Managing Agitation and Delirium.

Agitation at the end of life first requires assessing for pain or urinary retention, constipation, or another reversible cause. If pain, urinary retention, and constipation are ruled out as causes, delirium (acute confusion) is suspected. Delirium is an acute and fluctuating change in mental status and is accompanied by inattention, disorganized thinking, and/or an altered level of consciousness. It can be hyperactive, hypoactive, or mixed (both). *Hypoactive (quiet)* delirium is probably not uncomfortable for patients. *Agitated (noisy)* delirium with psychotic and behavioral symptoms (e.g., yelling, hallucinations) can be uncomfortable, especially for family. [Chapter 3](#) discusses delirium in more detail.

When delirium occurs in the week or two before death, it is referred to as *terminal delirium*. Possible causes include the adverse effects of opioids, benzodiazepines, anticholinergics, or steroids. If medications are suspected causes, they may be decreased or discontinued. Ideally antipsychotic drugs are given only to control psychotic symptoms such as hallucinations and delusions. However, if they are needed to facilitate COMFORT, they should be available.

## Nursing Safety Priority QSEN

### Drug Alert

Do not give the patient more than one antipsychotic drug at a time because of the risk for adverse drug events (ADEs). A neuroleptic drug such as a low dose of haloperidol (Haldol, Peridol) 0.5-2 mg orally, IV, subcutaneously, or rectally is commonly used at the end of life. Although haloperidol has the potential to cause extrapyramidal symptoms or adverse cardiovascular events and death in older adults with dementia, the benefits of treating psychosis associated with delirium usually outweigh the risks.

Benzodiazepines generally are not used as a first choice for older adults with agitation because of their risk for causing delirium. Development of increased agitation after receiving a benzodiazepine could represent a paradoxical reaction—the opposite of what is expected.

### Complementary and Integrative Health.

Music therapy may produce relaxation by quieting the mind and promoting a restful state. Aromatherapy with chamomile may also help overcome anxiety, anger, tension, stress, and insomnia in dying patients.

### Managing Seizures.

Seizures are not common at the end of life but may occur in patients with brain tumors, advanced AIDS, and pre-existing seizure disorders. Around-the-clock drug therapy is needed to maintain a

high seizure threshold for patients who can no longer swallow antiepileptic drugs (AEDs). Benzodiazepines such as diazepam (Valium) and lorazepam (Ativan) are the drugs of choice. For home use rectal diazepam gel or sublingual lorazepam oral solution (2 mg/mL) may be preferred. As a second choice, barbiturates such as phenobarbital may be given rectally or IV.

### Managing Refractory Symptoms of Distress.

Patients receiving opioids for pain or dyspnea and other drugs such as antiemetics or antianxiety agents may experience mild sedation as a side effect to therapy. Depending on the patient and how soon death is expected, sedation may decrease with time. What is important to understand is that drug therapy for symptoms of distress at the end of life are guided by protocols, using medications believed to be safe, with the intent of alleviating suffering. *There is no evidence that administering medications for symptoms of distress using established protocols hastens death.* The ethical responsibility of the nurse in caring for patients near death is to follow guidelines for drug use to manage symptoms and to facilitate prompt and effective symptom management until death.

A small percentage of patients have refractory symptoms of distress that do not respond to treatment near the end of life. These patients may be candidates for **proportionate palliative sedation**—a care management approach involving the administration of drugs such as benzodiazepines (e.g., midazolam [Versed]), neuroleptics, barbiturates, or anesthetic agents (e.g., propofol [Diprivan]) for the purpose of decreasing suffering by lowering patient consciousness. *The intent of proportionate palliative sedation to promote comfort and not hasten death distinguishes it from euthanasia (discussed later in this chapter).*

## Clinical Judgment Challenge 7-1

### Patient-Centered Care QSEN; Clinical Judgment

An 88-year-old woman has been in a Memory Care unit of a long-term care facility for the past 2 years because of advanced Alzheimer's disease. She does not recognize her family and stopped communicating or providing self-care about 6 months ago. Last week she developed a urinary tract infection and was transferred to the skilled unit in the same facility for IV antibiotics. She has a durable power of attorney for health care (her daughter) and a living will, which her family supports. For the past 2 days, the resident has refused to drink or eat anything. She is barely responsive when the staff attempts to arouse her but moans at times.

1. Why is the resident receiving antibiotic therapy in view of the fact that Alzheimer's disease is considered a terminal health problem?
2. With which members of the interprofessional health care team will you consult and collaborate and why?
3. Is the resident a candidate for hospice at this time? Why or why not?
4. Which symptoms of distress do you anticipate that she may have based on your clinical judgment?

### Meeting Psychosocial Needs.

The personal experience of dying or of losing a loved one through death is life altering. Unexpected deaths, particularly in young people, tend to be most traumatic. When a person has a chronic life-threatening disease, he or she and the family may have some knowledge of the expected outcome. However, others may have never considered their illness to be potentially terminal. It is important to first assess what patients and family understand about the illness and then help them identify the desired outcomes for care in its context.

Whereas death is the termination of life, dying is a process. People facing death may demonstrate emotional signs and symptoms of their response to the dying process through behaviors that equate to saying goodbye or through actual withdrawal. Some patients attempt to make families feel better by reassuring them that everything will be fine. Teach families that such behaviors are normal (see [Chart 7-2](#)).

## Assisting Patients During the Grieving Process.

**Grief** is the emotional feeling related to the perception of the loss. Patients who are dying suffer not only from the anticipated death but also from the loss of the ability to engage with others and in the world. **Mourning** is the outward social expression of the loss. Interventions to help patients and families grieve and mourn are based on cultural beliefs, values, and practices. Some patients and their families express their grief openly and loudly, whereas others are quiet and reserved. [Table 7-3](#) lists basic beliefs regarding death, dying, and afterlife for some of the major religions.

**TABLE 7-3**

### Basic Beliefs Regarding Care at End of Life and Death Rituals for Selected Religions

<b>Christianity</b>
<ul style="list-style-type: none"> <li>• There are many Christian denominations, which have variations in beliefs regarding medical care near the end of life.</li> <li>• Roman Catholic tradition encourages people to receive Sacrament of the Sick, administered by a priest at any point during an illness. This sacrament may be administered more than once. Not receiving this sacrament will NOT prohibit them from entering heaven after death.</li> <li>• People may be baptized as Roman Catholics in an emergency situation (e.g., person is dying) by a layperson. Otherwise they are baptized by a priest.</li> <li>• Christians believe in an afterlife of heaven or hell once the soul has left the body after death.</li> </ul>
<b>Judaism</b>
<ul style="list-style-type: none"> <li>• The dying person is encouraged to recite the confessional or the affirmation of faith, called the <i>Shema</i>.</li> <li>• According to Jewish law, a person who is extremely ill and dying should not be left alone.</li> <li>• The body, which was the vessel and vehicle to the soul, deserves reverence and respect.</li> <li>• The body should not be left unattended until the funeral, which should take place as soon as possible (preferably within 24 hours).</li> <li>• Autopsies are not allowed by Orthodox Jews, except under special circumstances.</li> <li>• The body should not be embalmed, displayed, or cremated.</li> </ul>
<b>Islam</b>
<ul style="list-style-type: none"> <li>• Based on belief in one God Allah and his prophet Muhammad. Qur'an is the scripture of Islam, composed of Muhammad's revelations of the Word of God (Allah).</li> <li>• Death is seen as the beginning of a new and better life.</li> <li>• God has prescribed an appointed time of death for everyone.</li> <li>• Qur'an encourages humans to seek treatment and not to refuse treatment. Belief is that only Allah cures but that Allah cures through the work of humans.</li> <li>• On death the eyelids are to be closed, and the body should be covered. Before moving and handling the body, contact someone from the person's mosque to perform rituals of bathing and wrapping body in cloth.</li> </ul>

Data from [Giger, J. N. \(2013\). \*Transcultural nursing: Assessment and intervention\* \(6th ed.\). St. Louis: Mosby.](#)

Nursing interventions are aimed at providing appropriate emotional support to allow patients and their families verbalize their fears and concerns. Support includes keeping the patient and family involved in health care decisions and emphasizing that the goal is to keep the patient as comfortable as possible until death.

*Intervene with those grieving an impending death by "being with" as opposed to "being there."* "Being with" implies that you are physically and psychologically with the grieving patient, empathizing to provide emotional support. Listening and acknowledging the legitimacy of the patient's and/or family's impending loss are often more therapeutic than speaking; this concept is often referred to as **presence**. Nurses facilitate the expression of grief by giving the person who is mourning permission to express himself or herself. Your manner and words show that these expressions of grief are acceptable and expected. An example of therapeutic communication might be "This must be very difficult for you" or "I'm sorry this is happening."

*Do not minimize a patient's or family member's reaction to an impending loss/death.* Avoid trite assurances such as "Things will be fine. Don't cry," "Don't be upset. She wouldn't want it that way," or "In a year you will have forgotten." Such comments can be barriers to demonstrating care and concern. Accept whatever the grieving person says about the situation. Remain present, be ready to listen attentively, and guide gently. In this way you can help the bereaved family and significant others prepare for the necessary reminiscence and integration of the loss.

*Storytelling through reminiscence and life review can be an important activity for patients who are dying.* **Life review** is a structured process of reflecting on what one has done through his or her life. This is often facilitated by an interviewer. **Reminiscence** is the process of randomly reflecting on memories of events in one's life. The benefits of storytelling through either method provide the ability to attain perspective and enhance meaning. Suggest that the patient and family record autobiographic stories (print or video), write memories in a journal, or develop a scrapbook. Young dying parents often write letters or record videos for their children when they are older.

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

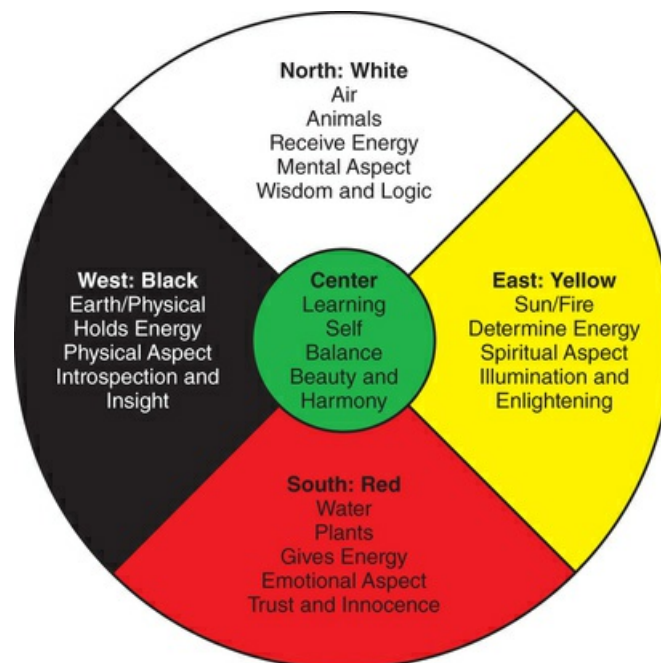

**Spirituality** is whatever or whoever gives ultimate meaning and purpose in one's life that invites particular ways of being in the world in relation to others, oneself, and the universe. A person's spirituality may or may not include belief in God. **Religions** are formal belief systems that provide

a framework for making sense of life, death, and suffering and responding to universal spiritual questions. Religions often have beliefs, rituals, texts, and other practices that are shared by a community. Spirituality and religion can help some patients cope with the thought of death, contributing to quality of life during the dying process.

Perform a spiritual assessment to identify the patient's spiritual needs and facilitate open expression of his or her beliefs and needs. A spiritual assessment could start with questions such as "What is important to you?" or "What gives you meaning or purpose in your life?"

When assessing the spiritual needs of the dying patient, consider end-of-life preferences based on ethnic beliefs and practices. For example, the medicine wheel represents the spiritual journey to find one's own path for indigenous people in many countries, including American Indians (e.g., Cherokee, Navajo, Lakota) and Aboriginal people (e.g., Inuit, First Nations) in Canada and Alaska (also known as *Canada or Alaska Natives*). The medicine wheel helps people in these groups maintain balance and harmony within four life dimensions (Fig. 7-2). Depending on specific tribal practices and beliefs, the dimensions may be represented by colors, seasons, or directions.

**FIG. 7-2** An example of a medicine wheel used by indigenous people to provide harmony and balance in life and transition into the spirit worlds after death.

As part of the dying process, certain tribal ceremonies must take place for patients to have a peaceful transition into the Spirit World and experience a "good death." One special ceremony involves smudging: Selected tribal medicines are burned, and the smoke is passed over the patient's body to cleanse it.

Regardless of whether a person has had an affiliation with a religion or a belief in God or other Supreme Being, he or she can experience what is referred to as *spiritual* or *existential distress*. Existential distress is brought about by the actual or perceived threat to one's continued existence. Terminal illness and facing death can pose a profound threat to one's personhood. The main task for a person at the end of life is coming to terms with one's losses, which may include loss of meaning, loss of relationships, and facing the unknown. Acknowledge the patient's spiritual pain and encourage verbalization. Use a family tree to discuss relationships, fears, hopes, and unfinished business. If the patient or family prefers, arrange for counseling with chaplains, spiritual leaders, or others trained in end-of-life care. *Do not try to explain the loss in philosophic or religious terms.* Statements such as "Everything happens for the best" or "God sends us only as much as we can bear" are not helpful when the person has yet to express feelings of anguish or anger.

Although emotionally challenging, witnessing the death of a loved one may help facilitate the family to accept death. Witnessing how ill a person is makes the event real and enhances an

understanding of how disease affects bodily function and decline. Describe the physical signs in detail—realistic enough to be unmistakable yet not so graphic as to alarm the listeners (see [Chart 7-1](#)). Booklets with this information should be provided to families to help them see what is expected and “normal” to the dying process.

Families witnessing the dying process often have difficulty distinguishing what is a normal finding of decline from signs and symptoms of distress. Instructing families about signs and symptoms of pain (e.g., grimacing, moaning, guarding behaviors) or dyspnea is essential. Emphasize that, in the absence of dyspnea or pain, patients often die very peacefully with cessation of breathing. Nurses and family members know that a person has died when he or she stops breathing. [Chart 7-3](#) lists other manifestations of death.

### **Chart 7-3**

## **Patient and Family Education: Preparing for Self-Management**

### **Physical Manifestations Indicating That Death Has Occurred**

- Breathing stops.
- Heart stops beating.
- Pupils become fixed and dilated.
- Body color becomes pale and waxy.
- Body temperature drops.
- Muscles and sphincters relax.
- Urine and stool may be released.
- Eyes may remain open, and there is no blinking.
- The jaw may fall open.
- Observers may hear trickling of fluids internally.

Nurses, patients, and families may benefit from written information about the dying process and what is known about the patient experience and needs. *Fast Facts and Concepts* are a group of evidence-based summaries on key palliative care topics available on the Palliative Care Network of Wisconsin (2016) website (<http://www.mypcnow.org>). They provide concise, practical, peer-reviewed information on topics common to patients facing serious illness.

In Canada, the Canadian Hospice Care Association provides information for patients, families, lay caregivers/volunteers, and members of the interprofessional health care team. A number of documents on palliative care and hospice services are available on the website ([www.chpca.net](http://www.chpca.net)).

### **NCLEX Examination Challenge 7-2**

#### **Psychosocial Integrity**

A client receiving palliative care asks the nurse, “Why is this happening to me?” What is the nurse's **best** response?

- A. “I don't know. God only knows when your time is up on this earth.”
- B. “I'm sorry. I know that this is a difficult time for you.”

C. "It's going to be OK; at least you aren't leaving any family behind."

D. "We'll make sure that all of your needs are met, so don't worry."

## Postmortem Care

If the death was in the home and expected, emergency assistance (911) should *not* be called. If the person was a patient in a hospice program, the family calls hospice. If a death is unexpected or suspicious, the medical examiner is notified. Otherwise the nurse or primary health care provider performs the pronouncement and completes a death certificate (Chart 7-4). Most states allow nurses to pronounce death in nursing homes and other long-term care facilities, but only a few states permit nurses to pronounce in acute care facilities such as hospitals. Be sure to check your health care agency policies for who can pronounce death and the specific procedure to follow.

### Chart 7-4

## Best Practice for Patient Safety & Quality Care QSEN

### Pronouncement of Death

- Note time of death that the family or staff reported the cessation of respirations.
- Identify the patient by identification (ID) tag if in facility. Note the general appearance of the body.
- Ascertain that the patient does not rouse to verbal or tactile stimuli. Avoid overtly painful stimuli, especially if family members are present.
- Auscultate for the absence of heart sounds; palpate for the absence of carotid pulse.
- Look and listen for the absence of spontaneous respirations.
- Document the time of pronouncement and all notifications in the medical record (i.e., to attending physician). Document if the medical examiner needs to be notified (may be required for unexpected or suspicious death). Document if an autopsy is planned per the attending primary health care provider and family.
- If your state and agency policy allows an RN to pronounce death, document as indicated on the death certificate.

After the patient dies, ask the family or other caregivers if they would like to spend time with the patient to help them cope with what has happened and say their good-byes. Even if the death has been anticipated, no one knows how he or she will feel until it occurs. It may take hours to days to weeks or months for each person to realize the full effect of the event. Some family members may find it therapeutic to bathe and prepare the person's body for transfer to the funeral home or the hospital morgue. Offer families this opportunity if it is culturally acceptable.

Before preparing the body for transfer, ask the primary health care provider whether an autopsy will be required. When the death is expected, an autopsy is not likely. An autopsy is generally performed only when the cause of death is not known. Some religions such as Orthodox Jews do not allow autopsies.

After the family or significant others view the body, follow agency procedure for preparing the patient for transfer to either the morgue or a funeral home. In the hospital a postmortem kit is generally used with a shroud and identification tags. Chart 7-5 describes best practice guidelines for postmortem care.

### Chart 7-5

## Best Practice for Patient Safety & Quality Care QSEN

### Postmortem Care

- Provide all care with respect to communicate that the person was important and valued.
- Ask the family or significant others if they wish to help wash the patient or comb his or her hair; respect and follow their cultural practices for body preparation.
- If no autopsy is planned, remove or cut all tubes and lines according to agency policy.
- Close the patient's eyes unless the cultural/religious practice is for a family member or other person to close the eyes.
- Insert dentures if the patient wore them.
- Straighten the patient and lower the bed to a flat position.
- Place a pillow under the patient's head.
- Wash the patient as needed and comb and arrange the patient's hair unless the family desires to perform bathing and body preparation.
- Place waterproof pads under the patient's hips and around the perineum to absorb any excrement.
- Clean the patient's room or unit.
- Allow the family or significant others to see the patient in private and to perform any religious or cultural customs they wish (e.g., prayer).
- Assess that all who need to see the patient have done so before transferring to the funeral home or morgue.
- Notify the hospital chaplain or appropriate religious leader if requested by the family or significant others.
- Ensure that the nurse or physician has completed and signed the death certificate.
- Prepare the patient for transfer to either a morgue or funeral home; wrap the patient in a shroud (unless the family has a special shroud to use), and attach identification tags per agency policy.

## Ethics and Dying

Euthanasia is a term that has been used to describe the process of ending one's life. *Active euthanasia* implies that primary health care providers take action (e.g., give medication or treatment) that purposefully and directly causes the patient's death. *Active euthanasia, even with the patient's permission, is not supported by most health professional organizations in the United States, including the American Nurses Association.*

*Physician-assisted suicide (PAS)*, sometimes referred to as assisted dying, is gaining worldwide public support. A few European countries, including Belgium, Switzerland, Luxembourg, and the Netherlands, have had legalized physician-assisted suicide for terminally ill patients for a number of years. In 2015 the Canadian Supreme Court recently overturned a ban on physician-assisted suicide. In the United States PAS is now legally approved in Oregon, Washington, Vermont, Montana, and New Mexico. Twenty-six other states and the District of Columbia are considering legislation on end-of-life options. At this time nurses are generally not involved in physician-assisted suicide but need to be knowledgeable about the legislation in the state where they practice.

*Withdrawing or withholding life-sustaining therapy*, formerly called *passive euthanasia*, involves discontinuing one or more therapies that might prolong the life of a person who cannot be cured by the therapy. Another phrase sometimes used is "letting the person die naturally" or "allowing natural death (AND)," as discussed earlier in this chapter. *In this situation, the withdrawal of the intervention does not directly cause the patient's death.* The progression of the patient's disease or poor health status is the cause of death. Professional health care organizations and some religious communities support the right of patients and their surrogate decision makers to refuse or stop treatment when patients are close to death and interventions are considered medically futile or capable of causing harm. The U.S. court system also supports withdrawal of aggressive treatment and the rights of surrogate decision makers to refuse or stop treatment.

A newer concept as the legal alternative method for death in all 50 states is *voluntary stopping of eating and drinking (VSED)*, also called *terminal dehydration* (Lachman, 2015). With VSED, competent patients with a terminal or incurable disease or illness refuse to eat or drink to hasten their death. Many patients want control over their lives and wish to die rather than continue experiencing severe pain and suffering. In addition, patients often want to end the caregiver burden that is often assumed by the family or significant other for their care. As described earlier in this chapter, terminal dehydration is not painful when discomfort is managed with palliative measures (Lachman, 2015).

Nurses are usually in the best and most immediate position to discuss these issues. To do this, they must be knowledgeable about terminology and ethical issues related to death and dying. In all cases the principles of informed consent must be met: the patient is competent, the death is voluntary, and the patient understands the benefit, burden, and consequences of the death.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Hospice care uses an interprofessional team-oriented approach to expert medical care, pain management, and emotional and spiritual support expressly tailored to the person's needs and wishes. Support is also provided to the person's family, friends, and lay caregivers. **QSEN: Teamwork and Collaboration**
- The decision by DPOAHC to withdraw or withhold life-sustaining therapy is supported by the US Supreme Court and other professional/religious organizations.
- Be aware that physician-assisted suicide is legal in several countries and five states in the United States. However, legislation for the right to die has been introduced in 26 other states and the District of Columbia. **Ethics**
- Be aware that nurses have an ethical obligation to provide timely information about expected care outcomes so patients and families can make the best end-of-life decisions. **Ethics**

### Health Promotion and Maintenance

- Assess the patient and family to determine if they have written advance directives such as a durable power of attorney for health care (DPOAHC), a living will, or portable DNR/DNAR.
- Stress the importance of having a DPOAHC to inform health care providers of your wishes if you lack capacity.
- Teach the patient and family that an advance directive is a written document that specifies what, if any, extraordinary actions the patient would want if he or she could no longer make decisions about care.

### Psychosocial Integrity

- Assess the patient's emotional signs of impending death; assess coping ability of the patient and family or other caregiver (see [Chart 7-2](#)).
- Incorporate the patient's personal cultural practices and spiritual beliefs regarding death and dying (see [Table 7-3](#)). **QSEN: Patient-Centered Care**
- Be aware that people facing death may experience fear and anxiety about their impending death and have difficulty coping.
- Provide psychosocial interventions to support the patient and family during the dying process.

### Physiological Integrity

- Death is defined as the cessation of integrated tissue and organ function, manifested by cessation of heartbeat, absence of spontaneous respirations, or irreversible brain dysfunction.
- Hospice and palliative care are different, as described in [Table 7-2](#).
- Assess the patient for pain, dyspnea, agitation, nausea, and vomiting, which are common problems at the end of life. **QSEN: Evidence-Based Practice**
- Recognize that older adults are often undertreated for pain or other symptoms at the end of life.
- Assess for the common physical signs of approaching death, as listed in [Chart 7-1](#).
- Medications are frequently given to control dyspnea, pain, nausea, vomiting, delirium, and seizures in patients near death.
- Because of the risk for delirium, particularly in older adults, providers may avoid use of benzodiazepines for treatment of anxiety, even at the end of life. Development of increased

agitation after receiving benzodiazepine could represent a paradoxical reaction. **QSEN: Safety**

- Terminal delirium may occur in a week or two before death. Haloperidol given orally or IV is the drug of choice to manage psychosis associated with delirium.
- Assessment of oxygen saturation for patients at the end of life is not necessary. Oxygen should be provided based on comfort. **QSEN: Evidence-Based Practice**
- Common complementary and integrative therapies used for symptom management at the end of life include aromatherapy, music therapy, and energy therapies such as Therapeutic Touch.
- Follow [Chart 7-5](#) for best-practice guidelines for performing postmortem care; incorporate the patient's cultural and religious beliefs in body preparation and burial (see [Table 7-3](#)). **QSEN: Patient-Centered Care**

## UNIT II

# Principles of Emergency Care and Disaster Preparedness

### OUTLINE

---

Chapter 8 Principles of Emergency and Trauma Nursing

Chapter 9 Care of Patients With Common Environmental Emergencies

Chapter 10 Principles of Emergency and Disaster Preparedness

## CHAPTER 8

# Principles of Emergency and Trauma Nursing

Linda Laskowski-Jones, Karen L. Toulson

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- SAFETY
- TEAMWORK AND INTERPROFESSIONAL COLLABORATION
- COMMUNICATION

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Describe the emergency department (ED) environment, including vulnerable populations seen.
2. Engage in TEAMWORK AND INTERPROFESSIONAL COLLABORATION with interprofessional team members in the ED.
3. Implement strategies to maintain staff and patient SAFETY in the ED.
4. Explain selected core competencies required of ED nurses.
5. Prioritize order of ED care delivery via triage.
6. Prioritize resuscitation interventions based on assessment of the injured patient.

### Psychosocial Integrity

7. Implement nursing interventions to support survivors after the death of a loved one.

### Physiological Integrity

8. Describe the expected sequence of events from admission through disposition of a patient treated in the ED.

The health care needs of individuals within the United States continue to see a rise in the demand for emergency care. Functioning as safety nets for communities of all sizes, emergency departments (EDs) provide services to insured and uninsured patients seeking medical care. They are also responsible for SAFETY through public health surveillance and emergency disaster preparedness. Some hospital-based EDs also provide observation, procedural care, and employee or occupational health services. Other hospital-based EDs have interprofessional specialty teams who take part in TEAMWORK AND INTERPROFESSIONAL COLLABORATION to provide first-line care for patients with stroke and cardiac problems ([The Joint Commission \[TJC\], 2017b](#)). The role of the ED is so vital that the [Centers for Medicare and Medicaid Services \(2013\)](#) has a process for designating small rural facilities of 25 inpatient beds or fewer as **critical access hospitals** if they provide around-the-clock emergency care services 7 days a week. Critical access hospitals are considered *necessary providers of health care* to community residents that are not close to other hospitals in a given region.

Emergency departments play a unique role within the US health care system because of the multi-specialty nature of the environment. More than 136.3 million people visit the ED each year, or 44.5 visits per 100 people ([Centers for Disease Control and Prevention \[CDC\], 2017](#)). The demand for emergency care has greatly increased over the past 15 years, and the health care consumer has higher expectations. However, the capacity to provide necessary resources has not kept pace in many systems. Emergency department crowding occurs when the need for care exceeds available

resources in the department, hospital, or both (Bellow & Gillespie, 2014). The Joint Commission (TJC, 2017c) has established a set of metrics (Core Measure Sets) based on ED length of stay (LOS) that hospitals are required to submit. The longer the ED length of stay for admitted patients, the more overcrowded the ED becomes. That, in turn, limits access to other patients who are in need of ED beds for emergency care. A prolonged LOS also indicates problems with inpatient bed availability and poor overall hospital throughput.

In 2010, the Affordable Care Act became the impetus for health care initiatives that impacted emergency services; the full spectrum of that impact has continued to evolve and may change again if this Act is repealed. Continued or changed availability, as well as the cost, of health insurance will influence how patients use emergency departments, primary care networks, disease management programs, home care services, and community resources. The widespread availability of health insurance may produce an increase in the number of patients who use the ED because they now have greater access to the necessary financial resources. Emergency department use may actually decrease for some types of patients as hospitals and providers partner in Accountable Care Organization models. This will better control costs by managing patient outcomes through primary care networks and disease management programs. Emergency departments may also experience a shift in focus from admitting the majority of acutely ill patients to the hospital for care to use of more TEAMWORK AND INTERPROFESSIONAL COLLABORATION with home care services and community access to resources that enable patients to be safely discharged home from the ED when possible.

## The Emergency Department Environment of Care

In the emergency care environment rapid change is expected. The typical ED is fast paced and, at the height of activity, might even appear chaotic. Patients seek treatment for a number of physical, psychological, spiritual, and social reasons. Many nurses work in this environment because they thrive in challenging, stimulating work settings. Although most EDs have treatment areas that are designated for certain populations such as patients with trauma or cardiac, psychiatric, or gynecologic problems, care can actually take place almost anywhere. In a crowded ED patients may receive initial treatment outside of the usual treatment rooms, including the waiting room and hallways.

The ED is typically alive with activity and noise, although the pace decreases at times because arrivals are random. Emergency nurses can expect background sounds that include ringing telephones, monitor alarms, vocal patients, crying children, and radio transmissions between staff and incoming ambulance or helicopter personnel. Interruptions and distractions are the norm, and the nurse must ensure to the best degree possible that these events do not impact patient SAFETY.

## Demographic Data and Vulnerable Populations

Staff members in the ED provide care for people across the life span with a broad spectrum of issues, illnesses, and injuries and various cultural and religious values. Especially vulnerable populations who visit the ED include the homeless, the poor, patients with mental health/behavioral health and substance abuse issues and older adults. During a given shift the emergency nurse may function as a cardiac nurse, a geriatric nurse, a psychiatric nurse, a pediatric nurse, and a trauma nurse. Patient acuity ranges from life-threatening emergencies to minor symptoms that could be addressed in a primary care office or community clinic. Some of the most common reasons that people seek ED care are:

- Abdominal pain
- Chest pain
- Breathing difficulties
- Injuries (especially falls in older adults)
- Headache
- Fever
- Pain (the most common symptom)

## Considerations for Older Adults

### Patient-Centered Care QSEN

Older adults often visit the ED because of worsening of an existing chronic condition or because the condition affects their ability to perform ADLs. Older adults are also sometimes admitted from nursing homes or assisted-living facilities for procedures (e.g., insertion of a percutaneous endoscopic gastrostomy [PEG] tube or peripherally inserted central catheter [PICC]) or treatments (e.g., blood transfusions). Some hospitals plan direct admission of the patient to same-day surgery or hold a bed for the procedure or treatment to bypass the ED. This arrangement decreases the patient's wait time and therefore decreases the risks for adverse events such as pressure injury development or hospital-acquired infection. Incorporating family members or caregivers of older adults into the ED care process can aid in overall patient evaluation, decision making, and satisfaction with the ED experience.

## Special Nursing Teams—Members of the Interprofessional Team

Many EDs have specialized nursing teams that deal with high-risk populations of patients. One example is the forensic nurse examiner team. **Forensic nurse examiners (RN-FNEs)** are educated to obtain patient histories; collect forensic evidence; and offer counseling and follow-up care for

victims of rape, child abuse, and domestic violence—also known as *intimate partner violence (IPV)* (International Association of Forensic Nurses, 2016). They recognize evidence of abuse and when to intervene on the patient's behalf. Forensic nurses who specialize in helping victims of sexual assault are called *sexual assault nurse examiners (SANEs)* or *sexual assault forensic examiners (SAFEs)*.

Interventions performed by forensic nurses may include providing information about developing a SAFETY plan or how to escape a violent relationship. Forensic nurse examiners document injuries and collect physical and photographic evidence. They may also provide testimony in court as to what was observed during the examination and information about the type of care provided.

The **psychiatric crisis nurse team** is another example of an ED specialty team. Many patients who visit the ED for their acute problems also have chronic mental health disorders. Patients who are experiencing an acute psychiatric crisis situation as their primary problem such as a suicide attempt secondary to severe depression or a new onset of psychosis may also arrive in the ED. The availability of mental health/behavioral health nurses can improve the quality of care delivered to these patients who require specialized interventions in the ED and can offer valuable expertise to the emergency health care staff. This team evaluates patients with emotional behaviors or mental illness and facilitates the follow-up treatment plan, including possible admission to an appropriate psychiatric facility. These nurses also interact with patients and families when sudden illness, serious injury, or death of a loved one may have caused a crisis. On-site interventions can help patients and families cope with these unexpected changes in their lives.

Some EDs have a specialized area to treat patients with psychiatric disorders that is designed to promote optimal safety. Features may include closed-circuit video monitoring, access-control door locks, solid ceilings (to prevent patients from climbing into the ceiling), a secured area to retain patient belongings, metal detectors, panic alarms, and elimination of any items or room features that could pose a safety risk to patients or staff.

## Interprofessional Team Collaboration

The emergency nurse is one member of the large interprofessional team who provides care for patients in the ED. A team approach to emergency care using TEAMWORK AND INTERPROFESSIONAL COLLABORATION is considered a standard of practice (Fig. 8-1). In this setting the nurse coordinates care with all levels of health care team providers, from prehospital emergency medical services (EMS) personnel to physicians, hospital technicians, and professional and ancillary support staff.

**FIG. 8-1** The ability to work as part of an interprofessional team is crucial to positive outcomes for emergency department (ED) patients. (From Rothrock, J. C. (2015). *Alexander's Care of the Patient in Surgery*. (15th ed.) St. Louis: Mosby.)

**Prehospital care providers** are typically the first caregivers that patients see before transport to the ED by an ambulance or helicopter (Fig. 8-2). Local protocols define the skill level of the EMS responders dispatched to provide assistance. **Emergency medical technicians (EMTs)** offer basic life support (BLS) interventions such as oxygen, basic wound care, splinting, spinal immobilization, and monitoring of vital signs. Some units carry automatic external defibrillators (AEDs) and may be authorized to administer selected drugs such as an EpiPen, intranasal naloxone (Narcan), or nitroglycerin based on established medical protocols. For patients who require care that exceeds BLS resources, paramedics are usually dispatched. **Paramedics** are advanced life support (ALS)

providers who can perform advanced techniques, which may include cardiac monitoring, advanced airway management and intubation, needle chest decompression, establishing IV or intraosseous access, and administering drugs en route to the ED (Fig. 8-3).

**FIG. 8-2** Advanced life support helicopter arriving at emergency department landing zone. Helicopters are used to rapidly transport critically ill and injured patients to the hospital for emergent care.

**FIG. 8-3** Prehospital providers take a patient from the ambulance to be brought into the emergency department.

The prehospital provider is a key source for valuable patient data. Emergency nurses rely on these providers to be the “eyes and ears” of the health care team in the prehospital setting and to ensure COMMUNICATION of this information to other staff members for continuity of care.

Another integral member of the emergency health care team is the **emergency medicine physician**. These medical professionals receive specialized education and training in emergency patient management. As emergency care has become increasingly complex and specialized, emergency medicine is a recognized physician specialty practice.

The emergency nurse interacts with a number of staff and community physicians involved in patient care but is involved in closest collaboration with emergency medicine physicians. Even though other physician specialists may be involved in ED patient treatment, the emergency medicine physician typically directs the overall care in the department. Many EDs also employ nurse practitioners (NPs) and physician assistants (PAs) to assume designated roles in patient assessment and treatment. Teaching hospitals have resident physicians who train in the ED. They act in collaboration with or under the supervision of the emergency medicine physician to assist with emergency care delivery.

The emergency nurse interacts and regularly takes part in TEAMWORK AND INTERPROFESSIONAL COLLABORATION with *professional and ancillary staff* who function in support roles. These personnel include radiology and ultrasound technicians, respiratory therapists, laboratory technicians, social workers, case managers, nursing assistants, and clerical staff. Each support staff member is essential to the success of the emergency health care team. For example, the respiratory therapist can help the

nurse troubleshoot mechanical ventilator issues. Laboratory technicians can offer advice regarding best practice techniques for specimen collection. During the discharge planning process, social workers or case managers can be tremendous patient advocates in locating community resources, including temporary housing, durable medical equipment (DME), drug and alcohol counseling, health insurance information, follow-up care, and prescription services. The ED nurse is accountable for COMMUNICATION of pertinent staff considerations, patient needs, and restrictions to support staff (e.g., physical limitations, safety concerns, Transmission-Based Precautions) to ensure that ongoing patient and staff safety issues are addressed.

The emergency nurse's interactions extend beyond the walls of the ED. Communication with nurses from the inpatient units is necessary to ensure continuity of patient care. Providing a concise but comprehensive report of the patient's ED experience is essential for the *hand-off communication* process and patient SAFETY. Information should include the patient's:

- Situation (reason for being in the ED) and admitting diagnosis
- Pertinent medical history, including implantable devices and any history of organ transplant
- Assessment and diagnostic findings, particularly critical results
- Transmission-Based Precautions and safety concerns (e.g., fall risk, allergies) as indicated
- Interventions provided in the ED and response to those interventions

**The Joint Commission's National Patient Safety Goals (NPSGs) (The Joint Commission [TJC], 2017a) advocate that hospitals and other health care agencies use a standardized approach to hand-off communications to prevent errors caused by poor or inadequate communication.** Many agencies use the SBAR method (situation, background, assessment, response) or some variation of that method to ensure complete and clearly understood COMMUNICATION. [Chapter 1](#) discusses the SBAR technique in more detail.

Both emergency nurses and nurses on inpatient units need to understand the unique aspects of their two practice environments to prevent conflicts. For example, nurses on inpatient units may be critical of the push to move patients out of the ED setting quickly, particularly when the unit activity is high. Similarly the emergency nurse may be critical of the inpatient unit's lack of understanding or enthusiasm for accepting admissions rapidly. Effective interpersonal COMMUNICATION skills and respectful negotiation can optimize TEAMWORK AND INTERPROFESSIONAL COLLABORATION between the emergency nurse and the inpatient unit nurse. For instance, when ED patient volume or acuity is overwhelming, the unit nurse can volunteer to assist the ED nurse by moving a monitored patient to the hospital bed. Whenever possible, the emergency nurse may decide to delay sending admitted patients to inpatient units during change of shift or crisis periods such as a cardiac arrest on the unit.

## Staff and Patient Safety Considerations

In the emergency department (ED) setting, staff and patient SAFETY are major concerns (Chart 8-1).

### Chart 8-1

## Best Practice for Patient Safety & Quality Care QSEN

### Maintaining Patient and Staff Safety in the Emergency Department

SAFETY CONSIDERATION	INTERVENTIONS TO MINIMIZE RISK
Patient identification	Provide an identification (ID) bracelet for each patient. Use two unique identifiers (e.g., name, date of birth). If patient identity is unknown, use a special identification system.
Injury prevention for patients	Keep rails up on stretcher. Keep stretcher in lowest position. Remind the patient to use call light for assistance. Reorient confused patient frequently. If patient is confused, ask a family member or significant other to remain with him or her. Implement measures to protect skin integrity for patients at risk for skin breakdown.
Risk for errors and adverse events	Obtain a thorough patient and family history. Check the patient for a medical alert bracelet or necklace. Search the patient's belongings for weapons or other harmful items such as drugs and drug paraphernalia when he or she has an altered mental status.
Injury prevention for staff	Use Standard Precautions at all times. Anticipate hostile, violent patient, family, and/or visitor behavior. Plan and practice options if violence occurs, including assistance from the security department.

## Staff Safety

*Staff safety* concerns center on the potential for transmission of disease and on personal safety when dealing with aggressive, agitated, or violent patients and visitors. The emergency nurse uses Standard Precautions at all times when a potential for contamination by blood or other body fluids exists. Patients with tuberculosis or other airborne pathogens are preferentially placed in a negative-pressure room if available. The nurse wears a powered air-purifying respirator (PAPR) or a specially fitted facemask before engaging in any close interaction with these patients (see Chapter 23).

## Nursing Safety Priority QSEN

### Action Alert

Hostile patient and visitor behaviors also pose injury risks to staff members. Be alert for volatile situations or people who demonstrate aggressive or violent tendencies through verbal abuse or acting out. Be sure to follow the hospital security plan, including identifying the nearest escape route, attempting de-escalation strategies before harm can occur, and notifying security and supervisory staff of the situation. Emergency visits resulting from gang or domestic violence can produce particularly hazardous conditions. Report all episodes of assaultive or violent behaviors through the hospital event documentation process so leaders and risk managers are aware of the scope of the problem and can plan safety strategies, including staff education, accordingly.

Emergency departments use several methods of ensuring SAFETY. Many EDs have at least one security guard present at all times for immediate assistance with these situations. Metal detectors may be used as a screening device for individuals who are suspected of having weapons. Strategically located panic buttons and remote door access controls allow staff to get help and secure major entrances. The triage reception area—a particularly vulnerable access point into the ED—is often designed to serve as a security barrier with bullet-proof glass and staff-controlled door entry into the treatment area. Hospitals may even employ canine units made up of specially trained officers and dogs to patrol high-risk areas and respond to handle threatening situations.

## Patient Safety

In addition to concerns about staff safety, some of the most common *patient SAFETY* issues are:

- Patient identification
- Fall risk
- Skin breakdown in vulnerable populations
- High risk for medical errors or adverse events

Hospital emergency departments have unique factors that can affect patient SAFETY. These factors include the provision of complex emergency care, constant interruptions, and the need to interact with the many providers involved in caring for one patient.

Correct *patient identification* is critical in any health care setting. All patients are issued an identification bracelet at their point of entry in the ED—generally at the triage registration desk or at the bedside if emergent needs exist. For patients with an unknown identity and those with emergent conditions that prevent the proper identification process (e.g., unconscious patient without identification, emergent trauma patient), hospitals commonly use a “Jane/John Doe” or another identification system. **Whatever method is used, always verify the patient's identity using two unique identifiers before each intervention and before medication administration per The Joint Commission's 2017 National Patient Safety Goals. Examples of appropriate identifiers include the patient's name, birth date, agency identification number, home telephone number or address, and/or Social Security number.**

*Fall prevention* starts with identifying people at risk for falls and then implementing appropriate fall precautions and SAFETY measures. Patients can enter the ED without apparent fall risk factors, but because of interventions such as pain medication, sedation, or lower-extremity cast application, they can develop a risk for falls. Falls can also occur in patients with medical conditions or drugs that cause syncope (“blackouts”). Many older adults experience orthostatic (postural) hypotension as a side effect of cardiovascular drugs. In this case patients become dizzy when changing from a lying or sitting position (see [Chapter 3](#)).

## Nursing Safety Priority QSEN

### Action Alert

Help patients move slowly from a supine to an upright position and when ambulating, if needed. In addition, confirm that side rails are up and locked on stretchers, that the call light is within reach, and that a patient's fall risk is communicated clearly to visitors and staff members who may assume responsibility for care.

Older adults who are on beds or stretchers should *always* have all side rails up and the bed or stretcher in the lowest position. Access to a call light is especially important; instruct the patient to call for the nurse if assistance is needed rather than attempt independent ambulation. Many older adults have difficulty adjusting to the noise and pace of the ED and/or have illnesses or injuries that cause delirium, an acute state of confusion. Reorient the patient frequently and re-assess mental status. Undiagnosed delirium increases the risk for mortality for older adults who are admitted to the hospital. Assess the need for a family member, significant other, or sitter to stay with the patient to prevent falls and help with reorientation. Additional safety strategies are listed in Chart 8-1.

Some patients spend a lengthy time on stretchers while awaiting unit bed availability—possibly as long as 1 to 2 days in some hospitals, especially during high census periods such as flu season. During that time basic health needs require attention, including providing nutrition, hygiene, SAFETY, and privacy for all ED patients. Waiting in the ED can cause increased pain in patients with back pain or arthritis.

*Protecting skin integrity* also begins in the ED. Emergency nurses need to assess the skin frequently and implement preventive interventions into the ED plan of care, especially when caring for older adults or those of any age who are immobilized. Interventions that promote clean, dry skin for incontinent patients, mobility techniques that decrease shearing forces when moving the immobile patient, and routine turning help prevent skin breakdown. [Chapter 25](#) describes additional nursing interventions for preventing skin breakdown.

A significant SAFETY risk for all patients who enter the emergency care environment is the *potential for medical errors or adverse events*, especially those associated with medication administration. The

episodic and often chaotic nature of emergency management in an environment with frequent interruptions can easily lead to errors.

To reduce error potential, the emergency nurse makes every attempt to obtain essential and accurate medical history information from the patient, family, or reliable significant others as necessary. When working with patients who arrive with an altered mental status, a quick survey to determine whether the individual is wearing a medical alert bracelet or necklace is important to gain medical information. In addition, a two-person search of patient belongings may yield medication containers; the name of a physician, pharmacy, or family contact person; or a medication list. Some EDs employ pharmacists or pharmacy technicians to help gather medication history to improve timeliness and accuracy of the information recorded. Through these processes the nurse may find information that promotes SAFETY, help determine the diagnosis, and influence the overall emergency treatment plan.

Automated electronic tracking systems are also available in some EDs to help staff identify the location of patients at any given time and monitor the progress of care delivery during the visit. These valuable safety measures are especially important in large or busy EDs with a high population of older adults (Laskowski-Jones, 2008).

In addition to falls and pressure injury development, another adverse event that can result from a prolonged stay in the ED is a *hospital-acquired infection*. Older adults in particular are at risk for urinary tract or respiratory infections. Patients who are immune suppressed, especially those on chronic steroid therapy or immune modulators, are also at a high risk. Nurses and other ED personnel must wash their hands frequently and thoroughly or use hand sanitizers to help prevent pathogen transmission.

## Clinical Judgment Challenge 8-1

### Safety QSEN

The emergency department manager has created a nursing task force to focus on fall prevention for patients who are seen in the ED. The task force created a list of questions about fall prevention and then discussed appropriate nursing interventions.

1. Which populations are at highest risk for falls while in the emergency department?
2. Which specific interventions can nurses implement to decrease falls?
3. Which actions can be appropriately delegated to unlicensed personnel to decrease fall risk?
4. How can the nursing staff reduce the risk for falls for patients who are confused (from dementia, medication side effects, or delirium)?

## Scope of Emergency Nursing Practice

The scope of emergency nursing practice encompasses management of patients across the life span from birth through death and all health conditions that prompt a person of any age to seek emergency care.

### Core Competencies

Emergency nursing practice requires that nurses be skilled in patient assessment, priority setting and clinical decision making, multitasking, documentation, and COMMUNICATION; a sound cognitive knowledge base is also essential (Harding et al., 2013). Flexibility and adaptability are vital traits because situations within the ED and individual patients can change rapidly.

Like that of any practicing nurse, the foundation of the emergency nurse's skill base is *assessment* (also known as *noticing*). He or she must be able to rapidly and accurately interpret assessment findings according to acuity and age. For example, mottling of the extremities may be a normal finding in a newborn, but it may indicate poor peripheral perfusion and a shock state in an adult.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Some older adults may not be able to provide an accurate history because of memory loss or acute delirium. If possible, review their prior hospitalization records to obtain complete histories or ask a family member or friend for pertinent information. Older adults usually have many pre-existing diseases (comorbidities) that must be considered as part of the assessment. *Knowing the history is vital because these conditions might adversely affect or complicate the cause for the ED visit.* For example, a patient who has rib fractures but has a history of severe chronic obstructive pulmonary disease (COPD) may not be able to maintain adequate gas exchange without endotracheal intubation and mechanical ventilatory support in the ED.

Another consideration for older-adult assessment is that the presenting symptoms of older adults are often different or less specific than those of younger adults. For example, increasing weakness, fatigue, and confusion may be the only admission concerns. These vague symptoms can be caused by serious illnesses such as an acute myocardial infarction (MI), urinary tract infection, or pneumonia. Diagnosing older adults often keeps them in the ED for extended periods, which can lead to patient safety concerns as discussed in the Patient Safety section.

Another skill for the emergency nurse is *priority setting*, which is essential in the triage process. Priority setting depends on accurate assessment and good critical thinking and clinical decision-making skills. These skills are generally gained through hands-on clinical experience in the ED. However, discussion of case studies and the use of human patient simulation and simulation software and aids can help prepare nurses to acquire this skill base in a nonthreatening environment and then apply it in the actual clinical situation (Jeffries et al., 2015).

The knowledge base for emergency nurses is broad and ranges from critical care emergencies to less common problems such as snakebites and hazardous materials contamination (see Chapters 9 and 10). ED nurses also learn to recognize and manage the legal implications of societal problems such as domestic violence, child maltreatment, elder abuse, and sexual assault.

Although most EDs have physicians available around the clock who are physically located within the ED, the nurse often initiates collaborative interprofessional protocols for lifesaving interventions such as cardiac monitoring, oxygen therapy, insertion of IV catheters, and infusion of appropriate parenteral solutions. In many EDs nurses function under clearly defined medical protocols that allow them to initiate drug therapy for emergent conditions such as anaphylactic shock and cardiac arrest. Emergency care principles extend to knowing which essential laboratory and diagnostic tests may be needed and, when necessary, obtaining them.

The emergency nurse must be proficient in performing a variety of technical skills (multitasking), sometimes in a stressful, high-pressure environment such as a cardiac or trauma resuscitation. In addition to basic skills, he or she may also need to be proficient with critical care equipment such as

invasive pressure-monitoring devices and mechanical ventilators. This type of equipment is commonly found in EDs that are part of Level I and Level II trauma centers.

The nurse also collaborates with and assists the ED provider of care with a number of procedures. Knowledge and skills related to procedural setup, patient preparation, teaching, and postprocedure care are key aspects of emergency nursing practice. Common ED procedures include:

- Simple and complex suturing for wound closure
- Foreign body removal
- Central line insertion
- Endotracheal intubation and initiation of mechanical ventilation
- Lumbar puncture
- Pelvic examination
- Chest tube insertion
- Paracentesis
- Fracture management

More than one nurse may be necessary to assist with some procedures. For example, if deep or moderate sedation is used to produce amnesia and relaxation during fracture reduction, one nurse assists the physician with the actual procedure while the other nurse monitors the patient before, during, and after the moderate-sedation medications are administered.

Finally an essential aspect of the emergency nurse's skill base is COMMUNICATION. The ED environment is complex; therefore multiple barriers to effective communication are likely. One common barrier is the patient's cultural beliefs and practices, especially if they differ from those of the health care team. Assess each patient as an individual and be careful not to stereotype anyone based on ethnicity, socioeconomic status, gender identity, or religion.

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Be aware of the various cultural and religious values of patients that may influence care. Many people have distinct beliefs that must be respected in the health care setting. For example, individuals from some cultures are modest and do not like to have their bodies exposed.

Patients with language barriers can present a challenge. The population of non-English-speaking people is rapidly increasing in the United States. When a patient who is not proficient in English arrives to the ED seeking care, access available resources such as telephone language lines and dedicated interpreters contracted by the hospital to ensure an understanding of all aspects of care. Similarly deaf interpreters are essential when providing care for patients who are hearing impaired.

A religious belief system can also affect the delivery of care. For example, Jehovah's Witness patients do not accept blood transfusions and may not accept certain medications that are derived from human blood components.

Be aware that not all patients identify themselves as male or female. Some patients may be in the process of changing their gender identity from male to female or female to male (transgender people), whereas others identify as gender neutral or gender fluid. Ask the patient which pronoun (he, she, or other term) the person prefers. Demonstrate professional behaviors that promote trust. Chapter 73 discusses the special care for this population in detail.

ED crowding and insufficient nursing personnel to meet the demand for services also create difficulties with COMMUNICATION of pertinent patient information and quality of written documentation. The high-stress ED environment can negatively affect effective interpersonal behaviors, particularly when nurses must deal with angry, violent, or demanding patients.

## Training and Certification

Two general types of certification are referred to in emergency nursing practice: the “certification” that marks successful completion of a particular course of study and emergency nursing specialty

certification (Table 8-1). As part of the orientation and employment requirements for staff nurses in most US EDs, successful completion of the Basic Life Support (BLS) for Healthcare Providers, Advanced Cardiac Life Support (ACLS), and Pediatric Advanced Life Support (PALS) provider courses through the American Heart Association is necessary. These courses provide instruction in fundamental, evidence-based management theory and techniques for cardiopulmonary resuscitation (CPR). Course participants include physicians, nurses, and prehospital personnel. The ACLS course builds on the BLS content to include:

**TABLE 8-1**  
**Descriptions of Training and Certifications for Emergency Nursing**

CERTIFICATION	DESCRIPTION
Basic Life Support (BLS) (required)	Noninvasive assessment and management skills for airway maintenance and cardiopulmonary resuscitation (CPR)
Advanced Cardiac Life Support (ACLS) (usually required)	Invasive airway-management skills, pharmacology, and electrical therapies; special resuscitation situations
Pediatric Advanced Life Support (PALS) (may be required)	Neonatal and pediatric resuscitation
Trauma Nursing Core Course (may be required)	Trauma nursing priorities, interventions, diagnostic studies, injury management
Certified Emergency Nurse (CEN) (optional)	Validates core emergency nursing knowledge base

- Advanced concepts in cardiac monitoring
- Invasive airway-management skills
- Pharmacologic and electrical therapies
- Intravascular access techniques
- Special resuscitation situations
- Post-resuscitation management considerations

Additional certification may be required through successful completion of trauma continuing education courses.

# Emergency Nursing Principles

## Triage

Emergency department **triage** is an organized system for sorting or classifying patients into priority levels, depending on illness or injury severity. The organization of emergency care and the ED is structured through triage principles. The key concept is that patients who present to the ED with the highest acuity needs receive the quickest evaluation; treatment; and prioritized resource utilization such as x-rays, laboratory work, and computed tomography (CT) scans. These patients also have priority for hospital service areas such as the operating room or cardiac catheterization laboratory. An individual with a lower-acuity problem may wait longer in the ED because a high-acuity patient is moved to the “head of the line.” The staff may need to communicate information about this system to the patient and family who may not understand why other patients are treated first.

The triage nurse is the gatekeeper in the emergency care system. When patients present to the ED, regulatory standards dictate that a registered nurse (RN), physician, or physician assistant (PA) perform a rapid assessment to determine triage priority. The RN is typically assigned to perform the triage function in most hospitals. The triage nurse requires appropriate training and experience in both emergency nursing and triage decision-making concepts to develop an expert knowledge base and provide ongoing mentoring and quality improvement feedback (Dateo, 2013). In some instances the triage nurse may seek the input of an emergency physician, advanced practice nurse (e.g., nurse practitioner [NP] or clinical nurse specialist [CNS]), or PA to help establish the acuity level if the patient's presentation is highly unusual.

Based on the triage priority, patients may be rushed into a treatment room, directed to a lower-acuity area within the ED, or asked to sit in the waiting room. Variations on this theme include:

- Triage nurse–initiated protocols for laboratory work or diagnostic studies that may be performed before the patient is actually evaluated by an ED provider of care
- Initiation of care while the patient is on a stretcher in the hallway of a crowded ED

These protocols are especially beneficial for certain populations who require rapid diagnosis and collaborative treatment within a defined time frame from ED arrival to meet established standards of care. Examples are patients with chest pain or those with a clinical presentation indicative of stroke, sepsis, or pneumonia.

## Emergent, Urgent, and Nonurgent Categories

Many triage systems can be used by a hospital ED. Any system must be applied consistently by triage nursing staff and endorsed by the emergency medicine physician staff. Based on the severity of the patient's condition, a well-known triage scheme used in the United States is the three-tiered model of “emergent, urgent, and nonurgent” (Table 8-2). In this system, for example, a patient experiencing crushing substernal chest pain, shortness of breath, and diaphoresis would be classified as emergent and triaged immediately to a treatment room within the ED. Similarly a critically injured trauma patient or an individual with an active hemorrhage would also be prioritized as emergent. The **emergent triage** category implies that a condition exists that poses an immediate threat to life or limb.

**TABLE 8-2**  
**Three-Tiered Triage System and Examples of Patients Triageed in Each Tier**

TIER LEVEL	EXAMPLES OF PATIENTS TRIAGED IN EACH TIER
Emergent (life threatening)	Respiratory distress Chest pain with diaphoresis Stroke Active hemorrhage Unstable vital signs
Urgent (needs quick treatment, but not immediately life threatening)	Severe abdominal pain Renal colic Displaced or multiple fractures Complex or multiple soft tissue injuries New-onset respiratory infection, especially pneumonia in older adults
Nonurgent (could wait several hours if needed without fear of deterioration)	Skin rash Strains and sprains “Colds” Simple fracture

The **urgent triage** category indicates that the patient should be treated quickly but that an immediate threat to life does not exist at the moment. Reassessment is needed if a health care provider cannot evaluate the patient in a timely manner. In people with evidence of clinical deterioration, triage priority may be upgraded from urgent to emergent. Examples of patients who typically fall into the urgent category are those with a new onset of pneumonia (as long as respiratory failure does not appear imminent), renal colic, complex lacerations not associated with major hemorrhage, displaced fractures or dislocations, and temperature greater than 101° F (38.3° C). Those categorized as **nonurgent** can generally tolerate waiting several hours for health care services without a significant risk for clinical deterioration. Conditions within this classification include patients with sprains and strains, simple fractures, “cold” symptoms, and general skin rashes.

### Other Multi-Tiered Models

To further sort patient conditions within an acuity classification or triage priority system, four- and five-tier triage models also exist. Such models are based either on comprehensive lists of conditions that indicate the particular triage priority to which a patient should be assigned or on the nature of resources that a patient will use in the ED setting. A patient situation may generate various triage classifications in different hospitals, depending on the triage priority system used at that particular institution. Some schemes may even take into account the presence of pre-existing conditions such as a history of anticoagulant use, diabetes, heart disease, and organ transplantation.

It is surprising that there is no universally accepted triage system recognized in the United States. Thus there is no standardization of triage acuity data to compare patient acuity among hospitals. Medical providers, health insurance companies, and patients often disagree on the definition of an emergent versus a nonurgent ED visit, making it essential to use a practical triage system to maintain department efficiency and allocation of resources. The Emergency Nurses Association in collaboration with the American College of Emergency Physicians studied the available research literature on acuity scales and concluded that two standardized five-level systems, the **Emergency Severity Index (ESI)** and the **Canadian Triage Acuity Scale (CTAS)**, are the most reliable (Shelton, 2010). The ESI model uses an algorithm that fosters rapid, reliable, and clinically pertinent categorization of patients into five groups, from Level 1 (emergent) to Level 5 (nonurgent). The CTAS model differs from ESI in that lists of descriptors are used to establish the triage level.

Whatever triage model is used, triage nurses must use a systematic approach, apply solid clinical decision-making skills, and maintain a caring ethic. Compassion fatigue, or burnout, can hinder objectivity in dealing with patients who present to the ED. A biased approach threatens the ED nurse's ability to triage patients accurately. Mistriage is a patient SAFETY risk that can be the “root cause” of delayed or inadequate treatment with potentially deadly consequences.

## NCLEX Examination Challenge 8-1

### Safe and Effective Care Environment

The ED nurse who is just beginning a shift is assigned to care for four clients. Which client does the nurse assess **first**?

- A. 19-year-old with a closed femur fracture who received pain medication 15 minutes earlier
- B. 24-year-old with nausea, vomiting, and diarrhea who has infusing IV fluids and is resting
- C. 33-year-old who cut hand while working in a kitchen and is awaiting suturing
- D. 41-year-old awaiting transport to the operating room for an emergency appendectomy

### Disposition

At the conclusion of the assessment the physician must make a decision regarding patient disposition (i.e., where the patient should go after being discharged from the ED). Should he or she be admitted to the hospital, transferred to a specialty care center, or be discharged to home with

instructions for continued care and follow-up? Usually the answer is straightforward. A patient who has an evolving myocardial infarction, sepsis, stroke, or acute surgical need is admitted.

Sometimes, though, the ED disposition decision is less clear. Often the ED provider of care discusses this decision in collaboration with the emergency nurse. The nurse may have a greater sense of how well a patient will manage in a home setting, depending on whether other family members or caregivers are available to assist and are reliable. For example, in the event that a patient with a minor head injury has suffered a loss of consciousness, someone is typically expected to remain with that person for the first 12 to 24 hours to be sure that he or she does not show any evidence of neurologic deterioration. Another common scenario involves the potential risk to the patient in cases of actual or suspected domestic violence. If discharge to home is not deemed safe, the patient may be admitted to the hospital in an observation status until resources can be organized to provide for a safe environment. Coordinate the discharge plan and continuing care with the social worker or case manager.

## Considerations for Older Adults

### Patient-Centered Care QSEN

If discharge from the ED to home is possible, ensure that safety issues are considered. For example, collaborate with the ED physician to evaluate the patient's current prescriptions and over-the-counter medications to determine if the drug regimen should be continued. Involve the ED-based pharmacist if one is available for consultation when necessary. If the medication regimen needs to be changed, be sure that the patient and family member or significant other has the new information in writing and that it is explained verbally. If needed, assess whether the patient has someone who can presort and place medications into a medication dispenser to ensure accuracy and prevent adverse drug events. Consider a social services or case-management referral for patients in need of financial resources to obtain prescribed medications.

To prevent future ED visits, screen older adults per agency policy for functional assessment, cognitive assessment, and risk for falls. Depression screening is also important because suicide rates are two times higher among older adults when compared with younger adults. White men older than 85 years are at the highest risk (Touhy & Jett, 2015).

Older patients are often admitted to the hospital directly from the ED. If hospitalization is needed, determine if the patient has advance directives or is able to make decisions about advance directives before admission. If the patient was admitted from a nursing home, contact the facility to let them know the patient's status. If the patient was receiving home health care services, notify the agency about the hospital admission. Contact the patient's primary physician and designated family member if he or she is not present with the patient.

### Case Management

Some EDs employ registered nurse case managers who screen ED patients and intervene when necessary to arrange appropriate referral and follow-up. This is an evolving role in the ED setting that can be beneficial in providing comprehensive care and as a strategy to avoid inappropriate use of resources.

ED case managers, supported by electronic information systems, can review the ED census on both a "real-time" and a retrospective basis to determine which patients have visited the ED frequently in a given period. The case manager can then determine the reasons they sought emergency services such as lack of a primary health care provider, exacerbation ("flare-up") of a chronic condition, a lack of health education, or lack of the financial resources necessary to manage the health condition. Collaborative case-management interventions include facilitating referrals to primary care providers or to subsidized community-based health clinics for patients or families in need of routine services.

For those with needs related to chronic conditions, the case manager can arrange referral into appropriate disease management programs in the community if available. Disease management programs are specific to a particular condition such as asthma, COPD, diabetes, hypertension, heart failure, and renal failure. They help patients learn how to manage their condition on a day-to-day basis to prevent exacerbations or clinical deterioration. The desired outcome is to keep the person out of the hospital as long as possible. Health teaching is a key component of these programs. For

other health teaching needs, the ED case manager directs the patient to the appropriate educational resources such as a health educator, registered dietitian, or community organization (e.g., the American Cancer Society, the American Heart Association).

Other functions of the ED case manager might include working in collaboration with staff to plan disposition for homeless people or veterans, locating a safe environment for victims of domestic violence or elder abuse, or providing information on resources for low-cost or free prescriptions. Homeless adults often have multiple chronic medical illnesses for which they visit EDs frequently. A large study of homeless adults with chronic medical illnesses demonstrated a decrease in ED visits and hospital admissions as a result of an organized follow-up system for housing and ongoing case-management support (Popovich et al., 2012). Another study demonstrated a decrease in ED visits and admissions for veterans based on a care-coordination program partnership between Veterans Affairs (VA) medical centers and Alzheimer's Association chapters (Bass et al., 2015). (See the Evidence-Based Practice box.)

## Evidence-Based Practice QSEN

### Community Partnerships to Decrease Hospital Admissions and ED Visits for Veterans With Dementia

Bass, D., et al. (2015). Impact of the care coordination program “Partners in Dementia Care” on veterans' hospital admissions and emergency department visits. *Alzheimer's & Dementia: Translational Research & Clinical Interventions*, 1(1), 13–22.

This study sought to determine whether “Partners in Dementia Care” (PDC), a care coordination partnership between Veterans Affairs (VA) medical centers and Alzheimer's Association chapters, would reduce the emergency department (ED) visits and hospital admissions for veterans with dementia, especially those with more profound behavioral and cognitive symptoms.

The sample included 328 veterans with dementia and their primary caregiver from five matched sites—two of which were randomly selected treatment sites. Veterans who were eligible received primary health care from the VA, resided outside a residential care facility at enrollment time, lived within an area where a partnering Alzheimer's Association chapter existed, were over the age of 60, and had at least one ICD-9 dementia diagnostic code. After initial assessment an action plan of approximately seven personalized activities—the core of PDC—was put in place for each veteran and caregivers. Action steps were easy-to-accomplish processes that were targeted to provide necessary services and answers for veterans and caregivers such as calling to inquire about service availability, creating a list of questions to ask the health care provider, and contacting other family members to assist with a caregiving task.

Data on VA and non-VA hospital and ED use (including the use of urgent care facilities) were collected electronically for 1 year after initial assessment. Caregivers were surveyed at 6-month intervals to report services used between months 1 and 6 and months 7 and 12. Logistic regression was used with dichotomous-dependent variables to analyze the data.

Data showed that just over one third of veterans had at least one hospital admission and over half had at least one ED visit. One hundred and eighteen veterans experienced at least one hospital admission. PDC veterans with more cognitive symptoms at the 6-month interval, and those with behavioral difficulties at baseline had fewer admissions.

#### Level of Evidence: 2

This quasi-experimental study provided for control at baseline and randomization of two of the five matched sites. It was built on the Stress Hospital Model, which further strengthens its credibility.

#### Commentary: Implications for Practice and Research

Cost and resource utilization for patients with dementia is substantial because of the nature of the disease, which requires progressive supervision and intervention as the patient's condition deteriorates over time. This study demonstrated that PDC did decrease the number of hospital admissions and ED visits for veterans with dementia but did not impact the likelihood of an initial admission. Nurses can use this information in practice by recognizing that partnerships and collaborations between community resource groups and hospital services may favorably impact

the frequency of subsequent admissions and ED visits for patients with dementia, particularly as symptoms progress, which often leads to high resource utilization and cost of care. Further research is ongoing in the form a replication study that is being conducted in Ohio, with the support of Administration for Community Living (grant 90DS0001), Ohio Department of Aging, Benjamin Rose Institute on Aging, Louis Stokes Cleveland VA Medical Center, the Western Reserve Area Agency on Aging, and the Greater East Ohio Area Alzheimer's Association Chapter.

## Patient and Family Education

A key role of the emergency nurse is health teaching. At the most basic level nurses review discharge instructions with the patient and family before signing them out of the department.

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Most discharge instructions are either preprinted or computer generated and can be customized to address the patient's needs. Consider his or her reading level, primary language, and visual acuity. Educational materials and instructions should be available at no higher than the sixth-grade reading level. For patients with English as a second language, many hospitals have educational materials available in Spanish and other regional languages. However, interpreters may be necessary to help the health care provider customize the information appropriately. For older adults and others with vision deficits, large-print materials may be helpful.

In addition to discharge instructions, the ED environment and community-at-large present many opportunities for health education. Emergency nurses are in an ideal position to educate the public about wellness and injury prevention strategies. If the patient presented after a motor vehicle crash, for instance, the nurse can reinforce the need to wear seat belts or use child safety seats correctly. ED visits that result from mishaps in the home provide an excellent opportunity to discuss home SAFETY issues (e.g., the need for smoke detectors and carbon monoxide detectors) and fall prevention tips (e.g., the need for proper lighting, removal of throw rugs). Injury is not the only topic that affords a teaching opportunity. A new onset or an exacerbation of a medical condition also allows for education, such as how to measure blood glucose and ways to control blood pressure or reduce the risk for heart disease.

## Death in the Emergency Department

Not all critically ill or injured patients who come to the ED can be saved. Sometimes a patient's death is expected by family members, typically when they have dealt with a loved one's terminal condition or age-related decline. Usually, however, a death in the ED is a sudden and unexpected event that produces a state of crisis and chaos for family and significant others. Emergency department staff members need to address the needs of the family members in this overwhelming time.

If resuscitation efforts are still under way when the family arrives, one or two family members may be given the opportunity to be present during lifesaving procedures. Family presence during resuscitation is gaining wider acceptance in the health care community; however, a significant number of hospitals still have not devised clear policies or guidelines to facilitate family-witnessed resuscitation (Porter et al., 2014).

If the patient dies before family members arrive, ED staff members try to prepare the body and the room for viewing by the family. However, certain types of ED deaths may require forensic investigation or become medical examiner's cases. Therefore ED staff may not be able to remove IV lines and indwelling tubes or clean the patient's skin if these actions could potentially damage evidence. Trauma deaths, suspected homicide, or abuse cases always fall into this category. In these situations cover the body with a sheet or blanket while leaving the patient's face exposed and dim the lights before family viewing.

When dealing with family members in crisis, simple and concrete COMMUNICATION is best. Words such as *death* or *died*, although seemingly harsh, create less confusion than terms such as *expired* or *passed away*. Demonstrate caring, compassion, and empathy during all interactions, even in periods

of heightened emotions. Intense grief can provoke a range of family reactions from silence to violence. If available, coordinate with crisis staff (social workers or psychiatric nurses) to assist families and maintain SAFETY during this time. Offer the family the option of speaking with clergy or calling someone of their choice for additional support. A family member may need to be admitted to the ED to be treated for anxiety or physical manifestations of stress such as chest pain, difficulty breathing, or severe headache.

Dealing with death is often difficult for ED personnel, especially during busy periods when the ability to console family members may be limited. In response, some EDs have developed bereavement committees that focus on meeting the needs of grieving families. Actions such as sending sympathy cards, attending funerals, making follow-up phone calls, and creating memory boxes are common. These actions facilitate COMMUNICATION of caring and compassion after the moment of crisis.

## The Impact of Homelessness

Homelessness affected 564,708 people on any given night in January 2015; one quarter of all homeless people were under the age of 18 ([United States Department of Housing and Urban Development, 2015](#)). The homeless population is made up of both adults and children who live from day to day in a state of fear, chaos, and confusion ([Gerber, 2013](#)). People become homeless as a result of a crisis or persistent poverty ([Gerber, 2013](#)). They have a high incidence of acute and chronic health conditions, psychiatric illnesses, physical disabilities or limitations, and problems with substance abuse ([Gerber, 2013](#)). They are vulnerable to physical trauma, weather exposure, sexually transmitted diseases, infestation, and infectious diseases such as tuberculosis and influenza.

Homeless patients often seek ED care for a variety of reasons. Because the ED is open 24 hours per day and is mandated by federal law to perform an emergency medical screening examination on all of its patients, patients who are homeless know that they will gain entry despite their inability to pay for services. The ED represents a safe place to go for shelter in poor weather and for food, medical care, pain relief, and human interaction. Some homeless patients simply seek a temporary respite from their current living conditions, which may be a park, homeless shelter, car, abandoned building, or cardboard box. People who have been persistently homeless may assimilate into the homeless culture, learn to take great pride in their survival skills, and fiercely protect their few belongings and their living space. They may develop a distrust of outsiders, including members of the health care profession, and are especially sensitive to any perceived bias or stereotyping ([Gerber, 2013](#)).

Patients who are homeless bring special challenges to their ED evaluation, treatment, and disposition. Some visit the ED frequently and do not adhere to treatment recommendations or follow up with community referrals. Those with mental illness or substance abuse may act out or become disruptive, posing a SAFETY risk to staff and patients.

To best care for homeless patients in the ED setting, nurses must first maintain their situational awareness and attend to their own needs for personal safety. These include not only anticipating the potential for violent behavior but also using Standard Precautions and assessing the need to isolate the patient in a negative-pressure room if airborne disease such as tuberculosis is a concern. The key nursing action is to demonstrate behaviors that promote trust. These include making eye contact (if culturally appropriate), speaking calmly, avoiding any prejudicial or stereotypical remarks, being patient, showing genuine care and concern by listening, following through on promises, and exercising caution when there is a need to enter into the patient's personal space ([Gerber, 2013](#)). Clear professional boundaries must be stated if the patient becomes disruptive, profane, or sexually inappropriate. While collaborating with the emergency care provider to ensure that the patient's emergency medical needs are identified and treated, consult a social worker or case manager to work with the patient to identify safety needs, referral options, and community resources. It is also important to develop an individual care plan with the interprofessional health care team if the patient uses the ED frequently. This type of care plan is extremely beneficial in establishing a consistent approach to patient management, especially when the patient has complex conditions or exhibits drug-seeking and disruptive behavior.

## Trauma Nursing Principles

The general public tends to use the term *trauma* to mean any type of crisis, ranging from a heart attack to psychological stress. Among health care professionals, though, **trauma** refers to bodily injury. More than 192,000 people in the United States die each year as a result of injuries; and over 2.4 million are hospitalized, often with permanent and disabling consequences (National Center for Injury Prevention and Control [NCIPC], 2017). Injuries can be categorized as either intentional (i.e., assault, homicide, suicide) or unintentional (i.e., accidents). *Unintentional injury* such as a motor vehicle crash is the leading cause of death for Americans younger than 35 years and is one of today's most significant public health problems (NCIPC, 2017).

Injury management is a key component of ED services. Over 30 million people in the United States visit the ED each year to receive treatment for injuries (NCIPC, 2017). Therefore a core competency in general trauma care is an important part of emergency nursing practice. For emergency nurses who work in accredited trauma centers, opportunities typically exist to further develop expertise in trauma nursing through ongoing clinical practice, specialty training programs, and continuing education. Trauma nursing is a field that encompasses the continuum of care from injury prevention and prehospital services to acute care, rehabilitation, and ultimately community reintegration.

## Trauma Centers and Trauma Systems

Trauma centers have their roots in military medicine. Injured soldiers who received rapid transport from the battlefield and treatment from skilled health care personnel had a survival advantage in the mobile army surgical hospital (MASH) units first deployed in the Korean and Vietnam wars. Consequently the MASH unit became the original model for the development of civilian trauma centers. In modern society the **trauma center** in the United States is a specialty care facility that provides competent and timely trauma services to patients, depending on its designated level of capability.

### Trauma Centers

Not all EDs that offer around-the-clock emergency services are trauma centers. The American College of Surgeons Committee on Trauma (2014) has set forth national standards for trauma center accreditation and categorizes the resource requirements necessary for the highest capability trauma center (Level I) to the lowest (Level IV) (Table 8-3).

**TABLE 8-3**  
**Levels and Functions of Trauma Centers**

LEVELS OF TRAUMA CENTER	FUNCTIONS OF TRAUMA CENTER
Level I	Usually located in large teaching hospital systems in densely populated areas Provides a full continuum of trauma services for adult and/or pediatric patients Conducting research is a requirement for trauma center verification
Level II and Level III	Both typically located in community hospitals <b>Level II</b> Provides care to most injured patients Transfers patient if needs exceed resource capabilities <b>Level III</b> Stabilizes patients with major injuries Transfers patient if needs exceed resource capabilities
Level IV	Usually located in rural and remote areas Provides basic trauma patient stabilization and advanced life support within resource capabilities Arranges transfer to higher trauma center levels as necessary

A *Level I trauma center* is a regional resource facility that is capable of providing leadership and total collaborative care for every aspect of injury, from prevention through rehabilitation. These centers also have a responsibility to offer professional and community education programs, conduct research, and participate in system planning. Because a significant resource and experience commitment is required to maintain strict accreditation standards, Level I trauma centers are usually located in large teaching hospitals and serve dense population areas (Fig. 8-4).

**FIG. 8-4** A trauma team participates in a realistic trauma resuscitation simulation. This type of training ensures that staff remain proficient in skills and able to care for any situation that might present to the emergency department.

*Level II trauma centers* are usually located in community hospitals and are capable of providing care to the vast majority of injured patients. However, a Level II trauma center may not be able to meet the resource needs of patients who require very complex or multi-system injury management. These people are generally transferred to a Level I trauma center for specialty care. In communities without a Level I trauma center, Level II centers play a significant leadership role in injury management, education, prevention, and emergency preparedness planning.

A *Level III trauma center* is a critical link to higher-capability trauma centers in communities that do not have ready access to Level I or II centers. The primary focus is initial injury stabilization and patient transfer. Level III trauma centers are often found in smaller, rural hospitals and serve areas with lower population density. Because Level III trauma centers have general surgeons and orthopedic surgeons immediately available, patients with some major injuries may be admitted for care. However, if the injuries are severe or critical, transfer to a Level I or II trauma center occurs after ED assessment, resuscitation, and stabilization—sometimes after emergent, lifesaving surgery. Patients are typically transported out in either an advanced life support ambulance or helicopter with critical care transport personnel in attendance.

The function of a *Level IV trauma center* is to offer advanced life support care in rural or remote settings that do not have ready access to a higher-level trauma center such as a ski area. Patients are stabilized to the best degree possible before transfer, using available personnel such as advanced practice nurses, physician assistants, nurses, and paramedics. Resources, including the consistent availability of a physician, may be extremely limited. Transport time to the final care center can be prolonged because of both distance and bad weather conditions that may prevent transfer by air.

Level III and Level IV trauma centers establish close collaborative relationships with Level I and Level II trauma centers. Based on accreditation standards, care providers at Levels I and II trauma centers have a responsibility to readily accept injured patients in transfer. They provide timely feedback to trauma personnel at referring hospitals and share expertise by offering educational opportunities to advance trauma care delivery in the region. In addition, personnel from all levels of trauma centers participate in focused system improvement and patient safety initiatives that enhance quality of care and solve identified problems.

## Trauma Systems

Trauma centers save lives, but a trauma center is only as good as the overall trauma system that supports it. A **trauma system** is an organized and integrated approach to trauma care designed to ensure that all critical elements of trauma care delivery are aligned to meet the injured patient's needs. These elements include (Cooper & Laskowski-Jones, 2006):

- Access to care through COMMUNICATION technology (e.g., an enhanced 911 service)
- Timely availability of prehospital emergency medical care
- Rapid transport to a qualified trauma center
- Early provision of rehabilitation services

- System-wide injury prevention, research, and education initiatives

The overall desired outcome of an organized trauma system is to enable an injured patient not only to recover from trauma but also to return to a productive role in society.

A well-functioning trauma system is also essential to general public health and SAFETY. It provides the structure necessary for disaster readiness and community emergency preparedness (see [Chapter 10](#)). Although most states in the United States now have at least some basic elements of a trauma system in place, significant gaps still exist in many regions.

## Mechanism of Injury

The **mechanism of injury (MOI)** describes how the patient's traumatic event occurred, such as a high-speed motor vehicle crash, a fall from a standing height, or a gunshot wound to the torso. Knowing key details about the MOI can provide insight into the energy forces involved and may help trauma care providers predict injury types, and in some cases, patient outcomes. Prehospital care providers report the MOI as a COMMUNICATION standard when handing off care to ED and trauma personnel. Similarly, patients who present to the ED for medical care will often relate the MOI by describing the particular chain of events that caused their injuries.

Two of the most common injury-producing mechanisms are blunt trauma and penetrating trauma. **Blunt trauma** results from impact forces such as those sustained in a motor vehicle crash; a fall; or an assault with fists, kicks, or a baseball bat. **Blast effect** from an exploding bomb also causes blunt trauma. The energy transmitted from a blunt-trauma mechanism, particularly the rapid **acceleration-deceleration** forces involved in high-speed crashes or falls from a great height, produces injury by tearing, shearing, and compressing anatomic structures. Trauma to bones, blood vessels, and soft tissues occurs.

**Penetrating trauma** is caused by injury from sharp objects and projectiles. Examples are wounds from knives, ice picks, other comparable implements, and bullets (gunshot wounds [GSWs]) or pellets. Fragments of metal, glass, or other materials that become airborne in an explosion (shrapnel) can also produce penetrating trauma. Each mechanism has the risk for specific injury patterns and severity that the trauma team considers when planning diagnostic evaluation and management strategies. Certain injury mechanisms such as a gunshot wound to the chest or abdomen or a stab wound to the neck are so highly associated with life-threatening consequences that they automatically require trauma team intervention for a rapid and coordinated resuscitation response.

## NCLEX Examination Challenge 8-2

### Safe and Effective Care Environment

The nurse is caring for a client who was attacked on a rooftop. The client was repeatedly kicked and then shot in the leg, which contributed to a fall from the five-story building. Which mechanism of injury will the nurse document? **Select all that apply.**

- A. Blunt
- B. Blast
- C. Penetration
- D. Acceleration-deceleration
- E. Laceration

## Primary Survey and Resuscitation Interventions

A basic tenet of emergency care in any environment is scene SAFETY. In the prehospital setting emergency care providers must ensure that they are aware of any hazards that might pose a threat to rescuers and take actions to decrease or eliminate the risk. This same concept applies to the hospital ED setting. Before engaging in trauma resuscitation as a nurse member of the trauma team,

keep in mind that there is a high risk for contamination with blood and body fluids. For this reason use Standard Precautions in *all* resuscitation situations and at other times when exposure to blood and body fluids is likely. Proper attire consists of an impervious cover gown, gloves, eye protection, a facemask, surgical cap, and shoe covers (if *significant* blood loss is anticipated such as during an ED procedure).

The initial assessment of the trauma patient is called the **primary survey**, which is an organized system to rapidly identify and effectively manage immediate threats to life. The primary survey is typically based on a standard “ABC” mnemonic plus a “D” and “E” for trauma patients: airway/cervical spine (**A**); breathing (**B**); circulation (**C**); disability (**D**); and exposure (**E**). Resuscitation efforts occur simultaneously with each element of the primary survey (Gurney & Westergard, 2014). Even though the resuscitation team may encounter multiple clinical problems or injuries, issues identified in the primary survey are managed before the team engages in interventions of lower priority such as splinting fractures and dressing wounds.

There is one notable exception to the standard ABCDE trauma resuscitation approach. Lessons learned from the military have made it clear that in the presence of massive, uncontrolled external bleeding, hemorrhage control techniques are the highest priority intervention (Gurney & Westergard, 2014). In this situation the sequence of priorities shifts to CAB, whereby the initial focus of resuscitation is to effectively stop the active bleeding (Gurney & Westergard, 2014).

### **A: Airway/Cervical Spine**

Even minutes without an adequate oxygen supply can lead to brain injury that can progress to anoxic brain death. Establishing a patent airway is the highest-priority intervention when managing a trauma patient unless massive, life-threatening external hemorrhage as described previously is present.

## **Nursing Safety Priority** QSEN

### **Critical Rescue**

Recognize that you must clear the airway of any secretions or debris either with a suction catheter or manually if necessary. Respond by protecting the trauma patient's cervical spine by manually aligning the neck in a neutral, in-line position and using a jaw-thrust maneuver when establishing an airway. Provide supplemental oxygen for patients who require resuscitation.

In general a nonrebreather mask is best for the spontaneously breathing patient. Bag-valve-mask (BVM) ventilation with the appropriate airway adjunct and a 100% oxygen source is indicated for the person who needs ventilatory assistance during resuscitation. A patient with significantly impaired consciousness (Glasgow Coma Scale [GCS] of 8 or less) requires an endotracheal tube and mechanical ventilation (Gurney & Westergard, 2014).

### **B: Breathing**

After the airway is successfully secured, breathing becomes the next priority in the primary survey. *This assessment determines whether or not ventilatory efforts are effective—not only whether or not the patient is breathing.* Listen to breath sounds and evaluate chest expansion, respiratory effort, and any evidence of chest wall trauma or physical abnormalities. Both apneic patients and those with poor ventilatory effort need BVM ventilation for support until endotracheal intubation is performed and a mechanical ventilator is used. If cardiopulmonary resuscitation (CPR) becomes necessary, the mechanical ventilator is disconnected, and the patient is manually ventilated with a BVM device. Lung compliance can be assessed through sensing the degree of difficulty in ventilating the patient with the BVM.

### **C: Circulation**

When effective ventilation is ensured, the priority shifts to circulation. The adequacy of heart rate, blood pressure, and overall perfusion becomes the focus of the assessment. Common threats to circulation include cardiac arrest, myocardial dysfunction, and hemorrhage leading to a shock state. Interventions are targeted at restoring effective circulation through cardiopulmonary resuscitation,

hemorrhage control, IV vascular access with fluid and blood administration as necessary, and drug therapy. *External* hemorrhage is usually quite obvious and best controlled with firm, direct pressure on the bleeding site with thick, dry dressing material. This method is effective in decreasing blood flow for most wounds. *Tourniquets that occlude arterial blood flow distal to the injury should be used to manage severe, compressible bleeding from extremity trauma when direct pressure fails to achieve hemorrhage control; hemostatic dressings (e.g., dressings impregnated with substances that speed the formation of a blood clot) are another essential tool to apply directly over the bleeding site in the management of life-threatening hemorrhage.* *Internal* hemorrhage is a more hidden complication that must be suspected in injured patients or those who present in a shock state.

In a resuscitation situation blood pressure (BP) can be quickly and easily estimated before a manual cuff pressure can be obtained by palpating for the presence or absence of peripheral and central pulses:

- Presence of a radial pulse: BP at least 80 mm Hg systolic
- Presence of a femoral pulse: BP at least 70 mm Hg systolic
- Presence of a carotid pulse: BP at least 60 mm Hg systolic

By the time hypotension occurs, compensatory mechanisms used by the body in an attempt to maintain vital signs in a shock state have been exhausted. Timely, effective intervention is critical to preserve life and vital organ function.

IV access is best achieved initially with insertion of large-bore (16-gauge) peripheral IV lines in the antecubital area (inside bend of the elbow). Additional access can be obtained via central veins in the femoral, subclavian, or jugular sites using large-bore (8.5 Fr) central venous catheters. Intraosseous access is an excellent initial approach for critically ill patients when veins cannot be rapidly accessed by the resuscitation team (see [Chapter 13](#) for discussion of intraosseous infusion therapy). Ringer's lactate and 0.9% normal saline (NS) are the crystalloid solutions of choice for resuscitation; hypertonic saline may also be prescribed in some situations, particularly in the case of head trauma. Fluids and blood products should be warmed before administration to prevent hypothermia. Anticipate the need for rapid blood component administration in a hemorrhagic shock state using packed red blood cells, fresh frozen plasma, and platelets to both replace blood loss and prevent coagulopathy. However, the priority intervention is always to stop the bleeding.

## D: Disability

The disability examination provides a rapid baseline assessment of neurologic status. A simple method to evaluate level of consciousness is the “AVPU” mnemonic:

- A: **A**lert
- V: Responsive to **v**oice
- P: Responsive to **p**ain
- U: **U**nresponsive

Another common way of determining and documenting level of consciousness is the [Glasgow Coma Scale \(GCS\)](#), an assessment that scores eye opening, verbal response, and motor response. The lowest score is 3, which indicates a totally unresponsive patient; a normal GCS score is 15. Metabolic abnormalities (e.g., severe hypoglycemia), hypoxia, neurologic injury, and illicit drugs or alcohol can impair level of consciousness. Frequent reassessment is needed for rapid intervention in the event of neurologic compromise or deterioration.

## E: Exposure

The final component of the primary survey is **exposure**.

## Nursing Safety Priority QSEN

### Action Alert

Remove all clothing to allow for thorough assessment. Always carefully cut away clothing with scissors:

- During resuscitation when rapid access to the patient's body is critical

- When manipulating a patient's limbs to remove clothing could cause further injury
- When thermal or chemical burns have caused fabrics to melt into the patient's skin

If evidence preservation is an issue, handle items per institutional policy. Evidence may include articles of clothing, impaled objects, weapons, drugs, and bullets. Emergency nurses are often called on to provide testimony in court regarding their recall of the presentation and treatment of patients in the ED. Examples of types of cases in which evidence collection is vital are rape, elder abuse, domestic violence, homicide, suicide, drug overdose, and assault.

Once clothing is removed, hypothermia (body temperature less than or equal to 95° F [36° C]) poses a risk to injured patients (Weaver et al., 2014), especially those with burns and traumatic shock states. Hypothermia is discussed in detail in Chapter 9.

Table 8-4 highlights the primary survey and associated resuscitation interventions.

**TABLE 8-4**  
**The Primary Survey and Resuscitation Interventions**

PRIORITIES OF THE PRIMARY SURVEY	EXAMPLES OF SPECIFIC INTERVENTIONS
A: Airway/cervical spine	Establish a patent airway by positioning, suctioning, and oxygen as needed. Protect the cervical spine by maintaining alignment; use a jaw-thrust maneuver if there is a risk for spinal injury. If the Glasgow Coma Scale (GCS) score is 8 or less or the patient is at risk for airway compromise, prepare for endotracheal intubation and mechanical ventilation.
B: Breathing	Assess breath sounds and respiratory effort. Observe for chest wall trauma or other physical abnormality. Prepare for chest decompression if needed. Prepare to assist ventilations if needed.
C: Circulation	Monitor vital signs, especially blood pressure and pulse. Maintain vascular access with a large-bore catheter. Use direct pressure for external bleeding; anticipate need for a tourniquet for severe, uncontrollable extremity hemorrhage and use of a hemostatic dressing.
D: Disability	Evaluate the patient's level of consciousness (LOC) using the GCS. Re-evaluate the patient's LOC frequently.
E: Exposure	Remove all clothing for a complete physical assessment. Prevent hypothermia (e.g., cover the patient with blankets, use heating devices, infuse warm solutions).

## NCLEX Examination Challenge 8-3

### Safe and Effective Care Environment

A flight nurse is preparing to care for a client who has been involved in a serious motor vehicle crash. When the helicopter lands, what is the nurse's **priority** action?

- Apply oxygen.
- Assess airway and stabilize cervical spine.
- Start two large-bore IVs and infuse normal saline.
- Apply pressure to any small bleeding wounds.

## The Secondary Survey and Resuscitation Interventions

After the ED resuscitation team addresses the immediate life threats, other activities that the emergency nurse can anticipate include insertion of a gastric tube for decompression of the GI tract to prevent vomiting and aspiration, insertion of a urinary catheter to allow careful measure of urine output, and preparation for diagnostic studies. The resuscitation team also performs a more comprehensive head-to-toe assessment, known as the **secondary survey**, to identify other injuries or medical issues that need to be managed or that might affect the course of treatment. Splints will be applied to fractured extremities, and temporary dressings will be placed over wounds while the patient undergoes diagnostic testing or preparation for more definitive management.

## Disposition

The patient may be transported immediately to the operating room or interventional radiology suite

directly from the ED, depending on the nature of the injury. When no immediate procedural intervention is indicated, patients are admitted to inpatient units for management and nursing care based on the nature and severity of their injuries and any other pre-existing medical conditions that could complicate trauma care. However, if the facility does not have the resource capabilities to manage the injured patient, the physician arranges for transfer to a higher level of care.

It is during this time that you should also assess for any signs of human trafficking, which affects more than 20 million people globally, with up to 80% of the victims being seen by a health care provider while under the trafficker's control (Byrne et al., 2017). This practice of sexual exploitation is a type of modern-day slavery in which the victim is forced or coerced to provide sex to others in exchange for money or valuables that are given to the trafficker. Nurses must be aware that patients seen for recurrent sexually transmitted infections (STIs), pregnancy tests, and abortions may be victims of human trafficking. Physical signs of trafficking include headaches, dizziness, back pain, missing patches of hair (where it has been pulled out), burns, bruises, vaginal or rectal trauma, jaw problems, and head injuries. The victim may also have unusual tattooing or "branding" marks, which are a sign of trafficker ownership. Psychosocial symptoms experienced by victims include stress, paranoia, fear, suicidal ideation, depression, anxiety, shame, and self-loathing (Byrne et al., 2017). You can assess the patient by asking questions such as, "Do you feel free to come and go anywhere as you please?", "Does anyone you work for make you feel unsafe?", and "Have you ever felt like you cannot leave your employer?" If you suspect that a patient is a trafficking victim, follow agency policy, contact local authorities, and report to the National Human Trafficking Resource Center.

Work in collaboration with the interprofessional team to address the trauma patient's complex health care needs, including early consultation with social services and the rehabilitation team. Coordinate with other support services as necessary such as pastoral care, nutrition support, psychiatry, mental health/behavioral health specialists, and substance abuse counselors. Trauma centers are required to incorporate systems to identify patients with high-risk alcohol use (American College of Surgeons Committee on Trauma, 2014). An effective strategy is to implement a SBIRT (screening, brief intervention, and referral to treatment) program in which interprofessional trauma team members, including emergency and trauma nurses, are educated to assess patients for problem drinking. The typical interaction involves a brief, respectful conversation that offers feedback, counsel, and motivation to reduce alcohol consumption.

Consider the needs of family members in crisis and address them when planning nursing care. A trauma advanced practice nurse, if available, can help coordinate trauma care by offering clinical expertise; facilitating COMMUNICATION among caregivers; and serving as an educator for the patient, staff, and family. He or she can organize family meetings with the interprofessional team and arrange for necessary resources. If this resource is not available, a case manager or specially educated direct-care nurse may perform these functions.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Understand that emergency departments (EDs) are fast-paced, often crowded environments where care occurs for patients with a variety of health problems across the life span.
- Recognize that vulnerable populations who seek care in the ED include patients who may be uninsured or underinsured, poor, homeless, and older adults. **Health Care Disparities**
- Anticipate that the most common reasons that patients seek ED care include chest pain, abdominal pain, difficulty breathing, injury, headache, fever, and pain.
- Collaborate with members of the interprofessional team in the ED and at subsequent points of care, which includes prehospital providers, physicians, nurses, specialty teams, and support staff. **QSEN: Teamwork and Collaboration**
- Review [Chart 8-1](#) to plan and implement best practices to maintain staff and patient SAFETY in the ED. **QSEN: Safety**
- Explain core competencies needed for ED nurses, including assessment, priority setting, knowledge, technical skills, and COMMUNICATION.
- Understand that the three-level triage model categorizes patients as emergent, urgent, and nonurgent (see [Table 8-2](#)). The Emergency Severity Index is a five-tier triage system that uses both acuity and the prediction of necessary resources to rapidly categorize the priority of patients.
- Recall that trauma centers are categorized as Levels I through IV, based on their resource capabilities as listed in [Table 8-3](#).
- Remember that the mechanism of injury describes the manner in which the traumatic event occurred.
- Recall that the two most common injury-producing mechanisms are blunt trauma and penetrating trauma.
- Prioritize resuscitation interventions based on the primary survey of the injured patient by implementing the steps of the primary survey and trauma resuscitation as outlined in [Table 8-4](#). **QSEN: Safety**
- Recall that ED nurses always include patient education as an important part of discharge planning.

### Psychosocial Integrity

- Implement TEAMWORK AND COLLABORATION strategies with the psychiatric crisis team as needed. **QSEN: Teamwork and Collaboration**

### Physiological Integrity

- Remember that the expected sequence of events from admission through discharge in the ED includes treatment, stabilization, and discharge to their homes or admission for observation or inpatient care.
- Recall that older adults who visit the ED are frequently admitted to the hospital. **QSEN: Patient-Centered Care**
- Understand that ED nurses are accountable for preventing or reducing risks such as falls, medication errors, pressure injuries, and hospital-acquired infections.
- Remember that communication with the older adult may be challenging if the patient has

memory loss or acute delirium while in the ED. **QSEN: Patient-Centered Care**

## CHAPTER 9

# Care of Patients With Common Environmental Emergencies

---

Linda Laskowski-Jones

## PRIORITY AND INTERRELATED CONCEPTS

***The priority concept for this chapter is TISSUE INTEGRITY.***

***The interrelated concept for this chapter is COMFORT.***

## LEARNING OUTCOMES

### **Safe and Effective Care Environment**

1. Collaborate with the interprofessional health care team when providing care for patients with environmental emergencies.

### **Health Promotion and Maintenance**

2. Teach people at risk how to prevent environmental emergencies.

### **Physiological Integrity**

3. Prioritize first aid/prehospital interventions for patients who have thermoregulation problems, arthropod bites or stings, or venomous snake bites affecting TISSUE INTEGRITY and COMFORT.
4. Apply knowledge of pathophysiology to identify best practices for care of patients with environmental emergencies.
5. Create an evidence-based plan of care for patients who have experienced an environmental emergency.

Every day people leave their homes to enjoy recreational activities. Although seemingly harmless, there are activities that can have environmental risks, especially for older adults. Some bites, stings, and environmental conditions also pose concerns indoors. This chapter provides an overview of selected environmental emergencies, their initial emergency management (first aid), and acute care interventions.

## Heat-Related Illnesses

The most common environmental factors causing heat-related illnesses are high environmental temperature (above 95° F [35° C]) and high humidity (above 80%). These thermoregulation-related illnesses include heat exhaustion and heat stroke. Some of the most vulnerable, at-risk populations for these problems are older adults (who have less body fluid volume and can easily become dehydrated), people with mental health/behavioral health conditions, those who work outside, homeless individuals, users of illicit drugs, athletes who engage in outdoor sports, and members of the military stationed in hot climates.

A patient's health status can also increase the risk for heat-related illness, especially obesity, heart disease, fever, infection, strenuous exercise, seizures, mental health disorders, and all degrees of burns (even sunburn). The use of prescribed drugs such as lithium, neuroleptics, beta-adrenergic blockers, anticholinergics, angiotensin-converting enzyme (ACE) inhibitors, and diuretics can also increase the risk for heat-related illness.

### Health Promotion and Maintenance

Teach older adults before participating in any hot weather activity how to take steps to eliminate or minimize risks whenever possible. Ask them to have a family member, friend, or neighbor check on them several times each day to ensure that there are no signs of heat-related illness. [Chart 9-1](#) lists other essential heat-related illness prevention strategies for older adults, many of which apply to adults of any age.

#### Chart 9-1

### Nursing Focus on the Older Adult

#### Heat-Related Illness Prevention

- Avoid alcohol and caffeine.
- Prevent overexposure to the sun; use a sunscreen with an SPF of at least 30 with UVA and UVB protection.
- Rest frequently and take breaks from being in a hot environment. Plan to limit activity at the hottest time of day.
- Wear clothing suited to the environment. Lightweight, light-colored, and loose-fitting clothing is best.
- Pay attention to your personal physical limitations; modify activities accordingly.
- Take cool baths or showers to help reduce body temperature.
- Stay indoors in air-conditioned buildings if possible.
- Ask a neighbor, friend, or family member to check on the older adult at least twice a day during a heat wave.

*SPF*, Sun protection factor; *UVA*, ultraviolet A; *UVB*, ultraviolet B.

## Heat Exhaustion

### ❖ Pathophysiology

**Heat exhaustion** is a syndrome resulting primarily from dehydration. It is caused by heavy perspiration and inadequate fluid and electrolyte intake during heat exposure over hours to days. Profuse diaphoresis can lead to profound, even fatal, dehydration and hyponatremia caused by excessive sodium lost in perspiration. *If untreated, heat exhaustion can lead to heat stroke, which is a true*

emergency condition that has a very high mortality rate.

### ❖ **Interprofessional Collaborative Care**

Patients with heat exhaustion usually have flu-like symptoms with headache, weakness, nausea, and/or vomiting. Body temperature may not be significantly elevated in this condition. The patient may continue to perspire despite dehydration.

## 📌 **Nursing Safety Priority** QSEN

### **Action Alert**

Patients should be assessed for orthostatic hypotension and tachycardia, especially the older adult who can dehydrate quickly. Older adults with dehydration often experience acute confusion and are at risk for falls.

Instruct the patient to immediately stop physical activity and move to a cool place. Use cooling measures such as placing cold packs on the neck, chest, abdomen, and groin. Soak the victim in cool water or fan while spraying water on the skin. Remove constrictive clothing. Sports drinks or an oral rehydration-therapy solution can be provided. Mistakenly drinking plain water can worsen the sodium deficit. *Do not give salt tablets*, which can cause stomach irritation, nausea, and vomiting. If signs and symptoms persist, call an ambulance to transport the patient to the hospital.

In the clinical setting, monitor vital signs. Rehydrate the patient with IV 0.9% saline solution if nausea or vomiting persists. Draw blood for serum electrolyte analysis. Hospital admission is indicated only for patients who have other health problems that are worsened by the heat-related illness or for those with severe dehydration and evidence of physiologic compromise. The management of hypovolemic dehydration is discussed in more detail in [Chapter 11](#).

## **Heat Stroke**

### ❖ **Pathophysiology**

**Heat stroke** is a *true medical emergency* in which body temperature may exceed 104° F (40° C). It has a high mortality rate if not treated in a timely manner. The victim's thermoregulation mechanisms fail and cannot adjust for a critical elevation in body temperature. If the condition is not treated or the patient does not respond to treatment, organ dysfunction and death can result.

**Exertional heat stroke** has a sudden onset and is often the result of strenuous physical activity (especially when wearing too heavy clothing) in hot, humid conditions. **Classic heat stroke**, also referred to as *nonexertional heat stroke*, occurs over a period of time as a result of chronic exposure to a hot, humid environment such as living in a home without air conditioning in the high heat of the summer.

### ❖ **Interprofessional Collaborative Care**

#### ◆ **Assessment: Noticing**

Victims of heat stroke have a profoundly elevated body temperature (above 104° F [40° C]). *Although the patient's skin is hot and dry, the presence of sweating does not rule out heat stroke—people with heat stroke may continue to perspire.*

Mental status changes occur as a result of thermal injury to the brain and are the hallmark findings in heat stroke. Symptoms can include confusion, bizarre behavior, seizures, or even coma ([Chart 9-2](#)). The patient may have hypotension, tachycardia, and tachypnea. Cardiac troponin I (cTnI) is frequently elevated during nonexertional heat-related illnesses; research indicates that this test can be used to cost effectively predict severity and organ damage at the beginning of heat stroke, even in a remote setting ([Audet et al., 2015](#)).

### 📌 **Chart 9-2**

## **Key Features**

## Heat Stroke

<ul style="list-style-type: none"><li>• Body temperature more than 104° F (40° C)</li><li>• Hot and dry skin; may or may not perspire</li><li>• Mental status changes such as:<ul style="list-style-type: none"><li>• Acute confusion</li><li>• Bizarre behavior</li><li>• Anxiety</li><li>• Loss of coordination</li><li>• Hallucinations</li><li>• Agitation</li><li>• Seizures</li><li>• Coma</li></ul></li></ul>	<ul style="list-style-type: none"><li>• Vital sign changes, including:<ul style="list-style-type: none"><li>• Hypotension</li><li>• Tachycardia</li><li>• Tachypnea (increased respiratory rate)</li><li>• Electrolyte imbalances, especially sodium and potassium</li><li>• Decreased renal function (oliguria)</li><li>• Coagulopathy (abnormal clotting)</li><li>• Pulmonary edema (crackles)</li></ul></li></ul>

### ◆ Planning and Implementation: Responding

Coordinate care with the health care team to recognize and treat immediately and aggressively to achieve optimal patient outcomes. [Chart 9-3](#) lists evidence-based emergency care of patients with heat stroke.

### 📊 Chart 9-3

## Best Practice for Patient Safety & Quality Care QSEN

### Emergency Care of the Patient With Heat Stroke: Restoring Thermoregulation

#### At the Scene

- Ensure a patent airway.
- Remove the patient from the hot environment (into air-conditioning or into the shade).
- Remove the patient's clothing.
- Pour or spray cold water on the patient's body and scalp.
- Fan the patient (not only the person providing care, but all surrounding people should fan the patient with newspapers or whatever is available).
- If ice is available, place ice in cloth or bags and position the packs on the patient's scalp, in the groin area, behind the neck, and in the armpits.
- Contact emergency medical services to transport the patient to the emergency department.

#### At the Hospital

- Give oxygen by mask or nasal cannula; be prepared for endotracheal intubation.
- Start at least one IV with a large-bore needle or cannula.
- Administer normal saline (0.9% sodium chloride) as prescribed, using cooled solutions if available.
- Use a cooling blanket.
- Do not give aspirin or any other antipyretics.
- Insert a rectal probe to measure core body temperature continuously or use a rectal thermometer and assess temperature every 15 minutes.
- Insert an indwelling urinary drainage catheter.
- Monitor vital signs frequently as clinically indicated.
- Obtain baseline laboratory tests as quickly as possible: serum electrolytes, cardiac enzymes, liver

enzymes, and complete blood count (CBC).

- Assess arterial blood gases.
- Administer muscle relaxants (benzodiazepines) if the patient begins to shiver.
- Measure urine output and specific gravity to determine fluid needs.
- Stop cooling interventions when core body temperature is reduced to 102° F (39° C).
- Obtain urinalysis and monitor urine output.

#### First Aid/Prehospital Care.

Do not give food or liquid by mouth because vomiting and aspiration are risks in patients with neurologic impairment. Immediate medical care using advanced life support is essential (see the [Evidence-Based Practice](#) box).

## Evidence-Based Practice QSEN

### What Does Evidence Say About On-Site Treatment of Exertional Heat Stroke?

Sloan, B. K., Kraft, E. M., Clark, D., Schmeissing, S., Byrne, B. C., & Rusyniak, D. E. (2015). On-site treatment of exertional heat stroke. *The American Journal of Sports Medicine*, 43(4), 823-829.

Exertional heat stroke can lead to morbidity and mortality if untreated or undertreated. The authors conducted a descriptive epidemiological study of people over an 8-year period who developed exertional heat stroke when participating in the Indianapolis half marathon. They identified signs of heat stroke, methods of treatment at the marathon site, and eventual outcomes whether treatment concluded on-site or the runner was sent to the hospital.

Of the 696 runners who received medical care on-site at the half marathon, 32 were diagnosed with heat stroke, 22 of whom were successfully treated on-site with cold-water immersion. Only 10 others, who did not undergo cold-water immersion, were transported from the site to a hospital; 4 of these were then discharged to go home.

#### Level of Evidence: 4

This is a descriptive epidemiological study.

#### Commentary: Implications for Practice and Research

This study demonstrates that rapid cooling is cost reasonable and is effective in decreasing morbidity and mortality of patients with heat stroke. The major nursing implication from this study is that nurses working at community events such as a 5K, half, or full marathon should be aware of and prepared to administer appropriate methods of rapid cooling for individuals who have heat stroke. Strengths of the study included the large sample size collected over a long period of time. A weakness might be the level of evidence, but this is likely outweighed by the sampling method and the time factor of review. Nurses are in a key position to advocate for individuals in the community and to implement interventions that can help treat heat stroke. Chart 9-1 lists best practices for decreasing the risk for heat-related illnesses in older adults.

## Nursing Safety Priority QSEN

### Critical Rescue

After ensuring that the patient has a patent airway, effective breathing, and adequate circulation, recognize that you must use rapid cooling as the first priority for care. Respond by implementing methods for rapid cooling, which include removing clothing; placing ice packs on the neck, axillae, chest and groin; immersing the patient or wetting the patient's body with cold water; and fanning rapidly to aid in evaporative cooling.

### Hospital Care.

*The first priority for collaborative care is to monitor and support the patient's airway, breathing, and circulatory status.* Provide high-concentration oxygen therapy, start several IV lines with 0.9% saline solution, and insert an indwelling urinary catheter. Continue aggressive interventions to cool the patient until the rectal temperature is 102° F (38.9° C). External continuous cooling methods include using cooling blankets and applying ice packs in the axillae and groin and on the neck and head. Internal cooling methods may include iced gastric and bladder lavage. Use a continuous core temperature-monitoring device (e.g., rectal or esophageal probe) or a temperature-monitoring urinary bladder catheter to prevent hypothermia.

If shivering occurs during the cooling process, give a parenteral benzodiazepine such as diazepam (Valium). Lorazepam (Ativan) is an alternative agent. Seizure activity can further elevate body temperature and is also treated with an IV benzodiazepine. Once the patient is stabilized, admission to a critical care unit is warranted to monitor for complications such as multi-system organ dysfunction syndrome and severe electrolyte imbalances; these problems increase mortality risk.

## NCLEX Examination Challenge 9-1

### Physiological Integrity

The nurse is caring for an older-adult client with heat exhaustion. Which assessment finding indicates to the nurse that the client may need hospitalization?

- A. Alert and oriented
- B. Reports nausea and weakness
- C. Continues to sweat while being cooled
- D. Mucous membranes are dry and sticky

## Snakebites and Arthropod Bites and Stings

Most snakes fear humans and attempt to avoid contact with them. Sudden, unexpected confrontations at close range often lead to defensive strikes. Awareness is the key to snakebite prevention. Although most snake species are nonvenomous (nonpoisonous) and harmless, there are two families of poisonous snakes in North America: pit vipers (*Crotalidae*) and coral snakes (*Elapidae*). [Chart 9-4](#) provides common-sense actions to avoid being bitten by a poisonous snake.

### Chart 9-4

## Patient and Family Education: Preparing for Self-Management

### Snakebite Prevention

- Do not keep venomous snakes as pets.
- Be extremely careful in locations where snakes may hide such as tall grass, rock piles, ledges and crevices, woodpiles, brush, boxes, and cabinets. Snakes are most active on warm nights.
- Don protective attire such as boots, heavy pants, and leather gloves. When walking or hiking, use a walking stick or trekking poles.
- Inspect suspicious areas before placing hands and feet in them.
- Do not harass any snakes you may encounter. Striking distance can be up to two thirds the length of the snake. Even young snakes pose a threat; they are capable of envenomation from birth.
- Be aware that newly dead or decapitated snakes can inflict a bite for up to an hour after death because of persistence of the bite reflex.
- Do not transport the snake with the victim to the medical facility for identification purposes; instead, take a digital photo of the snake at a safe distance if possible.

### Nursing Safety Priority QSEN

#### Critical Rescue

Recognize that the first priority is to move the person to a safe area away from the snake and encourage rest to decrease venom circulation. Respond (when in the safe area) by removing jewelry and constricting clothing before swelling worsens. Call for immediate emergency assistance. Do not attempt to capture or kill the snake, but do take digital photographs at a safe distance if possible to aid in snake identification.

Pit vipers are named for the characteristic depression or pit between each eye and nostril that serves as a heat-sensitive organ for locating warm-blooded prey. They include various species of rattlesnakes, copperheads, and cottonmouths and account for the majority of the poisonous snakebites in the United States ([Figs. 9-1](#) and [9-2](#)). Management of a patient who has a snakebite from a pit viper depends on the severity of envenomation (venom injection), as noted in [Table 9-1](#).

**FIG. 9-1** Southern copperhead (*Agkistrodon contortrix*) has markings that make it almost invisible when lying in leaf litter. (From Auerbach, P. S. [2017]. *Wilderness medicine* [7th ed.]. Philadelphia: Mosby; courtesy Michael Cardwell & Carl Barden Venom Laboratory.)

**FIG. 9-2** Cottonmouth water moccasin (*Agkistrodon piscivorus*). The open-mouthed threat gesture is characteristic of this semiaquatic pit viper. (From Auerbach, P. S. [2017]. *Wilderness medicine* [7th ed.]. Philadelphia: Mosby; courtesy Sherman Minton, MD.)

**TABLE 9-1**

**Grades of Pit Viper Envenomation**

ENVENOMATION CHARACTERISTICS	
None	Fang marks, but no local or systemic reactions
Minimal	Fang marks, local swelling and pain, but no systemic reactions
Moderate	Fang marks and swelling progressing beyond the site of the bite; systemic signs and symptoms such as nausea, vomiting, paresthesias, or hypotension.
Severe	Fang marks present with marked swelling of the extremity; subcutaneous ecchymosis; severe symptoms, including manifestations of coagulopathy

From Auerbach, P. S., Donner, H. J., & Weiss, E. A. (2013). *Field guide to wilderness medicine* (4th ed.). St. Louis: Mosby.

Coral snakes (Fig. 9-3) are found from North Carolina to Florida and in the Gulf states through Texas and the southwestern United States. They have broad bands of red and black rings separated by yellow or cream rings. Several harmless snake species closely resemble the coral snake. If a black band lies between the red and yellow bands, the snake is usually nonvenomous. If the red band touches the yellow band, the snake is venomous. A helpful memory aid for identifying coral snakes is “red on yellow can kill a fellow” and “red on black, venom lack.” *Be aware that this saying applies only to coral snakes found in the United States!* These nonaggressive snakes have short, fixed fangs and inject highly neurotoxic venom into prey.

**FIG. 9-3** Sonoran coral snake (*Micruroides euryxanthus*) is also known as the *Arizona coral snake*. No documented fatality has followed a bite by this species. (From Auerbach, P. S. [2017]. *Wilderness medicine* [7th ed.]. Philadelphia: Mosby; courtesy Michael Cardwell & Jude McNally.)

## **Nursing Safety Priority** QSEN

### **Critical Rescue**

Recognize that the most significant risk to the snakebite victim is airway compromise and respiratory failure. Respond by ensuring that the patient's IV lines are patent and that resuscitation equipment is immediately available.

Arthropods include spiders, scorpions, bees, and wasps. Unlike snakes, almost all species of spiders are venomous to some degree—most are not harmful to humans either because their mouth is too small to pierce human skin or the quantity or quality of their venom is inadequate to produce major health problems. Brown recluse (Figs. 9-4 and 9-5) and black widow spiders, scorpions (Fig. 9-6), bees, and wasps are examples of venomous arthropods that can cause toxic reactions in humans. Chart 9-5 lists actions that help prevent arthropod bites and stings.

**FIG. 9-4** Brown recluse spider (*Loxosceles reclusa*). (From Auerbach, P. S. [2017]. *Wilderness medicine* [7th ed.]. Philadelphia: Mosby; courtesy Indiana University Medical Center.)

**FIG. 9-5** Brown recluse spider bite after 24 hours, with central ischemia and rapidly advancing cellulitis. (From Auerbach, P. S. [2017]. *Wilderness medicine* [7th ed.]. Philadelphia: Mosby; courtesy Paul S. Auerbach, MD.)

**FIG. 9-6** The bark scorpion of Arizona (*Centruroides sculpturatus*). (From Auerbach, P. S. [2012]. *Wilderness medicine* [6th ed.] Philadelphia: Mosby.)

### **Chart 9-5**

## **Patient and Family Education: Preparing for Self-Management**

### **Arthropod Bite/Sting Prevention**

- Wear protective clothing, including gloves and shoes, when working in areas known to harbor venomous arthropods such as spiders, scorpions, bees, and wasps.
- Cover garbage cans. Bees and wasps are attracted to uncovered garbage.
- Use screens in windows and doors to prevent flying insects from entering buildings.
- Inspect clothing, shoes, and gear for insects before putting on these items.
- Shake out clothing and gear that have been on the ground to prevent arthropod “stowaways” and inadvertent bites and stings.
- Consult an exterminator to control arthropod populations in and around the home. Eliminating insects that are part of the arthropod’s food source may also limit their presence.
- Identify nesting areas such as yard debris and rock piles; remove them whenever possible.
- Do not place unprotected hands where the eyes cannot see.

- Avoid handling insects or keeping them as “pets.”
- Do not swat insects, wasps, and Africanized bees because they can send chemical signals that alert others to attack.
- Carry a prescription epinephrine autoinjector and antihistamines if known to be allergic to bee and wasp stings. Ensure that at least one family member is also able to use the autoinjector.

Bees and wasps are also venomous arthropods. Stings can produce a wide range of reactions from mild changes in levels of COMFORT at the sting site to severe pain, multi-system problems, and life-threatening anaphylaxis in allergic people. Bumblebees, hornets, and wasps are capable of stinging repeatedly when disturbed. They have a smooth stinger that may or may not become lodged in the victim. Honeybees can sting just once. When a honeybee stings a person, the stinger and venom sac pull away from the bee. The bee dies, but venom injection continues because the stinger and sac remain in the victim.

“Africanized” bees, also called “killer bees,” are a very aggressive species that are found in the southwestern United States. They are known to attack in groups and can remain agitated for several hours. People under attack should attempt to outrun the bees, if possible, and keep their mouth and eyes protected from the swarm. A person should never go into a body of water because the bees will attack when he or she comes up for air. When a person sustains multiple stings, reactions are more severe and may be fatal because multiple venom doses have cumulative toxic effects.

Table 9-2 provides detailed information about each of these organisms, their characteristics, pathophysiology of the bite/sting, first aid and prehospital care, and interprofessional collaborative care that takes place in an acute care setting. Chart 9-5 lists actions that may help prevent arthropod bites and stings.

**TABLE 9-2**  
**Quick Reference for Bites and Stings**

ORGANISM	CHARACTERISTICS	PATHOPHYSIOLOGY	FIRST AID/PRE-HOSPITAL CARE	INTERPROFESSIONAL COLLABORATIVE CARE
Pit viper (rattlesnakes, cottonmouths, copperheads)	Triangular head Two retractable curved fangs Rattlesnakes have vibrating horny rings in their tails	Venom immobilizes and aids in digestion of prey; may be lethal Has local and systemic effects Enzymes break down human tissue proteins, alter tissue integrity	Move to safety, away from snake. Call for immediate emergency assistance. Encourage rest to decrease venom circulation. Remove jewelry and constrictive clothing. Take photos of snake from a safe distance to aid in identification. Immobilize affected extremity in position of function—maintain at level of heart. Keep patient warm, provide calm environment Do <i>not</i> incise or suck wound, apply ice, or use a tourniquet.	<i>Assessment/Noticing:</i> Look for: • Puncture wounds in skin. • Pain, swelling, redness, and/or bruising around bite(s). • Vesicles or hemorrhagic bullae that may form later. • Patient identification of minty, rubbery, or metallic taste. • Tingling or paresthesias on scalp, face, and lips. • Muscle twitching, weakness. • Nausea and vomiting. • Hypotension, seizures. • Clotting abnormalities or DIC. <i>Hospital Care:</i> • Obtain complete history of event (snake appearance, time of bite, prehospital interventions, and any past snakebites or antivenom therapy). • Give supplemental oxygen. • Insert two large-bore IV lines. • Infuse normal saline or Ringer’s lactate. • Continuously monitor heart function and blood pressure. • Provide opioids to decrease pain. • Obtain coagulation panel, CBC, CK, type and crossmatch, urinalysis. • Obtain ECG. • Mark, measure, and record circumference of bitten extremity q15-30 minutes. • See Table 9-1 for envenomation severity. • Contact regional poison control for specific advice on antivenom dosing and medical management. • If indicated, administer Crotalidae, Polyvalent Immune Fab (CroFab) as ordered
Coral snakes	Bands of black, red, and yellow that encircle the snake’s body Small maxillary fangs	Venom contains nerve and muscle toxins Blocks neurotransmission Toxic effects may be delayed up to 13 hours and then produce rapid clinical deterioration (Norris, 2015)	Definitively identify snake as a coral snake, if possible. Encircle affected extremity with an elastic bandage or roller gauze dressing (do not wrap so tightly that arterial flow is impeded); then splint. Leave on until the patient is treated at an acute care facility.	<i>Assessment/Noticing:</i> Look for: • Weakness, cranial nerve deficits (ptosis, diplopia, swallowing difficulty), altered level of consciousness, and respiratory paralysis (Norris, 2015). • Pain at the site, which may be described as mild and transient. • Difficult to find fang marks. <i>Hospital Care:</i> • Identify snake as a coral snake if possible. If the snake cannot be identified, treat as if venom were injected. • Be aware that toxic effects of venom may be delayed up to 13 hours and then produce rapid clinical deterioration (Norris, 2015). • Monitor for elevation in CK level from muscle breakdown and myoglobinuria. • Continually monitor cardiac function, blood pressure, and pulse oximetry. Be prepared to admit to a critical care unit. • Be prepared to provide aggressive airway management if respiratory insufficiency or severe neurologic impairment occurs.

				<ul style="list-style-type: none"> <li>• Provide interventions to decrease risk for aspiration.</li> <li>• Coral snake antivenom is not manufactured in the United States. Supportive care is recommended (Norris, 2015).</li> <li>• Teach the patient that effects of a severe bite can persist for many days (Norris, 2015).</li> <li>• Contact regional poison control for specific advice on patient management.</li> </ul>
Brown recluse spiders	Medium-size, light brown, fiddle-shaped mark from eyes down their back (Fig. 9-4) Live in boxes, closets, basements, sheds, garages	Venom causes cellular damage and impaired tissue integrity	Apply cold compresses over site of bite. Do not apply heat because it increases enzyme activity and potentially worsens wound. Elevate affected extremity, provide local wound care, and rest.	<p><i>Assessment/Noticing:</i></p> <p>Look for:</p> <ul style="list-style-type: none"> <li>• Central bite mark, which may appear as a bleb or vesicle with edema and erythema.</li> <li>• Description of bite as painless, stinging, or sharp.</li> <li>• Center of bite to become bluish-purple.</li> <li>• Central part of the wound to become dark and necrotic over the following 1-3 days (Fig. 9-5) for some patients. This is called the classic <i>red, white, and blue sign</i> associated with severe bites.</li> <li>• Systematic toxicity, which rarely occurs (rash, fever, chills, nausea, vomiting, malaise, joint pain).</li> <li>• Rare, severe systemic complications (loxoscelism), which may include hemolytic anemia, thrombocytopenia, DIC, and death.</li> </ul> <p><i>Hospital Care:</i></p> <ul style="list-style-type: none"> <li>• Hospitalization is rarely indicated.</li> <li>• Teach patient supportive care measures.</li> <li>• Topical antiseptic and sterile dressings can be applied to wound.</li> <li>• Antibiotics may be prescribed.</li> <li>• Administer tetanus prophylaxis as needed.</li> <li>• For extensive wounds, débridement and skin grafting may be needed.</li> </ul>
Black widow spiders	Female shiny black with a red hourglass pattern on abdomen (hourglass pattern is faint in males) Inhabit cool, damp environments such as log piles, vegetation, and rocks; also live in barns, sheds, and garages	Venom is neurotoxic; produces a syndrome known as latrodectism in which the venom causes neurotransmitter release from nerve terminals	Apply ice pack to decrease action of neurotoxin. Monitor for systemic toxicity; support airway, breathing, and circulation as needed. Transport to acute care facility as soon as possible.	<p><i>Assessment/Noticing:</i></p> <p>Look for:</p> <ul style="list-style-type: none"> <li>• Description of bite as nearly painless to sharply painful.</li> <li>• Tiny papule or small, red punctate mark.</li> <li>• Systemic complications, which usually develop within an hour of bite and involve neuromuscular system.</li> <li>• Concerns that may include severe abdominal pain, muscle rigidity and spasm, hypertension, nausea, and vomiting. This may be initially incorrectly diagnosed as an acute abdomen because of similarity in symptoms.</li> </ul> <p><i>Hospital Care:</i></p> <ul style="list-style-type: none"> <li>• Monitor older adults, especially those with cardiovascular disease, for complications as sequelae of hypertension.</li> <li>• Monitor vital signs, especially blood pressure and respiratory function.</li> <li>• Observe for seizures related to rapidly rising blood pressure.</li> <li>• Administer opioid pain medication and muscle relaxants (e.g., diazepam) as ordered.</li> <li>• Administer tetanus prophylaxis as needed.</li> <li>• Monitor for signs of pulmonary edema, uncontrollable hypertension, respiratory arrest, and/or shock.</li> <li>• Administer antivenom as ordered. Monitor for signs of anaphylaxis and serum sickness.</li> <li>• Contact regional poison control for specific advice on antivenom dosing and medical management.</li> </ul>
Scorpions	Found within the United States, although not typically in the Midwest or New England Bark scorpion lives in southwestern United States; its sting can be potentially fatal (Fig. 9-6)	Venom injected via stinging apparatus on tail; effects are neurotoxic	Transport to acute care facility as soon as possible.	<p><i>Assessment/Noticing:</i></p> <p>Look for:</p> <ul style="list-style-type: none"> <li>• Symptoms arise immediately after the sting, reaching crisis level within 12 hours.</li> <li>• Gentle tapping at the site of sting usually causes increased pain.</li> <li>• Sting site may not be reddened.</li> <li>• Severe systemic symptoms include excessive salivation, hyperactivity, high fever, hypertension, GI disorders, tachycardia, cardiac dysfunction, pulmonary edema, nervous system involvement, and (rarely) death.</li> </ul> <p><i>Hospital Care:</i></p> <ul style="list-style-type: none"> <li>• Monitor older adults, especially those with cardiovascular disease, for complications as sequelae of hypertension.</li> <li>• Monitor vital signs, especially blood pressure and respiratory function.</li> <li>• Observe for seizures related to rapidly rising blood pressure.</li> <li>• Provide basic wound care with antiseptic agent and apply ice pack to sting site.</li> <li>• Administer tetanus prophylaxis as needed.</li> <li>• Administer analgesic and sedative agents with caution.</li> <li>• Be very cautious if administering opioids, benzodiazepines, and barbiturates, as these can cause loss of airway reflexes and precipitate respiratory failure.</li> <li>• Contact regional poison control for specific information on pharmacologic agents for scorpion stings.</li> </ul>
Bees and wasps	Found all over United States; "Africanized" or "killer" bees found in southwestern United States	Venom injected through stings; most can sting repeatedly when disturbed; only honeybees can sting just once	Quickly remove stinger with tweezers or by gently scraping or brushing it off with the edge of a knife blade, credit card, or needles (if present) (Auerbach, 2016b) and apply ice pack. Ensure that airway, breathing, and circulation are maintained. If patient has history of allergic reactions to stings or has wheezing, facial swelling, and respiratory distress, epinephrine must be given immediately. Allergic adult patients typically carry an epinephrine autoinjector (e.g., EpiPen®, Auvi-Q™). <sup>*</sup> (See Chapter 20 for further discussion of epinephrine administration for anaphylaxis management.) Follow with antihistamine.	<p><i>Assessment/Noticing:</i></p> <p>Look for:</p> <ul style="list-style-type: none"> <li>• Wheal-and-flare skin reactions; swelling can be extensive and involve an entire limb or body area.</li> <li>• Urticaria (hives), pruritus (itching), and swelling of lips and tongue in patients who have allergy to the venom.</li> <li>• Monitor for anaphylaxis, a true medical emergency evidenced by respiratory distress with bronchospasm, laryngeal edema, hypotension, decreased mental status, and cardiac dysrhythmias.</li> <li>• Systemic effects develop based on venom load and patient sensitivity. These may include generalized edema, nausea, vomiting, diarrhea, destruction of red and white blood cells and platelets, damage to the blood vessel walls, acute kidney injury, renal failure, liver injury, cardiac complications, and multi-system organ failure.</li> </ul> <p><i>Hospital Care:</i></p> <ul style="list-style-type: none"> <li>• Administer oxygen.</li> <li>• Continuously monitor cardiac function and blood pressure.</li> </ul>

				<ul style="list-style-type: none"> <li>• Administer antihistamines, albuterol, and corticosteroids as ordered.</li> <li>• Be certain that advanced life support drugs and resuscitation equipment are readily available.</li> <li>• Observe patients who have sustained multiple stings for several hours. Be prepared to admit to critical care if toxic venom effects are noted.</li> <li>• See <a href="#">Table 9-2</a> for a quick reference regarding bites and stings.</li> </ul>
--	--	--	--	--

\*In 2015 Sanofi U.S voluntarily recalled all AUVI-Q on the market, including the 0.15-mg and 0.3-mg strengths, in lot numbers 2081278 through 3037230, which expire October 2015 through December 2016. Patients may still have one of these in their possession; therefore educate patients about this recall. New approval for AUVI-Q was given in February 2017.

*CBC*, Complete blood count; *CK*, creatine kinase; *DIC*, disseminated intravascular coagulation; *ECG*, electrocardiogram.

## Clinical Judgment Challenge 9-1

### Safety QSEN

You are working as a nurse at a camp for adult leaders. The area of the camp is known for having rattlesnakes present. One of the leaders calls you on the phone and reports that a rattlesnake has bitten another leader.

1. Which initial teaching may have prevented exposure of the leaders to rattlesnakes?
2. What will you tell the leader who has called you by phone?
3. What is the priority of care of the individual who has been bitten?
4. Which interventions will you prioritize when the leader and the bitten patient reaches your location?

## Nursing Safety Priority QSEN

### Drug Alert

All patients who have sustained multiple stings (particularly more than 50) are observed in an emergency care setting for several hours to monitor for the development of toxic venom effects. A critical care admission may be needed.

## Nursing Safety Priority QSEN

### Action Alert

Teach anyone who develops an allergic reaction to bee or wasp stings to always carry a prescription epinephrine autoinjector and wear a medical alert tag or bracelet.

## Lightning Injuries

### ❖ Pathophysiology

Lightning is a year-round force of nature responsible for multiple injuries and deaths each year. It is caused by an electric charge generated within thunderclouds that may become cloud-to-ground lightning—the most dangerous form to people and structures. Young adult males account for the majority of lightning-related deaths. Most lightning-related injuries occur in the summer months during the afternoon and early evening because of increased thunderstorm activity and greater numbers of people spending time outside. Anyone without adequate shelter, including golfers, hikers, campers, beach-goers, and swimmers, is at risk.

Lightning has an enormous magnitude of energy and a different current flow than a typical high-voltage electric shock. The duration of contact is nearly instantaneous, resulting in a flashover phenomenon—an effect that may account for the relatively low overall mortality rate. Because water is a conductor of electricity and current takes the path of least resistance to the ground, any wetness on the body increases the flashover effect of a lightning strike. Lightning flashover produces an explosive force that can injure victims directly and cause them to fall or to be thrown. The clothing and shoes of victims may be damaged or blown off in the process.

Lightning produces injury by directly striking a victim, splashing off a nearby object, or traveling through the ground. Although few people die after a lightning strike, many survivors are left with permanent disabilities.

### Health Promotion and Maintenance

Injuries caused by lightning strike are highly preventable. Teach people to stay indoors during an electrical storm. [Chart 9-6](#) lists common prevention strategies. For more information the Wilderness Medical Society (<http://wms.org>) also offers evidence-based practice guidelines for the prevention and treatment of lightning injuries (Davis et al., 2014).

#### Chart 9-6

### Patient and Family Education: Preparing for Self-Management

#### Lightning Strike Prevention

- Observe weather forecasts when planning to be outside.
- Seek shelter when you hear thunder. Safe choices include going inside the nearest building or an enclosed vehicle. However, isolated sheds and the entrances to caves are dangerous. Do not stand under an isolated tall tree or structure (e.g., ski lift, flagpole, boat mast, power line) in an open area such as a field, ridge, or hilltop; lightning seeks the highest point. A stand of dense trees offers better protection.
- Leave the water immediately (including an indoor shower or bathtub) and move away from any open bodies of water.
- Avoid metal objects such as chairs or bleachers; put down tools, fishing rods, garden equipment, golf clubs, and umbrellas; stand clear of fences, exposed pipes, motorcycles, bicycles, tractors, and golf carts.
- If camping in a tent, stay away from the metal tent poles and wet walls.
- Once inside a building, stay away from open doors, windows, fireplaces, metal fixtures, and plumbing.
- Turn off electrical equipment, including computers, televisions, and stereos.

- Stay off a hard-wired telephone. Lightning can enter through the telephone line and produce head and neck trauma, including cataracts and tympanic membrane disruption. Death can result.
- If you are caught out in the open and cannot seek shelter, attempt to move to lower ground such as a ravine or valley; stay away from any tall trees or objects that could result in a lightning strike splashing over to you; place insulating material between you and the ground (e.g., sleeping pad, rain parka, life jacket). A lightning strike is imminent if your hair stands on end, you see blue halos around objects, and hear high-pitched or crackling noises. If you cannot move away from the area immediately, crouch on the balls of your feet and tuck your head down to minimize the target size; do not lie on the ground or have hand contact with the ground.

Data from Auerbach, P. S., Donner, H. J., & Weiss, E. A. (2013). *Field guide to wilderness medicine* (4th ed.). St. Louis: Mosby.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

Both the cardiopulmonary and the central nervous systems are profoundly affected by lightning injuries. *The most lethal initial effect of massive electrical current discharge on the cardiopulmonary system is cardiac arrest.* Because cardiac cells are autorhythmic, an effective cardiac rhythm may return spontaneously. However, prolonged respiratory arrest from impairment of the medullary respiratory center can produce hypoxia and subsequently a second cardiac arrest. Therefore, when attempting to manage multiple victims of a lightning strike, provide care to those who are in cardiopulmonary arrest first. Initiate resuscitation measures with immediate airway and ventilatory management, chest compressions, and other appropriate life support interventions.

People who survive the immediate lightning strike may be treated in a less emergent fashion. However, these victims can have serious myocardial injury, which may be manifested by electrocardiogram (ECG) and myocardial perfusion abnormalities such as angina and dysrhythmias. The initial appearance of mottled skin and decreased-to-absent peripheral pulses usually arises from arterial vasospasm and typically resolves spontaneously in several hours.

Central nervous system (CNS) injury is common in lightning strike victims. A classic finding is an immediate but temporary paralysis, known as *kerapno paralysis*, that affects the lower limbs to a greater extent than the upper limbs. This condition usually resolves within hours, but the patient must be evaluated for spinal injury. Other signs and symptoms and complications resulting from lightning strikes include cataracts, tympanic membrane rupture, cerebral hemorrhage, depression, and post-traumatic stress disorder. Lightning strikes also cause skin burns. Most burns are superficial and heal without incident. Patients may have full-thickness burns, charring, and contact burns from overlying metal objects. A characteristic skin manifestation of lightning is the appearance of tree-like branching or ferning marks on the skin called **Lichtenberg figures or kerapnographic markings**. These skin manifestations are not considered burns and are thought to be caused by the coagulation of blood cells in the capillaries.

### ◆ Interventions: Responding

#### First Aid/Prehospital Care.

Because of lightning's powerful impact to the body, patients are at great risk for multi-system trauma. The full extent of injury may not be known until thorough monitoring and diagnostic evaluation can be performed in the hospital. Initial care includes spinal stabilization with priority attention to maintenance of an adequate airway, effective breathing, and circulation through standard basic and advanced life support measures. Cardiopulmonary resuscitation (CPR) is performed immediately when a person is in cardiac arrest. If cardiopulmonary or CNS injury is present, skin burns are *not* an initial priority. However, if time and resources permit, a sterile dressing may be applied to cover the sites. *Victims of lightning strike are not electrically charged; the rescuer is in no danger from physical contact.* Nonetheless, the storm can present a continued threat to everyone in the vicinity who lacks adequate shelter. Contrary to popular belief, lightning can and does strike in the same place more than once.

#### Hospital Care.

Once in the acute care hospital setting, the focus of care is advanced life support management, including cardiac monitoring to detect cardiac dysrhythmias and a 12-lead ECG. The patient may require mechanical ventilation until spontaneous breathing returns. Collaborate with the health care team to perform a thorough physical and diagnostic evaluation to identify obvious and occult (hidden) traumatic injuries because the patient may have suffered a fall or blast effect during the strike. A computed tomography (CT) scan of the head may be performed to identify intracranial hemorrhage. A creatine kinase (CK) measurement may be requested to detect skeletal muscle damage resulting from the lightning strike. In severe cases, **rhabdomyolysis** (circulation of by-products of skeletal muscle destruction) can lead to renal failure. Burn wounds are assessed and treated according to standard burn care protocols. Tetanus prophylaxis is necessary for burns or any break in skin integrity. Some institutions transfer these victims to a burn center for follow-up management.

## Cold-Related Injuries

Two common cold-related injuries are hypothermia and frostbite. Both types of injury can be prevented by implementing protection from the cold. Teach patients at risk ways to prevent these injuries through methods to maintain thermoregulation, which can range from alterations in COMFORT to major systemic complications.

### Health Promotion and Maintenance

When participating in cold-weather activities, clothing choices are critical to the prevention of hypothermia and frostbite. Teach the importance of wearing synthetic clothing because it moves moisture away from the body and dries fast. Cotton clothing, especially as an undergarment, holds moisture, becomes wet, and contributes to the development of hypothermia. It should be strictly avoided in a cold outdoor environment; this rule applies to gloves and socks as well. Wet socks and gloves promote frostbite in the toes and fingers. Wearing too many pairs of socks can decrease circulation and lead to frostbite.

Clothing should be layered so it can be easily added or removed as the temperature changes. The inner layers, such as polyester fleece, provide warmth and insulation. The purpose of the outer layer is to block the wind and provide moisture protection. This layer is best made of a windproof, waterproof, breathable fabric. A hat is an essential clothing item that significantly decreases body heat loss through the head. Face protection with a facemask should be used on particularly cold days when wind chill poses a risk. Sunscreen (minimum sun protection factor [SPF] 30) and sunglasses are also important to protect skin and eyes from the sun's harmful rays.

Teach people to keep water, extra clothing, blankets, and food in their car when driving in winter in case the vehicle becomes stranded. Maintaining personal fitness and conditioning is also an important consideration to prevent hypothermia and frostbite. People should not diet or restrict food or fluid intake when participating in winter outdoor activities. Malnutrition and dehydration contribute to cold-related illnesses and injuries. Finally, it is important for people to know their physical limits and to come in out of the cold when these limits have been reached.

## Hypothermia

### ❖ Pathophysiology

**Hypothermia** is a core body temperature below 95° F (35° C). Common predisposing conditions that promote hypothermia include:

- Cold-water immersion
- Acute illness (e.g., sepsis)
- Traumatic injury
- Shock states
- Immobilization
- Cold weather (especially for the homeless and people working outdoors)
- Advanced age
- Selected medications (e.g., phenothiazines, barbiturates)
- Alcohol intoxication and substance abuse
- Malnutrition
- Hypothyroidism
- Inadequate clothing or shelter (e.g., the homeless population)

An environmental temperature below 82° F (28° C) can produce impaired thermoregulation and hypothermia in any susceptible person. *Therefore people, especially older adults, are actually at risk on a year-round basis in most areas of the world.* Wind chill is a significant factor: heat loss increases as wind speed rises. Wet conditions further increase heat loss through evaporation. Weather is the most common cause of hypothermia for outdoor sports enthusiasts and for those with inadequate clothing or shelter. It is also a problem for the older adult, the homeless, and the poor who cannot afford heating.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

Hypothermia is commonly divided into three categories by severity: *mild* (90° to 95° F [32° to 35° C]); *moderate* (82.4° to 90° F [28° to 32° C]); and *severe* (below 82.4° F [28° C]). Treatment decisions are based on the severity of hypothermia. [Chart 9-7](#) summarizes by category the common key features for the patient who is hypothermic.

#### Chart 9-7

### Key Features

#### Hypothermia

Mild	Severe
<ul style="list-style-type: none"> <li>• Shivering</li> <li>• Dysarthria (slurred speech)</li> <li>• Decreased muscle coordination</li> <li>• Impaired cognition (“mental slowness”)</li> <li>• Diuresis (caused by shunting of blood to major organs)</li> </ul>	<ul style="list-style-type: none"> <li>• Bradycardia</li> <li>• Severe hypotension</li> <li>• Decreased respiratory rate</li> <li>• Cardiac dysrhythmias, including possible ventricular fibrillation or asystole</li> <li>• Decreased neurologic reflexes</li> <li>• Decreased pain responsiveness</li> <li>• Acid-base imbalance</li> </ul>

### ◆ Interventions: Responding

#### First Aid/Prehospital Care.

For treatment of *mild hypothermia*, the person needs to be sheltered from the cold environment, have all wet clothing removed, and undergo passive or active external rewarming. Passive methods involve applying warm clothing or blankets. Active methods incorporate heating blankets, warm packs, and convective air heaters or warmers to speed rewarming. If a heating blanket is used, monitor the patient's skin at least every 15 to 30 minutes to reduce the risk for burn injury.

In the case of mild, uncomplicated hypothermia as the only health problem, having the victim drink warm high-carbohydrate liquids that do not contain alcohol or caffeine can aid in rewarming. Alcohol is a peripheral vasodilator; both alcohol and caffeine are diuretics. These effects can potentially worsen dehydration and hypothermia.

#### Hospital Care.

General management principles apply to both *moderate* and *severe* hypothermia. Protect patients from further heat loss and handle them gently to prevent ventricular fibrillation. Positioning the patient in the supine position prevents orthostatic changes in blood pressure from cardiovascular instability. Follow standard resuscitation efforts with special attention to maintenance of airway, breathing, and circulation as recommended by the [American Heart Association \(2015\)](#):

- Administer drugs with caution and/or spaced at longer intervals because metabolism is unpredictable in hypothermic conditions.
- Remember that drugs can accumulate without obvious therapeutic effect while the patient is cold but may become active and potentially lead to drug toxicity as effective rewarming is under way.
- Consider withholding IV drugs, except vasopressors, until the core temperature is above 86° F (30° C).
- Initiate CPR for patients without spontaneous circulation.
- For a hypothermic patient in ventricular fibrillation or pulseless ventricular tachycardia, one defibrillation attempt is appropriate. Be aware that defibrillation attempts may be ineffective until the core temperature is above 86° F (30° C).

Treatment of *moderate* hypothermia may involve both active external and core (internal) rewarming methods. Applying external heat with heating blankets can promote core temperature “after-drop” by producing peripheral vasodilation. **After-drop** is the continued decrease in core body temperature after the victim is removed from the cold environment; it is caused by the return

of cold blood from the periphery to the central circulation. Therefore the patient's trunk should be actively rewarmed before the extremities. Core rewarming methods for moderate hypothermia include administration of warm IV fluids; heated oxygen or inspired gas to prevent further heat loss via the respiratory tract; and heated peritoneal, pleural, gastric, or bladder lavage.

## Nursing Safety Priority QSEN

### Critical Rescue

Recognize that patients who are *severely* hypothermic are at high risk for cardiac arrest. Respond by avoiding active *external* rewarming with heating devices because it is dangerous and contraindicated in this population due to rapid vasodilation.

The treatment of choice for *severe* hypothermia is to use *extracorporeal* rewarming methods such as cardiopulmonary bypass or hemodialysis. Cardiopulmonary bypass is the fastest core rewarming technique. However, this device is not available in all hospitals. It also requires specialized personnel and resources to operate it properly. Monitor for early signs of complications that can occur after rewarming such as fluid, electrolyte, and metabolic abnormalities; acute respiratory distress syndrome (ARDS); acute renal failure; and pneumonia.

A long-standing principle in the treatment of patients with hypothermic cardiac arrest is that “no one is dead until he or she is warm and dead.” There is a factual basis to this statement when considering the number of survivors who have suffered a prolonged hypothermic cardiac arrest. Prolonged resuscitation efforts may not be reasonable in cases in which survival appears highly unlikely such as in an anoxic event followed by a hypothermic cardiac arrest.

### Frostbite

#### ❖ Pathophysiology

Another significant cold-related injury that may or may not be associated with hypothermia is frostbite. The main risk factor is inadequate insulation against cold weather (i.e., either the skin is exposed to the cold, or the person's clothing offers insufficient protection, leading to injury). Wet clothing in particular is a poor insulator and facilitates the development of frostbite. Fatigue, dehydration, and poor nutrition are other contributing factors. People who smoke, consume alcohol, or have impaired peripheral circulation have a higher incidence of frostbite. Any previous history of frostbite further increases a person's susceptibility.

## NCLEX Examination Challenge 9-2

### Health Promotion and Maintenance

The community nurse is educating a client about frostbite prevention. Which factors will the nurse teach that are risk factors for developing frostbite? **Select all that apply.**

- A. Dehydration
- B. Smoking history
- C. Previous frostbite
- D. Excessive fatigue
- E. Active smoker
- F. Wearing wool socks
- G. History of diabetes

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

**Frostbite** occurs when body tissue freezes and causes damage to TISSUE INTEGRITY. Like burns, frostbite injuries can be superficial, partial, or full thickness. By contrast, **frostnip** is a type of superficial cold injury that may produce pain, numbness, and pallor or a waxy appearance of the affected area but is easily relieved by applying warmth; it does not cause tissue damage (impaired TISSUE INTEGRITY). Frostnip typically develops on skin areas such as the face, nose, finger, or toes. Untreated, it is a precursor to more severe forms of frostbite.

*First-degree frostbite*, the least severe type of frostbite, involves **hyperemia** (increased blood flow) of the involved area and edema formation. In *second-degree frostbite*, large clear-to-milky fluid-filled blisters develop with partial-thickness skin necrosis (Fig. 9-7). *Third-degree frostbite* appears as small blisters that contain dark fluid and an affected body part that is cool, numb, blue, or red and does not blanch. Full-thickness and subcutaneous tissue necrosis occurs and requires débridement. In *fourth-degree frostbite*, the most severe form, there are no blisters or edema; the part is numb, cold, and bloodless. The full-thickness necrosis extends into the muscle and bone. At this stage, gangrene develops, which may require amputation of the affected part. Of note, except for frostnip, other degrees of frostbite may all have the same general appearance while the body part is frozen; the differentiating features of each degree of frostbite only become apparent after the part is thawed. Gangrene may evolve over days to weeks after injury.

**FIG. 9-7** Edema and blister formation 24 hours after frostbite injury occurring in an area covered by a tightly fitted boot. (From Auerbach, P. S. (2008). *Wilderness medicine* (5th ed.). Philadelphia: Mosby; courtesy Cameron Bangs, MD.)

### ◆ Interventions: Responding

#### First Aid/Prehospital Care.

*Recognition of frostbite is essential to early, effective intervention and prevention of further damage to TISSUE INTEGRITY.* Asking a partner to frequently observe for early signs of frostbite such as a white, waxy appearance to exposed skin, especially on the nose, cheeks, and ears is an effective strategy to identify the problem before it worsens. In people with dark skin, skin becomes paler, waxy, and somewhat gray. In this case the best remedy is to have the person seek shelter from the wind and cold and attend to the affected body part. Superficial frostbite is easily managed using body heat to warm the affected area. Teach patients to place their warm hands over the affected areas on their face or to place cold hands under the arms.

#### Hospital Care.

Patients with more severe and deeper forms of frostbite need aggressive management. For all degrees of partial-thickness-to-full-thickness frostbite, rapid rewarming in a water bath at a temperature range of 104° to 108° F (40° to 42° C) is indicated to thaw the frozen part (Della-Giustina & Ingebretsen, 2013). Because patients experience severe pain during the rewarming process, this intervention is best accomplished in a medical facility; however, it may be done in another setting if no other options exist for prompt transport or rescue. Administer analgesics, especially IV opiates, and IV rehydration. Ibuprofen 400 mg to 800 mg PO should also be administered every 8 hours as it decreases thromboxane production in the inflammatory cascade and may reduce secondary tissue injury in frostbite (Auerbach, 2016b; Della-Giustina & Ingebretsen, 2013).

## Nursing Safety Priority QSEN

### Critical Rescue

Recognize that dry heat or massage should not be used as part of the warming process for frostbitten areas because these actions can produce further damage to **TISSUE INTEGRITY**. Respond by using other interventions such as a rapid rewarming water bath of 104° to 108° F (40° to 42° C), to preserve tissue.

When the rewarming process is complete, handle the injured areas gently and elevate them above heart level if possible to decrease tissue edema. Sometimes splints are used to immobilize extremities during the healing process. Assess the person at least hourly for the development of compartment syndrome—a limb-threatening complication caused by severe neurovascular impairment. Observe for early manifestations, which include increasing alteration in levels of **COMFORT** (pain even after analgesics are given) and paresthesias (painful tingling and numbness). Compare the affected extremity with the unaffected one to assess for pallor. Assess for pulses and muscle weakness. Management of compartment syndrome is discussed in detail in [Chapter 51](#).

Frostbite destroys tissue and produces a deep tetanus-prone wound; the patient should be immunized to prevent tetanus. Apply only loose, nonadherent sterile dressings to the damaged areas. Avoid compression of the injured tissues. Both topical and systemic antibiotics may be used. Once a patient's frozen part has thawed, do not allow it to refreeze, which worsens the injury.

In cases of severe, deep frostbite, débridement of necrotic tissue may be needed to evaluate tissue viability and provide wound management. Amputation may be indicated for patients with severe injuries or those who develop gangrene or severe compartment syndrome.

## Altitude-Related Illnesses

### ❖ Pathophysiology

**High-altitude illnesses**, also known as **high-altitude disease (HAD)** or *altitude sickness*, cause pathophysiologic responses in the body as a result of exposure to low partial pressure of oxygen at high elevations. Although most consider high altitude to be an elevation over 5000 feet, millions of people worldwide who ascend to or live at altitudes above 2500 feet are at risk for acute and chronic mountain sickness.

As altitude increases, atmospheric (barometric) pressure decreases. Oxygen makes up 21% of the pressure. Therefore, as this pressure falls, the partial pressure of oxygen in the air decreases, resulting in less available oxygen to humans. The pathophysiologic consequence is hypoxia. Hypoxia is more pronounced as elevation increases. Elevations higher than 18,000 feet are extreme altitudes. Supplemental oxygen is necessary at these levels in nonacclimatized people to prevent altitude-related illnesses, including death, from occurring during abrupt ascent.

The cause of HAD is an interaction of environmental and genetic factors. Those who are obese or have chronic illnesses, especially cardiovascular problems, are more at risk than those who are thinner and healthier. Dehydration and CNS depressants such as alcohol also increase the risk. The age of the person does not seem to be a factor in altitude-related illnesses.

### ❖ Genetic/Genomic Considerations

#### Patient-Centered Care QSEN

Genetic differences among certain ethnic groups who live in high-altitude areas have been studied. For example, chronic mountain sickness is less common in Tibetans and Ethiopians than in Andeans (Ronen et al., 2014).

The pathogenesis of mountain sickness is associated with unidentified variations in hypoxia-related genes and the genes responsible for the human leukocyte antigen (HLA) system. Examples of genes with variants that may contribute to the development of HAD include:

- *EPO* (erythropoietin), which regulates red blood cell production
- *HIF1A* (hypoxia-inducible factor), which mediates the effects of hypoxia on body cells
- *EDN1* (endothelin), which causes vasoconstriction and thus increases blood pressure
- *NOS3* (endothelial nitric oxide synthase), which makes nitric acid in vascular tissue to maintain vessel tone and altitude adaptation

At this time, no clinical genetic testing to determine a person's risk for altitude sickness is available; however, further research is being conducted to identify specific gene variations that contribute to altitude-related illnesses.

The process of adapting to high altitude is called *acclimatization*. **Acclimatization** involves physiologic changes that help the body adapt to less available oxygen in the atmosphere. As the carotid bodies sense a decline in PaO<sub>2</sub> at about 5000 feet, they increase the respiratory rate to improve oxygen delivery. This mechanism is called the *hypoxic-ventilatory response*. Increased respiratory rate causes **hypocapnia** (decreased carbon dioxide) and respiratory alkalosis, which limit further increases in respiratory rate. Rapid eye movement (REM) sleep is impaired. Hypoxia can occur from periods of apnea. Within 24 to 48 hours of being at high altitude, the kidneys excrete the excess bicarbonate, which helps the pH to return to normal and ventilatory rate to again increase.

Increased sympathetic nervous system activity increases heart rate, blood pressure, and cardiac output. Pulmonary artery pressure rises as an effect of generalized hypoxia-induced pulmonary vasoconstriction. Cerebral blood flow increases to maintain cerebral oxygen delivery. Hypoxia also

induces red blood cell production by stimulating the release of erythropoietin. The result is an increase in red blood cells and hemoglobin concentration. Over time polycythemia can develop in people who remain in a high-altitude environment.

People who plan to climb to high altitudes are advised to ascend slowly, over the course of days or even weeks, depending on the degree of elevation. Ascending too rapidly is the primary cause of altitude-related illnesses. They are much more common in people who sleep at elevations above 8000 feet.

The three most common clinical conditions that are considered high-altitude illnesses are acute mountain sickness (AMS), high-altitude cerebral edema (HACE), and high-altitude pulmonary edema (HAPE). AMS may occur with HACE and/or HAPE; the underlying pathophysiology is hypoxia. Chronic mountain sickness can occur in people who live at high elevations. Although each syndrome has several unique manifestations, the basic assessment and management approach are the same.

## ❖ **Interprofessional Collaborative Care**

### ◆ **Assessment: Noticing**

Assessment findings for the typical patient with AMS include reports of throbbing headache, anorexia, nausea, and vomiting. Feeling chilled, irritable, and apathetic is also associated with AMS. The syndrome produces effects similar to an alcohol-induced hangover. The patient may relate a feeling of extreme illness. Vital signs are variable: the patient can be tachycardic or bradycardic, have normal blood pressure, or have postural hypotension. He or she may experience dyspnea both on exertion and at rest. Exertional dyspnea is expected as a person adjusts to high altitude. However, dyspnea at rest is abnormal and may signal the onset of HAPE.

If AMS progresses to *high-altitude cerebral edema (HACE)*, the extreme form of this disorder, the patient cannot perform ADLs and has extreme apathy. A key sign of HACE is the development of ataxia (defective muscular coordination). The patient also has a change in mental status with confusion and impaired judgment. Cranial nerve dysfunction and seizures may occur. If untreated, a further decline in the patient's level of consciousness results. Stupor, coma, and death can result from brain swelling and the subsequent damage caused by increased intracranial pressure over the course of 1 to 3 days.

**High-altitude pulmonary edema (HAPE)** often appears in conjunction with HACE but may occur during the progression of AMS within the first 2 to 4 days of a rapid ascent to high altitude, commonly on the second night. It is the most common cause of death associated with high altitude. Patients notice poor exercise tolerance and a prolonged recovery time after exertion. Fatigue, weakness, and other signs and symptoms of AMS are present. Important clinical indicators of HAPE include a persistent dry cough and cyanosis of the lips and nail beds. Tachycardia and tachypnea occur at rest. Crackles may be auscultated in one or both lungs. Pink, frothy sputum is a late sign of HAPE. A chest x-ray demonstrates pulmonary infiltrates and pulmonary edema. Arterial blood gas analysis shows respiratory alkalosis and hypoxemia (decreased oxygen). Pneumonia also may be present. Pulmonary artery pressure is usually very elevated because of pulmonary edema.

### ◆ **Interventions: Responding**

#### **First Aid/Prehospital Care.**

*The most important intervention to manage serious altitude-related illnesses is descent to a lower altitude.* Patients must be monitored carefully for any evidence of symptom progression. With mild AMS, the victim should be allowed to rest and acclimate at the current altitude. The person is instructed not to ascend to a higher altitude, especially for sleep, until symptoms lessen. If symptoms persist or worsen, he or she should be moved to a lower altitude as soon as possible. Even a descent of about 1600 feet may improve the patient's condition and reverse altitude-related pathologic effects. Oxygen should also be administered if available to effectively treat symptoms of AMS.

#### **Prevention and Treatment.**

The oral drug *acetazolamide* (Diamox, Apo-Acetazolamide ♣) is commonly used to both prevent and treat AMS. Acetazolamide is a carbonic anhydrase inhibitor. It acts by causing a bicarbonate

diuresis, which rids the body of excess fluid and induces metabolic acidosis. The acidotic state increases respiratory rate and decreases the occurrence of periodic respiration during sleep at night. In this way it helps patients acclimate faster to a high altitude. For best results, the drug should be taken 24 hours before ascent and be continued for the first 2 days of the trip.

## Nursing Safety Priority QSEN

### Drug Alert

Because acetazolamide is a sulfa drug, ask about an allergy to sulfa before the patient takes the drug because it may cause hypersensitivity reactions in those who are sulfa sensitive.

Another drug that is indicated in the treatment of moderate-to-severe AMS is dexamethasone (Decadron). The mechanism of action of this drug is unclear for AMS treatment, but it reduces cerebral edema by acting as an anti-inflammatory in the CNS. It does not speed acclimatization like acetazolamide does, but it does relieve the symptoms of AMS. Symptoms may recur when the drug is stopped, an effect termed the *rebound phenomenon*.

For the treatment of HACE, early recognition of ataxia or a change in level of consciousness should prompt a rapid descent by rescuers or companions to a lower altitude. While undergoing descent, the patient can be given supplemental oxygen and dexamethasone. If mental status is severely impaired and the patient's airway is at risk, all drugs should be given parenterally. Ultimately the patient with HACE must be admitted to the hospital. Critical care management may be necessary.

Like HACE, early recognition of HAPE is essential to improve the patient's chance for survival. Phosphodiesterase inhibitors such as tadalafil (Cialis) and sildenafil (Viagra) may be used to prevent HAPE because of their pulmonary vasodilatory effects. When it occurs, HAPE is a serious condition that requires quick evacuation to a lower altitude, oxygen administration, and bedrest to save the patient's life. If descent must be delayed because of weather conditions or other factors, oxygen administration as soon as possible is essential. Keep the patient warm at all times. Drugs are not substitutes for descent and oxygen. However, the treatment of HAPE may include the calcium channel blocker *nifedipine* (Procardia, Adalat , Apo-Nifed ) to decrease pulmonary vascular resistance. Hospital admission is required. In uncomplicated cases of HAPE recovery occurs quickly, but effects such as weakness and fatigue may persist for 2 weeks.

[Chart 9-8](#) summarizes best practices for preventing, recognizing, and treating altitude-related illnesses.

### Chart 9-8

## Best Practice for Patient Safety & Quality Care QSEN

### Preventing, Recognizing, and Treating Altitude-Related Illnesses

- Plan a slow ascent to allow for acclimatization.
- Learn to recognize signs and symptoms of altitude-related illnesses.
- Avoid overexertion and overexposure to cold; rest at present altitude before ascending further.
- Ensure adequate hydration and nutrition.
- Avoid alcohol and sleeping pills when at high altitude.
- For progressive or advanced acute mountain sickness (AMS), recognize symptoms and implement an immediate descent; provide oxygen at high concentration.
- To prevent the occurrence of AMS, discuss the use of acetazolamide (Diamox) and other agents as indicated with your health care provider.

- Protect skin and eyes from the harmful ultraviolet rays of the sun at high altitude. Wear sunscreen (at least SPF 30) and high-quality wraparound sunglasses or goggles.

*SPF*, Sun protection factor.

## **NCLEX Examination Challenge 9-3**

### **Physiological Integrity**

The nurse is caring for a client who was brought to the emergency department after being found very ill on a mountain climb. Which assessment findings does the nurse recognize as symptoms of high-altitude pulmonary edema (HAPE)? **Select all that apply.**

- A. Respiratory acidosis
- B. Cyanosis of the lips
- C. Tachycardia at rest
- D. Bilateral crackles
- E. Persistent dry cough

# Drowning

## ❖ Pathophysiology

Drowning is a leading cause of accidental death in the United States. It occurs when a person suffers primary respiratory impairment from submersion or immersion in a liquid medium (usually water). Near-drowning was previously defined as recovery after submersion; however, this term is no longer used because language that describes drowning incidents has been standardized. Today the drowning process is considered a continuum with outcomes that range from survival to death.

## Health Promotion and Maintenance

Prevention is the key to avoiding drowning incidents. When providing health teaching, include these points:

- Constantly observe people who cannot swim and are in or around water.
- Do not swim alone.
- Test the water depth before diving in head first; never dive into shallow water.
- Avoid alcoholic beverages when swimming and boating and while in proximity to water.
- Ensure that water rescue equipment such as life jackets, flotation devices, and rope is immediately available when around water.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

When water is aspirated into the lungs, the quantity and makeup of the water are key factors in the pathophysiology of the drowning event. Aspiration of both fresh water and salt water causes surfactant to wash out of the lungs. Surfactant reduces surface tension within the alveoli, increases lung compliance and alveolar radius, and decreases the work of breathing. Loss of surfactant destabilizes the alveoli and leads to increased airway resistance. Salt water—a hypertonic fluid—also creates an osmotic gradient that draws protein-rich fluid from the vascular space into the alveoli. In both cases, pulmonary edema results. Salt water and fresh water aspiration cause similar degrees of lung injury. Another concern is water quality; the victim's outcome may be negatively affected by contaminants in the water such as chemicals, algae, microbes, sand, and mud. These substances can worsen lung injury and cause a lung infection.

The duration and severity of hypoxia are the two most important factors that determine outcomes for victims of drowning. Very cold water seems to have a protective effect. Successful resuscitations have been reported even after prolonged arrest intervals. Hypothermia might offer some protection to the hypoxic brain by reducing cerebral metabolic rate. The diving reflex is a physiologic response to asphyxia, which produces bradycardia; a reduction in cardiac output; and vasoconstriction of vessels in the intestine, skeletal muscles, and kidneys. These physiologic effects are thought to reduce myocardial oxygen use and enhance blood flow to the heart and cerebral tissues. Survival may be linked to some combination of the effects of hypothermia and the diving reflex.

The cause of the drowning should also be determined if possible. The patient may have suffered a medical condition or injury that caused the drowning event such as a seizure, myocardial infarction, stroke, or spinal cord injury while in the water. Injuries sustained from diving into shallow water or body surfing, such as cervical spine trauma, can also increase the difficulty of rescue and resuscitation efforts.

### ◆ Interventions: Responding

#### First Aid/Emergency Care.

*Immediate emergency care focuses on a safe rescue of the victim.* Potential rescuers must consider their own swimming abilities and limitations and any natural or human-made hazards before attempting to save the victim; failure to do so could place additional lives in jeopardy. *Once rescuers gain access to the victim, the priority is safe removal from the water.* Spine stabilization with a board or flotation

device should be considered only for victims who are at high risk for spine trauma (e.g., history of diving, use of a water slide, signs of injury or alcohol intoxication), as opposed to all drowning victims. Time is of the essence; efforts directed toward a rapid rescue have the most potential benefit. Initiate airway clearance and ventilatory support measures, including delivering rescue breaths as soon as possible while the patient is still in the water. If hypothermia is a concern, handle the victim gently to prevent ventricular fibrillation.

## Nursing Safety Priority QSEN

### Critical Rescue

Recognize that you must not attempt to get the water out of the victim's lungs; respond by delivering abdominal or chest thrusts *only* if airway obstruction is suspected.

#### Hospital Care.

Once the person is safely removed from the water, airway and cardiopulmonary support interventions begin, including oxygen administration, endotracheal intubation, CPR, and defibrillation, if necessary. In the clinical setting, gastric decompression with a nasogastric or orogastric tube is needed to prevent aspiration of gastric contents and improve ventilatory function. After a period of artificial ventilation by mask, the victim typically has a distended abdomen, which impairs movement of the diaphragm and decreases lung ventilation. Patients who experience drowning require complex care to support their major body systems. The full spectrum of critical care technology may be needed to manage the pathophysiologic complications of drowning, including pulmonary edema, infection, acute respiratory distress syndrome (ARDS), and CNS impairment. These complications are discussed elsewhere in this text.

## Clinical Judgment Challenge 9-2

### Patient-Centered Care QSEN

The emergency department (ED) nurse is caring for a patient who is a drowning victim. The patient has cold, blue skin and significant abdominal swelling.

1. What further information will the nurse need to obtain from the paramedics who bring the client to the ED?
2. How does the nurse explain the major pathophysiologic event of drowning to the patient's significant other?
3. The paramedics state that the patient was submerged in saltwater from the ocean. How does that environment affect the patient?
4. What should the nurse know about a patient's potential cervical spine injury as it pertains to drowning?

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Collaborate with the interprofessional health care team to provide the most comprehensive care for patients with environment emergencies. **QSEN: Teamwork and Collaboration**

### Health Promotion and Maintenance

- Teach people how to prevent heat-related illnesses as outlined in [Chart 9-1](#), cold-related conditions, and bites and stings as described in [Charts 9-4](#) and [9-5](#).
- Teach people that the best way to prevent lightning injury is to avoid places where lightning is likely to strike (see [Chart 9-6](#)).
- Teach people that hypothermia and frostbite can be prevented by selecting appropriate layered clothing; cotton should not be worn.

### Physiological Integrity

- Remember that bites, stings, lightning injury, and cold injury can compromise TISSUE INTEGRITY. **QSEN: Safety**
- Recall that the priority for first aid for heat stroke after a patent airway is established is to cool the patient as quickly as possible (see [Chart 9-3](#)). **QSEN: Safety**
- Recall that the management of a patient who has a snakebite depends on the severity of envenomation (venom injection) (see [Table 9-1](#)).
- Remember that the priority for first aid/prehospital care when a patient has a poisonous snakebite is to decrease the venom circulation by administering antivenom drugs. **QSEN: Safety**
- Remember that cold applications, such as ice, should be used as first aid/prehospital care for poisonous spider bites.
- Understand that the effect of the bark scorpion venom is neurotoxic; monitor the patient for signs of respiratory failure that may require mechanical ventilation. **QSEN: Safety**
- Remember that epinephrine is the drug of choice for bee and wasp sting allergic reactions, followed by antihistamine drugs. **QSEN: Safety**
- Recall that lightning causes central nervous system, cardiovascular complications, and skin burns.
- Teach patients that in moderate-to-severe cases of hypothermia, coagulopathy (abnormal clotting) or cardiac failure can occur.
- Remember that the priority for care of a patient with a cold injury is warming; alcohol should be avoided.
- Review [Chart 9-8](#), which outlines best practice strategies for preventing, recognizing, and treating altitude-related illnesses.
- Remember that drowning victims often require cardiopulmonary support, including CPR, and are at risk for pulmonary infection, ARDS, and central nervous system impairment.

## CHAPTER 10

# Principles of Emergency and Disaster Preparedness

---

Linda Laskowski-Jones

## PRIORITY AND INTERRELATED CONCEPTS

---

**The priority concepts for this chapter are:**

- SAFETY
- TEAMWORK AND INTERPROFESSIONAL COLLABORATION
- COMMUNICATION

## LEARNING OUTCOMES

---

### **Safe and Effective Care Environment**

1. Apply triage principles to prioritize care delivery in a disaster situation.
2. Identify the roles of the nurse and interprofessional team in emergency preparedness and response.
3. Describe components of an emergency preparedness and response plan.
4. Develop a personal emergency preparedness plan.

### **Psychosocial Integrity**

5. Describe the role of the nurse in supporting people in various stages of adaptation who are coping with life changes after disaster.

### **Physiological Integrity**

6. Explain ways to maintain physical SAFETY when responding to disaster and mass casualty situations.

Defined as an event in which illness or injuries exceed resource capabilities of a health care facility or community because of destruction and devastation, a **disaster** can be either *internal* to a health care facility or *external* from situations that create casualties in the community. Both internal and external disasters can occur simultaneously, such as when Superstorm Sandy incapacitated several hospitals on the Atlantic Coast of New York and New Jersey in late October 2012 ([Fig. 10-1](#)).

**FIG. 10-1** The destruction after Superstorm Sandy ravaged the East Coast in 2012. (Copyright © The American National Red Cross 2012.)

## Types of Disasters

An event occurring inside a health care facility or campus that could endanger the SAFETY of patients or staff is considered to be an *internal* disaster. The event creates a need for evacuation or relocation. It often requires extra personnel and the activation of the facility's emergency preparedness and response plan (also called an *emergency management plan*). Examples of potential internal disasters include fire, explosion, loss of critical utilities (e.g., electricity, water, computer systems, and COMMUNICATION capabilities), and violence. Each health care organization develops policies and procedures for preventing these events through organized facility and security management plans. The most important outcome for any internal disaster is to maintain patient, staff, and visitor safety.

An event outside the health care facility or campus, somewhere in the community, which requires the activation of the facility's emergency management plan is considered an *external* disaster. The number of facility staff and resources may not be adequate for the incoming emergency department (ED) patients. External disasters can be either natural such as a hurricane, earthquake, or tornado, or technologic such as an act of terrorism with explosive devices or a malfunction of a nuclear reactor with radiation exposure. Recent external disasters include the 2015 Ebola virus crisis in a Dallas hospital, the 2013 Boston Marathon bombing, and the West Texas fertilizer plant explosion. St. John's Regional Medical Center in Joplin, Missouri, had an internal disaster compounding an external disaster in 2011 when it was directly hit by an EF-5 tornado that destroyed a large part of the town. Of the 142 dead, 6 people inside the hospital died (Letner, 2011).

Internal and external disasters can result in many casualties, including death. Multi-casualty and mass casualty (disaster) events are not the same. The main difference is based on the scope and scale of the incident, considering the number and severity of victims or casualties involved. Both require specific response plans to activate necessary resources. In general, a **multi-casualty event** can be managed by a hospital using local resources; a **mass casualty event** overwhelms local medical capabilities and may require the collaboration of multiple agencies and health care facilities to handle the crisis. State, regional, and/or national resources may be needed to support the areas affected by the event. Trauma centers have a special role in all emergency preparedness activities because they provide a critical level of expertise and specialized resources for complex injury management.

To maintain ongoing disaster preparedness, hospital personnel participate in emergency training and drills regularly. In the United States, The [Joint Commission \(2017\)](#) mandates that hospitals have an emergency preparedness plan that is tested through drills or actual participation in a real event at least twice a year. One of the drills or events must involve community-wide resources and an influx of actual or simulated patients to assess the ability of collaborative efforts and command structures. In addition, accredited health care organizations are required to take an "all-hazards approach" to disaster planning. Using this approach, preparedness activities must address *all credible threats* to the safety of the community that could result in a disaster situation. Disaster drills are ideally planned based on a risk assessment or vulnerability analysis that identifies the events most likely to occur in a particular community. For example, a flood is more likely in the Gulf of Mexico, and an avalanche is more likely in ski areas of the Rocky Mountains. Unfortunately, since the threat of gun violence is now a risk in all communities, "active-shooter" drills are commonplace in health care settings. It is essential that staff actively participate in these drills and take them seriously to enable their ability to act rapidly and maintain their ongoing competency. The importance of training has been emphasized in the wake of many disaster responses and has been credited with saving lives.

Hospitals are not the only health care agencies that are required to practice disaster drills. Nursing homes and other long-term care (LTC) facilities are also mandated to have annual drills to prepare for mass casualty events. Part of the response plan must include a method for evacuation of residents from the facility in a timely and safe manner.

An evacuation plan is also part of fire prevention and preparedness plans for health care facilities. The Life Safety Code® published by the [National Fire Protection Association \(2016\)](#) provides guidelines for building construction, design, maintenance, and evacuation. The [Centers for Medicare and Medicaid Services \(CMS\) \(2016\)](#) requires every health care facility to practice at least one fire drill or actual fire response once a year. Patient evacuation is not required if the event

is a drill. All facility personnel are mandated to have training on fire prevention and responsiveness each year. [Chart 10-1](#) lists general guidelines for fire responsiveness and building evacuation to ensure safety.

### **Chart 10-1**

## **Best Practice for Patient Safety & Quality Care** OSEN

### **Nurse's Role in Responding to Health Care Facility Fires**

- Remove any patient or staff from immediate danger of the fire or smoke.
- Discontinue oxygen for all patients who can breathe without it.
- For patients on life support, maintain their respiratory status manually until removed from the fire area.
- Direct ambulatory patients to walk to a safe location.
- If possible, ask ambulatory patients to help push wheelchair patients out of danger.
- Move bedridden patients from the fire area in bed, by stretcher, or in a wheelchair; if needed, have one or two staff members move patients on blankets or carry them.
- After everyone is out of danger, seek to contain the fire by closing doors and windows and using an ABC extinguisher (can put out any type of fire) if possible.
- Do not risk injury to yourself or staff members while moving patients or attempting to extinguish the fire.

## Impact of External Disasters

The events of September 11, 2001, substantially changed hospital and community disaster planning efforts. With the shocking terrorist attacks on the Twin Towers of the World Trade Center and the Pentagon, the loss of life in a field in Pennsylvania, and the actual and perceived threat of domestic terrorism, including the anthrax exposure that followed, hospital emergency preparedness concepts became integrated into the daily operations of emergency departments (EDs) by necessity. Weapons of mass destruction (WMDs) became a focus of public health risk.

The term “NBC” was coined to describe **n**uclear, **b**iotic, and **c**hemical threats. In response, emergency medical services (EMS) agencies and hospitals improved **SAFETY** by upgrading their decontamination facilities, equipment, and all levels of personal protective equipment to better protect staff. ED physician and nursing staff now routinely undergo hazardous materials (HAZMAT) training and learn how to recognize patterns of illness in patients who present for treatment that potentially indicate biologic terrorism agents such as anthrax or smallpox (Fig. 10-2). Protocols for the pharmacologic treatment of infectious disease agents and stockpiles of antibiotics and nerve agent antidotes are readily available.

**FIG. 10-2** Hazardous materials (HAZMAT) training to decontaminate people exposed to toxic agents in an outdoor decontamination area. (Courtesy Meg Blair, PhD, RN.)

The most immediate outcome of improving emergency preparedness after September 11, 2001, is that the ability to competently handle the more typical multi-casualty or mass casualty event such as a bus crash, tornado, chemical plant incident, or building collapse has been greatly improved in many communities. However, disaster situations can still exceed the scope of usual day-to-day crisis operations, pointing to the necessity of well-defined personal, facility, regional and national emergency preparedness plans, and ongoing drills. Research continues to call for nurses to be leaders in disaster preparedness and response (Veenema et al., 2016).

In 2005 Hurricane Katrina made landfall in Louisiana and other Gulf states as a category 4 storm and caused more than 1000 deaths and devastating environmental and property damage. Volunteers from all over the United States and local, regional, and federal agencies took part in the large-scale disaster evacuation, rescue, and relief effort that severely challenged available resources and established disaster plans. Critical systems failed and were eventually re-established through **TEAMWORK AND INTERPROFESSIONAL COLLABORATION** with multiple agencies to ensure that the most basic human needs were met (Fig. 10-3). Hurricane Katrina overwhelmed the existing emergency care system and caused the mobilization of a national mutual aid response on a level that had not been experienced in recent U.S. history.

**FIG. 10-3** Temporary shelter set up for homeless victims of Hurricane Katrina in New Orleans. (Courtesy Jeanne McConnell, MSN, RN.)

Health care facilities must proactively address structural changes to provide SAFETY and protection from flooding and utilities failures. Although Superstorm Sandy, the event that made landfall in New York City in October 2012, was downgraded from a category 1 hurricane, the flooding that occurred destroyed critical hospital equipment, including emergency power generators, in the lower levels of several health care facilities, causing the loss of utilities and crippling operations. Hospitals that were severely impacted had to evacuate patients to other facilities, many of which were already overwhelmed by an influx of patients from the storm's damage in the community. Staff worked for several days in harsh conditions, carrying glow sticks and flashlights and wearing headlamps while evacuating critical patients via stairwells since elevators were nonfunctional.

Lessons learned from Hurricane Katrina, Superstorm Sandy, earthquakes in Japan and Haiti, tsunamis, and terrorist attacks, prompt improved facility design, staff preparation, and coordination of efforts that are beneficial for future disasters. These insights also can be applied to health care facility and community agency plans for pandemic infections, including influenza.

A **pandemic** (an infection or disease that occurs throughout the population of a country or the world) leads a vast number of people to seek medical care, even the “worried well.” Although not yet ill, the “worried well” want evaluation, preventive treatment, or reassurance from a health care provider. The most recent global biologic threat is the Ebola virus disease outbreak that devastated West Africa in 2014 and 2015. The extremely high risk of contagion from blood and body fluids, and the deadly nature of the virus itself, prompted public health agencies and health facilities worldwide to initiate screening criteria for returning travelers from West Africa and facility-specific procedures to prevent exposure. These involved procuring effective personal protective equipment (PPE), teaching staff how to don and doff the PPE without self-contamination, and securing appropriate facilities and resources to isolate patients who are undergoing evaluation or treatment. Managing health care workers' fear of caring for these patients can pose ethical and leadership challenges that must be addressed through safety measures to protect staff, focused education, and utilization of evidence-based care standards (Casey, 2015).

Pandemic influenza outbreaks such as the 2009-2010 swine flu outbreak caused by the H1N1 virus raise significant concerns that the resource capabilities of the entire health care system could be overwhelmed and that community systems and critical supply chains could be severely damaged. Worker illness, absenteeism, and personal choices to remain quarantined to avoid being exposed to the illness negatively affect the number of health care staff available to care for patients. Because of the mass casualty nature of pandemic influenza, emergency preparedness planners must collaborate to incorporate strategies for handling an influx of ill patients into the system as part of ongoing disaster readiness. Quarantine of selected nursing units or the entire hospital could become necessary, prompting closure until the risk has passed.

Common to all mass casualty events, the goal of **emergency preparedness** is to effectively meet the extraordinary need for resources such as hospital beds, staff, drugs, PPE, supplies, and medical devices such as mechanical ventilators. The U.S. government stockpiles critical equipment and supplies in case they are needed for a pandemic influenza outbreak and organizes large-scale vaccination programs (see Chapter 23 for more information on emerging infections). Each state has

its own specific emergency preparedness plan for pandemic influenza, including who would receive vaccines in a mass casualty event.

# Emergency Preparedness and Response

## Mass Casualty Triage

Bystanders will always be first on the scene of a disaster. Resources such as the [Department of Homeland Security's \(2016\) "Stop the Bleed"](#) can be helpful teaching tools so individuals know what to do before professional emergency services arrive. A key process in any multi-casualty or mass casualty response is effective **triage** to rapidly sort ill or injured patients into priority categories based on their acuity and survival potential.

Triage functions may be performed by EMS providers in the field such as:

- Emergency medical technicians (EMTs) and paramedics
- Nurse and physician field teams who are called from the hospital to a disaster scene to assist EMS providers
- Nurse and physician hospital teams to assess and reassess incoming patients

Triage concepts in a mass casualty incident differ from the "civilian triage" methods discussed in [Chapter 8](#) that are practiced during usual emergency operations ([Table 10-1](#)). Although disaster triage practices can vary widely based on local EMS protocols, some concepts are fairly universal. Most mass casualty response teams in the field (at the disaster site) and in the hospital setting use a **disaster triage tag system** that categorizes triage priority by color and number:

**TABLE 10-1**  
**Comparison of Triage Under Usual Versus Mass Casualty Conditions**

TRIAGE UNDER USUAL CONDITIONS	TRIAGE UNDER MASS CASUALTY CONDITIONS
Emergent (immediate threat to life)	Emergent or class I (red tag) (immediate threat to life)
Urgent (major injuries that require immediate treatment)	Urgent or class II (yellow tag) (major injuries that require treatment)
Nonurgent (minor injuries that do not require immediate treatment)	Nonurgent or class III (green tag) (minor injuries that do not require immediate treatment)
Does not apply	Expectant or class IV (black tag) (expected and allowed to die)

- Emergent (class I) patients are identified with a red tag.
- Patients who can wait a short time for care (class II) are marked with a yellow tag.
- Nonurgent or "walking wounded" (class III) patients are given a green tag.
- Patients who are expected (and allowed) to die or are dead are issued a black tag (class IV).

### Nursing Safety Priority QSEN

#### Action Alert

In mass casualty or disaster situations, implement a military form of triage with the overall desired outcome of doing the greatest good for the greatest number of people. This means that patients who are critically ill or injured and might otherwise receive attempted resuscitation during usual operations may be triaged into an "expectant" or "black-tagged" category and allowed to die or not be treated until others received care.

Typical examples of *black-tagged* patients are those with massive head trauma, extensive full-thickness body burns, and high cervical spinal cord injury requiring mechanical ventilation. The rationale for this very difficult decision is that limited resources must be dedicated to saving the most lives rather than expending valuable resources to save one life at the possible expense of many others.

In general, *red-tagged* patients have immediate threats to life such as airway obstruction or shock, and they require immediate attention. *Yellow-tagged* patients have major injuries such as open fractures with a distal pulse and large wounds that need treatment within 30 minutes to 2 hours. *Green-tagged* patients have minor injuries that can be managed in a delayed fashion, generally more than 2 hours. Examples of green-tagged injuries include closed fractures, sprains, strains, abrasions, and contusions.

Green-tagged patients are often referred to as the "walking wounded" because they may actually

evacuate themselves from the mass casualty scene and go to the hospital in a private vehicle. Green-tagged patients usually make up the greatest number in most large-scale multi-casualty situations. Therefore they can overwhelm the system if provisions are not made to handle them as part of the disaster plan. Also, because they often come to the hospital on their own, the hospital may not be able to determine how many actual casualties will arrive. A related concern is that green-tagged patients who self-transport may unknowingly carry contaminants from a nuclear, biologic, or chemical incident into the hospital environment with potentially disastrous consequences. ED staff must anticipate these issues and collaborate to devise emergency response plans accordingly, including appropriate decontamination measures.

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

As a component of culturally competent care, disaster triage processes should also incorporate strategies to accommodate vulnerable patient populations such as the very young, the elderly, people with disabilities, the mentally ill, and those who require devices such as a mechanical ventilator or home oxygen (Danna & Bennett, 2013).

## NCLEX Examination Challenge 10-1

### Physiological Integrity

After a mass casualty event, the nurse is triaging clients in the field. Which client is correctly classified?

- A. 38-year-old with an open femur fracture: black tag
- B. 42-year-old with multiple abrasions and contusions: yellow tag
- C. 54-year-old with third-degree burns over 90% of the body: green tag
- D. 61-year-old who is having difficulty breathing and wheezing: red tag

Once patients are in the triage area of the hospital, they typically receive a special bracelet with a disaster number. Preprinted labels with this number can be applied to chart forms and personal belongings. Digital photos may be used as part of the identification process in some systems. The standard hospital registration process and identification band can be applied after the patient's identity is confirmed.

Automated tracking systems using infrared and radiofrequency technology (RFT) are available in some EDs to track a patient's triage priority on arrival, location, and process of care. The interactions the patient has with caregivers can also be tracked. This is an important SAFETY strategy if the patient is later found to have contaminants or a disease that could pose a risk to staff members who had close contact and require decontamination or prophylaxis (Laskowski-Jones, 2008). These systems are valuable components of the hospital's emergency preparedness infrastructure because they can rapidly portray the overall census and acuity of patients. They also enable ED leaders to determine how many casualties of a particular acuity level a hospital can safely accept from the incident scene.

## Notification and Activation of Emergency Preparedness/Management Plans

When the number of casualties exceeds the usual resource capabilities, a disaster situation exists. What may be considered a routine day in the ED of a large urban trauma center could be defined as a disaster for a small rural community hospital if the same number of patients arrived. Therefore each facility decides when criteria are met to declare a disaster. Flexibility is needed because resources may change by time of day and by day of the week. For example, hospitals typically have

the fewest staff available after midnight on the weekend. An incident that occurs in this time frame may require activation of the emergency preparedness plan to bring extra resources into the hospital. The same incident during weekday business hours might be handled with on-site personnel alone without the need for activation of the plan.

Notification that a multi-casualty or mass casualty situation exists usually occurs by radio, cellular, or electronic COMMUNICATION between the ED and EMS providers at the scene. A state or regional emergency management agency may also notify the ED of the event. Each hospital has its own policy that specifies *who* has the authority to activate and *how* to activate the disaster or emergency preparedness plan. Group paging systems, telephone trees, and instant computer-based automated alert messages are the most common means of notifying essential personnel of a mass casualty incident or disaster.

A catastrophic event such as a major earthquake or tornado, or a terrorist incident involving weapons of mass destruction (WMDs), also requires the TEAMWORK AND INTERPROFESSIONAL COLLABORATION of volunteers from all members of the health care team in the region. The media may be contacted to facilitate COMMUNICATION by broadcasting messages to the health care community-at-large via television, radio, or social media (Woo et al, 2015). For such incidents, the National Guard, the American Red Cross, the public health department, various military units, a Medical Reserve Corps (MRC), or a Disaster Medical Assistance Team (DMAT) can be activated by state and federal government authorities.

- An MRC is made up of a group of volunteer medical and public health care professionals, including physicians and nurses. They offer their services to health care facilities or to the community in a supportive or supplemental capacity during times of need such as a disaster or pandemic disease outbreak. This group may help staff hospitals or community health settings that face personnel shortages and establish first aid stations or special-needs shelters. As a means to alleviate ED and hospital overcrowding, the MRC may also set up an acute care center (ACC) in the community for patients who need acute care (but not intensive care) for days to weeks.
- A DMAT is a medical relief team made up of civilian medical, paraprofessional, and support personnel that is deployed to a disaster area with enough medical equipment and supplies to sustain operations for 72 hours (U.S. Department of Health & Human Services, 2015). DMATs are part of the National Disaster Medical System (NDMS) in the United States. They provide relief services ranging from primary health care and triage to evacuation and staffing to assist health care facilities that have become overwhelmed with casualties. *Because licensed health care providers such as nurses act as federal employees when they are deployed, their professional licenses are recognized and valid in all states.* Additional examples of services provided by the NDMS include:
  - Disaster Mortuary Operational Response Teams (DMORTs) to manage mass fatalities
  - National Veterinary Response Teams (NVRTs) for emergency animal care; and
  - International Medical Surgical Response Teams (IMSURTs) to establish fully functional field surgical facilities wherever they are needed in the world

Nurses can join these teams, complete the required training, and offer their expertise as part of a coordinated federal response team in times of critical need (U.S. Department of Health & Human Services, 2016).

Before going to the incident in the field, all members of the interprofessional team must have adequate training to prepare them to recognize the risks in an unstable environment (Laskowski-Jones, 2010; Yin et al., 2012). Such risks can include the potential for structural collapse, becoming the secondary target of a terrorist attack, interpersonal violence in unsecured locales, and working in an environment in which contagious diseases and natural hazards are possible (e.g., poisonous snake bites and mosquito-borne illnesses). Disaster workers must take measures such as obtaining prophylactic medications and vaccinations, having a personal evacuation plan, and ensuring access to necessary supplies and protective equipment so they do not become victims as well.

The National Disaster Life Support Foundation, Inc. (2014) offers Core, Basic, and Advanced Disaster Life Support training courses that include all essential aspects of disaster response and management. They include the core competencies of disaster management to all levels of health care professionals. In addition, the Federal Emergency Management Agency (FEMA) (2016) provides numerous online resources, including Community Emergency Response Team (CERT) training so people are better prepared for disasters and are able to respond more self-sufficiently to incidents and hazard situations in their own communities. These courses include mass casualty

triage education.

## Hospital Emergency Preparedness: Personnel Roles and Responsibilities

Nurses play a major role in the emergency preparedness or emergency management plan. Because multiple health system resources are necessary to effectively manage the disaster, the Hospital Incident Command System is typically established for organization and structure.

### Hospital Incident Command System

The facility-level organizational model for disaster management is the **Hospital Incident Command System (HICS)**, which is a part of the National Incident Management System (NIMS) implemented by the Department of Homeland Security and FEMA to standardize disaster operations. In this system, roles are formally structured under the hospital or long-term care facility incident commander with clear lines of authority and accountability for specific resources (FEMA, 2016). Officers are named to oversee essential emergency preparedness functions such as public information, safety and security, and medical command. Chiefs are appointed to manage logistics, planning, finance, and operations as appropriate to the type and scale of the event. In turn, chiefs delegate specific duties to other departmental officers and unit leaders. The idea is to achieve a manageable span of control over the personnel or resources allocated to achieve efficiency. FEMA offers free courses on the NIMS model and HICS structure through its website located at [www.training.fema.gov/IS/](http://www.training.fema.gov/IS/).

Because mass casualty events typically involve large numbers of people and can create a chaotic work environment, many EMS agencies and health care facilities use brightly colored vests with large lettering to help identify key leadership positions. Specific job action sheets are distributed to all personnel with leadership roles in HICS that pre-define reporting relationships and list prioritized tasks and responsibilities. The HICS personnel also establish an **emergency operations center (EOC)** or **command center** in a designated location with accessible communication technology. They then use their collective expertise to manage the overall incident. All internal requests for additional personnel and resources and COMMUNICATION with field teams and external agencies should be coordinated through the EOC to maintain unity of command.

The roles and responsibilities of health care personnel in a mass casualty event or disaster are defined within the institution's emergency response or preparedness plan (Table 10-2). Each plan can be as individual as the particular facility's operations. However, virtually all plans identify certain key functions. For example, one of the primary roles to be established at the onset of an incident is that of a **hospital incident commander** who assumes overall leadership for implementing the institutional plan. This person is usually either a physician in the ED or a hospital administrator who has the authority to activate resources. This role can also be fulfilled by a nursing supervisor functioning as the on-site hospital administrator after usual business hours. The hospital incident commander's role is to take a global view of the entire situation and facilitate patient movement through the system, while bringing in personnel and supply resources to meet patient needs. For example, a hospital incident commander might dictate that all patients due to be discharged from an inpatient unit be moved to a lounge area immediately to free up hospital beds for mass casualty victims. He or she could also direct departments such as physical therapy or a surgical clinic to cancel their usual operations to convert the space into a minor treatment area. The incident commander assists in the organization of hospital-wide services to rapidly expand hospital capacity, recruit paid or volunteer staff, and ensure the availability of medical supplies.

**TABLE 10-2**

**Summary of Key Personnel Roles and Functions for Emergency Preparedness and Response Plan**

PERSONNEL ROLE	PERSONNEL FUNCTION
Hospital incident commander	Physician or administrator who assumes overall leadership for implementing the emergency plan
Medical command physician	Physician who decides the number, acuity, and resource needs of patients
Triage officer	Physician or nurse who rapidly evaluates each patient to determine priorities for treatment
Community relations or public information officer	Person who serves as a liaison between the health care facility and the media

Another typical role defined in hospital or other health care emergency preparedness plans is that

of the **medical command physician**. He or she focuses on determining the number, acuity, and medical resource needs of victims arriving from the incident scene to the hospital and organizing the emergency health care team response to the injured or ill patients. Responsibilities include identifying the need for and calling in specialty-trained providers such as:

- Surgeons (trauma, neuro, orthopedic, plastic, and/or burn)
- Pulmonologists
- Infectious disease physicians
- Industrial hygienists
- Radiation safety personnel

In smaller hospitals with limited specialty resources, the medical command physician might also help determine which patients should be transported out of the facility to a higher level of care or to a specialty hospital (e.g., burn center).

Closely affiliated with the medical command physician is the **triage officer**. This person is generally a physician in a large hospital who is assisted by triage nurses. When physician resources are limited, an experienced nurse may assume this role. The triage officer rapidly evaluates each person who presents to the hospital, even those who come in with triage tags in place. Patient acuity is re-evaluated for appropriate disposition to the area within the ED or hospital best suited to meet the patient's needs.

Many other roles and responsibilities can be defined within the institutional emergency response plan and may include the supply officer, the COMMUNICATIONS officer, the infection control officer, and the community relations/public information officer, to name a few. The community relations or public information officer is an especially important role to delineate in advance. Mass casualty incidents tend to attract a large amount of media attention. This staff member can draw media away from the clinical areas so essential hospital operations are not hindered. He or she can also serve as the liaison between hospital administration and the media to release only appropriate and accurate information.

## **Role of Nursing in Health Care Facility Emergency Preparedness and Response**

Nurses play key roles before, during, and after a disaster. The core components of the nursing process apply in the overall assessment of the emergency situation; the identification of needs, capabilities, and priorities; and planning, implementing, and evaluating the disaster response. Before an event, nurses contribute to developing internal and external emergency response plans, including defining specific nursing roles. Nurses take into account the security needs; COMMUNICATION methods; training; alternative treatment areas; staffing for high-demand or surge situations; and requirements for resources, equipment, and supplies. They then test the plans by actively participating in disaster drills and evaluating the outcomes.

During an actual disaster, the ED charge nurse, trauma program manager, and other ED nursing leadership personnel act in collaboration with the medical command physician and triage officer to organize nursing and ancillary services to meet patient needs. Telephone trees or automated group notification systems may be activated to call in ED nurses who are not working or are not scheduled to work. ED areas are identified and prepared to stage, triage, resuscitate, and treat the disaster victims. Efforts are made to quickly discharge or admit other ED patients as appropriate to make room for the new arrivals. ED nurses apply principles of triage to prioritize care delivery as disaster victims enter the system and direct patients to the designated areas best suited to meet their needs. To maintain ongoing readiness, ED nurses require disaster response education that specifically addresses their roles in the ED environment and in overall hospital operations (Whetzel et al., 2013).

Nursing roles in a disaster extend to all areas within a health care facility. The level of involvement is determined by the scope and scale of the disaster. In any mass casualty event, nurses from medical-surgical nursing units may be asked, in collaboration with the health care provider, to recommend patients for discharge to free up inpatient beds for disaster victims. Patients who are the most medically stable may be discharged early, including those who:

- Were admitted for observation and are not bedridden
- Are having diagnostic evaluations and are not bedridden
- Are soon scheduled to be discharged or could be cared for at home with support from family or home health care services

- Have had no critical change in condition for the past 3 days
- Could be cared for in another health care facility such as rehabilitation or long-term care

## NCLEX Examination Challenge 10-2

### Safe and Effective Care Environment

A number of nurses are floated to the ED to care for clients affected by an earthquake. Which appropriate float nurse assignments will the ED charge nurse make? **Select all that apply.**

- A. GI laboratory nurse assigned to clients undergoing sedation
- B. Orthopedic nurse assigned to accompany clients to radiology
- C. Nursing administrator assigned to monitor loved ones in the waiting room
- D. Community health nurse assigned to care for clients with fractures
- E. Medical-surgical nurse assigned to health care worker who is feeling overwhelmed

General staff nurses also may be recruited to collaborate in providing care for stable ED patients, thus allowing ED nurses to focus their efforts on aiding the mass casualty victims. Critical care unit nurses need to identify patients who can be transferred out of the unit to rapidly expand critical care bed capacity. In addition, they can supplement ED nurses in the resuscitation setting or assist in monitored care and transport to critical care units. Hospital and ED nurse leaders also typically direct the ancillary departments to deliver supplies, instrument trays, medications, food, and personnel to meet service demands.

Hospital staff of all levels may be required to alter their routine operations to accommodate a high volume of patients, including those with special needs such as decontamination, burn management, or quarantine. Inpatient unit nurses may be assigned a higher number of patients than usual. They may also be asked to provide care in nontraditional locations such as hallways or lounges to help rapidly decompress the ED so new arrivals can be readily managed.

Emergency plans dictate specific actions by all members of the interprofessional team such as who should be called when the plan is activated, who should report, where to report, which supplies or equipment carts should be brought to a pre-designated location, and which type of paperwork or system should be implemented for patient identification in a large-scale event. Some staff may even have their roles changed completely. For example, administrative nurses may be reassigned to fulfill a clinical responsibility for a nursing unit. The key concept is that staff members are expected to remain flexible in a mass casualty situation and perform at their highest level to address the needs of both the health care system and the patients. The greatest good for the greatest number of people is still the organizing principle when considering roles and responsibilities in mass casualty events—not necessarily individual staff preferences. However, the SAFETY of all patients is vital.

Creativity and flexibility of nursing leaders and nursing staff are essential to provide the staffing coverage necessary for a large-scale or extended incident. The willingness of staff to show up for work is directly impacted by their concerns for their home and family in a disaster; inadequate staffing can jeopardize a facility's ability to provide care. A **personal emergency preparedness plan** developed by each nurse can help in such situations. It should outline the preplanned specific arrangements that are to be made for child care, pet care, and older adult care if the need arises, especially if the event prevents returning home for an extended period.

## NCLEX Examination Challenge 10-3

### Safe and Effective Care Environment

The experienced nurse is teaching a new nurse about hospital emergency plans and personal emergency preparedness. Which specific arrangements should the experienced nurse discuss?

**Select all that apply.**

- A. Assembly of a “go bag”
- B. Plans for child and/or elder care
- C. Neighbor who is willing to care for dog
- D. Who will be called when the plan is activated
- E. How long an emergency is expected to last
- F. Where a nurse is expected to report if the emergency plan is activated
- G. Names, addresses, and telephone numbers to be used if a crisis occurs

**Nursing Safety Priority** QSEN

**Action Alert**

Include emergency contact names, addresses, and telephone numbers to use in a crisis as part of a personal emergency preparedness plan. In addition, preassemble **personal readiness supplies** or a “go bag” (disaster supply kit) for the home and automobile with clothing and basic survival supplies, which allows for a rapid response for disaster staffing coverage (Table 10-3). “Go bags” are needed for all members of the family, including pets, in the event the disaster requires evacuation of the community or people to take shelter in their own homes.

**TABLE 10-3**  
**Basic Supplies for Personal Preparedness (3-Day Supply)**

<ul style="list-style-type: none"><li>• Backpack</li><li>• Clean, durable weather-appropriate clothing; sturdy footwear</li><li>• Potable water—at least 1 gallon per person per day for at least 3 days</li><li>• Food—nonperishable, no cooking required</li><li>• Headlamp or flashlight—battery powered; extra batteries and/or chemical light sticks (NOTE: a headlamp is superior because it allows hands-free operation)</li><li>• Pocket knife or multi-tool</li><li>• Personal identification (ID) with emergency contacts and phone numbers, allergies, and medical information; lists of credit card numbers and bank accounts (keep in watertight container)</li><li>• Towel and washcloth; towelettes, soap, hand sanitizer</li><li>• Paper, pens, and pencils; regional maps</li><li>• Cell phone and charger</li><li>• Sunglasses/protective and/or corrective eyewear</li><li>• Emergency blanket and/or sleeping bag and pillow</li><li>• Work gloves</li><li>• Personal first aid kit with over-the-counter (OTC) and prescription medications</li><li>• Rain gear</li><li>• Roll of duct tape and plastic sheeting</li><li>• Radio—battery powered or hand-crank generator</li><li>• Toiletries (toothbrush and toothpaste, comb, brush, razor, shaving cream, mirror, feminine supplies, deodorant, shampoo, lip balm, sunscreen, insect repellent, toilet paper)</li><li>• Plastic garbage bags and ties, resealable plastic bags</li><li>• Matches in a waterproof container</li><li>• Whistle</li><li>• Household liquid bleach for disinfection</li></ul>
---

When called to respond to work during a mass casualty event or pandemic infectious disease outbreak, some nurses may experience ethical and moral conflict among their own personal preparedness for disaster response, family obligations, and professional responsibilities (Bell et al., 2014; Nash, 2015). The American Nurses Association (ANA) Code of Ethics for Nurses with Interpretive Statements (2015) offers general guidance that can be helpful to nurses. Each person has to make a personal choice about whether to be involved in helping during the emergency or when to become involved.

## Event Resolution and Debriefing

When the last major casualties have been treated and no more are expected to arrive in numbers that could overwhelm the health care system, the incident commander considers “standing down” or deactivating the emergency response plan. Although the casualties may have left the ED, other areas in the hospital may still be under stress and need the support of the supplemental resources provided by emergency plan activation. Before terminating the response, it is essential to ensure that the needs of the other hospital departments have been met and all are in agreement to resume normal operations.

A vital consideration in event resolution is staff and supply availability to meet ongoing operational needs. If nursing staff and other personnel were called in from home during their off hours or if they worked well beyond their scheduled shifts to meet patient and departmental needs, provision for adequate rest periods should be made. Exhaustion poses a risk to patient safety and to the nurse when he or she must drive home. Sleeping quarters at the hospital might be necessary in this case, especially if the disaster event contributed to treacherous travel conditions.

Severe shortages of supplies also pose a threat to usual operations at the conclusion of a mass casualty incident. Taking inventory and restocking the ED are high-priority assignments. TEAMWORK AND INTERPROFESSIONAL COLLABORATION between the ED and the central supply department are essential to resolving stock availability problems. Instrument trays must be washed, packaged, and re-sterilized. Critical supplies that have been depleted from hospital stores must be reordered and delivered to the hospital quickly. Contracts with key vendors outlining emergency re-supply expectations and arrangements should be a part of the hospital's overall emergency preparedness plan.

Two general types of **debriefing**, or formal systematic review and analysis, occur after a mass casualty incident or disaster. The first type entails bringing in critical incident stress debriefing (CISD) teams to provide sessions for small groups of staff to promote effective coping strategies. The second type of debriefing involves an administrative review of staff and system performance during the event to determine whether opportunities for improvement in the emergency management plan exist.

## Critical Incident Stress Debriefing

CISD is only one component of a much broader critical incident stress management (CISM) program. CISM programming addresses pre-crisis through post-crisis interventions for small-to-large groups, including communities. After working through the turmoil and the emotional impact of the incident and the aftermath, the staff may find it difficult to “get back to normal.” Without intervention during *and* after the emergency, they may develop acute stress disorder (ASD), or post-traumatic stress disorder (PTSD). ASD, although similar to PTSD, focuses on dissociative symptoms such as numbing, reduced awareness, depersonalization, derealization, or amnesia, experienced within the first month after a traumatic event; it is also predictive of subsequent PTSD (Gibson, 2016). PTSD can lead to multiple characteristic psychological and physical effects, including flashbacks, avoidance, less interest in previously enjoyable events, detachment, rapid heart rate, and insomnia. People suffering from PTSD can have great difficulty relating in their usual way to family and friends. Ultimately, professional “burnout” can stem from the inability to cope with the stress effectively. A resource for CISM is the [International Critical Incident Stress Foundation, Inc. \(2016\)](#); their mission is “to provide leadership, education, training, consultation, and support services in comprehensive crisis intervention and disaster behavioral health services to the emergency response professions, other organizations, and communities worldwide”. [Chart 10-2](#) lists recommendations proposed by several national organizations to help prevent staff ASD and PTSD following an emergency situation.

### Chart 10-2

## Best Practice for Patient Safety & Quality Care QSEN

### Preventing Staff Acute Stress Disorder and Post-Traumatic Stress Disorder Following

## a Mass Casualty Event

- Use available counseling.
- Encourage and support co-workers.
- Monitor each other's stress level and performance.
- Take breaks when needed.
- Talk about feelings with staff and managers.
- Drink plenty of water and eat healthy snacks for energy.
- Keep in touch with family, friends, and significant others.
- Do not work more than 12 hours per day.

Adapted from Papp, E. (2005). Preparing for disasters: Helping yourself as you help others. *The American Journal of Nursing*, 105(5), 112.

A CISD team comprises two or three specially trained people who come together quickly when called to deal with the emotional needs of health care team members after a particularly devastating or disturbing incident. The team leader typically has background in a mental health/behavioral health field. The co-leader is ideally a peer of the group being debriefed. Thus, if nurses are debriefed, a nurse member of the CISD team is generally assigned to the session. CISD-trained physicians, police, firefighters, EMTs, and paramedics may also be used, depending on the needs of the group. The third member of the team is known as the “doorkeeper.” This person is responsible for keeping inappropriate people out (e.g., media, spectators) and talking with anyone who leaves the session early in an effort to have him or her return or accept follow-up care. Staff involved in the incident need protected time to undergo stress debriefing, which generally lasts from 1 to 3 hours per session.

Typical “ground rules” for stress debriefing include strict confidentiality of information shared during the session and unconditional acceptance of the thoughts and feelings expressed by people within the group. The usual arrangement for the most effective group interaction is a circular configuration of chairs in a private setting. Food should be available so hunger is not a distraction. CISD group leaders encourage group discussion by asking a series of questions designed to get everyone involved to tell his or her own story about the incident and explain the personal impact. The group leaders enable participants to place the incident into perspective and dispel any feelings of blame or guilt. They also educate participants about self-care concepts and coping strategies to use immediately. People who require more than a CISD session may need referral for mental health/behavioral health counseling.

## Administrative Review

The second type of debriefing is an administrative evaluation directed at analyzing the hospital or agency response to an event while it is still in the forefront of the minds of everyone who participated in it. The goal of this debriefing is to discern what went right and what went wrong during activation and implementation of the emergency preparedness plan so needed changes can be made. Typically, representatives from all groups who were involved in the incident come together soon after plan activation has been discontinued. They each are given an opportunity to hear and express both positive and negative comments related to their experiences with the event. In the days after the plan activation, written critique forms are also solicited to gain additional information after participants have had time to consider their overall impressions of the response and the impact it had on their respective departments or clinical areas.

Although drills are important, implementing the emergency preparedness plan during an actual mass casualty event is the most effective means of “reality testing” the plan's utility. Feedback provided by participants can be used to modify or revise the plan and create new processes in preparation for future events.

## Role of Nursing in Community Emergency Preparedness and Response

During a community disaster, nurses and other emergency personnel may be needed for triage, first aid/emergency care, and shelter assistance. The first action of first responders in a disaster is to remove people from danger, both the injured and uninjured. Firefighters and other disaster-trained emergency personnel typically manage this job; unless they have had specific search-and-rescue training, nurses are not usually involved in this process. In all cases developing and maintaining accurate *situational awareness* are critical for appropriate priority setting and SAFETY in a rapidly changing environment.

After removal from danger, victims are triaged by health care personnel as described earlier in this chapter. After triage, nurses often provide on-site first aid and emergency care. They may also be involved in teaching and supervising volunteers. The American Red Cross sets up shelters for people who have lost their homes or have been evacuated from their homes.

Nurses may also need to teach those living temporarily in shelters about procedures that will be needed for SAFETY when they return home. For example, clean drinking water may not be available for several days or longer. Community residents may need to boil their water before drinking. If electricity and gas are not available, an outdoor grill or camp stove can be used for this purpose. As alternative procedures, commercial water purification filters, sterilizing ultraviolet pens, or 10 to 20 drops of chlorine bleach added to a gallon of water will make the water safe to drink.

Human waste management creates another challenge if toilets do not flush. If not managed safely, enteric pathogens spread disease. A toilet bowl or bucket lined with a plastic bag can be used for human waste. To sanitize it and provide odor control, chlorine bleach can be added, and the bag tied and sealed. Portable toilet chemicals or chlorinated lime may be used as alternatives. To prevent a toxic gas reaction, remind residents not to mix any chemicals. Treated human waste bags can be buried in the ground. In an austere environment a pit can be dug in the ground as an improvised toilet. In all cases, emphasize the importance of handwashing with soap and water or using a hand sanitizer to prevent disease transmission.

## Psychosocial Response of Survivors to Mass Casualty Events

One of the most important roles of the nurse during and after a community disaster is health assessment (also known as “noticing”), including psychosocial health. Experiencing a disaster can produce both immediate and long-lasting psychological and psychosocial effects in people personally affected by the event. Depending on the nature and magnitude of the incident, survivors experience the tragic loss of loved ones, pets, property, and valued possessions. They and their loved ones may have suffered injuries or illnesses brought about by the catastrophe. Lifestyles, roles, and routines are drastically altered, preventing people from achieving any sense of normalcy in the hours, days, and perhaps even weeks and months that follow a disaster. Coping abilities in survivors are severely stressed, leading to many individual responses, which can range from functional and adaptive behaviors to maladaptive coping.

Survivors have to confront feelings of vulnerability resulting from the devastating event, knowing that it could occur again. This may be a particularly relevant issue for people who live in areas prone to acts of terrorism or natural disasters. The decision, be it voluntary or involuntary, to abandon a family home or geographic region and then relocate to a “safe” area either temporarily or permanently results in a further sense of loss, grief, and disorientation. Some people may feel guilty about living through an event that caused so many others to die. The range of intense emotions can appear as physical illness and as psychological and social dysfunction.

When helping people in crisis after a mass casualty event, be calm and reassuring. Establish rapport through active listening and honest COMMUNICATION. Survivors benefit from talking about their experiences and putting them in chronological order, which provides clarity and helps them begin to problem solve. Offer resources whenever possible to help survivors gain a sense of personal control. Help survivors adapt to their new surroundings and routines through simple, concrete explanations. Convey caring behaviors, and provide a sense of safety and security to the best extent possible. If available, request that crisis counselors respond and assist in providing compassionate support to victims and their families.

A disaster may cause some survivors to develop acute stress disorder (ASD) or post-traumatic stress disorder (PTSD). People who are unable to sleep, are easily startled, have “flashbacks” to relive the disaster, or report “feeling numb” 2 weeks or more after a disaster or traumatic event are at risk for PTSD.

### Clinical Judgment Challenge 10-1

#### Patient-Centered Care QSEN

You are part of a DMAT team that has been dispatched to help a community after an EF-3 tornado touched down in a rural, underserved area. You have been notified that so far six people have been identified as killed, and over 100 have been identified as injured. The main street of the town has been demolished, and many people are without shelter.

1. How do you prepare to maintain your own personal health and safety while assisting others?
2. Which resources do you anticipate may be of highest need for this population?
3. Many residents are fearful about being transported to a facility several counties away, as most have lived in this town for their entire life. How would you respond?
4. After returning from the DMAT mission, you notice that a peer who served with you appears to feel disengaged with regular nursing employment and exhibits signs of depression. How will you support this nurse?

Nurses caring for survivors with these symptoms should perform further assessment. One tool that can be used to assess survivor response to a disaster is the Impact of Event Scale—Revised (IES-

R). The IES-R is a 22-item self-administered questionnaire that includes several subscales such as avoidance. Before giving the tool, determine the patient's reading level because it is written at a 10th-grade reading level. The tool should not be used for patients with short-term memory loss. For this reason, many older survivors often are not adequately assessed for post-disaster PTSD. Assess all older survivors of a disaster for this complication when possible.

## Nursing Safety Priority QSEN

### Action Alert

A high score on any IES-R subscale indicates a need for further evaluation and counseling. Refer the patient to a social worker, psychiatric mental health nurse specialist, or qualified mental health counselor. A high score on all subscales requires referral to a psychiatrist, clinical psychologist, or psychiatric mental health nurse practitioner or clinical specialist to evaluate the possibility of current or past trauma, such as abuse or neglect.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Describe the hospital emergency preparedness and response team that all hospitals are required to have in case of mass casualty (disaster). **QSEN: Teamwork and Collaboration**
- Apply principles of triage by using the typical triage system for a mass casualty situation, which includes an additional category for patients allowed to die (black-tagged) (see [Table 10-1](#)). **Ethics**
- Describe the special roles that are assigned in a mass casualty incident as identified in [Table 10-2](#).
- Understand how to assist in determining the need for initiating the emergency preparedness plan based on available resources and staffing. **QSEN: Teamwork and Collaboration**
- Develop a personal emergency preparedness plan (see [Table 10-3](#)).
- Compare key nursing and interprofessional team roles in emergency preparedness and in response plan and debriefing. **QSEN: Teamwork and Collaboration**
- Recall that nurses play a major role in triage, first aid and emergency care, and shelter assistance in external community disasters.

### Psychosocial Integrity

- Assess survivors and families for their ability to adapt to the effects of disaster changes or traumatic events, including acute stress disorder (ASD) or post-traumatic stress disorder (PTSD). **QSEN: Patient-Centered Care**
- Provide emotional support to the person and/or family coping with life changes resulting from a disaster through active listening and appropriate referrals. **QSEN: Patient-Centered Care**
- Be honest with victims and their families. Avoid giving false reassurance. Offer orienting information and help them adapt to their changed or new surroundings. **Ethics**
- Provide support by taking precautions to prevent staff from developing ASD or PTSD as outlined in [Chart 10-2](#).
- Recognize that older adults may not be properly assessed for ASD or PTSD. **Health Care Disparities**

### Physiological Integrity

- Take precautions for meeting basic needs in a mass casualty situation; know your own limitations and develop situational awareness when responding. **QSEN: Safety**

## UNIT III

# Interprofessional Collaboration for Patients With Problems of Fluid, Electrolyte, and Acid-Base Balance

## OUTLINE

---

Chapter 11 Assessment and Care of Patients With Problems of Fluid and Electrolyte Balance

Chapter 12 Assessment and Care of Patients With Problems of Acid-Base Balance

Chapter 13 Concepts of Infusion Therapy

---

## CHAPTER 11

# Assessment and Care of Patients With Problems of Fluid and Electrolyte Balance

M. Linda Workman

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concept for this chapter is FLUID AND ELECTROLYTE BALANCE.**

✚ The FLUID AND ELECTROLYTE BALANCE concept exemplar for this chapter is Dehydration, p. 167.

**The interrelated concept for this chapter is PERFUSION.**

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with the interprofessional team to perform a complete assessment of patients for FLUID AND ELECTROLYTE BALANCE.
2. Protect the patient with a problem of FLUID AND ELECTROLYTE BALANCE from injury and complications, especially those related to PERFUSION.
3. Teach the patient and caregiver(s) how home safety is affected by problems of FLUID AND ELECTROLYTE BALANCE.

### Health Promotion and Maintenance

4. Teach all adults measures to take to prevent problems of FLUID AND ELECTROLYTE BALANCE.

### Psychosocial Integrity

5. Implement nursing interventions to help the patient and family cope with the psychosocial impact of continuing risk for problems with FLUID AND ELECTROLYTE BALANCE.

### Physiological Integrity

6. Apply knowledge of anatomy and physiology to perform an evidence-based assessment for the patient who has a problem with FLUID AND ELECTROLYTE BALANCE.
7. Interpret assessment findings for the patient experiencing a problem of FLUID AND ELECTROLYTE BALANCE.
8. Teach the patient and caregivers about diagnostic procedures and drug therapies associated with conditions affecting FLUID AND ELECTROLYTE BALANCE.

## Anatomy and Physiology Review

Optimal body function depends on maintaining FLUID AND ELECTROLYTE BALANCE in each body fluid space (compartment). Keeping this balance within normal ranges is part of homeostasis. Because the range of normal is so narrow, the body has many control actions (known as *homeostatic mechanisms*) to prevent dangerous changes (Walker, 2016).

Water (fluid) makes up about 55% to 60% of total weight for younger adults and 50% to 55% of total weight for older adults. This water is divided into two main compartments (spaces)—the fluid outside the cells (**extracellular fluid [ECF]**) and the fluid inside the cells (**intracellular fluid [ICF]**). The ECF space is about one third (about 15 L) of the total body water. The ECF includes **interstitial fluid** (fluid between cells, “third space”); blood, lymph, bone, and connective tissue water; and the transcellular fluids. Transcellular fluids include cerebrospinal fluid, synovial fluid, peritoneal fluid, and pleural fluid. ICF is about two thirds (about 25 L) of total body water. Fig. 11-1 shows normal total body water distribution.

FIG. 11-1 Normal distribution of total body water in adults.

Water delivers dissolved nutrients and electrolytes to all organs, tissues, and cells. In health the volume of water in the fluid compartments remains within the normal range, although the water moves constantly between compartments. Changes in either the amount of water or the amount of electrolytes in body fluids can reduce the function of all cells, tissues, and organs.

Body fluids are composed of water and particles dissolved or suspended in water. The **solvent** is the water portion of fluids. **Solutes** are the particles dissolved or suspended in the water. Solutes vary in type and amount from one fluid space to another. When solutes express an overall electrical charge, they are known as *electrolytes*.

Three processes control FLUID AND ELECTROLYTE BALANCE to keep the internal environment stable even when the external environment changes. These processes (filtration, diffusion, and osmosis) determine whether fluids and particles move across cell membranes.

## Filtration

### Physiologic Action

**Filtration** is the movement of fluid (water) through a cell or blood vessel membrane because of water pressure (**hydrostatic pressure**) differences on both sides of the membrane. This pressure is caused by water volume pressing against confining membranes.

Water molecules in a confined space constantly press outward against the membranes, creating hydrostatic pressure (also known as *water pressure*). This is a “water-pushing” pressure, because it forces water outward from a confined space through a membrane (Fig. 11-2).

**FIG. 11-2** The process of filtration.

The amount (volume) of water in any body fluid space determines the hydrostatic pressure of that space. Blood, which is “thicker” than water (more *viscous*), is confined within the blood vessels. Blood has hydrostatic pressure because of its weight and volume and also from the pressure in arteries generated by the pumping action of the heart.

The hydrostatic pressures of two fluid spaces can be compared whenever a porous (**permeable**) membrane separates the two spaces. If the hydrostatic pressure is the same in both fluid spaces, there is no pressure difference between the two spaces, and the hydrostatic pressure is at *equilibrium*. If the hydrostatic pressure is not the same in both spaces, **disequilibrium** exists. This means that the two spaces have a graded difference (*gradient*) for hydrostatic pressure: one space has a higher hydrostatic pressure than the other. *The human body constantly seeks equilibrium*. When a gradient exists, water movement (filtration) occurs until the hydrostatic pressure is the same in both spaces (see Fig. 11-2).

Water moves through the membrane (**filters**) from the space with higher hydrostatic pressure to the space with lower pressure. Filtration continues only as long as the hydrostatic pressure gradient exists. Equilibrium is reached when enough fluid leaves one space and enters the other space to make the hydrostatic pressure in both spaces equal. Then water molecules are evenly exchanged between the spaces, but no net movement of fluid occurs. Neither space gains or loses water molecules, and the hydrostatic pressure in both spaces is the same.

### Clinical Application

Blood pressure is an example of a hydrostatic filtering force. It moves whole blood from the heart to capillaries where filtration can occur to exchange water, nutrients, and waste products between the blood and the tissues. The hydrostatic pressure difference between the capillary blood and the interstitial fluid (fluid in the tissue spaces) determines whether water leaves the blood vessels and enters the tissue spaces.

Capillary membranes are only one cell layer thick, making a thin “wall” to hold blood in the capillaries. Large spaces (**pores**) in the capillary membrane help water filter freely when a hydrostatic pressure gradient is present (Fig. 11-3).

**FIG. 11-3** The basic structure of a capillary.

**Edema** (excess tissue fluid) forms with changes in hydrostatic pressure differences between the blood and the interstitial fluid such as in right-sided heart failure (McCance et al., 2014). In this condition the volume of blood in the right side of the heart increases because the right ventricle is too weak to pump blood well into lung blood vessels. As blood backs up into the venous and capillary systems, the capillary hydrostatic pressure rises until it is higher than the pressure in the interstitial space. Excess filtration from the capillaries into the interstitial tissue space then forms visible edema.

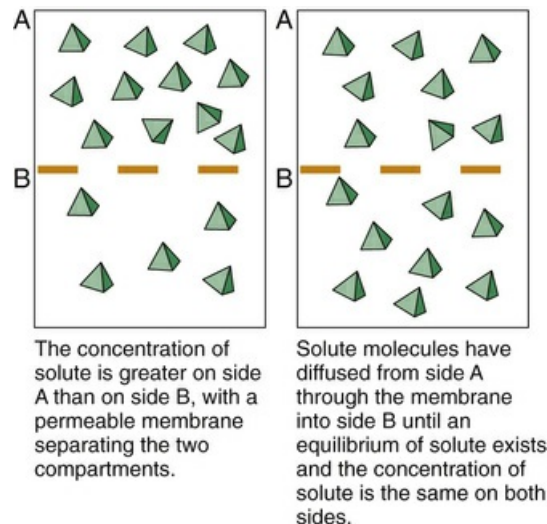

## Diffusion

### Physiologic Action

**Diffusion** is the movement of particles (solute) across a permeable membrane from an area of higher particle concentration to an area of lower particle concentration (*down a concentration gradient*). Particles in a fluid have random movement from the vibration of atoms in the nucleus. Random movement allows molecules to bump into each other in a confined fluid space. Each collision increases the speed of particle movement. The more particles (higher concentration) present in the confined fluid space, the greater the number of collisions.

As a result of the collisions, molecules in a solution spread out evenly through the available space. They move from an area of higher molecule concentrations to an area of lower concentrations until an equal concentration (amount) is present in all areas. Spaces with many particles have more collisions and faster particle movement than spaces with fewer particles.

A concentration gradient exists when two fluid spaces have different concentrations of the same type of particles. Particle collisions cause them to move down the concentration gradient. Any membrane that separates two spaces is struck repeatedly by particles. When the particle strikes a pore in the membrane that is large enough for it to pass through, diffusion occurs (Fig. 11-4). The chance of any single particle hitting the membrane and going through a pore is much greater on the side of the membrane with a higher solute particle concentration.

**FIG. 11-4** Diffusion of solute particles through a permeable membrane from an area of higher solute concentration to an area of lower solute concentration until an equilibrium is reached.

The speed of diffusion is related to the difference in amount of particles (concentration gradient) between the two sides of the membrane. The degree of difference is the *steepness* of the gradient: the larger the concentration difference between the two sides, the steeper the gradient. Diffusion is more rapid when the gradient is steeper (just as a ball rolls downhill faster when the hill is steep than when the hill is nearly flat). Particles move from the fluid space with a higher concentration of solute particles to the fluid space with a lower concentration of solute particles.

Particle diffusion continues as long as a concentration gradient exists between the two sides of the membrane. *When the concentration of particles is the same on both sides of the membrane, the particles are in equilibrium, and only an equal exchange of particles continues.*

### Clinical Application

Diffusion transports most electrolytes and other particles through cell membranes. Cell membranes, unlike capillary membranes, are *selective* for which particles can diffuse. They permit diffusion of some particles but not others. Some particles cannot move across a cell membrane, even when a steep “downhill” gradient exists, because the membrane is **impermeable** (closed) to that particle. For these particles the concentration gradient is maintained across the membrane.

Impermeability and special transport systems cause differences in the amounts of specific particles from one fluid space to another. For example, usually the fluid outside the cell (the *extracellular fluid [ECF]*) has ten times more sodium ions than the fluid inside the cell (the *intracellular fluid [ICF]*). This extreme difference is caused by cell membrane impermeability to sodium and by special “sodium pumps” that move any extra sodium present inside the cell out of the cell “uphill” against its concentration gradient and back into the ECF.

For some particles diffusion cannot occur without help, even down steep concentration gradients, because of selective membrane permeability. One example is glucose. Even though the amount of glucose may be much higher in the ECF than in the ICF (creating a steep gradient for glucose), glucose cannot cross some cell membranes without the help of insulin. Insulin binds to insulin receptors on cell membranes, which then makes the membranes much more permeable to glucose. Then glucose can cross the cell membrane down its concentration gradient into the cell.

Diffusion across a cell membrane that requires a membrane-altering system (e.g., insulin) is called **facilitated diffusion**. This type of movement is still a form of diffusion because it does not require extra energy.

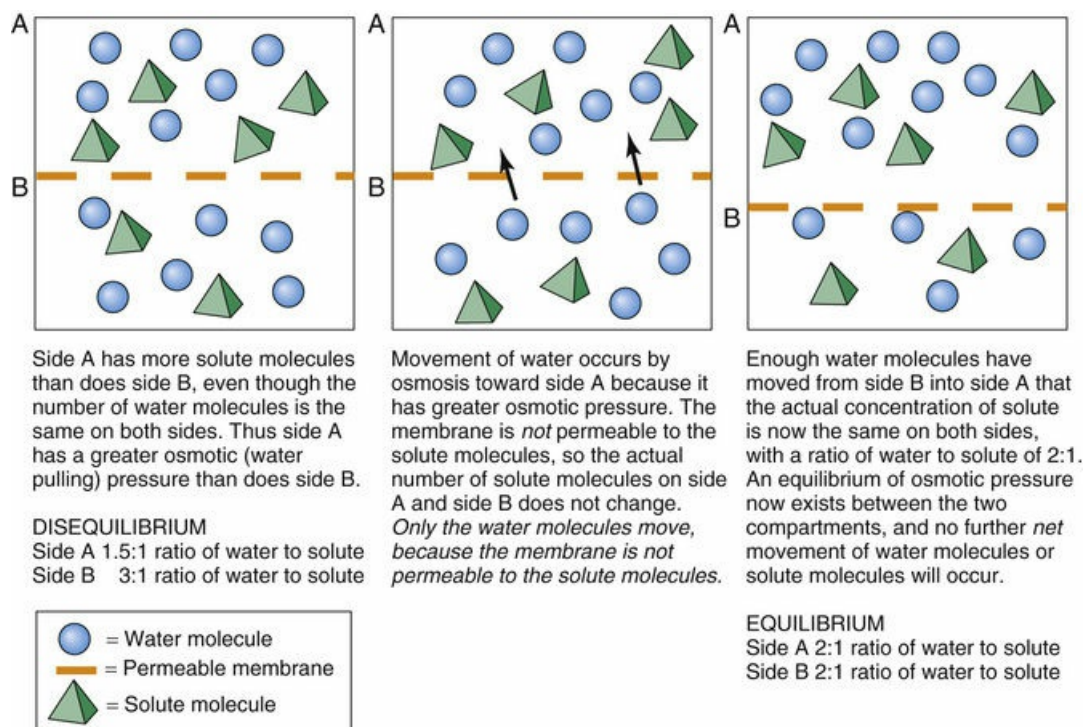

## Osmosis

### Physiologic Action

**Osmosis** is the movement of *water only* through a selectively permeable (*semipermeable*) membrane. For osmosis to occur, a membrane must separate two fluid spaces, and one space must have

particles that cannot move through the membrane. (The membrane is impermeable to this particle.) A concentration gradient of this particle must also exist. Because the membrane is impermeable to these particles, they cannot cross the membrane, but water molecules can.

For the fluid spaces to have equal concentrations of the particle, the water molecules move down their concentration gradient from the side with the higher concentration of water molecules (and a lower concentration of particles along with a greater hydrostatic pressure) to the side with the lower concentration of water molecules (and a higher concentration of particles along with a lower hydrostatic pressure). This movement continues until both spaces contain the same proportions of particles to water. Dilute fluid is less concentrated and has fewer particles and more water molecules than more concentrated fluid. Thus water moves by osmosis down its hydrostatic pressure gradient from the dilute fluid to the more concentrated fluid until a concentration equilibrium occurs (Fig. 11-5).

**FIG. 11-5** The process of osmosis to generate a concentration equilibrium (but not a volume equilibrium) for a solute particle that cannot move through a cell membrane.

At this point the *concentrations* of particles in the fluid spaces on both sides of the membrane are equal, even though the total amounts of particles and volumes of water are different. *The concentration equilibrium occurs by the movement of water molecules rather than the movement of solute particles.*

Particle concentration in body fluid is the major factor that determines whether and how fast osmosis and diffusion occur (McLafferty et al., 2014). This concentration is expressed in milliequivalents per liter (mEq/L), millimoles per liter (mmol/L), and milliosmoles per liter (mOsm/L). **Osmolarity** is the number of milliosmoles in a *liter* of solution; **osmolality** is the number of milliosmoles in a *kilogram* of solution. Because 1 L of water weighs 1 kg, in human physiology osmolarity and osmolality are considered the same, although osmolarity is the actual concentration measured most often. The normal osmolarity value for plasma and other body fluids ranges from 270 to about 300 mOsm/L. The body functions best when the osmolarity of all body fluid spaces is close to 300 mOsm/L. When all fluids have this particle concentration, the fluids are **isosmotic** or **isotonic** (also called **normotonic**) to each other.

Fluids with osmolarities greater than 300 mOsm/L are **hyperosmotic**, or **hypertonic**, compared with isosmotic fluids. These fluids have a *greater* osmotic pressure than do isosmotic fluids and tend to pull water from the isosmotic fluid space into the hyperosmotic fluid space until an osmotic balance occurs. If a hyperosmotic (hypertonic) IV solution (e.g., 3% or 5% saline) were infused into a

patient with normal extracellular fluid (ECF) osmolarity, the infusing fluid would make the adult's blood hyperosmotic. To balance this situation, the interstitial fluid would be pulled into the circulation in an attempt to dilute the blood osmolarity back to normal. In addition, fluid would also be drawn from the intracellular fluid (ICF) compartment. As a result, the interstitial and ICF volumes would shrink, and the plasma volume would expand.

Fluids with osmolarities of less than 270 mOsm/L are **hypo-osmotic**, or **hypotonic**, compared with isosmotic fluids. Hypo-osmolar fluids have a *lower* osmotic pressure than isosmotic fluids, and water is pulled from the hypo-osmotic fluid space into the isosmotic fluid spaces of the interstitial and ICF fluids. As a result, the interstitial and ICF fluid volumes would expand, and the plasma volume would shrink. An example of a hypotonic IV fluid is 0.45% saline.

### Clinical Application

Osmosis and filtration act together at the capillary membrane to maintain both extracellular fluid (ECF) and intracellular fluid (ICF) volumes within their normal ranges. The thirst mechanism is an example of how osmosis helps maintain homeostasis. The feeling of thirst is caused by the activation of cells in the brain that respond to changes in ECF osmolarity. These cells, so very sensitive to changes in ECF osmolarity, are called *osmoreceptors*. When an adult loses body water but most of the particles remain, such as through excessive sweating, ECF volume is decreased, and its osmolarity is increased (is hypertonic). The cells in the thirst center shrink as water moves from the cells into the hypertonic ECF. The shrinking of these cells triggers an adult's awareness of thirst and increases the urge to drink. Drinking replaces the amount of water lost through sweating and dilutes the ECF osmolarity, restoring it to normal.

## NCLEX Examination Challenge 11-1

### Physiological Integrity

What **immediate** response does the nurse expect as a result of infusing 1 L of an isotonic intravenous solution into a client over a 3-hour time period if urine output remains at 100 mL per hour?

- A. Extracellular fluid (ECF) osmolarity increases; body weight increases.
- B. Extracellular fluid (ECF) osmolarity decreases; body weight decreases.
- C. Extracellular fluid (ECF) osmolarity is unchanged; body weight increases.
- D. Extracellular fluid (ECF) osmolarity is unchanged; body weight decreases.

# Fluid Balance

## Body Fluids

Fluid balance is closely linked to and affected by electrolyte concentrations. [Table 11-1](#) lists the normal ranges of the major serum electrolytes. [Chart 11-1](#) lists the normal electrolyte values for people older than 60 years.

**TABLE 11-1**  
**Serum Electrolyte Concentrations and Significance of Abnormal Values**

ELECTROLYTE	REFERENCE RANGE	CANADIAN UNITS	SIGNIFICANCE OF ABNORMAL VALUES
Sodium (Na <sup>+</sup> )	136-145 mEq/L	136-145 mmol/L	<i>Elevated:</i> Hyponatremia; dehydration; kidney disease; hypercortisolism <i>Low:</i> Hyponatremia; fluid overload; liver disease; adrenal insufficiency
Potassium (K <sup>+</sup> )	3.5-5.0 mEq/L	3.5-5.0 mmol/L	<i>Elevated:</i> Hyperkalemia; dehydration; kidney disease; acidosis; adrenal insufficiency; crush injuries <i>Low:</i> Hypokalemia; fluid overload; diuretic therapy; alkalosis; insulin administration; hyperaldosteronism
Calcium (Ca <sup>2+</sup> )	9.0-10.5 mg/dL	2.25-2.75 mmol/L	<i>Elevated:</i> Hypercalcemia; hyperthyroidism; hyperparathyroidism <i>Low:</i> Hypocalcemia; vitamin D deficiency; hypothyroidism; hypoparathyroidism; kidney disease; excessive intake of phosphorus-containing foods and drinks
Chloride (Cl <sup>-</sup> )	98-106 mEq/L	98-106 mmol/L	<i>Elevated:</i> Hyperchloremia; metabolic acidosis; respiratory alkalosis; hypercortisolism <i>Low:</i> Hypochloremia; fluid overload; excessive vomiting or diarrhea; adrenal insufficiency; diuretic therapy
Magnesium (Mg <sup>2+</sup> )	1.8-2.6 mEq/L	0.74-1.07 mmol/L	<i>Elevated:</i> Hypermagnesemia; kidney disease; hypothyroidism; adrenal insufficiency <i>Low:</i> Hypomagnesemia; malnutrition; alcoholism; ketoacidosis

Data from Pagana, K., Pagana, T., & Pagana, T. (2017). *Mosby's diagnostic and laboratory test reference* (13th ed.). St. Louis: Mosby; and Pagana, K., Pagana, T., & Pike-MacDonald, S. (2013). *Mosby's Canadian manual of diagnostic and laboratory tests* (1st ed.). St. Louis: Mosby.

### Chart 11-1

## Nursing Focus on the Older Adult

### Normal Plasma Electrolyte Values for People Older Than 60 Years

ELECTROLYTE	REFERENCE RANGE		CANADIAN UNITS	
	60-90 YEARS	>90 YEARS	60-90 YEARS	>90 YEARS
Calcium (Ca <sup>2+</sup> )	9.0-10.5 mg/dL	8.2-9.6 mg/dL	2.2-2.75 mmol/L	2.05-2.40 mmol/L
Chloride (Cl <sup>-</sup> )	98-106 mEq/L	98-111 mEq/L	98-106 mmol/L	98-111 mmol/L
Magnesium (Mg <sup>2+</sup> )	1.8-2.6 mEq/L	1.8-2.6 mEq/L	0.74-1.07 mmol/L	0.74-1.07 mmol/L
Potassium (K <sup>+</sup> )	3.5-5.0 mEq/L	3.5-5.0 mEq/L	3.5-5.0 mmol/L	3.5-5.0 mmol/L
Sodium (Na <sup>+</sup> )	136-145 mEq/L	132-146 mEq/L	136-145 mmol/L	132-146 mmol/L

Data for adults 60 to 90 years from Pagana, K., Pagana, T., & Pagana, T. (2017). *Mosby's diagnostic and laboratory test reference* (13th ed.). St. Louis: Mosby; and Pagana, K., Pagana, T., & Pike-MacDonald, S. (2013). *Mosby's Canadian manual of diagnostic and laboratory tests* (1st ed.). St. Louis: Mosby.

Data for adults >90 years from Tietz, N. W. (Ed.). (1995). *Clinical guide to laboratory tests* (3rd ed.). Philadelphia: Saunders.

Age, gender, and amount of fat affect the amount and distribution of body fluids. An older adult has less total body water than a younger adult. [Chart 11-2](#) shows age-related changes in fluid balance. An obese adult has less total water than a lean adult of the same weight because fat cells contain almost no water.

### Chart 11-2

## Nursing Focus on the Older Adult

### Impact of Age-Related Changes on Fluid Balance

SYSTEM	CHANGE	RESULT
Skin	Loss of elasticity Decreased turgor Decreased oil production	Skin becomes an unreliable indicator of fluid status, especially the back of the hand Dry, easily damaged skin
Kidney	Decreased glomerular filtration Decreased concentrating capacity	Poor excretion of waste products Increased water loss, increasing the risk for dehydration
Muscular	Decreased muscle mass	Decreased total body water Greater risk for dehydration

Neurologic	Diminished thirst reflex	Decreased fluid intake, increasing the risk for dehydration
Endocrine	Adrenal atrophy	Poor regulation of sodium and potassium, increasing the risk for hyponatremia and hyperkalemia

Data from Touhy, T., & Jett, K. (2016). *Ebersole and Hess' toward health aging* (9th ed.). St. Louis: Mosby.

## Gender Health Considerations

### Patient-Centered Care QSEN

Women of any age have less total body water and a higher risk for dehydration than men of similar sizes and ages. This difference is because men tend to have more muscle mass than women and because women have more body fat. (Muscle cells contain mostly water, and fat cells have little water.)

Body fluids are constantly filtered and replaced as fluid balance is maintained through intake and output. The total amount of water in each fluid space is stable, but water in all spaces is exchanged continually while maintaining constant fluid volume.

*Fluid intake* is regulated through the thirst drive. Fluid enters the body as liquids and solid foods, which contain up to 85% water (Table 11-2). A rising blood osmolarity or a decreasing blood volume triggers the sensation of thirst (Arai et al., 2013). An adult takes in about 2300 mL of fluid daily from food and liquids.

**TABLE 11-2**  
**Routes of Fluid Ingestion and Excretion**

INTAKE	OUTPUT
<b>Measurable</b>	
Oral fluids	Urine
Parenteral fluids	Emesis
Enemas*	Feces
Irrigation fluids*	Drainage from body cavities
<b>Not Measurable</b>	
Solid foods	Perspiration
Metabolism	Vaporization through the lungs

\*Measured by subtracting the amount returned from the amount instilled.

*Fluid loss* occurs through several routes (see Table 11-2). The kidney is the most important and the most sensitive water loss route because it is regulated and adjustable. The volume lost through urine elimination daily varies, depending on the amount of fluid taken in and the body's need to conserve fluids.

The minimum amount of urine per day needed to excrete toxic waste products is 400 to 600 mL. This minimum volume is called the **obligatory urine output**. If the 24-hour urine output falls below the obligatory output amount, wastes are retained and can cause lethal electrolyte imbalances, acidosis, and a toxic buildup of nitrogen.

The ability of the kidneys to make either concentrated or very dilute urine helps maintain fluid balance. The kidney works with various hormones to maintain fluid balance when extracellular fluid (ECF) concentrations, volumes, or pressures change.

Other normal water loss occurs through the skin, the lungs, and the intestinal tract. Water losses also can result from salivation, drainage from fistulas and drains, and GI suction. This loss is called **insensible water loss** because no mechanisms control it. In a healthy adult insensible water loss is about 500 to 1000 mL/day. This loss increases greatly during thyroid crisis, trauma, burns, states of extreme stress, and fever. Patients at risk for excess insensible water loss include those being mechanically ventilated, those with rapid respirations, and those undergoing continuous GI suctioning. Water loss through stool increases greatly with severe diarrhea or excessive fistula drainage. If not balanced by intake, insensible loss can lead to severe dehydration and electrolyte imbalances.

## Hormonal Regulation of Fluid Balance

Three hormones help control FLUID AND ELECTROLYTE BALANCE. These are aldosterone, antidiuretic hormone (ADH), and natriuretic peptide (NP).

*Aldosterone* is secreted by the adrenal cortex whenever sodium levels in the extracellular fluid

(ECF) are low. Aldosterone prevents both water and sodium loss. When aldosterone is secreted, it acts on the kidney nephrons, triggering them to reabsorb sodium and water from the urine back into the blood. This action increases blood osmolarity and blood volume. Aldosterone also promotes kidney potassium excretion.

*Antidiuretic hormone (ADH)*, or vasopressin, is released from the posterior pituitary gland in response to changes in blood osmolarity. The hypothalamus contains the osmoreceptors that are sensitive to changes in blood osmolarity. Increased blood osmolarity, especially an increase in the level of plasma sodium, results in a slight shrinkage of these cells and triggers ADH release from the posterior pituitary gland. Because the action of ADH retains just water, it only indirectly regulates electrolyte retention or excretion.

ADH acts on kidney nephrons, making them more permeable to water. As a result, more water is *reabsorbed* by these tubules and returned to the blood, decreasing blood osmolarity by making it more dilute. When blood osmolarity decreases with low plasma sodium levels, the osmoreceptors swell slightly and inhibit ADH release. Less water is then reabsorbed, and more is excreted in the urine, bringing extracellular fluid (ECF) osmolarity up to normal.

*Natriuretic peptides (NPs)* are hormones secreted by special cells that line the atria of the heart (atrial natriuretic peptide [ANP]) and the ventricles of the heart. (The peptide secreted by the heart ventricular cells is known as brain natriuretic peptide [BNP].) These peptides are secreted in response to increased blood volume and blood pressure, which stretch the heart tissue. NP binds to receptors in the nephrons, creating effects that are opposite of aldosterone. Kidney reabsorption of sodium is inhibited at the same time that urine output is increased. The outcome is decreased circulating blood volume and decreased blood osmolarity.

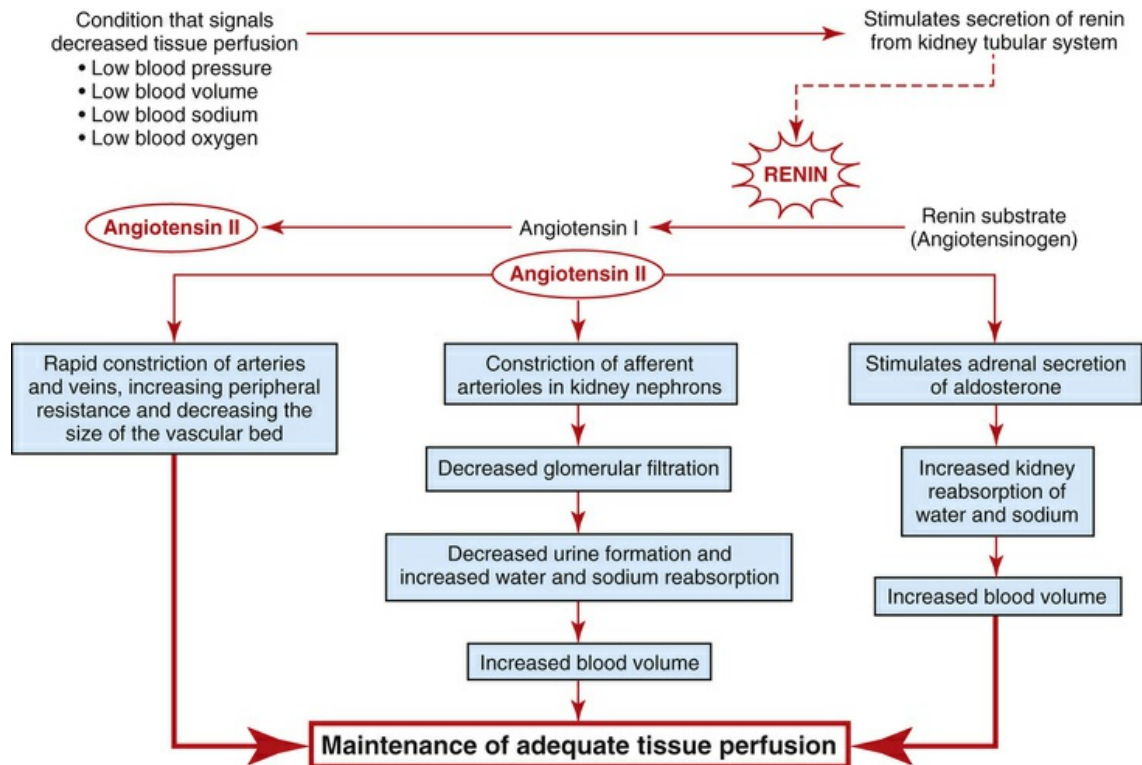

## Significance of Fluid Balance

### The Renin-Angiotensin II Pathway

The most important body fluids to keep in balance for optimal function are the blood volume (plasma volume) and the fluid inside the cells (intracellular fluid). Maintaining blood volume at a sufficient level for blood pressure to remain high enough to ensure adequate **PERFUSION** is critical for life. A major regulator of fluid balance is the renin-angiotensin II pathway, also known as the renin-angiotensin system (RAS).

Because low blood volume and low blood pressure can rapidly lead to death, the body has many compensatory mechanisms that guard against low plasma volume. These involve specific responses to change how water and sodium are handled to maintain blood pressure.

Because the kidney is a major regulator of water and sodium balance to maintain blood pressure and perfusion to all tissues and organs, the kidneys monitor blood pressure, blood volume, blood oxygen levels, and blood osmolarity (related to sodium concentration). When the kidneys sense that any one of these parameters is getting low, they begin to secrete a substance called *renin* that sets into motion a group of hormonal and blood vessel responses to ensure that blood pressure is raised back up to normal. [Fig. 11-6](#) summarizes these responses.

**FIG. 11-6** The role of the renin-angiotensin II pathway in fluid and electrolyte balance and blood pressure regulation.

So the triggering event for renin secretion is any change in the blood indicating that **PERFUSION** is at risk. Low blood pressure is a triggering event because it reduces perfusion to tissues and organs. Anything that reduces blood volume (e.g., dehydration, hemorrhage) below a critical level *always* lowers blood pressure. Low blood oxygen levels also are triggering events because with too little oxygen in the blood it cannot supply the needed oxygen and the tissues and organs could die. A low blood sodium level also is a triggering event because sodium and water are closely linked. Where sodium goes, water follows. So anything that causes the blood to have too little sodium prevents water from staying in the blood. The result is low blood volume with low blood pressure and poor tissue perfusion.

Once the kidneys sense that **PERFUSION** is at risk, special cells in the kidney tubule begin to secrete renin into the blood. Renin then activates *angiotensinogen*. Activated angiotensinogen is *angiotensin I*, which is activated by the enzyme *angiotensin-converting enzyme* or *ACE* to its most active form, *angiotensin II* (McCance et al., 2014).

*Angiotensin II* starts several actions to increase blood volume and blood pressure. First it constricts arteries and veins throughout the body. This action increases peripheral resistance and reduces the size of the vascular bed, which raises blood pressure as a compensatory mechanism without adding more blood volume. *Angiotensin II* also constricts the size of the arterioles that feed the kidney nephrons. This action results in a lower glomerular filtration rate and a huge reduction of urine output. Decreasing urine output prevents further water loss so more is retained in the blood to help raise blood pressure. *Angiotensin II* also causes the adrenal glands to secrete the hormone aldosterone. Aldosterone is nicknamed the “water-and-sodium-saving hormone” because it causes the kidneys to reabsorb water and sodium, preventing them from being excreted into the urine. This response allows more water and sodium to be returned to the blood, increasing blood pressure, blood volume, and **PERFUSION**.

### Clinical Application

The renin-angiotensin II pathway is stimulated whenever the patient is in shock. This is why urine output is used as an indicator of **PERFUSION** adequacy after surgery or any time the patient has undergone an invasive procedure and is at risk for hemorrhage.

This pathway also is related to management of *hypertension* (high blood pressure). Patients who have hypertension are often asked to limit their intake of sodium. The reason for this is that a high

sodium intake raises the blood level of sodium, causing more water to be retained in the blood volume and raising blood pressure. Drug therapy for hypertension management may include diuretic drugs that increase the excretion of sodium so less is present in the blood, resulting in a lower blood volume. Another class of drugs often used to manage blood pressure is the “ACE inhibitors” (ACEIs). These drugs disrupt the renin-angiotensin II pathway by reducing the amount of angiotensin-converting enzyme (ACE) made so less angiotensin II is present. With less angiotensin II, there is less vasoconstriction and reduced peripheral resistance, less aldosterone production, and greater excretion of water and sodium in the urine. All of these responses lead to decreased blood volume and blood pressure. Another class of drugs used to manage hypertension is the angiotensin receptor blockers (ARBs). These drugs disrupt the renin-angiotensin II pathway by blocking the receptors that bind with angiotensin II so the tissues cannot respond to it and blood pressure is lowered. The most recent class of drugs to manage hypertension by changing the renin-angiotensin II pathway is the direct renin inhibitors. These drugs act early in the pathway and prevent the enzyme renin from changing angiotensinogen into angiotensin I. These drugs may be combined with an ARB to block the pathway in more than one place, leading to greater reduction in blood pressure. See [Chapter 36](#) for more information about antihypertensive agents.

# Disturbances of Fluid and Electrolyte Balance

## Fluid and Electrolyte Balance Concept Exemplar Dehydration

### Pathophysiology

In **dehydration** fluid intake or retention is less than what is needed to meet the body's fluid needs, resulting in a deficit of fluid volume, especially plasma volume. It is a condition rather than a disease and can be caused by many factors (Table 11-3). Dehydration may be an *actual* decrease in total body water caused by either too little intake of fluid or too great a loss of fluid. It also can occur without an actual loss of total body water such as when water shifts from the plasma into the interstitial space. This condition is called *relative* dehydration.

**TABLE 11-3**

**Common Causes of Fluid Imbalances**

Dehydration	Fluid Overload
<ul style="list-style-type: none"><li>• Hemorrhage</li><li>• Vomiting</li><li>• Diarrhea</li><li>• Profuse salivation</li><li>• Fistulas</li><li>• Ileostomy</li><li>• Profuse diaphoresis</li><li>• Burns</li><li>• Severe wounds</li><li>• Long-term NPO status</li><li>• Diuretic therapy</li><li>• GI suction</li><li>• Hyperventilation</li><li>• Diabetes insipidus</li><li>• Difficulty swallowing</li><li>• Impaired thirst</li><li>• Unconsciousness</li><li>• Fever</li><li>• Impaired motor function</li></ul>	<ul style="list-style-type: none"><li>• Excessive fluid replacement</li><li>• Kidney failure (late phase)</li><li>• Heart failure</li><li>• Long-term corticosteroid therapy</li><li>• Syndrome of inappropriate antidiuretic hormone (SIADH)</li><li>• Psychiatric disorders with polydipsia</li><li>• Water intoxication</li></ul>

## Considerations for Older Adults

### Patient-Centered Care QSEN

Older adults are at high risk for dehydration because they have less total body water than younger adults. In addition, many older adults have decreased thirst sensation and may have difficulty with walking or other motor skills needed for obtaining fluids. They also may take drugs such as diuretics, antihypertensives, and laxatives that increase fluid excretion. Assess the FLUID AND ELECTROLYTE BALANCE status of all older adults in any setting.

Dehydration may occur with just water (fluid) loss or with water and electrolyte loss (isotonic dehydration). *Isotonic dehydration is the most common type of fluid loss problem.* Fluid is lost only from the extracellular fluid (ECF) space, including both the plasma and the interstitial spaces. There is no shift of fluids between spaces, so the intracellular fluid (ICF) volume remains normal (Fig. 11-7). Circulating blood volume is decreased (**hypovolemia**) and leads to reduced perfusion. The body's defenses compensate during dehydration to maintain PERFUSION to vital organs in spite of hypovolemia. The main defense is increasing vasoconstriction and peripheral resistance to maintain blood pressure and circulation.

**FIG. 11-7** Changes in fluid compartment volumes with dehydration. (© 1992 by M. Linda Workman. All rights reserved.)

## Health Promotion and Maintenance

Mild dehydration is very common among healthy adults and is corrected or prevented easily by matching fluid intake with fluid output. Teach all adults to drink more fluids, especially water, whenever they engage in heavy or prolonged physical activity or live in dry climates or at higher altitudes. Beverages with caffeine can increase fluid loss, as can drinks containing alcohol; thus these beverages should not be used to prevent or treat dehydration.

### ❖ Interprofessional Collaborative Care

Dehydration can occur in any setting. Mild dehydration can be managed in the home or other residential setting. Severe dehydration may require temporary hospitalization, depending on the cause and the effects on PERFUSION.

### ◆ Assessment: Noticing

#### History.

Ask specific questions about food and liquid intake. Also assess the types of fluids and foods ingested to determine amount and osmolarity. Many patients do not know that solid foods contain liquid. Other foods such as ice cream, gelatin, and ices are liquids at body temperature and are included when calculating fluid intake.

Collect specific information about exact intake and output volumes and obtain serial daily weight measurements. If possible, weigh the patient directly rather than asking what he or she weighs. Weight loss is an indication of dehydration. *Because 1 L of water weighs 2.2 lbs (1 kg), changes in daily weights are the best indicators of fluid losses or gains. A weight change of 1 lb corresponds to a fluid volume change of about 500 mL.*

Ask specific questions about prescribed and over-the-counter drugs and check the dosage, the length of time taken, and the patient's adherence to the drug regimen. Older adults may use diuretics or laxatives that can lead to impaired FLUID AND ELECTROLYTE BALANCE.

Ask about the presence of kidney or endocrine diseases. Assess the patient's level of consciousness and mental status because changes in mental status occur with fluid imbalance. Ask the patient about changes in ring or shoe tightness. A sudden decrease in tightness may indicate dehydration.

#### Physical Assessment/Signs and Symptoms.

Nearly all body systems are affected by dehydration to some degree. The most obvious changes occur in the cardiovascular and integumentary systems.

*Cardiovascular changes* are good indicators of hydration status because of the relationship between plasma fluid volume, blood pressure, and PERFUSION. Heart rate increases to help maintain blood pressure with less blood volume. Peripheral pulses are weak, difficult to find, and easily blocked.

Blood pressure also decreases, as does pulse pressure, with a greater decrease in diastolic blood pressure. Hypotension is more severe with the patient in the standing position than in the sitting or lying position (**orthostatic** or **postural hypotension**). Measure blood pressure first with the patient lying down, then sitting, and finally standing. (These measures are also called *ortho checks* or *ortho changes*.) As the blood pressure decreases when changing position, perfusion to the brain decreases, causing light-headedness and dizziness. This problem increases the risk for falling, especially among older adults.

Neck veins are normally distended when a patient is in the supine position, and hand veins are distended when lower than the level of the heart. Neck veins normally flatten when the patient moves to a sitting position. With dehydration, neck and hand veins are flat, even when the neck and hands are not raised above the level of the heart.

*Respiratory changes* include an increased rate because the decreased blood volume reduces perfusion and gas exchange. The increased respiratory rate is a compensatory mechanism that attempts to maintain oxygen delivery when perfusion is decreased.

*Skin changes* can indicate dehydration. Assess the skin and mucous membranes for color, moisture, and turgor. Assess skin turgor by checking:

- How easily the skin over the back of the hand and arm can be gently pinched between the thumb and the forefinger to form a “tent”
- How soon the pinched skin resumes its normal position after release

In dehydration skin turgor is poor, with the tent remaining for minutes after pinching the skin. The skin is dry and scaly.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Assess skin turgor in an older adult by pinching the skin over the sternum or on the forehead rather than on the back of the hand (Fig. 11-8). With aging the skin loses elasticity and tents on hands and arms even when the adult is well hydrated.

**FIG. 11-8** Examining the skin turgor of an older patient.

In dehydration oral mucous membranes may be dry and covered with a thick, sticky coating and may have cracks and fissures. The tongue surface may have deep furrows.

*Neurologic changes* with dehydration include changes in mental status and temperature with reduced PERFUSION in the brain. Changes in cognition are more common among older adults and may be the first indication of a fluid imbalance.

The patient with dehydration often has a low-grade fever, and fever can also cause dehydration. For every degree (Celsius) increase in body temperature above normal, a minimum of an additional 500 mL of body fluid is lost.

*Kidney changes* in dehydration affect urine volume and concentration. Monitor urine output, comparing total output with total fluid intake and daily weights. The urine may be concentrated, with a specific gravity greater than 1.030, and have a dark amber color and a strong odor. *Urine*

output below 500 mL/day for a patient without kidney disease is cause for concern. Use daily weights to assess fluid loss. Weight loss over a half pound per day is fluid loss.

### Laboratory Assessment.

No single laboratory test result confirms or rules out dehydration. Instead dehydration is determined by laboratory findings along with signs and symptoms (see [Table 11-1](#)). Usually laboratory findings with dehydration show elevated levels of hemoglobin, hematocrit, serum osmolarity, glucose, protein, blood urea nitrogen, and electrolytes because more water is lost and other substances remain, increasing blood concentration (**hemoconcentration**). Hemoconcentration is not present when dehydration is caused by hemorrhage because loss of all blood and plasma products occurs together.

## NCLEX Examination Challenge 11-2

### Safe and Effective Care Environment

When evaluating the hydration status of a new 84-year-old nursing home client, the nurse observes tenting of the skin on the back of the client's hand. What is the nurse's **best** action?

- A. Assess the skin turgor on the client's forehead.
- B. Ask the client when he or she last had anything to drink.
- C. Examine the client's dependent body areas, especially the ankles.
- D. Document this observation in the client's record as the only action.

#### ◆Analysis: Interpreting

The priority problems for the patient who has dehydration are:

1. Dehydration due to excess fluid loss or inadequate fluid intake
2. Potential for injury due to blood pressure changes and muscle weakness

#### ◆Planning and Implementation: Responding

The focus of management for the patient with dehydration is to prevent further fluid loss, to increase fluid volumes to normal, and to prevent injury. Nursing priorities include fluid replacement, drug therapy, and patient safety.

### Restoring Fluid Balance

#### Planning: Expected Outcomes.

The patient with dehydration is expected to have sufficient fluid volume for adequate perfusion. Indicators include that the patient has:

- Blood pressure at or near his or her normal range
- Daily urine output within 500 mL of total daily fluid intake (or at least 30 mL per hour)
- Moist mucous membranes
- Normal skin turgor

#### Interventions.

Interventions for restoring fluid balance include fluid replacement and drug therapy.

#### Fluid Replacement.

Replacement of fluids is key to correcting dehydration and preventing death from reduced PERFUSION. Best practices for nursing care of the patient with dehydration are listed in [Chart 11-3](#). Mild-to-moderate dehydration is corrected with oral fluid replacement if the patient is alert enough to swallow and can tolerate oral fluids. Encourage fluid intake and measure the amount ingested.

### Chart 11-3

## Best Practice for Patient Safety & Quality Care QSEN

### The Patient With Dehydration

- When possible, provide oral fluids that meet the patient's dietary restrictions (e.g., sugar-free, low-sodium, thickened).
- Collaborate with other members of the interprofessional team to determine the amount of fluids needed during a 24-hour period.
- Ensure that fluids are offered and ingested on an even schedule at least every 2 hours throughout 24 hours.
- Teach unlicensed assistive personnel to actively participate in the hydration therapy and not to withhold fluids to prevent incontinence.
- Infuse prescribed IV fluids at a rate consistent with hydration needs and any known cardiac, pulmonary, or kidney problems.
- Monitor the patient's response to fluid therapy at least every 2 hours for indicators of adequate rehydration or the need for continuing therapy, especially:
  - Pulse quality
  - Urine output
  - Pulse pressure
  - Weight (every 8 hours)
- Monitor for and report indicators of fluid overload, including:
  - Bounding pulse
  - Difficulty breathing
  - Neck vein distention in the upright position
  - Presence of dependent edema
- Assess the IV line and the infusion site at least hourly for indications of infiltration, extravasation, or phlebitis (e.g., swelling around the site, pain, cordlike veins, reduced drip rate).
- Administer drugs prescribed to correct the underlying cause of the dehydration (e.g., antiemetics, antidiarrheals, antibiotics, antipyretics).

Provide fluid the patient enjoys and time the intake schedule. Dividing the total amount of fluids needed by nursing shifts helps meet fluid needs more evenly over 24 hours with less danger of overload. Offer the conscious patient small volumes of fluids hourly.

Coordinate with unlicensed assistive personnel (UAP) to meet patients' specific fluid needs. Teach UAP to offer 60 to 120 mL of fluid every hour to patients who are dehydrated or who are at

risk for dehydration. If incontinence is a concern, ensure that UAP understand that withholding fluids is not appropriate to prevent the problem. Instruct them to take the time to stay with patients while they drink the fluid and to note the exact amount ingested.

Use of oral rehydration solutions (ORSs) for rehydration therapy is an effective way to replace fluids. Specifically formulated solutions containing glucose and electrolytes are absorbed even when the patient is vomiting or has diarrhea. These are more often used in the home setting; in long-term care; and for patients who have poor veins, making IV therapy difficult. A variety of commercial ORSs are available over the counter.

When dehydration is severe or the patient cannot tolerate oral fluids, IV fluid replacement is needed. Calculation of how much fluid to replace is based on the patient's weight loss and symptoms. The rate of fluid replacement depends on the degree of dehydration and the patient's cardiac, pulmonary, or kidney status.

The type of fluid prescribed varies with the patient's cardiac status and blood osmolarity (Bridges, 2013; Pierce et al., 2016). Crystalloids are IV fluids that contain water, minerals (electrolytes), and sometimes other water-soluble substances such as glucose. These fluids rapidly disperse to all body fluid compartments and are most useful when dehydration includes both the intracellular and extracellular compartments. Colloids are IV fluids that contain larger non-water-soluble molecules that increase the osmotic pressure in the plasma volume. These fluids are most useful in helping to maintain plasma volume with a lower infused volume (Pierce et al., 2016).

Table 11-4 lists types of common IV fluids. *The two most important areas to monitor during rehydration are pulse rate and quality and urine output.*

**TABLE 11-4**  
**Characteristics of Common Intravenous Therapy Solutions**

SOLUTION	OSMOLARITY (mOsm/L)	pH	CALORIES (Kcal) PER LITER	TONICITY
0.9% saline	308	5	0	Isotonic
0.45% saline	154	5	0	Hypotonic
5% dextrose in water (D <sub>5</sub> W)	272	3.5-6.5	170	Isotonic*
10% dextrose in water (D <sub>10</sub> W)	500	3.5-6.5	340	Hypertonic*
5% dextrose in 0.9% saline	560	3.5-6.5	170	Hypertonic*
5% dextrose in 0.45% saline	406	4	170	Hypertonic*
5% dextrose in 0.225% saline	321	4	170	Isotonic*
Ringer's lactate	273	6.5	9	Isotonic
5% dextrose in Ringer's lactate	525	4-6.5	179	Hypertonic*

\*Solution tonicity at the time of administration. Within a short time after administration, the dextrose is metabolized, and the tonicity of the infused solution decreases in proportion to the osmolality or tonicity of the nondextrose components (electrolytes) within the water.

Data from Trissel, L. (2013). *Handbook on injectable drugs* (17th ed.). Bethesda, MD: American Society of Hospital-System Pharmacists.

## Drug Therapy.

Drug therapy may correct some causes of the dehydration. Antidiarrheal drugs are prescribed when diarrhea causes dehydration. Antimicrobial therapy may be used in patients with bacterial diarrhea. Antiemetics may be used when vomiting causes dehydration. Antipyretics to reduce fever are helpful when fever makes dehydration worse.

## Preventing Injury

### Planning: Expected Outcomes.

The patient with dehydration is expected to avoid injury. Indicators include that the patient:

- Asks for assistance when ambulating
- Does not fall

### Interventions.

Patient safety issues and strategies are priorities of care before and during other therapies for dehydration. Monitor vital signs, especially heart rate and blood pressure. The patient with dehydration is at risk for falls because of orthostatic hypotension, dysrhythmia, muscle weakness, and possible confusion. Assess his or her muscle strength, gait stability, and level of alertness. Instruct the patient to get up slowly from a lying or sitting position and to immediately sit down if he or she feels light-headed. Stress the importance of asking for assistance to ambulate. Implement

other fall precautions listed in [Chart 3-4](#).

### Care Coordination and Transition Management

Because dehydration is a symptom or complication of another health problem or drug therapy, even severe dehydration is resolved before patients return home or to residential care. Education is the most important management strategy to prevent recurrence among adults who remain at some risk for recurrence such as patients who have diabetes insipidus or diabetes mellitus. See [Chapter 62](#) for a detailed discussion of the care coordination needed for diabetes insipidus and [Chapter 64](#) for care coordination for diabetes mellitus.

#### ◆Evaluation: Reflecting

Depending on the cause of dehydration, most patients return to an acceptable fluid balance with proper management. Indications that the patient's underlying cause of dehydration is well managed and that the imbalance is corrected include that the patient:

- Maintains a daily fluid intake of at least 1500 mL (or drinks at least 500 mL more than his or her daily urine output)
- Can state the indications of dehydration
- Starts fluid replacement at the first indication of dehydration
- Correctly follows treatment plans for ongoing health problems that increase the risk for dehydration

## NCLEX Examination Challenge 11-3

### Safe and Effective Care Environment

For which clients is it **most** important for the nurse to check frequently for dehydration? **Select all that apply.**

- A. 24-year-old athlete who is NPO for 4 hours awaiting an appendectomy
- B. 42-year-old client who has diabetes insipidus
- C. 56-year-old client recently diagnosed with syndrome of inappropriate antidiuretic hormone (SIADH)
- D. 68-year-old client with poorly controlled type 2 diabetes mellitus
- E. 72-year-old client taking 80 mg of furosemide orally every day
- F. 74-year-old undergoing a bowel preparation with multiple enemas before colon surgery

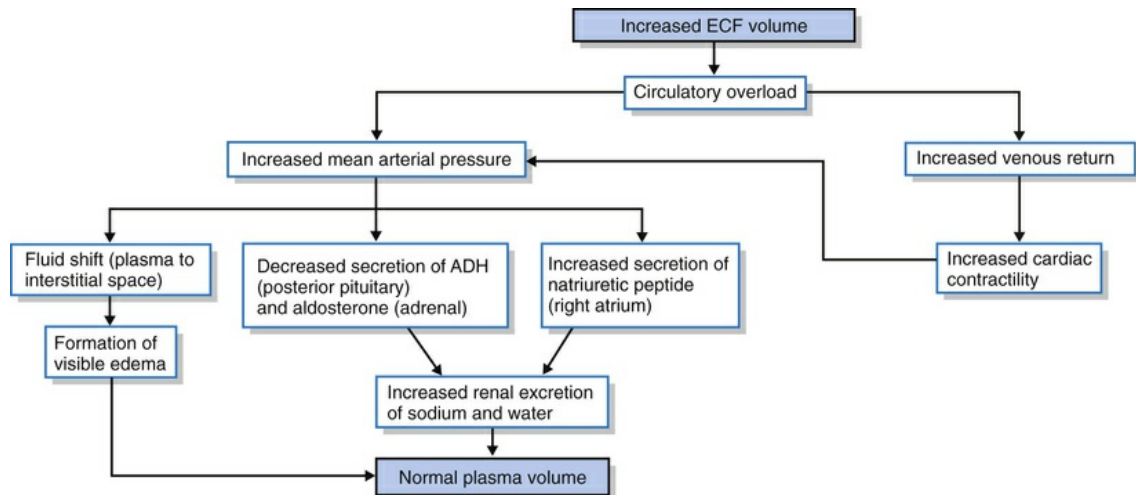

## Fluid Overload

### ❖Pathophysiology

**Fluid overload**, also called *overhydration*, is an excess of body fluid. It is a clinical indication of a problem in which fluid intake or retention is *greater* than the body's fluid needs. The most common type of fluid overload is hypervolemia ([Fig. 11-9](#)) because the problems result from excessive fluid in the extracellular fluid (ECF) space. Most problems caused by fluid overload are related to excessive fluid in the vascular space or to dilution of specific electrolytes and blood components. The conditions leading to fluid overload are related to excessive intake or inadequate excretion of fluids. See [Table 11-3](#) for causes of fluid overload. [Fig. 11-10](#) outlines the adaptive changes the body makes in response to mild or moderate fluid overload, especially increased urine output, and edema formation. When overload is severe or occurs in an adult with poor cardiac or kidney function, it can lead to heart failure and pulmonary edema. Dilution of sodium and potassium can lead to seizures, coma, and death.

**FIG. 11-9** Changes in fluid compartment volumes with fluid overload. (© 1992 by M. Linda Workman. All rights reserved.)

**FIG. 11-10** Adaptive actions and mechanisms to prevent cardiac and pulmonary complications during fluid overload. (ADH, Antidiuretic hormone; ECF, extracellular fluid.)

### ❖ Interprofessional Collaborative Care

#### ◆ Assessment: Noticing

Patients with fluid overload often have pitting edema (Fig. 11-11). Other symptoms are usually seen in the cardiovascular, respiratory, neuromuscular, integumentary, and GI systems (Chart 11-4).

**FIG. 11-11** Pitting edema of the left foot and ankle.

#### ▶ **Chart 11-4**

### **Key Features**

#### **Fluid Overload**

##### **Cardiovascular Changes**

- Increased pulse rate
- Bounding pulse quality
- Elevated blood pressure
- Decreased pulse pressure
- Elevated central venous pressure
- Distended neck and hand veins
- Engorged varicose veins
- Weight gain

##### **Respiratory Changes**

- Increased respiratory rate
- Shallow respirations
- Shortness of breath
- Moist crackles present on auscultation

##### **Skin and Mucous Membrane Changes**

- Pitting edema in dependent areas
- Skin pale and cool to touch

##### **Neuromuscular Changes**

- Altered level of consciousness

- Headache
- Visual disturbances
- Skeletal muscle weakness
- Paresthesias

### Gastrointestinal Changes

- Increased motility
- Enlarged liver

Fluid overload is diagnosed based on assessment findings and the results of laboratory tests. Usually serum electrolyte values are normal; but decreased hemoglobin, hematocrit, and serum protein levels may result from excessive water in the vascular space (**hemodilution**).

#### ◆Interventions: Responding

The focus of priority nursing interventions is to ensure patient safety, restore normal fluid balance, provide supportive care until the imbalance is resolved, and prevent future fluid overload. Drug therapy, nutrition therapy, and monitoring are the basis of intervention.

*Patient safety* is the first priority. Interventions are implemented to prevent fluid overload from becoming worse, leading to pulmonary edema, heart failure, and complications of electrolyte dilution. Any patient with fluid overload, regardless of age, is at risk for these complications. Older adults or those with cardiac problems, kidney problems, pulmonary problems, or liver problems are at greater risk.

## 🚨Nursing Safety Priority QSEN

### Critical Rescue

Assess the patient with fluid overload at least every 2 hours to recognize pulmonary edema, which can occur very quickly and can lead to death. If indications of worsening fluid overload are present (bounding pulse, increasing neck vein distention, presence of crackles in lungs, increasing peripheral edema, reduced urine output), respond by notifying the health care provider.

The patient with fluid overload and edema is at risk for skin breakdown. Use a pressure-reducing or pressure-relieving overlay on the mattress. Assess skin pressure areas daily for signs of redness or open area, especially the coccyx, elbows, hips, and heels. Because many patients with fluid overload may be receiving oxygen by mask or nasal cannula, check the skin integrity around the mask, nares, and ears and under the elastic band. Help the patient change positions every 2 hours or ensure that unlicensed assistive personnel (UAP) perform this action.

*Drug therapy* focuses on removing excess fluid. Diuretics are used for fluid overload if kidney function is normal. Drugs may include high-ceiling (loop) diuretics such as furosemide (Lasix, Furoside 🍀). If there is concern that too much sodium and other electrolytes would be lost using loop diuretics or if the patient has syndrome of inappropriate antidiuretic hormone (SIADH), conivaptan (Vaprisol) or tolvaptan (Samsca) may be prescribed.

Monitor the patient for response to drug therapy, especially weight loss and increased urine output. Observe for indications of electrolyte imbalance, especially changes in electrocardiogram (ECG) patterns. Assess sodium and potassium values every 8 hours or whenever they are drawn.

*Nutrition therapy* for the patient with *chronic* fluid overload may involve restrictions of both fluid and sodium intake. Often sodium restriction involves only “no added salt” to ordinary table foods when fluid overload is mild. For more severe fluid overload, the patient may be restricted to 2 g/day to 4 g/day of sodium. When sodium restriction is ongoing, teach the patient and family how to check food labels for sodium content and how to keep a daily record of sodium ingested. Explain to the patient and family the reason for any fluid restriction and the importance of adhering to the

restriction.

*Monitoring* intake and output and weight provides information on therapy effectiveness. Teach UAP that these measurements need to be accurate, not just estimated, because treatment decisions are based on these findings. Schedule fluid offerings throughout the 24 hours. Teach UAP to check urine for color and character and to report these findings. If the patient is receiving IV therapy, infuse the exact amount prescribed.

*Fluid retention may not be visible. Rapid weight gain is the best indicator of fluid retention and overload.* Metabolism can account for only a half-pound (250 g) of weight gain in 1 day. Each pound (0.5 kg) of weight gained (after the first half pound) equates to about 500 mL of retained fluid. Weigh the patient at the same time every day (before breakfast), using the same scale. Have the patient wear the same type of clothing for each weigh-in. When in-bed weights are taken, lift tubing and equipment off the bed. Record the number of blankets and pillows on the bed at the initial weigh-in and ensure that ongoing weights always include the same number.

If the patient is discharged to home before the fluid overload has completely resolved or has continuing risk for fluid overload, teach him or her and the family to monitor weight at home. Teach them to keep a record of daily weights to show the health care provider at checkups. Patients may choose to use mobile “apps” to record and trend this information. Instruct the patient to call the health care provider for more than a 3-lb (1.5-kg) gain in a week or more than a 2-lb (1-kg) gain in 24 hours.

## Electrolyte Balance and Imbalances

**Electrolytes**, or **ions**, are substances dissolved in body fluid that carry an electrical charge. **Cations** have positive charges; **anions** have negative charges. Body fluids are electrically neutral, which means that the number of positive ions is balanced by an equal number of negative ions. Most ions have different concentrations in the extracellular fluid (ECF) and the intracellular fluid (ICF) (Fig. 11-12). This concentration difference helps maintain membrane excitability and allows nerve impulse transmission. The normal ranges of blood electrolytes are narrow, so even small changes in these levels can cause major problems.

Plasma volume	Interstitial fluid	Intracellular fluid
Volume 3.5-5.5 L Osmolarity 270-300 mOsm Sodium 136-145 mEq/L Potassium 3.5-5.0 mEq/L Chloride 96-109 mEq/L Calcium 9.0-10.5 mg/dL Magnesium 1.3-2.1 mEq/L Protein 7-8 g/L	Volume ~10 L Osmolarity 270-300 mOsm Sodium 135-145 mEq/L Potassium 3.5-5.0 mEq/L Chloride ~118 mEq/L Calcium 7.0-9.0 mg/dL Magnesium ~1.3 mEq/L Protein ~2 g/L	Volume 25-30 L Osmolarity 270-300 mOsm Sodium 14 mEq/L Potassium 140 mEq/L Chloride ~4-6 mEq/L Calcium 1.0-8.0 mg/dL Magnesium 6-30 mEq/L Protein 16 g/L

FIG. 11-12 The electrolyte composition of various body fluids.

Electrolyte imbalances can occur in healthy people as a result of changes in fluid intake and output. These imbalances are usually mild and are easily corrected. Severe electrolyte imbalances with actual losses or retention of electrolytes are life threatening and can occur in any setting. Adults at greatest risk for severe imbalances are older patients, patients with chronic kidney or endocrine disorders, and those who are taking drugs that alter fluid and electrolyte balance. *All ill adults are at some risk for electrolyte imbalances.*

Table 11-1 lists the normal serum levels of the major electrolytes, and Chart 11-1 lists the normal electrolyte values for older adults. Most electrolytes enter the body in ingested food.

Electrolyte balance occurs when dietary intake of electrolytes matches kidney electrolyte excretion or reabsorption. For example, serum potassium level is maintained between 3.5 and 5.0 mEq/L (mmol/L). The high potassium level in foods such as meat and citrus fruit could increase the ECF potassium level and lead to major problems. In health, kidney excretion of potassium keeps pace with potassium intake and prevents major changes in the blood potassium level.

### Considerations for Older Adults

#### Patient-Centered Care QSEN

Older adults are at risk for electrolyte imbalances as a result of age-related organ changes. Always ask the older adult which drug(s) he or she takes because older adults are more likely to be taking drugs that affect fluid and electrolyte balance.

### Sodium

**Sodium (Na<sup>+</sup>)** is the major *cation* (positively charged particle) in the extracellular fluid (ECF) and maintains ECF osmolarity. Sodium levels of the ECF are high (136 to 145 mEq/L [mmol/L]), and the intracellular fluid (ICF) sodium levels are low (about 14 mEq/L [mmol/L]). Keeping this difference

in sodium levels is vital for muscle contraction, cardiac contraction, and nerve impulse transmission. Sodium levels and movement influence water balance because “where sodium goes, water follows.” The ECF sodium level determines whether water is retained, excreted, or moved from one fluid space to another. Changes in plasma sodium levels seriously change fluid volume and the distribution of other electrolytes.

Sodium enters the body through the ingestion of many foods and fluids. Foods with the highest sodium levels are those that are processed or preserved such as smoked or pickled foods, snack foods, and many condiments. Foods lowest in sodium include fresh fish and poultry and most fresh vegetables and fruit.

Despite variation in daily sodium intake, blood sodium levels usually remain within the normal range. Serum sodium balance is regulated by the kidney under the influences of aldosterone, antidiuretic hormone (ADH), and natriuretic peptide (NP) (see the [Hormonal Regulation of Fluid Balance](#) section).

Low serum sodium levels inhibit the secretion of ADH and NP and trigger aldosterone secretion. Together these compensatory actions increase serum sodium levels by increasing kidney reabsorption of sodium and enhancing kidney loss of water.

High serum sodium levels inhibit aldosterone secretion and stimulate secretion of ADH and NP. Together these hormones increase kidney sodium excretion and water reabsorption.

## Hyponatremia

### ❖ Pathophysiology

**Hyponatremia** is an electrolyte imbalance in which the serum sodium ( $\text{Na}^+$ ) level is below 136 mEq/L (mmol/L). Sodium imbalances often occur with a fluid imbalance because the same hormones regulate both sodium and water balance. The problems caused by hyponatremia occur from two changes—reduced excitable membrane depolarization and cellular swelling.

Excitable cell membrane depolarization depends on high extracellular fluid (ECF) levels of sodium being available to cross cell membranes and move into cells in response to a stimulus. Hyponatremia makes depolarization slower so excitable membranes are less excitable.

With hyponatremia the osmolarity of the ECF is lower than that of the intracellular fluid (ICF). As a result, water moves into the cell, causing swelling. Even a small amount of swelling can reduce cell function. Larger amounts of swelling can make the cell burst (*lysis*) and die.

Many conditions and drugs can lead to hyponatremia ([Table 11-5](#)). A common cause of low sodium levels is the prolonged use and overuse of diuretics, especially in older adults. When these drugs are used to manage fluid overload, sodium is lost along with water. Hyponatremia can result from the loss of total body sodium, the movement of sodium from the blood to other fluid spaces, or the dilution of serum sodium from excessive water in the plasma.

**TABLE 11-5**

### Common Causes of Hyponatremia

Actual Sodium Deficits	Relative Sodium Deficits (Dilution)
<ul style="list-style-type: none"> <li>• Excessive diaphoresis</li> <li>• Diuretics (high-ceiling diuretics)</li> <li>• Wound drainage (especially GI)</li> <li>• Decreased secretion of aldosterone</li> <li>• Hyperlipidemia</li> <li>• Kidney disease (scarred distal convoluted tubule)</li> <li>• Nothing by mouth</li> <li>• Low-salt diet</li> <li>• Cerebral salt-wasting syndrome</li> <li>• Hyperglycemia</li> </ul>	<ul style="list-style-type: none"> <li>• Excessive ingestion of hypotonic fluids</li> <li>• Psychogenic polydipsia</li> <li>• Freshwater submersion accident</li> <li>• Kidney failure (nephrotic syndrome)</li> <li>• Irrigation with hypotonic fluids</li> <li>• Syndrome of inappropriate antidiuretic hormone secretion</li> <li>• Heart failure</li> </ul>

### ❖ Interprofessional Collaborative Care

#### ◆ Assessment: Noticing

The signs and symptoms of hyponatremia are caused by its effects on excitable cellular activity. The cells especially affected are those involved in cerebral, neuromuscular, and intestinal smooth muscle and cardiovascular functions.

*Cerebral changes* are the most obvious problems of hyponatremia. Behavioral changes result from cerebral edema and increased intracranial pressure. Closely observe and document the patient's

behavior, level of consciousness, and cognition. A sudden onset of acute confusion or increased confusion is often seen in older adults who have low serum sodium levels (Reynolds, 2015). When sodium levels become very low, seizures, coma, and death may occur (Schreiber, 2013b).

*Neuromuscular changes* are seen as general muscle weakness. Assess the patient's neuromuscular status during each nursing shift for changes from baseline. Deep tendon reflexes diminish, and muscle weakness is worse in the legs and arms. Assess muscle strength and deep tendon reflex responses as described in Chapter 41.

## Nursing Safety Priority QSEN

### Action Alert

If muscle weakness is present, immediately check respiratory effectiveness because ventilation depends on adequate strength and function of respiratory muscles.

*Intestinal changes* include increased motility, causing nausea, diarrhea, and abdominal cramping. Assess the GI system by listening to bowel sounds and observing stools. Bowel sounds are hyperactive, and bowel movements are frequent and watery.

*Cardiovascular changes* are seen as changes in cardiac output. The cardiac responses to hyponatremia with **hypovolemia** (decreased plasma volume) include a rapid, weak, thready pulse. Peripheral pulses are difficult to palpate and are easily blocked. Blood pressure is decreased, and the patient may have severe orthostatic hypotension, leading to light-headedness or dizziness. The central venous pressure is low.

When hyponatremia occurs with **hypervolemia** (fluid overload), cardiac changes include a full or bounding pulse with normal or high blood pressure. Peripheral pulses are full and difficult to block; however, they may not be palpable if edema is present.

### ◆Interventions: Responding

The cause of the low sodium level is determined to plan appropriate management. Interventions with drug therapy and nutrition therapy are used to restore serum sodium levels to normal and prevent complications from fluid overload or a too-rapid change in serum sodium level. *The priorities for nursing care of the patient with hyponatremia are monitoring the patient's response to therapy and preventing hyponatremia and fluid overload.*

*Drug therapy* involves reducing the doses of any drugs that increase sodium loss such as most diuretics (Kaufman, 2014). When hyponatremia occurs with a fluid deficit, IV saline infusions are prescribed to restore both sodium and fluid volume. Severe hyponatremia may be treated with small-volume infusions of hypertonic saline, most often 3% saline (Schreiber, 2013b), although 5% saline can be used for extreme hyponatremia. These infusions are delivered using a controller to prevent accidental increases in infusion rate. Monitor the infusion rate and the patient's response.

When hyponatremia occurs with fluid excess, drug therapy includes drugs that promote the excretion of water rather than sodium such as conivaptan (Vaprisol) or tolvaptan (Samsca) (Friedman & Cirulli, 2013). Drug therapy for hyponatremia caused by inappropriate secretion of antidiuretic hormone (ADH) may include lithium (Carbolith, Lithane ♣) and demeclocycline (Declomycin). Assess hourly for signs of excessive fluid loss, potassium loss, and increased sodium levels.

*Nutrition therapy* can help restore sodium balance in mild hyponatremia. Therapy involves increasing oral sodium intake and restricting oral fluid intake. Collaborate with the registered dietitian (RD) to teach the patient about which foods to increase in the diet. Fluid restriction may be needed long-term when fluid overload is the cause of the hyponatremia or when kidney fluid excretion is impaired. Nursing actions for patient safety, skin protection, monitoring, and patient and family teaching are the same as those for fluid overload.

## NCLEX Examination Challenge 11-4

### Safe and Effective Care Environment

A client is receiving 250 mL of a 3% sodium chloride solution intravenously for severe hyponatremia. Which signs or symptoms indicate to the nurse that this therapy is effective?

- A. The client reports hand swelling.
- B. Bowel sounds are present in all four abdominal quadrants.
- C. Serum potassium level has decreased from 4.4 mEq/L (mmol/L) to 4.2 mEq/L (mmol/L).
- D. Blood pressure has increased from 100/50 mm Hg to 112/70 mm Hg.

## Hypernatremia

### ❖Pathophysiology

**Hypernatremia** is a serum sodium level over 145 mEq/L (mmol/L). It can be caused by or can cause changes in fluid volume. [Table 11-6](#) lists causes of hypernatremia.

**TABLE 11-6**

**Common Causes of Hypernatremia**

Actual Sodium Excesses	Relative Sodium Excesses
<ul style="list-style-type: none"> <li>• Hyperaldosteronism</li> <li>• Kidney failure</li> <li>• Corticosteroids</li> <li>• Cushing's syndrome or disease</li> <li>• Excessive oral sodium ingestion</li> <li>• Excessive administration of sodium-containing IV fluids</li> </ul>	<ul style="list-style-type: none"> <li>• Nothing by mouth</li> <li>• Increased rate of metabolism</li> <li>• Fever</li> <li>• Hyperventilation</li> <li>• Infection</li> <li>• Excessive diaphoresis</li> <li>• Watery diarrhea</li> <li>• Dehydration</li> </ul>

As serum sodium level rises, a larger difference in sodium levels occurs between the extracellular fluid (ECF) and the intracellular fluid (ICF). More sodium is present to move rapidly across cell membranes during depolarization, making excitable tissues more easily excited. This condition is called **irritability**, and excitable tissues over-respond to stimuli. In addition, water moves from the cells into the ECF to dilute the hyperosmolar ECF. Thus, when serum sodium levels are high, severe cellular dehydration with cellular shrinkage occurs. Eventually the dehydrated excitable tissues may no longer be able to respond to stimuli.

### ❖Interprofessional Collaborative Care

#### ◆Assessment: Noticing

Symptoms of hypernatremia vary with the severity of sodium imbalance and whether a fluid imbalance is also present. Changes are first seen in excitable membrane activity, especially nerve, skeletal muscle, and cardiac function.

*Nervous system changes* start with altered cerebral function. Assess the patient's mental status for attention span and cognitive function. In hypernatremia with normal or decreased fluid volumes, the patient may have a short attention span and be agitated or confused. When hypernatremia occurs with fluid overload, the patient may be lethargic, stuporous, or comatose.

*Skeletal muscle changes* vary with the degree of sodium increases. Mild rises cause muscle twitching and irregular muscle contractions. As hypernatremia worsens, the muscles and nerves are less able to respond to a stimulus, and muscles become progressively weaker. Late, the deep tendon reflexes are reduced or absent. Muscle weakness occurs bilaterally and has no specific pattern. Observe for twitching in muscle groups. Assess muscle strength by having the patient perform handgrip and arm flexion against resistance as described in [Chapters 41](#) and [49](#). Assess deep tendon reflexes by lightly tapping the patellar (knee) and Achilles (heel) tendons with a reflex hammer and measuring the movement.

*Cardiovascular changes* include decreased contractility because high sodium levels slow the movement of calcium into the heart cells. Measure blood pressure and the rate and quality of the apical and peripheral pulses. Pulse rate is increased in patients with hypernatremia and hypovolemia. Peripheral pulses are difficult to palpate and are easily blocked. Hypotension and severe orthostatic (postural) hypotension are present, and pulse pressure is reduced. Patients with hypernatremia and hypervolemia have slow-to-normal bounding pulses. Peripheral pulses are full

and difficult to block. Neck veins are distended, even with the patient in the upright position. Blood pressure, especially diastolic blood pressure, is increased.

#### ◆Interventions: Responding

Drug and nutrition therapies are used to prevent further sodium increases and to decrease high serum sodium levels. *Nursing care priorities for the patient with hypernatremia include monitoring his or her response to therapy and ensuring patient safety by preventing hyponatremia and dehydration.*

*Drug therapy* is used to restore fluid balance when hypernatremia is caused by fluid loss. Isotonic saline (0.9%) and dextrose 5% in 0.45% sodium chloride are most often prescribed (Schreiber, 2013a). Although the dextrose 5% in 0.45% sodium chloride is hypertonic in the IV bag, once it is infused, the glucose is rapidly metabolized, and the fluid is really hypotonic. Hypernatremia caused by reduced kidney sodium excretion requires drug therapy with diuretics that promote sodium loss such as furosemide (Lasix, Furoside 🍀) or bumetanide (Bumex, Burinex 🍀). Assess the patient hourly for symptoms of excessive losses of fluid, sodium, or potassium.

*Nutrition therapy* to prevent or correct mild hypernatremia involves ensuring adequate water intake, especially among older adults. Dietary sodium restriction may be needed to prevent sodium excess when kidney problems are present. Collaborate with the dietitian to teach the patient how to determine the sodium content of foods, beverages, and drugs. Nursing actions for patient safety, skin protection, monitoring, and patient and family teaching are similar to those for fluid overload.

## Potassium

Potassium ( $K^+$ ) is the major cation of the intracellular fluid (ICF). The normal plasma potassium level ranges from 3.5 to 5.0 mEq/L (mmol/L) (see Table 11-1). The normal ICF potassium level is about 140 mEq/L (mmol/L). Keeping this large difference in potassium concentration between the ICF and the extracellular fluid (ECF) is critical for excitable tissues to depolarize and generate action potentials.

Because potassium levels in the blood and interstitial fluid are so low, any change seriously affects physiologic activities. For example, a decrease in blood potassium of only 1 mEq/L (from 4 mEq/L [mmol/L] to 3 mEq/L [mmol/L]) is a 25% difference in total ECF potassium concentration.

Almost all foods contain potassium. It is highest in meat, fish, and many (but not all) vegetables and fruits. It is lowest in eggs, bread, and cereal grains. Typical potassium intake is about 2 to 20 g/day. Despite heavy potassium intake the healthy adult keeps plasma potassium levels within the narrow range of normal values.

The main controller of ECF potassium level is the sodium-potassium pump within the membranes of all body cells. This pump moves extra sodium ions from the ICF and moves extra potassium ions from the ECF back into the cell. In this way the serum potassium level remains low, and the cellular potassium remains high. At the same time, this action also helps the serum sodium level remain high and the cellular sodium level remain low.

About 80% of potassium is removed from the body by the kidney. Kidney excretion of potassium is enhanced by aldosterone.

## Hypokalemia

### ❖Pathophysiology

Because most potassium ( $K^+$ ) is inside cells, minor changes in extracellular potassium levels cause major changes in cell membrane excitability. **Hypokalemia** is a serum potassium level below 3.5 mEq/L (mmol/L). *It can be life threatening because every body system is affected.*

Low serum potassium levels reduce the excitability of cells. As a result, the cell membranes of all excitable tissues such as nerve and muscle are less responsive to normal stimuli. Gradual potassium loss may have no symptoms until the loss is extreme. Rapid reduction of serum potassium levels causes dramatic changes in function. Table 11-7 lists causes of hypokalemia.

---

**TABLE 11-7**

### Common Causes of Hypokalemia

---

Actual Potassium Deficits • Inappropriate or excessive use of drugs:	Relative Potassium Deficits • Alkalosis
---	--

<ul style="list-style-type: none"> <li>• Diuretics</li> <li>• Digitalis-like drugs</li> <li>• Corticosteroids</li> <li>• Increased secretion of aldosterone</li> <li>• Cushing's syndrome</li> <li>• Diarrhea</li> <li>• Vomiting</li> <li>• Wound drainage (especially GI)</li> <li>• Prolonged nasogastric suction</li> <li>• Heat-induced excessive diaphoresis</li> <li>• Kidney disease impairing reabsorption of potassium</li> <li>• Nothing by mouth</li> </ul>	<ul style="list-style-type: none"> <li>• Hyperinsulinism</li> <li>• Hyperalimentation</li> <li>• Total parenteral nutrition</li> <li>• Water intoxication</li> <li>• IV therapy with potassium-poor solutions</li> </ul>
---	--

Actual potassium depletion occurs when potassium loss is excessive or when potassium intake is not adequate to match normal potassium loss. Relative hypokalemia occurs when total body potassium levels are normal but the potassium distribution between fluid spaces is abnormal or diluted by excess water.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

*Age* is important because urine concentrating ability decreases with aging, which increases potassium loss. Older adults are more likely to use drugs that lead to potassium loss.

*Drugs*, especially diuretics, corticosteroids, and beta-adrenergic agonists or antagonists, can increase potassium loss through the kidneys. Ask about prescription and over-the-counter drug use. In patients taking digoxin (Lanoxin, Novo-Digoxin 🍀, Toloxin 🍀), hypokalemia increases the sensitivity of the cardiac muscle to the drug and may result in digoxin toxicity, even when the digoxin level is within the therapeutic range. Ask whether the patient takes a potassium supplement such as potassium chloride (KCl) or eats foods that have high concentrations of potassium such as bananas, citrus juices, raisins, and meat. The patient may not be taking the supplement as prescribed because of its unpleasant taste.

*Disease* can lead to potassium loss. Ask about chronic disorders, recent illnesses, and medical or surgical interventions. A thorough nutrition history, including a typical day's food and beverage intake, helps identify patients at risk for hypokalemia.

*Respiratory changes* occur because of respiratory muscle weakness, resulting in shallow respirations. Assess the patient's breath sounds, ease of respiratory effort, color of nail beds and mucous membranes, and rate and depth of respiration.

## 📌 Nursing Safety Priority QSEN

### Action Alert

Assess respiratory status of a patient with hypokalemia at least every 2 hours because respiratory insufficiency is a major cause of death.

*Musculoskeletal changes* include skeletal muscle weakness. A stronger stimulus is needed to begin muscle contraction. Patients may be too weak to stand. Hand grasps are weak, and deep tendon reflexes are reduced (hyporeflexia). Severe hypokalemia causes flaccid paralysis. Assess for muscle weakness and the patient's ability to perform ADLs.

*Cardiovascular changes* are assessed by palpating the peripheral pulses. In hypokalemia the pulse is usually thready and weak. Palpation is difficult, and the pulse is easily blocked. Pulse rate ranges from very slow to very rapid, and an irregular heartbeat (dysrhythmia) may be present. Measure blood pressure with the patient in the lying, sitting, and standing positions, because orthostatic (postural) hypotension occurs with hypokalemia.

*Neurologic changes* from hypokalemia include altered mental status. The patient may have short-term irritability and anxiety followed by lethargy that progresses to acute confusion and coma as hypokalemia worsens.

*Intestinal changes* occur with hypokalemia because GI smooth muscle contractions are decreased, which leads to decreased peristalsis. Bowel sounds are hypoactive, and nausea, vomiting, constipation, and abdominal distention are common. Measure abdominal girth and auscultate for bowel sounds in all four abdominal quadrants. *Severe hypokalemia can cause the absence of peristalsis (paralytic ileus).*

*Laboratory data* confirm hypokalemia (serum potassium value below 3.5 mEq/L [mmol/L]).

Hypokalemia causes ECG changes in the heart, including ST-segment depression, flat or inverted T waves, and increased U waves. *Dysrhythmias can lead to death, particularly in older adults who are taking digoxin.*

#### ◆Interventions: Responding

Interventions for hypokalemia focus on preventing potassium loss, increasing serum potassium levels, and ensuring patient safety. Drug and nutrition therapies help restore normal serum potassium levels. *The priorities for nursing care of the patient with hypokalemia are ensuring adequate gas exchange, patient safety for falls prevention, prevention of injury from potassium administration, and monitoring the patient's response to therapy.* Chart 11-5 highlights best practice activities when caring for a patient with hypokalemia.

### 📊Chart 11-5

## Best Practice for Patient Safety & Quality Care QSEN

### The Patient With Hypokalemia

- Question the continued use of drugs that increase excretion of potassium (e.g., thiazide and loop diuretics).
- Give prescribed oral potassium supplement, well diluted and with a meal or just after a meal or snack to prevent nausea and vomiting.
- Prevent accidental overdose of IV potassium by checking and re-checking the concentration of potassium in the IV solution, ensuring that the maximum concentration is no greater than 1 mEq (mmol)/10 mL of solution.
- Establish an IV access in a large vein with a high volume of flow, avoiding the hand.
- Assess the IV access for placement and an adequate blood return before administering potassium-containing solutions.
- Use a controller for solution delivery, maintaining an infusion rate not faster than 5-10 mEq (mmol) of potassium per hour.
- Assess the IV site hourly.
- Stop the infusion immediately if the patient reports pain or burning or if any sign of infiltration occurs.
- If possible, monitor electrocardiography continuously.
- Monitor patient responses every 1-2 hours to determine therapy effectiveness and the potential for hyperkalemia.
- Indications of therapy effectiveness:
  - Respiratory rate is greater than 12 breaths/min.
  - Oxygen saturation is at least 95% (or has returned to the patient's normal baseline).
  - The patient can cough effectively.
  - Hand-grasp strength increases.

- Deep tendon reflexes are present.
- Bowel sounds are present and active.
- Pulse is easily palpated and regular.
- Systolic blood pressure when standing remains within 20 mm Hg of the systolic pressure obtained when the patient is sitting or lying down.
- ST segment returns to the isoelectric line.
- T waves increase in size and are positive.
- U waves decrease or disappear.
- Patient's cognition resembles his or her prehypokalemic state.
- Serum potassium level is between 3.5 and 5.0 mEq/L (mmol/L).
- Indications of hyperkalemia:
  - Heart rate is less than 60 beats/min.
  - P waves are absent.
  - T waves are tall.
  - PR intervals are prolonged.
  - QRS complexes are wide.
  - Deep tendon reflexes are hyperactive.
  - Bowel sounds are hyperactive.
  - Numbness or tingling is present in the hands and feet and around the mouth.
  - The patient is anxious.
  - Serum potassium level is above 5.0 mEq/L (mmol/L).
- Keep patient on bedrest until hypokalemia resolves or provide assistance when out of bed to prevent falls.

*Drug therapy* for management and prevention of hypokalemia includes additional potassium and drugs to prevent potassium loss (Scotto et al., 2014). Most potassium supplements are potassium chloride, potassium gluconate, or potassium citrate. The amount and route of potassium replacement depend on the degree of loss.

**Potassium is given intravenously for severe hypokalemia. The drug is available in different concentrations, and it carries a high-alert warning as a concentrated electrolyte solution. The Joint Commission's National Patient Safety Goals mandate that concentrated potassium be diluted and added to IV solutions only in the pharmacy by a registered pharmacist and that vials of concentrated potassium not be available in patient care areas. Before infusing any IV solution containing potassium chloride (KCl), check and re-check the dilution of the drug in the IV solution container.**

## Nursing Safety Priority QSEN

### Drug Alert

A dilution no greater than 1 mEq (mmol/L) of potassium to 10 mL of solution is recommended for IV administration. The maximum recommended infusion rate is 5 to 10 mEq/hr (mmol/hr); this rate is never to exceed 20 mEq/hr (mmol/hr) under any circumstances. In accordance with National Patient Safety Goals, potassium is not given by IV push to avoid causing cardiac arrest.

*Potassium is a severe tissue irritant and is never given by IM or subcutaneous injection.* Tissues damaged by potassium can become necrotic, causing loss of function and requiring surgery. IV potassium solutions irritate veins and cause phlebitis. Check the prescription carefully to ensure that the patient receives the correct amount of potassium. Assess the IV site hourly and ask the patient whether he or she feels burning or pain at the site.

## Nursing Safety Priority QSEN

### Action Alert

If infiltration of solution containing potassium occurs, stop the IV solution immediately, remove the venous access, and notify the health care provider or Rapid Response Team. Document these actions along with a complete description of the IV site.

Oral potassium preparations may be taken as liquids or solids. Potassium has a strong, unpleasant taste that is difficult to mask, although it can be mixed with many liquids. Because potassium chloride can cause nausea and vomiting, give the drug during or after a meal and advise patients using the drug at home not to take it on an empty stomach.

Diuretics that increase the kidney excretion of potassium can cause hypokalemia, especially high-ceiling (loop) diuretics (e.g., furosemide [Lasix, Furoside ] and bumetanide [Bumex, Burinex ]) and the thiazide diuretics. These drugs are avoided in patients with hypokalemia. A potassium-sparing diuretic may be prescribed to increase urine output without increasing potassium loss. Potassium-sparing diuretics include spironolactone (Aldactone, TEVA-spironolactone ) , triamterene (Dyrenium, TEVA-triamterene ) , and amiloride (Midamor, Novamilor ) .

*Nutrition therapy* involves collaboration with a dietitian to teach the patient how to increase dietary potassium intake. Eating foods rich in potassium helps prevent further loss, but supplementation is needed to restore normal potassium levels.

*Implement safety measures* with a patient who has muscle weakness from hypokalemia, including the fall precautions listed in [Chart 3-4](#). Be sure to have the patient wear a gait belt when ambulating with assistance.

*Respiratory monitoring* is performed at least hourly for severe hypokalemia. Also check oxygen saturation by pulse oximetry to determine breathing effectiveness. Assess respiratory muscle effectiveness by checking the patient's ability to cough. Examine the face, oral mucosa, and nail beds for pallor or cyanosis. Evaluate arterial blood gas values (when available) for decreased blood oxygen levels (**hypoxemia**) and increased arterial carbon dioxide levels (**hypercapnia**), which indicate inadequate gas exchange.

## Clinical Judgment Challenge 11-1

### Safety; Patient-Centered Care QSEN

A patient with severe hypokalemia from an accidental overdose of furosemide is to receive IV potassium replacement through a peripheral inserted central catheter placed in the right upper arm. The ordered IV solution contains 120 mEq (mmol/L) of potassium chloride in 1000 mL of normal saline to be infused at a rate of 150 mL/hr.

1. Should this solution be infused using a pump or controller? Why or why not?
2. How many mEq of potassium per hour will the patient receive at this rate?
3. Is this rate permissible? Explain your rationale.
4. Which parameter changes would indicate to you that the patient is responding well to this therapy?
5. For which changes should you assess to determine whether the patient is becoming hyperkalemic?

## Hyperkalemia

### ❖ Pathophysiology

**Hyperkalemia** is a serum potassium level higher than 5.0 mEq/L (mmol/L). Even small increases above normal values can affect excitable tissues, especially the heart.

A high serum potassium increases cell excitability, causing excitable tissues to respond to less intense stimuli. The heart is very sensitive to serum potassium increases; and hyperkalemia interferes with electrical conduction, leading to heart block and ventricular fibrillation.

The problems that occur with hyperkalemia are related to how rapidly ECF potassium levels increase. Sudden potassium rises cause severe problems at serum levels between 6 and 7 mEq/L (mmol/L). When serum potassium rises slowly, problems may not occur until potassium levels reach 8 mEq/L (mmol/L) or higher.

Hyperkalemia is rare in people with normal kidney function ([Hannibal, 2015](#)). Most cases of hyperkalemia occur in hospitalized patients and in those undergoing medical treatment ([Adis Medical Writers, 2015](#)). Those at greatest risk are chronically ill patients, debilitated patients, and older adults ([Table 11-8](#)).

**TABLE 11-8**

### Common Causes of Hyperkalemia

Actual Potassium Excesses	Relative Potassium Excesses
<ul style="list-style-type: none"><li>• Overingestion of potassium-containing foods or medications</li><li>• Salt substitutes</li><li>• Potassium chloride</li><li>• Rapid infusion of potassium-containing IV solution</li><li>• Bolus IV potassium injections</li><li>• Transfusions of whole blood or packed cells</li><li>• Adrenal insufficiency</li><li>• Kidney failure</li><li>• Potassium-sparing diuretics</li><li>• Angiotensin-converting enzyme inhibitors (ACEIs)</li></ul>	<ul style="list-style-type: none"><li>• Tissue damage</li><li>• Acidosis</li><li>• Hyperuricemia</li><li>• Uncontrolled diabetes mellitus</li></ul>

### ❖ Interprofessional Collaborative Care

#### ◆ Assessment: Noticing

Age is important because kidney function decreases with aging. Ask about kidney disease; diabetes mellitus; recent medical or surgical treatment; and urine output, including frequency and amount of voidings. Ask about drug use, particularly potassium-sparing diuretics and angiotensin-converting enzyme inhibitors (ACEIs) ([Adis Medical Writers, 2015](#)). Obtain a nutrition history to determine the intake of potassium-rich foods and the use of salt substitutes (which contain potassium).

Ask whether the patient has had palpitations, skipped heartbeats, or other cardiac irregularities; and muscle twitching, leg weakness, or unusual tingling or numbness in the hands, feet, or face. Ask about recent changes in bowel habits, especially diarrhea.

*Cardiovascular changes are the most severe problems from hyperkalemia and are the most common cause of death in patients with hyperkalemia.* Cardiac symptoms include bradycardia; hypotension; and ECG changes of tall, peaked T waves, prolonged PR intervals, flat or absent P waves, and wide QRS complexes. Ectopic beats may appear. Complete heart block, asystole, and ventricular fibrillation are life-threatening complications of severe hyperkalemia.

*Neuromuscular changes* with hyperkalemia have two phases. Skeletal muscles twitch in the early stages of hyperkalemia, and the patient may be aware of tingling and burning sensations followed by numbness in the hands and feet and around the mouth (**paresthesia**). As hyperkalemia worsens, muscle weakness occurs, followed by flaccid paralysis. The weakness moves up from the hands and feet and first affects the muscles of the arms and legs. Respiratory muscles are not affected until serum potassium levels reach lethal levels.

*Intestinal changes* include increased motility with diarrhea and hyperactive bowel sounds. Bowel movements are frequent and watery.

*Laboratory data* confirm hyperkalemia (potassium level over 5.0 mEq/L [mmol/L]). If it is caused by dehydration, levels of other electrolytes, hematocrit, and hemoglobin also are elevated. Hyperkalemia caused by kidney failure occurs with elevated serum creatinine and blood urea nitrogen, decreased blood pH, and normal or low hematocrit and hemoglobin levels.

#### ◆Interventions: Responding

Interventions for hyperkalemia focus on reducing the serum potassium level, preventing recurrences, and ensuring patient safety. Drug therapy is key. *The priorities for nursing care of the patient with hyperkalemia are assessing for cardiac complications, patient safety for falls prevention, monitoring the patient's response to therapy, and health teaching.*

*Drug therapy* can restore potassium balance by enhancing potassium excretion and promoting the movement of potassium from the extracellular fluid (ECF) into the cells. A newly approved drug to treat hyperkalemia is patiomer (Veltassa). This oral drug binds with potassium in the GI tract and decreases its absorption (**Aschenbrenner, 2016**).

Stop potassium-containing infusions and keep the IV access open. Withhold oral potassium supplements and provide a potassium-restricted diet.

Increasing potassium excretion helps reduce hyperkalemia if kidney function is normal. Potassium-excreting diuretics are prescribed. When kidney problems exist, more invasive interventions may be needed (see **Chapter 68**).

Movement of potassium from the extracellular fluid (ECF) to the intracellular fluid (ICF) can help reduce serum potassium levels temporarily. Potassium movement into the cells is enhanced by insulin. Insulin increases the activity of the sodium-potassium pumps, which move potassium from the ECF into the cell. IV fluids containing glucose and insulin are prescribed to help decrease serum potassium levels (usually 100 mL of 10% to 20% glucose with 10 to 20 units of regular insulin). These IV solutions are hypertonic and are infused through a central line or in a vein with a high blood flow to avoid local vein inflammation. Observe the patient for indications of hypokalemia and hypoglycemia during this therapy.

*Cardiac monitoring* allows for the early recognition of dysrhythmias and other symptoms of hyperkalemia on cardiac muscle. Compare recent ECG tracings with the tracings obtained when the patient's serum potassium level was close to normal.

### Nursing Safety Priority QSEN

#### Critical Rescue

Assess anyone who has or is at risk for hyperkalemia to recognize cardiac changes. If the patient's heart rate falls below 60 beats/min or if the T waves become spiked, both of which accompany hyperkalemia, respond by notifying the Rapid Response Team.

*Health teaching is key to the prevention of hyperkalemia and the early detection of complications.* The teaching plan includes diet, drugs, and recognition of the indicators of hyperkalemia. Collaborate

with the dietitian to teach the patient and family about which foods to avoid (those high in potassium). Foods that are low in potassium are listed in [Chart 11-6](#). Instruct the patient and family to read the labels on drug and food packages to determine the potassium content. Warn them to avoid salt substitutes, which contain potassium.

### **Chart 11-6**

## **Patient and Family Education: Preparing for Self-Management**

### **Nutritional Management of Hyperkalemia**

#### **You Should Avoid**

- Meats, especially organ meat and preserved meat
- Dairy products
- Dried fruit
- Fruits high in potassium:
  - Bananas
  - Cantaloupe
  - Kiwi
  - Oranges
- Vegetables high in potassium:
  - Avocados
  - Broccoli
  - Dried beans or peas
  - Lima beans
  - Mushrooms
  - Potatoes (white or sweet)
  - Seaweed
  - Soybeans
  - Spinach

## You May Eat

- Eggs
- Breads
- Butter
- Cereals
- Sugar
- Fruits low in potassium (fresh, frozen, or canned):
  - Apples
  - Apricots
  - Berries
  - Cherries
  - Cranberries
  - Grapefruit
  - Peaches
  - Pineapple
- Vegetables low in potassium:
  - Alfalfa sprouts
  - Cabbage
  - Carrots
  - Cauliflower
  - Celery
  - Eggplant
  - Green beans
  - Lettuce

- Onions
- Peas
- Peppers
- Squash

Data from Pennington, J. A., & Spungen, J. S. (2010). *Bowes and Church's food values of portions commonly used* (19th ed.). Philadelphia: Lippincott Williams & Wilkins.

## NCLEX Examination Challenge 11-5

### Health Promotion and Maintenance

Which food items selected by a client who must restrict potassium because of a continuing risk for hyperkalemia indicates to the nurse that more teaching is needed?

- A. Strawberries, Cheerios, eggs
- B. Cantaloupe, broccoli, sweet potatoes
- C. Apple pie, black coffee with sugar, carrot sticks
- D. Whole wheat toast with butter, canned pineapple chunks

### Calcium

Calcium ( $\text{Ca}^{2+}$ ) is an ion having two positive charges (*divalent cation*) that exists in the body in a bound form and an ionized (unbound or free) form. Bound calcium is usually attached to serum proteins, especially albumin. Ionized calcium is present in the blood and other extracellular fluid (ECF) as free calcium. Free calcium is the active form and must be kept within a narrow range in the ECF (see [Table 11-1](#)). Calcium has a steep gradient between ECF and intracellular fluid (ICF) because the amount of calcium in the ICF is very low. This mineral is important for maintaining bone strength and density, activating enzymes, allowing skeletal and cardiac muscle contraction, controlling nerve impulse transmission, and allowing blood clotting.

Calcium enters the body by dietary intake and absorption through the intestinal tract. Absorption of dietary calcium requires the active form of vitamin D. Calcium is stored in the bones. When more calcium is needed, parathyroid hormone (PTH) is released from the parathyroid glands. PTH increases serum calcium levels by:

- Releasing free calcium from bone storage sites (*bone resorption* of calcium)
- Stimulating vitamin D activation to help increase intestinal *absorption* of dietary calcium
- Inhibiting kidney calcium excretion
- Stimulating kidney calcium *reabsorption*

When excess calcium is present in plasma, PTH secretion is inhibited, and the secretion of *thyrocalcitonin* (TCT), a hormone secreted by the thyroid gland, is increased. TCT causes the plasma calcium level to decrease by inhibiting bone resorption of calcium, inhibiting vitamin D–associated intestinal uptake of calcium, and increasing kidney excretion of calcium in the urine.

### Hypocalcemia

#### ❖ Pathophysiology

**Hypocalcemia** is a total serum calcium ( $\text{Ca}^{2+}$ ) level below 9.0 mg/dL or 2.25 mmol/L. Because the normal blood level of calcium is so low, any change in calcium levels has major effects on function.

Calcium is an excitable membrane stabilizer, regulating depolarization and the generation of action potentials. It decreases sodium movement across excitable membranes, slowing the rate of depolarization. Low serum calcium levels increase sodium movement across excitable membranes, allowing depolarization to occur more easily and at inappropriate times.

Hypocalcemia is caused by many chronic and acute conditions, as well as medical or surgical treatments. Table 11-9 lists causes of hypocalcemia. Acute hypocalcemia results in the rapid onset of life-threatening symptoms. Chronic hypocalcemia occurs slowly over time, and excitable membrane symptoms may not be severe because the body has adjusted to the gradual reduction of serum calcium levels.

**TABLE 11-9**  
**Common Causes of Hypocalcemia**

Actual Calcium Deficits	Relative Calcium Deficits
<ul style="list-style-type: none"> <li>• Inadequate oral intake of calcium</li> <li>• Lactose intolerance</li> <li>• Malabsorption syndromes:               <ul style="list-style-type: none"> <li>• Celiac sprue</li> <li>• Crohn's disease</li> </ul> </li> <li>• Inadequate intake of vitamin D</li> <li>• End-stage kidney disease</li> <li>• Diarrhea</li> <li>• Steatorrhea</li> <li>• Wound drainage (especially GI)</li> </ul>	<ul style="list-style-type: none"> <li>• Hyperproteinemia</li> <li>• Alkalosis</li> <li>• Calcium chelators or binders               <ul style="list-style-type: none"> <li>• Citrate</li> <li>• Mithramycin</li> <li>• Penicillamine</li> </ul> </li> <li>• Sodium cellulose phosphate (Calcibind)</li> <li>• Aredia</li> <li>• Acute pancreatitis</li> <li>• Hyperphosphatemia</li> <li>• Immobility</li> <li>• Removal or destruction of parathyroid glands</li> </ul>

## Gender Health Considerations

### Patient-Centered Care QSEN

Postmenopausal women are at risk for chronic calcium loss. This problem is related to reduced weight-bearing activities and a decrease in estrogen levels. As they age, many women decrease weight-bearing activities such as running and walking, which allows osteoporosis to occur at a more rapid rate. In addition, the estrogen secretion that protects against osteoporosis diminishes. Teach older women to continue walking and other weight-bearing activities.

### Interprofessional Collaborative Care

#### Assessment: Noticing

Assess the nutrition history for the risk for hypocalcemia. Ask the patient about his or her intake of dairy products and whether he or she takes a calcium supplement regularly.

One indicator of hypocalcemia is a report of frequent, painful muscle spasms (“charley horses”) in the calf or foot during rest or sleep. Ask about a history of recent orthopedic surgery or bone healing. Thyroid surgery, therapeutic irradiation of the upper middle chest and neck area, or a recent anterior neck injury increases the risk for hypocalcemia. Most symptoms of acute hypocalcemia are caused by overstimulation of the nerves and muscles.

*Neuromuscular changes* often occur first in the hands and feet. Paresthesias occur at first, with sensations of tingling and numbness. If hypocalcemia continues or worsens, muscle twitching or painful cramps and spasms occur. Tingling may also affect the lips, nose, and ears. These problems may signal the onset of neuromuscular overstimulation and tetany.

Assess for hypocalcemia by testing for Trousseau's and Chvostek's signs. To test for Trousseau's sign, place a blood pressure cuff around the arm, inflate the cuff to greater than the patient's systolic pressure, and keep the cuff inflated for 1 to 4 minutes. Under these hypoxic conditions, a positive Trousseau's sign occurs when the hand and fingers go into spasm in palmar flexion (Fig. 11-13). To test for Chvostek's sign, tap the face just below and in front of the ear to trigger facial twitching of one side of the mouth, nose, and cheek (Fig. 11-14).

**FIG. 11-13** Palmar flexion indicating a positive Trousseau's sign in hypocalcemia.

**FIG. 11-14** Facial muscle response indicating a positive Chvostek's sign in hypocalcemia.

*Cardiovascular changes* involve heart rate and ECG changes. The heart rate may be slower or slightly faster than normal, with a weak, thready pulse. Severe hypocalcemia causes severe hypotension and ECG changes of a prolonged ST interval and a prolonged QT interval (Moore et al., 2014).

*Intestinal changes* include increased peristaltic activity. Assess the abdomen for hyperactive bowel sounds. The patient may report painful abdominal cramping and diarrhea.

*Skeletal changes* are common with chronic hypocalcemia. Calcium leaves bone storage sites, causing a loss of bone density (osteoporosis). The bones are less dense, more brittle, and fragile and may break easily with slight trauma. Vertebrae become more compact and may bend forward, leading to an overall loss of height. See [Chapter 50](#) for discussion of osteoporosis.

Ask about changes in height and any unexplained bone pain. Observe for spinal curvatures and any unusual bumps or protrusions in bones that may indicate old fractures.

#### ◆Interventions: Responding

Interventions focus on restoring normal calcium levels and preventing complications. These include drug therapy, nutrition therapy, reducing environmental stimuli, and preventing injury. Patient safety during restoration of serum calcium levels is a nursing care priority.

*Drug therapy* includes direct calcium replacement (oral and IV) and drugs that enhance the absorption of calcium such as vitamin D. When neuromuscular symptoms are troublesome, drugs that decrease nerve and muscle responses also may be used.

*Nutrition therapy* involves a calcium-rich diet for patients with mild hypocalcemia and for those who are at continuing risk for hypocalcemia. Collaborate with the dietitian to help the patient select calcium-rich foods.

*Environmental management* for safety is needed because the excitable membranes of the nervous system and the skeletal system are overstimulated in hypocalcemia. Reduce stimulation by keeping the room quiet, limiting visitors, adjusting the lighting, and using a soft voice.

*Injury prevention strategies* are needed because the patient with long-standing calcium loss may have brittle, fragile bones that fracture easily and cause little pain. When lifting or moving a patient with fragile bones, use a lift sheet rather than pulling the patient. Observe for normal range of joint motion and for any unusual surface bumps or depressions over bony areas that may indicate bone fracture.

## Hypercalcemia

### ❖Pathophysiology

**Hypercalcemia** is a total serum calcium level above 10.5 mg/dL or 2.62 mmol/L. Even small increases above normal have severe effects, and all systems are affected. Hypercalcemia causes excitable tissues to be less sensitive to normal stimuli, thus requiring a stronger stimulus to function. The excitable tissues affected most by hypercalcemia are the heart, skeletal muscles, nerves, and intestinal smooth muscles. Causes of hypercalcemia are listed in [Table 11-10](#).

**TABLE 11-10**  
**Common Causes of Hypercalcemia**

Actual Calcium Excesses	Relative Calcium Excesses
<ul style="list-style-type: none"> <li>• Excessive oral intake of calcium</li> <li>• Excessive oral intake of vitamin D</li> <li>• Kidney failure</li> <li>• Use of thiazide diuretics</li> </ul>	<ul style="list-style-type: none"> <li>• Hyperparathyroidism</li> <li>• Malignancy</li> <li>• Hyperthyroidism</li> <li>• Immobility</li> <li>• Use of glucocorticoids</li> <li>• Dehydration</li> </ul>

### ❖Interprofessional Collaborative Care

#### ◆Assessment: Noticing

The signs and symptoms of hypercalcemia are related to its severity and how quickly the imbalance occurred. The patient with a mild but rapidly occurring calcium excess often has more severe problems than the patient whose imbalance is severe but has developed slowly.

*Cardiovascular changes* are the most serious and life-threatening problems of hypercalcemia. Mild hypercalcemia at first causes increased heart rate and blood pressure. Severe or prolonged calcium imbalance depresses electrical conduction, slowing heart rate.

Measure pulse rate and blood pressure and observe for indications of poor PERFUSION such as cyanosis and pallor. Examine ECG tracings for dysrhythmias, especially a shortened QT interval.

Hypercalcemia allows blood clots to form more easily whenever blood flow is poor. Blood clotting is more likely in the lower legs, the pelvic region, areas where blood flow is blocked by internal or external constrictions, and areas where venous obstruction occurs.

Assess for slowed or impaired PERFUSION. Measure and record calf circumferences with a soft tape measure. Assess the feet for temperature, color, and capillary refill to determine PERFUSION to and from the area.

*Neuromuscular changes* include severe muscle weakness and decreased deep tendon reflexes without paresthesia. The patient may be confused and lethargic.

*Intestinal changes* are first reflected as decreased peristalsis. Constipation, anorexia, nausea, vomiting, abdominal distention, and pain are common. Bowel sounds are hypoactive or absent. Assess abdominal size by measuring abdominal girth with a soft tape measure in a line circling the abdomen at the umbilicus.

#### ◆Interventions: Responding

Interventions for hypercalcemia focus on reducing serum calcium levels through drug therapy; rehydration; and, depending on the cause and severity, dialysis. Cardiac monitoring is also

important.

*Drug therapy* involves preventing increases in calcium and drugs to lower calcium levels. IV solutions containing calcium (e.g., Ringer's lactate) are stopped. Oral drugs containing calcium or vitamin D (e.g., calcium-based antacids) are discontinued.

Fluid volume replacement can help restore normal serum calcium levels. IV normal saline (0.9% sodium chloride) is usually given because sodium increases kidney excretion of calcium.

Thiazide diuretics are discontinued and replaced with diuretics that enhance the excretion of calcium such as furosemide (Lasix, Furoside 🍀). Calcium chelators (calcium binders) help lower serum calcium levels. Such drugs include plicamycin (Mithracin) and penicillamine (Cuprimine).

Drugs to prevent hypercalcemia include agents that inhibit calcium resorption from bone such as phosphorus, calcitonin (Calcimar), bisphosphonates (etidronate [Didronel, Etidrocal 🍀, NOVO-etidronatecal 🍀]), and prostaglandin synthesis inhibitors (aspirin, NSAIDs).

*Cardiac monitoring* of patients with hypercalcemia is needed to identify dysrhythmias and decreased cardiac output. Compare recent ECG tracings with the patient's baseline tracings. Especially look for changes in the T waves and the QT interval and changes in rate and rhythm.

## Magnesium

**Magnesium (Mg<sup>2+</sup>)** is a cation mostly stored in bones and cartilage. Little magnesium is present in the blood (see [Table 11-1](#)). The intracellular fluid (ICF) has more magnesium, and it has more functions inside the cells than in the blood. It is important for skeletal muscle contraction, carbohydrate metabolism, generation of energy stores, vitamin activation, blood coagulation, and cell growth.

### Hypomagnesemia

**Hypomagnesemia** is a serum magnesium (Mg<sup>2+</sup>) level below 1.8 mEq/L or 0.74 mmol/L. It is most often caused by decreased absorption of dietary magnesium or increased kidney magnesium excretion. Two major causes of hypomagnesemia are inadequate intake and the use of loop or thiazide diuretics. [Table 11-11](#) lists additional causes of hypomagnesemia.

**TABLE 11-11**

**Common Causes of Magnesium Imbalance**

Hypomagnesemia	Hypermagnesemia
<ul style="list-style-type: none"><li>• Malnutrition</li><li>• Starvation</li><li>• Diarrhea</li><li>• Steatorrhea</li><li>• Celiac disease</li><li>• Crohn's disease</li><li>• Drugs (diuretics, aminoglycoside antibiotics, cisplatin, amphotericin B, cyclosporine)</li><li>• Citrate (blood products)</li><li>• Ethanol ingestion</li></ul>	<ul style="list-style-type: none"><li>• Increased magnesium intake:</li><li>• Magnesium-containing antacids and laxatives</li><li>• IV magnesium replacement</li><li>• Decreased kidney excretion of magnesium resulting from kidney disease</li></ul>

The effects of hypomagnesemia are caused by increased membrane excitability and the accompanying serum calcium and potassium imbalances. Excitable membranes, especially nerve cell membranes, may depolarize spontaneously.

*Cardiovascular changes* associated with hypomagnesemia are serious. Low magnesium levels increase the risk for hypertension, atherosclerosis, hypertrophic left ventricle, and a variety of dysrhythmias ([McCance et al., 2014](#)). The dysrhythmias include premature contractions, atrial fibrillation, ventricular fibrillation, and long QT intervals. One aspect of the conduction problems is that, when serum magnesium levels are low, intracellular potassium levels are also low. This changes the resting membrane potential in cardiac muscle cells, slowing normal conduction and triggering ectopic beats. Low magnesium levels also are associated with greater cardiac muscle cell damage after myocardial infarction.

*Neuromuscular changes* are caused by increased nerve impulse transmission. Normally magnesium inhibits nerve impulse transmission at synapse areas. Decreased levels increase impulse transmission from nerve to nerve or from nerve to skeletal muscle. The patient has hyperactive deep tendon reflexes, numbness and tingling, and painful muscle contractions. Positive Chvostek's and Trousseau's signs may be present because hypomagnesemia may occur with hypocalcemia (see the earlier discussion of these assessment signs of neuromuscular changes in the [Hypocalcemia](#) section). The patient may have tetany and seizures as hypomagnesemia worsens.

*Intestinal changes* are from decreased intestinal smooth muscle contraction. Reduced motility, anorexia, nausea, constipation, and abdominal distention are common. A paralytic ileus may occur when hypomagnesemia is severe.

Interventions for hypomagnesemia aim to correct the imbalance and manage the specific problem that caused it. In addition, because hypocalcemia often occurs with hypomagnesemia, interventions also aim to restore normal serum calcium levels.

Drugs that promote magnesium loss such as high-ceiling (loop) diuretics, osmotic diuretics, aminoglycoside antibiotics, and drugs containing phosphorus are discontinued. Magnesium is replaced intravenously with magnesium sulfate ( $\text{MgSO}_4$ ) when hypomagnesemia is severe. Assess deep tendon reflexes at least hourly in the patient receiving IV magnesium to monitor effectiveness and prevent hypermagnesemia. If hypocalcemia is also present, drug therapy to increase serum calcium levels is prescribed.

## Hypermagnesemia

**Hypermagnesemia** is a serum magnesium level above 2.6 mEq/L or 1.07 mmol/L. Table 11-11 lists the specific causes of hypermagnesemia.

Magnesium is a membrane stabilizer. Most symptoms of hypermagnesemia occur as a result of reduced membrane excitability. They usually are not apparent until serum magnesium levels exceed 4 mEq/L (1.6 mmol/L).

*Cardiac changes* include bradycardia, peripheral vasodilation, and hypotension. These problems become more severe as serum magnesium levels increase. ECG changes show a prolonged PR interval with a widened QRS complex. Bradycardia can be severe, and cardiac arrest is possible. Hypotension is also severe, with a diastolic pressure lower than normal. *Patients with severe hypermagnesemia are in grave danger of cardiac arrest.*

*Central nervous system changes* result from depressed nerve impulse transmission. Patients may be drowsy or lethargic. Coma may occur if the imbalance is prolonged or severe.

*Neuromuscular changes* include reduced or absent deep tendon reflexes. Voluntary skeletal muscle contractions become progressively weaker and finally stop.

Hypermagnesemia has no direct effect on the lungs; however, when the respiratory muscles are weak, respiratory insufficiency can lead to respiratory failure and death.

Interventions for hypermagnesemia focus on reducing the serum level and correcting the underlying problem that caused the imbalance. All oral and parenteral magnesium is discontinued. When kidney failure is not present, giving magnesium-free IV fluids can reduce serum magnesium levels. High-ceiling (loop) diuretics such as furosemide (Lasix, Furoside ♣) can further reduce serum magnesium levels. When cardiac problems are severe, giving calcium may reverse the cardiac effects of hypermagnesemia.

## Clinical Judgment Challenge 11-2

### Patient-Centered Care; Evidence-Based Practice; Teamwork and Collaboration **QSEN**

A 73-year-old patient who is being managed for viral cardiomyopathy with heart failure is going home today after an acute exacerbation of his heart failure. He has been taking furosemide 40 mg orally daily, rivaroxaban 20 mg orally daily, lisinopril 5 mg orally daily, and carvedilol 25 mg orally twice daily. He is now being prescribed to also take magnesium 500 mg orally once daily. He tells you that he understands why he is to continue to take the previously prescribed drugs but wants to know how the magnesium will help him. Your responsibility is to help him become a partner in his therapy to prevent worsening heart failure.

1. Is this patient at risk for dehydration or fluid overload? Explain this risk.
2. Which parameters will you teach him to self-monitor at home for indications of needing to see the health care provider? Provide a rationale for your selection.
3. Which electrolytes are most likely to be disturbed by his drug therapy. Explain your selections and the directions of the potential disturbances.

4. What will you tell him about the magnesium?
5. Which additional members of the interprofessional team would be most helpful in this patient's management and why?

# Get Ready for the NCLEX<sup>®</sup> Examination!

## Key Points

Review these key points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Assess any patient with a problem of fluid and electrolyte balance for fall risk. **QSEN: Safety**
- Supervise the oral fluid therapy and intake and output measurement aspects of care delegated to unlicensed assistive personnel. **QSEN: Safety**
- Use a pump or controller to deliver IV fluids to patients with fluid overload. **QSEN: Safety**
- Do not give IV potassium at a rate greater than 20 mEq/hr (mmol/hr). **QSEN: Safety**
- Never give potassium supplements by the IM, subcutaneous, or IV push routes. **QSEN: Safety**
- Use a pump or controller when giving IV potassium-containing solutions. **QSEN: Safety**
- Assess the IV site hourly of an adult receiving IV solutions containing potassium and document its condition. **QSEN: Safety**
- Use a gait belt when assisting a patient with muscle weakness to walk or transfer. **QSEN: Safety**
- Use a lift sheet to move or reposition a patient with chronic hypocalcemia. **QSEN: Safety**

### Health Promotion and Maintenance

- Encourage all patients to maintain an adequate fluid intake (minimum of 1.5 L per day) unless another condition requires fluid restriction. **QSEN: Evidence-Based Practice**
- Teach all adults to increase fluid intake when exercising, when in hot or dry environments, or during conditions that increase metabolism (e.g., fever). **QSEN: Patient-Centered Care**
- Instruct patients at risk for fluid imbalance to weigh themselves on the same scale daily, close to the same time each day, and with about the same amount of clothing on each time and to monitor these daily weights for changes or trends. **QSEN: Patient-Centered Care**
- Ensure access to adequate fluids for patients who cannot talk or who have limited mobility. **QSEN: Patient-Centered Care**
- Instruct caregivers of older adults who have cognitive impairments or mobility problems to schedule offerings of fluids at regular intervals throughout the day. **QSEN: Evidence-Based Practice**
- Teach patients how to determine electrolyte content of processed foods by reading labels. **QSEN: Patient-Centered Care**

### Psychosocial Integrity

- Explain the purpose of fluid restriction to the patient and the family to ensure cooperation and prevent any misunderstandings. **QSEN: Patient-Centered Care**
- Assess patients who have a sudden change in cognition for a change in fluid and electrolyte balance. **QSEN: Patient-Centered Care**
- Determine the patient's food preferences and dislikes when planning an electrolyte-restricted diet. **QSEN: Patient-Centered Care**

### Physiological Integrity

- Assess skin turgor on the forehead or sternum of older patients. **QSEN: Evidence-Based Practice**
- Use daily weights to determine fluid gains or losses. **QSEN: Evidence-Based Practice**
- Ask patients about the use of drugs such as diuretics, laxatives, salt substitutes, and

antihypertensives that may alter fluid and electrolyte balance. **QSEN: Patient-Centered Care**

- Monitor the cardiac and pulmonary status at least every hour when patients with dehydration are receiving IV fluid replacement therapy. **QSEN: Patient-Centered Care**
- Collaborate with the registered dietitian to teach patients about diets that are restricted in potassium, sodium, or calcium. **QSEN: Teamwork and Collaboration**
- Immediately stop the infusion of potassium-containing solutions if infiltration is suspected. **QSEN: Evidence-Based Practice**
- Assess all patients with hyperkalemia for cardiac dysrhythmias and ECG abnormalities, especially tall T waves, conduction delays, and heart block. **QSEN: Evidence-Based Practice**
- Assess the respiratory status of all patients with hypokalemia. **QSEN: Evidence-Based Practice**
- Assess the bowel sounds; heart rate, rhythm and quality; and muscle strength to evaluate the patient's responses to therapy for an electrolyte imbalance. **QSEN: Evidence-Based Practice**

## CHAPTER 12

# Assessment and Care of Patients With Problems of Acid-Base Balance

M. Linda Workman

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concept for this chapter is ACID-BASE BALANCE.**

 The ACID-BASE BALANCE concept exemplar for this chapter is Acidosis, p. 190.

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with the interprofessional team to perform a complete assessment of patients for ACID-BASE BALANCE.

### Health Promotion and Maintenance

2. Explain how physiologic aging changes the effectiveness of mechanisms to maintain ACID-BASE BALANCE and increases the risk for imbalance.
3. Teach all adults measures to take to prevent disturbances of ACID-BASE BALANCE.

### Psychosocial Integrity

4. Implement patient-centered nursing interventions to help the patient and family cope with the psychosocial impact of continuing risk for disturbances of ACID-BASE BALANCE.

### Physiological Integrity

5. Apply knowledge of anatomy, physiology, and pathophysiology to perform an evidence-based assessment for the patient with a disturbance of ACID-BASE BALANCE.
6. Interpret assessment findings for the patient experiencing a disturbance of ACID-BASE BALANCE.
7. Teach the patient and caregivers about diagnostic procedures associated with conditions affecting ACID-BASE BALANCE.

As defined in [Chapter 2](#), ACID-BASE BALANCE is the maintenance of arterial blood pH between 7.35 and 7.45 through regulation of hydrogen ion ( $H^+$ ) production and elimination. The pH is an indirect measure of the free hydrogen ion level in the blood and other body fluids. Maintaining the pH within the narrow normal range is critical for life and body function. Even small changes in the free hydrogen ion level (pH) of body fluids can cause major problems in function. Thus the level of free hydrogen ions, formed from acids, must be rigidly controlled.

The normal free hydrogen ion level of blood and other body fluids is quite low (less than 0.0001 mEq/L [mmol/L]), and its concentration is calculated in negative logarithm units. The value of pH is *inversely* related (negatively related) to the level of free hydrogen ions. Thus the *lower* the pH value of a fluid, the *higher* the level of free hydrogen ions in that fluid. The pH of a solution may range from 1 (as acidic as possible) to 14 (as alkaline as possible), with 7 being neutral. *A change of 1 pH unit actually represents a tenfold change in free hydrogen ion level* (McCance et al., 2014). Therefore any pH unit change (e.g., a change from 7.4 to 7.3) represents a large increase in the free hydrogen ion level.

Maintaining ACID-BASE BALANCE is important because changes from normal pH interfere with many functions. These include:

- Changing the shape and reducing the function of hormones and enzymes
- Changing the distribution of other electrolytes, causing fluid and electrolyte imbalances
- Changing excitable membranes, making the heart, nerves, muscles, and GI tract either less or more active than normal
- Decreasing the effectiveness of many drugs

## Maintaining Acid-Base Balance

Most body fluids have a pH value between 7.35 and 7.45 even though they contain acidic substances and basic substances. This value is slightly alkaline rather than strictly neutral (7.0 is neutral). Normal body fluid pH remains at this near-neutral value when the acids and bases are nearly balanced, limiting the total number of free or unbalanced hydrogen ions. ACID-BASE BALANCE occurs by matching the rate of hydrogen ion production (which is a continuous normal process) with hydrogen ion loss.

## Acid-Base Chemistry

### Acids

**Acids** are substances that release hydrogen ions when dissolved in water (H<sub>2</sub>O) or body fluids, *increasing* the amount of free hydrogen ions in that solution. The strength of an acid is measured by how easily it releases a hydrogen ion in solution. A strong acid such as hydrochloric acid (HCl) separates completely in water and releases *all* of its hydrogen ions, as shown in Fig. 12-1.

**FIG. 12-1** Release of hydrogen ions by a strong acid (hydrochloric acid) in which the strong acid completely dissociates in water.

A weak acid releases only *some*, not all, of its hydrogen ions. In the following example each molecule of acetic acid (CH<sub>3</sub>COOH), a weak acid, contains a total of four hydrogen molecules. When acetic acid combines with water, as shown in Fig. 12-2, it releases only *one* of its four hydrogen molecules, keeping the other three hydrogen molecules bound to the molecule (CH<sub>3</sub>COO<sup>-</sup>).

**FIG. 12-2** Release of hydrogen ions by a weak acid (acetic acid) in which the weak acid only partially dissociates in water and most of its hydrogen ions remain bound.

### Bases

A **base** binds free hydrogen ions in solution and *lowers* the amount of free hydrogen ions in solution. Strong bases bind hydrogen ions easily. Examples are sodium hydroxide (NaOH) and ammonia (NH<sub>3</sub>).

Weak bases bind hydrogen ions less readily. An example of a weak base is bicarbonate (HCO<sub>3</sub><sup>-</sup>). Although a weak base, the many bicarbonate ions in the body are critical in preventing major changes in body fluid pH.

### Buffers

Buffers are critical in keeping body fluid pH at normal levels because they can react either as an acid (releasing a hydrogen ion) or as a base (binding a hydrogen ion). How a buffer reacts depends on the existing pH of that fluid. Buffers always try to bring the fluid as close as possible to the normal body fluid pH of 7.35 to 7.45. If the fluid is basic (with few free hydrogen ions), the buffer *releases hydrogen ions* into the fluid (Fig. 12-3). If the fluid is acidic (with many free hydrogen ions), the buffer *binds some of the excess hydrogen ions*. In this way buffers act like hydrogen ion “sponges,” soaking up hydrogen ions when too many are present and squeezing out hydrogen ions when too

few are present. This flexibility allows buffers to keep body fluid pH in the normal range.

**FIG. 12-3** Action of buffer in solution. (© 1992 by M. Linda Workman. All rights reserved.)

Liquids with a pH of 7.0 are neutral by having a free hydrogen ion level in which the amount and strength of acids and bases are equal. Fig. 12-4 shows the concept of neutral pH in which the combined *strength* and *amount* of all acids are equal to the combined *strength* and *amount* of all bases in a given solution. With human acid-base homeostasis, the relative amounts and strengths of acids and bases are nearly equal, and normally hydrogen ion production is balanced with hydrogen ion loss so the overall free hydrogen ion levels remain constant.

**FIG. 12-4** Concept of acidic versus normal pH. (A = acid; B = base.)

Liquids with a pH ranging from 1.0 to 6.99 have more or stronger (or both) acids compared with bases. These liquids are *acidic* (see Fig. 12-4), with more free hydrogen ions released than bound, increasing the amount of free hydrogen ions in the liquid.

Liquids with a pH ranging from 7.01 to 14.0 have more or stronger (or both) bases compared with acids. These liquids are *basic*, in which more hydrogen ions are being bound than released, decreasing the amount of free hydrogen ions (Fig. 12-5).

**FIG. 12-5** Concept of alkaline versus normal pH. (A = acid; B = base.)

## Body Fluid Chemistry

### Bicarbonate Ions

Body fluids contain different types of acids and bases. The most common base in human body fluid

is bicarbonate ( $\text{HCO}_3^-$ ); the most common acid is carbonic acid ( $\text{H}_2\text{CO}_3$ ). In health the body keeps these substances at a constant ratio of 1 molecule of carbonic acid to 20 free bicarbonate ions (1 : 20) (Fig. 12-6). To maintain this ratio, both carbonic acid and bicarbonate must be carefully controlled. This constant ratio is related to balancing the production and elimination of carbon dioxide ( $\text{CO}_2$ ) and hydrogen ions ( $\text{H}^+$ ).

**FIG. 12-6** Normal ratio of carbonic acid to bicarbonate is 1 : 20. (From McCance, K., Huether, S., Brashers, V., & Rote, N. [2014]. *Pathophysiology: The biologic basis for disease in adults and children* [7th ed.]. St. Louis: Mosby.)

## Relationship Between Carbon Dioxide and Hydrogen Ions

A key process in understanding ACID-BASE BALANCE is the carbonic anhydrase equation. This equation, driven by the enzyme carbonic anhydrase, shows how hydrogen ion levels and carbon dioxide levels are directly related to one another so an increase in one causes an equal increase in the other (Fig. 12-7).

**FIG. 12-7** The carbonic anhydrase equation showing that the concentration of carbon dioxide is directly related to the concentration of hydrogen ions.

Carbon dioxide is a gas that forms carbonic acid when combined with water, making carbon dioxide a part of carbonic acid. Carbonic acid is not stable, and the body needs to keep a 1 : 20 ratio of carbonic acid to bicarbonate. When carbonic acid is formed from water and carbon dioxide, it begins to separate into free hydrogen ions and bicarbonate ions. *Therefore the carbon dioxide content of a fluid is directly related to the amount of hydrogen ions in that fluid. Whenever conditions cause carbon dioxide to increase, more free hydrogen ions are created. Likewise, whenever free hydrogen ion production increases, more carbon dioxide is produced.*

When excess carbon dioxide is produced, the equation shifts to the *right*, causing an *increase* in hydrogen ions (and a *decrease* in pH), as shown in Fig. 12-8. When very little carbon dioxide is produced, no free hydrogen ions are created by this equation.

**FIG. 12-8** Increased carbon dioxide levels force the equation to the right and increase the concentration of hydrogen ions proportionately.

When excess hydrogen ions are present, the carbonic anhydrase equation shifts to the *left*, causing the creation of more carbon dioxide, as shown in Fig. 12-9. When the amount of free hydrogen ions in body fluids is low, no extra carbon dioxide is produced.

**FIG. 12-9** Increased hydrogen ion levels force the equation to the left and increase the concentration of carbon dioxide levels proportionately.

How is the relationship between free hydrogen ions and carbon dioxide helpful? Carbon dioxide is a gas that can be eliminated during exhalation, and this action is important for ACID-BASE BALANCE. When any condition causes the hydrogen ion concentration of body fluids to increase, extra CO<sub>2</sub> is produced in the same proportion. This extra CO<sub>2</sub> is eliminated during exhalation, helping to bring the hydrogen ion concentration down to normal. Whenever the CO<sub>2</sub> level changes, the pH changes to the same degree, in the opposite direction. Thus, when the CO<sub>2</sub> level of a liquid increases, the pH drops, indicating more free hydrogen ions (more acidic). Likewise, when the CO<sub>2</sub> level of a liquid decreases, the pH rises, indicating fewer free hydrogen ions (more alkaline).

An increase in bicarbonate causes the amount of hydrogen ions to decrease and the pH to increase, becoming more alkaline (basic). Likewise, a decrease in bicarbonate causes the free hydrogen ion level to increase and the pH to decrease, becoming more acidic.

Because the kidneys control bicarbonate levels and the lungs control CO<sub>2</sub> levels, pH is also the result of how well the kidneys are functioning to retain or eliminate bicarbonate divided by how well the lungs are functioning to eliminate carbon dioxide (Fig. 12-10). A problem in either organ system can lead to disturbed ACID-BASE BALANCE.

$$\text{pH} = \frac{\text{(Slow but powerful response)} \quad \text{Kidney function} = \text{Bicarbonate levels}}{\text{Lung function} = \text{Carbon dioxide levels} \quad \text{(Rapid but limited response)}}$$

**FIG. 12-10** Contribution of pH balance by kidney and lung function.

## Sources of Acids and Bicarbonate

When acids are present in body fluids, free hydrogen ions are released and must be controlled for ACID-BASE BALANCE. Acids and hydrogen ions are produced continuously through normal body physiologic work and metabolism.

*Normal metabolism* of carbohydrate, protein, and fat creates natural waste products. Carbohydrate metabolism forms carbon dioxide (CO<sub>2</sub>). Carbon dioxide is exhaled by the lungs during breathing. One factor that determines blood pH is how much CO<sub>2</sub> is produced by body cells during metabolism versus how rapidly that CO<sub>2</sub> is removed by breathing. Protein breakdown forms sulfuric acid. Fat breakdown forms fatty acids and ketoacids.

*Incomplete breakdown of glucose*, which occurs whenever cells metabolize under **anaerobic** (no oxygen) conditions, forms lactic acid. Anaerobic conditions occur with hypoxia, sepsis, and shock. Incomplete breakdown of fatty acids, occurring when large amounts of fatty acids are being metabolized, forms ketoacids.

*Cell destruction* allows cell contents to be released, including the structures that contain acids. These released acids in the extracellular fluid (ECF) increase free hydrogen ion levels.

*Bicarbonate*, a weak base, is the main buffer of the ECF. It comes from the GI absorption of ingested bicarbonate, pancreatic production of bicarbonate, movement of cellular bicarbonate into the ECF, kidney reabsorption of filtered bicarbonate, and the breakdown of carbonic acid. Once bicarbonate is in the ECF, it is kept at a level 20 times greater than that of carbonic acid.

## Acid-Base Regulatory Actions and Mechanisms

As long as body cells are healthy, they continuously produce acids, carbon dioxide, and free hydrogen ions. Despite this production, hydrogen ion, bicarbonate, oxygen, and carbon dioxide levels are kept within normal limits when ACID-BASE BALANCE controlling actions are normal. [Chart 12-1](#) lists the normal values in arterial and venous blood. This homeostasis depends on:

### Chart 12-1

## Laboratory Profile

### Acid-Base Assessment

NORMAL RANGE FOR ADULTS			
TEST	ARTERIAL	VENOUS	SIGNIFICANCE OF ABNORMAL FINDINGS
<b>pH</b>			
Adult <90 yr	7.35-7.45	7.31-7.41	Increased: Metabolic alkalosis, loss of gastric fluids, decreased potassium intake, diuretic therapy, fever, salicylate toxicity, respiratory alkalosis, hyperventilation
>90 yr	7.25-7.45	7.31-7.41	Decreased: Metabolic or respiratory acidosis, ketosis, renal failure, starvation, diarrhea, hyperthyroidism
<b>PaO<sub>2</sub></b>			
Adult <90 yr	80-100 mm Hg		Increased: Increased ventilation, oxygen therapy, exercise Decreased: Respiratory depression, high altitude, carbon monoxide poisoning, decreased cardiac output
>90 yr	70-90 mm Hg		
<b>PaCO<sub>2</sub></b>	35-45 mm Hg	40-50 mm Hg	Increased: Respiratory acidosis, emphysema, pneumonia, cardiac failure, respiratory depression Decreased: Respiratory alkalosis, excessive ventilation, diarrhea
<b>Bicarbonate</b>	21-28 mEq/L (21-28 mmol/L)	24-29 mEq/L (24-29 mmol/L)	Increased: Metabolic alkalosis, bicarbonate therapy Decreased: Metabolic acidosis, diarrhea, pancreatitis
<b>Lactate</b>	3-7 mg/dL 0.3-0.8 mmol/L	5-20 mg/dL 0.6-2.2 mmol/L	Increased: Hypoxia, exercise, insulin infusion, alcoholism, pregnancy Decreased: Fluid overload

$P_{aCO_2}$ , Partial pressure of arterial carbon dioxide;  $P_{aO_2}$ , partial pressure of arterial oxygen.

Data from Pagana, K., Pagana, T., & Pagana, T. (2017). *Mosby's diagnostic and laboratory test reference* (13th ed.). St. Louis: Mosby; and Pagana, K., Pagana, T., & Pike-MacDonald, S. (2013). *Mosby's Canadian manual of diagnostic and laboratory tests* (1st ed.). St. Louis: Mosby.

- Hydrogen ion production being consistent and not excessive
- CO<sub>2</sub> loss from the body through breathing keeping pace with all forms of hydrogen ion production

To keep the free hydrogen ion level (pH) of the ECF within the narrow normal range, the body has chemical, respiratory, and kidney actions (mechanisms) for acid-base balance ([Table 12-1](#)).

**TABLE 12-1**

### Acid-Base Regulatory Mechanisms

MECHANISM TYPE	KEY CHARACTERISTICS
<b>Chemical</b> Protein buffers (albumin, globulins, hemoglobin) Chemical buffers (bicarbonate, phosphate)	Very rapid response Provide immediate response to changing conditions Can handle relatively small fluctuations in hydrogen ion production during normal metabolic and health conditions
<b>Respiratory</b> Increased hydrogen ions or increased carbon dioxide: Triggers the brain to increase the rate and depth of breathing, causing more carbon dioxide to be lost and decreasing the hydrogen ion concentration Decreased hydrogen ions or decreased carbon dioxide: Inhibits brain stimulation, leading to decreased rate and depth of breathing, causing carbon dioxide to be retained and increasing the hydrogen ion concentration	Primarily assist buffering systems when the fluctuation of hydrogen ion concentration is acute
<b>Kidney</b> Actions to decrease pH: Increased kidney excretion of bicarbonate Increased kidney reabsorption of hydrogen ions Actions to increase pH: Decreased kidney excretion of bicarbonate Decreased kidney reabsorption of hydrogen ions	The most powerful regulator of acid-base balance Respond to large or chronic fluctuations in hydrogen ion production or elimination Slowest response (hours to days) Longest duration

### Chemical Acid-Base Control Actions

Buffers are the first line of defense against changes in free hydrogen ion levels. These buffers are always present in body fluids and act fast to reduce or raise the amount of free hydrogen ions to normal. By acting as hydrogen ion “sponges,” buffers can bind hydrogen ions when too many are present or release hydrogen ions when not enough are present.

Buffers are composed of chemicals or proteins. The two most common chemical buffers are

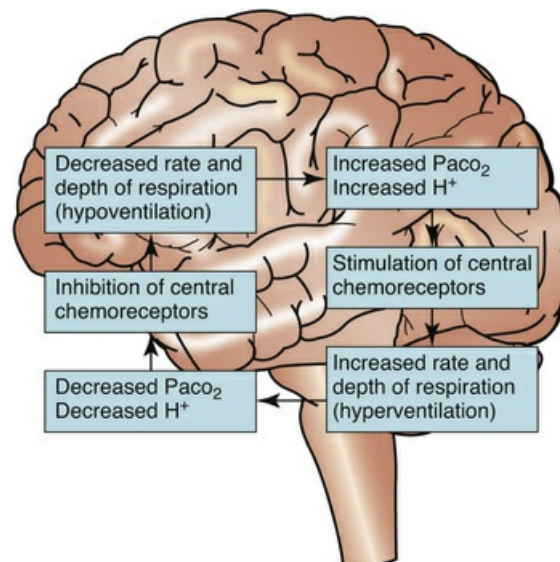

bicarbonate (which is active in both the extracellular fluid [ECF] and intracellular fluid [ICF]) and phosphate (which is active in the ICF). Protein buffers are the most common buffers. Extracellular protein buffers are albumin and globulins. A major intracellular protein buffer is hemoglobin (McCance et al., 2014). When the amount of free hydrogen ions in the blood increases, some of the excess hydrogen ions cross the membranes of red blood cells and bind to the large numbers of hemoglobin molecules in each red blood cell. Binding of hydrogen ions to hemoglobin results in fewer hydrogen ions remaining in the blood, bringing blood pH back up toward normal.

### Respiratory Acid-Base Control Actions

When chemical buffers alone cannot prevent changes in blood pH, the respiratory system is the second line of defense against changes. Breathing controls the amount of free hydrogen ions by controlling the amount of carbon dioxide ( $\text{CO}_2$ ) in arterial blood. Because  $\text{CO}_2$  is converted into hydrogen ions with the carbonic anhydrase reaction, the  $\text{CO}_2$  level is *directly* related to the hydrogen ion level. Breathing rids the body of any excess  $\text{CO}_2$ .

The  $\text{CO}_2$  level in venous blood increases with metabolism. This  $\text{CO}_2$  moves into lung capillary blood. Because the amount (pressure) of  $\text{CO}_2$  is far higher in lung capillary blood than it is in the air in the alveoli,  $\text{CO}_2$  diffuses freely from the blood into the alveolar air. Once in the alveoli,  $\text{CO}_2$  is exhaled during breathing and is lost from the body. Because the amount of  $\text{CO}_2$  in room air is nearly zero,  $\text{CO}_2$  can continue to be exhaled even when breathing is impaired.

Respiratory regulation of ACID-BASE BALANCE is under the control of the central nervous system (Fig. 12-11). Special receptors in the respiratory areas of the brain are sensitive to changes in the amount of  $\text{CO}_2$  in brain tissues. As the amount of  $\text{CO}_2$  begins to rise above normal in brain blood and tissues, these central receptors trigger the neurons to increase the rate and depth of breathing (**hyperventilation**). As a result, more  $\text{CO}_2$  is exhaled (“blown off”) from the lungs, and the  $\text{CO}_2$  level in the ECF decreases. When the arterial  $\text{CO}_2$  level returns back down to normal, the rate and depth of breathing return to levels that are normal for the patient.

**FIG. 12-11** Neural regulation of respiration and hydrogen ion concentration. ( $\text{H}^+$ , Hydrogen ion,  $\text{PaCO}_2$ , partial pressure of arterial carbon dioxide.)

If the amount of ECF free hydrogen ions is too low, the  $\text{CO}_2$  level also is too low. Central receptors sense these low  $\text{CO}_2$  levels and stop or slow the neuron activity in the respiratory centers of the brain, decreasing the rate and depth of breathing (**hypoventilation**). As a result, less  $\text{CO}_2$  is lost through the lungs, and more  $\text{CO}_2$  is retained in arterial blood. This retention of already-formed  $\text{CO}_2$ , together with the normal production of  $\text{CO}_2$  from metabolism, results in a rapid return of the arterial  $\text{CO}_2$  levels (and hydrogen ion levels) back up to normal. When these levels are normal, the

rate and depth of breathing also return to normal levels.

The respiratory system's response in ACID-BASE BALANCE is rapid. Changes in the rate and depth of breathing occur within minutes after changes in the hydrogen ion level or CO<sub>2</sub> level of the ECF occur.

### Kidney Acid-Base Control Actions

The kidneys are the third line of defense against wide changes in body fluid pH. Kidney actions are stronger for regulating ACID-BASE BALANCE but take 24 to 48 hours to completely respond. When blood pH changes are persistent, kidney actions to increase excretion and reabsorption rates of acids or bases (depending on which way pH changes) start. These actions are kidney movement of bicarbonate, formation of acids, and formation of ammonium.

*Kidney movement of bicarbonate* is the first kidney pH control action. It occurs in the kidney tubules in two ways: (1) kidney movement of bicarbonate produced elsewhere in the body, and (2) kidney movement of bicarbonate produced in the kidneys. Much of the bicarbonate made in other body areas is excreted in the urine. When blood hydrogen ion levels are high, this bicarbonate is reabsorbed from the kidneys back into circulation, where it can help buffer excess hydrogen ions. The kidney tubules also can make additional bicarbonate and reabsorb it to increase the buffer effect. When blood hydrogen ion levels are low, the bicarbonate stays in the urine and is excreted.

*Formation of acids* occurs through the phosphate-buffering system inside the cells of the kidney tubules. When the newly created bicarbonate made in kidney cells is reabsorbed into the blood, the urine has an excess of anions, including phosphate (HPO<sub>4</sub><sup>2-</sup>). This negatively charged fluid draws hydrogen ions (which have a positive charge) into the urine. Once in the urine, the hydrogen ion binds to phosphate ions, forming an acid (H<sub>2</sub>PO<sub>4</sub>) that is then excreted in the urine.

*Formation of ammonium* converts the ammonia (NH<sub>3</sub>), which is formed during normal protein breakdown, into ammonium (NH<sub>4</sub><sup>+</sup>) in the urine. The ammonium “traps” the hydrogen ions and then allows them to be excreted in the urine. The result is a loss of hydrogen ions and an increase in blood pH.

### Compensation

In the process of *compensation*, the body adapts to attempt to correct changes in blood pH and maintain ACID-BASE BALANCE. A pH below 6.9 or above 7.8 is usually fatal. The normal pH range for human extracellular fluid (ECF) is 7.35 to 7.45. Both the kidneys and the lungs can compensate for acid-base imbalances, but they are not equal in their final responses. The respiratory system is much more sensitive to acid-base changes and can begin compensation efforts within seconds to minutes after a change in pH. However, these efforts are limited and can be overwhelmed easily. The kidney compensatory actions are much more powerful and result in rapid changes in ECF composition. However, these more powerful actions are not fully triggered unless the acid-base imbalance continues for several hours to several days.

*Respiratory compensation* occurs through the lungs, usually to correct for acid-base imbalances from metabolic problems. For example, when prolonged running causes buildup of lactic acid, hydrogen ion levels in the ECF increase, causing the pH to drop. To bring the pH back to normal, breathing is triggered in response to increased carbon dioxide levels. Both the rate and depth of respiration increase. These respiratory efforts cause the blood to lose carbon dioxide with each exhalation, so ECF levels of carbon dioxide and free hydrogen ions gradually decrease. When the lungs can *fully compensate*, the pH returns to normal (Blevins, 2014).

*Kidney compensation* results when a healthy kidney works to correct for changes in blood pH that occur when the respiratory system either is overwhelmed or is not healthy. For example, in an adult with chronic obstructive pulmonary disease (COPD), the respiratory system cannot exchange gases adequately. Carbon dioxide is retained continuously, hydrogen ion levels increase, and the blood pH falls (becomes more acidic). The kidneys oppose this by excreting more hydrogen ions and increasing the movement of bicarbonate back into the blood. Then blood pH remains either within or closer to the normal range. When adaptive actions are completely effective, acid-base problems are *fully compensated*; and the pH of the blood returns to normal, even though the levels of oxygen and bicarbonate may be abnormal (Blevins, 2014).

However, sometimes the respiratory problem causing the acid-base imbalance is so severe that kidney actions can only *partially compensate* and the pH is not quite normal. Partial compensation

prevents the acid-base imbalance from becoming severe (Blevins, 2014; Larkin & Zimmanck, 2015).

## **NCLEX Examination Challenge 12-1**

### **Physiological Integrity**

How are blood hydrogen ion levels and blood carbon dioxide levels related?

- A. These two blood values are negatively related to the extent that, as carbon dioxide levels rise, the concentration of hydrogen ions decreases.
- B. Carbon dioxide is attached to and becomes part of hydrogen ions in the blood so the loss of one always leads to the loss of the other.
- C. There is no relation between blood hydrogen ion level and carbon dioxide, making the concentration of each substance independent of the other.
- D. Blood hydrogen ion levels and blood carbon dioxide levels are directly related so, when the level of one increases, the level of the other increases to the same degree.

## Acid-Base Imbalances

Acid-base imbalances are problems of ACID-BASE BALANCE resulting from changes in the blood hydrogen ion level or pH. These changes are caused by problems with the acid-base regulatory actions or exposure to dangerous conditions. Imbalances in which blood pH is below normal reflect **acidosis**, and imbalances in which blood pH is above normal reflect **alkalosis**. Acid-base imbalances impair the function of many organs and can be life threatening.

### Acid-base Balance Concept Exemplar Acidosis

#### Pathophysiology

In acidosis the ACID-BASE BALANCE of the blood and other extracellular fluid (ECF) is upset by an excess of hydrogen ions ( $H^+$ ). This is seen as an arterial blood pH below 7.35. The amount of acids present is greater than normal compared with the amount or strength of bases.

Acidosis is not a disease; it is a condition caused by a disorder or pathologic process. It can be caused by metabolic problems, respiratory problems, or both. Patients at greatest risk for acute acidosis are those with problems that impair breathing. Older adults with chronic health problems are at greater risk for developing acidosis (Chart 12-2) (McCance et al., 2014).

#### Chart 12-2

### Nursing Focus on the Older Adult

#### The Older Patient Experiencing Acid-Base Imbalance

##### When Obtaining a Patient's History

- Assess risk factors for acid-base imbalance, including drugs, chronic health problems (especially kidney disease, pulmonary disease), and acute health problems.
- Ask the patient to list all prescribed and over-the-counter drugs (especially diuretics and antacids). If the patient is unable to provide this information, ask the family to bring the drugs in from home.
- Ask the patient to recall which liquids were taken in the past 24 hours and whether urination amounts have changed.

##### When Assessing the Patient

- Compare the patient's mental status with what the family, significant other, or health record states is the patient's baseline.
- Observe the rate and depth of respiration.
- Determine whether the patient can complete a sentence without stopping for breath.
- Examine the color of nail beds and mucous membranes.
- Obtain a urine specimen and observe for color and character. Test for specific gravity and pH.
- Examine skin turgor for dehydration. Attempt to pinch the skin to form a tent over the sternum and on the forehead. If a tent forms, record how long it remains.
- Measure the rate and quality of the pulse.
- Monitor clinical responses and laboratory values while the acid-base imbalance is being corrected.
- Administer IV therapy by pump or controller.

Modified from Touhy, T., & Jett, K. (2016). *Ebersole & Hess' Toward healthy aging: Human needs & nursing response*. St. Louis: Elsevier.

Acidosis can result from an actual or relative increase in the amount or strength of acids. An *actual acid excess* results in acidosis by either overproducing acids (and release of hydrogen ions) or undereliminating normally produced acids (retention of hydrogen ions). Either way, more hydrogen ions are present than should be. Problems that increase acid production include diabetic ketoacidosis and seizures. Problems that decrease acid elimination include respiratory impairment and kidney impairment.

In *relative acidosis* the amount of acids does not increase. Instead the amount or strength of the bases decreases (to create a *base deficit*), which makes the fluid relatively more acidic than basic. A relative acidosis (*base deficit*) is caused by either overeliminating or underproducing bicarbonate ions ( $\text{HCO}_3^-$ ) (see Fig. 12-4). Problems that underproduce bases include pancreatitis and dehydration. A condition that overeliminates bases is diarrhea.

Regardless of its cause, acidosis causes major changes in body function. The main problems occur because hydrogen ions are positively charged ions. An increase in hydrogen ions creates imbalances of other positively charged electrolytes, especially potassium. The changes in potassium levels because of excess hydrogen ions are described in the Laboratory Assessment section for acidosis. These electrolyte imbalances then disrupt the functions of nerves, cardiac muscle, and skeletal muscle. Symptoms of acidosis first appear in the musculoskeletal, cardiac, respiratory, and central nervous systems. Even slight increases in blood hydrogen ion levels reduce the activity of many hormones and enzymes, leading to death.

Acidosis can be caused by metabolic problems, respiratory problems, or combined metabolic and respiratory problems. Specific causes of acidosis are listed in Table 12-2.

**TABLE 12-2**  
**Common Causes of Acidosis**

PATHOLOGY	CONDITION
<b>Metabolic Acidosis</b>	
Overproduction of hydrogen ions	Excessive oxidation of fatty acids: Diabetic ketoacidosis Starvation Hypermetabolism: Heavy exercise Seizure activity Fever Hypoxia, ischemia Excessive ingestion of acids: Ethanol or methanol intoxication Salicylate intoxication
Underelimination of hydrogen ions	Kidney failure
Underproduction of bicarbonate	Kidney failure Pancreatitis Liver failure Dehydration
Overelimination of bicarbonate	Diarrhea
<b>Respiratory Acidosis</b>	
Underelimination of hydrogen ions	Respiratory depression: Anesthetics Drugs (especially opioids) Electrolyte imbalance Inadequate chest expansion: Muscle weakness Airway obstruction Alveolar-capillary block

### Metabolic Acidosis

Four processes can result in metabolic acidosis: overproduction of hydrogen ions, underelimination of hydrogen ions, underproduction of bicarbonate ions, and overelimination of bicarbonate ions.

*Overproduction of hydrogen ions* can occur with excessive breakdown of fatty acids, anaerobic glucose breakdown (*lactic acidosis*), and excessive intake of acids. Excessive breakdown of fatty acids occurs with diabetic ketoacidosis or starvation. When insufficient glucose is available for fuel, the body breaks down fats (lipids). The products of excessive fatty acid breakdown are strong acids (*ketoacids*), which release large amounts of hydrogen ions.

Lactic acidosis occurs when cells use glucose without adequate oxygen (*anaerobic metabolism*); glucose then is incompletely broken down and forms lactic acid. This acid releases hydrogen ions, causing acidosis. Lactic acidosis occurs whenever the body has too little oxygen to meet metabolic oxygen demands (e.g., heavy exercise, seizure activity, reduced oxygen).

Excessive intake of acids floods the body with hydrogen ions. Agents that cause acidosis when ingested in excess include ethyl alcohol, methyl alcohol, and acetylsalicylic acid (aspirin).

*Underelimination of hydrogen ions* leads to acidosis when hydrogen ions are produced at the normal rate but are not removed at the same rate they are produced. Most hydrogen ion loss occurs through the lungs and the kidneys. Kidney failure causes acidosis when the kidney tubules cannot secrete hydrogen ions into the urine and they are retained. Severe lung problems also can result in retention of CO<sub>2</sub> with a corresponding retention of hydrogen ions.

*Underproduction of bicarbonate ions* (base deficit) leads to acidosis when hydrogen ion production and removal are normal but too few bicarbonate ions are present to balance the hydrogen ions. Because bicarbonate is made in the kidneys and pancreas, kidney failure and impaired liver or pancreatic function can cause a base-deficit acidosis.

*Overelimination of bicarbonate ions* (base deficit) leads to acidosis when hydrogen ion production and removal are normal but too many bicarbonate ions have been lost. One cause of base deficit acidosis is diarrhea.

## Respiratory Acidosis

Respiratory acidosis results when respiratory function is impaired and the exchange of oxygen (O<sub>2</sub>) and carbon dioxide (CO<sub>2</sub>) is reduced. This problem causes CO<sub>2</sub> retention, which leads to the same increase in hydrogen ion levels and acidosis (McCance et al., 2014). (See the carbonic anhydrase equation in Fig. 12-7.)

Unlike metabolic acidosis, respiratory acidosis results from only one cause—retention of CO<sub>2</sub>, causing increased production of free hydrogen ions. Table 12-2 lists the four types of respiratory problems and their possible causes.

*Respiratory depression* results from depressed function of the brainstem neurons that trigger breathing movements. This lowered rate and depth of breathing leads to poor gas exchange and retention of carbon dioxide. Common causes include anesthetic agents, opioids, and poisons. Physical respiratory depression occurs when respiratory neurons are damaged or destroyed by trauma or when problems in the brain increase the intracranial pressure. Problems causing cerebral edema and respiratory depression include brain tumors, cerebral aneurysm, stroke, and fluid overload.

*Inadequate chest expansion* reduces gas exchange and leads to acidosis. Chest expansion can be restricted by skeletal trauma or deformities, respiratory muscle weakness, or external constriction. Respiratory muscle weakness, caused by electrolyte imbalances, fatigue, muscular dystrophy, muscle damage, or muscle breakdown, reduces chest movement. External conditions such as casts, tight scar tissue around the chest, obesity, and the internal condition of ascites can restrict chest movement.

*Airway obstruction* prevents air movement into and out from the lungs (*ventilation*) and leads to poor gas exchange, CO<sub>2</sub> retention, and acidosis. External obstruction can be caused by clothing, neck edema, and local lymph node enlargement. Internal obstruction can be caused by aspiration of foreign objects, bronchoconstriction, mucus, and edema.

*Reduced alveolar-capillary diffusion* causes poor gas exchange and leads to CO<sub>2</sub> retention and acidosis. Disorders that reduce diffusion include pneumonia, pneumonitis, tuberculosis, emphysema, acute respiratory distress syndrome, chest trauma, pulmonary emboli, pulmonary edema, and drowning.

In addition to pathologic conditions, improper mechanical ventilation can cause respiratory acidosis. If either the tidal volume or the number of ventilations per minute is set too low, the patient can develop respiratory acidosis because the ventilations are not sufficient to rid the body of excess CO<sub>2</sub> (Lian, 2013).

## Combined Metabolic and Respiratory Acidosis

Metabolic and respiratory acidosis can occur at the same time. Uncorrected acute respiratory acidosis always leads to poor oxygenation and lactic acidosis (McCance et al., 2014). For example, an adult who has diabetic ketoacidosis and chronic obstructive pulmonary disease has a combined metabolic and respiratory acidosis. Combined acidosis is more severe than either metabolic acidosis or respiratory acidosis alone.

## ❖ **Interprofessional Collaborative Care**

Episodes of acidosis that are severe enough to require intervention are usually managed in an acute care setting. Patients are discharged from the hospital when ACID-BASE BALANCE is restored. For patients who are at continuing risk for acidosis, especially respiratory acidosis, management interventions must be continued in the home or other residential setting.

## ◆ **Assessment: Noticing**

### **History.**

Collect data about risk factors related to the development of acidosis. Information about age, nutrition, and current symptoms is especially important.

Older adults are more at risk for problems leading to acid-base imbalance, including cardiac, kidney, or pulmonary impairment (Touhy & Jett, 2016). They also may be taking drugs that disrupt ACID-BASE BALANCE, especially diuretics and aspirin. Ask about specific risk factors such as any type of breathing problem, kidney failure, diabetes mellitus, diarrhea, pancreatitis, and fever.

Obtain a detailed nutrition history to determine total caloric intake and the proportions of carbohydrates, fats, and proteins ingested. Ask whether the patient has fasted or followed a strict diet within the past week.

Ask about headaches, behavior changes, increased drowsiness, reduced alertness, reduced attention span, lethargy, anorexia, abdominal distention, nausea or vomiting, muscle weakness, or increased fatigue. Ask the patient to relate activities of the previous 24 hours to identify activity intolerance, behavior changes, and fatigue. Because the central nervous system is often depressed in acidosis, you may need to obtain this information from the patient's family.

### **Physical Assessment/Signs and Symptoms.**

Symptoms of acidosis are similar whether the cause is metabolic or respiratory (Chart 12-3). Acidosis reduces the ability of excitable membranes to respond appropriately, especially in cardiovascular tissue, neurons, skeletal muscle, and GI smooth muscle.

## ▶ **Chart 12-3**

### **Key Features**

#### **Acidosis**

#### **Cardiovascular Signs and Symptoms**

- Delayed electrical conduction:
- Ranges from bradycardia to heart block
- Tall T waves
- Widened QRS complex
- Prolonged PR interval
- Hypotension
- Thready peripheral pulses

#### **Central Nervous System Signs and Symptoms**

- Depressed activity (lethargy, confusion, stupor, coma)

## Neuromuscular Signs and Symptoms

- Hyporeflexia
- Skeletal muscle weakness
- Flaccid paralysis

## Respiratory Signs and Symptoms

- Kussmaul respirations (in metabolic acidosis with respiratory compensation)
- Variable respirations (generally ineffective in respiratory acidosis)

## Integumentary Signs and Symptoms

- Warm, flushed, dry skin in metabolic acidosis
- Pale-to-cyanotic and dry skin in respiratory acidosis

*Cardiovascular changes* are first seen with mild acidosis and are more severe as the condition worsens. Early changes include increased heart rate and cardiac output. With worsening acidosis or with acidosis and **hyperkalemia** (elevated blood potassium levels), heart rate decreases, T waves become tall and peaked, and QRS complexes are widened. Peripheral pulses may be hard to find and are easily blocked. Hypotension occurs with vasodilation.

## Nursing Safety Priority QSEN

### Critical Rescue

Assess the cardiovascular system **first** in any patient at risk for acidosis because acidosis can lead to cardiac arrest from the accompanying hyperkalemia. If cardiac changes are present, respond by reporting these changes immediately to the health care provider.

*Central nervous system (CNS) changes* include depression of CNS function. Problems may range from lethargy to confusion, especially in older patients. As acidosis worsens, the patient may become unresponsive.

*Neuromuscular changes* include reduced muscle tone and deep tendon reflexes as a result of the accompanying hyperkalemia. Assess arm muscle strength by having the patient squeeze your hand. Assess leg muscle strength by having the patient push both feet against a flat surface (such as a box or a board) while you apply resistance to the opposite side of the surface. Muscle weakness is bilateral and can progress to paralysis.

*Respiratory changes* may cause the acidosis and can be caused by the acidosis (Larkin & Zimmanck, 2015). Assess the patient's rate, depth, and ease of breathing. Use pulse oximetry to determine how well oxygen is delivered to the peripheral tissues.

If acidosis is metabolic in origin, the rate and depth of breathing increase as the hydrogen ion level rises. Breaths are deep and rapid and not under voluntary control, a pattern called **Kussmaul respiration**.

If acidosis is caused by respiratory problems, breathing efforts are reduced. Respirations are usually shallow and rapid. Muscle weakness makes this problem worse.

*Skin changes* occur with metabolic or respiratory acidosis. With metabolic acidosis breathing is unimpaired, the rate is increased, and CO<sub>2</sub> is lost. This causes vasodilation and makes the skin and mucous membranes warm, dry, and pink. With respiratory acidosis breathing is ineffective, and skin and mucous membranes are pale to cyanotic.

### Psychosocial Assessment.

*Cognitive changes may be the first signs of acidosis.* Assess the patient's mental status for awareness of

time, place, and person (see [Chapter 41](#)). Determine whether the patient is able to perform simple cognitive tasks such as counting backward by threes. Behavior changes may accompany acidosis. Observe and document the patient's behavior by description (objectively) rather than by interpretation (subjectively). Ask family members if the patient's behavior is typical for him or her and establish a baseline for comparison with later assessment findings.

### Laboratory Assessment.

Arterial blood pH is the laboratory value used to confirm acidosis. Acidosis is present when arterial blood pH is less than 7.35. However, this test alone does not indicate what is causing the acidosis. Symptoms of metabolic acidosis and respiratory acidosis are similar, but their treatments are different. *Therefore it is critical to obtain and interpret other laboratory data such as arterial blood gas (ABG) values and blood levels of electrolytes (Chart 12-4).*

### Chart 12-4

## Laboratory Profile

### Acid-Base Imbalances (Uncompensated)

LABORATORY VALUE CHANGES							
IMBALANCE	pH	HCO <sub>3</sub> <sup>-</sup>	PaO <sub>2</sub>	PaCO <sub>2</sub>	K <sup>+</sup>	Ca <sup>2+</sup>	Cl <sup>-</sup>
Metabolic acidosis	↓	↓	∅	∅ and ↓	↑	∅	∅ and ↑
Respiratory acidosis	↓	∅ or ↑	↓	↑	↑	∅	↑ and ↓
Combined acidosis	↓	↓	↓	↑	↑	∅	↑
Metabolic alkalosis	↑	↑	∅	∅ and ↑	↓	↓	↓
Respiratory alkalosis	↑	∅ or ↑	∅	↓	↓	↓	↑
Combined alkalosis	↑	↑	∅	↓	↓	↓	↓

↑, Above normal; ↓, below normal; ↑ ↓, value can increase or decrease depending on other factors; ∅, normal; Ca<sup>2+</sup>, calcium ions; Cl<sup>-</sup>, chloride ions; PaCO<sub>2</sub>, partial pressure of arterial carbon dioxide; PaO<sub>2</sub>, partial pressure of arterial oxygen; HCO<sub>3</sub><sup>-</sup>, bicarbonate ions; K<sup>+</sup>, potassium ions.

*Metabolic acidosis* is reflected by several changes in ABG values. The pH is low (<7.35) because buffering and respiratory compensation are not adequate to keep the amount of free hydrogen ions at a normal level. The bicarbonate level is low (<21 mEq/L [mmol/L]). It is low because (1) bicarbonate has been lost, causing a base-deficit acidosis; (2) bicarbonate production is inadequate, causing a base-deficit acidosis; or (3) bicarbonate may be bound to other substances. The partial pressure of arterial oxygen (PaO<sub>2</sub>) is normal because gas exchange is not impaired. The partial pressure of arterial carbon dioxide (PaCO<sub>2</sub>) is normal or even slightly decreased because gas exchange is adequate and carbon dioxide retention is not a factor.

The serum potassium level is often high in acidosis as the body attempts to maintain electroneutrality during buffering. [Fig. 12-12](#) shows the movement of potassium ions as serum pH changes. As the blood hydrogen ion level rises, some of the excess hydrogen ions enter red blood cells for intracellular buffering. The movement of hydrogen ions into the cells creates an excess of positive ions inside the cells. To balance these extra positive charges, an equal number of potassium ions (that also have a positive charge) move from the cells into the blood. This increases the blood potassium level, causing hyperkalemia ([Gooch, 2015](#)).

**FIG. 12-12** Movement of potassium ( $K^+$ ) in response to changes in the extracellular fluid hydrogen ion ( $H^+$ ) concentration.

*Respiratory acidosis* is reflected by several changes in ABG values. The pH is low ( $<7.35$ ) because of the increased amount of free hydrogen ions in the blood. Buffering and kidney compensation are not adequate to keep the amount of free hydrogen ions at a normal level. If the kidneys partially compensate for this acidosis, pH is low but not as abnormal as could be expected with the degree of  $CO_2$  retention.

The partial pressure of arterial oxygen ( $PaO_2$ ) is low, and the partial pressure of arterial carbon dioxide ( $PaCO_2$ ) is high because the pulmonary problem impairs gas exchange, causing poor oxygenation and  $CO_2$  retention. (*The hallmarks of respiratory acidosis are a decreasing  $PaO_2$  coupled with a rising  $PaCO_2$ .*) Because carbon dioxide diffuses more easily across the alveolar membrane than oxygen, a decreased  $PaO_2$  usually occurs before an increased  $PaCO_2$ .

The serum bicarbonate level is variable. A patient with rapid onset of respiratory acidosis often has a normal bicarbonate level because kidney compensation has not started. When the acidosis persists for 24 hours or longer, kidney compensation increases the levels of bicarbonate. Chronic respiratory acidosis is indicated by an elevated bicarbonate level and increased  $PaCO_2$ .

Serum potassium levels are elevated in acute respiratory acidosis. They are normal or low in chronic respiratory acidosis when kidney compensation is present.

## NCLEX Examination Challenge 12-2

### Physiological Integrity

Which blood laboratory values does the nurse need to evaluate to determine whether the client's acidosis has a respiratory origin or a metabolic origin? **Select all that apply.**

- A. Calcium
- B.  $HCO_3^-$
- C. Lactic acid (lactate)
- D.  $PaCO_2$
- E.  $PaO_2$
- F. pH
- G. Potassium

### ◆Analysis: Interpreting

Patients experiencing acidosis have problems associated with the decreased function of excitable membranes. For metabolic acidosis these problems include hypotension and decreased perfusion, impaired memory and cognition, and increased risk for falls. For patients who have respiratory acidosis in addition to the general problems, life-threatening problems are related to the cause of the respiratory impairment. The priority collaborative problem for the patient experiencing respiratory acidosis is:

1. Decreased gas exchange due to underlying pulmonary disease

### ◆Planning and Implementation: Responding

Interventions for acidosis focus on correcting the underlying problem and monitoring for changes. Remember that acidosis is not a disease. It is a symptom of another health problem. To ensure appropriate interventions, first identify the specific type of acidosis present.

#### Metabolic Acidosis.

Interventions for metabolic acidosis include hydration and drugs or treatments to control the problem causing the acidosis. For example, if the acidosis is a result of diabetic ketoacidosis, insulin is given to correct the hyperglycemia and halt the production of ketone bodies. Rehydration and antidiarrheal drugs are given if the acidosis is a result of prolonged diarrhea. *Bicarbonate is administered only if serum bicarbonate levels are low and the pH is less than 7.2 (Ellis, 2015).*

*Nursing priorities* include continuously monitoring the patient for indications either that he or she is responding to the treatment or the acidosis is becoming worse. The cardiovascular and skeletal muscle systems are sensitive to acidosis and are the most important systems to monitor. Interpreting ABG results is an important part of monitoring.

#### Respiratory Acidosis

##### Improving Gas Exchange

##### Planning: Expected Outcomes.

The patient being managed for respiratory acidosis is expected to have a reduction in acidosis signs and symptoms. Indications include:

- Arterial pH approaching 7.35
- PaO<sub>2</sub> levels above 90 mm Hg
- PaCO<sub>2</sub> levels below 45 mm Hg or at least 15 mm Hg below the patient's admission level

##### Interventions.

Interventions for the patient who has a condition that causes him or her to remain at continued risk include drug therapy, oxygen therapy, pulmonary hygiene (positioning and breathing techniques), and ventilatory support. These interventions are the same as those used for a patient who has chronic obstructive pulmonary disease (COPD), which is the most common health problem associated with continuing risk for respiratory acidosis. A brief overview of these interventions is provided here. For in-depth discussion of these interventions, see [Chapter 30](#) under the Gas Exchange Exemplar: Chronic Obstructive Pulmonary Disease.

*Drug therapy* is focused on improving ventilation and gas exchange rather than directly on altering pH. Drug categories useful for respiratory acidosis include bronchodilators, anti-inflammatories, and mucolytics.

*Oxygen therapy* helps promote gas exchange for patients with respiratory acidosis. Carefully monitor oxygen saturation levels to ensure that the lowest flow of oxygen that prevents hypoxemia is used to avoid oxygen-induced tissue damage.

*Ventilation support* with mechanical ventilation may be needed for patients who cannot keep their oxygen saturation at 90% or who have respiratory muscle fatigue. [Chapter 32](#) discusses the nursing care needs of patients who are being mechanically ventilated.

*Preventing complications* is a nursing priority when caring for a patient with respiratory acidosis. Monitoring breathing status hourly and intervening when changes occur are critical in preventing

complications. Listen to breath sounds and assess how easily air moves into and out of the lungs. Check for any muscle retractions, the use of accessory muscles (especially the neck muscles [sternocleidomastoids]), and whether breathing produces a grunt or wheeze that can be heard without a stethoscope. Assess nail beds and oral membranes for cyanosis (a late finding).

### Care Coordination and Transition Management

Because respiratory acidosis is a symptom or complication of another health problem, most often COPD, care during the acute phase occurs in a hospital setting. Ongoing management for continuing risk is the same as for COPD. See [Chapter 30](#) for a detailed discussion of the care coordination needed for this problem.

#### ◆Evaluation: Reflecting

Depending on the cause of the respiratory acidosis and the patient's continuing risk, some patients may not return to full ACID-BASE BALANCE, even with meticulous care. Indications that the patient's underlying disease process is well managed and that the imbalance is reduced include the expected outcomes that he or she:

- Maintains adequate gas exchange
- Has an arterial pH above 7.2 and closer to 7.35
- Has a PaO<sub>2</sub> level above 90 mm Hg or at least 10 mm Hg higher than his or her admission level
- Has a PaCO<sub>2</sub> levels below 45 mm Hg or at least 15 mm Hg below his or her admission level

## Clinical Judgment Challenge 12-1

### Patient-Centered Care; Safety; Evidence-Based Practice QSEN

A patient who comes to the emergency department for a sports injury suddenly goes into cardiac arrest and has neither a pulse nor any respiratory effort. He is successfully resuscitated within 5 minutes of the initial arrest.

1. Which specific type of impairment of acid-base balance would this situation cause? Provide a rationale for your choice.
2. Should you prepare to administer intravenous sodium bicarbonate? Why or why not?
3. Should oxygen be applied to this patient in the initial post-resuscitation period? Why or why not?

## Alkalosis

### ❖Pathophysiology

In patients with alkalosis, the ACID-BASE BALANCE of the blood is disturbed and has an excess of bases, especially bicarbonate (HCO<sub>3</sub><sup>-</sup>). The amount or strength of the bases is greater than normal compared with the amount of the acids. Alkalosis is a *decrease* in the free hydrogen ion level of the blood and is reflected by an arterial blood pH *above* 7.45. Like acidosis, alkalosis is not a disease but rather is an indication of a problem. It can be caused by metabolic problems, respiratory problems, or both ([Table 12-3](#)).

**TABLE 12-3**

**Common Causes of Alkalosis**

PATHOLOGY	CONDITION
<b>Metabolic Alkalosis</b>	
Increase of base components	Oral ingestion of bases: Antacids Parenteral base administration: Blood transfusion Sodium bicarbonate Total parenteral nutrition
Decrease of acid components	Prolonged vomiting Nasogastric suctioning Hypercortisolism Hyperaldosteronism

	Thiazide diuretics
<b>Respiratory Alkalosis</b>	
Excessive loss of carbon dioxide	Hyperventilation, fear, anxiety Mechanical ventilation Salicylate toxicity High altitudes Shock Early-stage acute pulmonary problems

Alkalosis can result from an actual or relative increase in the amount or strength (or both) of bases. In an actual base excess, alkalosis occurs when base (usually bicarbonate) is either overproduced or undereliminated.

In *relative* alkalosis the actual amount or strength of bases does not increase; but the amount of the acids decreases, creating an *acid deficit*. A relative base-excess alkalosis (actual acid deficit) results from an overelimination or underproduction of acids (Fig. 12-13).

The problems of alkalosis are serious and can be life threatening. Management focuses on correcting the cause after identifying whether the alkalosis origin is respiratory or metabolic.

Whether metabolic, respiratory, or both, alkalosis affects specific functions. The pathologic effects are caused by the electrolyte imbalances that occur in response to decreased blood cation (positively charged particles) levels. Most problems of alkalosis are related to increased stimulation of the nervous, neuromuscular, and cardiac systems.

*Metabolic alkalosis* is an acid-base imbalance caused by either an increase of bases (base excess) or a decrease of acids (acid deficit). Base excesses are caused by excessive intake of bicarbonates, carbonates, acetates, and citrates. Excessive use of bicarbonate-containing antacids can cause a metabolic alkalosis. Other base excesses can occur during medical treatments such as citrate excesses during massive blood transfusions and IV sodium bicarbonate given to correct acidosis. The hallmark of a base excess acidosis is an ABG result with an elevated pH and an elevated bicarbonate level, along with normal oxygen and carbon dioxide levels.

Acid deficits can be caused by disease processes or medical treatment. Disorders causing acid deficits include prolonged vomiting, excess cortisol, and hyperaldosteronism. Treatments that promote acid loss causing metabolic alkalosis include thiazide diuretics and prolonged gastric suctioning.

*Respiratory alkalosis* is usually caused by an excessive loss of CO<sub>2</sub> through hyperventilation (rapid respirations). Patients may hyperventilate in response to anxiety, fear, or improper settings on mechanical ventilators. Hyperventilation can also result from direct stimulation of central respiratory centers because of fever, central nervous system lesions, and salicylates. The hallmark of respiratory alkalosis is an ABG result with an elevated pH coupled with a low carbon dioxide level. Usually the oxygen and bicarbonate levels are normal.

### ❖ Interprofessional Collaborative Care

#### ◆ Assessment: Noticing

Symptoms of problems with ACID-BASE BALANCE regulation are the same for metabolic and respiratory alkalosis. Many symptoms are the result of the low calcium levels (**hypocalcemia**) and low potassium levels (**hypokalemia**) that usually occur with alkalosis (see Fig. 12-12). These problems change the function of the nervous, neuromuscular, cardiac, and respiratory systems (Chart 12-5).

### ▶ Chart 12-5

## Key Features

## Alkalosis

### Central Nervous System Signs and Symptoms

- Increased activity
- Anxiety, irritability, tetany, seizures
- Positive Chvostek's sign
- Positive Trousseau's sign
- Paresthesias

### Neuromuscular Signs and Symptoms

- Hyperreflexia
- Muscle cramping and twitching
- Skeletal muscle weakness

### Cardiovascular Signs and Symptoms

- Increased heart rate
- Normal or low blood pressure
- Increased digitalis toxicity

### Respiratory Signs and Symptoms

- Increased rate and depth of ventilation in respiratory alkalosis
- Decreased respiratory effort associated with skeletal muscle weakness in metabolic alkalosis

*Central nervous system (CNS) changes* are caused by overexcitement of the nervous systems. Patients have dizziness, agitation, confusion, and hyperreflexia, which may progress to seizures. Tingling or numbness may occur around the mouth and in the toes. Other indicators of alkalosis with hypocalcemia are positive Chvostek's and Trousseau's signs (see [Chapter 11](#)).

*Neuromuscular changes* are related to the hypocalcemia and hypokalemia that occur with alkalosis. Nervous system activity increases, causing muscle cramps, twitches, and "charley horses." Deep tendon reflexes are hyperactive. **Tetany** (continuous contractions) of muscle groups also may be present. Tetany is painful and indicates a rapidly worsening condition.

Skeletal muscles may contract as a result of nerve stimulation, but they become weaker because of the hypokalemia. Handgrip strength decreases, and the patient may be unable to stand or walk. Respiratory efforts become less effective as the respiratory muscles weaken.

*Cardiovascular changes* occur because alkalosis increases myocardial irritability, especially when accompanied by hypokalemia. Heart rate increases, and the pulse is thready. When decreased blood volume is also present, the patient may have severe hypotension. The hypokalemia increases heart sensitivity to digoxin, which increases the risk for digoxin toxicity.

*Respiratory changes*, especially increases in the rate of breathing, are the main causes of respiratory alkalosis. Although the volume of air inhaled and exhaled with each breath is nearly normal, the total volume of air inhaled and exhaled each minute rises with the increased respiratory rate. The increased minute volume may be caused by anxiety or physiologic changes.

Arterial blood pH greater than 7.45 confirms alkalosis, but this test alone does not identify its cause. Because the symptoms of metabolic alkalosis and respiratory alkalosis are similar, it is critical to obtain additional laboratory data, especially arterial blood gas (ABG) values and specific serum electrolyte levels (see [Chart 12-4](#)) ([Blevins, 2014](#)).

## NCLEX Examination Challenge 12-3

### Health Promotion and Maintenance

A client asks why the provider has recommended that he breathe into a paper bag for several minutes when his anxiety disorder causes him to hyperventilate. What is the nurse's **best** response?

- A. "Even your exhaled breath still has some oxygen in it, and rebreathing this air ensures that you won't pass out from lack of oxygen."
- B. "When you breathe fast, you can lose too much carbon dioxide, and rebreathing this air keeps you from becoming dizzy and falling."
- C. "Rapid breathing can lead to dehydration from excessive fluid loss, and rebreathing this air helps you retain fluid in the form of vapor moisture."
- D. "Breathing into the bag for several minutes helps you become distracted from whatever is making you anxious and allows you to calm down."

### ◆Interventions: Responding

Interventions are planned to prevent further losses of hydrogen, potassium, calcium, and chloride ions; to restore fluid balance; to monitor changes; and to provide for *patient safety*. Treatments that may have caused alkalosis (e.g., prolonged gastric suctioning, excessive infusion of certain IV solutions, drugs that promote hydrogen ion excretion) are modified or stopped. Drug therapy is prescribed to resolve the causes of alkalosis and to restore normal fluid, electrolyte, and ACID-BASE BALANCE. For example, the patient with metabolic alkalosis caused by diuretic therapy receives fluid and electrolyte replacement, and the diuretic therapy is adjusted or stopped. Antiemetic drugs are prescribed for vomiting. Monitor the patient's progress and adjust fluid and electrolyte therapy. Monitor electrolytes daily until they return to near normal.

During correction of alkalosis, a nursing care priority is prevention of injury from falls. The patient with alkalosis has hypotension and muscle weakness, which increase the risk for falls, especially among older adults. Implement the general falls prevention nursing interventions and the high-risk falls prevention nursing interventions outlined in Chart 2-4.

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Assess the cardiovascular system first in any patient at risk for acidosis because acidosis can lead to cardiac arrest from the accompanying hyperkalemia. **QSEN: Safety**
- Assess the airway of any patient who has acute respiratory acidosis. **QSEN: Safety**
- Assess heart rate and rhythm at least every 2 hours for any patient with an acid-base imbalance. **QSEN: Safety**
- Monitor the neurologic status at least every 2 hours in patients being treated for a problem with ACID-BASE BALANCE. **QSEN: Safety**
- Assess the ACID-BASE BALANCE of any patient with new-onset muscle weakness. **QSEN: Safety**
- Use fall precautions for any patient with a problem in ACID-BASE BALANCE. **QSEN: Safety**

### Health Promotion and Maintenance

- Teach patients to take drugs as prescribed, especially diuretics, antihypertensives, and cardiac drugs. **QSEN: Patient-Centered Care**
- Instruct patients at continuing risk for respiratory acidosis to stop smoking. **QSEN: Patient-Centered Care**

### Psychosocial Integrity

- Assess the gas exchange status of any patient with acute confusion. **QSEN: Patient-Centered Care**
- Perform a mental status assessment in any patient with or at risk for problems of ACID-BASE BALANCE. **QSEN: Patient-Centered Care**
- Assist patients who have anxiety-induced respiratory alkalosis to identify causes of anxiety. **QSEN: Patient-Centered Care**

### Physiological Integrity

- Be aware of how the following principles, processes, and mechanisms influence the regulation of ACID-BASE BALANCE:
  - The normal pH of the body's extracellular fluids (including blood) is 7.35 to 7.45.
  - The more hydrogen ions present, the more acidic the fluid; the fewer hydrogen ions present, the more alkaline the fluid.
  - pH values below 7.35 indicate acidosis; pH values above 7.45 indicate alkalosis.
  - Anything that increases the CO<sub>2</sub> level in the blood increases the hydrogen ion content and lowers the pH.
  - Acids are normally formed in the body as a result of metabolism.
  - Chemical blood buffers are the immediate way that acid-base imbalances are corrected.
  - The lungs control the amount of CO<sub>2</sub> that is retained or exhaled.
  - The kidneys regulate the amount of hydrogen and bicarbonate ions that are retained or excreted by the body.
  - If a lung problem causes retention of carbon dioxide, the healthy kidney compensates by increasing the amount of bicarbonate that is produced and retained.
  - Acidosis reduces the excitability of cardiovascular muscle, neurons, skeletal muscle, and GI smooth muscle.
  - Alkalosis increases the sensitivity of excitable tissues, allowing them to over-respond to normal

stimuli and respond even without stimulation.

- Check the serum potassium level for any patient who has acidosis. **QSEN: Evidence-Based Practice**
- Monitor arterial blood gas (ABG) values to evaluate the effectiveness of therapy for acid-base imbalances. **QSEN: Patient-Centered Care**

## CHAPTER 13

# Concepts of Infusion Therapy

Jeanette Spain Adams

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concept for this chapter is FLUID AND ELECTROLYTE BALANCE.**  
**The interrelated concept for this chapter is TISSUE INTEGRITY.**

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Prevent infusion administration errors by following best practices that ensure patient and staff safety.
2. Describe the benefits and limitations of selected safety-enhancing technologies used for infusion therapy.
3. Identify the evidence-based guidelines for prevention of intravenous (IV) catheter-related bloodstream infection (CRBSI).

### Health Promotion and Maintenance

4. Describe the special needs and care for older adults receiving infusion therapy, including careful monitoring of FLUID AND ELECTROLYTE BALANCE.
5. Teach the patient and family about the type and care related to the patient's infusion therapy.

### Physiological Integrity

6. Explain how to check the accuracy of prescriptions for infusion fluids and drug therapy to promote patient safety.
7. Identify the appropriate veins for peripheral IV catheter insertion.
8. Differentiate types of vascular access devices (VADs) used for peripheral and central IV therapy.
9. Outline evidence-based practice for inserting peripheral VADs.
0. Assess the patient's infusion site frequently for local complications, including impaired TISSUE INTEGRITY.
  1. Prioritize nursing interventions for maintaining an infusion system.
  2. Use clinical judgment to assess, prevent, document, and manage systemic complications related to infusion therapy and VADs.
  3. Describe nursing care associated with intra-arterial, intraperitoneal, subcutaneous, intraosseous, and intraspinal infusion therapy.

**Infusion therapy** is the delivery of medications in solution and fluids by parenteral (piercing of skin or mucous membranes) route through a wide variety of catheter types and locations using multiple procedures. Intravenous (IV) therapy is the most common route for infusion therapy. It delivers solutions directly into the veins of the vascular system. This chapter focuses on access for and administration of all types of infusion therapy.

## Overview

Infusion therapy is delivered in all health care settings, including hospitals, home care, ambulatory care clinics, primary health care providers' offices, and long-term care facilities. The most common reasons for using infusion therapy are to:

- Maintain FLUID BALANCE or correct fluid imbalance
- Maintain ELECTROLYTE or acid-base BALANCE or correct electrolyte or acid-base imbalance
- Administer medications
- Replace blood or blood products

IV therapy is the most common invasive therapy administered to hospitalized patients. Advances in medicine and technology have made it possible for people with chronic diseases such as diabetes mellitus, chronic kidney disease, and malabsorption syndromes to live long and productive lives. These patients often depend on long-term infusion therapy of some kind. They often have very poor vascular integrity; therefore accessing their peripheral veins takes a high level of skill.

Having a specialized team of infusion nurses to initiate and maintain infusion therapy has been recommended as best practice by the Centers for Disease Control and Prevention (CDC) to reduce complications of infusion therapy. These teams have demonstrated value in cost savings, patient satisfaction, and patient outcomes.

Infusion nurses may perform any or all of these activities:

- Develop evidence-based policies and procedures.
- Insert and maintain various types of peripheral, midline, and central venous catheters and subcutaneous and intraosseous accesses.
- Monitor patient outcomes of infusion therapy.
- Educate staff, patients, and families regarding infusion therapy.
- Consult on product selection and purchasing decisions.
- Provide therapies such as blood withdrawal, therapeutic phlebotomy, hypodermoclysis, intraosseous infusions, and administration of medications.

The registered nurse (RN) generalist is taught to insert peripheral IV lines; most institutions have a process for demonstrating competency for this skill. Depending on the state's nurse practice act, licensed practical/vocational nurses (LPNs/LVNs) and technicians may be trained and verified competent to perform the skill of peripheral IV insertion and assist with infusions. *The RN is ultimately accountable for all aspects of infusion therapy and delegation of associated tasks (Infusion Nurses Society [INS], 2016; Weinstein & Hagle, 2014).*

The Infusion Nurses Society (INS) publishes guidelines and standards of practice for policy and procedure development in all health care settings. These standards establish the criteria for all nurses delivering infusion therapy. The Infusion Nurses Certification Corporation (INCC) offers a written certification examination. Nurses who successfully complete this examination have mastered an advanced body of knowledge in this specialty and may use the initials *CRNI*, which stand for *certified registered nurse infusion*.

## Types of Infusion Therapy Fluids

Many types of parenteral fluids are used for infusion therapy. These fluids are IV solutions, including parenteral nutrition, blood and blood components, biologics, and pharmacological therapy.

### Intravenous Solutions

More than 200 IV fluids (solutions) are available that meet the requirements established by the United States Pharmacopeia (USP). Each solution is classified by its tonicity (concentration) and pH. Tonicity is typically categorized by comparison with normal blood plasma as osmolarity (mOsm/L). As discussed in [Chapter 11](#), normal serum osmolarity for adults is between 270 and 300 mOsm/L. Parenteral solutions within that normal range are **isotonic**; fluids greater than 300 mOsm/L are **hypertonic**; and fluids less than 270 mOsm/L are **hypotonic**.

When an *isotonic infusate* (solution that is infused into the body) is used, water does not move

into or out of the body's cells. Therefore patients, especially older adults, receiving isotonic solutions are at risk for fluid overload (see [Chapter 11](#)). *Hypertonic* solutions are used to correct altered FLUID AND ELECTROLYTE BALANCE and acid-base imbalances by moving water out of the body's cells and into the bloodstream. Electrolytes and other particles also move across cell membranes across a concentration gradient (from higher concentration to lower concentration). Parenteral nutrition solutions are hypertonic (see [Chapter 60](#)). Instead of moving water out of cells, *hypotonic* infusates move water into cells to expand them. Patients receiving either hypertonic or hypotonic fluids are at risk for phlebitis and infiltration. **Phlebitis** is the inflammation of a vein caused by mechanical, chemical, or bacterial irritation. **Infiltration** occurs when IV solution leaks into the tissues around the vein.

The pH of IV solutions is a measure of acidity or alkalinity and usually ranges from 3.5 to 6.2. Extremes of both osmolarity and pH can cause vein damage, leading to phlebitis and **thrombosis** (blood clot in the vein). Thus fluids and medications with a pH value less than 5.0 and more than 9.0 and with an osmolarity more than 600 mOsm/L are best infused in the central circulation where greater blood flow provides adequate hemodilution ([McClelland, 2014](#)). For example, total parenteral nutrition (TPN) solutions have an osmolarity greater than 1400 mOsm/L. TPN should not be infused in peripheral circulation because it can damage blood cells and the endothelial lining of the veins and decrease perfusion.

## Nursing Safety Priority QSEN

### Drug Alert

Drugs such as amiodarone (Cordarone), vancomycin (Vancocin), and ciprofloxacin (Cipro IV) are venous irritants that have a pH less than 5.0. Phlebitis occurs when patients require long-term infusion of these drugs in peripheral circulation. Drugs with vasoconstrictive action (e.g., dopamine or chemotherapeutic agents [e.g., vinblastine]) are **vesicants** (chemicals that damage body tissue on direct contact) that can cause extravasation. **Extravasation** results in severe TISSUE INTEGRITY impairment as manifested by blistering, tissue sloughing, or necrosis from infiltration into the surrounding tissues. (See the Complications of Intravenous Therapy section for further explanation and [Chapter 22](#) for more detail.) Monitor the IV insertion site carefully for early manifestations of infiltration, including swelling, coolness, or redness. If any of these symptoms are present, discontinue the drug immediately and notify the infusion therapy team, if available. If an infusion specialist is not available, notify the primary health care provider and remove the IV catheter.

## Blood and Blood Components

Blood transfusion is given by using packed red blood cells, created by removing a large part of the plasma from whole blood. Other available blood components include platelets, fresh frozen plasma, albumin, and several specific clotting factors. Each component has detailed requirements for blood-type compatibility and infusion techniques. **For patient safety, The Joint Commission's (TJC) 2015 National Patient Safety Goals (NPSGs) require agencies to ensure that blood components are properly ordered, handled and dispensed, and administered, and that patients are appropriately monitored. Positive patient identification using two patient identifiers and requiring two qualified health care professionals is essential before any blood or blood component is administered. Automated bar coding can be used for positive patient identification in ambulatory care, acute care, and critical access hospitals, and office-based surgery-accredited programs.**

Most organizations use the International Society of Blood Transfusion (ISBT) universal bar-coding system to ensure the right blood for the right patient ([Fig. 13-1](#)). The ISBT system includes four components that must be present on the blood label both in bar code and in eye-readable format. These four components are (1) a unique facility identifier, (2) the lot number relating to the donor, (3) the product code, and (4) the ABO group and Rh type of the donor. [Chapter 40](#) describes blood and blood product administration in more detail.

**FIG. 13-1** Unit of blood showing the International Society of Blood Transfusion (ISBT) universal bar code for blood transfusions. (From Perry, A., Potter, P., & Ostendorf, W. [2017]. *Clinical nursing skills & techniques* [9th ed.]. St. Louis: Mosby.)

## Drug Therapy

IV drugs provide a rapid therapeutic effect but can lead to immediate serious reactions, called **adverse drug events (ADEs)**. Hundreds of drugs are available for infusion by a variety of techniques. As with all drug administration, nurses must be knowledgeable about drug indications, proper dosage, contraindications, and precautions. IV administration also requires knowledge of appropriate dilution, rate of infusion, pH and osmolarity, compatibility with other IV medications, appropriate infusion site (peripheral versus central circulation), potential for vesicant/irritant effects, and specific aspects of patient monitoring because of its immediate effect. *Regardless of familiarity with the drug, never assume that IV administration is the same as giving that drug by other routes.* New information is continuously being published, and new drugs are rapidly being introduced.

Medication safety is extremely important in all health care settings today. **The Joint Commission's 2014 NPSGs include as a major goal improving the safety of high-alert drugs. Examples of this type of drug are concentrated electrolyte solutions (e.g., potassium chloride), which require restricted access, prominent warnings about the concentration, and storage in a secured location.**

Procedures must be established to prevent errors resulting from look-alike, sound-alike drugs such as Celebrex IV (celecoxib) and Cerebyx (fosphenytoin). Other strategies to reduce errors include limiting available concentrations of drugs and dispensing all drugs, including catheter flush solutions, in single-dose containers. Smart pumps with drug libraries (see [Infusion Systems](#) section), in combination with computer provider (physician, nurse practitioner, physician assistant) order entry (CPOE) and bar-code medication administration (BCMA) systems, use recent technology to help reduce adverse drug events (ADEs). **Electronic medication administration records (MARs) and multiple checks by pharmacists, as required by The Joint Commission's NPSGs, also help reduce errors.**

## Prescribing Infusion Therapy

A prescription for infusion therapy written by an authorized primary health care provider (physician, nurse practitioner, or physician assistant) is necessary before IV therapy begins. To be complete, the prescription for infusion fluids should include:

- Specific type of fluid
- Rate of administration written in milliliters per hour (mL/hr) or the total amount of fluid and the total number of hours for infusion (e.g., 125 mL/hr or 1000 mL/8 hrs)
- Drugs and the specific dose to be added to the solution such as electrolytes or vitamins
- A drug prescription should include:

- Drug name, preferably by generic name
- Specific dose and route
- Frequency of administration
- Time of administration
- Length of time for infusion
- Purpose (required in some health care agencies, especially nursing homes)

Some continuously infused drugs such as those for pain management are prescribed as milligrams per hour. The type and volume of dilution for infusion medications may be included in the prescription or calculated by the infusion pharmacist.

## Nursing Safety Priority QSEN

### Action Alert

Determine that the IV prescription is appropriate for the patient and clarify any questions with the primary health care provider before administration. Be sure to check for the accuracy and completeness of the treatment prescription. An example of an incomplete one is “5% dextrose in water to keep the vein open” (TKO or KVO). This statement does not specify the rate of infusion and is not considered complete.

## Vascular Access Devices

An infusion catheter, also known as a **vascular access device (VAD)**, is a plastic tube placed in a blood vessel to deliver fluids and medications. This catheter should not be confused with the ventricular assist device, also called a VAD. In this chapter VAD refers to vascular access devices. The specific type and purpose of the therapy determine whether the infusion can be given safely through peripheral veins or if the large central veins of the chest are needed. Advances in catheter materials and insertion techniques have radically expanded the types of VADs currently used. This discussion includes the description of each type of catheter used for peripheral and central IV therapy. Seven major types are described:

- Short peripheral catheters
- Midline catheters
- Peripherally inserted central catheters (PICCs)
- Nontunneled percutaneous central venous catheters (CVCs)
- Tunneled catheters
- Implanted ports
- Hemodialysis catheters

Assess the patient's needs for vascular access and choose the device that has the best chance of infusing the prescribed therapy for the required length of time. Depending on the patient and type of VAD to be inserted, a topical anesthetic agent or intradermal lidocaine HCl 1% may be helpful to decrease patient discomfort. Obtain a primary health care provider's prescription and check for patient allergies before administering any anesthetic.

## NCLEX Examination Challenge 13-1

## Safe and Effective Care Environment

A client receiving gentamycin intravenously reports that the peripheral IV insertion site has become painful and reddened. What action will the nurse take **first**?

- A. Report the client's problem to the primary health care provider.
- B. Document findings and actions in the electronic health record.
- C. Change the IV insertion site to a new location.
- D. Stop the infusion of the drug immediately.

## Peripheral Intravenous Therapy

Short infusion catheters are the most commonly used vascular access devices (VADs) for **peripheral IV therapy**. They are usually placed in the veins of the arm. Another catheter used for peripheral IV therapy is a midline catheter.

### Short Peripheral Catheters

**Short peripheral catheters** are composed of a plastic cannula built around a sharp stylet extending slightly beyond the cannula (Fig. 13-2). The stylet (sharp) allows for the venipuncture, and the cannula is advanced into the vein. Once the cannula is advanced into the vein, the stylet is withdrawn. These catheters are designed with a safety mechanism to cover the sharp end of the stylet after it is removed from the patient. The stylet is a hollow-bore, blood-filled needle that carries a high risk for exposure to bloodborne pathogens if needlestick injury occurs. A federal law enacted in 2000 amended the Bloodborne Pathogen Standards from the Occupational Safety and Health Administration (OSHA) requiring the use of catheters with an engineered safety mechanism to prevent needlesticks.

**FIG. 13-2** BD Insyte Autoguard IV catheter. With the push of a button, the needle instantly retracts, reducing the risk for accidental needlestick injuries. (Courtesy and © Becton, Dickinson and Company.)

### Insertion and Placement Methods

Short peripheral catheters are most often inserted into superficial veins of the forearm using sterile technique. In emergent situations these catheters can also be used in the external jugular vein of the neck. *Avoid the use of veins in the lower extremities of adults, if possible, because of an increased risk for deep vein thrombosis and infiltration.*

Short catheters range in length from  $\frac{3}{4}$  inch to  $1\frac{1}{4}$  inch, with gauge sizes from 26 gauge (the smallest) to 14 gauge (large bore). Choose the smallest-gauge catheter capable of delivering the prescribed therapy with consideration of all the contributing factors, including expected duration, vascular characteristics, and comorbidities (INS, 2016). Current design improves the fluid flow through the catheter while using a smaller gauge and thereby decreases the possibility of vein irritation from a large catheter. For example, a thin-walled 24-gauge Insyte catheter has about the same flow-rate ability as a 22-gauge non-thin-walled Angiocath. Larger gauge sizes allow for faster flow rates but also cause phlebitis more often. Table 13-1 lists each gauge size and its common uses.

**TABLE 13-1**  
**Choosing the Gauge Size for Peripheral Catheters**

CATHETER GAUGE	INDICATIONS	APPROXIMATE FLOW RATES
24-26 gauge Smallest, shortest ( $\frac{3}{4}$ -inch length)	Not ideal for viscous infusions Expect blood transfusion to take longer Preferred for infants and small children	24 mL/min (1440 mL/hr)
22 gauge	Adequate for most therapies; blood can infuse without damage	38 mL/min (2280 mL/hr)
20 gauge (1- $\frac{1}{4}$ -inch length)	Adequate for all therapies Most providers of anesthesia prefer not to use a smaller size than this for surgery cases	65 mL/min (3900 mL/hr)
18 gauge	Preferred size for surgery Vein needs to be large enough to accommodate the catheter	110 mL/min (6600 mL/hr)
14-16 gauge	For trauma and surgical patients requiring rapid fluid resuscitation Needs to be in a vein that can accommodate it	Over 200 mL/min (12,000 mL/hr)

The current recommendations for dwell (stay-in) time of short peripheral catheters do not include a specific time frame. The recommendations from both the CDC and the INS are that the catheter should be removed and/or rotated to a different site based on clinical indications (e.g., signs of phlebitis [warmth, tenderness, erythema or palpable venous cord], infection, or malfunction) (INS, 2016). This process requires conscientious and frequent assessment of the site. INS (2016) recommends assessment at least every 4 hours—every 1 to 2 hours for vulnerable patients and

every 4 hours for continuous infusions for outpatient and home care patients; otherwise site assessment should be done once a day. If the patient's therapy is expected to be longer than 6 days, a midline catheter or PICC should be chosen (Wojnar, 2013). When selecting the site for insertion of a peripheral catheter, consider the patient's age, history, and diagnosis; the type and duration of the prescribed therapy; and, whenever possible, the patient's preference. Chart 13-1 lists the major criteria for the placement of peripheral VADs.

### Chart 13-1

## Best Practice for Patient Safety & Quality Care QSEN

### Placement of Short Peripheral Venous Catheters

- Verify that the prescription for infusion therapy is complete and appropriate for infusion through a short peripheral catheter.
- For adults choose a site for placement in the upper extremity. DO NOT USE THE WRIST.
- Choose the patient's nondominant arm when possible.
- Choose a distal site and make all subsequent venipunctures proximal to previous sites.
- Do not use the arm on the side of a mastectomy, lymph node dissection, arteriovenous shunt or fistula, or paralysis.
- Avoid choosing a site in an area of joint flexion.
- Avoid choosing a site in a vein that feels hard or cordlike.
- Avoid choosing a site close to areas of cellulitis, dermatitis, or complications from previous catheter sites.
- Choose a vein of appropriate length and width to fit the size of the catheter required for infusion.
- Limit unsuccessful attempts to two per clinician and no more than four total (INS, 2016).

Vascular visualization technology (e.g., near infrared and ultrasound devices) are now available as tools to assist in IV line placement. Several different types of portable *vein transilluminators* are available such as VeinViewer, Veinlite LED, and AccuVein AV 300 (Fig. 13-3). Although they may have different mechanisms of action (some use infrared light and some use laser), these devices penetrate only up to about 10 mm and are limited to finding *superficial* veins.

**FIG. 13-3** The AccuVein AV300 is a vein illumination device that helps health care professionals locate veins for blood draw, IV infusion, and blood donation by projecting a pattern of light on the patient's skin to reveal the position of underlying veins on the skin's surface. The device uses red and infrared light, which the hemoglobin in blood absorbs to detect the position of the vein. (Courtesy AccuVein, LLC.)

*Ultrasound-guided* peripheral IV insertion can allow insertion into *deeper* veins (Arbique et al., 2014). This technology has been shown to be very valuable in assisting with cannulation of peripheral veins that the nurse cannot access with sight and touch. However, there are risks the nurse must be aware of when using ultrasound guidance. This technology should be used only by nurses who have been trained and whose competencies are maintained. Arteries and nerves lie parallel to deep veins, and training is needed to learn to identify these structures and avoid damaging them. In addition, when deeper veins are accessed, infiltration may go undetected until a significant amount of fluid has collected in the tissues. This complication can be particularly devastating if the solution is an irritant or vesicant.

For patients who need IV access but are at risk for fluid overload or do not need extra IV fluids, the peripheral vascular access device (VAD) can be converted into an intermittent IV lock, also called a *saline lock*. This device allows administration of specific drugs given IV push (e.g., furosemide [Lasix, Furoside]) or on an intermittent basis using a medication administration set. IV antibiotics are frequently given this way. In some cases the saline lock is placed in case there is a need for emergency drug administration via IV push. The intermittent device is flushed with saline before and after drug administration to ensure patency and prevent occlusion with a blood clot.

### Site Selection and Skin Preparation

The most appropriate veins for peripheral catheter placement include the dorsal venous network (i.e., basilic, cephalic, and median veins and their branches) (Fig. 13-4). However, cannulation of veins on the hand is not appropriate for older patients with a loss of skin turgor and poor vein condition and for active patients receiving infusion therapy in an ambulatory care clinic or home care. Use of veins on the dorsal surface of the hands should be reserved as a last resort for short-term infusion of nonvesicant and nonirritant solutions in young patients.

**FIG. 13-4** Common IV sites in the inner arm.

Mastectomy, axillary lymph node dissection, lymphedema, paralysis of the upper extremity, and the presence of dialysis grafts or fistulas alter the normal pattern of blood flow through the arm. Using veins in the extremity affected by these conditions requires a primary health care provider's request and order. Short peripheral catheters are not recommended for obtaining routine blood samples.

## **Nursing Safety Priority** QSEN

### **Critical Rescue**

Avoid veins on the palmar side of the wrist because the median nerve is located close to veins in this area, making the venipuncture more painful and difficult to stabilize. The cephalic vein begins above the thumb and extends up the entire length of the arm. This vein is usually large and prominent, appearing as a prime site for catheter insertion. Damage to the nerve from any injury can result in permanent loss of function or complex regional pain syndrome, type 2 (CRPS) (Kim et al., 2014). Reports of tingling, feeling “pins and needles” in the extremity, or numbness during the venipuncture procedure can indicate nerve puncture. If any of these symptoms occur, stop the IV insertion procedure immediately, remove the catheter, and choose a new site.

Winged needles (“butterfly needles”) are easy to insert but are associated with a high frequency of infiltration. They are most commonly used for injecting single-dose drugs or drawing blood samples. Like a short peripheral catheter, winged needles should also have an engineered safety mechanism to house the needle when removed.

Aseptic skin preparation and technique before IV insertion are crucial. **Catheter-related bloodstream infection (CRBSI)** can occur from a peripheral IV site. To help prevent these infections, CDC recommendations include:

- Perform evidence-based hand hygiene before palpating the insertion site.
- Clip hair—do not shave.

- Ensure that skin is clean. If visibly soiled, cleanse with soap and water.
- Wear clean gloves for peripheral IV insertion; do not touch the access site after application of antiseptics.
- Prepare clean skin with a skin antiseptic (chlorhexidine 2% with 70% alcohol, 70% isopropyl alcohol, or povidone-iodine) with a back-and-forth motion for 30 seconds and allow the solution to dry before peripheral venous catheter insertion.
- Do not retouch the proposed insertion site. If retouching occurs, prepare the skin antiseptic again and allow to dry.

## Midline Catheters

**Midline catheters** can be anywhere from 3 to 8 inches long, 3 to 5 Fr, and double or single lumen. They are inserted through the veins of the upper arm. The median antecubital vein is used most often if insertion is done without the aid of ultrasound guidance. With ultrasound guidance deeper veins can be accessed, and the insertion site can be farther above the antecubital fossa. The basilic vein is preferred over the cephalic vein because of its larger diameter and straighter path. It also allows greater hemodilution of the fluids and medications being infused. The catheter tip is located in the upper arm, with the tip residing no further into the venous network than the axillary vein (Fig. 13-5).

**FIG. 13-5** Midline catheter; the tip of this catheter resides in a peripheral vein.

Midline catheters have been found to reduce the number of repeated IV cannulations, which reduces patient discomfort, increases patient satisfaction, and contributes to organizational efficiency (Owen, 2014). A midline catheter can be used when skin integrity or limited peripheral veins make it difficult to maintain a short peripheral catheter. Indications for these catheters include fluids for hydration and drug therapy that are given longer than 6 days and up to 4 weeks such as antibiotics, heparin, steroids, and bronchodilators. There are currently no recommendations for the

optimal dwell time. In a 2014 study the average dwell time for midlines was identified as 6.9 days (Dumont et al., 2014). Because of the extended dwell time, strict sterile technique is used for insertion and dressing changes for a midline catheter. Additional education and skill assessment are required for the nurse to be qualified to insert midline catheters.

Midline catheters are considered to dwell in the peripheral circulation; the recommendations for infusates (fluids or drugs) are the same as for short peripheral IV lines. Fluids and medications infused through a midline catheter should have a pH between 5 and 9 and a final osmolarity of less than 600 mOsm/L (McClelland, 2014). The pH and osmolarity outside these parameters increase the risk for complications such as phlebitis and thrombosis. Midline catheters should not be used for infusion of **vesicant medications**—drugs that cause severe tissue damage if they escape into the subcutaneous tissue (**extravasation**). There is concern that at a midline tip location, larger amounts of the drug may extravasate before the problem is detected.

All parenteral nutrition formulas, including those with low concentrations of dextrose and solutions that have an osmolarity greater than 600 mOsm/L, should not be infused through a midline. Do not draw blood from these catheters routinely. Midline catheters should not be placed in extremities affected by mastectomy with lymphedema, paralysis, or dialysis grafts and fistulas. When using a double-lumen midline catheter, do not administer incompatible drugs simultaneously through both lumens because the blood flow rate in the axillary vein is not high enough to ensure adequate hemodilution and prevention of drug interaction in the vein. Currently new midlines with power-injectable technology are available for use with computed tomography.

## NCLEX Examination Challenge 13-2

### Physiological Integrity

The primary health care provider prescribes 1 L 5% D/0.45% NS to be infused over 8 hours. The nurse sets the rate at \_\_\_ mL/hr of IV solution.

## Central Intravenous Therapy

In **central IV therapy** the vascular access device (VAD) is placed in the central circulation, specifically within the superior vena cava (SVC) near its junction with the right atrium, also called the *caval-atrial junction (CAJ)*. Blood flow in the SVC is about 2 L/min compared with about 200 mL/min in the axillary vein. Most central vascular access devices require confirmation of tip location at the CAJ by chest x-ray before solutions are infused. However, newer technologies use either a magnet tip locator or identification of the CAJ by electrocardiogram rather than by x-ray. Both the Sherlock 3CG by Bard and the VasoNova/Teleflex systems have received Food and Drug Administration (FDA) approval as alternatives to chest x-ray or fluoroscopy to verify PICC tip location.

A number of types of central vascular access devices (CVADs) are available, depending on the purpose, duration, and insertion site availability. Several recent improvements in catheter materials allow antimicrobial and heparin coatings to reduce infection risk and improve the longevity of the catheter. Not all central-line catheters are approved for power injection used in radiologic tests. The catheter can rupture if it is not designed to handle the injection pressure necessary for some tests such as pulmonary CT angiography or CT angiography of the aorta (5 mL/sec and 300 per square inch [psi]). Even with power-injectable designed catheters, dislodgment may occur (Boon & Babu, 2013). Be sure to confirm if the PICC is power injectable or not.

## Peripherally Inserted Central Catheters

A **peripherally inserted central catheter (PICC)** is a long catheter inserted through a vein of the antecubital fossa (inner aspect of the bend of the arm) or the middle of the upper arm. Nurses who insert these CVADs require special training and competency confirmation.

In adults the PICC length ranges from 18 to 29 inches (45 to 74 cm), with the tip residing in the superior vena cava (SVC) ideally at the caval-atrial junction (CAJ) (Fig. 13-6). Placement of the catheter tip in veins distal to the SVC is avoided. This inappropriate tip location, often called a *mid-clavicular catheter*, is associated with much higher rates of thrombosis than when the tip is located in the SVC at the CAJ. Mid-clavicular tip locations are used only when anatomic or pathophysiologic changes prohibit placing the catheter into the SVC.

**FIG. 13-6** Peripherally inserted central catheter (PICC) is placed peripherally in a vein of the upper arm with the tip resting in the superior vena cava.

PICCs should be inserted early in the course of therapy before veins of the extremity have been damaged from multiple venipunctures and infusions. Insertion methods using guidewires and ultrasound systems greatly improve insertion success. The basilic vein is the preferred site for insertion; the cephalic vein can be used if necessary. Two brachial veins are not recommended because they are more difficult to access; they are deeper in the arm and run close to the brachial artery. *Sterile technique is used for insertion to reduce the risk for CRBSI. Before the catheter can be used for infusion, a chest x-ray indicating that the tip resides in the lower SVC is required when the catheter is not placed under fluoroscopy or with the use of the electrocardiogram tip-locator technique.*

PICCs are available in single-, dual-, or triple-lumen configurations and with both the Groshong valve and the pressure-activated safety valve (PASV). PICCs are also available as “Power PICCs” and can be used for contrast injection at a maximum of 5 mL/sec and a maximum pressure of 300 psi. They can also be connected to transducers and used to monitor central venous pressure.

The most common complications from PICCs include phlebitis, thrombophlebitis, deep vein thrombosis (DVT), and CRBSIs. When infections occur from a central line, they are also referred to as **central line-associated bloodstream infection, or CLABSI**. Thrombophlebitis and DVT can be very serious, threaten the integrity of the vein, and decrease perfusion. The smallest possible French size should be used to decrease the rate of upper-extremity DVT, a potentially life-threatening event.

CRBSI has been noted to be less common in PICCs than in other central venous catheters (CVCs) because of the insertion site in the upper extremity. The cooler, drier skin of the upper arm has fewer types and numbers of microorganisms, leading to lower rates of infection. Accidental arterial puncture or excessive bleeding can occur on insertion and is controlled by direct pressure. Infiltration and extravasation are rare. Insertion complications such as pneumothorax associated with other CVCs do not occur with PICCs.

PICCs can accommodate infusion of all types of therapy because the tip resides in the SVC where the rapid blood flow quickly dilutes the fluids being infused. Therefore there are no limitations on the pH or osmolality of fluids that can be infused through a PICC. For example, patients requiring lengthy courses of antibiotics, chemotherapy agents, parenteral nutrition formulas, and vasopressor

agents can benefit from this type of catheter. PICCs have been reported to dwell successfully for months or even years; however, the optimal dwell time is not known.

PICCs can be used for blood sampling; however, lumen sizes of 4 Fr or larger are recommended. Using lumens with small diameters may not yield a sample capable of producing the needed test results. In addition, frequent entry into any central line should be minimized and treated with strict aseptic technique to prevent CRBSI. Transfusion of blood through a PICC usually requires the use of an infusion pump. Packed red blood cells are cold and viscous. The length of the catheter adds resistance and may prevent the blood from infusing within the 4-hour limit.

Teach patients with a PICC to perform usual ADLs; however, they should avoid excessive physical activity. Muscle contractions in the arm from physical activity such as heavy lifting can lead to catheter dislodgment and possible lumen occlusion. PICCs may be contraindicated in paraplegic patients who rely on their arms for mobility and in patients using crutches that provide support in the axilla.

PICC insertion is commonly performed in the patient's hospital room, an ambulatory care treatment facility, or the imaging department. Regardless of where they are inserted, the same precautions must be taken as with any other central line insertion using the **catheter-related bloodstream infection (CRBSI) prevention bundle**. Major components of this prevention bundle include:

- Hand hygiene
- Measuring upper arm circumference as a baseline before insertion (INS, 2016)
- Maximal barrier precautions on insertion
- Chlorhexidine skin antisepsis
- Optimal catheter site selection and post-placement care with avoidance of the femoral vein for central venous access in adult patients
- Daily review of line necessity with prompt removal of unnecessary lines

Other helpful interventions include use of a checklist for sterility during the procedure, a line cart with all equipment, and a stop sign on the door of the room to stop unnecessary traffic through the room during the procedure. The checklist should be completed by another professional health care member who can stop the inserter when any breaks in technique are observed (INS, 2016).

## Nursing Safety Priority QSEN

### Action Alert

The INS recommendation for flushing PICC lines not actively used is 5 mL of heparin (10 units/mL) in a 10-mL syringe at least daily when using a nonvalved catheter and at least weekly with a valved catheter. Use 10 mL of sterile saline to flush before and after medication administration; 20 mL of sterile saline is flushed after drawing blood. *Always use 10-mL barrel syringes to flush any central line because the pressure exerted by a smaller barrel poses a risk for rupturing the catheter.*

## Nontunneled Percutaneous Central Venous Catheters

**Nontunneled percutaneous central venous catheters (CVCs)** are inserted by a physician, physician assistant, or nurse practitioner through the subclavian vein in the upper chest or the internal jugular veins in the neck using sterile technique. Occasionally the patient's condition may require insertion of the CVC in a femoral vein, but the rate of infection is very high. If the femoral site must be used, it is removed as soon as possible.

CVCs are usually 7 to 10 inches (18 to 25 cm) long and have one to as many as five lumens (Fig. 13-7). These catheters are also available with antimicrobial coatings such as chlorhexidine and silver sulfadiazine. The tip resides in the superior vena cava (SVC) and is confirmed by a chest x-ray. Nontunneled percutaneous CVCs are most commonly used for emergent or trauma situations, critical care, and surgery. There is no recommendation for optimal dwell time. However, these catheters are commonly used for short-term situations and are *not* the catheter of choice for home care or ambulatory clinic settings.

**FIG. 13-7** Edwards Lifesciences PreSep central venous catheter (CVC); often placed in the subclavian or internal jugular vein with the tip of the catheter resting in the superior vena cava. (Courtesy Edwards Lifesciences, Irvine, CA.)

Insertion of these central catheters requires the patient to be placed in the Trendelenburg position, usually with a rolled towel between the shoulder blades. This position may be difficult or contraindicated for patients with respiratory conditions, spinal curvatures, and increased intracranial pressure, especially for older adults. Trauma, surgery, or radiation in the neck or chest prohibits the use of these devices as well. Insertion with ultrasound guidance has been demonstrated to improve the safety of insertion in the internal jugular site (Bowen et al., 2014). The presence of a tracheotomy increases the risk for cross-contamination of the insertion site. The warmer, moister skin of the neck and upper chest has more types and higher numbers of microorganisms, resulting in more CRBSIs with this type of catheter.

## Tunneled Central Venous Catheters

**Tunneled central venous catheters** are VADs that have part of the catheter lying in a subcutaneous tunnel, separating the points where the catheter enters the vein from where it exits the skin. This separation is intended to prevent the organisms on the skin from reaching the bloodstream (Fig. 13-8). Today these catheters are usually inserted by physicians in the radiology suite rather than placed surgically. The catheter has a cuff made of a rough material that is positioned inside the subcutaneous tunnel. These cuffs commonly contain antibiotics, which also reduce the risk for infection. The tissue granulates into the cuff, providing a mechanical barrier to microorganisms and anchoring the catheter in place.

**FIG. 13-8** Tunneled catheter. Part of this catheter lies in a subcutaneous tunnel, separating the point where the catheter enters the vein from where it exits the skin.

The design of tunneled CVCs requires surgical techniques for insertion and removal. Single, dual, and triple lumens are available. These catheters were originally named for the physicians who designed them, including Broviac, Hickman, and Leonard catheters.

Tunneled catheters are used primarily when the need for infusion therapy is frequent and long term. Patients needing parenteral nutrition for months, years, or the remainder of their lives commonly choose a tunneled catheter. Tunneled catheters are also chosen when several weeks or months of infusion therapy are needed and a PICC is not a good choice. For example, paraplegic patients needing 6 to 8 weeks of antibiotics are not good candidates for a PICC because of the excessive use of the upper extremities for mobility. Some oncology patients may prefer a tunneled catheter instead of an implanted port because they cannot tolerate the needlesticks required for accessing those devices.

## Implanted Ports

**Implanted ports** are very different from other central vascular access devices (CVADs). This type of device is chosen for patients who are expected to require IV therapy for more than a year (Zhou et al., 2014). Implanted ports typically are inserted by a physician in the radiology department or a surgeon in the operating suite. Implanted ports consist of a portal body, a dense septum over a reservoir, and a catheter. They can be single or double lumen and come in various sizes. A subcutaneous pocket is surgically created to house the port body. The catheter is inserted into the vein and attached to the portal body. The septum is made of self-sealing silicone and is located in the center of the port body over the reservoir; the catheter extends from the side of the port body. The incision is closed, and no part of the catheter is visible externally; therefore this device has the least impact on body image (Fig. 13-9).

**FIG. 13-9** Positioning of an implanted port.

Some implanted ports are power injectable and can be used for obtaining contrast-enhanced computed tomography (CECT). These devices can withstand 5 mL/sec at up to 300 psi pressure. The BARD PowerPort can be identified by palpation of three bumps on the top of the septum and a triangular-shaped port. Be careful not to press firmly on the bumps because it can be painful to the patient. Be sure to use a power-injection-rated noncoring needle with this type of port when it is used for this purpose. These needles come with labeling identifying that they are power-injection rated (Fig. 13-10).

**FIG. 13-10** A noncoring needle for accessing an implanted power port.

Venous ports may be placed on the upper chest or the upper extremity. The venous catheter may enter either the subclavian or internal jugular vein. Although an implanted port is most commonly used in the venous system, the catheter may be placed in arteries, the epidural space, or the peritoneal cavity, with the port pocket located over a bony prominence.

Implanted ports are accessed by using a noncoring needle (a common brand name is *Huber*) that is specially designed with a deflected tip. This design slices through the dense septum without coring out a small piece of it, thus preserving the integrity of the septum. Port bodies placed in the chest have a larger septum and usually tolerate about 2000 punctures. Port bodies placed in the

upper extremity are smaller and are rated to tolerate about 750 punctures.

Port access should be done only by formally trained health care professionals using a mask and aseptic technique. Implanted ports are used most often for patients receiving chemotherapy. These patients are immune compromised, making them highly susceptible to infection. Before puncture, palpate the port to locate the septum. Carefully palpate to feel the shape and depth of the port body to ensure puncture of the septum, not the attached catheter. Some have attached extension sets and wings to stabilize the needle. One important feature is an engineered safety mechanism to contain the needle when it is removed from the septum. Because the dense septum holds tightly to the needle, there can be a rebound when it is pulled from the septum, which can result in needlestick injury to the nurse.

Implanted ports need to be flushed after each use and at least once a month between courses of therapy. This procedure is done to prevent clot formation in the internal chamber of the port and is often referred to as “locking” or “de-accessing.” The INS recommendation for locking or de-accessing a port is the use of a 10-mL syringe with either heparin 10 units per milliliter or preservative-free 0.9% normal saline (INS, 2016). When the port is not accessed, there is no external catheter requiring a dressing. Puncture of the skin over the port is required to gain access to the port body, causing pain for some patients. Topical anesthetic creams can be used to make the access procedure more tolerable.

## Nursing Safety Priority QSEN

### Drug Alert

Before giving a drug through an implanted port, always check for blood return. INS (2016) defines blood return “as the color and consistency of whole blood upon aspiration” (p.S147). If there is no blood return, withhold the drug until patency and adequate noncoring needle placement of the port are established. Serious extravasations of vesicant drugs can occur because a fibrin sheath (flap or tail) may occur at the tip of the catheter, clot it, and cause retrograde subcutaneous leakage.

## Hemodialysis Catheters

Hemodialysis catheters have very large lumens to accommodate the hemodialysis procedure or a pheresis procedure that harvests specific blood cells. They may be tunneled for long-term needs or nontunneled for short-term needs. A hemodialysis catheter is critical to the management of renal failure and must function well. CRBSIs and vein thrombosis are common problems; therefore this catheter should not be used for administration of other fluids or drugs except in an emergency.

The concentration of heparin used to lock hemodialysis catheters ranges from 1000 to 10,000 units/mL. Researchers have demonstrated that using 1000 units/mL reduces the incidence of postinsertion bleeding but may be associated with an increased need for recombinant tissue plasminogen activator (tPA) to maintain patency. A flush of 1000 units heparin/mL or a solution of 4% sodium citrate in the amount of the dwell volume of each lumen has been recommended. Heparin is most often used because sodium citrate has not been as commercially available in the preparation needed. To prevent systemic anticoagulation and subsequent bleeding, be sure to aspirate the heparin from the lumens before use.

## Infusion Systems

Nurses administering infusion therapies need to understand how infusion systems work. This knowledge ensures that the patient can benefit from a particular system's advantages while minimizing any potential complications.

### Containers

Infusion containers are made of glass or plastic. *Glass* bottles were the original fluid container to be mass produced. They are easily sterilized, and it is easy to read the amount of fluid remaining in the bottle. Also, glass is inert and thus cannot interact with some drugs such as plastic can. However, glass bottles are heavy and cannot be used easily in many situations such as patient transport during emergencies. These containers require an air vent for fluids to flow freely from them. The most common method is to use an administration set with a special filtered vent. Some bottles may have a straw tube open to the room air through the rubber stopper in the bottle and extending to above the level of the fluid. Bottles with a venting straw do not have a barrier to prevent contaminants in the air from entering the fluid.

*Plastic* containers are considered *closed systems* because they do not rely on outside air to allow the fluid to infuse. Instead atmospheric pressure pushes against the flexible sides of the container, allowing the fluid to flow by gravity. For this reason plastic containers do not require vented administration sets. These containers are lightweight, resistant to breaking, easier to store, and easy to use in emergency conditions. Therefore they are used more frequently than glass containers.

All plastic containers were commonly made of polyvinyl chloride (PVC). To increase flexibility and strength, PVC required the addition of a plasticizer such as di-2-ethylhexyl-phthalate or DEHP. Concern has been growing in the past few years over the exposure of patients to this chemical because it can leach from the plastic fluid container or tubing and infuse into the patient with the IV fluid or medication. The FDA has determined that there is little to no risk posed to most patients by exposure to the amount of DEHP released from IV bags with infusion of crystalloids or drugs. However, there is concern about the buildup of chemical exposure from many sources over a lifetime and specifically the potential effects of DEHP on the development of the male reproductive system (Meer et al., 2014). Therefore many hospitals are using PVC-free and DEHP-free IV bags, especially for high-risk groups.

One disadvantage of removing DEHP from the plastic bags is that the bags are less pliable and more prone to rupture. Some institutions do not allow these bags to be sent through a pneumatic tube system because the pressure exerted has caused the bags to rupture during transport.

A problem with plastic containers is that they are not compatible with insulin, nitroglycerin, lorazepam (Ativan), fat emulsions, and lipid-based drugs. Nitroglycerin and insulin adhere to the walls of the PVC container, making it impossible to know exactly how much medication the patient is receiving. Another concern with plastic bags is the accuracy of reading the amount of fluid remaining in the container and the residual volume in some sets. As much as 20% of a medication in an attached 100-mL bag may not be infused, which in a 24-hour period may result in a patient missing a whole dose of medication (Lee, 2015).

### Nursing Safety Priority QSEN

#### Action Alert

Regardless of the type of fluid container being used, check it for cracks or pinholes before use. Always observe the fluid for **turbidity** (cloudiness) or any unusual color that could indicate contamination.

### Administration Sets

The administration set is the connection between the catheter and the fluid container. Numerous sets are available in many different configurations. The type and purpose of the infusion determine the type of administration set needed. Some sets are *generic*, meaning that they are appropriate for

most infusions. Other sets are used for specific types of infusions such as blood transfusion. Still others are *dedicated*, meaning that they must be used with a specific manufacturer's infusion controlling device. Information that describes their proper use is provided on the packaging of administration sets.

### Secondary Administration Sets

A primary continuous administration set is used to infuse the primary IV fluid by either a gravity infusion or an electronic infusion pump. A short **secondary administration set**, also known as a **piggyback set**, is attached to the primary set at a Y-injection site and is used to deliver intermittent medications (Fig. 13-11). Directions and diagrams for use typically are on the packaging. Once attached, these sets should remain connected as an infusion system. Primary and secondary continuous infusion administration sets used to infuse fluids other than parenteral nutrition and lipids can be used for up to 96 hours unless the closed system has been compromised (INS, 2016).

**FIG. 13-11** Secondary IV administration set attached to the primary set at a Y-injection site. (Courtesy Rick Brady, Riva, Maryland. In Lilley, L., Collins, S., & Snyder, J. [2014]. *Pharmacology and the nursing process* [7th ed.]. St. Louis: Mosby.)

### Intermittent Administration Sets

When no primary continuous fluid is being infused, use an intermittent administration set to infuse multiple doses of medications through a catheter that has been capped with a needleless connection device. Remove the medication bag from the previous dose and attach the new one. Remove the sterile cap covering the distal end of the set and attach the set to the catheter. Because both ends of the set are being manipulated with each dose, the INS standards of practice state that this set should be changed every 24 hours. When the administration set is used for infusion of parenteral nutrition or lipid solution, change it every 24 hours. Change blood tubing within 4 hours.

Administration sets are sterile in the fluid pathway and under the sterile caps on each end of the set. The set is not packaged as a completely sterile product and cannot be added to a sterile field. Careful attention is required to maintain the sterility of the spike and the connection end of the tubing to prevent introduction of microorganisms into the catheter and bloodstream.

### Add-on Devices

Several other types of add-on devices include short extension sets, injection caps, and filters.

Extension sets may be packaged as a sterile product for adding to a sterile field; however, always check the product label for this information.

Administration sets have two ways to connect to the catheter hub: a slip lock or a Luer-Lok. The *slip lock* is a male end that slips into the female catheter hub. A *Luer-Lok* connection has the same male end with a threaded collar that requires twisting onto the corresponding threads of the catheter hub. All connections, including *extension sets*, should have a Luer-Lok design to ensure that the set remains firmly connected. Loose connections lead to fluid leakage and increase the risk for contamination and subsequent bloodstream infection. When using a central venous catheter, a Luer-Lok connection is critical to reduce the risk for air embolism. Tape is not considered an adequate mechanism for securing set connections.

Luer-Lok devices may be purposefully or accidentally disconnected. Patients or visitors may disconnect the system to allow the patient to get out of bed or the chair, or the device may become accidentally disconnected when the patient turns or moves. In either case be sure to reconnect the device by following the proper sequence to reassemble the IV system components. Fatalities have resulted when nurses have accidentally reconnected IV tubing to a tracheostomy or other inappropriate port.

*Filters* may be part of the administration set or separate add-on pieces. Their purpose is to remove particulate matter, microorganisms, and air from the infusion system. Filter sizes depend on the pore size, with common sizes being 1.2 microns used to filter lipid-containing parenteral nutrition and 0.2 microns intended to remove all particles and bacteria. Filters should be placed as close to the catheter hub as possible.

Particulate matter in the IV fluid, a primary reason to use filters, comprises undissolved, unintended substances and may include rubber pieces, glass particles, cotton fibers, drug particles, paper, and metal fibers. These particles become trapped in the small circulation of the lungs. A red blood cell is about 5 microns in diameter and is the largest size that can pass through the pulmonary capillary bed; IV fluids may contain particles larger than 5 microns. For patients receiving infusion therapy for long periods, a significant number of particles could block the blood flow through the pulmonary circulation. Microcirculation in the spleen, kidneys, and liver could also be affected. Particulate matter has also been implicated in the development of phlebitis in peripheral veins.

Other concerns with using filters include the possibility for their rupture, their use with certain drugs that bind to the filter surface, using the incorrect size of filter for drugs with large molecules, and choosing a filter that will not tolerate the pressure exerted by infusion pumps. Rupture is most commonly associated with the exertion of high pressure exceeding the limit tolerated by the specific filter. Some drugs cannot be filtered because they are retained inside the filter because of their chemical nature or molecule size. For these reasons medication filtration during the process of admixing is commonly used today as an alternative to final filtration at the bedside. Drugs of a very small quantity should be administered below the filter.

Filters used on blood administration sets have much larger pore size and are not interchangeable with filters used for fluids and medications. A standard blood filter ranges from 170 to 260 microns and removes microclots and other debris caused by blood collection and storage. Microaggregate filters have a pore size of 20, 40, or 80 microns and are used to remove degenerating platelets, white blood cells, and fibrin strands. Leukocyte-removal filters are used to remove white blood cells that cause febrile and allergic blood transfusion reactions.

### **Needleless Connection Devices**

In July 1992, the Occupational Safety and Health Administration (OSHA) published guidelines entitled *Occupational Exposure to Bloodborne Pathogens, Final Rule*. This document requires health care organizations to initiate engineering controls “that isolate or remove the bloodborne pathogen hazard from the workplace.” This standard was amended in 2001 with the passage of the Needlestick Safety and Prevention Act. This regulation requires the use of devices engineered with safety mechanisms and mandates that staff who perform these tasks be directly involved with selecting products. It also requires each employer to maintain a sharps injury log with details of each incident. Many products are designed to minimize health care workers’ exposure to contaminated needles. Luer-Lok-activated devices are the most common design for needleless systems today.

Although these devices have reduced the incidence of accidental needlesticks for health care

professionals, it is imperative that the connector be disinfected with alcohol or chlorhexidine/alcohol before and after each use with a *vigorous scrub* for 5 to 60 seconds (INS, 2016). This method is known as “scrub the hub.” Blood and bacteria can be trapped in the crevices, and meticulous disinfecting is required with each use.

Various designs are available for connectors that provide positive or negative displacement of fluid when the needleless syringe is removed. Needleless positive-pressure valve (PPV) connectors were developed to prevent backflow of blood into the IV catheter, thereby decreasing chances of thrombus formation and CRBSI. Several newer connectors are silver-impregnated to reduce bacterial growth (Fig. 13-12). Be sure to check which type of connector valve is used in your facility because the flushing technique differs depending on type.

**FIG. 13-12** Example of a needleless connector.

Conclusive studies are needed to determine the best design for needleless systems. Until then, implement these interventions to reduce infection risk:

- Clean all needleless system connections vigorously with antimicrobial for 60 seconds (usually 70% alcohol or alcohol and 2% chlorhexidine swabs) before connecting infusion sets or syringes, paying special attention to the small ridges in the Luer-Lok device. Newer caps that are impregnated with alcohol or chlorhexidine may be used to keep the port aseptic; however, these will increase costs, and research is needed to demonstrate the benefit.
- Do not tape connections between tubing sets.
- Use evidence-based hand hygiene guidelines from the CDC and OSHA.

## Rate-Controlling Infusion Devices

The ability to regulate the rate and volume of infusions is critical to the safe and accurate administration of medications and fluids to patients. Nurses have a choice of numerous devices that can be electronically or mechanically regulated.

Electronic infusion devices (IV pumps) are used universally in acute care institutions. They are also used in long-term care settings and at home. In addition, “smart pumps” provide the latest infusion computer technology to promote patient safety and save nursing time. *Remember that the use of pumps does not decrease your responsibility to carefully monitor the patient’s infusion site and the infusion rate.*

In inpatient settings IV pumps are pole mounted. As their name implies, these electronic devices with battery backup pump drugs or fluids under pressure. They accurately measure the volume of fluid being infused by using one of three mechanisms:

- A syringe-type mechanism that fills and empties
- A wavelike, peristaltic action that pushes fluid along the tubing
- A series of microchambers that fill and empty

Regardless of the pumping mechanism, these devices require dedicated cassette tubing designed to match the pump.

**Syringe pumps** use an electronic or battery-powered piston to push the plunger continuously at a selected milliliter-per-hour rate. The use of syringe pumps is limited to small-volume continuous or intermittent infusions and depends on the syringe size. Antibiotics and patient-controlled analgesia are frequently delivered with syringe pumps. Patients requiring fluid restrictions can also

benefit from using a syringe pump because smaller yet accurate volumes can be used to dilute medications.

**Ambulatory pumps** are generally used for home care patients and allow them to return to their usual activities while receiving infusion therapy. These pumps have a wide range of sizes, with some requiring a backpack, but they usually weigh less than 6 lb. They are typically used to accurately deliver continuous infusions such as parenteral nutrition, pain medication, and many programmable drug schedules. Frequent battery recharging or replacement is usually necessary.

*Electronic infusion devices* can be programmed in many different ways and require a thorough knowledge of the specific brand being used. Infusion rate and the volume to be infused are usually entered in single milliliter increments, but some can be programmed as fractions of a milliliter. Some pumps allow the rate to be programmed to taper or ramp up and down at the beginning and ending of the infusion. Secondary syringe infusion, secondary infusion rate, remote site programming, adjustable infusion pressure, and integration into the nurse call system also are possible.

Electronic infusion devices have a variety of alarms such as air-in-line, upstream and downstream occlusion, infusion complete, and low-battery or power warnings. All devices must have some mechanism to prevent free flow of the infusing fluid or medication. When the cassette or tubing is removed from the pump, this mechanism automatically stops fluid flow until it is properly replaced in the pump. This safety measure prevents accidental rapid infusion of large amounts of fluid or medication, which could lead to serious clinical problems.

In the past few years, **smart pumps** (infusion pumps with dosage calculation software) have been promoted to reduce adverse drug events (ADEs). Incorrect programming of pumps without this feature is one of the most common types of drug errors, especially in hospitals. Multiple libraries of drug information are stored in the pump manufacturer's medical management system. This software allows the facility to preprogram dosing limits, especially for high-alert drugs. Examples of smart pumps are the B. Braun Outlook 400ES and the Baxter Sigma Spectrum infusion system.

The newest development in smart pumps is a wireless network connection. Drug libraries can be updated via a wireless connection, thus eliminating the necessity of manually updating each pump. In addition to preventing drug errors, smart-pump systems record potential errors that would have occurred without these safety mechanisms (Waterson, 2013).

Dose-track technology is intended to transmit the infusion data to the institution's pharmacy so the correct patient receives the correct medication. Dose-guard technology alerts the nurse if institution-defined dose limits are exceeded. These newer technologies provide safeguards for patients to keep them safe. However, the "smarter" the pump, the more extensive the programming steps, and the more alarms to which the nurse must respond. In addition, technology and wireless connections can fail. The challenge for nurses is to maintain the skill of manual dose calculation and rate control, acknowledge and validate all alarms, and guard against becoming desensitized to alarms.

*Mechanically regulated devices* can be used to deliver intermittent medications such as antibiotics or continuous pain medications in community-based health or home care settings. In acute care settings devices called "infusers" may be found in surgical services. They are powered by positive pressure from the collapsing balloon or roller returning to its coiled position.

The systems include elastomeric balloons, spring-coiled syringes and containers, and a multi-chambered fluid container placed in a mechanical roller (Accufuser or ON-Q PainBuster) (Fig. 13-13). These small portable devices do not require power sources such as batteries or electricity. They deliver a preset infusion rate, and fluid volume is determined by the size of the fluid container; however, most hold only 50 to 100 mL.

**FIG. 13-13** ON-Q PainBuster pump (mechanical infuser). (Courtesy Kimberly-Clark Corporation.)

# Nursing Care for Patients Receiving Intravenous Therapy

## Educating the Patient

The current trend in health care demands that we partner with our patients to provide the best patient-centered care. In 2010 The Joint Commission added the requirement that all patients who have central lines placed in the hospital must have education on prevention of catheter-related bloodstream infection (CRBSI). Before catheter insertion, educate the patient and family about:

- The type of catheter to be used
- Hand hygiene and aseptic technique for care of the catheter
- The therapy required
- Alternatives to the catheter and therapy
- Activity limitations
- Any signs or symptoms of complications that should be reported to a health care professional

Provide written information before placement of a long-term catheter and continue to assess the patient's knowledge level and provide more information or answers as needed. Most manufacturers of PICCs, tunneled catheters, and implanted ports provide patient information booklets. However, specific information about the chosen procedures and supplies may be required. Conversation and pictures are helpful for patients who are **literacy challenged** (have a low reading level ability.) Patients who do not speak or read English will need a translator.

## Performing the Nursing Assessment

All central VADs require documentation of tip location at the CAJ by electrocardiogram technology, fluoroscopy, or chest x-ray. The initial verbal and subsequent written report should contain specific information about the catheter tip location in relation to anatomic structures. The nurse's knowledge of accurate tip location is required before beginning infusion through the catheter. Repeating the x-ray during catheter use may be necessary if the patient reports unusual pain or sensation.

Nursing assessment for all infusion systems should be systematic. Begin with the insertion site and work upward, following the tubing. Know the type of catheter your patient has in place. Be sure to find out the length of catheter, the insertion site, and tip location to perform a complete assessment. Assess the insertion site by looking for redness, swelling, hardness, or drainage. Also assess the skin underneath the dressing especially for signs of medical adhesive–related skin injury (MARS) (INS, 2016). Lightly palpate the area over the dressing. When a midline catheter or PICC is used, assess the entire extremity and upper chest for signs of phlebitis and thrombosis. When a tunneled catheter is used, assess the exit site, the entire length of the tunnel, and the point where the catheter enters the vein. For a well-healed catheter, it may not be possible to detect the vein entrance site. On newly inserted catheters there could be a small puncture site with a suture or other securement device. For implanted ports, assess the incision and surgically created subcutaneous pocket.

Assess the integrity of the dressing, making sure that it is clean, dry, and adherent to the skin on all sides. Check all connections on the administration set and ensure that they are secure. Be sure that they are not taped. Check the rate of infusion for all fluids by either counting drops or checking the infusion pump. Assess the amount of fluid that has infused from the container. Is it accurate, or is it infusing too fast or too slow? Adjust the rate to the prescribed flow rate. Check all labels on containers for the patient's name and fluid or medication. *Be sure that the correct solution is being infused!*

## Nursing Safety Priority QSEN

### Action Alert

Remind unlicensed assistive personnel (UAP) to avoid taking blood pressures in an extremity with any type of catheter in place. If a short peripheral catheter is being used for continuous infusion, the compression while taking the blood pressure can increase venous pressure, causing fluid to overflow from the puncture site and infiltration. When a midline catheter or PICC is being used, compression from the blood pressure cuff could increase vein irritation and lead to phlebitis.

Draw blood samples in the extremity opposite from all catheters. Blood should not be drawn from a venipuncture site proximal to (above) an infusing peripheral catheter because the infusing fluid could alter the results of the test to be performed. Venipuncture at or near the insertion site of a midline catheter or PICC could damage the catheter, add to areas of venous inflammation, and decrease perfusion.

## Securing and Dressing the Catheter

Adequate catheter securement is vital to prevent many complications. Tape, sutures, and specially designed securement devices can be used for this purpose. For a short peripheral catheter, tape strips are most common; however, the tape should be *clean*. Tape strips from a peripheral IV start kit are preferred. Strips of tape should not be taken from rolls of tape moved between patient's rooms, from other procedures, or from uniform pockets. Precutting tape and placing it on the patient's bedrails, your uniform or scrubs, or other object should also be avoided to prevent transmission of microorganisms.

Newer *securement devices* are designed for all catheter types and provide an evidence-based method to prevent VAD movement (INS, 2016). Recent studies have shown that these devices such as the StatLock IV stabilization device prevent peripheral and central catheters from becoming dislodged (Fig. 13-14) (see the Evidence-Based Practice box). In addition, they prevent complications such as phlebitis and infiltration. To prevent skin tears, remove the adhesive on a StatLock with 70% alcohol.

**FIG. 13-14** The StatLock provides a standardized method to prevent catheter movement. (Courtesy Venetec International, San Diego, CA.)

## Evidence-Based Practice USEN

### What Is the Best Method for Securing a Patient's Central Venous Access Device?

Ullman, A.J., Cooke, M., & Rickard, C.M. (2015). Examining the role of securement and dressing products to prevent central venous access device failure: A narrative review. *Journal of the Association for Vascular Access*, 20(2), 99–110.

Central venous catheters require stabilization to ensure an extended lifeline. Dislodgment is one

of the major complications associated with failure of the access device. The researchers undertook a narrative methodology to explore the fundamental principles of securement and dressing products to prevent central venous access device failure. The researchers use a narrative review that included articles that reported the underpinning of central catheter securement and dressing to prevent dislodgment failure, which totaled 21 studies out of the 213 studies retrieved.

Findings included characteristics focused on providing a microbial barrier for contamination and colonization, reducing external and internal motion, and the effect of dressing disruption. The researchers concluded that patients with central venous access devices are a heterogeneous group and there is not one securement device that fits everyone. Individualized assessment is required to select the appropriate securement. Future studies are needed to determine the most effective securement that is cost-effective for all populations.

### Level of Evidence: 1

This study used a narrative research review and analysis methodology to determine best practices for use of IV securement devices.

### Commentary: Implications for Practice and Research

This research validated the effectiveness of IV catheter securement and stabilization devices for all patients receiving central infusion therapy. Clinicians need to recognize the priority of using an appropriate securement and dressing for the patient. Institutions need to recognize the long-term savings of using a securement and dressing to prevent catheter failure for improved patient outcomes. Future clinical research and innovative solutions need to be ongoing.

PICCs and nontunneled percutaneous central catheters may be sutured in place; however, this creates additional breaks in the skin that could become infected. If these sutures are loose or broken, notify the primary health care provider to replace them. IV catheter sutures are being replaced with securement devices and Dermabond glue in some facilities, which can decrease infection and avoid the need to remove sutures after infusion therapy is discontinued.

Tunneled catheters usually have sutures placed near the skin exit site, which are removed after the tunnel has healed. The incision over an implanted port pocket will have sutures until it has healed. After it is healed and when it is not accessed, no dressing is required. When an implanted port is accessed, the sterile occlusive dressing should cover the entire needle and site.

*Sterile dressings* used over the insertion site protect the skin and puncture site. For a short peripheral catheter, the transparent membrane dressings do not require routine changes. Short peripheral lines do not usually dwell longer than a few days; and, as long as the dressing is dry, clean, and intact, it does not have to be changed. Any VAD dressing should be changed when it is loose or soiled.

For central lines and midline catheters, tape and sterile gauze or a transparent membrane dressing may be used. Change tape and gauze dressings every 48 hours; change transparent membrane dressings such as Tegaderm, every 5 to 7 days (INS, 2016). The initial dressing on a midline catheter or PICC is usually tape and gauze, changed within 24 hours after insertion because some bleeding is likely. Transparent membrane dressings can be used for subsequent dressing. For patients who develop erythema (redness) from Tegaderm, the IV3000 dressing from Smith and Nephew may be used. Document when you change the sterile dressing and your IV site assessments in the appropriate electronic health record according to agency policy.

## Nursing Safety Priority QSEN

### Action Alert

Site protection may be needed for short peripheral catheters or for port access needles. Plastic shields can be placed over the site to prevent accidental bumping or pressure from clothing. Make sure that you can easily assess the site frequently. Never place a restraint or opaque dressing over a peripheral IV site, especially when infusing an irritant or vesicant.

When changing the dressing, remove it by pulling laterally from side to side. It can also be removed by holding the external catheter and pulling it off toward the insertion site. *Never pull it off*

by pulling away from the insertion site because this could dislodge the catheter!

After removing the dressing from a midline catheter or any central venous catheter, note the external catheter length. Compare this length with the original length at insertion. If the length has changed, the catheter tip location has also changed and may no longer be in a vein appropriate for infusion. Follow agency policy or notify the primary health care provider about the length change. A chest x-ray may be needed, and careful assessment of the type of therapy and remaining length of therapy will likely be required.

Protect the external catheter, dressing, and all attached tubing from water because it is a source of contamination. *Remind unlicensed assistive personnel (UAP) to cover the extremity where the IV line is located when giving the patient a bath.* A plastic bag or wrap can be taped over the extremity to keep the dressing and site dry.

## Clinical Judgment Challenge 13-1

### Evidence-Based Practice; Safety

A new graduate nurse is being oriented to your medical-surgical nursing unit. Today he is assigned to care for three patients. One patient is an older adult with an infiltrated peripheral IV line in her forearm. The second patient has a PICC line for antibiotic therapy, and the third patient has an arterial implanted port for chemotherapy. As his preceptor, you are responsible for teaching him how to assess patients with these devices and prevent and/or monitor for complications. Your unit has several memory checklists for IV care that you plan to review with him.

1. Which best clinical practices will you teach the new nurse about how to care for patients who have a PICC line?
2. For which life-threatening complication is the patient with the implanted port most at risk?
3. You observe the new nurse as he prepares to restart the IV line for the older-adult patient. He chooses a vein in the dorsum of the hand. What is your best response about his IV site selection?
4. What is the value of memory checklists to ensure consistency among nurses caring for patients receiving IV therapy?

## Changing Administration Sets and Needleless Connectors

Plan the change of administration sets and fluid containers to occur at the same time, if possible, to minimize the number of times the system is opened. For short peripheral catheters, the administration set and catheter should also be changed at the same time to avoid excessive manipulation of the catheter. Document these changes per agency policy.

Needleless connector devices can be changed when the administration set is changed. If it is being used for intermittent infusions, the device should be changed at least once per week. Fluid leakage from the device indicates that the integrity has been compromised, and it should be changed immediately.

Precautions to prevent *air emboli* are required when changing the set or connectors attached to any catheter; however, central venous catheters require special attention. Most catheters have a pinch clamp that can be closed during this procedure. Techniques used to increase the intrathoracic pressure and prevent air embolism during IV set change include:

- Placing the patient in a flat or Trendelenburg position to ensure that the catheter exit site is at or below the level of the heart
- Asking the patient to perform a Valsalva maneuver by holding his or her breath and bearing down
- Timing the IV set change to the expiratory cycle when the patient is spontaneously breathing
- Timing the IV set change to the inspiratory cycle when the patient is receiving positive-pressure mechanical ventilation

## Controlling Infusion Pressure

Fluid flow through the infusion system requires that the pressure on the external side be greater than the pressure at the catheter tip. Fluid flow can be slowed or obstructed by many causes. Inside the catheter lumen, resistance is created by the catheter length and diameter or by deposits of fibrin, thrombus, or drug precipitate. Near the catheter tip, resistance to flow comes from the catheter tip impinging on the vein wall, thrombus, or venous spasm.

All catheter manufacturers have warnings about the use of excessive pressure. Gravity and infusion pumps do not exert pressure too high for the catheter to handle; however, excessive pressure from syringes can lead to catheter damage. For this reason use 10-mL syringes for central venous catheters. Although these larger syringes generate less pressure, it is still possible to reach excessive pressure levels if great force is applied against a syringe attached to a catheter that is partially occluded.

## Flushing the Catheter

Catheter flushing prevents contact between incompatible drugs and maintains patency of the lumens. Normal saline alone or normal saline followed by heparinized saline may be used. When using valved catheters and certain positive fluid-displacement needleless devices, normal saline alone is acceptable because these devices have mechanisms that prevent the backflow of blood into the catheter lumen.

### Nursing Safety Priority QSEN

#### Critical Rescue

Assess catheter patency carefully before each use. Use sterile technique to flush with normal saline while applying slow, gentle pressure to the syringe plunger. If you feel any resistance, stop the procedure immediately! If you continue, catheter rupture or forcing a blood clot into circulation could result. During the flushing procedure always aspirate for a brisk blood return from the catheter lumen.

If the catheter will not yield a blood return, further diagnostic studies may be needed to determine the cause of the problems. Thrombolytic agents such as alteplase (Cathflo Activase) may be used to dissolve blood clots in venous catheters.

For short peripheral catheters, usually 3 mL normal saline is adequate to flush the catheter. For all other catheters 5 to 10 mL of preservative-free normal saline is needed. Bacteriostatic normal saline is limited to no more than 30 mL in a 24-hour period in adults. By using 10 mL before and after each dose of medication, it is easy to exceed this limitation. Check your agency's policy and procedure about specific flushing amounts.

Flush catheters immediately after each use. Delay in disconnecting the intermittent administration set and flushing the catheter could cause lumen occlusion from blood that backflows into the lumen when the infusion pressure is lower than venous pressure.

All fluids used to flush catheters should be obtained from single-dose containers or prefilled syringes. Vials used for multiple doses contribute to medication errors and increase the risk for contamination.

## Obtaining Blood Samples From Central Venous Catheters

Short peripheral catheters should not be used routinely for obtaining blood samples. This additional manipulation could lead to vein irritation that requires removal of the catheter. Central venous catheters and midlines can be used for obtaining blood samples after a careful assessment of the risks versus the benefits. If your patient has no peripheral venipuncture sites or is fearful of needles, using the central venous catheter may be appropriate. The risks associated with obtaining blood samples from a central venous catheter are numerous. This procedure requires additional hub manipulation, which is a major cause of CRBSI. Consider the laboratory tests needed and the types of fluids that have recently been infused. For example, heparin interferes with coagulation

studies, and electrolytes in the fluid may alter the results of serum electrolytes. Drawing blood from catheters for blood culture should not be done within an hour of completion of antimicrobial infusions.

If blood sampling from a central venous catheter is the best alternative, vigorous cleaning of the connections with 70% alcohol is necessary. Use methods that do not require exposed needles. Vacuum tubes attached via a “vacutainer” to the catheter hub eliminate the need to transfer the blood from a syringe into the tubes. For small-diameter catheters, the vacuum in the tube may cause the catheter to temporarily collapse, preventing the backflow of blood into the tube. In this situation small syringes should be used because they create less pressure on aspiration, the opposite of what small syringes do on injection. Transfer of the blood from the syringe to the vacuum tube requires the use of a “vacutainer needle holder.” This device keeps the needle housed in a plastic case and covered, preventing needlestick injuries (Fig. 13-15). After blood draw from any catheter, a flush of 10 to 20 mL sterile normal saline is necessary to ensure a patent line. Be sure to clear the line and cap of blood to prevent a breeding ground for infection.

**FIG. 13-15** Vacutainer needle holder prevents needlestick injuries when drawing blood. (Courtesy and © Becton, Dickinson and Company.)

## Removing the Vascular Access Device

To remove a short peripheral IV line, lift opposite sides of the transparent dressing and pull laterally to remove the dressing from the site while stabilizing the catheter. Slowly withdraw the catheter from the skin and immediately cover the puncture site with dry gauze. Hold pressure on the site until hemostasis is achieved. Assess the catheter tip to make sure that it is intact and completely removed. Document the time of catheter removal and the appearance of the IV site.

Removal of midline catheters and PICCs must be performed with the same slow, gentle techniques used to insert the catheter. Veins can develop venospasms when rapid or forceful techniques are used. After explaining to the patient that this procedure will not be painful, remove the dressing and withdraw the catheter in short segments by pulling from the insertion site. *If you feel resistance, always stop and never apply force to the catheter. Extreme traction or force could cause the catheter to break and embolize (travel) to the heart or pulmonary circulation.*

Simple distraction techniques and deep breathing may be sufficient to relax the patient and remove the catheter. If these fail, replace the dressing and apply heat; allow time for the vein wall to relax. Keeping the extremity warm and dry and asking the patient to drink warm liquids could

facilitate removal. Use of medications to relax the vein wall may be required if the catheter cannot be removed after several hours. Imaging studies may also be needed to determine whether the cause is a thrombosis instead of venospasm.

Nontunneled percutaneous central catheters are removed by clipping any sutures and withdrawing the catheter in short segments. Venospasm does not commonly occur when removing these catheters because the vein diameter is large.

To prevent venous air embolism when removing any central venous catheter (including PICCs), position the patient in a flat supine or Trendelenburg position according to agency policy. To ensure that the intrathoracic pressure is higher than atmospheric pressure, have the patient hold his or her breath or perform a Valsalva maneuver during removal. If the patient is mechanically ventilated, time the removal to the delivery of an inhalation by the ventilator. Be sure to keep the catheter clamped during this procedure. When a central venous catheter is removed, a tract between the skin and vein may create a conduit that could allow air to be pulled into the vein.

After removal, measure the catheter length and compare it with the length documented on insertion. *If the entire catheter length was not removed, contact the primary health care provider immediately!* Removal of tunneled catheters and implanted ports is usually performed by nurse practitioners or physicians.

## Documenting Intravenous Therapy

Intravenous therapy is risk prone. Nurses can protect themselves from malpractice claims with conscientious assessment, intervention, and documentation. Be sure that you document after insertion of a vascular access device (VAD) and throughout the course of the therapy. When inserting a venous catheter, remember to document the:

- Date and time of the VAD insertion
- Name of the nurse (you) who inserted the VAD
- Vein that was used for insertion
- Type of VAD used
- Number of insertion attempts and locations of attempts before successful insertion
- Response of the patient to the VAD insertion process
- Type of dressing applied
- Type of securement device, if used
- Special barrier precautions used, if any
- Patient and family education provided related to IV therapy

During the course of the patient's infusion therapy, be sure to continue documenting in the electronic health record your assessments and any interventions needed as a result of complications. Follow your agency's policies and procedures for additional requirements.

## Complications of Intravenous Therapy

Complications from IV therapy can be minor and limited or life threatening. Serious life-altering or life-threatening complications are dramatically increasing in frequency and severity and present a tremendous financial burden to the U.S. health care system. Catheter-related bloodstream infection (CRBSI) is one of the most serious problems, often resulting in patient death. They are more common in patients with central VADs but can also occur with peripheral catheters.

### Catheter-Related Bloodstream Infection

The Institute for Healthcare Improvement identified CRBSI as one of several preventable hospital-acquired infections (HAIs). As part of their previous *100,000 Lives Campaign*, a number of evidence-based interventions were combined into the CRBSI prevention bundle. As a nurse your accountability is to ensure that these interventions are followed (Table 13-2).

**TABLE 13-2**

#### The Catheter-Related Bloodstream Infection (CRBSI) Prevention Bundle

- Use a *checklist* during insertion to make sure that everything is done correctly. Tell anyone who violates the correct steps to stop the procedure immediately.
- *Hand hygiene* before inserting a central line must be thorough (i.e., no quick scrub). Anyone who touches the central line must also perform thorough hand hygiene.
- *Maximal barrier precautions* during line insertion require that the patient be draped from head to toe with a sterile barrier.
- The primary health care provider who inserts the VAD wears *sterile gloves, gown, and mask*. Anyone in the room during the procedure must also wear a mask.
- *Traffic in and out of the room must be minimized*. Many institutions use a “stop” sign on the door of the room to prevent people from coming in and going out during the procedure and a special “central line cart” to ensure that they have everything they need in the room.
- *Chlorhexidine is used for skin disinfection* because it has best outcomes for preventing infection.
- *Use preferred sites*. PICC in the upper arm and subclavian veins are the first choice. The next preference is the internal jugular vein, and the least preferred is the femoral vein.
- *Post-placement care* requires meticulous dressing changes and care of all parts of the IV system such as keeping ports and stopcocks clean; hanging bags using sterile technique; vigorously scrubbing catheter hub with alcohol when used.
- *Review daily the need* for the patient’s VAD. The incidence of CRBSI increases each day the device is in place. As soon as it is determined that the patient no longer needs the IV line, it should be removed.

PICC, Peripherally inserted central catheter; VAD, vascular access device.

### Other Complications of Intravenous Therapy

*Local complications* of IV therapy occur at or near the catheter. A priority for care for patients with IV therapy is to prevent, assess, and detect these complications. In some cases nurses also manage these problems. Definitions, causes, signs and symptoms, treatment, and prevention of local complications are summarized in Table 13-3. *Systemic complications* of IV therapy involve the entire vascular system or multiple systems. Information on common systemic complications can be found in Table 13-4. For central venous catheters (CVCs), complications can occur during the insertion procedure or during the dwell time (Table 13-5). Tables 13-6 and 13-7 are the INS criteria for grading phlebitis and infiltrations. Document all assessments and complications in the patient's electronic health record. Notify the infusion therapy team and/or primary health care provider per agency policy when complications occur.

**TABLE 13-3**

#### Local Complications of Intravenous Therapy

COMPLICATION	CAUSE	SIGNS AND SYMPTOMS	INTERVENTIONS	PREVENTION
<b>Infiltration</b> Leakage of a nonvesicant IV solution or medication into the extravascular tissue	Peripheral catheter has punctured opposite vein wall Obstruction of blood flow causing backflow through original entrance site Inflammatory process causing fluid leakage at the capillary level Fibrin sheath fully encasing a central venous catheter, leading to retrograde flow and leakage from venipuncture site Damaged septum of implanted port Dislodged port access needle	IV rate slows Increasing edema around site Patient report of skin tightness; blanching or coolness of skin; burning, tenderness, or general discomfort at the insertion site; fluid leaking from puncture site; absence of a blood return (though this may not be reliable with a short peripheral catheter)	Stop infusion and remove short peripheral catheter immediately after identification of problem. Apply sterile dressing if weeping from tissue occurs. Elevate extremity. Warm or cold compresses may be used according to the solution infiltrated and organizational policy. Warm compresses increase circulation to the area and speed healing. Cool compresses may be used to relieve discomfort and reduce swelling. Insert a new catheter in the opposite extremity. For all central venous catheters, obtain a study to determine the cause of the problem. For implanted port, remove and insert a new port access needle. Rate the infiltration using the INS Infiltration Scale and document (Table 13-7).	Catheter stabilization—use smallest catheter appropriate; avoid area of flexion or use armboard. Avoid placing restraints at IV site. Make successive venipunctures proximal to the previous site. Monitor site frequently; educate patient about activities and signs and symptoms. Central venous catheters—obtain a brisk blood return before using the catheter for infusion. Frequently assess proper positioning of port access needle.

				Stabilize it well and protect from clothing.
<b>Extravasation</b>				
Leakage of a vesicant IV solution or medication into the extravascular tissue Can occur with both peripheral and central catheters	Same as for infiltration	Same as for infiltration Blistering and tissue sloughing may not appear for a few days and resolves over 1-4 wks with infiltration of some chemotherapeutic agents such as anthracycline and alkylating agents	Stop infusion and disconnect administration set. Aspirate drug from short peripheral catheter or port access needle. Leave short peripheral catheter or port access needle in place to deliver antidote, if indicated by established policy. If possible, aspirate residual drug from the exit site of a central venous catheter. Administer antidote according to established policy. Apply cold compresses for all drugs EXCEPT vinca alkaloids and epipodophyllotoxins. Photograph site. Monitor at 24 hrs, 1 wk, 2 wks, and as needed. Surgical interventions may be required. Provide written instructions to patient and family.	Same as for infiltration. Know the vesicant potential before giving any IV medication. Prevention is key.
<b>Phlebitis</b>				
Inflammation of the vein Post-infusion phlebitis presents within 48-96 hrs after the catheter has been removed	Mechanical cause from insertion technique, catheter size, and lack of catheter securement Chemical cause from extremes of pH and/or osmolality of the fluid or medication Bacterial cause from a break in aseptic technique, poor securement, and extended dwell time	Patient may report pain at the IV site; nurse may observe that vein appears red and inflamed along the length; vein may become hard and cordlike (Table 13-6)	Remove short peripheral catheter at the first sign of phlebitis; use warm compresses to relieve pain. Monitor frequently. Document using Phlebitis Scale. Insert a new catheter using the opposite extremity. Mechanical phlebitis occurring in the first week after PICC insertion may be treated without catheter removal. Apply continuous heat; rest and elevate the extremity. Significant improvement is seen in 24 hrs, and complete resolution is seen within 72 hrs. Remove catheter if treatment is unsuccessful.	Choose the smallest-gauge catheter for the required therapy. Avoid sites of joint flexion or stabilize with an armboard. Avoid infusing fluids or medications with a pH below 5.0 or above 9.0 through a peripheral vein. Avoid infusing fluids or medications with a final osmolality above 500 mOsm/L through a peripheral vein. Rotate sites every 72-96 hrs according to established policy. Adequately secure the catheter. Use aseptic technique. For PICCs, teach patient to avoid excessive physical activity with the extremity.
<b>Thrombosis</b>				
Blood clot inside the vein	Anything that damages the endothelial lining of the intima can initiate clot formation Traumatic venipuncture Multiple venipuncture attempts Use of catheters too large for the chosen vein Hypercoagulable state and venous stasis	Slowed or stopped infusion rate Swollen extremity Tenderness and redness Engorged peripheral veins of the ipsilateral chest and extremity	Stop infusion and remove short peripheral catheter immediately. Apply cold compresses to decrease blood flow and stabilize the clot. Elevate extremity. Surgical intervention may be required. For central venous catheters, notify the physician and obtain requests for a diagnostic study. Low-dose thrombolytic agents can be used to lyse the clot.	Use evidence-based venipuncture technique. Make only two attempts to perform venipuncture. Choose the smallest-gauge catheter in the largest vein possible. Secure catheter adequately. Use armboards if short peripheral catheters are placed in areas of joint flexion. Ensure adequate hydration to avoid changes in blood composition and flexion of the extremity. Prophylactic low-dose warfarin (Coumadin, Warfilone) may be prescribed for patients with a central venous catheter.
<b>Thrombophlebitis</b>				
Presence of a blood clot and vein inflammation	Same as for phlebitis and thrombosis	Same as for phlebitis and thrombosis	Same as for phlebitis and thrombosis. Apply cold compresses initially, followed by warm.	Same as for phlebitis and thrombosis.
<b>Echymosis and Hematoma</b>				
Echymosis results from infiltration of blood into the surrounding tissue Hematoma results from uncontrolled bleeding	Unskilled or multiple IV insertion attempts Patients with coagulopathy or fragile veins (e.g., older adults and patients on steroids) Accidental laceration of a large vein or artery	Swelling Bruising Pain or tenderness	When removing device, apply light pressure; excessive pressure could cause other fragile veins in the area to rupture. For hematoma, apply direct pressure until bleeding has stopped. Elevate extremity, apply ice for first 24 hours and then warm compress for comfort.	Avoid veins that cannot be easily seen or palpated. Use extra caution in patients with coagulopathies. Use evidence-based venipuncture technique.
<b>Site Infection</b>				
Invasion of microorganisms at the insertion site in the absence of simultaneous bloodstream infection Infection localized at the insertion site, the port pocket, or subcutaneous tunnel	Break in aseptic technique during insertion or the handling of sterile equipment Lack of proper hand hygiene and skin antisepsis	Site appears red, swollen, and warm; patient may report tenderness at the site; may observe purulent or malodorous exudates	Clean exit site with alcohol, expressing drainage if present. For short peripheral catheter, midline catheter, or PICC, remove using sterile technique and avoid contact between skin and catheter. Send catheter tip for culture, if requested. Clean site with alcohol and cover with dry, sterile dressing; physician to evaluate for septic phlebitis and need for antimicrobial therapy or surgical intervention.	Use strict aseptic technique when inserting, maintaining, or removing catheters. Practice evidence-based hand hygiene. Ensure that dressing remains clean, dry, and adherent to skin at all times.
<b>Venous Spasm</b>				
Sudden contraction of the vein	Normal response to irritation or injury of the vein wall	Cramping or pain at or above the insertion site Numbness in the area Slowing of the infusion rate Inability to withdraw midline catheter or PICC	Temporarily slow infusion rate. Apply warm compress. Do not immediately remove short peripheral catheter. If occurring during midline catheter or PICC removal, do not apply tension or attempt forceful removal. Reapply a dressing, apply heat, encourage patient to drink warm liquids, and keep extremity covered and dry. 12-24 hrs may be required before catheter can be removed.	Allow time for vein diameter to return to normal after tourniquet removal and before advancing catheter. Infuse fluids at room temperature if possible. For a midline catheter or PICC, gently withdraw the catheter

				in short segments.
<b>Nerve Damage</b>				
Inadvertent piercing or complete transection of a nerve	Venipuncture near known nerve locations Unanticipated nerve locations	Reports of tingling or feeling "pins and needles" at or below the insertion site Numbness at or near the insertion site	Immediately stop the insertion procedure if the patient reports extreme pain. Remove the catheter if reports of discomfort do not improve when the catheter is secured.	Avoid using the cephalic vein near the wrist. Avoid using veins on the palm side of the wrist. Adequately secure the catheter, but avoid tape that is too tight. Support areas of joint flexion with an armboard.

INS, Infusion Nurses Society; PICC, peripherally inserted central catheter.

**TABLE 13-4**  
**Systemic Complications of Intravenous Therapy**

COMPLICATION	CAUSE	SIGNS AND SYMPTOMS	INTERVENTIONS	PREVENTION
<b>Circulatory Overload</b>				
Disruption of fluid homeostasis with excess fluid in the circulatory system	Infusion of fluids at a rate greater than the patient's system can accommodate	Patient may report shortness of breath and cough; patient's blood pressure is elevated, and there is puffiness around the eyes and edema in dependent areas; patient's neck veins may be engorged, and nurse may hear moist breath sounds.	Slow the IV rate and notify physician; raise patient to an upright position; monitor vital signs and administer oxygen as prescribed; administer diuretics as prescribed.	Monitor intake and output carefully and notify physician as soon as an imbalance is noticed between the patient's intake and output.
<b>Speed Shock</b>				
Systemic reaction to the rapid infusion of a substance unfamiliar to the patient's circulatory system	Rapid infusion of drugs or bolus infusion, which causes the drug to reach toxic levels quickly	Patient may report light-headedness or dizziness and chest tightness; nurse may note that patient has a flushed face and an irregular pulse; without intervention, patient may lose consciousness and go into shock and cardiac arrest.	Immediately discontinue the drug infusion and hang isotonic solution to keep the vein open; monitor vital signs carefully and notify physician for further treatments.	Be aware of the appropriate infusion rate of medications and adhere to them; use of infusion control devices helps to prevent speed shock.
<b>Catheter Embolism</b>				
A shaving or piece of catheter breaks off and floats freely in the vessel	Anything that damages the catheter—during insertion, dressing change, excessive force with flushing, or medication administration	Depending on where the catheter embolizes, this could be life threatening. Cardiopulmonary arrest could occur.	Emergently notify the physician. Remove the catheter and apply a tourniquet high on the limb of the catheter site; inspect catheter to determine how much may have embolized; an x-ray is taken to determine the presence of any catheter piece; surgical intervention may be necessary.	When inserting over-the-needle catheters, never reinsert the needle into the catheter; avoid pulling a through-the-needle catheter back through the needle during insertion. Avoid scissors near the catheter with dressing changes.

**TABLE 13-5**  
**Complications During the Dwell of Central Venous Catheters**

COMPLICATION	POSSIBLE CAUSES	SIGNS AND SYMPTOMS	TREATMENT	PREVENTION
<b>Catheter Migration</b>				
Movement of a properly placed catheter tip to another vein No change in the external catheter length	Changes in intrathoracic pressure caused by coughing, vomiting, sneezing, heavy lifting, and congestive heart failure	For migration to the jugular vein—reports of hearing a running stream or gurgling sound on the side of catheter insertion For migration to the azygos vein—back pain between the shoulder blades Neurologic complications if medications are infused	Stop all infusions and flush catheter. Notify physician. Obtain a chest x-ray, if required, to assess tip location. Spontaneous repositioning back to the SVC is possible. Repositioning by radiology may be required.	Place catheter tip properly in the lower third of the SVC near the junction with the right atrium. Instruct patient to perform usual ADLs but to avoid excessive physical activity.
<b>Catheter Dislodgment</b>				
Movement of catheter into or out of the insertion site	Inadequate catheter securement Excessive physical activity with a PICC	External catheter length has changed, also changing the internal tip location No other signs or symptoms may be noticed immediately	Stop all infusions and flush catheter. NEVER re-advance the catheter into the insertion site. Determine the amount of external catheter length and compare with the length documented on insertion. Notify the physician or nurse inserting the catheter for further assessment.	Use proper catheter securement device. Instruct patient to perform normal ADLs but to avoid excessive physical activity.
<b>Catheter Rupture</b>				
Catheter is broken, damaged, or separated from hub or port body	Forcefully flushing a catheter with any size syringe against resistance Using scissors to remove a dressing Catheter compression of a subclavian-inserted catheter between the clavicle and first rib (also known as <i>pinch-off syndrome</i> )	Fluid leaking from insertion site Pain or swelling during infusion Reflux of blood into the catheter extension Inability to aspirate blood from catheter	Repair the damaged segment; depends on the availability of a repair kit designed for the specific brand of catheter being used; repair may be considered a temporary measure instead of a permanent treatment. Remove catheter.	NEVER use excessive force when flushing a catheter, regardless of syringe size. On injection, small syringes generate more pressure than larger syringes. Use of a 10-mL syringe is generally recommended for flushing procedures. Insert catheter through jugular or upper-extremity sites instead of subclavian site.
<b>Lumen Occlusion</b>				
Catheter lumen is partially or totally blocked	Drug or mineral precipitate (calcium, diazepam, and phenytoin are common) Lipid sludge from long-term infusion of fat emulsion Blood clots and fibrin sheath caused by blood reflux into lumen Allowing administration sets to remain connected for extended periods after medication has infused	Infusion stops or pump alarm sounds Inability or difficulty administering fluids Inability or difficulty drawing blood Increased resistance to flushing of the catheter	Assess history of catheter use. A suddenly developing problem may indicate contact between incompatible medications. A problem that develops over an extended period may indicate a gradual clot formation. For drug precipitate, determine the pH of the precipitated drug. Use hydrochloric acid for acidic drug. Use sodium bicarbonate for alkaline drugs. For blood clot use thrombolytic enzymes such as alteplase.	Always flush with normal saline between, before, and after each medication given through the catheter. Use positive-pressure flushing techniques when a negative fluid-displacement needleless connector is being used. Use a positive fluid-displacement needleless connector. Flush catheters immediately when medication infusion is complete.
<b>Catheter-Related Bloodstream Infection (CRBSI)</b>				
Pathogenic organisms invade the patient's circulation The CDC has specific criteria	Lack of sterile field during insertion Inadequate skin antiseptic agents and application techniques Manipulation of the catheter hub leading to intraluminal	Early symptoms include fever, chills, headache, and general malaise	Change the entire infusion system from solution to IV device; notify physician, obtain cultures, and administer antibiotics as prescribed. If the infusate is the suspected cause, send a specimen to the laboratory for evaluation.	Maintain sterile technique. Use the recommended CRBSI prevention bundle.

to classify these infections	contamination Inadequate hand hygiene Long dwell time

## Intravenous Therapy and Care of the Older Adult

The aging process causes numerous changes in all body functions, and yet aging occurs differently in each person. Nutrition, environment, genetics, social factors, and education are just a few of the factors that influence the older adult's needs. Because all body functions are affected, IV therapy can be affected by these changes.

### Skin Care

Aging skin becomes thinner and loses subcutaneous fat, decreasing the skin's ability for thermal regulation. Fewer nerve endings mean the decreased ability to feel pain. Older patients *may* not perceive acute pain from traumatic venipuncture requiring excessive probing or multiple attempts. However, this action increases the risk for fluid leakage and subsequent infiltration or extravasation injury. Inserting and removing a catheter and dressing could tear the skin layers.

Skin antisepsis is extremely important because of the decreased immunity seen as part of the aging process. Lipids are normally found in skin as a protective agent, and alcohol easily dissolves lipids. Although greater numbers of organisms may be killed, the skin can also become excessively dry and cracked. Current recommendations call for using friction when cleaning the skin to penetrate the layers of the epidermis. However, excessive friction may damage fragile skin and cause impaired TISSUE INTEGRITY. Chlorhexidine is the preferred agent, and the product currently available contains alcohol. Check for allergies to iodine before using iodine or iodophors. Iodophors such as povidone-iodine require contact with the skin for a minimum of 2 minutes to be effective. All antiseptic solutions must be thoroughly dry before applying the dressing or tape.

Skin should never be shaved before venipuncture, but excessive amounts of hair should be clipped. Shaving causes micro-abrasions that can lead to infection. The skin of an older adult may be more delicate and therefore more easily nicked while shaving.

Skin and TISSUE INTEGRITY can easily be compromised by the application of tape or dressings. Use of skin protectant solutions puts a protective barrier between the skin and dressing and improves the adherence of the dressing to the skin. Removal of tape and dressings may require adhesive remover solutions, or an alcohol pad may accomplish the same purpose. Securement devices such as the StatLock require the use of a skin protectant (e.g., Skin-Prep) before applying the device. The protectant prevents skin tearing when the device is removed.

### Vein and Catheter Selection

Vein and catheter selection are of highest importance in older adults. Choose insertion sites carefully after considering the patient's skin integrity, vein condition, and functional ability. The general principle of starting with the most distal sites usually indicates use of hand veins. *However, avoid fragile skin and small, tortuous veins on the back of the hand (dorsum); select the initial IV site higher on the arm.*

Venous distention must be accomplished with a flat tourniquet; however, the veins may require longer to adequately distend. Allowing a tourniquet to remain in place for extended periods causes an overfilling of the vein and can result in a hematoma when the vein is punctured. On extremely fragile skin the tourniquet application can lead to ecchymotic areas or skin tears. Protect the skin by placing a washcloth or the patient's gown between the skin and tourniquet. A tourniquet may not be required in veins that are already distended; however, carefully palpate these veins to determine their condition. Avoid hard, cordlike veins. Blood pressure cuffs can also be used for venous distention. Inflate the cuff and release until the pressure is slightly less than diastolic pressure.

Other methods to distend veins include:

- Tapping lightly, but avoiding forceful slapping
- Asking the patient to open and close the fist so the muscles can force blood into the veins, making sure that the hand is relaxed when the venipuncture is attempted
- Placing the extremity lower than the heart
- Applying warm compresses or a heating pad (be careful not to make it too hot) to the entire extremity for 10 to 20 minutes and removing just before making the venipuncture

As with all patients, venipuncture technique requires adequate skin and vein stabilization during the puncture and complete catheter advancement. Veins of an older adult are more likely to roll away from the needle. Low angles of 10 to 15 degrees between the skin and catheter will improve your success with venipuncture.

As soon as the catheter enters the vein, it may be necessary to release the tourniquet. Release of venous pressure from the puncture can lead to ecchymosis. Allowing the tourniquet to remain in place during the complete catheter advancement could increase this problem.

## Nursing Safety Priority QSEN

### Action Alert

Catheter securement may mean that administration sets are placed out of easy reach of a confused patient. Use flexible netting over the extremity to help prevent the patient from pulling at the dressing or tubing, while allowing easy access to the site. A device such as the I.V. House UltraDressing shown in Fig. 13-16 can also protect the site. Do not use rolled bandages to cover the extremity because they prevent insertion site assessment. Complications may progress to an advanced state before they are noticed.

**FIG. 13-16** I.V. House UltraDressing IV site protector, a safety device used for IV site protection, guards the integrity of the older adult's skin while helping secure the site. (Courtesy I.V. House, Hazelwood, MO.)

Choosing a midline catheter or PICC may be best in older patients with poor skin turgor; limited venous sites; or veins that are fragile, tortuous, or hard. These catheters are placed in the upper extremity where venous distention techniques can be used. Inserting nontunneled percutaneous central catheters in older adults can be much more challenging. Venous distention for insertion requires the Trendelenburg position and a well-hydrated patient. Fluid volume deficit prevents adequate distention of the subclavian or jugular veins. Patients with conditions such as chronic obstructive pulmonary disease and kyphosis cannot tolerate the Trendelenburg position. Tunneled catheters and implanted ports may be appropriate after considering the surgical techniques required to insert these catheters.

## Cardiac and Renal Changes

Because of changes in cardiac and renal status in older adults, the accuracy of infusion volume and flow rate measurements is very important in the older adult. The primary health care provider's prescription for infusion therapy should be assessed for appropriateness for the patient's condition. Older adults are very prone to fluid overload and resulting heart failure. Electronic controlling devices may be required to ensure the necessary accuracy. Signs and symptoms of fluid overload are described in [Chapter 11](#).

When fluid restrictions are required, medications could be diluted in small quantities and delivered using a syringe pump or a manual IV push. Consult with a pharmacist to determine the smallest amount of diluent required. This alternative may allow the patient to have more fluid to drink. Serum sodium levels should be considered when normal saline is routinely used for dilution in patients with hypertension or cardiac problems.

## Clinical Judgment Challenge 13-2

### Patient-Centered Care; Teamwork and Collaboration; Informatics QSEN

A 79-year-old obese woman with diabetes is transferred from the hospital to the skilled nursing facility (SNF) where you work as a charge nurse. The resident is being managed with IV cefoxitin 2 g IV piggyback (IVPB) every 8 hours for osteomyelitis resulting from an infected diabetic foot ulcer. On review of her admission orders, you note that she has a newly inserted intermittent saline lock in her right forearm and is prescribed to receive the antibiotic for 4 more weeks.

1. The SNF policy for administration of drugs prescribed every 8 hours is a 6 PM–2 AM–10 AM schedule. Would you schedule her antibiotic at these times? Why or why not?
2. Two days later as you are planning to end your shift, the resident reports that her IV site seems red and swollen. Which action will you take at this time? What will you document on the resident's electronic health record?
3. Is a peripheral vascular access device (VAD) the best choice for this resident? Why or why not? With whom will you or the oncoming nurse collaborate to make this decision? What does the evidence say about the type of VAD that would be best to meet this resident's needs? Where would you go to find the answer to this clinical question?
4. Using the SBAR technique, what will you report to the oncoming nurse about the resident's IV complications?

An increasing number of patients with chronic illness require repeated and frequent IV therapies. Many of these patients are vein depleted and need vein preservation. Subcutaneous and intraosseous routes have demonstrated effectiveness in emergency resuscitation. These procedures may also be beneficial for routine infusion of isotonic, nonirritant, nonvesicant solutions in patients with chronic illness and vein depletion ([Benson, 2015](#)).

Specific therapies requiring infusion into arteries and peritoneal, epidural, and intrathecal space are also available. These therapies are most commonly used to administer chemotherapy, lytic therapy, or pain medication.

## Subcutaneous Infusion Therapy

**Subcutaneous infusion therapy** has been used for a variety of drug infusions. Most commonly it is used for administration of pain medications and insulin therapy. It is beneficial for palliative care patients who cannot tolerate oral medications, when IM injections are too painful, or when vascular access is not available or is too difficult to obtain.

**Hypodermoclysis or “clysis”** involves the slow infusion of isotonic fluids into the patient's subcutaneous tissue. Although common in the early twentieth to mid-twentieth century, this method had not been widely used again until the 1990s. The growth of geriatric and palliative health care has helped spur the use of this method of infusion therapy for selected patients and the emergent biologics.

Hypodermoclysis can be used for short-term fluid volume replacement. The patient must have sufficient sites of intact skin without infection, inflammation, bruising, scarring, or edema. The most common sites are the front and sides of the thighs and hips, the upper abdomen, and the area under the clavicle. Unlike IV therapy, the upper extremities should not be used because fluid is absorbed more readily from sites with larger stores of adipose tissue. Hypodermoclysis is not appropriate for emergency resuscitations and should not be used if the fluid replacement needs (Smith, 2014).

Hyaluronidase may be prescribed by the primary health care provider and is mixed with each liter of infusion fluid. This substance is an enzyme that improves the absorption of the infusion from the subcutaneous tissue.

A small-gauge (25 to 27) winged infusion or “butterfly” needle, a small-gauge short peripheral catheter, or an infusion set specially designed for subcutaneous infusion can be chosen. The subcutaneous infusion sets have a small needle extending at a right angle from a flat disk that helps stabilize the needle.

When choosing the infusion site, consider the patient's level of activity. The area under the clavicle or the abdomen prevents difficulty with ambulation. Clip excess hair in the area and clean the chosen site with the antiseptic solution, preferably 2% chlorhexidine gluconate in 70% isopropyl alcohol to prevent infection (Smith, 2014). Prime the infusion tubing and the attached subcutaneous infusion set or winged needle. Gently pinch an area of about 2 inches (5 cm) and insert the needle using sterile technique. After securing the needle, cover the site with a transparent dressing. Flow rates for hydration fluids begin at 30 mL/hr. After 1 hour the rate can be increased if the patient has experienced no discomfort. The maximum rate is usually 2 mL/min or 120 mL/hr. Assess the site every 4 hours while in a hospital setting and at least twice daily while at home. Redness, warmth, leakage, bruising, swelling, and reports of pain indicate tissue irritation and possible impaired tissue integrity. If these symptoms occur, remove the infusion needle. Rotate the site at least once a week. More frequent rotation may be needed, depending on TISSUE INTEGRITY (INS, 2016).

Other complications include pooling of the fluid at the insertion site and an uneven fluid drip rate. Both of these problems may be resolved by restarting the infusion in another location. An infusion pump may also be used. Small ambulatory infusion pumps can be used to allow for greater mobility.

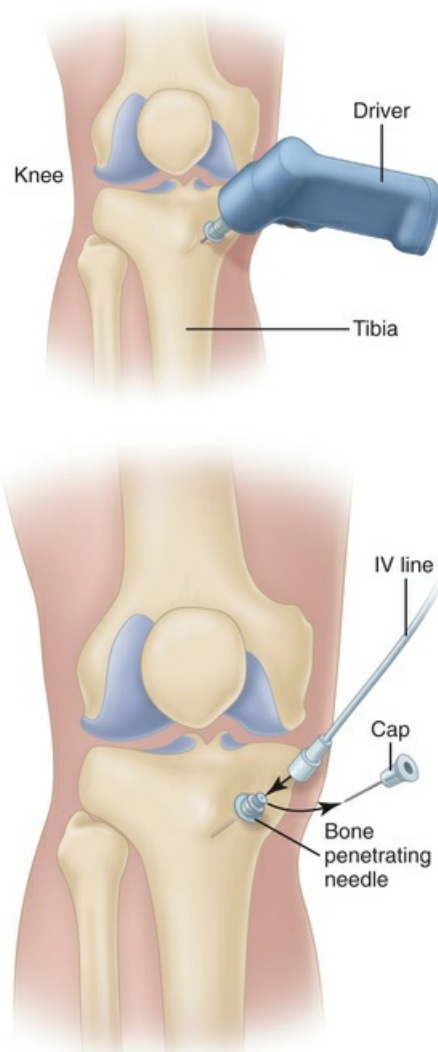

## Intraosseous Infusion Therapy

**Intraosseous (IO) therapy** allows access to the rich vascular network in the red marrow of bones. Although IO has previously been regarded as a pediatric procedure, it is now considered acceptable for use in adults. Victims of trauma, burns, cardiac arrest, diabetic ketoacidosis, and other life-threatening conditions benefit from this therapy because often clinicians cannot access these patients' vascular systems for traditional IV therapy (Benson, 2015). IO catheters may be established in the prehospital setting when IV access cannot be readily obtained in an emergency.

Absorption rates of large-volume parenteral (LVP) infusions and drugs administered via the IO route are similar to those achieved with peripheral or central venous administration. The IO route should be used only during the immediate period of resuscitation and should not be used longer than 24 hours (Benson, 2015). After establishing access, efforts should continue to obtain IV access as well.

There are few contraindications for IO infusion. The only absolute contraindication is fracture in the bone to be used as a site. Conditions such as severe osteoporosis, osteogenesis imperfecta, or other conditions that increase the risk for fracture with insertion of the IO needle and skin infection over the site may also be contraindications for some patients. Repeated attempts to access the same site should be avoided (Anson et al., 2015).

Any needle could be used to provide therapy and access the medullary space (marrow). However, 15- or 16-gauge needles specifically designed for IO therapy are preferred. New technology using a battery-powered drill has improved the ease of IO insertion. A number of sites can be used, including the proximal tibia (tibial tuberosity), distal femur, medial malleolus (inner ankle), proximal humerus, and iliac crest. The proximal tibia is the most common site accessed for IO therapy (Fig. 13-17).

**FIG. 13-17** Proximal tibial intraosseous (IO) access.

If IV access cannot be obtained within the first few minutes of resuscitation procedures, IO therapy may be attempted. The leg is restrained, and the site is cleaned with an antiseptic agent such as chlorhexidine. After successful insertion the needle must be secured to prevent movement out of the bone. The same doses of fluids and medications can be infused by IO therapy as IV. An infusion pump may be used for rapid flow rates.

During the procedure most patients rate the pain as a 2 or 3 on a scale of 0 to 10. Lidocaine 1% is used to anesthetize the skin, the subcutaneous tissue, and the periosteum to promote comfort. Pain is also reported during the initial infusion. This may be reduced by injecting 0.5 mg/kg of preservative-free lidocaine through the IO port before initiating the infusion (Phillips & Gorski, 2014).

Improper needle placement with infiltration into the surrounding tissue is the most common complication of IO therapy. An accumulation of fluid under the skin at either the insertion site or on the other side of the limb indicates that the needle either is not far enough in to penetrate the bone marrow or is too far into the limb and has protruded through the other side of the shaft. Needle obstruction occurs when the puncture has been accomplished but flushing has been delayed. This delay may cause the needle to become clotted with bone marrow.

Osteomyelitis is an unusual but serious complication of IO therapy. You can help prevent this with meticulous aseptic technique, hand hygiene, and removal of the catheter as soon as it is no longer needed.

**Compartment syndrome** is a condition in which increased tissue pressure in a confined anatomic space causes decreased perfusion (peripheral blood flow to the area). The decreased circulation to the area leads to hypoxia and pain in the area. Although the complication is rare in IO therapy, the

nurse should monitor the site carefully and alert the primary health care provider promptly if the patient exhibits any signs of decreased circulation to the limb such as coolness, swelling, mottling, or discoloration. Without improvement in perfusion to the limb, the patient could ultimately require amputation of the limb. Nursing assessment and interventions for compartment syndrome are discussed in detail in [Chapter 51](#).

## Intra-Arterial Infusion Therapy

Catheters are placed into arteries to obtain repeated arterial blood samples, to monitor various hemodynamic pressures continuously, and to infuse chemotherapy agents or fibrinolytics (**intra-arterial infusion therapy**). Catheters placed in the radial, brachial, or femoral arteries are used for obtaining blood samples and arterial pressure monitoring. Arterial waveforms and pressures are converted to digital values displayed on attached monitors. Between the catheter and the monitor is a special administration set capable of handling high infusion pressure, a pressurized fluid container, a continuous flush attachment, a three-way stopcock, and a transducer. The transducer is positioned at the level of the patient's atrium and secured to an IV pole to enable correct arterial pressure measurements.

The pulmonary artery is used to monitor pressures in the heart and lungs. This artery is cannulated via the large central venous system and through the right side of the heart. Hemodynamic monitoring and how to interpret these values are described in [Chapter 38](#).

Chemotherapy agents administered arterially allow infusion of a high concentration of drug directly to the tumor site before it is diluted in blood or metabolized by the liver or kidneys. Drug infusion through the same blood supply feeding the tumor optimizes cell destruction at the tumor site while minimizing systemic side effects. The most common arterial sites include the hepatic and celiac arteries for liver tumors, although the carotid artery for tumors of the head, neck, or brain and pelvic arteries for cervical tumors have been used. Arterial catheter insertion can be performed through the skin via a surgical procedure or by an interventional radiologist. Implanted ports are commonly used for extended therapies. For short-term therapy, an external catheter may be used for 3 to 7 days, although the risks for complications increase during dwell time.

### Nursing Safety Priority QSEN

#### Critical Rescue

Carefully secure all junctions on the administration sets with Luer-Lok devices. Life-threatening hemorrhage can occur if an accidental disconnection occurs! When an infusion pump is used, be sure that it has a pressure high enough to overcome arterial pressure. Closely monitor the arterial insertion site and affected extremity. Assess the extremity for warmth, sensation, capillary refill, and pulse.

When the carotid artery is involved, perform neurologic assessments. When a femoral catheter is used, apply antiembolic stockings or other measures to prevent deep vein thrombosis. Complications from arterial catheters are similar to those from venous catheters, including infection, bleeding from the insertion site, hemorrhage from a catheter disconnection, catheter migration, infiltration, and catheter lumen or arterial occlusion. Specialized training is required to manage patients with arterial catheters.

## Intraperitoneal Infusion Therapy

**Intraperitoneal (IP) infusion therapy** is the administration of chemotherapy agents into the peritoneal cavity. IP therapy is used to treat intra-abdominal malignancies such as ovarian and GI tumors that have moved into the peritoneum after surgery.

Catheters used for IP therapy may be an implanted port for long-term treatment or an external catheter for temporary use. These catheters, including those attached to an implanted port, have large internal lumens with multiple side-holes along the catheter length to allow for delivery of large quantities of fluid. Administration of IP therapy includes three phases: the instillation phase; the dwell phase, usually 1 to 4 hours; and the drain phase. Because this treatment involves the delivery of biohazardous agents, additional competency is required to handle the infusion properly.

The patient should be in the semi-Fowler's position for the infusion. He or she may experience nausea and vomiting caused by increasing pressure on the internal organs from the infusing fluid. Pressure on the diaphragm may cause respiratory distress. Reducing the flow rate and treatment with antiemetic drugs may be needed. Severe pain may indicate that the catheter has migrated, and an abdominal x-ray is needed to determine its location.

During the dwell and drainage phases, the patient may need assistance in frequently moving from side to side to distribute the fluid evenly around the abdominal cavity. After the fluid has drained, the catheter is flushed with normal saline, although heparinized saline may be used in implanted ports. Catheter lumen occlusion is caused by the formation of fibrous sheaths or fibrin clots or plugs inside the catheter or around the tip.

Exit site infection, indicated by redness, tenderness, and warmth of the tissue around the catheter, can occur. Microbial peritonitis and inflammation of the peritoneal membranes from the invasion of microorganisms are other complications. If peritonitis occurs, the patient may experience a fever and report abdominal pain. Abdominal rigidity and rebound tenderness may be present. This condition is preventable by using strict aseptic technique in the handling of all equipment and infusion supplies. Management includes antimicrobial therapy administered either IV or intraperitoneally.

## Intraspinal Infusion Therapy

The spinal column is covered by three layers: the dura mater, or outermost covering; the arachnoid, or middle layer; and the pia mater, which is closest to the spinal cord. Two spaces used for infusion are the **epidural** space between the dura mater and vertebrae and the **subarachnoid** space. The epidural space consists of fat, connective tissue, and blood vessels that protect the spinal cord. Medications infused into the epidural space must diffuse through the dura mater, and there is the possibility that some drug will be absorbed systemically. **Intrathecal** medications are infused into the subarachnoid space and directly into the cerebral spinal fluid, allowing reduced doses (Prager et al., 2014). Care of patients with these therapies requires competency training and validation.

Postoperative and chronic pain is the primary indication for epidural infusion (see Chapter 4). Opioids administered epidurally slowly diffuse across the dura mater to the dorsal horn of the spinal cord. They lock onto receptors and block pain impulses from ascending to the brain. The patient receives pain relief from the level of the injection caudally (toward the toes). Local anesthetics administered epidurally work on the sensory nerve roots in the epidural space to block pain impulses. The primary health care provider administers the first dose of medication; then, depending on state law, the type of medication, and facility policies, nurses trained in epidural therapy may administer subsequent doses.

Intrathecal infusion of chemotherapy has been used for treating central nervous system (CNS) cancers. The belief was that lower total body doses delivered directly to the tumor would help prevent side effects. Intrathecal infusion has also been used to manage chronic pain and treat spasticity of neurologic diseases such as cerebral palsy, multiple sclerosis, reflex sympathetic dystrophy, and traumatic and anoxic acquired brain injuries (Shamsoddini et al., 2014).

A temporary catheter used for epidural therapy can be a percutaneous catheter that is secured at the site and extends up the back toward the shoulder. These catheters are used for postoperative pain management and usually dwell for only several hours or a few days. Infection and subsequent meningitis and catheter migration are the possible complications.

Epidural catheters used for longer periods include a tunneled catheter and implanted port. Tunneled catheters are tunneled toward the abdomen and have a subcutaneous cuff to act as a barrier to infection. The external catheter exits the skin on the abdomen so it can be reached easily for use by the patient or caregiver. An epidural implanted port is the same design as an IV implanted port and is accessed with the same noncoring needle. The catheter extends from the lumbar puncture site to the port pocket and is located over a bony prominence on the abdomen through a subcutaneous tunnel. Surgically implanted pumps can also be used to deliver epidural and intrathecal infusion.

Using sterile technique, an intraspinal catheter usually is inserted in the lumbar region. The external part of a temporary epidural catheter is laid along the back toward the head and usually extends over the shoulder. The entire catheter length is taped for added security. Dressings are usually not routinely changed because they are used only for short periods. If bleeding or fluid leakage requires dressing removal, use extreme care to prevent dislodging the catheter.

For a tunneled catheter or implanted port, the entire subcutaneous tunnel and port pocket should be assessed frequently. Measurement of an external catheter segment could help identify catheter migration.

An in-line filter is used on all intraspinal infusions to block the infusion of particulate matter. Medications commonly contain preservatives such as alcohol, phenols, or sulfites; however, these are toxic to the CNS. All medications used for intraspinal infusion must be free of preservatives. Alcohol and products containing alcohol should not be applied to the insertion site because the solution could track along the catheter and cause nerve damage. Povidone-iodine solutions are preferred for skin antisepsis before insertion and during catheter dwell, including tunneled catheter exit sites and implanted port pockets.

Complications from epidural and intrathecal infusion can be caused by the type of medication being infused or can be related to the catheter. It is important to know the specific location of the intraspinal catheter because the doses of medications are quite different. When used for pain management, doses are usually 10 times greater for epidural than for intrathecal infusion. Assess the patient for response to the drugs being given, level of alertness, respiratory status, and itching.

Catheter-related complications include infection, bleeding, leakage of cerebrospinal fluid (CSF),

occlusion of the catheter lumen, and catheter migration. It is important to be aware of coagulopathy and timing of anticoagulant therapy when epidural catheters are inserted. An epidural hematoma can cause neurologic damage if not corrected promptly. Infection in the patient receiving either epidural or intrathecal therapy could be the result of a lack of asepsis when handling the medication or during the administration. Evidence of local infection such as redness or swelling at the catheter exit site may be present. The patient may also exhibit neurologic and systemic signs of infection (e.g., meningitis) such as headache, stiff neck, or temperature higher than 101° F (38.3° C). Report any neurologic change to the primary health care provider immediately!

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Check infusion administration prescriptions for accuracy and completeness before implementing them. **QSEN: Safety**
- Prevent infusion administration errors by using smart pumps and other emerging technology-based safety infusion systems; these devices do not replace careful monitoring and assessment of the patient receiving infusion therapy. **QSEN: Informatics**
- Devices engineered with safety mechanisms are required by the Occupational Safety and Health Administration (OSHA) to prevent staff injuries from needles, thus preventing bloodborne pathogen hazards. **QSEN: Safety**
- Use the evidence-based catheter-related bloodstream infection (CRBSI) prevention bundle during insertion and care of patients who have central lines, including using a checklist during insertion, hand hygiene, maximal barrier precautions, and chlorhexidine for skin disinfection (see [Table 13-2](#)). **QSEN: Evidence-Based Practice**

### Health Promotion and Maintenance

- Older adults present special challenges when infusion therapy is used; physiologic changes of **TISSUE INTEGRITY** and cardiac/renal systems must be considered.
- Use small IV catheters for older adults and insert using a 10- to 15-degree angle to prevent rolling of the vein. **QSEN: Patient-Centered Care**
- Teach patients and their families about the patient's infusion therapy, including purpose, type, and safety precautions.

### Physiological Integrity

- Infusion therapy is the delivery of parenteral medications and fluids through a wide variety of catheters and locations.
- Infusion therapy is used for establishing **FLUID AND ELECTROLYTE BALANCE**, achieving optimum nutrition, maintaining hemostasis, and treating or preventing illnesses with medications.
- Vascular access devices (VADs) are catheters that are used to deliver fluids and electrolytes and medications into the intravascular space.
- Common types of VADs include short peripheral catheters, midline catheters, peripherally inserted central catheters (PICCs), nontunneled percutaneous and tunneled central catheters, implanted ports, and hemodialysis catheters.
- Use best practice for placement of short peripheral VADs, including avoiding the small veins of the hands (see [Chart 13-1](#)). **QSEN: Evidence-Based Practice**
- Document care for the patient receiving IV therapy, including the type of VAD inserted. **QSEN: Informatics**
- The type of VAD that is used depends on the reason for infusion therapy, the patient's condition, and the length of therapy. **Clinical Judgment**
- Choose the appropriate peripheral catheter gauge size of the VAD, depending on its purpose (see [Table 13-1](#)).
- PICCs, tunneled central catheters, and implanted ports are commonly used for long-term infusion therapy.
- Infusion controllers and pumps are electronic devices used to regulate the flow of infusion fluids

and medications, but be sure to monitor the infusion rate.

- Nursing care for patients receiving all types of infusion therapy includes using sterile technique when starting the therapy and when changing components of the infusion system, changing and securing the site dressing, and assessing the site for local complications (see [Table 13-3](#)). **QSEN: Evidence-Based Practice**
- Assess and document the presence of phlebitis using the INS Phlebitis Scale (see [Table 13-6](#)). **QSEN: Evidence-Based Practice**
- Use normal saline to flush IV catheters on a periodic basis per agency policy.
- Assess, prevent, and manage systemic complications related to IV therapy as outlined in [Table 13-4](#). **Clinical Judgment**
- Assess, prevent, and manage complications during the course of central IV therapy as listed in [Table 13-5](#). **Clinical Judgment**
- Subcutaneous therapy of fluids (hypodermoclysis) involves a slow infusion for a short time; the thighs, hips, and abdomen are commonly used.
- Intraosseous infusion therapy allows fluids and medications to be absorbed by the rich vascular network of the bones; it is used for both children and adults, particularly in emergency situations.
- Arterial therapy is used primarily for the administration of chemotherapy agents directly into a tumor site; the liver is the most common arterial site for this purpose.
- Intraperitoneal therapy is used for chemotherapy agent administration into the peritoneal cavity, especially for ovarian and gastrointestinal tumors that have metastasized into the peritoneum.
- Epidural and intrathecal administration of medications are the common uses for intraspinal infusion. Epidural infusions are usually for pain management; intrathecal infusions are usually chemotherapy agents used for cancers that cross the blood-brain barrier into the central nervous system.

## UNIT IV

# Interprofessional Collaboration for Perioperative Patients

### OUTLINE

---

Chapter 14 Care of Preoperative Patients  
Chapter 15 Care of Intraoperative Patients  
Chapter 16 Care of Postoperative Patients

## CHAPTER 14

# Care of Preoperative Patients

Rebecca M. Patton, Cynthia Danko

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concept for this chapter is SAFETY.**

**The interrelated concepts for this chapter are:**

- TEAMWORK AND INTERPROFESSIONAL COLLABORATION
- ETHICS

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with the interprofessional team to coordinate high-quality care for patients in the preoperative setting.
2. Differentiate SAFETY implications associated with the various types and purposes of surgery.
3. Examine risk factors associated with potential threats to patient and personnel SAFETY.
4. Ensure SAFETY by protecting patients from injury, wrong-site surgery, and health care–associated infection during the preoperative period.

### Health Promotion and Maintenance

5. Teach patients about preoperative preparations and postsurgical interventions to prevent complications.

### Psychosocial Integrity

6. Implement nursing interventions to decrease the psychosocial impact of the preoperative experience.
7. Using principles of ETHICS, respond with advocacy to patient concerns and needs.

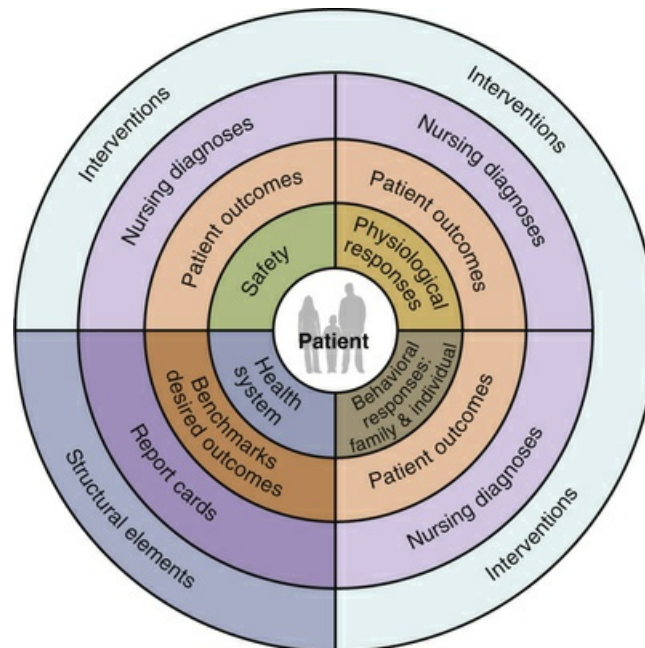

### Physiological Integrity

8. Apply knowledge of anatomy and physiology to perform a complete preoperative assessment.
9. Implement evidence-based nursing interventions to reduce the risk for preoperative complications.
0. Interpret clinical and laboratory data to assess the patient's response to drugs, anesthesia, and surgery.

Advances in surgical techniques, anesthesia, pharmacology, medical devices, and supportive interventions have greatly benefitted patients undergoing surgery. New interventions and advances in anesthetic agents and techniques have made surgery safer than ever before. Outpatient ambulatory care facilities, known as *ambulatory surgical centers (ASCs)*, are being used for many surgical procedures outside acute care hospitals and account for about two thirds of surgical procedures performed in the United States ([American Hospital Association, 2015](#)). Additional factors that have had a positive impact on perioperative care include Population Health Management, Triple Aims, and Value Based Purchasing ([Douglas et al., 2016](#); [Hohenberger & Delahanty, 2015](#); [Zhao et al., 2015](#)).

These positive changes affect the role of the perioperative nurse and have an impact on how patient teaching is performed and perioperative care is provided. Each of these initiatives focuses on health care costs, value-added elements of care and SAFETY, and quality outcomes. However, all changes keep the patient as the central focus of interprofessional care during the surgical experience

(Fig. 14-1).

**FIG. 14-1** Perioperative patient-focused model. (Redrawn from Rothrock, J. C., & Smith, D. A. [2000]. Selecting the perioperative patient focused model. *AORN Journal*, 71[5], 1030-1037. doi:10.1016/s0001-2092(06)61552-4.)

Cost reduction is a driving force for the management of the surgical patient. Shortened stays and ambulatory surgeries are common. Patient histories may be conducted by telephone or online before surgery rather than in person. Some patients may be observed only after surgery and not admitted as an inpatient. In response to the ongoing health care delivery changes and the use of multiple settings, nurses have modified their interventions, remaining focused on patient care before (**preoperative**), during (**intraoperative**), and after (**postoperative**) surgery. Together these time periods are known as the **perioperative** experience.

Patient **SAFETY** throughout the perioperative period is the number-one priority and requires **TEAMWORK AND INTERPROFESSIONAL COLLABORATION**. Fig. 14-2 shows an overview of a surgical safety checklist as recommended by the World Health Organization (WHO), The Joint Commission, and the Association of periOperative Registered Nurses (AORN). Quality measures such as wrong-site surgery, patient falls, hospital-acquired pressure injuries, and vascular catheter-associated infections must now be reported to the Centers for Medicare and Medicaid Services (CMS). These data are used for tracking patient outcomes and ensuring patient-centered care and accountability on the part of health care facilities.

# COMPREHENSIVE SURGICAL CHECKLIST

Blue = World Health Organization (WHO)    Green = The Joint Commission - Universal Protocol 2016 National Patient Safety Goals    Teal = Joint Commission and WHO

PREPROCEDURE CHECK-IN	SIGN-IN	TIME-OUT	SIGN-OUT

The Joint Commission does not stipulate which team member initiates any section of the checklist except for site marking. The Joint Commission also does not stipulate where these activities occur. See the Universal Protocol for details on the Joint Commission requirements.

**FIG. 14-2** Comprehensive surgical checklist. (Created in collaboration with AORN Perioperative Nursing Specialist Robin Chard, PhD, RN, CNOR, AORN; President Charlotte Guglielmi, RN, BSN, MA, CNOR; contributors to the WHO Surgical Safety Checklist, including Atul Gawande, MD, MPH; and representatives from The Joint Commission.)

Because surgery is invasive and involves exposure to various anesthetic agents and drugs, positioning, and other environmental hazards, complications are common. Some complications are predictable and are considered preventable or “never events.” As a result, The Joint Commission (TJC) partnered with other groups and agencies in 2006 and developed a plan for the reduction and eventual elimination of preventable surgical complications known as the Surgical Care Improvement Project (SCIP). Implementation of a set of core compliance measures resulted in a change in the process of managing surgical care. Extensive data about the core measures were collected and publically reported to demonstrate compliance with the process change. Research has demonstrated the effectiveness of the SCIP measures on lowering surgical site infections (SSIs) (Guido et al., 2014). In 2015, data on most measures were no longer collected because the actions associated with this initiative evolved into standard practice for most perioperative departments. Although the SCIP initiative has changed practice in many perioperative settings, additional research is needed to explore the overall impact and the complexity of SSI risks.

The current SCIP foci remain on infection prevention, prevention of serious cardiac events, prevention of venous thromboembolism (VTE) (also known as deep vein thrombosis [DVT]), and maintaining normothermia. Table 14-1 provides an overview of these core measures as currently addressed in the perioperative environment. The preoperative areas of responsibility for these core measures and their prevention strategies are highlighted in the appropriate areas of this chapter. In addition, some core measures also are discussed in patient care chapters most associated with the complication.

**TABLE 14-1**  
**Surgical Care Improvement Project (SCIP) Core Measure Overview**

CORE MEASURE IDENTIFICATION	MEASUREMENT NAME/DESCRIPTION
SCIP Infection-1 (SCIP Inf-1)	<i>Prophylactic Antibiotic Received Within One Hour Prior to Surgical Incision</i> The purpose is to use short-duration antibiotics to establish bactericidal blood and tissue levels by the time the surgical incision is made.

SCIP Infection-2 (SCIP Inf-2)*	<i>Prophylactic Antibiotic Selection for Surgical Patients</i> The purpose is to ensure that prophylactic antibiotics are used for patients who are at increased risk for surgical site infections. The guidelines for risk and for the exact antibiotic to be used are specific to each type of surgical procedure and follow evidence-based published recommendations.
SCIP Infection-3 (SCIP Inf-3)*	<i>Prophylactic Antibiotics Discontinued Within 24 Hours After Surgery End Time</i> The purpose is to ensure that prophylactic antibiotic therapy provides benefit without risk. Prolonged prophylactic antibiotic therapy has not been shown to increase benefit and is known to increase the risk for <i>C. difficile</i> infection and the development of microorganisms that are resistant to antimicrobial drugs.
SCIP Infection-4 (SCIP Inf-4)†	<i>Cardiac Surgery Patients With Controlled 6 AM Postoperative Blood Glucose (Applies to cardiac surgery patients only)</i> The purpose is to avoid hyperglycemia (which is defined as blood glucose levels above 200 mg/dL and is associated with increased complications and mortality) in cardiac surgery patients, especially patients undergoing coronary artery bypass graft surgery and patients with diabetes who are having cardiac surgery.
SCIP Infection-6 (SCIP Inf-6)*	<i>Surgery Patients With Appropriate Hair Removal</i> The purpose is to avoid hair-removal procedures, specifically shaving, that cause skin abrasions and increase the risk for surgical site infections. If hair must be removed from the surgical site, removal is performed with electric clippers or chemical depilatories.
SCIP Infection-9 (SCIP Inf-9)	<i>Urinary Catheter Removed on Postoperative Day 1 (POD 1) or Postoperative Day 2 (POD 2) With Day of Surgery Being Day Zero</i> The purpose is to avoid urinary catheter-associated urinary tract infections, which increase with longer-duration indwelling catheters. It is unacceptable to have an indwelling urinary catheter in place longer than 48 hours after surgery unless there is a documented specific and medically validated reason for it.
SCIP Infection-10 (SCIP Inf-10)	<i>Surgery Patients With Perioperative Temperature Management</i> The purpose is to prevent prolonged hypothermia, which is associated with impaired wound healing, serious cardiac complications, altered drug metabolism, coagulation problems, and a higher incidence of surgical site infections. Temperature must be measured within 15 minutes from the end of anesthesia administration. Intentional hypothermia must be documented.
SCIP CARD-2*	<i>Surgery Patients on Beta-Blocker Therapy Prior to Arrival Who Received a Beta-Blocker During the Perioperative Period</i> The purpose is to ensure that patients with specific medical conditions receive beta-blocker therapy before surgery and continue the therapy in the immediate postoperative period. This evidence-based action has resulted in a significant reduction in coronary events, cardiovascular mortality, and overall mortality.
SCIP Venous thromboembolism-1 (SCIP VTE-1)*	<i>Surgery Patients With Recommended Venous Thromboembolism Prophylaxis Ordered</i> The purpose is to reduce the complications from postoperative venous thromboembolism (VTE). Surgery is a major risk factor responsible for VTE formation and subsequent pulmonary embolism. Although VTE prophylaxis is effective, it is underused. Specific preoperative and postoperative VTE prophylaxis strategies are recommended on the basis of patient risk, type and duration of surgery, and extent of expected postoperative immobilization.
SCIP Venous thromboembolism-2 (SCIP VTE-2)*	<i>Surgery Patients Who Received Appropriate Venous Thromboembolism Prophylaxis Within 24 Hours Prior to Surgery to 24 Hours After Surgery</i> The purpose is to reduce the complications from postoperative venous thromboembolism (VTE), particularly among patients undergoing the types of surgeries in which the risk is highest.

\*Retired in 2015 by CMS and JC. Initiatives have evolved into standard practice; therefore data measurement and submission to CMS no longer required.

†Retired in 2016 by CMS and JC. Initiatives have evolved into standard practice; therefore data measurement and submission to CMS no longer required.

*C. difficile, Clostridium difficile.*

Data from The Joint Commission. (2014). *National Patient Safety Goals*.

## Overview

The preoperative period begins when the patient is scheduled for surgery and ends at the time of transfer to the surgical suite. As a perioperative nurse, you will function primarily as an advocate. The perioperative nurse collaborates with the other team members to plan and implement an individualized care plan for the surgical patient. The surgical environment demands the use of knowledge, judgment, and skills based on the principles of nursing science. Perioperative nursing places special emphasis on SAFETY, advocacy, and patient education, although ensuring a “culture of safety” is the responsibility of all health care team members.

The Association of periOperative Registered Nurses (AORN) is the specialty organization that provides ETHICS and practice standards and recommended practices for safe care for patients undergoing operative and other invasive procedures. AORN has developed a perioperative-specific vocabulary known as the Perioperative Nursing Data Set (PNDS) that describes nursing interventions and outcomes in the perioperative environment. PNDS is integral to evidence-based practice. The Perioperative Patient Focused Model illuminates the relationship among the patient, the family, and the care provided by the perioperative nurse (see Fig. 14-1). The model is the fundamental basis of the PNDS (AORN, 2011). The graphic represents the patient and the family and the extension of the nursing domains. When available in the electronic health record, PNDS can help the perioperative nurse recognize the link between interventions and outcomes (Behairy, 2015).

The patient's readiness for surgery is critical to the outcome. Preoperative care focuses on preparing the patient for the surgery and ensuring patient SAFETY. This care includes assessing patient knowledge and educational needs. Implement interventions needed before surgery to reduce anxiety and complications and promote patient compliance after surgery. In addition, during the nursing assessment before surgery, validate, clarify, and reinforce information the patient has received from the surgical team. Problems identified may warrant further patient assessment or intervention before the procedure. **As required by The Joint Commission's National Patient SAFETY Goals (NPSGs), communication and collaboration with the surgical team are essential so correct actions are taken to achieve the desired outcome.**

## Categories and Purposes of Surgery

Surgical procedures are categorized by the purpose, body location, extent, and degree of urgency. Table 14-2 explains the categories and gives examples of surgical procedures.

**TABLE 14-2**  
**Selected Categories of Surgical Procedures**

CATEGORY	DESCRIPTION	CONDITION OR SURGICAL PROCEDURE
<b>Reasons for Surgery</b>		
Diagnostic	Performed to determine the origin and cause of a disorder or the cell type for cancer	Breast biopsy Exploratory laparotomy Arthroscopy
Curative	Performed to resolve a health problem by repairing or removing the cause	Cholecystectomy Appendectomy Hysterectomy
Transplant	Replacing malfunctioning structures	Kidney transplant Heart transplant Liver transplant
Restorative	Performed to improve a patient's functional ability	Total knee replacement Finger reimplantation
Palliative	Performed to relieve symptoms of a disease process but does not cure	Colostomy Nerve root resection Tumor debulking Ileostomy
Cosmetic	Performed primarily to alter or enhance personal appearance	Liposuction Revision of scars Rhinoplasty Blepharoplasty
<b>Urgency of Surgery</b>		
Elective	Planned for correction of a nonacute problem	Cataract removal Hernia repair Hemorrhoidectomy Total joint replacement
Urgent	Requires prompt intervention; may be life threatening if treatment is delayed more than 24-48 hrs	Intestinal obstruction Bladder obstruction Kidney or ureteral stones Bone fracture Eye injury Acute cholecystitis
Emergent	Requires immediate intervention because of life-threatening consequences	Gunshot or stab wound

		Severe bleeding Abdominal aortic aneurysm Compound fracture Appendectomy
<b>Surgical Approach</b>		
Simple	Only the most overtly affected areas involved in the surgery	Simple/partial mastectomy
Minimally invasive surgery (MIS)	Surgery performed in a body cavity or body area through one or more endoscopes; can correct problems, remove organs, take tissue for biopsy, re-route blood vessels and drainage systems; is a fast-growing and ever-changing type of surgery	Arthroscopy Tubal ligation Hysterectomy Lung lobectomy Coronary artery bypass Cholecystectomy
Radical	Extensive surgery beyond the area obviously involved; is directed at finding a root cause	Radical prostatectomy Radical hysterectomy

## Surgical Settings

The term **inpatient** refers to a patient who is admitted to a hospital. The patient may be admitted the day before or, more often, the day of surgery (often termed same-day admission [SDA]), or he or she may already be an inpatient when surgery is needed. The terms **outpatient** and **ambulatory** refer to a patient who goes to the surgical area the day of the surgery and returns home on the same day (i.e., *same-day surgery* [SDS]). Hospital-based ambulatory surgical centers, freestanding surgical centers, physicians' offices, and ambulatory care centers are common. Regardless of the surgical setting, patient SAFETY, teamwork and interprofessional collaboration, and use of professional ETHICS remain priorities.

The advantages of outpatient surgery centers include cost-effective care, service-oriented processes, and a high degree of patient satisfaction. The complexity of procedures being performed in outpatient surgery centers (e.g., laparoscopic cholecystectomy, total knee replacements) places more responsibility on the patient and family, especially for care after surgery. Often a case manager is needed to coordinate post-discharge care for the patient to ensure follow-up treatments and avoid postprocedure hospital admission.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

The surgical patient assessment begins in the preoperative phase and continues throughout the perioperative experience. Using a patient-centered approach focuses the assessment on the patient's physical, psychosocial, and spiritual needs. The assessment process is key to identifying potential patient problems, planning care, and forecasting potential outcomes.

### History.

Data collection about the patient before surgery begins in various settings (e.g., the surgeon's office, the preadmission or admission office, the inpatient unit, the telephone, the Internet). Completing an assessment and gathering data should take place in a private setting to ensure that the patient's confidentiality is protected. Privacy increases the patient's comfort with the interview process and may help reduce the stress associated with the surgery and anesthesia.

Essential data elements include:

- Age
- Use of tobacco, alcohol, or illicit substances, including marijuana
- Current drugs (prescribed and over-the-counter)
- Use of complementary or alternative practices such as herbal therapies, folk remedies, or acupuncture
- Medical history
- Prior surgical procedures and how these were tolerated
- Prior experience with anesthesia, pain control, and management of nausea or vomiting
- Autologous or directed blood donations
- Allergies, including sensitivity to latex products
- General health
- Family history
- Type of surgery planned

- Knowledge about and understanding of events during the perioperative period
- Adequacy of the patient's support system

When taking a history, assess the patient for problems that increase the risk for complications during and after surgery. Some of these problems are listed in [Table 14-3](#). The American Society of Anesthesiologists (ASA) created the [ASA Physical Status Classification system](#) to assess the fitness of patients before surgery ([American Society of Anesthesiologists, 2014](#)). See [Table 14-4](#) for definitions of the ASA system. Each surgical patient is assigned a classification by the anesthesia provider to indicate overall physical health or sickness before surgery. The ASA Classification has been associated with patient's risks before surgery and provides a baseline for intraoperative care.

**TABLE 14-3**  
**Selected Factors That Increase the Risk for Surgical Complications**

<p><b>Age</b></p> <ul style="list-style-type: none"> <li>• Older than 65 years</li> </ul> <p><b>Medications</b></p> <ul style="list-style-type: none"> <li>• Antihypertensives</li> <li>• Tricyclic antidepressants</li> <li>• Anticoagulants</li> <li>• Nonsteroidal anti-inflammatory drugs (NSAIDs)</li> <li>• Immunosuppressives</li> </ul> <p><b>Medical History</b></p> <ul style="list-style-type: none"> <li>• Decreased immunity</li> <li>• Diabetes</li> <li>• Pulmonary disease</li> <li>• Cardiac disease</li> <li>• Hemodynamic instability</li> <li>• Multi-system disease</li> <li>• Coagulation defect or disorder</li> <li>• Anemia</li> <li>• Dehydration</li> <li>• Infection</li> <li>• Hypertension</li> <li>• Hypotension</li> <li>• Any chronic disease</li> </ul>	<p><b>Prior Surgical Experiences</b></p> <ul style="list-style-type: none"> <li>• Less-than-optimal emotional reaction</li> <li>• Anesthesia reactions or complications</li> <li>• Postoperative complications</li> </ul> <p><b>Health History</b></p> <ul style="list-style-type: none"> <li>• Malnutrition or obesity</li> <li>• Drug, tobacco, alcohol, or illicit substance use or abuse</li> <li>• Altered coping ability</li> <li>• Herbal use</li> </ul> <p><b>Family History</b></p> <ul style="list-style-type: none"> <li>• Malignant hyperthermia</li> <li>• Cancer</li> <li>• Bleeding disorder</li> <li>• Anesthesia reactions or complications</li> </ul> <p><b>Type of Surgical Procedure Planned</b></p> <ul style="list-style-type: none"> <li>• Neck, oral, or facial procedures (airway complications)</li> <li>• Chest or high abdominal procedures (pulmonary complications)</li> <li>• Abdominal surgery (paralytic ileus, venous thromboembolism)</li> </ul>
---	---

**TABLE 14-4**  
**ASA PHYSICAL STATUS CLASSIFICATION SYSTEM**

ASA PS Classification	Definition	Examples, including, but not limited to:
ASA I	Normal healthy patient	Healthy, nonsmoking, no or minimal alcohol use
ASA II	Patient with mild systemic disease	Mild diseases only without substantive functional limitations; examples include (but not limited to): current smoker, social alcohol drinker, pregnancy, obesity (30 < BMI < 40), well-controlled DM/HTN, mild lung disease
ASA III	Patient with severe systemic disease	Substantive functional limitations; one or more moderate-to-severe diseases; examples include (but not limited to): poorly controlled DM or HTN; COPD; morbid obesity (BMI ≥40); active hepatitis; alcohol dependence or abuse; implanted pacemaker; moderate reduction of ejection fraction; ESRD undergoing regularly scheduled dialysis; premature infant PCA <60 weeks; history (>3 months) of MI, CVA, TIA, or CAD/stents
ASA IV	Patient with severe systemic disease that is a constant threat to life	Examples include (but not limited to): recent (<3 months) MI, CVA, TIA, or CAD/stents, ongoing cardiac ischemia or severe valve dysfunction, severe reduction of ejection fraction, sepsis, DIC, ARD or ESRD not undergoing regularly scheduled dialysis
ASA V	Moribund patient who is not expected to survive without the operation	Examples include (but not limited to): ruptured abdominal/thoracic aneurysm, massive trauma, intracranial bleed with mass effect, ischemic bowel in the face of significant cardiac pathology or multiple organ/system dysfunction
ASA VI	Declared brain-dead patient whose organs are being removed for donor purposes	

ARD, Acute renal dysfunction; BMI, body mass index; CAD, coronary artery disease; COPD, chronic obstructive pulmonary disease; CVA, cerebrovascular accident; DIC, disseminated intravascular coagulopathy; DM, diabetes mellitus; ESRD, end-stage renal disease; HTN, hypertension; MI, myocardial infarction; PCA, post-conceptual age; TIA, transient ischemic attack.

**NOTE:** The addition of "E" denotes Emergency surgery. (An emergency is defined as existing when delay in treatment of the patient would lead to a significant increase in the threat to life or body part.) Adopted in 2014 by the American Society of Anesthesiologists (ASA).

Older patients are at increased risk for complications from both anesthesia and surgery ([Deiner et al., 2014](#)). The normal aging process decreases immune system functioning and delays wound healing. The frequency of chronic illness increases in older patients. Gas exchange is more profoundly affected by general anesthetic agents and opioid analgesics. Age-related changes in kidney and liver function may delay the elimination of anesthetic and analgesic agents, increasing the risk for adverse reactions. See [Chart 14-1](#) for other changes in older adults that may alter the operative response or risk.

**Chart 14-1**

**Nursing Focus on the Older Adult**

## Age-Related Changes as Surgical Risk Factors

PHYSIOLOGIC CHANGE	NURSING INTERVENTIONS	RATIONALES
<b>Cardiovascular System</b>		
Decreased cardiac output Increased blood pressure	Determine normal activity levels and note when the patient tires.	Knowing limits helps prevent fatigue.
Decreased peripheral circulation	Monitor vital signs, peripheral pulses, and capillary refill.	Having baseline data helps detect deviations.
<b>Respiratory System</b>		
Reduced vital capacity Loss of lung elasticity	Teach coughing and deep-breathing exercises.	Pulmonary exercises help prevent pulmonary complications.
Decreased oxygenation of blood	Monitor respirations and breathing effort.	Having baseline data helps detect deviations.
<b>Renal/Urinary System</b>		
Decreased blood flow to kidneys Reduced ability to excrete waste Decline in glomerular filtration rate	Monitor intake and output. Assess overall hydration. Monitor electrolyte status.	Ongoing assessment helps detect fluid and electrolyte imbalances and decreased renal function.
Nocturia common	Assist frequently with toileting needs, especially at night.	Frequent toileting helps prevent incontinence and falls.
<b>Neurologic System</b>		
Sensory deficits Slower reaction time Cognitive impairment	Orient the patient to the surroundings. Allow extra time for teaching the patient. Keep patient informed of activities before implementation	An individualized preoperative teaching plan is developed based on the patient's orientation and any neurologic deficits.
Decreased ability to adjust to changes in the surroundings	Provide for the patient's safety.	Safety measures help prevent falls and injury.
<b>Musculoskeletal System</b>		
Increased incidence of deformities related to osteoporosis or arthritis	Assess the patient's mobility. Teach turning and positioning. Encourage ambulation. Place on falls precautions, if indicated.	Interventions help prevent complications of immobility. Safety measures help prevent injury.
<b>Skin</b>		
Dry with less subcutaneous fat makes the skin at greater risk for damage; slower skin healing increases risk for infection	Assess the patient's skin before surgery for lesions, bruises, and areas of decreased circulation. Pad bony prominences. Use pressure-avoiding or pressure-reducing overlays. Avoid applying tape to skin. Teach the patient to change position at least every 2 hours. Use safe patient-handling devices to avoid shearing during patient movement.	Having baseline data helps detect changes and evaluate interventions. Padding can protect at-risk areas. Overlays can prevent pressure injury formation by redistributing body weight. Tape removal damages thin skin. Changing position frequently helps prevent reduced blood flow to an area and changes external pressure patterns.

*Drugs and substance use* may affect patient responses to surgery. Tobacco use increases the risk for pulmonary complications because of changes to the lungs, blood vessels, and chest cavity. Alcohol and illicit substance use can alter the patient's responses to anesthesia and pain medication. Withdrawal of alcohol before surgery may lead to delirium tremens. Prescription and over-the-counter drugs may also affect how the patient reacts to the operative experience. Adverse effects can occur with the use of some herbs. Thus a thorough assessment and documentation of past and current use of herbs or botanicals is essential.

*Medical history* is important to obtain because many chronic illnesses increase surgical risks and need to be considered when planning care. For example, a patient with systemic lupus erythematosus may need additional drugs to offset the stress of the surgery. A patient with immunity issues such as rheumatoid arthritis may need special considerations during the positioning process because of decreased movement and mobility. Any infection present requires intervention before surgery, which may include cancellation of the procedure.

Ask the patient specifically about cardiac problems because complications from anesthesia occur more often in patients with cardiac problems (Devereaux & Sessler, 2015). A patient with a history of rheumatic heart disease may be prescribed antibiotics before surgery. Cardiac problems that increase surgical risks include coronary artery disease, angina, myocardial infarction (MI) within 6 months before surgery, heart failure, hypertension, and dysrhythmias. These problems impair the patient's ability to withstand hemodynamic changes and alter the response to anesthesia. The risk for an MI during surgery is higher in patients who have heart problems. Patients with cardiac disease who are prescribed beta-blocking drugs should continue the therapy before surgery and in the immediate postoperative period (Wong & Irwin, 2016).

Pulmonary complications during or after surgery are more likely to occur in older patients, those with chronic respiratory problems, and smokers because of smoking- or age-related lung changes. Increased chest rigidity and loss of lung elasticity reduce anesthetic excretion. Smoking increases the blood level of **carboxyhemoglobin** (carbon monoxide on oxygen-binding sites of the hemoglobin molecule), which decreases oxygen delivery to organs. Action of cilia in pulmonary mucous membranes decreases, which leads to retained secretions and predisposes the patient to infection (pneumonia) and **atelectasis** (collapse of alveoli). Atelectasis reduces gas exchange and causes intolerance of anesthesia. It is also a common problem after general anesthesia.

Chronic lung problems such as asthma, emphysema, and chronic bronchitis also reduce the elasticity of the lungs, which reduces gas exchange. As a result, patients with these problems have reduced tissue oxygenation.

*Previous surgical procedures and anesthesia* affect the patient's readiness for surgery. Previous experiences, especially with complications, may increase anxiety about the scheduled surgery. Assess the patient's past experiences with anesthesia and all allergies. These data provide information about tolerance of and possible fears about the use of anesthesia. The family medical history and problems with anesthetics may indicate possible reactions to anesthesia such as malignant hyperthermia (see [Chapter 15](#)). This information will be critical for the anesthesia team's plan of care.

An allergy to certain substances alerts you to a possible reaction to anesthetic agents or to substances that are used before or during surgery. For example, povidone-iodine (e.g., Betadine) used for skin cleansing contains the same allergens found in shellfish. Patients who are allergic to shellfish may have an adverse reaction to povidone-iodine. The patient with an allergy to avocados, bananas, strawberries, and other fruits may also have a latex sensitivity or allergy. Patients who have an egg, peanut, or soy allergy may be at risk for a reaction to propofol (Diprivan), which is an anesthetic agent often used in the induction and maintenance of anesthesia, although literature suggests that there is less risk for anaphylaxis to the components of propofol (egg, soy, legumes, peanuts) than previously documented ([Mehta & Chehade, 2014](#)). Carefully assess all patients for food allergies during the preoperative phase. Document in the electronic health record and communicate any allergies to all members of the perioperative team.

*Blood donation* for surgery can be made by the patient (**autologous donations**) a few weeks before the scheduled surgery date. If blood is needed during or after surgery, an autologous blood transfusion can be given. This practice eliminates transfusion reactions and reduces the risk for acquiring bloodborne disease. Specific patient criteria, which may vary by surgical type and patient's health status, must be met to qualify for autologous transfusion.

A special tag is placed on the blood bag when an autologous blood donation has been made. **The blood donor center gives the patient a matching tag that he or she wears or brings to the surgical area before surgery as required by The Joint Commission's National Patient Safety Goals (NPSGs).** This procedure helps ensure that patients receive only their own donated blood.

Patients may wish to have family and friends donate blood exclusively for their use, if needed. This practice (called *directed blood donation*) is possible only if the blood types are compatible and the donor's blood is acceptable. Directed donation is not practiced in all blood donation centers. When directed blood donations are used, a special tag is attached to the blood bag. This tag notes the names of the patient and the donor and bears the patient's signature.

Ask whether autologous or directed blood donations have been made and document this information in the electronic health record. It is important to know the specific blood collection center where the donation was made and whether the blood has arrived before the patient goes into surgery. The hospital receives and stores the blood units until they are used or are no longer needed. Unused blood is returned to the collection center.

Increased use of "bloodless surgery" and minimally invasive surgery (MIS) provides alternatives for patients with religious or medical restrictions to blood transfusions. (Part of professional ETHICS requires interprofessional team members to honor patient requests based on religious views.) These programs reduce the need for transfusion during and after surgery. Some techniques used are limiting blood samples (the number of samples and the volume of blood drawn per sample) before surgery and stimulating the patient's own red blood cell production with epoetin alpha (e.g., Epogen, Procrit). Supplemental iron, folic acid, vitamin B<sub>12</sub>, and vitamin C may be prescribed to help red blood cell formation. Newer equipment and surgical techniques cause less blood loss. Such advances include intraoperative cell salvage machines commonly known as *cell savers*, which suction, wash, and filter blood so it can be given back to the patient's body instead of being discarded. One advantage to this is that the patient receives his or her own blood instead of donor blood, so there is no risk of contracting outside diseases. Because the blood is recirculated, there is no limit to the amount of blood that can be given back to the patient. The cell salvage is a cost-effective and safe option for autologous transfusion. Cell salvage is also a viable alternative for patients with religious objections to receiving blood transfusions ([Kudela et al., 2015](#)). It is important to assess, monitor, teach, and advocate for the patient during the bloodless surgery process.

*Discharge planning* is started before surgery. Assess the patient's home environment, self-care capabilities, and support systems and anticipate postoperative needs before surgery. *All patients, regardless of how minor the procedure or how often they have had surgery, should have discharge planning.*

Older patients and dependent adults may need transportation referrals to and from the physician's office or the surgical setting. A home care nurse may be needed to monitor recovery and provide instructions. Patients with few support systems may need follow-up care at home. Some patients need a planned direct admission to a rehabilitation facility or center for physical therapy after surgery, especially joint-replacement surgery. Shortened hospital stays require adequate discharge planning to achieve the desired outcomes after surgery.

## NCLEX Examination Challenge 14-1

### Safe and Effective Care Environment

A client was originally scheduled for surgery at noon. The surgeon is delayed, and the surgery has been rescheduled for 3:00 PM. How will the nurse plan to administer the preoperative prophylactic antibiotic?

- A. Give at noon as originally prescribed.
- B. Cancel orders; preoperative prophylactic antibiotics are given optionally.
- C. Adjust the administration time to be given within 1 hour before surgery.
- D. Hold the preoperative antibiotic so it can be administered immediately following surgery.

### Physical Assessment/Signs and Symptoms.

The preoperative patient may be any age, with a health status that varies from well to debilitated. Perform a complete assessment before surgery to obtain baseline data. Use this information to identify current health problems, potential complications related to anesthesia, and risk for complications that may occur after surgery.

Begin the assessment by obtaining a complete set of vital signs. You may need to obtain vital signs several times at different time intervals for accurate baseline values. Previous vital signs from another admission (if available) are helpful to compare with current vital signs. Abnormal vital signs may require postponement of surgery until the problem is treated and the patient's condition is stable. Also assess for anxiety, which could increase blood pressure, pulse, and respiratory rate. Document these findings as part of the overall assessment.

Throughout the assessment focus on problem areas identified from the patient's history and on all body systems affected by the surgical procedure. The older adult ([Chart 14-2](#); see also [Chapter 3](#)) or chronically ill patient is at increased risk for complications during and after surgery. The number of serious diseases (**morbidity**) and death (**mortality**) during or after surgery is higher in older and chronically ill patients ([Deiner et al., 2014](#); [Oresanya et al., 2014](#)).

### Chart 14-2

## Nursing Focus on the Older Adult

### Specific Considerations When Planning Care for the Older Preoperative Patient

- Greater incidence of chronic illness (e.g., hypertension, diabetes, cardiac)
- Greater incidence of malnutrition and dehydration
- More allergies
- Increased abnormal laboratory values (anemia, low albumin level)
- Increased incidence of impaired self-care abilities
- Inadequate support systems

- Decreased ability to withstand the stress of surgery and anesthesia
- Increased risk for cardiopulmonary complications after surgery
- Risk for a change in mental status when admitted (e.g., related to unfamiliar surroundings, change in routine, drugs)
- Increased risk for a fall and resultant injury
- Mobility changes

**Report any abnormal assessment findings to the surgeon and to anesthesia personnel, as required by The Joint Commission's NPSGs.** In this way, you are a proactive patient advocate exercising professional legal and ETHICAL responsibility and demonstrating critical thinking skills. Often established protocols or care maps identify which interventions are to be performed before surgery.

*Cardiovascular status* is critical to assess because cardiac problems are associated with many surgery-related deaths. Check the patient for hypertension, which is common, is often undiagnosed, and can affect the response to surgery. Cardiac assessment includes listening to heart sounds for rate, regularity, and abnormalities. Ask whether the patient has ever had a venous thromboembolism (VTE). Examine the patient's hands and feet for temperature, color, peripheral pulses, capillary refill, and edema. Report any problems (e.g., absent peripheral pulses, pitting edema, cardiac symptoms, chest pain, shortness of breath, and dyspnea) to the surgeon for further assessment and evaluation. (Cardiac assessment is discussed in [Chapter 33](#).)

*Respiratory status* considers age, smoking history (including exposure to secondhand smoke), and any chronic illness. Obese patients may have undiagnosed respiratory problems such as obstructive sleep apnea (OSA), which can lead to complications from anesthesia ([Ramly et al., 2015](#); [Shah et al., 2016](#)). Observe the patient's posture; respiratory rate, rhythm, and depth; overall respiratory effort; and lung expansion. Document any clubbing of the fingertips (swelling at the base of the nail beds caused by a chronic lack of oxygen) or cyanosis. Auscultate the lungs to assess for any abnormal breath sounds (crackles, wheezes, rubs). (More information on respiratory assessment is found in [Chapter 27](#).)

*Kidney* function affects the excretion of drugs and waste products, including anesthetic and analgesic agents. If kidney function is reduced, fluid and electrolyte balance can be altered, especially in older patients. Ask about problems such as urinary frequency, **dysuria** (painful urination), **nocturia** (awakening during nighttime sleep because of a need to void), difficulty starting urine flow, and **oliguria** (scant amount of urine). Ask the patient about the appearance and odor of the urine. Assess the patient's usual fluid intake and degree of continence. If the patient has kidney or urinary problems, consult with the surgeon about further workup. (Kidney/urinary assessment is discussed further in [Chapter 65](#).)

Kidney impairment with a reduced glomerular filtration rate decreases the excretion of drugs and anesthetic agents. As a result, drug responses may be prolonged. Scopolamine (Buscopan ) , morphine, other opioids, benzodiazepines, and barbiturates often cause confusion, disorientation, apprehension, and restlessness when given to patients with decreased kidney function.

*Neurologic status* includes the patient's overall mental status, level of consciousness, orientation, and ability to follow commands. This information is needed before planning preoperative teaching and care after surgery. A problem in any of these areas affects the type of care needed during the surgical experience. Determine the patient's baseline neurologic status to be able to identify changes that may occur later. Also assess for any motor or sensory deficits. (See [Chapter 41](#) for complete nervous system assessment.) **The Joint Commission's NPSGs require that you ensure patient SAFETY by assessing the patient's risk for falling, especially older patients.** Evaluate factors such as mental status, muscle strength, steadiness of gait, and sense of independence to determine the patient's risk. Document the patient's ability to ambulate and the steadiness of gait as baseline data.

The usual neurologic status of a mentally impaired patient may be difficult to assess. Psychiatric issues may be overlooked in the perioperative environment; but an assessment of coping skills, a mental health history, and recent behavioral changes is the minimum standard of care for patients at risk or patients with previously diagnosed mental illness. The patient who has been independent and oriented at home may become disoriented in the hospital setting. Family members can often

provide information about what the patient was like at home.

*Musculoskeletal status* problems may interfere with positioning during and after surgery. For example, patients with arthritis may be able to assume surgical positions but have discomfort after surgery from prolonged joint immobilization. Other anatomic features such as the shape and length of the neck and the shape of the chest cavity may interfere with respiratory and cardiac function or require special positioning during surgery.

## Nursing Safety Priority QSEN

### Action Alert

Ask about a history of joint replacement and document the exact location of any prostheses. Communicate this information to operating room personnel to ensure that electrocautery pads, which could cause an electrical burn, are not placed on or near the area of the prosthesis. Other areas to avoid when placing electrocautery pads include on or near bony prominences, pacemakers, scar tissue, hair, tattoos, weight-bearing surfaces, pressure points, and metal piercings.

*Nutrition status*, especially malnutrition and obesity, can increase surgical risk. Surgery increases metabolic rate and depletes potassium and vitamins C and B, all of which are needed for wound healing and blood clotting. In poorly nourished patients decreased serum protein levels may slow recovery. Negative nitrogen balance may result from depleted protein stores. This problem increases the risk for skin breakdown, delayed wound healing, possible dehiscence or evisceration (see [Chapter 16](#)), dehydration, and sepsis.

Some older patients may have poor nutrition because of chronic illness, diuretic or laxative use, poor dietary planning or habits, anorexia, lack of motivation, or financial limitations ([Touhy & Jett, 2015](#)). Indications of poor fluid or nutrition status include:

- Brittle nails
- Muscle wasting
- Dry or flaky skin, decreased skin turgor, and hair changes (e.g., dull, sparse, dry)
- Orthostatic (postural) hypotension
- Decreased serum protein levels and abnormal serum electrolyte values

The obese patient is often malnourished because of an imbalanced diet. Obesity increases the risk for poor wound healing because of excessive *adipose* (fatty) tissue. Fatty tissue has few blood vessels, little collagen, and decreased nutrients, all of which are needed for wound healing. Obesity stresses the heart and reduces the lung volumes, which can affect the surgery and recovery. Obese patients may need larger drug doses and may retain them longer after surgery.

*Skin assessment* is an important component of the preoperative assessment. Assess skin color, turgor, and temperature; signs of breakdown; open sores; or areas that may be exposed to excessive pressure during the surgical procedure. Be attentive to body piercing, body modifications, and tattoos. Document these findings and communicate this information to members of the interprofessional perioperative team so precautions can be taken to prevent injury during surgery. Keeping patients safe and free from skin injury caused by pressure injuries, surgical burns, or bruises is the responsibility of all members of the team. Many insurers no longer reimburse hospitals for care provided to patients who develop skin breakdown or pressure injuries during the perioperative period.

### Psychosocial Assessment.

Most patients have some degree of anxiety or fear before surgery. The extent of these reactions varies according to the type of surgery, the perceived effects of the surgery and its potential outcome, and the patient's personality. Surgery may be seen as a threat to life, body image, self-esteem, self-concept, or lifestyle. Patients may fear death, pain, helplessness, a change in role or work status, a diagnosis of life-threatening conditions, possible disabling or crippling effects, or the unknown.

Anxiety or fear affects the patient's ability to learn, cope, and cooperate with teaching and

operative procedures. Anxiety may also influence the amount and type of anesthetic needed and may slow recovery. In some cases, severe preoperative anxiety can increase the degree of pain after surgery. Be aware of potential anxiety when interviewing the patient and planning teaching.

Perform a psychosocial assessment to determine the patient's level of anxiety, coping ability, and support systems. Provide information and support to the patient and family as needed. Identify coping mechanisms used by the patient under similar situations or in the past when confronted with a stressful situation. Ask open-ended questions about the patient's feelings about the entire surgical experience. Factors that influence coping include age, previous surgical or sick-role experiences, and physical discomfort. Indications of anxiety include anger, crying, restlessness, profuse sweating, increased pulse rate, palpitations, sleeplessness, diarrhea, and urinary frequency.

### Laboratory Assessment.

Laboratory tests before surgery provide baseline data about the patient's health and help predict potential complications. The patient scheduled for surgery in an ambulatory surgical center or admitted to the hospital on the morning of or day before surgery may have preadmission testing (PAT) performed from 24 hours to 28 days before the scheduled surgery. These test results are usually valid unless there has been a change in the patient's condition that warrants repeated testing or the patient is taking drugs that can alter laboratory values (e.g., warfarin [Coumadin], aspirin, diuretics). Some facilities have time limits for tests, especially pregnancy testing or any other test results that would require altering the surgical plan.

The choice of laboratory testing before surgery varies among facilities and depends on the patient's age, medical history, and type of anesthesia planned (Rothrock, 2014). The most common tests include:

- Urinalysis
- Blood type and screen
- Complete blood count or hemoglobin level and hematocrit
- Clotting studies (prothrombin time [PT], international normalized ratio [INR], activated partial thromboplastin time [aPTT], platelet count)
- Electrolyte levels
- Serum creatinine and blood urea nitrogen levels
- Depending on a female patient's age and the nature of the planned procedure, a pregnancy test may also be needed

Urinalysis is performed to assess for abnormal substances in the urine such as protein, glucose, blood, and bacteria. If kidney disease is suspected or if the patient is older, the physician may request other tests to determine the type and degree of disease present.

Report electrolyte imbalances or other abnormal laboratory results to the anesthesia team and the surgeon before surgery begins. **Hypokalemia** (decreased serum potassium level) increases the risk for toxicity if the patient is taking digoxin, slows recovery from anesthesia, and increases cardiac irritability. **Hyperkalemia** (increased serum potassium level) increases the risk for dysrhythmias, especially with the use of anesthesia.

## Nursing Safety Priority QSEN

### Critical Rescue

Review laboratory findings to recognize any potassium imbalance. If either hypokalemia or hyperkalemia is present, respond by communicating this information to the surgical team so the imbalance can be corrected before surgery.

Other studies may be needed, depending on the patient's medical history. For example, baseline arterial blood gas (ABG) values are assessed before surgery for patients with chronic pulmonary problems. Laboratory values and their significance are found in [Chapters 11, 12, 39, and 65](#).

### Imaging Assessment.

A chest x-ray may be requested before surgery. Healthy adults are often not required to have a

chest x-ray. A chest x-ray determines the size and shape of the heart, lungs, and major vessels and provides evidence of the presence of pneumonia or tuberculosis. It also provides baseline data in case of complications. Abnormal x-ray findings alert the surgeon to potential cardiac or pulmonary complications. Heart failure, cardiomyopathy, pneumonia, or infiltrates may cause cancellation or delay of elective surgery. For emergency surgery, x-ray results help the anesthesia provider select anesthesia type.

Other imaging studies are based on patient need, medical history, and the nature of the surgical procedure. For example, a patient with back pain may have computed tomography (CT) scans or magnetic resonance imaging (MRI) examinations before spinal surgery to identify the exact location of the problem.

### Other Diagnostic Assessment.

An electrocardiogram (ECG) may be required for patients older than a specific age who are to have general anesthesia. The age varies among facilities but is often 40 to 45 years. An ECG may also be required for patients with a history of cardiac disease or those at risk for cardiac complications. It provides baseline information on new or existing cardiac problems such as an old myocardial infarction (MI). A patient with a known cardiac problem may need a cardiology consultation before surgery.

Drugs for problem prevention such as nitroglycerin, beta-blockers, and antibiotics may be needed throughout the perioperative period to reduce or prevent stress on the heart. Abnormal or potentially life-threatening ECG results may cause the cancellation of surgery until the patient's cardiac status is stable.

A focused assessment of the preoperative patient is shown in [Chart 14-3](#).

#### Chart 14-3

### Focused Assessment

#### The Preoperative Patient

As part of the cardiopulmonary assessment, take and record vital signs; report:

- Hypotension or hypertension
- Heart rate less than 60 or more than 120 beats/min
- Irregular heart rate
- Chest pain
- Shortness of breath or dyspnea
- Tachypnea
- Pulse oximetry reading of less than 94%

Assess for and report any signs or symptoms of infection, including:

- Fever
- Purulent sputum

- Dysuria or cloudy, foul-smelling urine
- Any red, swollen, draining IV or wound site
- Increased white blood cell count

Assess for and report signs or symptoms that could contraindicate surgery, including:

- Increased prothrombin time (PT), international normalized ratio (INR), or activated partial thromboplastin time (aPTT)
- Hypokalemia or hyperkalemia
- Patient report of possible pregnancy or positive pregnancy test

Assess for and report other clinical conditions that may need further evaluation before proceeding with the surgical plans, including:

- Change in mental status
- Vomiting
- Rash
- Recent administration of an anticoagulant drug

Assess and determine functionality of any implantable cardiovascular devices:

- Pacemaker
- Implantable cardioverter defibrillators (ICDs)

Evaluate patient and family past medical history that may need further evaluation:

- History of ischemic heart disease and interventions
- History of cerebrovascular disease and interventions

## NCLEX Examination Challenge 14-2

### Safe and Effective Care Environment

Which assessment data finding for a client scheduled for total knee replacement surgery is **most** important for the nurse to communicate to the surgeon and the anesthesia provider before the procedure? **Select all that apply.**

A. The oxygen saturation is 97%.

- B. The serum potassium level is 3.0 mEq/L (3.0 mmol/L).
- C. The client took a total of 1300 mg of aspirin yesterday.
- D. The client requests to talk with a registered dietitian about weight loss.
- E. The client took a regularly scheduled antihypertensive drug with a sip of water 2 hours ago.
- F. After receiving the preoperative medications, the client tells the nurse that he lied on the assessment form and that he really is a current smoker.

### ◆**Analysis: Interpreting**

The priority collaborative problems for preoperative patients are:

1. Need for health teaching due to unfamiliarity with surgical procedures and preparation
2. Anxiety due to new or unknown experience, possibility of pain, and possible surgical outcomes

### ◆**Planning and Implementation: Responding**

The role of the perioperative nurse in the preoperative setting is to advocate for the patient and coordinate all aspects of care before the patient transfer to the operating room. The preoperative nurse participates in the assessment of risk for the surgical patient and collaborates with other members of the perioperative team to safely transition the patient to the intraoperative phase of care (Malley et al., 2015) (see the [Evidence-Based Practice](#) box).

## **Evidence-Based Practice** OSEN

### **Preoperative Assessment—Does It Assist With Transitions in Care in the Perioperative Environment?**

Malley, A., Kenner, C., Kim, T., & Blakeney, B. (2015). The role of the nurse and the preoperative assessment in patient transitions. *AORN Journal*, 102(2), 181.e1-181.e9.

Perioperative care occurs in a complex environment that involves numerous members of the interdisciplinary team, multiple transitions of care, various communication pathways, and extensive use of technology. The nursing preoperative assessment is designed to highlight patient vulnerabilities that significantly increase the risk for perioperative surgical and anesthesia complications.

Information obtained during the preoperative phase is used to evaluate the patient's status and plan for interventions that effectively meet care needs and minimize poor outcomes. During this assessment, the nurse serves as a patient advocate by accurately communicating the plan of care to interdisciplinary team members during transitions in care levels.

Research identifies communication as a critical element in maintaining patient safety in the perioperative environment. Lack of communication contributes to adverse events and unexpected negative outcomes. Using Dr. Afaf Meleis' transitions theory as a framework, the complexities of the transitions inherent in the perioperative environment were studied in this research.

#### **Level of Evidence: 3**

The study is a qualitative descriptive design used to identify: (1) nursing's contributions to transitions in care as the patient moved between care settings in the perioperative environment, and (2) the role of the preoperative assessment in the transitions. Focus groups were conducted with 24 nurses in a 975-bed medical center. Five open-ended questions were presented to the participants. Time was allotted for the nurses to provide detailed information about the use of the nursing preoperative assessment and the gaps in information incurred as patients moved between care settings. As recurring patterns emerged, four themes were identified:

1. Understanding patient vulnerabilities
2. Multidimensional communication

### 3. Managing patients' expectations

### 4. Nursing's role in compensating for gaps

Because the study was conducted in a single academic health care setting with a small number of participants, findings may not be transferable to all other health care settings.

#### Commentary: Implications for Practice and Research

Nurses contribute to transitions in care by integrating and reconciling data from diverse sources. Identifying “red flags” that emerge during transitions in care were critical. The preoperative assessment, which established an accurate patient baseline, was viewed as helpful in identifying the red flags for both preoperative and postoperative nurses. Additional research is needed to discern how nurses and other members of the interdisciplinary team can identify and address patient vulnerabilities in the perioperative environment.

## Providing Information

### Planning: Expected Outcomes.

The patient needs to know what to expect during and after surgery, as well as how to participate in his or her recovery as indicated by consistently demonstrating these behaviors:

- Explaining in his or her own words the purpose and expected results of the planned surgery
- Asking questions when a term or procedure is not known
- Adhering to the NPO requirements
- Stating an understanding of preoperative preparations (e.g., skin preparation, bowel preparation)
- Demonstrating correct use of exercises and techniques to be used after surgery for the prevention of complications (e.g., splinting the incision, using an incentive spirometer, performing leg exercises, ambulating as early as permitted)

### Interventions.

Because the surgical experience is foreign to many people, focus on teaching the patient and family members. Teaching may begin in the surgeon's office for planned or elective surgery. Pamphlets, written instructions, approved websites, and video recordings or DVDs may be given or sent to the patient. More teaching may occur when the patient has preadmission testing. Some facilities hold classes before surgery for groups of patients or show videos for those who are having the same or similar surgical procedures. A tour of the operating suite and the postanesthesia care unit (PACU) may be included.

Explore the patient's level of knowledge and understanding. Increased access to information via the Internet may be helpful but is also a concern. Some Internet information may not be accurate or may not apply to a specific patient's plan of care.

**The Joint Commission's NPSGs require that you provide information about informed consent, dietary restrictions, specific preparation for surgery (bowel and skin preparations), exercises after surgery, and plans for pain management to promote patients' participation and help achieve the expected outcome.** A sample educational checklist is shown in [Table 14-5](#). Because education occurs in a variety of settings, coordination of patient teaching efforts is challenging. When you care for the patient just before surgery (same-day, ambulatory surgery [outpatient] unit, inpatient hospital unit), assess the patient's and family members' knowledge and provide additional information as needed. If the patient is receiving sedation or general anesthesia, stress the importance of having another adult drive the patient home after the procedure. Document information in the electronic health record about who was involved in teaching, what specifically was taught, and which education materials were given to the patient and family.

---

**TABLE 14-5**

### Preoperative Teaching Checklist

---

Consider these items when planning individualized preoperative teaching for patients and families: <ul style="list-style-type: none"><li>• Fears and anxieties</li><li>• Surgical procedure</li><li>• Preoperative routines (e.g., NPO, blood samples, showering)</li></ul>
---

- Invasive procedures (e.g., lines, catheters)
- Coughing, turning, deep breathing
- Incentive spirometer
- How to use
- How to tell when used correctly
- Lower extremity exercises
- Stockings and pneumatic compression devices
- Early ambulation
- Splinting
- Pain management

### Ensuring Informed Consent.

Surgery of any type involves invasion of the body and requires informed consent from the patient or legal guardian (Fig. 14-3). **The Joint Commission's NPSGs state that patients deserve to be informed and involved in decisions affecting their health care.** Consent implies that the patient has sufficient information to understand:

**GENERAL REQUEST AND CONSENT**

**FOR OFFICE USE ONLY:**  
 Patient Name: \_\_\_\_\_  
 Date of Birth: \_\_\_\_\_  
 Date of Procedure: \_\_\_\_\_

I \_\_\_\_\_ (Type or print patient name) request and give consent to \_\_\_\_\_ (Type or print Doctor or Practitioner Name(s))  
to perform the following procedure(s) \_\_\_\_\_ (Please list site and side if appropriate)

---

The benefits, risks, complications, and alternatives to the above procedure(s) have been explained to me.  
I understand that the procedure(s) will be performed at Christiana Care by and under supervision of my doctor or practitioner. My doctor or practitioner may use the services of other doctors or practitioners, or members of the resident staff as he or she deems necessary or advisable.  
I authorize my doctor or practitioner and his or her associates and assistants to perform such additional procedures, which in their judgment are necessary and appropriate to carry out my diagnosis or treatment.  
I authorize the hospital to retain, preserve and use for scientific, teaching or transplant purposes, or to make other dispositions of, at their convenience, any specimens, tissues, or parts taken from my body during the course of this operation.  
I consent to observers in the operating room in accordance with hospital policy. I consent to photography or video taping of my surgical procedure for educational purposes, provided my identity remains anonymous and confidential.  
I agree to being given blood or blood products as deemed advisable during the course of my procedure. The risks, benefits, and alternatives to receiving blood or blood products have been explained to me.  
I consent to the administration of sedation or analgesia during my procedure. The risks, benefits, and alternatives to receiving sedation or analgesia have been explained to me.  
If anesthesia is required, I consent to the administration of anesthesia by members of the Department of Anesthesiology. I also consent to the use of non-invasive and invasive monitoring techniques as deemed necessary. I understand that anesthesia involves risks that are in addition to those resulting from the operation itself including, but not limited to, dental injury, hoarseness, vocal cord injury, infection, nerve injury, corneal abrasion, seizures, heart attack, stroke and even death.  
Please initial one of the following statements (females only):  
\_\_\_\_\_ To the best of my knowledge I am not pregnant. \_\_\_\_\_ I believe I am pregnant.  
I certify that I have read and understand the above consent statements. In addition, I have been offered the opportunity to ask my doctor or practitioner any questions I have regarding the procedure(s) to be performed and they have been answered to my satisfaction. I acknowledge that I have been given no guarantee or assurance as to the results that may be obtained from the procedure(s).

**FIG. 14-3** Surgical consent form. (Courtesy Christiana Care Health Services, Newark, DE.)

- The nature of and reason for surgery
- Who will be performing the surgery and whether others will be present during the procedure (e.g., students, vendors)
- All available options and the benefits and risks associated with each option
- The risks associated with the surgical procedure and its potential outcomes
- The risks associated with the use of anesthesia
- The risks, benefits, and alternatives to the use of blood or blood products during the procedure

Informed consent is one way to help ensure patient SAFETY and reflects professional ETHICS. It helps protect the patient from any unwanted procedures and protects the surgeon and the facility

from lawsuit claims related to unauthorized surgery or uninformed patients. Written record of informed consent is documented on a “consent form” but can also be documented in the surgeon's notes. The consent form documents the patient's consent and signature for the procedure(s) listed.

As a competent adult, it is the patient's right to refuse treatment for any reason, even when refusal might lead to death. For example, in the case of Jehovah's Witnesses, some patients will not accept blood transfusions because of their religious convictions.

It is the surgeon's responsibility to provide a complete explanation of the planned surgical procedure and to have the consent form signed before sedation is given and before surgery is performed. The perioperative nurse *is not responsible for providing detailed information about the surgical procedure. The nurse's role is to clarify facts that have been presented by the surgeon and dispel myths that the patient or family may have about the surgical experience. The nurse must verify that the consent form is signed, and he or she may serve as a witness to the signature, not to the fact that the patient is informed* (Rock & Hoebeke, 2014).

## Nursing Safety Priority QSEN

### Action Alert

If you believe that the patient has not been adequately informed, that he or she has questions about his or her procedure, or there is a discrepancy related to surgical site, it is your professional and ETHICAL duty to contact the surgeon and request that he or she see the patient for further clarification. Document this action in the electronic health record.

Patients who cannot write may sign with an X, which must be witnessed by two people. In an emergency, telephone or telegram authorization is acceptable and should be followed up with written consent as soon as possible. The number of witnesses (usually two) and the type of documentation vary according to the facility policy. For a life-threatening situation in which every effort has been made to contact the individual with medical power of attorney, consent is desired but not essential. In place of written or oral consent, written consultation by at least two physicians who are not associated with the case may be requested by the surgeon. This formal consultation legally supports the decision for surgery until the appropriate individual can sign a consent form. If the patient is not capable of giving consent and has no family, the court can appoint a legal guardian to represent the patient's best interests.

A blind patient may sign his or her own consent form, which usually needs to be witnessed by two people. Patients who do not speak the general language of the facility or who are hearing impaired may require a qualified translator and a second witness. Many facilities have consent forms written in more than one language and also have health care professionals who are proficient with American Sign Language. Qualified translators may be health care professionals or other types of hospital employee. Family members should not serve as translators because the health care team may not be able to validate that the medical information is being translated accurately. Translators are part of the interprofessional care team and are required to keep patient information confidential.

Some surgical procedures such as sterilization and experimental procedures may require a special permit in addition to the standard consent. National and local governing bodies and the individual facility determine which procedures require a separate permit. Separate consents for anesthesia and blood products may be required.

Surgical procedures that are site specific, such as left, right, or bilateral, require patient identification before surgery. **As required by The Joint Commission's NPSGs, to ensure that the correct site is selected and the wrong site is avoided, the site is marked by a licensed independent practitioner and, whenever possible, involves the patient.** The surgeon is accountable and should be present during the procedure. The nurse is an important part of this SAFETY measure. Before starting the operative procedure, facilities use a “time-out” procedure to verify the correct site, patient, and procedure. The perioperative nurse is in a position of ensuring that these SAFETY measures are implemented immediately before the procedure is started (AORN, 2015). The “time-out” involves the participation of all members of the procedure team, including the surgeon, anesthesia provider, circulating nurse, scrub person, and any other active participants.

## Nursing Safety Priority QSEN

### Action Alert

At a minimum the patient's identity, correct side and site, correct patient position, and agreement on the proposed procedure must be verified by all members of the surgical team before the incision.

### Patient Self-Determination.

Patients receiving medical care have the right to have or to initiate advance directives such as a living will or durable power of attorney, as mandated by the Patient Self-Determination Act. Advance directives provide legal instructions to the primary health care providers about the patient's wishes and are to be followed. *Surgery does not provide an exception to a patient's advance directives or living will* (AORN, 2016a). [Chapter 7](#) discusses advance directives in more detail.

### Implementing Dietary Restrictions.

Regardless of the type of surgery and anesthesia planned, the patient is restricted to NPO status before surgery. NPO means no eating, drinking (including water), or smoking (nicotine stimulates gastric secretions). The exact amount of time a patient must be NPO before surgery is controversial. Patients, especially older adults, who fast for 8 or more hours may have imbalances of fluids, electrolytes, and blood glucose levels. The American Society of Anesthesiologists (ASA) recommends a reduced NPO time—6 or more hours for easily digested solid food and 2 hours for clear liquids (Gebremedhn & Nagaratnam, 2014). A major problem is that these guidelines for duration of fasting have not been implemented universally.

NPO status ensures that the stomach contains a limited volume of gastric secretions, which decreases the risk for aspiration. Outpatients and patients who are scheduled for admission to the hospital on the same day that surgery is performed must receive written and oral instructions about when to begin NPO status.

## Nursing Safety Priority QSEN

### Action Alert

Emphasize the importance of adhering to the prescribed NPO restriction. Failure to adhere can result in postponing or canceling surgery and an increased risk for aspiration during or after surgery.

### Administering Regularly Scheduled Drugs.

On the day of surgery, the patient's usual drug schedule may need to be altered. Consult the medical health care provider and the anesthesia provider for instructions about drugs such as those taken for diabetes, cardiac disease, or glaucoma and regularly scheduled anticonvulsants, antihypertensives, anticoagulants, antidepressants, and corticosteroids. The surgeon may prescribe some drugs, including over-the-counter drugs such as aspirin, other NSAIDs, and herbal supplements, to be stopped until after surgery. Other drugs may be given IV to maintain the drug level in the blood. *Drugs for cardiac disease, respiratory disease, seizures, and hypertension are commonly allowed with a sip of water before surgery.* Some antihypertensive or antidepressant drugs are withheld on the day of surgery to reduce adverse effects on blood pressure during surgery. Even when beta blockers are not part of a patient's usual medications, they may be prescribed for some patients who are at risk for cardiac problems. Check with the primary health care provider, surgeon, or anesthesia provider to determine whether a specific patient requires perioperative therapy with beta-blocking drugs.

The patient who takes insulin for diabetes may be given a reduced dose of intermediate- or long-acting insulin based on the blood glucose level, or regular (fast-acting) insulin in divided doses on the day of surgery. As an alternative, an IV infusion of 5% dextrose in water may be given with the insulin to prevent low blood sugar during surgery. Because of the many treatment approaches to diabetes, clarify drug and IV prescriptions with the primary health care provider. (See [Chapter 64](#)

for more information about diabetes.)

### Intestinal Preparation.

Bowel or intestinal preparations are performed to prevent injury to the colon and reduce the number of intestinal bacteria. Bowel evacuation is needed for major abdominal, pelvic, perineal, or perianal surgery. In addition, colonoscopy procedures, routinely performed in outpatient ambulatory care facilities, require the patient to follow a strict preoperative protocol for bowel evacuation. The surgeon's preference and the type of surgical procedure determine the type of bowel preparation. An enema ordered to be given until return flow is clear is a stressful procedure, especially for the older patient. Repeated enemas can cause electrolyte imbalance, fluid volume imbalances, vagal stimulation, and postural (orthostatic) hypotension. Enemas cause severe anal discomfort in patients with hemorrhoids. Some physicians prescribe potent laxatives instead of enemas, especially for older patients. Bowel preparations can exhaust the patient, and SAFETY precautions must be taken to prevent falls.

### Skin Preparation.

The skin is the body's first line of defense against infection. A break in this barrier increases the risk for infection, especially for older patients. Skin preparation before surgery is the first step to reduce the risk for surgical site infection (AORN, 2016b).

One or two days before the scheduled surgery, the surgeon may ask the patient to shower using an antiseptic solution. Instruct the patient to be especially careful to clean well around the proposed surgical site. If the patient is hospitalized before surgery, showering and cleaning are repeated the night before surgery or in the morning before transfer to the surgical suite. This cleaning reduces contamination of the surgical field and the number of organisms at the site. Remove any soil or debris from the surgical site and surrounding areas.

Factors that predispose to wound contamination and surgical site infection (SSI) include bacteria found in hair follicles, disruption of the normal protective mechanisms of the skin, and nicks in the skin. Shaving of hair creates the potential for infection. **Hair clipping with electrical clippers and depilatories are to be used for hair removal as required by The Joint Commission's NPSGs (Markatos et al., 2015).**

The Centers for Disease Control and Prevention (CDC) recommends that, if shaving is necessary, the hair should be removed using disposable sterile supplies and aseptic principles *immediately* before the start of the surgical procedure. If needed, shaving is performed in the treatment room, the holding area of the operating suite, or the operating room (OR). Fig. 14-4 shows areas of hair removal for various surgical procedures.

**FIG. 14-4** Skin preparation of common surgical sites. Shaded areas indicate preparation sites.

### Preparing the Patient for Tubes, Drains, and Vascular Access.

Prepare the patient for possible placement of tubes, drains, and vascular access devices. Preparation reduces the patient's anxiety and fear and the family's negative reaction. Be careful not to scare the patient while providing information about the purpose of each tube.

*Tubes* of all sorts are common after surgery. A nasogastric (NG) tube may be inserted before abdominal surgery to decompress or empty the stomach and the upper bowel. Usually the tube is

placed after the induction of anesthesia, when insertion is less disturbing to the patient and is easier to perform. The patient may need an indwelling urinary (Foley) catheter before, during, or after surgery to keep the bladder empty and monitor kidney function.

*Drains* are often placed during surgery to help remove fluid from the surgical site. Some drains are under the dressing; others are visible and require emptying. Drains come in various shapes and sizes (see [Chapter 16](#)). Inform the patient that drains are often used routinely and that generally they are not painful but may cause some discomfort. Discuss the reasons drains should not be kinked or pulled.

*Vascular access* is placed for patients receiving a general anesthetic and for most patients receiving other types of anesthetics. Access is needed to give drugs and fluids before, during, and after surgery. Patients who are dehydrated or are at risk for dehydration may receive fluids before surgery.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Older adult patients are at greater risk for dehydration because their fluid reserves are lower than those of young or middle-age adults. Hemodynamic monitoring of older adult patients and patients with cardiac disease receiving IV fluids is essential. (See [Chapter 13](#) for more information on IV therapy.)

The IV access is usually placed in the arm using a large-bore, short catheter (e.g., 18-gauge, 1-inch catheter) or in the back of the hand using a smaller-bore (20-gauge) catheter. A larger vein provides the least resistance to fluid or blood infusion, especially in an emergency when rapid infusion may be needed. Depending on the patient's needs and the facility policies, the IV access can be placed before surgery when the patient is in the hospital room, in the holding or admission area of the surgical suite, or in the OR.

### Postoperative Procedures and Exercises.

Teach the patient and family members about exercises and procedures (e.g., checking dressings, obtaining vital signs frequently) to be performed after surgery. Family members can be helpful in reminding patients to perform the exercises. Teaching before surgery reduces apprehension and fear, increases cooperation and participation in care after surgery, and decreases respiratory and vascular complications. When the fear or anxiety level is high, explore the patient's feelings before beginning to teach the procedures.

Discussion, demonstration with return demonstration, and practice by the patient aid in the ability to perform various breathing ([Chart 14-4](#)) and leg ([Chart 14-5](#)) exercises after surgery. Stress the need to begin exercises early in the recovery phase and to continue them, with 5 to 10 repetitions each, every 1 to 2 hours after surgery for at least the first 48 hours. Explain that the patient may need to be awakened for these activities.

### Chart 14-4

## Patient and Family Education: Preparing for Self-Management

### Perioperative Respiratory Care

#### Deep (Diaphragmatic) Breathing

1. Sit upright on the edge of the bed or in a chair, being sure that your feet are placed firmly on the floor or a stool. (After surgery, deep breathing is done with the patient in Fowler's position or in semi-Fowler's position.)
2. Take a gentle breath through your mouth.

3. Breathe out gently and completely.
4. Take a deep breath through your nose and mouth, and hold this breath to the count of five.
5. Exhale through your nose and mouth.

### Expansion Breathing

1. Find a comfortable upright position, with your knees slightly bent. (Bending the knees decreases tension on the abdominal muscles and decreases respiratory resistance and discomfort.)
2. Place your hands on each side of your lower rib cage, just above your waist.
3. Take a deep breath through your nose, using your shoulder muscles to expand your lower rib cage outward during inhalation.
4. Exhale, concentrating first on moving your chest, then on moving your lower ribs inward, while gently squeezing the rib cage and forcing air out of the base of your lungs.

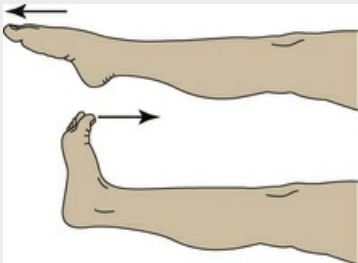

### Splinting of the Surgical Incision

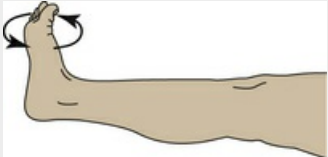

1. Unless coughing is contraindicated, place a pillow, towel, or folded blanket over your surgical incision and hold the item firmly in place.
2. Take three slow, deep breaths to stimulate your cough reflex.
3. Inhale through your nose and exhale through your mouth.
4. On your third deep breath, cough to clear secretions from your lungs while firmly holding the pillow, towel, or folded blanket against your incision.

## Chart 14-5

# Patient and Family Education: Preparing for Self-Management

## Postoperative Leg Exercises

<p><b>Exercise No. 1</b></p> <ol style="list-style-type: none"> <li>1. Lie in bed with the head of your bed elevated to about 45 degrees.</li> <li>2. Beginning with your right leg, bend your knee, raise your foot off the bed, and hold this position for a few seconds.</li> <li>3. Extend your leg by straightening your knee and lower the leg to the bed.</li> <li>4. Repeat this sequence four more times with your right leg; then perform this same exercise five times with your left leg.</li> </ol>	
<p><b>Exercise No. 2</b></p> <ol style="list-style-type: none"> <li>1. Beginning with your right leg, point your toes toward the bottom of the bed.</li> <li>2. With the same leg, point your toes up toward your face.</li> <li>3. Repeat this exercise several times with your right leg; then perform this same exercise with your left leg.</li> </ol>	
<p><b>Exercise No. 3</b></p> <ol style="list-style-type: none"> <li>1. Beginning with your right leg, make circles with your ankle, first to the left and then to the right.</li> </ol>	

<p>2. Repeat this exercise several times with your right leg; then perform this same exercise with your left leg.</p>	
<p><b>Exercise No. 4</b></p> <p>1. Beginning with your right leg, bend your knee and <i>push</i> the ball of your foot into the bed or floor until you feel your calf and thigh muscles contracting.</p> <p>2. Repeat this exercise several times with your right leg; then perform this same exercise with your left leg.</p>	

### Procedures and Exercises to Prevent Respiratory Complications.

*Breathing exercises* include deep, or diaphragmatic, breathing to enlarge the chest cavity and expand the lungs. After demonstrating and explaining the technique, urge the patient to practice deep breathing.

For patients with chronic lung disease or limited chest expansion, as seen in older patients because of the aging process, expansion breathing exercises are useful. For the patient having chest surgery, expansion breathing exercises strengthen accessory muscles and are started before surgery. Expansion breathing after surgery during chest physiotherapy (percussion, vibration, postural drainage) may help loosen secretions and maintain an adequate air exchange.

*Incentive spirometry* is another way to encourage the patient to take deep breaths. Its purposes are to promote complete lung expansion and prevent pulmonary problems. Various types of incentive spirometers are available; [Fig. 14-5](#) shows a patient using one type. With all types, the patient must be able to seal the lips tightly around the mouthpiece, inhale spontaneously, and hold his or her breath for 3 to 5 seconds for effective lung expansion. Goals (e.g., attaining specific volumes) can be set according to the patient's ability and the type of incentive spirometer. Seeing a ball move up a column or a bellows expanding reinforces and motivates the patient to continue performance.

**FIG. 14-5** Patient using an incentive spirometer. (From Perry, A. G., & Potter, P. A. (2010). *Clinical nursing skills and techniques* (7th ed.). St. Louis: Mosby.)

*Coughing and splinting* may be performed along with deep breathing every 1 to 2 hours after surgery. The purposes of coughing are to expel secretions, keep the lungs clear, allow full aeration, and prevent pneumonia and atelectasis. Coughing may be uncomfortable for the patient; but, when performed correctly, it should not harm the incision. Splinting (i.e., holding) the incision area provides support, promotes a feeling of security, and reduces pain during coughing. The proper technique for splinting the incision site and coughing is described in [Chart 14-4](#). A folded bath

blanket or pillow is helpful to use as a splint. Cardiac surgery patients may receive their own heart-shaped pillow for splint use.

The use of routine coughing exercises after surgery is controversial. Some surgeons believe that coughing may harm the surgical wound and that it would be better to use other, safer measures for lung hygiene, such as deep-breathing and incentive spirometer exercises. When routine coughing exercises should be avoided for a specific patient such as after a hernia repair or craniotomy, the surgeon usually writes a “do not cough” order.

### **Procedures and Exercises to Prevent Cardiovascular Complications.**

Venous stasis and venous thromboembolism (VTE) (a group of vascular disorders that includes deep vein thrombosis [DVT] and pulmonary embolism [PE]) are potential but often avoidable complications of surgery. VTE or DVT can lead to a PE if the blood clot breaks off and travels to the lungs. Risk factors for development of VTE include:

- Obesity
- 40 years of age or older
- Cancer
- Decreased mobility or immobility
- Spinal cord injury
- History of VTE, DVT, PE, varicose veins, or edema
- Oral contraceptives use
- Smoking
- Decreased cardiac output
- Hip fracture or total hip or total knee surgery

Always assess for VTE before surgery. Sudden swelling in one leg is a common physical finding of VTE caused by DVT. A patient may feel a dull ache in the calf area that becomes worse with ambulation. A careful assessment and timely intervention may prevent the potentially fatal complication of pulmonary embolism.

Because surgical-related VTE can be prevented, prophylaxis is a standard of care established by the Surgical Care Improvement Project (SCIP) core measures (see [Table 14-1](#)). All patients should be evaluated for VTE risk based on history, type and duration of surgery, and expected time of immobilization after surgery. VTE prophylaxis may involve devices and drug therapy, depending on a specific patient's evaluated risk. Devices may be used during and after surgery, along with leg exercises and early ambulation to promote venous return.

*Antiembolism stockings* (TED or Jobst stockings) and elastic (Ace) wraps provide graduated compression of the legs, starting at the end of the foot and ankle. Measure the patient's leg length and circumference before ordering the stocking size. Elastic wraps are used when the legs are too large or too small for the stockings. Help the patient apply the stockings or wraps and ensure that they are neither too loose (are ineffective) nor too tight (inhibit blood flow). They need to be worn properly and should be removed two to three times per day for 30 minutes for skin inspection and skin care.

*Pneumatic compression devices* enhance venous blood flow by providing intermittent periods of compression on the legs. Measure the patient's legs and order the correct size. Place the boots on the patient's legs and set and check the compression pressures (usually 35 to 55 mm Hg). *Unless these devices are applied properly, there is no benefit (Elpern et al., 2013).* [Fig. 14-6](#) shows various types of sequential compression devices. Antiembolism stockings may be worn in addition to the boots and may reduce some of the uncomfortable sensations of the boots (e.g., itching, sweating, and heat).

**FIG. 14-6** External pneumatic compression device used to promote venous return and prevent deep vein thrombosis (DVT). (From Angelo, R., Ryu, R., & Esch, J. (2010). *AANA advanced arthroscopy: The shoulder*. Philadelphia: Saunders.)

*Leg exercises* also promote venous return. Teach the leg exercises outlined in [Chart 14-5](#) and urge the patient to practice them before surgery. The exercises are important, even when other devices are used.

*Mobility* soon after surgery (early ambulation) has many cardiovascular and other benefits. It stimulates intestinal motility, enhances lung expansion, mobilizes secretions, promotes venous return, prevents joint rigidity, and relieves pressure. For most types of surgery, teach the patient to turn at least every 2 hours after surgery while confined to bed. Teach patients how to use the bed side rails safely for turning and how to protect the surgical wound by splinting when turning. Assure patients that assistance and pain medication will be given as needed to reduce any anxiety and pain they may have with this activity.

For certain surgical procedures, such as some brain, spinal, and orthopedic procedures, the surgeon may prescribe turning restrictions. Ask the surgeon about other interventions to prevent complications of immobility in patients with turning restrictions. During preoperative teaching, inform the patient of anticipated turning restrictions.

Most patients are allowed and encouraged to get out of bed the day of or the day after surgery. Assist the patient into a chair or with ambulation after the surgery, the next day, or when the surgeon specifies. If a patient must remain in bed, help him or her turn, deep breathe, and perform leg exercises at least every 2 hours to prevent complications from immobility.

## **NCLEX Examination Challenge 14-3**

### **Health Promotion and Maintenance**

What client teaching will the nurse provide regarding postoperative leg exercises to minimize the risk for development of deep vein thrombosis after surgery?

- A. Only perform each exercise one time to prevent overuse.
- B. Begin exercises by sitting at a 90-degree angle on the side of the bed.
- C. Point toes of one foot toward bottom of bed; then point toes of same leg toward his or her face. Repeat several times; then switch legs.
- D. Bend knee, and push heel of foot into the bed until the calf and thigh muscles contract. Repeat several times; then switch legs.

### **Minimizing Anxiety**

#### **Planning: Expected Outcomes.**

Before surgery, the patient is expected to have manageable anxiety as indicated by consistently demonstrating these behaviors:

- Expressing a reduced level of anxiety

- Showing an absence of body language indicators of anxiety (e.g., hand wringing, facial tension, restlessness, dilated pupils, sweating, elevated blood pressure, elevated pulse rate)

### **Interventions.**

Anxiety often causes restlessness and sleeplessness. The patient may perceive the surgical experience as a threat to life and function. Assess his or her level of anxiety as discussed in the Psychosocial Assessment section. Interventions such as teaching and communicating with the patient before surgery, enabling the patient to use previously successful coping mechanisms, and giving antianxiety drugs may help reduce the anxiety. Incorporate available support systems into the plan of care.

*Preoperative teaching* involves first assessing the patient's knowledge about the surgical experience (see the [Providing Information](#) section) and then providing factual information to promote his or her understanding. Allow ample time for questions. Respond to the questions accurately and refer unanswered questions to the proper professional. During the discussion, continually assess the patient's responses and anxiety level. Be careful not to provide information that might increase anxiety. The informed, educated patient is better able to anticipate events and maintain self-control and is thus less anxious.

*Encouraging communication* by having the patient state feelings, fears, and concerns can help reduce anxiety. Use an honest and open approach so the patient can express feelings freely without fear of ridicule or judgment. Keep the patient informed by clarifying information, answering questions, and allaying fears about the surgery.

*Promoting rest* is helpful because the stress and anxiety of impending surgery often interfere with the patient's ability to sleep and rest the night before surgery. The period before surgery is physically and emotionally stressful. To help the patient relax, determine what he or she usually does to relax and fall asleep. If the patient is able, urge him or her to continue these methods of relaxation. A back rub is relaxing and can be performed by a nurse, unlicensed assistive personnel (UAP), or family member. The surgeon may prescribe a sedative or hypnotic drug to help the patient rest for surgery.

*Distraction* may be used as an intervention for anxiety, especially in the 24 hours immediately before surgery. Listening to music may decrease anxiety, as may watching television, reading, or visiting with family members.

*Teaching family members* helps reduce anxiety by increasing the likelihood of support and involvement in the patient's care. Assess the readiness and desire of the family to take an active part in the patient's care. A positive sign of family interest is that of members asking questions about the surgical experience. After family readiness is determined, keep family members informed and encourage their involvement in all aspects of education. Emphasize the important role of the family before surgery, but guide discussions and practice sessions so the patient is the focus of the discussion. Family members can encourage and help the patient practice exercises to be performed after surgery.

Inform the family of the time for surgery, if known, and of any schedule changes. If the patient is an outpatient, provide clear directions to the patient and family regarding any specific night-before procedures, what time and where to report, and what to bring with them. Encourage the family to stay with the patient before surgery for support.

Most families are anxious about the surgery planned for their loved one. To reduce their anxiety, explain the routines expected before, during, and after surgery. Tell the family that, after the patient leaves the hospital room or admission area, there is usually a 30- to 60-minute preparation period in the operating area (holding room, treatment area) before the surgery actually begins. After surgery, the patient is taken to the postanesthesia care unit (PACU) usually for 1 to 2 hours before returning to the hospital room or discharge area. The length of stay in the PACU depends on the type of surgery, the type of anesthesia, any complications, and the patient's responses. Tell the family about the best place to wait for the patient or surgeon according to the facility policy and the surgeon's preference. Many hospitals and surgical centers have surgical waiting areas so families can wait in comfortable surroundings and be easily located when the procedure is completed. Often families are provided with a beeper to let them know when to report to a specific area to receive updates about the patient's status, meet with the surgeon, or see the patient.

### **Preoperative Electronic Health Record Review.**

Review the patient's electronic health record to ensure that all documentation, preoperative procedures, and orders are completed. Check the surgical informed consent form and, if indicated, any other special consent forms to see that they are signed and dated and that they contain the witnesses' signatures. Confirm that the scheduled procedure, including the identification of left versus right when necessary, is what is listed on the consent form. Even though it might be obvious, inform the patient that the site for surgery will be marked before the procedure begins. **If possible, encourage the patient to assist with the marking, as suggested by The Joint Commission's NPSGs. Document allergies according to facility policy.** Accurate measuring and recording of height and weight are important for proper dosage of the anesthetic agents. Ensure that the results of all laboratory, radiographic, and diagnostic tests are on the electronic health record. Document any abnormal results, and report them to the surgeon and the anesthesia provider. If the patient is an autologous blood donor or has had directed blood donations made, those special slips must be included in the electronic health record. Record a current set of vital signs (within 1 to 2 hours of the scheduled surgery time), and document any significant physical or psychosocial observations.

**Report special needs, concerns, and instructions (including advance directives) to the surgical team, as required by The Joint Commission's NPSGs.** For example, advise the surgical team if the patient is a member of Jehovah's Witnesses and does not accept blood products or if the patient is hard of hearing and does not have his or her hearing aid. This information helps the surgical team provide continuity of care while the patient is in the surgical area.

### **Preoperative Patient Preparation.**

Facilities usually require the patient to remove most clothing and wear a hospital gown into the OR; however, underpants may be worn in above-the-waist surgery; and socks may be worn, except in foot or leg surgery. If prescribed by the surgeon, apply antiembolism stockings or pneumatic compression devices before surgery. In some ambulatory settings, such as for cataract surgery, no or minimal clothing is removed.

Patients are advised to leave all valuables at home. If he or she has valuables, including jewelry, money, or clothes, they are given to a family member or locked in a safe place, according to the facility policy. If rings cannot be removed, assess the risk for swelling. If swelling makes it necessary, rings may be cut off to avoid further injury. It is preferable that all pierced jewelry be removed before surgery. Religious emblems may be pinned or fastened securely to the patient's gown. Care must be provided to avoid loss or theft of these items. Some facilities have paper emblems from a religious leader.

The patient wears an identification band that clearly gives the first and last name, hospital number, surgeon, and birthdate. An additional bracelet, usually red, identifies any allergies. A bracelet indicating that a blood sample for type and screen has been drawn may be worn, depending on the facility policy.

If dentures are to be removed, including partial dental plates, place them in a labeled denture cup. Denture removal is a SAFETY measure to prevent aspiration and obstruction of the airway. If a patient has any capped teeth, document this finding on the checklist.

All prosthetic devices, such as artificial eyes and limbs, are removed and given to a family member or safely stored, as are contact lenses, glasses, wigs, and toupees. Check and remove hairpins and clips, which can conduct electrical current used during surgery and cause scalp burns.

Some facilities allow hearing aids in the surgical suite to help communication before and after surgery. Some facilities allow dentures, wigs, and glasses to be worn into the operating suite to prevent embarrassment to the patient. These items are removed when absolutely necessary. If the patient is sent to surgery with any assistive devices (e.g., hearing aid, glasses), communicate this to the perioperative nurse to prevent accidental loss of or damage to the device. In the electronic health record, document all valuables going into the operating room with the patient.

The removal of fingernail polish or artificial nails is controversial. Polish and artificial nails have been thought to affect the accuracy of pulse oximetry readings. Recent studies have indicated that pulse oximetry readings taken on fingers are affected by brown or blue polish but not by red or lighter color polish. In addition, pulse oximetry does not have to be measured on fingers only. Some facilities still require that at least one artificial nail must be removed to monitor oxygen saturation by pulse oximetry.

After the patient is prepared for surgery and just before transport into the operating suite, ask the patient to empty the bladder. This action prevents incontinence or overdistention and is a starting

point for intake and output measurement.

### Preoperative Drugs.

Preoperative drugs may be prescribed, regardless of the type of planned anesthesia. Various drugs reduce anxiety, promote relaxation, prevent laryngospasm, reduce vagal-induced bradycardia, inhibit oral and gastric secretions, and decrease the amount of anesthetic needed for the induction and maintenance of anesthesia. Drug selection is based on the patient's age, physical and psychological condition, medical history, and height and weight; other drugs the patient takes routinely; test results; and the type and extent of the planned surgical procedure. If more than one response is required, combination therapy may be prescribed.

Drug types for preoperative purposes may include sedatives (e.g., hydroxyzine [Atarax, Vistaril]); hypnotics (e.g., lorazepam [Ativan]); anxiolytics (e.g., midazolam [Versed]); opioid analgesics (e.g., morphine, hydromorphone); and an anticholinergic agent (e.g., atropine). Other specific-purpose drugs also may be added. For example, if rapid emptying of the stomach is needed, metoclopramide (Reglan) may be prescribed. When procedures are long or stress ulcers are likely, an H<sub>2</sub> histamine blocker (e.g., cimetidine [Tagamet]; ranitidine [Zantac]) is used.

Preoperative drugs may be given when the patient is “on call” to the surgical suite. **After positively identifying the patient as required by The Joint Commission's NPSGs, (using the armband and asking the patient to state his or her name and birthdate) and making sure that the operative permit is signed, give the correct drugs in the correct doses.** Then raise the side rails, place the call light within easy reach of the patient, and remind him or her not to try to get out of bed. Place the bed in a low position. Tell the patient that he or she may become drowsy and have a dry mouth as a result of the drugs.

A more common practice is for the preoperative drugs to be given *after* the patient is transferred to the preoperative area. This practice permits the surgical team and anesthesia personnel to make more accurate assessments and have last-minute discussions with a patient not yet affected by drugs. In addition, after the patient is in the preoperative area, drugs can be given by the IV route. Monitoring equipment such as continuous pulse oximetry and ECG is more readily available in this area. The oral or IM route is used less often because of variable absorption rates. **The surgeon may prescribe a prophylactic antibiotic to be given right before or during surgery to reduce the risk for a surgical site infection, as suggested by The Joint Commission's NPSGs. When needed, the antibiotic is given within 60 minutes before the incision is made, as mandated by the Surgical Care Improvement Project (SCIP) core measures, SCIP Inf-1 (see Table 14-1).**

### Patient Transfer to the Surgical Suite.

In the immediate preoperative period, review and update the patient's electronic health record, reinforce teaching, ensure that the patient is correctly dressed for surgery, and give prescribed preoperative drugs. Use an electronic or hard-copy preoperative checklist for a smooth, efficient transfer to the surgical suite (Fig. 14-7). The patient, along with the signed consent form, the completed preoperative checklist, and the patient identification card, is transported to the surgical suite.

**PREOPERATIVE CHECKLIST**

**FIG. 14-7** Preoperative checklist.

Most patients in the hospital setting are transferred to the surgical suite on a stretcher with the side rails up. In special circumstances (e.g., patients requiring traction, those having some types of orthopedic surgery, those who should be moved as little as possible), the patient is transferred in the hospital bed. Other factors that influence the decision to transfer in a bed are the patient's age, size, and physical condition. In ambulatory settings, patients either walk or are transferred to the surgical suite on a stretcher or in a wheelchair.

**◆ Evaluation: Reflecting**

Evaluate the care of the preoperative patient based on the identified patient problems. The expected outcomes include that the patient:

- States understanding of the informed consent and preoperative procedures
- Demonstrates postoperative exercises and techniques for prevention of complications

- Verbalizes reduced anxiety

## Clinical Judgment Challenge 14-1

### Patient-Centered Care QSEN

You are caring for a patient who is scheduled for surgery, which must be performed under general anesthesia, to alleviate pain and stabilize the spinal column. During the preoperative assessment in which the patient's husband is present, you ask the patient if she has had anything to eat or drink since midnight. The patient states, "I have not eaten anything since midnight. I only drank a can of soda this morning before I came to the hospital." The patient's husband immediately responds, "This won't keep her from having surgery, will it? I better not have to take off from work another day for this nonsense."

1. What are the possible implications of the patient's consumption of soda before surgery?
2. What is your response to the patient's disclosure that she has consumed a can of soda on the morning of the scheduled surgery?
3. How would you address the husband's response?
4. Would you tell the surgeon about the patient's consumption of soda? Why or why not?
5. What teaching will you provide at this time?

# Get Ready for the NCLEX<sup>®</sup> Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Determine the purpose and expected outcomes of surgery for each patient.
- Assess each patient's risk factors for threats to SAFETY.
- Ensure that proper patient identification occurs (ID bands).
- Use at least two appropriate identifiers (e.g., patient identification number, patient name and/or birthdate as stated by the patient) when providing instruction, administering drugs, marking surgical sites, and performing any procedure. *Do not use room number or bed number to identify the patient.* **QSEN: Safety**
- Validate that the informed consent has been properly executed (signed by the patient, surgeon, and witness as necessary). Confirm that presurgical checklist is complete and accurate.
- Communicate to the perioperative team any physical or laboratory change that may alter the patient's response to drugs, anesthesia, or surgery. **QSEN: Safety**
- Ask the patient to explain in his or her own words which surgical procedure is being done and why.
- If the patient's explanation of the scheduled surgery is not consistent with the documentation, notify the surgeon and request that he or she speak to the patient. **QSEN: Safety**
- Validate correct patient, correct procedure, correct operative site (left, right, spinal level). **QSEN: Safety**
- Confirm that the operative permit or any other legal documents are signed before preoperative drug administration. **Ethics**
- After the patient has received preoperative drugs, keep the side rails up and the bed in the low position. **QSEN: Safety**
- Communicate during hand-off to the operating room personnel all care that has been provided and what care may still be needed.

### Health Promotion and Maintenance

- Teach patients about preoperative preparations and specific postoperative interventions to prevent complications (incision splinting, deep-breathing exercises, range-of-motion exercises—as described in [Charts 14-4](#) and [14-5](#)). **QSEN: Patient-Centered Care**

### Psychosocial Integrity

- Assess the patient's and family members' knowledge about the scheduled surgical procedure to identify learning needs. **QSEN: Patient-Centered Care**
- Encourage the patient to express his or her feelings regarding the surgical procedure or its possible outcome(s).
- Explain and provide written information for all diagnostic procedures, restrictions, and follow-up care to the patient and his or her family. **Ethics**
- Communicate to the perioperative team any concerns, fears, or preferences the patient has. **Ethics**
- Implement appropriate interventions to reduce patient anxiety.

### Physiological Integrity

- Perform a complete and accurate preoperative assessment.

- Ensure that dentures and any other personal items are removed from the patient before he or she is transferred to the surgical suite.
- Apply prescribed antiembolic stockings, sequential compression boots, or other devices to reduce or prevent vascular complications. **QSEN: Evidence-Based Practice**
- Communicate to the perioperative team any physical or laboratory change(s) that may alter the patient's response to drugs, anesthesia, or surgery. **QSEN: Safety**

## CHAPTER 15

# Care of Intraoperative Patients

Rebecca M. Patton, Cynthia Danko

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concept for this chapter is SAFETY.**

**The interrelated concepts for this chapter are:**

- GAS EXCHANGE
- TISSUE INTEGRITY
- TEAMWORK AND INTERPROFESSIONAL COLLABORATION

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with the interprofessional team to coordinate high-quality care for patients in the intraoperative setting.
2. Maintain SAFETY by using appropriate patient identifiers when administering drugs, ensuring informed consent, and verifying surgical sites during the intraoperative period.
3. Ensure SAFETY by protecting patients from injury, poor thermoregulation, and health care–associated infection during the intraoperative period.

### Psychosocial Integrity

4. Implement nursing interventions to minimize stressors for the patient and family regarding the intraoperative experience.
5. Using ethical principles, respond with advocacy to patient and family concerns and needs during the intraoperative period.

### Physiological Integrity

6. Apply knowledge of anatomy, physiology, and principles of aging to prioritize care and prevent patient harm resulting from skin breakdown and positioning injury during the intraoperative period.
7. Implement nursing interventions to minimize risk for potential intraoperative emergencies such as malignant hyperthermia, allergic reactions, and cardiac events.

As one of the most complex and demanding environments in the health care setting, the challenges of managing patient care during a surgical procedure in the operating room (OR) requires expertise and TEAMWORK AND INTERPROFESSIONAL COLLABORATION within the perioperative team. Perioperative nursing as a specialty, in the inpatient or ambulatory setting, provides care for patients undergoing operative or other invasive procedures and has a distinct clinical focus. Nursing care during this period affects the patient's physical needs, spiritual needs, comfort, SAFETY, dignity, and psychological status. Patient-centered care is the key to optimal outcomes in the OR. Recognizing the patient as the source of control and including the family in the plan of care plan ensure compassionate and coordinated care based on the preferences, values, and needs of the patient (QSEN, 2016). Specific procedures and policies may differ among hospital and OR settings but should all reflect the standards and recommended practices as established by the [Association of periOperative Registered Nurses \(AORN\) \(2016a\)](#). Perioperative nurses practice within a specific,

patient-focused model that incorporates professional practice with attainable, measurable outcomes.

The patient undergoing surgery may recognize the experience as a time of great anxiety, fear, and vulnerability. Few other episodes of care put patients in such a defenseless condition as a surgical procedure. Continual communication with the patient provides a level of comfort and control in a situation that seems out of his or her control. Patient engagement and positive patient experiences have been linked to clinical SAFETY and effectiveness (Doyle et al., 2013).

## Overview

The *intraoperative period* begins when the patient enters the surgical suite and ends at the time of transfer to the postanesthesia recovery area, same-day surgery unit, or intensive care unit. The priorities for perioperative nurses are SAFETY and patient advocacy by preventing, reducing, avoiding, and managing the risk factors in the perioperative environment. In the OR the patient is at risk for infection, impaired skin TISSUE INTEGRITY, increased anxiety, inadequate thermoregulation and altered body temperature, and injury related to positioning and other intraoperative interventions. The surgical phase is filled with unfamiliar experiences and uncertain outcomes.

## Members of the Surgical Team

The surgical team consists of a multidisciplinary interprofessional cohort of caregivers representing several clinical specialties. Each team member has specific duties in the OR and uses his or her expertise to enhance the care and SAFETY of the perioperative patient. The number of assistants, circulating nurses, and scrub nurses depends on the complexity and length of the surgical procedure. For minor procedures only a circulating nurse and scrub person may be needed in addition to the surgeon. More complex procedures may require additional nursing staff to either circulate or scrub. See [Table 15-1](#), which identifies perioperative team member responsibilities and duties.

**TABLE 15-1**

**Perioperative Team Members—Responsibilities and Duties**

TEAM MEMBER	RESPONSIBILITIES	DUTIES/INTERVENTIONS
Surgeon	Manages the surgical procedure and makes surgical judgments about the patient's care	Initiates, participates, and completes the essential components of the surgical procedure
Surgical assistant • Another surgeon • Physician • Physician Assistant/Surgical Assistant • Resident • Intern • Advanced practice nurse • Certified registered nurse first assistant	Under the direction of the surgeon (and within the legal scope of practice for each role/state), the assistant performs specific task during the surgical procedure	The assistant may hold retractors, suction the wound, cut tissue, suture and dress wounds
Anesthesiologist (MD)	Administers anesthetic agents and continually monitors patient status	Plans medications for anesthesia, analgesia, and blocks Monitors major bodily functions (such as breathing, heart rate and rhythm, body temperature, blood pressure, and blood oxygen levels) during surgery Addresses any problems that might arise during surgery
Certified registered nurse anesthetist (CRNA)	Administers anesthetic agents under the supervision of physician (either anesthesiologist or surgeon)	Provides fluids and blood products as needed; medications for anesthesia, analgesia, and blocks; monitors patient during surgery by assessing: • Level of anesthesia (using a peripheral nerve stimulator) • Cardiopulmonary function (electrocardiographic [ECG] monitoring) • Capnography (monitors ventilation for nonintubated patients) • Vital signs • Intake and output
Circulator—registered nurse	Uses clinical decision-making skills to develop a plan of care and coordinates care delivery to patients and their family members; coordinates, oversees, and implements nursing care interventions to support the patient during the surgical procedure	Sets up the operating room, gathers supplies, anticipates equipment needed, and inspects all equipment for safety and functionality; prepares positioning devices and ensures that the physical environment is clean and at the proper temperature for the patient's arrival Throughout the surgery the circulating nurse: • Protects the patient's privacy • Ensures the patient's safety • Monitors traffic in the room • Assess urinary output and blood loss • Communicates finding to surgeon and anesthesiologist • Monitors sterile field and provides sterile supplies and medications to the sterile field • Anticipates the patient's and surgical team's needs • Communicates patient's status to family member(s) per protocol • Documents care, events, interventions, and findings
Scrub person—registered nurse or certified surgical technologist (CST)	Provides patient care at the surgical field, assisting the surgeon and assistants; maintains the integrity, safety, and efficiency of the sterile field during the procedure	Sets up the sterile field, hands up sterile instrumentation/equipment With the circulating nurse, maintains accurate count of sponges, sharps, and instruments and monitors the amount of irrigation fluid and medication used
Specialty team members (e.g., cardiac, orthopedic, ophthalmology)	Provide patient care in surgical specialty areas; assess, maintain, and recommend equipment, instruments, and supplies used in that specialty	May circulate or scrub on procedures in a specific surgical specialty; participate in scheduling process for surgical cases and organize personnel in the clinical specialty area
Laser nurse	Coordinates activities and equipment for surgical cases using laser technology	Functions as coordinator for laser cases, monitors laser function, maintains safety, and completes documentation required for a laser log
Perfusionist	Specialized health care professional who uses the heart-lung machine during cardiac surgery and other surgeries that require cardiopulmonary bypass to manage the patient's physiological status.	Sets up heart-lung machine and continually monitors and manages the patient's blood flow, fluids, and electrolyte levels just before, during, and on completion of the cardiac bypass procedure

## The Surgical Suite—Patient and Team Safety

Protecting the patient when he or she is unable to protect himself or herself during surgery is the priority for all members of the surgical team. Patient SAFETY and safety of personnel in the OR are addressed through various means.

*Construction and design* of the OR suite centers on preventing infection by reducing contaminants through controlled air exchanges in the room, maintaining recommended temperature and humidity levels, and limiting the traffic and activities in the OR by means of sliding door closures and designated traffic patterns.

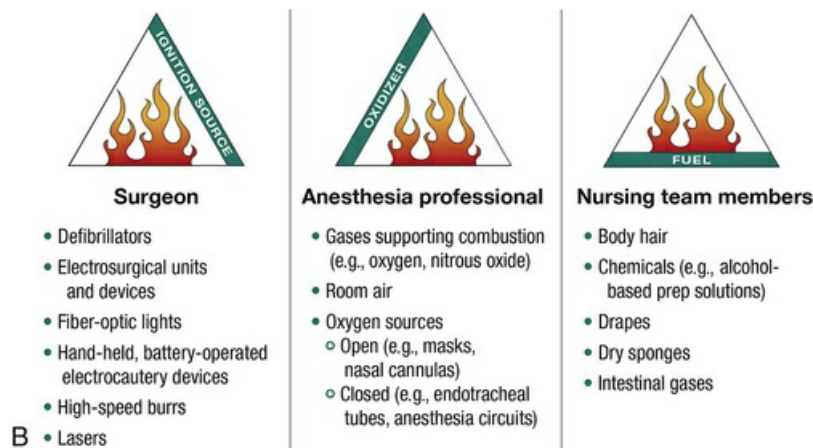

*Electrical and fire SAFETY* is an integral part of the design process. Multiple outlets on separate circuits are required to avoid overloads that prevent short circuits and the potential loss of power. The nurse ensures safety through the use of electrical equipment that meets specific standards. All equipment used during surgery must be functional and in proper working condition as determined by the safety procedure of that facility.

Electrosurgical devices are a primary energy source in the OR. Proper placement of grounding pads; inspection of the electrosurgical device; and avoiding patient contact with metal components of the OR table, other electrical equipment, or pooling preparation solutions help to prevent surgical burns and injury.

All OR personnel strive to prevent fire and complications from the use of electrical devices or hazardous substances. Ignition sources, oxidizers, and fuels (commonly referred to as the *fire triangle*; Fig. 15-1A) are present in the OR and increase the risk for fires (Seifert et al., 2015). Such events are rare but can occur during any procedure. Completing a fire risk assessment for each patient is critical to determine the likelihood for a fire occurrence. Eliminating any elements of the fire triangle avoids or minimizes the risk for injury (see Fig. 15-1B). Managing room temperature (between 68° and 73° F [20° to 23° C]) and humidity (30% to 60%) at recommended levels is optimal for fire SAFETY (AORN, 2015a). The entire surgical team must remain knowledgeable of emergency measures to take in the event of a fire.

**FIG. 15-1** **A**, Fire Triangle from Association of periOperative Nurses. (AORN). **B**, Role of team members in managing components of the fire triangle. (A reprinted with permission from *Guidelines for Perioperative Practice*. Copyright © 2017, AORN, Inc, 2170 S. Parker Road, Suite 400, Denver, CO 80231. All rights reserved. **B** from Seifert, P. C., Peterson, E., Graham, K. [2015]. Crisis management of fire in the OR. *AORN Journal*, Feb; 101[2]:250-63. DOI: 10.1016/j.aorn.2014.11.002.)

*Patient SAFETY devices* and nursing interventions are used to manage risk during surgical procedures. Safety straps are required for the patient, and the OR bed is locked in place. Blankets or warming units are used to prevent hypothermia from inadequate thermoregulation, and interventions (e.g., positioning devices, gel pads, frames) are used to prevent skin breakdown and injury during the positioning process.

The OR setting presents multiple occupational hazards that can put the surgical team at risk for injury, resulting in lost work time and potential long-term disability. Working conditions in the OR that could lead to injury include lifting and transferring patients; carrying heavy instrument sets; moving equipment; and exposure to sharps, bloodborne pathogens, anesthetic gases, radiation, and chemicals. Slips, trips, and falls related to clutter in the room; cords on the floor; or wet surfaces can also lead to unsafe conditions in the work environment.

The use of patient-transfer and personal protective equipment (gowns, non-powdered gloves, masks, and eye protection), ongoing monitoring of the environment for trace anesthetic gases, and monitoring of radiation badges worn by personnel (for exposure levels to radiation) and lead shielding are basic safety precautions that are used in the OR to manage personnel safety and minimize known risk factors. Constant awareness of the environment and adherence to practice standards will reduce staff injuries. Observing safety precautions and using safe patient-handling devices to move patients are effective for both patients and staff.

## Surgical Suite Layout

The surgical suite is located out of the mainstream of the hospital and adjacent to the postanesthetic care unit (PACU) and support services (e.g., blood bank, pathology, and laboratory departments). Traffic flow is restricted to reduce contamination from outside the suite. Within the suite, clean and contaminated areas are separate. The surgical area is divided into three zones—unrestricted, semi-restricted, and restricted—to ensure proper movement of patients and personnel.

Surgical departments contain areas related to patient care, surgery, surgical support, and staff areas. Patient care areas include an admission or holding area, the ORs, and the PACU. Support areas include instrument storage, cabinets for sterile supplies, separate utility rooms for clean and soiled equipment, and a clean linen room. Staff areas include locker rooms and staff lounges.

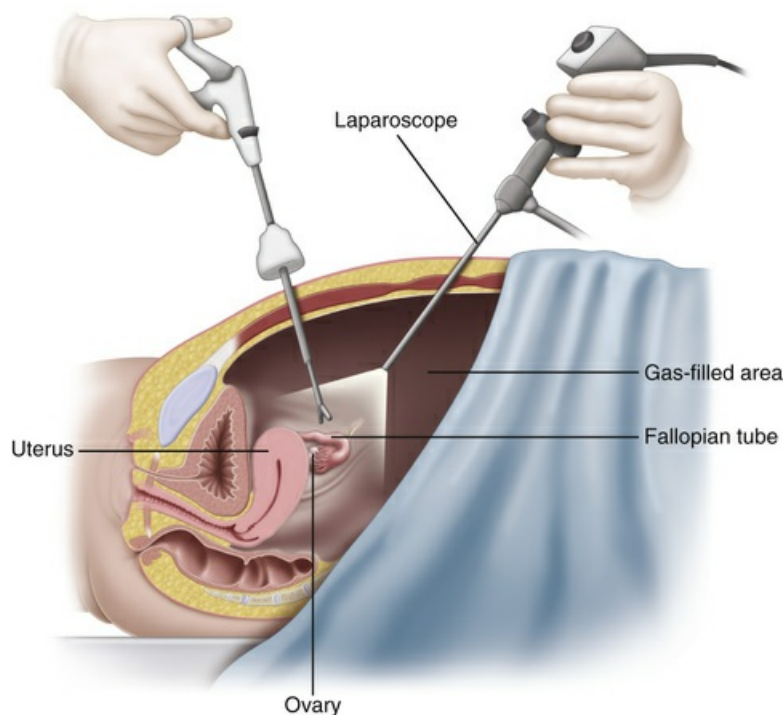

The OR is equipped with tables and equipment based on the needs of each patient and the complexity of the procedure. A communication system links the OR with the main desk of the surgical suite, including monitors for in-room cameras and an intercom with separate systems for routine and emergency calls.

OR design continues to evolve as technology advances. The use of computers, video, and digital imaging has transformed ORs into high-tech care settings. Many ORs have voice-activated command systems to operate some equipment and robotic technology that can transmit surgical images to remote sites.

## Minimally Invasive and Robotic Surgery

*Minimally invasive surgery (MIS)* is a common practice and now is the preferred technique for many types of surgery, including cholecystectomy, cardiac surgery, splenectomy, and spinal surgery. It is even being used for cancer surgeries such as the removal of a lung lobe (lobectomy) or even the entire lung (pneumonectomy) and colectomy. Benefits of MIS include reduced surgery time for some surgeries, smaller incisions, reduced blood loss, faster recovery time, and less pain after surgery.

During MIS one or more small incisions are made in the surgical area, and an **endoscope** (a tube that allows viewing and manipulation of internal body areas) is placed through the opening (Fig. 15-2). These instruments may be rigid, semi-rigid, or flexible and usually have self-contained light sources. Endoscopes have different functions and configurations for different surgical purposes. For example, laparoscopes are used for abdominal surgery, arthroscopes are used for joint surgery, and ureteroscopes are used for urinary tract surgery.

**FIG. 15-2** How an operative laparoscope is used.

In addition to being used for examination and obtaining specimens for biopsy, endoscopes can be used for organ removal, reconstruction, blood vessel grafting, and many other procedures. Cutting, suturing, stapling, cautery, and laser surgery can all be performed through or with endoscopes. An important part of MIS for abdominal surgery, pelvic surgery, and surgery in some other body cavity areas is injecting gas or air into the cavity before the surgery to separate organs and improve visualization. This injection is known as **insufflation** and may contribute to complications and patient discomfort. This factor is considered when deciding whether to perform a procedure by traditional surgery or endoscopy.

Patient preparation for endoscopic surgery is similar to the preparation for the same procedure when performed by open surgical methods. An endoscopic surgical procedure has a chance for becoming an open surgical procedure, depending on which patient- or procedure-related variables are discovered or develop during the surgery.

*Robotic technology* takes MIS to a new level and is changing how surgery is performed and how the OR is organized. Many gynecologic, urologic, and cardiovascular procedures are being performed by using robotics. The robotic system consists of a console, surgical arm cart, and video cart (Fig. 15-3). The surgeon first inserts the required instruments and positions the articulating arms; he or she then breaks scrub and performs the surgery while sitting at the console. A three-dimensional (3-D) view of the patient's anatomy allows precise control and dexterity. This new technology requires additional education for the perioperative nurse.

**FIG. 15-3** Operating room layout for robotic surgery with da Vinci Robotic Surgery System. (©2016 Intuitive Surgical, Inc.)

Mechanical trauma and thermal injury are two types of injury that a patient can incur during MIS and robotic surgery ([The Joint Commission, 2014](#)). Both MIS and robotic surgery are limited by the cost of special equipment, OR settings, and the lengthy training and practice periods for the surgeon to become proficient in even one procedure using these methods.

### **Health and Hygiene of the Surgical Team**

People are a source of contamination in the surgical setting from the bacteria on skin, on hair, and in the airways. To avoid transmitting these organisms to the patient, policies and procedures for special health standards and dress must be followed. All members of the surgical team and support personnel in the surgical suite must be free of communicable diseases. No one who has an open wound, cold, or any infection should participate in surgery.

Good personal hygiene and frequent handwashing help prevent and control infection. Jewelry carries many organisms and should be minimal. All personnel must wash their hands before and after contact with patients and performing procedures. Hands of surgical personnel may be cultured on a regular basis to assess for potential health care–associated infections and to identify sources of pathogens. Further interventions or cultures are needed if quality reports indicate a problem. Adhering to proper surgical attire policies and the surgical scrub protocols also helps prevent contaminations.

### **Surgical Attire**

All members of the surgical team and all OR personnel must wear scrub attire while in the surgical suite. Scrub attire, provided by the hospital, is clean, not sterile, and is worn to reduce contamination and risk for infection from areas outside of the surgical setting. Basic surgical attire is a shirt, pants, and a cap or hood ([Fig. 15-4](#)). Shoe coverings may be worn to protect the shoes. *Staff change into clean surgical attire in the OR suite locker rooms, not at home* ([AORN, 2016b](#)). All members of the surgical team must cover their hair, including any facial hair.

**FIG. 15-4** Typical attire for all scrubbed personnel. Note complete hair covering, eye shields, mask, and the sterile gloves over the sleeves of the sterile gown. Note that, when not in use, the hands are typically folded in front of the body, never below the waist.

In addition to basic attire, everyone must wear personal protective equipment (mask, eyewear, non-powdered gloves, head covering, and gown). Everyone who enters an OR where a sterile field is present must wear a mask. Surgical team members who are scrubbed and at the surgical field during the surgery must also wear a sterile fluid-resistant gown, sterile non-powdered gloves, and eye protectors or face shields. Team members who are *not* scrubbed (e.g., anesthesia provider, circulating nurse) may wear cover scrub jackets that are snapped or buttoned closed and eyewear, as warranted.

### **Surgical Scrub**

The surgeon, assistants, and the scrub nurse perform a surgical scrub after putting on a mask and before putting on a sterile gown and non-powdered gloves (Fig. 15-5). Rings, watches, and bracelets are removed before scrubbing. *The surgical scrub does not make the skin sterile.* Correctly performed, the scrub reduces the number of organisms from the hands, arms, and nails. Fingernails are kept short, clean, and healthy. Artificial nails, which have been proven to harbor organisms even after appropriate scrub techniques are used, should not be worn.

**FIG. 15-5** The scrubbing, gowning, and gloving process. **A**, The surgical scrub. **B**, Rinsing. Note the water falling off the hands and arms. Also note the foot-operated handle that controls the water flow. (After scrubbing and rinsing, the scrub nurse dries his hands and arms with a sterile towel inside the operating room and then is assisted into a sterile gown.) **C**, The scrub nurse prepares sterile non-powdered gloves. Note that the scrub nurse's hands are *inside* the sleeve of the gown and that he is touching the sterile gloves only with the sterile sleeve. **D**, The scrub nurse puts on his first sterile glove while the sterile gown is being tied in the back. Note again that his hand never emerges from under the sterile sleeve. **E**, The scrub nurse puts on his second sterile glove.

A surgical antimicrobial solution is used for the surgical scrub. Plain or antimicrobial soap is used for washing hands immediately before the surgical scrub. Vigorous rubbing that creates friction is used from the fingertips to the elbow. The scrub continues for 3 to 5 minutes, followed by a rinse. For rinsing, hands and arms are positioned so water runs off, rather than up or down, the arms (AORN, 2016c). After scrubbing, personnel enter the OR with their hands held higher than the elbows and thoroughly dry their hands and forearms with a sterile towel. Each person is then assisted into a sterile gown (“gowning”) and puts on sterile non-powdered gloves (“gloving”). Alcohol-based surgical scrub products will reduce transient and resident flora on the hands as effectively as the standard surgical scrub with an antimicrobial agent when used according to manufacturer instructions (Shen et al., 2015).

Gowns, non-powdered gloves, and materials used at the operative field must be sterile. These items are changed between procedures and as they become contaminated. The surgical gown is considered sterile only on the front from the chest to the level of the sterile field. The entire sleeves of the gown are considered sterile from 2 inches above the elbow to the cuff. The back of the gown is not considered sterile because it cannot be seen by the wearer. Only when they are properly scrubbed and attired do members of the surgical team handle sterile drapes and equipment.

## NCLEX Examination Challenge 15-1

### Safe and Effective Care Environment

A scrub person is discussing artificial nail use with the nurse. The scrub person states, “I do not use artificial nails; I’m wearing gel polish to strengthen my nails.” What is the appropriate nursing response?

- A. “I understand. That is my nail treatment of choice also.”
- B. “Hand hygiene is enhanced by covering natural nails.”

C. “Wear double gloves to prevent puncture or contamination.”

D. “Gel polish is a type of artificial nail that alters skin flora and impedes hand hygiene.”

## Anesthesia

Anesthesia reduces or temporarily eliminates sensory perception. Anesthesia administration has evolved into a precise science. Anesthesia providers include an anesthesiologist, a certified registered nurse anesthetist (CRNA) working under the direction of an anesthesiologist or another physician, or an anesthesiologist assistant (AA)—(working under the direction of an anesthesiologist).

**Anesthesia** is an induced state of partial or total loss of sensory perception, with or without loss of consciousness. The purposes of anesthesia are to block nerve impulse transmission, suppress reflexes, promote muscle relaxation and, in some cases, achieve a controlled level of unconsciousness. Anesthesia providers document medications given, vital signs, and other interventions during the procedure in a separate section of the electronic health record.

Usually the anesthesia provider selects the type of anesthesia to be used after consulting with the patient and surgeon and after considering specific patient risk factors. The nurse and the anesthesia provider collaborate to assess and address the patient's preferences and fears about the anesthesia intervention. Patient health problems are factors in the selection and dose of anesthetic. Selection is also influenced by:

1. Type and duration of the procedure
2. Area of the body having surgery
3. SAFETY issues to prevent injury, such as airway management
4. Status of procedure (elective, emergent)
5. Pain management options after surgery
6. How long it has been since the patient ate, had any liquids, or had any drugs
7. Patient position needed for the surgical procedure
8. Requirement of the patient to be alert enough to follow instructions during surgery
9. Patient's previous responses and reactions to anesthesia

The physical status of a patient is ranked according to a classification system developed by the American Society of Anesthesiologists (ASA). The anesthesiologist assesses the patient and assigns him or her to one of six categories based on current health and the presence of diseases and disorders. The categories rank patients in a range from a totally healthy patient (ASA1 ranking) to a patient who is brain dead (ASA6 ranking) ([American Society of Anesthesiologists, 2014](#)) (see [Chapter 14, Table 14-4](#)). This system is used to estimate potential risks during surgery and patient outcomes.

Anesthesia care begins with selecting and administering preoperative drugs (see [Chapter 14](#)). The nurse must know the actions of the drugs used, contraindications, and their effects during and after surgery. Anesthetic agents affect many systems and have the potential to negatively impact other health conditions. For example, most anesthetics are metabolized by the liver and excreted by the kidneys. Liver or kidney impairment increases anesthetic effects and the risk for toxicity. In addition, interactions may occur between the anesthetics and other drugs the patient has received.

Anesthesia can be induced in many ways ([Table 15-2](#)). The most common forms of anesthesia used in North America include general, regional, and local anesthesia. Less commonly used forms include hypnosis, cryothermia (use of cold), and acupuncture.

---

**TABLE 15-2**

**Features of Various Types of Anesthesia**

---

TYPE	FEATURES
General: inhalation	<ul style="list-style-type: none"> <li>Most controllable method</li> <li>Suppresses central nervous system activity and results in unconsciousness</li> <li>Medications administered either as inhalation agents, intravenous, or combination of the two</li> <li>Inhalation agents either inhaled through a breathing mask or endotracheal tube</li> <li>Intravenous medications given</li> <li>Induction and reversal accomplished with pulmonary ventilation</li> <li>Must be used in combination with other anesthetic agents for painful or prolonged procedures</li> <li>Limited muscle relaxant effects</li> <li>Postoperative nausea and shivering common</li> </ul>
General: intravenous	<ul style="list-style-type: none"> <li>Rapid and pleasant induction</li> <li>Low incidence of postoperative nausea and vomiting</li> <li>Must be metabolized and excreted from the body for complete reversal</li> <li>Contraindicated in presence of liver or kidney disease</li> <li>Increased cardiac and respiratory depression</li> </ul>
Balanced	<ul style="list-style-type: none"> <li>Minimal disturbance to physiologic function</li> <li>Can be used with older and high-risk patients</li> <li>Drug interactions can occur</li> </ul>
Regional or local: spinal, epidural, nerve block	<ul style="list-style-type: none"> <li>Local anesthetic agent injected around major nerves or the spinal cord to block sensation and pain from limited part of the body</li> <li>Allows participation and cooperation by the patient</li> <li>Gag and cough reflexes stay intact</li> <li>Less disruption of physical and emotional body functions</li> <li>No way to control agent after administration</li> <li>Increased nervous system stimulation (overdose)</li> <li>Not practical for extensive procedures because of the amount of drug that would be required to maintain anesthesia</li> <li>Often used for lower abdominal, pelvic, rectal, or lower-extremity surgery; involves injecting a single dose of the anesthetic agent directly into the spinal cord in the lower back, causing numbness in the lower body</li> </ul>

## General Anesthesia

**General anesthesia** is a reversible loss of consciousness induced by inhibiting neuronal impulses in areas of the central nervous system (CNS). This state can be achieved with a single agent or a combination of agents. General anesthesia depresses the CNS, resulting in **analgesia** (pain relief or pain suppression), **amnesia** (memory loss of the surgery), and unconsciousness. General anesthesia is used most often in surgery of the head, neck, upper torso, and abdomen. For certain procedures, muscle relaxation is also required. This is achieved with paralytic agents.

### Stages of General Anesthesia.

Induction of general anesthesia involves four stages. [Table 15-3](#) lists the expected patient responses and nursing care for each stage. The speed of **emergence** (recovery from the anesthesia) depends on the anesthetic agent, the duration of anesthesia administration, and whether a reversal agent is used. Gagging, vomiting, and restlessness may occur during emergence, although not all patients have these responses. Suction equipment must be available at all times. During recovery, shivering, rigidity, and slight cyanosis may occur. These responses are caused by a temporary change in the body's thermoregulation. The nurse provides warm blankets, radiant heat, and oxygen to decrease the effects of emergence.

**TABLE 15-3**

**The Four Stages of General Anesthesia and Related Nursing Interventions**

DESCRIPTION	NURSING INTERVENTIONS	RATIONALES
<b>Stage 1 (Analgesia and Sedation, Relaxation)</b>		
Begins with induction and ends with loss of consciousness.	Close operating room doors, dim the lights, and control traffic in the operating room.	Avoiding external stimuli in the environment promotes relaxation.
Patient feels drowsy and dizzy, has a reduced sensation to pain, and is amnesic.	Position patient securely with safety belts.	Using safety measures in stage 1 prepares for stage 2.
Hearing is exaggerated.	Keep discussions about the patient to a minimum.	Being sensitive to the patient maintains his or her dignity.
<b>Stage 2 (Excitement, Delirium)</b>		
Begins with loss of consciousness and ends with relaxation, regular breathing, and loss of the eyelid reflex.	Avoid auditory and physical stimuli.	Sensory stimuli can contribute to the patient's response.
Patient may have irregular breathing, increased muscle tone, and involuntary movement of the extremities.	Protect the extremities.	Safety measures help prevent injury.
Laryngospasm or vomiting may occur.	Assist the anesthesiologist or CRNA with suctioning as needed.	Adequate suctioning of vomitus can prevent aspiration.
Patient is susceptible to external stimuli.	Stay with patient.	Staying with the patient is emotionally supportive.
<b>Stage 3 (Operative Anesthesia, Surgical Anesthesia)</b>		
Begins with generalized muscle relaxation and ends with loss of reflexes and depression of vital functions. The jaw is relaxed, and breathing is quiet and regular. The patient cannot hear. Sensations (i.e., to pain) are lost.	Assist the anesthesiologist or CRNA with intubation. Place patient into operative position. Prepare (scrub) the patient's skin over the operative site as directed.	Providing assistance helps promote smooth intubation and prevent injury. Performing procedures as soon as possible promotes time management to minimize total anesthesia time for the patient.
<b>Stage 4 (Danger)</b>		
Begins with depression of vital functions and ends with respiratory failure, cardiac arrest, and possible death. Respiratory muscles are paralyzed; apnea occurs. Pupils are fixed and dilated.	Prepare for and assist in treatment of cardiac and/or pulmonary arrest. Document occurrence in the patient's chart.	Teamwork and preparedness help decrease injuries and complications and promote the possibility of a desired outcome for the patient.

CRNA, Certified registered nurse anesthetist.

### Administration of General Anesthesia.

General anesthesia agents are administered by inhalation and IV injection. A combination of types of agents (balanced anesthesia) is used to provide hypnosis, amnesia, analgesia, muscle relaxation,

and reduced reflexes with minimal disturbance of physiologic function. This method provides safe and controlled anesthetic delivery, especially for older and high-risk patients. An example of balanced anesthesia is the use of thiopental or propofol for induction, morphine or fentanyl for analgesia, and pancuronium or rocuronium for muscle relaxation. Agent selection is based on the individual patient risks (age, comorbidities, airway issues, anesthesia history, and current drugs) and the specific surgical procedure (type and duration of procedure).

Other drugs such as hypnotics, opioid analgesics, and neuromuscular blocking agents may be used as part of the anesthesia plan. Hypnotics and opioid analgesics can be used for sedation before surgery, for IV moderate sedation for short procedures, and as an adjunct to general anesthesia during surgery. The neuromuscular blocking agents are used to relax the jaw and vocal cords immediately after induction so the endotracheal tube can be placed. These drugs also may be used during surgery to provide continued muscle relaxation.

### Complications of General Anesthesia.

Complications can range from minor harm (e.g., sore throat) to death. Improvement in anesthesia care and surgical techniques has resulted in a decline in anesthesia-related deaths, even among higher-risk patients. Although the anesthesia provider has the main responsibility for monitoring patient responses during surgery, the circulating nurse also remains alert for changes in the patient's condition.

*Malignant hyperthermia (MH)*, an inherited muscle disorder, is an acute, life-threatening complication of certain drugs used for general anesthesia. It is characterized by many problems, including inadequate thermoregulation. The reaction begins in skeletal muscles exposed to the drugs, causing increased calcium levels in muscle cells and increased muscle metabolism. Serum calcium and potassium levels are increased, as is the metabolic rate, leading to acidosis, cardiac dysrhythmias, and a high body temperature.

MH may start immediately after anesthesia induction, several hours into the procedure, or even after anesthesia is completed. Symptoms, caused by increased muscle calcium and increased metabolism, include tachycardia, dysrhythmias, muscle rigidity of the jaw and upper chest, hypotension, tachypnea, skin mottling, cyanosis, and **myoglobinuria** (muscle proteins in the urine). The most sensitive indication is an unexpected rise in the end-tidal carbon dioxide level with a decrease in oxygen saturation and tachycardia. Extremely elevated temperature, as high as 111.2° F (44° C), is a late sign of MH. Survival depends on early diagnosis and the immediate actions of the entire surgical team. Dantrolene sodium, a skeletal muscle relaxant, is the drug of choice along with other interventions (Rosenberg et al., 2015).

## NCLEX Examination Challenge 15-2

### Safe and Effective Care Environment

Which emergency care does the nurse recognize that will be implemented for a client with malignant hyperthermia? **Select all that apply.**

- A. Removal of endotracheal tube
- B. Cessation (stopping) of surgery when possible
- C. Insertion of Foley catheter to monitor urine output
- D. Transfer of patient to intensive care unit when stabilized
- E. Assessment of arterial blood gases (ABGs) for respiratory alkalosis
- F. Use of active cooling techniques such as a cooling blanket and ice packs around the axillae and groin

### Nursing Safety Priority QSEN

## Critical Rescue

Recognize that you must monitor patients for the cluster of elevated end-tidal carbon dioxide level, decreased oxygen saturation, and tachycardia to identify symptoms of malignant hyperthermia. If these changes begin, respond by alerting the surgeon and anesthesia provider immediately.

When the patient has a known history for MH, treatment with dantrolene can begin before, during, and after surgery to prevent it. [Chart 15-1](#) lists best practices for care of the patient with MH. AORN recommends that all ORs have a dedicated MH cart containing drugs for management (normal saline, dantrolene, sodium bicarbonate, insulin, 50% dextrose, lidocaine, calcium chloride), a protocol card listing interventions, and the MH hotline number. Additional nursing care and anesthesia support are needed during this perioperative emergency.

### Chart 15-1

## Best Practice for Patient Safety & Quality Care QSEN

### Emergency Care of the Patient With Malignant Hyperthermia

- Stop all volatile inhalation anesthetic agents and succinylcholine.
- If an endotracheal tube (ET) is not already in place, intubate immediately.
- Ventilate the patient with 100% oxygen at the highest possible flow rate to flush anesthetics and lower end-tidal carbon dioxide.
- Administer dantrolene sodium (Dantrium) IV at a dose of 2 to 3 mg/kg. Repeat as needed.
- If possible, terminate surgery. If termination is not possible, maintain general anesthesia with IV anesthetic agents that do not trigger malignant hyperthermia (MH) (IV sedatives, narcotics, amnestics and nondepolarizing neuromuscular blockers).
- Assess arterial blood gases (ABGs) and serum chemistries for metabolic acidosis and hyperkalemia.
- If metabolic acidosis is evident by ABG analysis, administer sodium bicarbonate IV.
- If hyperkalemia is present, administer 10 units of regular insulin in 50 mL of 50% dextrose IV.
- Use active cooling techniques:
- Administer iced saline (0.9% NaCl) IV at a rate of 15 mL/kg every 15 minutes as needed.
- Apply a cooling blanket over the torso.
- Pack bags of ice around the patient's axillae, groin, neck, and head.
- Lavage the stomach, bladder, rectum, and open body cavities with sterile iced normal saline.
- Insert a nasogastric tube and a rectal tube.
- Monitor core body temperature to assess effectiveness of interventions and avoid hypothermia.

- Monitor cardiac rhythm by electrocardiography (ECG) to assess for dysrhythmias.
- Insert a Foley catheter to monitor urine output.
- Treat any dysrhythmias that do not resolve on correction of hyperthermia and hyperkalemia with antidysrhythmic agents. Avoid *calcium channel blockers*.
- Administer intravenous fluids at a rate and volume sufficient to maintain urine output above 2 mL/kg/hr.
- Monitor urine for presence of blood or myoglobin.
- If urine output falls below 2 mL/kg/hr, consider using osmotic or loop diuretics, depending on the patient's cardiac and kidney status.
- Contact the Malignant Hyperthermia Association of the United States (MHAUS) hotline for more information regarding treatment: (800) 644-9737.
- Transfer the patient to the intensive care unit (ICU) when stable.
- Continue to monitor the patient's temperature, ECG, ABGs, electrolytes, creatine kinase, coagulation studies, and serum and urine myoglobin levels until they have remained normal for 24 hours.
- Instruct the patient and family about testing for MH risk.
- Refer the patient and family to the Malignant Hyperthermia Association of the United States at (800) 986-4287 or [www.mhaus.org](http://www.mhaus.org).
- Report the incident to the North American Malignant Hyperthermia Registry at the Malignant Hyperthermia Association of the United States: (800) 644-9737.

Data from Malignant Hyperthermia Association of the United States. (2016). *Managing an MH crisis*. <http://www.mhaus.org/healthcare-professionals/managing-a-crisis>.

## Genetic/Genomic Considerations

### Patient-Centered Care QSEN

Malignant hyperthermia (MH) is a genetic disorder with an autosomal-dominant pattern of inheritance. The patient with a genetic predisposition for MH is at risk when exposed to halothane, enflurane, isoflurane, desflurane, sevoflurane, and succinylcholine. The problem is most common in young adult males (despite the autosomal-dominant pattern of inheritance) because of gender differences in muscle mass. The muscle biopsy tested with the caffeine halothane contracture test (CHCT) is still considered the most commonly used MH test (Rosenberg et al., 2015). There is also a genetic test that is performed on blood to assess whether a mutation in the *RYR1* gene is present. Usually the cost of the genetic test is not covered by insurance. Always ask the patient about any previous problems or difficulties with anesthesia.

*Overdose of anesthetic* can occur if the patient's metabolism and drug elimination are slower than expected, such as with patients who are older or who have liver or kidney problems. Drugs (e.g., antihypertensives, diuretics, and herbal supplements) can alter metabolism, and interactions can occur between the anesthetic and the patient's regular drugs. Accurate information about the patient's height, weight, and medical history, especially liver and kidney function, is vital in determining the anesthetic type and dosage.

*Unrecognized hypoventilation* is an anesthesia-induced complication. Failure of adequate GAS EXCHANGE can lead to cardiac arrest, permanent brain damage, and death. Monitoring standards include the use of capnography (an end-tidal carbon dioxide monitor) to confirm carbon dioxide levels in the patient's expired gas (Spiegel, 2013) and a breathing system–disconnect monitor to

detect any break in the breathing circuit equipment.

*Intubation complications* can include many problems (e.g., broken teeth and caps, swollen lip, vocal cord trauma). Difficult intubation may be caused by anatomic issues or disease presence (e.g., small oral cavity, tight jaw joint, tumor). Improper neck extension during intubation may cause injury. The surgeon should be in the OR during the intubation process in case of complications. In difficult airway situations, a tracheotomy may be needed if the endotracheal tube (ET) is unable to be placed. Intubation causes tracheal irritation and edema. A common complaint after surgery is a sore throat.

## Local or Regional Anesthesia

Local or regional anesthesia briefly disrupts sensory nerve impulse transmission, providing a reversible regional loss of sensation in a predetermined area of the body to reduce pain and facilitate the surgical procedure (Gmyrek & Elston, 2015). Motor function may or may not be affected. The patient remains conscious and can follow instructions. The gag and cough reflexes remain intact, and the risk for aspiration is low. This type of anesthesia may be supplemented with sedatives, opioid analgesics, or hypnotics to reduce anxiety and increase comfort. The OR nurse provides the patient with information, directions, and emotional support before, during, and after the procedure.

### Local Anesthesia.

**Local anesthesia** is delivered topically (applied to the skin or mucous membranes of the area to be anesthetized) and by local infiltration (injected directly *into* the tissue around an incision, wound, or lesion). The term *local* anesthesia may mean *any* form of anesthesia that is not general or monitored anesthesia.

### Regional Anesthesia.

**Regional anesthesia** is a type of local anesthesia that blocks multiple peripheral nerves and reduces sensation in a specific body region. It can be used for a variety of conditions and procedures. Anesthesia and surgeon preference along with patient input can determine the use of regional anesthetics. Regional anesthesia is often used when pain management after surgery is desired such as after a total knee replacement. If the patient has eaten and the surgery is an emergency, it may be possible to perform surgery with the patient under regional anesthesia to decrease the risk for aspiration. Regional anesthesia includes field block, nerve block, spinal, and epidural (Table 15-4). Figs. 15-6 and 15-7 show common sites of nerve blocks, spinal anesthesia, and epidural anesthesia.

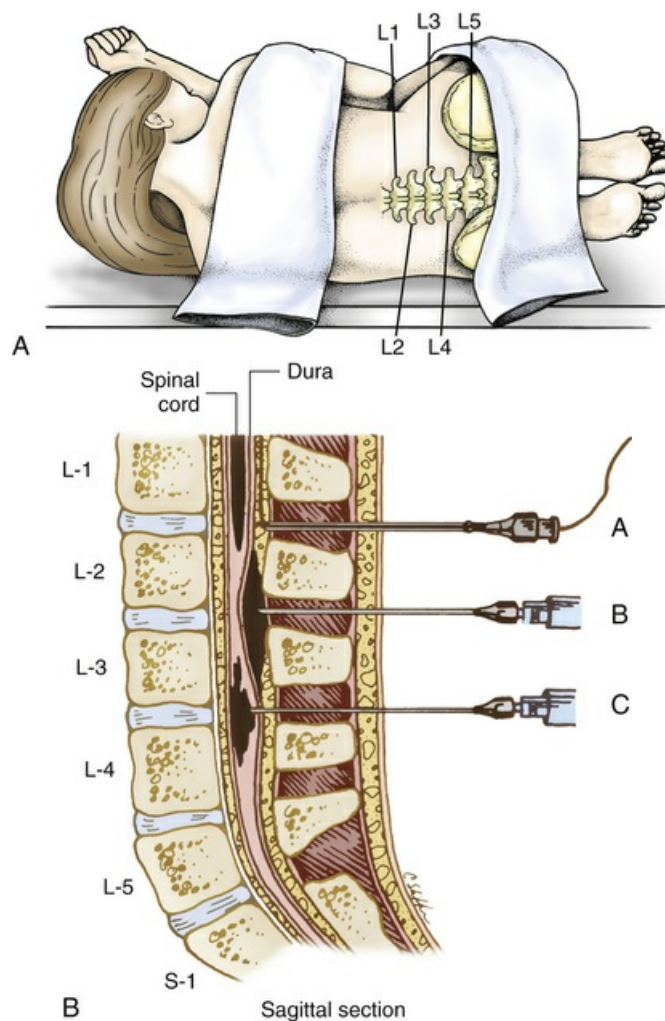

**TABLE 15-4**

**Types of Regional Anesthesia**

ANESTHESIA TYPE	DEFINITION AND COMMON USE
Field block	Series of injections <i>around</i> the operative field Most commonly used for chest procedures, hernia repair, dental surgery, and some plastic surgeries
Nerve block	Injection of the local anesthetic agent <i>into or around</i> one nerve or group of nerves in the involved area Most commonly used for limb surgery or to relieve chronic pain
Spinal anesthesia	Injection of an anesthetic agent into the cerebrospinal fluid in the subarachnoid space Most commonly used for lower abdominal, pelvic, hip, and knee surgery
Epidural anesthesia	Injection of an agent into the epidural space (see Fig. 15-7) Most commonly used for anorectal, vaginal, perineal, hip, and lower-extremity surgeries

**FIG. 15-6** Nerve block sites.

**FIG. 15-7** Administration of spinal and epidural anesthesia. (B from Rothrock, J. [2014]. *Alexander's care of the patient in surgery* [15th ed.]. St. Louis: Elsevier.)

The nurse's role in providing regional anesthesia includes:

- Assisting the anesthesia provider
- Positioning the patient comfortably and safely
- Offering information and reassurance
- Staying with the patient and providing emotional support
- Observing for breaks in sterile technique
- Recognizing and responding to signs and symptoms of possible reactions to the anesthetics

### Complications of Local or Regional Anesthesia.

Complications of local or regional anesthesia are related to patient sensitivity to the anesthetic agent (anaphylaxis), incorrect delivery technique, systemic absorption, and overdose. Complications seen early after administration of a local anesthetic agent include edema and inflammation. Abscess formation, tissue necrosis, and/or gangrene may occur later. Abscesses result from contamination during injection of the agent. Necrosis and gangrene may occur as a result of prolonged blood vessel constriction in the injected area.

Systemic toxicity of a local agent may result in adverse reactions in the central nervous and cardiovascular systems (Gmyrek & Elston, 2015). The nurse continually assesses for restlessness; excitement; incoherent speech; headache; blurred vision; metallic taste; nausea; tremors; seizures; and increased pulse, respiration, and blood pressure. Interventions include establishing an open airway, giving oxygen, and notifying the surgeon. Usually a fast-acting barbiturate is needed for treatment. If the toxic reaction is untreated, unconsciousness, hypotension, apnea, cardiac arrest, and death may result.

Cardiac arrest may occur as a rare complication of spinal anesthesia. Epinephrine is given to prevent cardiac arrest in patients who develop sudden, unexplained bradycardia.

### Moderate Sedation

Moderate sedation (conscious sedation) is the IV delivery of sedative, hypnotic, and opioid drugs to reduce sensory perception but allow the patient to maintain a patent airway. The amnesia action is short, and the patient has a rapid return to normal function and activities. Etomidate (Amidate), diazepam (Valium, Vivol ♣, Novo-Dipam ♣), midazolam (Versed), fentanyl (Sublimaze), alfentanil (Alfenta), propofol (Diprivan), and morphine sulfate are the most commonly used drugs. Moderate sedation is used to reduce the level of consciousness during minor surgical procedures, endoscopy, cardiac catheterization, closed fracture reduction, and cardioversion.

Selection of patients for moderate sedation is based on specific criteria. The physician determines whether the patient is a candidate. In most states, a registered nurse may administer moderate sedation under physician supervision and within the state-defined scope of nursing practice. Additional credentialing is required, which may include advanced training in IV drug delivery, airway management, and advanced cardiac life support (ACLS).

The nurse monitors the patient during and after the procedure for response to the procedure and the drugs. The airway, level of consciousness, oxygen saturation, capnography (measure of carbon dioxide level), electrocardiogram (ECG) status, and vital signs are monitored every 15 to 30 minutes until the patient is awake and oriented and vital signs have returned to baseline levels (AORN, 2016d).

The nurse performs evaluation of consciousness during and after moderate sedation. A variety of sedation scales are available to use based on patient and procedural situations. The Ramsay Sedation Scale (RSS) was developed for ICU patients and is one of the scoring systems most widely used during moderate sedation (Lazear, 2014). Additional scales are listed in Table 15-5. Each scale has specific patient responses or behaviors to a continuum of environmental stimulation indicating degree of arousal from sedation or readiness for discharge.

**TABLE 15-5**

**Scales Used to Evaluate Patient Responses to Moderate Sedation**

Interprocedural Scales (Used During Procedure to Assess Level of Sedation)
<ul style="list-style-type: none"><li>• Modified Observer's Assessment of Alertness/Sedation Scale</li><li>• Ramsay Sedation Scale (RSS)</li><li>• Sedation-Agitation Score</li><li>• Richmond Agitation-Sedation Scale (RASS)</li></ul>

• Motor Activity Assessment Scale
<b>Postprocedure Scales (Used After Procedure to Determine Readiness for Discharge)</b>
• Postanesthesia Discharge Scoring System (PADSS)
• Modified Postanesthesia Discharge Scoring System (MPADSS)
• Modified Aldrete Score

The patient receiving IV moderate sedation can be discharged to home with a responsible adult if capnography indicates GAS EXCHANGE is adequate and arousal from sedation is at a preprocedural level. If the patient returns to the general medical-surgical nursing unit, the unit nurses continue monitoring. The patient is expected to be sleepy but arousable for several hours after the procedure. Oral intake is not permitted until 30 minutes after the patient received the last dose of sedation or according to the physician's orders. If the patient had oral endoscopy, return of the gag reflex is required before oral intake. When fluids are permitted, the nurse makes sure that the patient is awake and positioned upright to avoid aspiration.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

#### History.

On arrival in the surgical suite, the patient is taken to the preoperative holding area or directly into the operating suite. The preoperative holding area nurse or the circulating nurse greets the patient on arrival. **As indicated in The Joint Commission's National Patient Safety Goals (NPSGs), correct identification of the patient is the responsibility of every member of the health care team. Check the patient's identification bracelet and ask, "What is your name and birthdate?"** This practice prevents errors by drowsy or confused patients. For example, avoid asking a patient, "Are you Mr. Gates?" He may respond inappropriately if he is anxious or sedated. The nurse always validates patient identification for safety using two unique identifiers. The electronic health record and identification bracelet should be consistent with the information the patient shares with the perioperative staff.

## 📌 Nursing Safety Priority QSEN

### Action Alert

**The Joint Commission's NPSGs require that you verify the patient's identity with two types of identifiers (name, date of birth, electronic health record number, telephone number, or other person-specific identifier). Ask the patient to tell you his or her name.**

After completing the identification process, the nurse validates that the surgical consent form has been signed and witnessed. The nurse asks, "What kind of operation are you having today?" to ascertain that the patient's perception of the procedure, the surgical consent, the surgeon's order, and the operative schedule are the same. *When the procedure involves a specific site, validating the side on which a procedure is to be performed (e.g., for amputation, cataract removal, hernia repair) is the responsibility of each health care professional before and at the time of surgery. The Joint Commission now recommends that the patient and the licensed independent practitioner who is ultimately accountable for the procedure and will be present during the procedure (usually the surgeon performing the surgery) mark the surgical site (The Joint Commission [TJC], 2017).* Before proceeding, each health care professional thoroughly investigates any discrepancy and notifies the surgeon and anesthesia provider. The Joint Commission (TJC) has developed a Universal Protocol for Preventing Wrong Site, Wrong Procedure, Wrong Person Surgery; and the Association of periOperative Registered Nurses has developed recommendations based on this protocol (AORN, 2015b). The nurse asks the patient about any allergies and determines whether autologous blood was donated. A special allergy bracelet on the patient's wrist and the medical record must be verified with what has been communicated.

## 📌 Nursing Safety Priority QSEN

### Critical Rescue

Assess the patient's knowledge of his or her scheduled surgical procedure and site. If you recognize that the patient's description of the surgical site is different from that listed on the informed consent, respond by contacting the surgeon to validate the procedure with the patient and to mark the correct site.

The nurse checks the patient's attire to ensure adherence with facility policy. Dentures and dental prostheses, jewelry (including body piercing), eyeglasses, contact lenses, hearing aids, wigs, and other prostheses are removed. Denture removal before anesthesia is controversial because, although the denture plate may come loose and obstruct the airway, the anesthesia provider may request that dentures be left in place to ensure a snug fit of the bag-mask. In some facilities, patients may wear eyeglasses and hearing aids until after anesthesia induction.

### Electronic Health Record Review.

The circulating nurse and anesthesia provider review the patient's electronic health record in the perioperative holding area or the operating room (OR). This record provides information to identify patient needs during surgery and allows the nurse to assess and plan specific care during and after surgery. It is the main source of information on the type and location of the planned surgery. The nurse checks the medical record to ensure that required data are present before surgery is started.

### Advance Directives and Do-Not-Resuscitate Orders.

Ethical dilemmas may occur during or after surgery. As a patient advocate, the nurse may have to intervene on behalf of the patient's rights and wishes. The nurse must be familiar with the advance directives and do-not-resuscitate (DNR) orders for each patient. It may be difficult for some health care providers in the surgical setting to care for a patient who has an existing DNR order. Some agencies suspend DNR orders while a patient is undergoing a surgical procedure. The position statement of the Association of periOperative Registered Nurses states that automatically suspending a DNR or allow-natural-death order during surgery undermines a patient's right to self-determination (AORN, 2014).

## Clinical Judgment Challenge 15-1

### Patient-Centered Care; Teamwork and Collaboration; Ethics QSEN

You are caring for a 70-year-old patient who was alert and oriented to person, place, and time during the preoperative assessment. At that time, the patient confirmed that she has a current do-not-resuscitate (DNR) order in place and stated that she is “ready to die” if surgery to remove a malignant tumor “does not go well.” During the surgery, complications arise, and members of the interprofessional health care team prepare to administer life-saving measures.

1. How do you serve as the patient's advocate at this time?
2. What information do you communicate to the interprofessional health care team?
3. Should the DNR order be suspended during surgery, especially if it appears that the patient can be saved?
4. What information will you share with the family when they ask why you did not save their loved one?

## Nursing Safety Priority QSEN

### Action Alert

Advance directives are to be honored in the surgical environment regardless of the situation.

### Allergies and Previous Reactions to Anesthesia or Transfusions.

The nurse asks about allergies and previous reactions to anesthesia and blood transfusions. Allergies to iodine products or shellfish indicate a risk for a reaction to the agents used to clean the surgical area. Latex allergies are assessed with all patients because anaphylaxis can occur with latex contact during surgery. Latex-free equipment and supplies are used when there is a latex allergy. The nurse documents the allergy in the medical record and communicates the allergy information to the entire surgical team.

The patient's previous experience with anesthesia helps the surgical team anticipate needs and plan interventions. For example, if a patient is restless or agitated as a reaction to anesthesia, the nurse must plan patient SAFETY interventions (including padding for the side rails and protective restraints). The use of blood products during surgery will be influenced by the patient's history, religious beliefs, preferences, and past transfusion reactions.

## NCLEX Examination Challenge 15-3

### Safe and Effective Care Environment

The nurse is performing an assessment on a client who has arrived in the preoperative holding area. Which client statement requires **immediate** nursing intervention?

- A. "I'm a little bit anxious about my surgery."
- B. "When I eat shrimp, my tongue swells, and I have difficulty breathing."
- C. "This left knee replacement will help me walk much more comfortably again."
- D. "Before I get discharged home, I want to have my eyeglasses and hearing aids returned."

### Autologous Blood Transfusion.

**Autologous blood transfusion** (reinfusing the patient's own blood) may be used for surgery. [Chapters 14](#) and [40](#) discuss autologous transfusion in more detail. [Chart 15-2](#) outlines best practices for autologous blood transfusion using blood salvage techniques during surgery.

## Chart 15-2

### Best Practice for Patient Safety & Quality Care

#### Intraoperative Autologous Blood Salvage and Transfusion

- Be aware of the cell-processing method to be used.
- Make sure that collection containers are labeled for the patient.
- Assist with sterile setup as necessary.
- Assist with processing and reinfusing procedures as needed.
- Document the transfusion process.
- Monitor the patient's vital signs during the transfusion procedure.

### Laboratory and Diagnostic Test Results.

The OR nurse reviews the most recent laboratory findings and test results to inform the surgical team about the patient's health and alert them for potential problems. These results are usually obtained within 24 to 48 hours before surgery for hospitalized patients and within 4 weeks for ambulatory surgery patients. The nurse reports all abnormal findings or results to the surgeon and anesthesia provider. Laboratory values greater or less than the normal range are potentially life threatening during surgery (see [Chapter 14](#)). For example, if the hemoglobin level is less than 10

g/dL, oxygen transport and GAS EXCHANGE are reduced, affecting the amount and type of anesthesia used.

### Medical History and Physical Examination Findings.

The nurse performs a final assessment to identify risk factors related to patient SAFETY, starting with the patient's age and general physical condition. Older patients and those who are thin or overweight are at greater risk for injury during the positioning process. Assessing mental status is important because confused patients and those who are unable to either follow instructions or communicate may not be able to tell you when a problem exists. Patients who have impaired sensory perception of any type are at increased risk for injury. Specific drugs, such as long-term steroid use (which increases capillary fragility and thins the skin) or immunosuppressives (which inhibit the immune system and may delay healing), and limitations of range or motion, require modification during positioning and may increase risk for injury for some patients.

The OR nurse ensures that the medical history and physical examination findings, including usual pulse and blood pressure, are recorded. This information provides baseline data to assess the patient's reaction to the surgery and anesthesia. Drugs taken before surgery may affect the patient's reaction to surgery and wound healing. For example, aspirin and other NSAIDs can increase clotting time and the risk for hemorrhage.

## NCLEX Examination Challenge 15-4

### Safe and Effective Care Environment

The nurse is caring for four clients who will undergo surgery today. Which client does the nurse recognize as at **highest** risk for surgical complication?

- A. 52-year old who takes aspirin daily
- B. 58-year old who has well-controlled type II diabetes
- C. 64-year old who has just received presurgical prophylactic antibiotics
- D. 69-year old who will be discharged after surgery to an extended-care facility

Knowing the patient's medical history and age allows the nurse to plan interventions for the care and SAFETY of high-risk patients. The nurse carefully monitors older patients ([Chart 15-3](#)) and those with cardiac disease for potential fluid overload.

### Chart 15-3

## Nursing Focus on the Older Adult

### Intraoperative Nursing Interventions

- Allow patients to retain eyeglasses, dentures, and hearing aids until anesthesia has begun.
- Use a small pillow under the patient's head if his or her head and neck are normally bent slightly forward.
- Lift patients into position to prevent shearing forces on fragile skin.
- Position arthritic and artificial joints carefully to prevent postoperative pain and discomfort from strain on those joints.
- Pad bony prominences to prevent pressure sores.
- Provide extra padding for patients with decreased peripheral circulation.

- Use warming devices to prevent hypothermia.
- Cover the patient's head and feet.
- Warm IV and irrigation fluids as indicated by agency policy and manufacturer recommendations.
- Follow strict aseptic technique.
- Carefully monitor intake and output, including blood loss.

Data from Oster, K., & Oster, C. (2015). Special needs population: Care of the geriatric patient population in the perioperative setting. *AORN Journal*, 101(4), 443-456.

After completing the electronic health record review, the nurse may insert an IV catheter and administer preoperative medications as ordered. Providing patient-centered care by involving the patient in the plan and addressing identified needs will optimize care and may improve the overall surgical experience. Emotional support, ongoing explanation of procedures, and including family as appropriate will help decrease patient's anxiety in the preoperative period. After the preoperative routine is completed, the patient is moved to the OR.

## Nursing Safety Priority QSEN

### Action Alert

Once the patient has been moved into the OR, do not leave him or her alone. Apply a safety belt across the mid-thigh area of the patient to protect him or her from falls/injury.

### ◆ Analysis: Interpreting

The priority collaborative problems for patients during surgery are:

1. Potential for injury due to improper perioperative positioning
2. Potential for infection due to invasive procedures
3. Decreased GAS EXCHANGE due to anesthesia, pain, reduced respiratory effort

### ◆ Planning and Implementation: Responding

#### Preventing Injury

##### Planning: Expected Outcomes.

The patient is expected to be free of injury as indicated by:

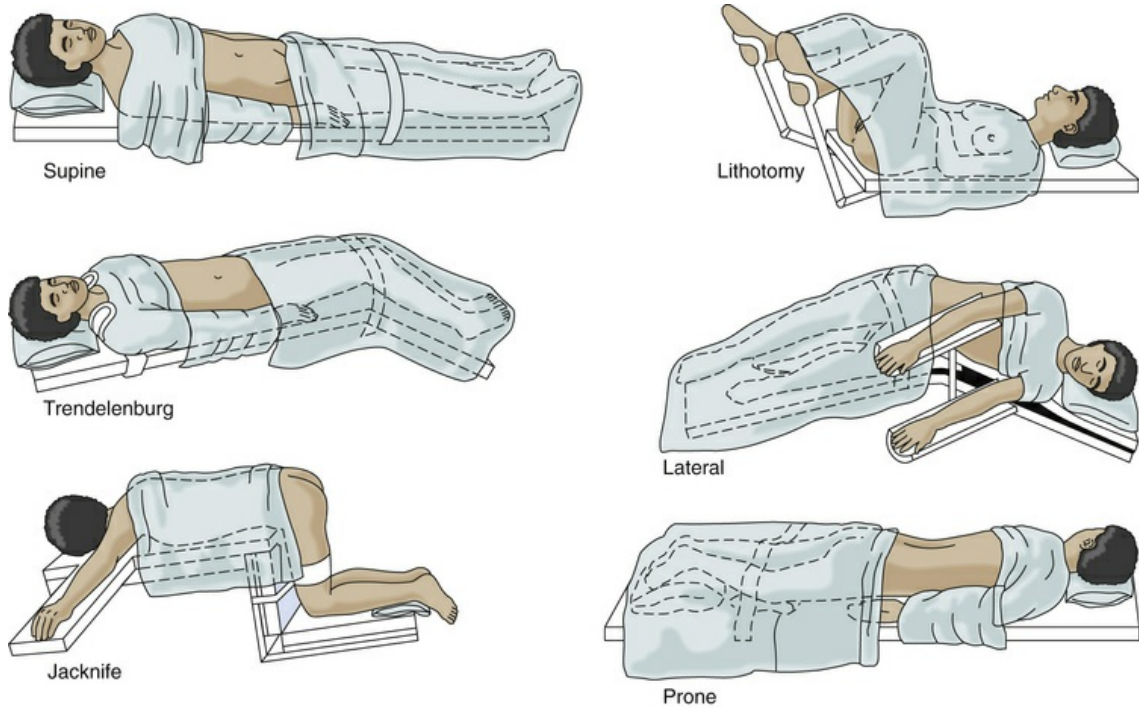

- Adequate capillary refill and peripheral pulses in all extremities
- Sensory perception and motor function after surgery at the same level as before surgery
- Absence of injury to the skin (redness, open skin areas, bruising, burns)
- Absence of retained surgical items

##### Interventions.

Interventions are needed to prevent injury from positioning based on patient risk factors, anesthesia method, and type and duration of the surgical procedure. Proper positioning is critical. Pressure injuries and nerve injuries can occur if attention is not paid to all areas of the body that are in contact with the OR table. The circulating nurse pads the operating bed with foam and/or silicone gel pads and coordinates the patient's transfer to the operating table. The skin is assessed, especially of older patients, for bruising or injury, and extra padding is placed as indicated (Spruce & VanWicklin, 2015).

The patient is usually in a supine position after transfer to the operating bed. Anesthesia may be initiated with the patient supine, and the patient then may be repositioned for surgery (Fig. 15-8).

Before or just after anesthesia induction and before positioning begins, a time-out is conducted to prevent wrong-site, wrong-side, wrong-procedure or wrong-person surgery. A time-out is a critical pause in the progression of care to confirm the patient's identity, the procedure and the site, and other pertinent information. The time-out is initiated by a member of the surgical team and is documented in the electronic health record (Fig. 15-9) by the circulating nurse. Once the time-out has been completed, patient care activities such as positioning, skin preparation, and draping of the surgical site may begin.

**FIG. 15-8** Common surgical positions.

The circulating nurse coordinates positioning of the patient for surgery and modifies the position according to the patient's risk factors and special needs. The OR nurse ensures that there is an adequate number of personnel to assist in positioning the patient.

Factors influencing the positioning process include:

- The surgical site (procedure being performed)
- The age, weight, and size of the patient
- The anesthetic delivery technique
- Pain on movement (conscious patient)
- The surgeon's preference
- Any pulmonary, skeletal, or muscular limitations such as arthritis, joint replacements, emphysema, or implanted devices

Chart 15-4 lists best practices to prevent complications related to intraoperative positioning, and thus prolonged immobility, during surgery.

### Chart 15-4

## Best Practice for Patient Safety & Quality Care QSEN

### Prevention of Complications Related to Intraoperative Positioning

#### Prevention of Brachial Plexus Complications (Paralysis, Loss of Sensation in Arm and Shoulder)

- Pad the elbow if tucked at the side.

- Avoid excessive abduction (less than 90 degrees).
- Secure the arm firmly on a padded armboard, positioned at shoulder level, and extended less than 90 degrees.

### **Prevention of Radial Nerve Complications (Wrist Drop)**

- Support the wrist with padding.
- Be careful not to overtighten wrist straps.

### **Prevention of Medial or Ulnar Nerve Complications (Hand Weakness, Claw Hand)**

- Place the safety strap above or below the nerve locations (do not overtighten).
- Place the arm of supine patient with palm up.

### **Prevention of Peroneal Nerve Complications (Foot Drop)**

- Pad knees and ankles.
- Maintain minimal external rotation of the hips.
- Support the lower extremities.
- Be careful not to overtighten leg straps.

### **Prevention of Tibial Nerve Complications (Loss of Sensation on the Plantar Surface of the Foot)**

- Place the safety strap above the ankle.
- Do not place equipment on lower extremities.
- Urge operating room (OR) personnel to avoid leaning on the patient's lower extremities.

### **Prevention of Joint Complications (Stiffness, Pain, Inflammation, Limited Motion)**

- Place a pillow or foam padding under bony prominences.
- Maintain the patient's extremities in good anatomic alignment.
- Slightly flex joints and support with pillows, trochanter rolls, or pads.

Data from Association of periOperative Registered Nurses. (2016). Recommended practices for positioning the patient in the perioperative practice setting. In *Perioperative standards and recommended practices* Denver, p. 649-688; and Rothrock, J. (2014). *Alexander's Care of the patient in surgery* (15th ed.). St. Louis: Elsevier.

The dorsal recumbent (supine), prone, lithotomy, and lateral positions are most often used for surgery. Fig. 15-8 shows many surgical positions and the use of protective padding. When general anesthesia is used, the surgical team positions the patient slowly to prevent hypotension from blood vessel dilation. Proper positioning is ensured by assessing for:

- Optimal exposure of the operative site and IV line
- Adequate access to the patient for the anesthesia provider
- Interference with circulation and breathing
- Anatomic alignment
- Protection of skeletal and neuromuscular structures
- Patient comfort, SAFETY, and dignity

Care is modified to reduce the potential injury from specific positions. For example, patients in

the lithotomy position may develop leg swelling, pain in the legs or back, reduced foot pulses, or reduced sensory perception from compression of the peroneal nerve. Following the nursing process addresses the key aspects of properly positioning a patient in the OR. Assess the patient risk factors before surgery; plan for the availability of personnel, equipment, and positioning devices based on patient specific need; implement the positioning plan once the patient is in the OR; and evaluate the final position before prepping and draping to ensure safe intraoperative care and minimize the risk of a positioning injury.

Before the incision occurs, during the procedure, and upon closing the surgical wound, surgical counts are done to acknowledge and verify that all surgical items (sponges, instruments, and sharps) are present and accounted for. Retained surgical items (RSIs) pose immediate and long-term risks for patients. RSIs can cause pain, infection, and the need for additional surgery to remove the item. Any discrepancies in the surgical counting process must be investigated and resolved before the patient leaves the OR. All team members must participate in resolving any count-related events.

## Preventing Infection

### Planning: Expected Outcomes.

The patient is expected to have an uninfected surgical wound or wounds. Indicators include:

- Aseptic technique is maintained throughout the surgical procedure.
- Wound edges are closed and not excessively red or swollen.
- Wound is free from purulent drainage.
- White blood cell counts remain at expected levels after surgery.
- Patient is afebrile.

### Interventions.

Surgical wound infections interfere with recovery, delay wound healing, contribute to rising health care costs, and are a source of nosocomial infections. The Centers for Disease Control and Prevention (CDC) defines surgical site infections as occurring 30 days after surgery ([CDC, 2016](#)).

**Aseptic technique must be strictly practiced by all OR personnel to ensure that the patient is free from infection, as required by The Joint Commission's NPSGs.**

Assess the risk for infection by identifying patients with health problems such as diabetes mellitus, reduced immunity, obesity, and kidney disease. Interventions that minimize risk for infection include performing prescribed skin preparation, protecting against cross-contamination, keeping traffic to a minimum, and administering prescribed antimicrobial prophylaxis. Surgery increases risk for wound complications such as infection, incisional dehiscence, and loss of body fluids. Sterile surgical technique and the use of protective drapes, skin closures, and dressings reduce complications and promote wound healing. When a wound is already infected or is at high risk for infection, antibiotics may be used directly in the wound before wound closure.

Skin and tissue closures include sutures, staples, special tape, and tissue adhesive (surgical “glue”). [Fig. 15-10](#) shows commonly used wound closures. They are used to:

**FIG. 15-10** Common skin closures.

- Hold wound edges in place until wound healing is complete
- Occlude blood vessels, preventing poor clotting and hemorrhage
- Prevent wound contamination and infection

Sutures are absorbable or nonabsorbable. *Absorbable sutures* dissolve over time by body enzymes. *Nonabsorbable sutures* become encapsulated in the tissue during the healing process and remain in the tissue unless they are removed. Body enzymes do not affect nonabsorbable sutures. Retention (stay) sutures (see Fig. 15-10) may be used in addition to standard sutures for patients at high risk for impaired wound healing (obese patients, patients with diabetes, and those taking steroids).

After the incision is closed, the surgeon may inject a local anesthetic or instill an antibiotic into the wound. A gauze or spray dressing may be applied to protect the incision from contamination. A variety of dressings are used to absorb drainage, protect the wound, and support the incision. A pressure dressing may be applied to prevent poor clotting and bleeding. One or more drains (see Chapter 16) may be inserted to remove secretions and fluids around the surgical area. These secretions, if not drained, slow healing and promote bacterial growth, which could result in wound infection.

At the end of the surgical procedure, the surgical team safely transfers the patient from the operating bed to a stretcher or bed. The circulating nurse and anesthesia provider go with the patient to the postanesthesia care unit (PACU) and communicate the hand-off report to the PACU nurse (see Chapter 16).

## Preventing Hypoventilation

### Planning: Expected Outcomes.

The patient is expected to be free of respiratory complications related to impaired GAS EXCHANGE and hypoventilation as indicated by:

- Maintenance of  $\text{SaO}_2$ ,  $\text{PaO}_2$ , and blood pH within normal limits
- Vital signs within normal limits
- Return to presurgical level of cognitive function

### Interventions.

The purpose of interventions is to prevent respiratory and circulatory complications resulting from the effect of anesthesia on breathing and GAS EXCHANGE. The nurse, surgeon, and anesthesia provider monitor the patient throughout the procedure according to evidence-based practice standards. These standards, adopted by both the American Society of Anesthesiologists and the

American Association of Nurse Anesthetists, include continuous monitoring of breathing, circulation, and cardiac rhythms; blood pressure and heart rate recordings every 5 minutes; and the constant presence of an anesthesia provider during the case.

◆ **Evaluation: Reflecting**

The nurse evaluates the care of the patient during surgery based on the identified priority patient problems. The expected outcomes include:

- Safe anesthesia care provided without complications
- Remains injury free related to surgical positioning or equipment (no skin tears, bruises, redness, or other injury over pressure points)
- Remains free of skin or tissue contamination and infection during surgery
- Maintains normal thermoregulation and body temperature

# Get Ready for the NCLEX<sup>®</sup> Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

Review preoperative checklist and informed consent forms, including any allergies.

- Highlight any known allergies. **QSEN: Safety**
- Ensure that all personnel entering the OR are wearing proper OR attire for their role.
- Observe for and inform OR personnel of any break in sterile field or sterile technique. **QSEN: Safety**
- Use appropriate patient identifiers when administering drugs or marking surgical sites. **QSEN: Safety**
- Report to the surgeon any discrepancy between the type and location of surgery the patient says is going to be performed and what the informed consent form indicates. **QSEN: Safety**
- Apply grounding pads as needed. **QSEN: Safety**
- Complete any needed skin preparation.
- Perform an accurate “sharps,” sponge, and instrument count with the scrub nurse or surgical technologist. **QSEN: Safety**
- Complete a “time-out” with the entire surgical team before incision. **QSEN: Safety**

### Psychosocial Integrity

- Communicate patient preferences or fears about anesthesia to the anesthesia provider. **QSEN: Patient-Centered Care**
- Respect the patient's privacy and dignity by minimizing body exposure. **Ethics**
- Stay with the patient during induction of anesthesia. **Ethics**
- Communicate information about the patient's status to waiting family members.
- Ensure that the patient's wishes, as expressed in the advance directives statement, are honored in the surgical setting. **Ethics**

### Physiological Integrity

- Apply padding to the OR bed to maintain the patient's skin integrity. **QSEN: Evidence-Based Practice**
- Position the patient comfortably and safely.
- Maintain awareness of signs and symptoms of malignant hyperthermia. **QSEN: Safety**
- Monitor the patient's airway, level of consciousness, oxygen saturation, ECG, and vital signs during and immediately after moderate sedation. **QSEN: Safety**
- Assess the patient for tachycardia, increased end-tidal carbon dioxide level, and increased body temperature as indicators of malignant hyperthermia. **QSEN: Safety**
- Assess all skin areas and document findings before transferring the patient to the postanesthesia care unit.
- Communicate clearly and accurately information about patient's surgical experience when handing off the patient to the postanesthesia care nurse. **QSEN: Teamwork and Collaboration**

## CHAPTER 16

# Care of Postoperative Patients

Rebecca M. Patton, Cynthia Danko

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- GAS EXCHANGE
- COMFORT
- SAFETY
- TISSUE INTEGRITY

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with the interprofessional team to coordinate high-quality care for patients in the postoperative period.
2. Ensure SAFETY by protecting patients from injury, infection, and complications of surgery during the postoperative period.

### Health Promotion and Maintenance

3. Provide postoperative education for patients and family members after surgery.
4. Coordinate with the interprofessional health care team to obtain postsurgical supplies and assistive devices.

### Psychosocial Integrity

5. Implement nursing interventions to minimize stressors for the patient and family regarding the postoperative experience.

### Physiological Integrity

6. Perform ongoing, complete assessments of the patient throughout the postoperative period.
7. Implement appropriate pain relief strategies to improve COMFORT for the postoperative patient.
8. Apply knowledge of anatomy, physiology, and pathophysiology to prevent patient harm such as shock, respiratory depression, and impaired wound healing.
9. Prioritize nursing interventions for the patient during the postoperative period.
0. Collaborate with members of the interprofessional health care team when performing emergency procedures for surgical wound dehiscence or wound evisceration.

Ongoing evaluation and stabilization of patients after surgery takes place in a **postanesthesia care unit (PACU)** or recovery room). Here nurses anticipate, prevent, and manage complications after surgery. The PACU, usually a large and open room that provides direct observation of all patients and easy access to supplies and emergency equipment, is usually located close to the surgical suite for ease of access and patient transfer. The patient area may be divided into individual cubicles, and privacy is managed using ceiling mounted curtains or floor screens that are fully closed during bedside procedures. Each cubicle has equipment to monitor and care for the patient such as oxygen, suction equipment, cardiac monitors, pulse oximetry, airway equipment, and emergency drugs.

## Overview

The **postoperative period** starts with completion of the surgical procedure and transfer of the patient to a specialized area for monitoring such as the PACU or an ICU. This period may extend beyond discharge from the hospital until activity restrictions have been lifted. The period of postanesthesia care is divided into three phases that are based on the level of care needed, not the physical place of care. Not every patient needs to transition through all three phases.

*Phase I* care occurs immediately after surgery, most often in a PACU. For patients who have very complicated procedures or many serious health problems, phase I care may occur in an ICU. The length of time the patient remains at a phase I level of care depends on his or her health status, the surgical procedure, anesthesia type, and rate of progression to regain alertness and hemodynamic stability. It can range from less than 1 hour to days. This level requires ongoing monitoring of the airway, vital signs, and evidence of recovery that varies from every 5 to 15 minutes initially. The time between assessments gradually increases as the patient progresses toward recovery.

*Phase II* care focuses on preparing the patient for care in an extended-care environment such as a medical-surgical unit, step-down unit, skilled nursing facility, or home. This phase can occur in a PACU, on a medical-surgical unit, or in the same-day surgery (SDS) unit (ambulatory care unit) and may last only 15 to 30 minutes, although 1 to 2 hours is more typical. Patients are discharged from this phase when presurgery level of consciousness has returned, oxygen saturation is at baseline, and vital signs are stable. Some patients achieve this level of recovery in phase I and can be discharged directly to home. Others may require further observation.

*Phase III* care, known as the *extended-care environment*, most often occurs on a hospital unit or in the home. For patients who have continuing care needs that cannot be met at home, discharge may be from the hospital unit to an extended-care facility. Although vital signs continue to be monitored in this type of environment, the frequency ranges from several times daily to just once daily.

Ambulatory surgery units provide same-day procedural care. Patients recover in a PACU environment that advances them quickly from a phase I to a phase III level, preparing them for discharge to home. Discharge criteria must be met before the patient is discharged from the facility. If the patient experiences ongoing issues related to unstable vital signs, poor GAS EXCHANGE, excessive nausea and vomiting, or unmanageable alterations in COMFORT, admission to an acute care setting or extended-care facility may be necessary.

The actual time spent away from home after surgery varies according to age, physical health, self-care ability, support systems, type and length of the surgical procedure, anesthesia, any complications, home environmental conditions, and community resources. Preoperative assessment determines factors that may have an impact in the recovery process. Communication and planning for management of identified issues to the interprofessional postoperative care team aids in minimizing complications after surgery (Malley et al., 2015).

After the surgery is completed, the circulating nurse and the anesthesia provider accompany the patient to the PACU. For patients in critical condition, transfer may be directly from the operating room (OR) to the ICU. On arrival the anesthesia provider and the circulating nurse give the PACU nurse a verbal “hand-off” report to communicate the patient’s condition and care needs.

**A hand-off report that meets the Joint Commission’s National Patient Safety Goals requires effective communication between health care professionals.** It is at least a two-way verbal interaction between the health care professional giving the report and the nurse receiving it. The language used to give the report is clear and concise in interpretation. The nurse receiving the report focuses on the report and is not distracted by the environment, other responsibilities, or other caregivers. Standardizing the information reported helps prevent omission of critical patient-centered information and helps avoid irrelevant details (AORN, 2016). The receiving nurse takes the time to restate (report back) the information to verify what was said and to make certain that he or she has the same understanding as the reporting person. The receiving nurse takes the time to ask questions, and the reporting professional must respond to the questions until a common understanding is established. [Chart 16-1](#) gives an example of critical information to include in a standard hand-off report.

### Chart 16-1

### Postoperative Hand-off Report

- Type and extent of the surgical procedure
- Type of anesthesia and length of time the patient was under anesthesia
- Allergies (especially to latex or drugs)
- Any health problems or pathophysiologic conditions
- Any relevant events/complications during anesthesia or surgery such as a traumatic intubation
- If intraoperative complications, how were they managed and patient responses (e.g., laboratory values, excessive blood loss, injuries)
- Status of vital signs, including temperature and oxygen saturation
- Intake and output, including current IV fluid administration and estimated blood loss
- Type and amount of IV fluids or blood products
- Medications administered and when last dose of pain medication given
- When the next dose of medications is due, especially antibiotics, cardiac drugs
- Primary language, any sensory impairments, any communication difficulties
- Special requests that were verbalized by the patient before surgery, including communications with family
- Preoperative and intraoperative respiratory function and dysfunction
- Location and type of incisions, dressings, catheters, tubes, drains, or packing
- Prosthetic devices
- Joint or limb immobility while in the operating room, especially in the older patient
- Other intraoperative positioning that may be relevant in the postoperative phase

The PACU nurse is skilled in the care of patients with multiple medical and surgical problems immediately after a surgical procedure. This area requires in-depth knowledge of anatomy and physiology, anesthetic agents, pharmacology, pain management, airway management, surgical procedures, and advanced cardiac life support (ACLS). The PACU nurse is skilled in assessment and can make knowledgeable, critical decisions if emergencies or complications occur. The patient is monitored continuously, and the anesthesia provider and surgeon are consulted as needed.

### ❖ Interprofessional Collaborative Care

#### ◆ Assessment: Noticing

#### History.

Using the surgical team's report, the nurse creates an individualized plan of care. After receiving the report and assessing the patient, the nurse reviews the preoperative assessment and the electronic health record for information about the patient's history, physical condition, and emotional status. If the patient remains as an inpatient, the surgical and anesthesia information is incorporated into the postoperative plan of care. [Table 16-1](#) identifies potential complications of

surgery.

### Physical Assessment/Signs and Symptoms.

Once the patient is assessed, the data are documented in the electronic health record or on a PACU flow chart record (Fig. 16-1). Assessment data include level of consciousness, temperature, pulse, respiration, oxygen saturation, and blood pressure. Examine the surgical area for bleeding. Monitor vital signs per facility policy, per surgeon orders, or as the patient's condition warrants. On discharge from the PACU, vital signs are measured as prescribed or as often as the patient's condition indicates.

## Nursing Safety Priority OSEN

### Action Alert

Respiratory assessment is the most critical assessment to perform after surgery for any patient who has undergone general anesthesia or moderate sedation or has received sedative or opioid drugs.

The health care team determines the patient's readiness for discharge from the PACU by the presence of a recovery score rating of 9 to 10 on the recovery scale (see Fig. 16-1) (see Chapter 15 for additional scoring algorithms). Other criteria for discharge (e.g., stable vital signs; normal body temperature; no overt bleeding; return of gag, cough, and swallow reflexes; the ability to take liquids; and adequate urine output) may be facility specific. After determining that all criteria have been met, the patient is discharged by the anesthesia provider to the hospital unit or to home. If an

anesthesia provider has not been involved, which may be the case with local anesthesia or moderate sedation, the surgeon or nurse discharges the patient once the discharge criteria have been met.

Assessment continues from the PACU to the intensive care or medical-surgical nursing unit. When the patient is discharged from the PACU to home, assessment and any needed nursing care are continued by home care nurses or by the patient or family members after home-going instructions are completed. When the patient is transferred to an inpatient unit, a comprehensive initial assessment is completed on arrival ([Chart 16-2](#)).

## **Chart 16-2**

### **Focused Assessment**

#### **The Patient on Arrival at the Medical-Surgical Unit After Discharge From the Postanesthesia Care Unit**

##### **Airway**

- Is it patent?
- Is the neck in proper alignment?

##### **Breathing**

- What is the quality and pattern of the breathing?
- What is the respiratory rate and depth?
- Is the patient using accessory muscles to breathe?
- Is the patient receiving oxygen? At which setting and method of delivery?
- What is the pulse oximetry reading?

##### **Cardiovascular Status**

- Are these values within the patient's baseline range?
- Are peripheral pulses palpable?
- What is the rate and rhythm of the heartbeat?
- Are these values significantly different from when the patient was in the postanesthesia care unit (PACU)?

##### **Mental Status**

- Is the patient awake, able to be aroused, oriented, and aware?
- Does the patient respond to verbal stimuli?

##### **Surgical Incision Site**

- How is it dressed?
- Review the amount of drainage on the dressing immediately.
- Is there any bleeding or drainage under the patient?
- Are any drains present?

- Are the drains set properly (e.g., compressed if they should be compressed, not kinked, patient not lying on them)?
- How much drainage is present in the drainage container?

### Temperature

- Is the value significantly different from baseline and when the patient was in the PACU?

### Intravenous Fluids

- Which type of solution is infusing and with which additives?
- How much solution was remaining on arrival?
- How much solution was infused in the transport time from PACU?
- At what rate is the infusion supposed to be set? Is it?

### Other Tubes

- Is there a nasogastric or intestinal tube?
- What is the color, consistency, and amount of drainage?
- Is suction applied to the tube if ordered? Is the suction setting correct?
- Is there a Foley catheter?
- Is the Foley draining properly?
- What is the color, clarity, and volume of urine output?

*During the postoperative period, all patients remain at risk for pneumonia, shock, cardiac arrest, respiratory arrest, clotting and venous thromboembolism (VTE), and GI bleeding. These serious complications can be prevented, or the consequences reduced with collaborative care. Nursing observations and interventions are part of critical rescue management for patient SAFETY and quality care.*

### Respiratory System.

When the patient is admitted to the PACU, immediately assess for a patent airway and adequate GAS EXCHANGE. Although some patients may be awake and able to speak, talking is not a reliable indicator of adequate GAS EXCHANGE. An artificial airway such as an endotracheal tube (ET), a nasal trumpet, or an oral airway may be in place. If the patient is receiving oxygen, document the type of delivery device and the concentration or liter flow of the oxygen. Continuously monitor pulse oximetry for oxygen saturation (SpO<sub>2</sub>). The SpO<sub>2</sub> should be above 95% (or at the patient's presurgery baseline).

## Nursing Safety Priority QSEN

### Critical Rescue

If you recognize that your patient's oxygen saturation drops below 95% (or below his or her presurgery baseline), immediately respond by notifying the surgeon or anesthesia provider. If the patient's condition continues to deteriorate or he or she becomes symptomatic, an emergency response is imperative.

Assess the rate, pattern, and depth of breathing to determine adequacy of GAS EXCHANGE. A respiratory rate of less than 10 breaths per minute may indicate anesthetic- or opioid analgesic-induced respiratory depression. Rapid, shallow respirations may signal shock, cardiac problems,

increased metabolic rate, or pain.

Auscultate over all lung fields to assess breath sounds. Also check symmetry of breath sounds and chest wall movement. For example, if the patient has an ET tube, it could move down into the right bronchus and prevent left lung expansion. In this case lung sounds on the left are absent or decreased, and only the right chest wall rises and falls with breathing.

Continue to inspect the chest wall for accessory muscle use, sternal retraction, and diaphragmatic breathing. These symptoms may indicate an excessive anesthetic effect, airway obstruction, or paralysis, which could result in hypoxia. Listen for snoring and **stridor** (a high-pitched crowing sound). Snoring and stridor occur with airway obstruction resulting from tracheal or laryngeal spasm or edema, mucus in the airway, or blockage of the airway from edema or tongue relaxation. When neuromuscular blocking agents are retained, the patient has muscle weakness, which could affect the diaphragm and impair GAS EXCHANGE. Indicators of muscle weakness include the inability to maintain a head lift, weak hand grasps, and an abdominal breathing pattern.

If the patient returns to an inpatient unit, an initial assessment is completed on arrival (see [Chart 16-2](#)), and he or she is then continually assessed for respiratory depression or hypoxemia. Listen to the lungs to check for effective expansion and abnormal breath sounds. Check the lungs at least every 4 hours during the first 24 hours after surgery and then every 8 hours or more often, as indicated. Older patients, smokers, and patients with a history of lung disease are at greater risk for respiratory complications after surgery and need more frequent assessment ([Ramly et al., 2015](#)). Obese patients are also at high risk for respiratory complications.

### Cardiovascular System.

*Vital signs* and heart sounds are assessed on admission to the PACU and then at least every 15 minutes until the patient's condition is stable. Automated blood pressure cuffs and cardiac monitoring assist in continuous assessment.

Assess vital signs after surgery for trends and compare them with those taken before surgery. Report blood pressure changes that are 25% higher or lower than values obtained before surgery (or a 15- to 20-point difference, systolic or diastolic) to the anesthesia provider or the surgeon. Decreased blood pressure, pulse pressure, and abnormal heart sounds indicate possible cardiac depression, fluid volume deficit, shock, hemorrhage, or the effects of drugs (see [Chapters 11](#) and [37](#)). Bradycardia could indicate an anesthesia effect or hypothermia. Older patients are at risk for hypothermia because of age-related changes in the hypothalamus (the temperature regulation center), low levels of body fat, or prolonged exposure to the cool environment of the OR suite ([Touhy & Jett, 2015](#)). An increased pulse rate could indicate hemorrhage, shock, or pain.

*Cardiac monitoring* is maintained until the patient is discharged from the PACU. For patients at risk for dysrhythmias, monitoring may continue either on telemetry units or on general medical-surgical units. In assessing the vital signs of a patient who is not being monitored continuously, compare the rate, rhythm, and quality of the apical pulse with the rate, rhythm, and quality of a peripheral pulse such as the radial pulse. A **pulse deficit** (a difference between the apical and peripheral pulses) could indicate a dysrhythmia.

*Peripheral vascular assessment* needs to be performed because anesthesia and positioning during surgery (e.g., the lithotomy position for genitourinary procedures) may impair the peripheral circulation and contribute to clotting and venous thromboembolism (VTE), especially deep vein thrombosis (DVT). Compare distal pulses on both feet for pulse quality, observe the color and temperature of extremities, evaluate sensation and motion, and determine the speed of capillary refill. Palpable pedal pulses indicate adequate circulation and perfusion of the legs.

Prophylactic interventions initiated before surgery for prevention of clot formations and VTE should be continued during the postoperative period as prescribed ([Piazza et al., 2015](#)). These interventions vary in type (e.g., drug therapy with anticoagulants or antiplatelet drugs, sequential compression devices, antiembolic stockings or elastic wraps, early ambulation), depending on the patient's specific risk factors. Any preventive strategies started before surgery are usually needed for at least the first 24 hours after surgery. It is important to daily reassess the patient's risk for clotting, VTE, and the effectiveness of all preventive strategies implemented. Assess the feet and legs for redness, pain, warmth, and swelling, which may occur with DVT. Foot and leg assessment may be performed once during a nursing shift or once daily, depending on the patient's risk for complications and the facility policy. (See [Chapters 14](#) and [36](#) for more information on prevention of inappropriate clotting and VTE.)

## Neurologic System.

*Cerebral functioning* and the level of consciousness or awareness must be assessed in *all* patients who have received general anesthesia (Table 16-2) or any type of sedation. Observe for lethargy, restlessness, or irritability and test coherence and orientation. Determine awareness by observing responses to calling the patient's name, touching the patient, and giving simple commands such as "Open your eyes" and "Take a deep breath." Eye opening in response to a command indicates wakefulness or arousability but not necessarily awareness. Assess the degree of orientation to person, place, and time by asking the conscious patient to answer questions such as, "What is your name?" (person), "Where are you?" (place), and "What day is it?" (time).

**TABLE 16-2**

### Immediate Postoperative Neurologic Assessment: Return to Preoperative Level

<b>Order of Return to Consciousness After General Anesthesia</b>
1. Muscular irritability
2. Restlessness and delirium
3. Recognition of pain
4. Ability to reason and control behavior
<b>Order of Return of Motor and Sensory Functioning After Local or Regional Anesthesia</b>
1. Sense of touch
2. Sense of pain
3. Sense of warmth
4. Sense of cold
5. Ability to move

## Clinical Judgment Challenge 16-1

### Safety QSEN

You are caring for a 57-year-old patient who came from the OR to the postanesthesia recovery unit 30 minutes ago after surgery for a hernia repair. He responds when you say his name, but he is mildly confused about where he is and why he is here. He continuously attempts to remove the oxygen cannula from his nose and says it itches, but allows you to gently replace it several times. Vital signs taken 15 minutes ago were BP 130/90, pulse 88, respirations 20. Vital signs now show BP 120/80, pulse 86, respirations 18.

1. Are any of the changes in vital signs a cause for concern? If so, which ones?
2. Should you be assessing for postsurgical bleeding? Why or why not? If so, where would you assess for this bleeding?
3. Should you remove oxygen from the patient? Why or why not?
4. Should you notify the surgeon or anesthesia provider? Why or why not?

## Considerations for Older Adults

### Patient-Centered Care QSEN

For an older adult a rapid return to his or her level of orientation before surgery may not be realistic. Preoperative drugs and anesthetics may delay the older patient's return of orientation. Inform family members that most episodes of postoperative confusion or delirium resolve within a day or two (Rajesh, 2015).

Compare the patient's baseline neurologic status (obtained before surgery) with the findings after surgery. Patients who had altered cerebral functioning before surgery because of another condition usually continue to have the same alteration after surgery. After the patient is alert (and all other criteria have been met), he or she is discharged from the PACU. On the medical-surgical nursing unit, assess the level of consciousness every 4 to 8 hours or as indicated by the patient's condition and facility policy.

*Motor and sensory function after general anesthesia* are altered and must be assessed. General

anesthesia depresses all voluntary motor function. Regional anesthesia alters the motor and sensory function of only part of the body. (See [Chapter 15](#) for more information on anesthesia.)

*Motor and sensory function after spinal and epidural anesthesia* are profoundly affected. Assess the level of sensation loss remaining by lightly pricking the patient's skin with a needle or pin and having the patient indicate when the sensation feels sharp rather than dull (just pressure). Evaluate motor function by asking the patient to move each extremity. The patient who had epidural or spinal anesthesia remains in the PACU until sensory function (feeling) and voluntary motor movement of the legs have returned (see [Table 16-2](#)). It is critical to assess the strength of each limb and compare the results on both sides. Test for the return of sympathetic nervous system tone by gradually elevating the patient's head and monitoring for hypotension. Begin this evaluation after the patient's sensation has returned to at least the spinal dermatome level of T10 (see [Chapter 41](#)).

Specific assessment findings for complications of spinal and epidural anesthesia are listed in [Chart 16-3](#). After the patient is transferred to the nursing unit, continue neurologic assessment as indicated.

### **Chart 16-3**

## **Best Practice for Patient Safety & Quality Care** QSEN

### **Recognizing Serious Complications of Spinal and Epidural Anesthesia**

#### **Respiratory Depression (Can Occur if the Anesthetic Agent Moves Higher in the Epidural or Subarachnoid Space)**

- What is the quality and pattern of the breathing?
- What is the respiratory rate and depth?
- Is the patient receiving oxygen? At which setting and method of delivery? What is the pulse oximetry result?
- Notify the anesthesia provider if pulse oximetry drops or if the patient is unable to increase the depth of respiration.

#### **Hypotension (Can Occur When Regional Anesthesia Causes Widespread Vasodilation)**

- What is the patient's blood pressure?
- Is the blood pressure now lower than in the preoperative or operative period?
- Has the pulse pressure widened?
- Notify the anesthesia provider if systolic blood pressure remains more than 10 mm Hg below the patient's baseline or if other manifestations of shock are present.
- Notify the anesthesia provider if hypotension is accompanied by other manifestations of autonomic nervous system blockade (bradycardia, nausea, vomiting).

#### **Epidural Hematoma**

- Assess for delayed or regressing return of sensory and motor function.
- If return is delayed or is taking longer than usual, alert the anesthesia provider.
- Determine whether sensory or motor deficits are improving, remaining the same, or worsening.
- If motor deficits are worsening or decreasing after brief improvement, notify the anesthesia provider immediately.

- Assess for return of deep tendon reflexes of extremities on both sides.
- Compare reflexes from one side of the body with the other.
- If reflexes regress, notify the anesthesia provider immediately.
- Assess pain level in the back.
- If the patient feels pressure or increasing back pain while coughing or straining, notify the anesthesia provider immediately.

### Infection (Meningitis)

- Assess for mental status changes.
- Assess for increasing temperature.
- Assess for ability to turn the neck.
- Notify the anesthesia provider immediately for temperature elevations above 101° F (38.3° C), inability to move the neck, acute confusion.

### Postdural Puncture Headache

- Assess for report of headache in the occipital region, especially when the patient is permitted to sit upright.

## NCLEX Examination Challenge 16-1

### Physiological Integrity

Which assessment is **most** important for the nurse to perform for the client admitted to the postanesthesia care unit (PACU) after surgery under general anesthesia?

- Determining the client's level of consciousness
- Checking for pain on dorsi and plantar flexion of the foot
- Assessing the response to pin-prick stimulation from feet to mid-chest level
- Comparing blood pressure taken in the right arm to blood pressure taken in the left arm

### Fluid, Electrolyte, and Acid-Base Balance.

NPO status before surgery, the loss of fluid during the procedure, and the type and amount of blood or fluid given affect the patient's fluid and electrolyte balance after surgery. Fluid volume deficit or fluid volume overload may occur after surgery. Sodium, potassium, chloride, and calcium imbalances may also result, as may changes in other electrolyte levels. Fluid and electrolyte imbalances occur more often in older or debilitated patients and in those with health problems such as diabetes mellitus, Crohn's disease, or heart failure.

*Intake and output* measurement is recorded in the operative record and is reported by the circulating nurse and anesthesia provider to the PACU nurse. Intake or output, including IV fluid intake, vomitus, urine, wound drainage, and nasogastric (NG) tube drainage are all recorded. The total intake and output from both the OR and the PACU must be accurate to assess fluid balance correctly within a 24-hour period.

*Hydration status* is assessed in the PACU and the medical-surgical unit. To determine hydration status, inspect the color and moisture of mucous membranes; the turgor, texture, and "tenting" of the skin (test over the sternum or forehead of an older patient); the amount of drainage on dressings; and the presence of axillary sweat. Measure and compare total output (e.g., NG tube drainage, urine output, wound drainage) with total intake to identify a possible fluid imbalance.

Consider insensible fluid loss such as sweat when reviewing total output. Continue to assess intake and output as long as the patient is at risk for fluid imbalances. All patients receiving IV fluids or those who have a catheter, drains, or an NG tube are on an intake and output monitoring protocol. In addition, patients who have heart disease or kidney disease are monitored closely for fluid and electrolyte imbalances.

*IV fluids* are closely monitored to promote fluid and electrolyte balance. Isotonic solutions such as lactated Ringer's (LR), 0.9% sodium chloride (normal saline), and 5% dextrose with lactated Ringer's (D<sub>5</sub>/LR) are used for IV fluid replacement in the PACU. After the patient returns to the medical-surgical unit, the type and rate of IV infusions are based on need.

*Acid-base balance* is affected by the patient's respiratory status; metabolic changes during surgery; and losses of acids or bases in drainage. For example, NG tube drainage or vomitus causes a loss of hydrochloric acid and leads to metabolic alkalosis. Monitor arterial blood gas (ABG) values and other laboratory values to identify potential consequences of an acid-base imbalance. (See [Chapter 12](#) for more detailed information on acid-base imbalances.)

### **Kidney/Urinary System.**

Control of urination may return immediately after surgery or may not return for hours after general or regional anesthesia. The effects of preoperative drugs (especially atropine), anesthetic agents, or manipulation during surgery can cause urine retention. Assess for urine retention by inspection, palpation, and percussion of the lower abdomen for bladder distention or by the use of a bladder scanner (see [Chapter 65](#)). Assessment may be difficult to perform after lower abdominal surgery. Urine retention or incontinence may occur early after surgery and requires intervention such as intermittent (straight) catheterization or an indwelling catheter to empty the bladder.

When the patient has an indwelling urinary (Foley) catheter, assess the urine for color, clarity, and amount. If the patient is voiding, assess the frequency, amount per void, and any symptoms. Urine output should be close to the total intake for a 24-hour period. Consider sweat, vomitus, or diarrhea stools as sources of fluid output. Report a urine output of less than 30 mL/hr (240 mL per 8-hour nursing shift) to the surgeon. Decreased urine output may indicate hypovolemia or renal complications. (See [Chapter 65](#) for kidney/urinary assessment.)

### **Gastrointestinal System.**

*Postoperative nausea and vomiting (PONV)* are among the most common reactions after surgery. Many patients who receive general anesthesia have some form of GI upset within the first 24 hours after surgery; however, some patients are more at risk than others ([Smith & Ruth-Sahd, 2016](#)). Patients with a history of motion sickness are more likely to develop nausea and vomiting after surgery. Obese patients may be at risk because many anesthetics are retained by fat cells and remain in the body longer. Abdominal surgery and the use of opioid analgesics reduce intestinal peristalsis after surgery. These problems increase the risk for prolonged nausea and vomiting after surgery. Preventive drug therapy, often started in the preoperative period, is effective in reducing the incidence. Drugs often used are a serotonin antagonist such as ondansetron (Zofran), a sedating H<sub>1</sub> histamine antagonist such as dimenhydrinate (Dramamine), and an anticholinergic agent such as scopolamine.

PONV can stress and irritate abdominal and GI wounds, increase intracranial pressure in patients who had head and neck surgery, elevate intraocular pressure in patients who had eye surgery, and increase the risk for aspiration. Assess the patient continuously for PONV. Often patients have nausea as the head of the bed is raised early after surgery. Help reduce this distressing symptom by having the patient in a side-lying position before raising the head slowly.

*Intestinal peristalsis* return may be delayed because of prolonged anesthesia time, the amount of bowel handling during surgery, and opioid analgesic use. In the PACU and later on the medical-surgical unit, assess for the return of peristalsis. *Patients who are recovering from abdominal surgery often have decreased or no peristalsis for at least 24 hours.* This problem may persist for several days for those who have GI surgery.

Listen for bowel sounds in all four abdominal quadrants and at the umbilicus. If NG suction is being used, turn off the suction before listening to prevent mistaking the sound of the suction for bowel sounds. *The presence of active bowel sounds usually indicates return of peristalsis; however, the absence of bowel sounds does not confirm a lack of peristalsis. The best indicator of intestinal activity is the passage of flatus or stool (Rothrock, 2014).* Abdominal cramping along with distention denotes

trapped, nonmoving gas—not peristalsis.

Decreased peristalsis occurs in patients who have a paralytic ileus. The abdominal wall is distended with no visible intestinal movement. Assess for signs and symptoms of paralytic ileus (distended abdomen, abdominal discomfort, vomiting, no passage of flatus or stool). In some patients bowel sounds can be heard even when a true paralytic ileus is present. The passage of flatus or stool is the best indicator of resolution of a paralytic ileus.

A nasogastric (NG) tube may be inserted during surgery to decompress and drain the stomach, promote GI rest, and allow the lower GI tract to heal. It may also be used to monitor any gastric bleeding and prevent intestinal obstruction. Usually low suction is applied to promote drainage. Suction is either continuous or intermittent.

Record the color, consistency, and amount of the NG drainage every 8 hours. In some instances an occult blood test (Gastrocult) may be performed. Normal NG drainage fluid is greenish yellow. Red or pink drainage fluid indicates active bleeding, and brown liquid or drainage with a “coffee-ground” appearance indicates old bleeding. The NG tube should be secured to prevent any chance of displacement.

Assess the patient for complications related to NG tube use such as fluid and electrolyte imbalances, aspiration, and nares discomfort. To prevent aspiration, check the tube placement every 4 to 8 hours and before instilling any liquid, including drugs, into the tube. (See [Chapter 55](#) for information on tube placement and care.) Electrolyte imbalances can result from NG drainage and tube irrigation with water instead of saline. Imbalances include fluid volume deficit, hypokalemia and hyponatremia (see [Chapter 11](#)), hypochloremia, and metabolic alkalosis (see [Chapter 12](#)).

## Nursing Safety Priority QSEN

### Action Alert

After gastric surgery do not move or irrigate the NG tube unless ordered.

*Constipation* may occur after surgery as a result of anesthesia, analgesia (especially opioids), decreased activity, and decreased oral intake. Assess the abdomen by inspection, auscultation, palpation, and percussion and record the elimination pattern to determine whether intervention is needed. *Auscultate before palpation or percussion because these two maneuvers are thought to affect peristalsis.* Increased dietary fiber intake, the use of mild laxatives or bulk-forming agents, or the use of enemas may be needed. Encourage ambulation as early as possible after surgery to promote peristalsis ([Economou, 2015](#)).

## NCLEX Examination Challenge 16-2

### Safe and Effective Care Environment

The PACU nurse caring for a client with a nasogastric (NG) tube notes that 300 mL of bright red blood has collected. What is the appropriate nursing action?

- A. Document as a normal finding.
- B. Immediately remove the NG tube.
- C. Place the client in Trendelenburg position.
- D. Call the client's surgeon to report the drainage.

### Skin Assessment.

The clean surgical wound regains **TISSUE INTEGRITY** (heals) at skin level in about 2 weeks in the absence of trauma, infection, connective tissue disease, malnutrition, or the use of some drugs such as steroids. Patients who are older, are obese, smoke, or have diabetes or whose immunity is reduced have delayed wound healing. Complete tissue integrity (healing) of all layers within the surgical wound may take 6 months to 2 years. The physical health and age of the patient, size and

location of the wound, and stress on the wound all affect healing time. Head and facial wounds heal more quickly than abdominal and leg wounds because there is less stress on these locations and better blood flow to the head and neck area.

### Normal Wound Healing.

During the first few days of normal wound healing, the incised tissue regains blood supply and begins to bind together. Fibrin and a thin layer of epithelial cells seal the incision. After 1 to 4 days, epithelial cells continue growing in the fibrin, and strands of collagen begin to fill in the wound gaps. *This process continues for 2 to 3 weeks. At that time TISSUE INTEGRITY appears regained; however, healing is not complete for up to 2 years, until the scar is strengthened.* (See [Chapters 24](#) and [25](#) for discussion of wound healing and wound infection.)

When the patient is an inpatient, the surgeon usually removes the original dressing on the first or second day after surgery. Assess the TISSUE INTEGRITY of the incision on a regular basis, at least every 8 hours, for redness, increased warmth, swelling, tenderness or COMFORT alterations, and the type and amount of drainage. Some drainage (e.g., changing from **sanguineous** (bloody) to serosanguineous to **serous** (serum-like, or yellow) is normal during the first few days. Serosanguineous drainage continuing beyond the fifth day after surgery or increasing in amount instead of decreasing is a sign of possible dehiscence (discussed in the next paragraph), and the surgeon should be notified. Crusting on the incision line is normal, as is a pink color to the line itself, which is caused by inflammation from the surgical procedure. Slight swelling under the sutures or staples is also normal. Redness or swelling of or around the incision line, excessive tenderness or pain on palpation, and purulent or odorous drainage indicate surgical site infection (SSI) and must be reported to the surgeon.

### Impaired Wound Healing.

Impaired healing and a breakdown of the surgical wound with loss of TISSUE INTEGRITY may be caused by infection, distention, stress at the surgical site, and other health problems (comorbidities) that cause delayed wound healing (e.g., diabetes, renal disease, immune deficiency). Wound **dehiscence** is a partial or complete separation of the outer wound layers, sometimes described as a *splitting open of the wound*. **Evisceration** is the total separation of all wound layers and protrusion of internal organs through the open wound ([Fig. 16-2](#)). *Evisceration is a surgical emergency; the surgeon is contacted immediately, and the patient returned to the OR.* Both dehiscence and evisceration occur most often between the fifth and tenth days after surgery. Wound separation occurs more often in obese patients and those with diabetes, immune deficiency, or malnutrition or in those who are using steroids. Dehiscence or evisceration may follow forceful coughing, vomiting, or straining and not splinting the surgical site during movement. The patient may state, “Something popped” or “I feel as if I just split open.”

**FIG. 16-2** Complications of surgical wound healing. (From Harkreader, H., Hogan, M. A., & Thobaben, M. (2007). *Fundamentals of nursing: Caring and clinical judgment*. (3rd ed.). Philadelphia: Saunders.)

## Dressings and Drains.

Assess all dressings, including casts and elastic (Ace) bandages, for bleeding or other drainage on admission to the PACU and then hourly thereafter. When the patient is on the nursing unit, assess the dressing each time vital signs are taken (at least every 8 hours). During dressing inspection check for drainage and record its amount, color, consistency, and odor. If drainage is present on a dressing or cast, monitor its progression by outlining it with a pencil and indicating the date and time. Large amounts of sanguineous drainage may indicate poor clotting and possible internal bleeding. Check the area underneath the patient also, because drainage or blood may leak from the side of the dressing and not appear on the dressing itself.

Dressings vary with the surgical procedure and the surgeon's preference. Common dressings for large incisions consist of gauze or nonadherent pads covered with a larger absorbent pad held in place by tape, a tubular stretchy net, or Montgomery straps (Fig. 16-3). Some incisions may be covered with a transparent plastic surgical dressing (e.g., OpSite) or a spray in the OR. This type of dressing stays intact for 3 to 6 days, allows direct observation of the wound, prevents contamination, and eliminates the need for dressing changes. Ensure that the dressing does not restrict circulation or sensation. This problem is most likely to occur when dressings are tight or completely encircle an arm or a leg. Chest dressings that are too tight or that encircle the chest can restrict breathing.

**FIG. 16-3** Patient with a dressing held in place with Montgomery straps. (From Harkreader, H., Hogan, M. A., & Thobaben, M. (2007). *Fundamentals of nursing: Caring and clinical judgment*. (3rd ed.). Philadelphia: Saunders.)

The surgeon inserts a drain into or close to the wound if more than a minimal amount of drainage is expected. A Penrose drain (a single-lumen, soft, open, latex tube) is a gravity-type drain under the dressing. Drainage on the dressing is expected with open-tube drains. Closed-suction drains such as Hemovac, VacuDrain, and Jackson-Pratt drains include a reservoir that collects drainage. Drainage on the dressing around the drain is not usually present. Assess closed drainage systems for maintenance of suction. Specialty drains such as a T-tube may be placed for specific drainage purposes. For example, a T-tube drains bile after a cholecystectomy. Chronic wounds or wounds that heal by delayed primary intention are typically drained with a negative-pressure wound device. Negative-pressure wound therapy has been shown to improve healing of closed surgical incisions and reduce SSI (Hudson et al., 2015). Fig. 16-4 shows commonly used drains.

**FIG. 16-4** Types of surgical drains. Gravity drains such as the Penrose (A) and the T-tube (B) drain directly through a tube from the surgical area. In closed-wound drainage systems such as the Jackson-Pratt (C) and Hemovac (D), drainage collects in a collecting vessel by means of compression and reexpansion of the system. (A from Sirois, M. (2011). *Principles and practice of veterinary technology*. (3rd ed.). St. Louis: Mosby; B courtesy 2014 C. R. Bard, Inc. Covington, GA. Used with permission; C and D courtesy C.R. Bard, Inc., Covington, GA.)

### Comfort Alterations/Pain Assessment.

The patient almost always has pain or alterations in COMFORT after surgery. Pain is a subjective experience and must be assessed based on individual conditions (see the [Evidence-Based Practice](#) box). Pain after surgery is related to the surgical wound, tissue manipulation, drains, positioning during surgery, presence of an ET, and the patient's experience with pain (Ward, 2014). Assess the patient's discomfort and need for medication by considering the type, extent, and length of the surgical procedure. Assess for physical and emotional signs of acute pain such as increased pulse and blood pressure, increased respiratory rate, profuse sweating, restlessness, confusion (in the older adult), wincing, moaning, and crying. When possible, ask the patient to rate the pain before and after drugs are given (e.g., on a scale of 0 to 10, with 0 being no pain and 10 being extreme pain). Plan the patient's activities around the timing of analgesia to improve mobility. Observe for a return of baseline physical and emotional behaviors. (See [Chapter 4](#) for further discussion of pain assessment.)

## Evidence-Based Practice OSEN

### Opium Usage in Older Adults

Clarke, H., et al. (2014). Rates and risk factors for prolonged opioid use after major surgery: Population based cohort study. *BMJ*, 348, g1251. doi: <http://dx.doi.org/10.1136/bmj.g1251>.

Acute pain management in the postoperative older adult can be challenging. Subjectivity in the pain experience, physiologic differences in patients, and ongoing pharmacodynamic changes associated with aging create critical clinical challenges when intervening to manage postoperative pain. Inadequate management can contribute to persistent postsurgical pain for the older adult who already has chronic pain from degenerative bone, joint, and spine diseases.

Over 200 million patients worldwide experience a major surgical procedure annually. Patients typically experience some level of pain that requires management with drugs, often opioids, which are the key analgesic drugs most commonly prescribed. It can be challenging to effectively treat postoperative pain while managing patient concerns about long-term opioid use, potential misuse, and addiction.

### Level of Evidence: 3

This population-based retrospective cohort study reviewed rates and associated risk factors of prolonged postoperative opioid use in older-adult patients who had never used opioids before surgery. Patients were older than 66 years and had major elective surgery, including cardiac, intrathoracic, intra-abdominal, and pelvic procedures in Ontario, Canada. Of the 39,140 patients included in the study, 49.2% (n=19,256) were discharged from hospital with an opioid prescription. After more than 90 postoperative days, 3.1% (n=1,229) continued to receive opioids. The analysis identified specific patient and surgical characteristics associated with prolonged opioid usage: of a lower income demographic, with specific comorbidities, use of specific preoperative drugs, having undergone a thoracic surgical procedure, and younger age (closer to 66).

### Commentary: Implications for Practice and Research:

The study findings validate that opioids can be used appropriately to treat postoperative pain. Nurses must recognize patient and surgical characteristics and conditions that increase the risk for prolonged opioid usage. Appropriate initial and ongoing pain assessments are important to identify which patients may require interventions to prevent progression to prolonged postoperative opioid use.

Pain assessment is continuous during PACU care. Pain remains poorly assessed in the older adult; and specific care should be taken to determine the level of pain in older patients, especially in patients who are cognitively impaired. Challenges in assessing pain in the older patient include poor communication (cognitive deficits), comorbidities, stoic character, and a reluctance to report alterations in COMFORT (Schofield, 2014). Drug dosages may need to be adjusted for the older patient to account for age-related changes (frailty, comorbidities, reduced physiological reserve (Schofield, 2014)). After the patient is transferred from the PACU, the medical-surgical nurse continues to assess his or her COMFORT level. Pain can increase after surgery, when the patient is more awake and more active and the anesthetic agents and drugs given during surgery have been excreted.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Pain remains poorly assessed in the older adult, and specific care should be taken to determine the level of pain in older patients, especially those who are cognitively impaired. Challenges in assessing pain in the older patient include poor communication (cognitive deficits), comorbidities, stoic character, and a reluctant to report pain (Schofield, 2014). Drug dosages may need to be adjusted for the older patient to account for age-related changes (e.g., frailty, comorbidities, reduced physiological reserve) (Schofield, 2014).

### Psychosocial Assessment.

Consider the psychological, social, cultural, and spiritual issues of the patient as postoperative care is provided. This assessment may be difficult to perform in the PACU when the patient is drowsy or confused and may be deferred until he or she is more alert. The patient's age and medical history; the surgical procedure; and the impact of surgery on recovery, body image, roles, and lifestyle are all considerations to take into account.

Indications of anxiety include restlessness; increased pulse, blood pressure, and respiratory rate;

and crying. The patient may be anxious and ask questions about the results or findings of the surgical procedure. Reassure the patient that he or she is safe and that the surgeon will speak with him or her after he or she is fully awake. If the surgeon has already spoken with the patient, reinforce what was said. Assess the family members as well for any psychosocial discomfort or need for additional support related to the patient's condition and postoperative care.

### **Laboratory Assessment.**

Laboratory tests are performed after surgery to evaluate the patient's recovery responses. Tests are based on the surgical procedure, the patient's medical history, and clinical signs and symptoms after surgery. Common tests include analysis of electrolytes and a complete blood count. Changes in electrolyte, hematocrit, and hemoglobin levels often occur during the first 24 to 48 hours after surgery because of blood and fluid loss and the body's reaction to the surgical process. Fluid loss with minimal blood loss may cause elevated laboratory values. Such test results appear increased but actually are concentrated normal values.

An indication of infection is an increase in the band cells (immature neutrophils) in the white blood cell differential count, known as a "left-shift" or "bandemia." The source of infection may be the respiratory system, urinary tract, surgical wound, or IV site. Obtain specimens for culture and sensitivity testing and review the culture reports at 24, 48, and 72 hours. Notify the surgeon of positive culture results. (See [Chapters 17](#) and [23](#) for information on infection.)

Arterial blood gas (ABG) tests may be needed for patients who have respiratory or cardiac disease, those undergoing mechanical ventilation after surgery, and those who had chest surgery. Review ABG results and notify the surgeon of any acid-base imbalance or hypoxemia that indicates poor GAS EXCHANGE. (For more discussion on arterial blood gases and acidosis, see [Chapter 12](#).)

Urine and kidney laboratory tests also may be obtained (e.g., urinalysis, urine electrolyte levels, and serum creatinine levels). Other laboratory tests depend on the diagnosis, type of surgical procedure, and other health problems. For example, a serum amylase level may be ordered for a patient who had pancreatic surgery, and a blood glucose level may be ordered for a patient with diabetes.

### **◆Analysis: Interpreting**

The priority collaborative problems for patients in the immediate postoperative period are:

1. Potential for decreased GAS EXCHANGE due to the effects of anesthesia, pain, opioid analgesics, and immobility
2. Potential for infection and delayed healing due to wound location, decreased mobility, drains and drainage, and tubes
3. Acute pain due to the surgical incision, positioning during surgery, and endotracheal tube (ET) irritation
4. Potential for decreased peristalsis due to surgical manipulation, opioid use, and fluid and electrolyte imbalances

### **◆Planning and Implementation: Responding**

#### **Improving Gas Exchange**

##### **Planning: Expected Outcomes.**

The patient is expected to attain and maintain optimal lung expansion and breathing patterns after surgery as indicated by:

- Partial pressure of arterial oxygen ( $P_{aO_2}$ ) within normal range
- Partial pressure of arterial carbon dioxide ( $P_{aCO_2}$ ) within normal range
- Oxygen saturation values within normal range

##### **Interventions**

### Airway Maintenance.

After assessing respiratory status, an airway may need to be inserted if the patient does not demonstrate adequate GAS EXCHANGE. An oral airway pulls the tongue forward and holds it down to prevent obstruction. If the patient had oral surgery or has clenched teeth, a large tongue, or upper airway obstruction, insert a nasal airway (nasal trumpet) to keep the airway open. A manual resuscitation bag and emergency equipment for intubation or tracheostomy should remain readily available in the PACU area. For patients whose only airway is a tracheostomy or laryngectomy stoma, alert other staff members by posting signs in the room and notes on the chart.

### Monitoring.

Monitor the patient's oxygen saturation (SpO<sub>2</sub>) for adequacy of GAS EXCHANGE with pulse oximetry with each set of vital signs or at least every hour, according to the patient's condition. Patients who normally have a low Pao<sub>2</sub> such as those with lung disease or older adults are at higher risk for hypoxemia. An older adult is often prescribed low-dose oxygen therapy for the first 12 to 24 hours after surgery to reduce confusion from anesthesia and sedation. Patients who received moderate sedation with a benzodiazepine such as midazolam (Versed) or lorazepam (Ativan, Nu-Loraz) may be overly sedated or have respiratory depression sufficient to need reversal with flumazenil (Romazicon) (Chart 16-4). Hypothermia after surgery causes shivering, which increases oxygen demand and can induce hypoxemia. Many rewarming methods can be used, although prevention is more important. The highest incidence of impaired GAS EXCHANGE after surgery occurs on the second postoperative day.

#### Chart 16-4

### Best Practice for Patient Safety & Quality Care QSEN

#### Emergency Care of the Patient Experiencing a Benzodiazepine Overdose

- Secure the airway and IV access before starting benzodiazepine antagonist therapy.
- Prepare to administer flumazenil\* (Romazicon) in a dose of 0.2 mg to 1 mg IV (recommended for IV only).
- Repeat drug every 2 to 3 minutes up to 3 mg, as needed, depending on the patient's response.
- Give oxygen if hypoxia is present or if respirations are below 10 breaths/min.
- Have suction equipment available because flumazenil can trigger vomiting and a drowsy patient is at risk for aspiration.
- Continuously monitor vital signs and level of consciousness for reversal of overdose.
- Do not leave the patient until he or she is fully responsive.
- Continue to monitor the patient's vital signs and level of consciousness every 10 to 15 minutes for the first 2 hours because flumazenil is eliminated from the body more quickly than is the benzodiazepine.
- Determine the need for additional flumazenil therapy 1 to 2 hours after the patient initially becomes fully responsive.
- Observe the patient for tremors or convulsions because flumazenil can lower the seizure threshold in patients who have seizure disorders.
- Assess the IV site every shift because flumazenil can cause thrombophlebitis at the injection site.
- Observe the patient for side effects of flumazenil, including skin rash, hot flushes, dizziness, headache, sweating, dry mouth, and blurred vision. The incidence of these side effects increases

with higher total doses of flumazenil.

\*There are other benzodiazepine antagonists; however, flumazenil is used most often to manage adult complete or partial reversal of the sedative effects of benzodiazepine in cases in which general anesthesia was induced and or maintained with benzodiazepines, sedation was produced with benzodiazepines for diagnostic procedures, or in management of benzodiazepine overdose.

### Positioning.

*In the PACU immediately position the patient in a semi-Fowler's position unless contraindicated. If the patient cannot have the head of the bed raised, either place him or her in a side-lying position or turn the head to the side to prevent aspiration.*

### Oxygen Therapy.

Impaired GAS EXCHANGE is prevented and managed with oxygen therapy. Apply oxygen by face tent, nasal cannula, or mask to eliminate inhaled anesthetic agents, increase oxygen levels, raise the level of consciousness, and reduce confusion. After the patient is fully reactive and stable, raise the head of the bed to support respiratory function.

For some patients oxygen therapy may continue through the second day after surgery. When hypoxemia occurs despite preventive care, interventions such as respiratory treatments and mechanical ventilation may be used to manage the cause of the hypoxemia.

### Breathing Exercises.

After the patient regains the gag and cough reflexes and meets criteria for extubation (if intubated), remove the airway or ET tube. Usual extubation criteria include the ability to raise and hold the head up and evidence of thoracic breathing. Help the patient splint the incision, cough, and deep breathe to promote GAS EXCHANGE and eliminate anesthetic agents. [Chart 14-4](#) in [Chapter 14](#) reviews breathing exercises and splinting of the surgical area. As soon as the patient is awake enough to follow commands, urge coughing, using the incentive spirometer, and breathing deeply hourly while awake throughout the postoperative period. The patient who is unable to remove mucus or sputum requires oral or nasal suctioning. Perform mouth care after removing secretions.

### Movement.

Assist the patient out of bed and to ambulate as soon as possible to help remove secretions and promote ventilation. Even when the patient has had extensive surgery, the expectation may be to get out of bed the day of or the first day after surgery. If this is not possible, help him or her turn at least every 2 hours (side to side) and ensure that breathing exercises and leg exercises are performed (see [Charts 14-4](#) and [14-5](#) in [Chapter 14](#)). Early ambulation reduces the risk for pulmonary complications, especially after abdominal, pelvic, or spinal surgery. It increases circulation to extremities and reduces the risk for clotting and venous thromboembolism (VTE), especially deep vein thrombosis (DVT). The patient may resist getting up, but you must stress the importance of activity to prevent complications. When indicated, offer the patient pain medication 30 to 45 minutes in advance of scheduled activities to allow for maximum effect of the analgesic agent.

## Preventing Wound Infection and Delayed Healing

### Planning: Expected Outcomes.

The patient is expected to have incision healing without wound complications as indicated by:

- Wound edges remaining together
- No purulent drainage, induration, or redness in, from, or around the incision

### Interventions.

Nursing assessment of the surgical area is critical (see the [Skin Assessment](#) section). Although most wound complications do not require additional surgical intervention, emergency surgical procedures may be needed.

### Nonsurgical Management.

Wound care includes reinforcing the dressing, changing the dressing, and assessing the wound for healing and infection; caring for drains, including emptying drainage containers/reservoirs; measuring drainage; and documenting drainage features. Emphasize the importance of early deep-breathing exercises to prevent forceful coughing. Urge the patient to bend the hips when in the supine position to reduce tension on a chest or abdominal wound. Remind him or her to always splint the chest or abdominal incision when coughing. Promote wound healing and protection of the skin, especially for the older patient. [Chart 16-5](#) lists best practices for skin care of the older patient after surgery.

#### Chart 16-5

### Nursing Focus on the Older Adult

#### Best Practice in Postoperative Skin Care

Improve perfusion to the wound to promote wound healing:

- Keep the patient adequately hydrated to maintain cardiac output.
- Keep the airway patent and provide adequate oxygenation.
- Keep the patient's oxygen saturation on pulse oximetry at greater than 93%.
- Use strict aseptic technique (e.g., IV or other catheters, indwelling urethral catheter, wound).
- Promote adequate sleep and rest periods throughout the day.
- If necessary, administer drugs to combat pain and sleeplessness.
- Provide rest periods throughout the day.
- Control the patient's room temperature.
- Place the patient on a safety program to prevent falls if indicated.
- Maintain the patient's psychosocial health.
- Maintain personal hygiene.
- Protect fragile skin.
- Minimize the use of tape on the skin.
- Use hypoallergenic tape or Montgomery straps.
- Change dressings as soon as they become wet.
- Lift the patient during transfer or repositioning.

#### Dressings.

The surgeon usually performs the first dressing change to assess the wound, remove any packing, and advance (pull partially out) or remove drains. Before the first dressing change, reinforce the dressing (add more dressing material to the existing dressing) if it becomes wet from drainage. Document the added material and the color, type, amount, and odor of drainage fluid and time of observation. Assess the surgical site at least every shift and report any unexpected findings to the surgeon.

After removal of the dressing, the surgeon may leave the suture or staple line open to the air, which allows easy assessment of the wound and early detection of poor wound edge adherence,

drainage, swelling, or redness. Some surgeons believe that air-drying promotes healing. However, a draining wound is always covered with a dressing.

Dressing changes are prescribed by the surgeon; however, the facility or unit may have standards or policies that dictate specific protocols for dressing changes and incision care. An unchanged wet or damp dressing is a source of infection. Change dressings using aseptic technique until the sutures or staples are removed.

Dressings vary with the surgical procedure and the surgeon's preference. Common dressings for large incisions consist of gauze or nonadherent pads covered with a larger absorbent pad held in place by tape, a tubular stretchy net, or Montgomery straps (see Fig. 16-3). Some incisions may be covered with a transparent plastic surgical dressing (e.g., OpSite) or a spray in the OR. This type of dressing stays intact for 3 to 6 days, allows direct observation of the wound, prevents contamination, and eliminates the need for dressing changes.

Wound or suture line care consists of changing gauze dressings at least once during a nursing shift or daily and may include cleaning the area with sterile saline or another prescribed solution. Some suture lines are left open to air without any dressing to cover the incision. The hospital policy, the unit's standards, and the surgeon's preference determine which solution, if any, is used to clean the wound and how often dressings are changed. For large dressing changes or drain removal, offer the patient a prescribed analgesic before the procedure. Always assess the skin for redness, rash, or blisters in areas where tape has been used. Tape can cause a skin reaction after surgery even among patients who are not known to be tape sensitive.

Skin sutures or staples are usually removed 5 to 10 days after surgery, although this varies up to 30 days, depending on the type of surgery and the patient's health. After sutures or staples are removed, the incision may then be secured with Steri-Strips, which stay in place until they fall off on their own. The surgeon or the nurse removes the sutures or staples, depending on agency policy. Clean the incision with the prescribed solution before removing sutures or staples. Before removing sutures examine the condition and healing stage of the wound. First remove every other suture or staple and re-assess the wound for integrity. If wound healing is progressing normally, the rest of the sutures or staples may then be removed. If the wound does not appear to be healing well or if any signs or symptoms of infection are present, notify the surgeon before removing any sutures.

### Drains.

Drains (see Fig. 16-4) may be placed in the wound or through a separate small incision (known as a *stab* wound) close to the incision during surgery. Drains provide an exit route for air, blood, and bile. Drains also help prevent deep infection and abscess formation during healing.

The Penrose drain is placed into the external aspect of the incision and drains directly onto the dressing and skin around the incision. Change a damp or soiled dressing and carefully clean under and around the Penrose drain. Then place absorbent pads under and around the exposed drain to prevent skin irritation, wound contamination, and infection. Whether sutured in place or not, the drain can be dislodged or pulled out accidentally during a dressing change. It is also possible for the drain to slip back through the wound into the patient. Usually this complication is prevented when the drain is first placed in the OR. The surgeon pins a sterile safety pin through the drain at an angle perpendicular to the drain and the wound, which prevents the drain from slipping. As the wound heals, the surgeon or nurse shortens (advances) the drain by pulling it out a short distance and trimming off the excess external part so only 2 to 3 inches of drain protrudes through the incision. The safety pin must be repositioned each time the drain is advanced. The drain remains in place until drainage stops.

Jackson-Pratt and Hemovac drains are two self-contained drainage systems that drain wounds directly through a tube via gravity and vacuum. These drains are sutured in place with a suture that seals the area when the drain is removed. Use sterile technique to empty the reservoir. Record the amount and color of drainage during every nursing shift or more often if prescribed. After emptying and compressing the reservoir to restore suction, secure the drain to the patient's gown (never to the sheet or mattress) to prevent pulling and stress on the surgical wound.

### Drug Therapy.

Wound infection is a major complication after surgery. It usually results from contamination during surgery, preoperative infection, debilitation, or immunosuppression. In accordance with the Surgical Care Improvement Project (SCIP) core measures for prevention of surgical site infection, a

patient at risk for wound infection may have received antibiotic therapy with drugs that are effective against organisms common to the specific surgical site both before and during surgery. The need for these antibiotics is re-evaluated at 24 hours after surgery. If signs or symptoms of infection are not present, the antibiotic is discontinued at that time (SCIP Infection-3, see [Table 14-1](#)). If signs or symptoms of wound infection are present, they are documented to justify continuation of antibiotic therapy.

Wounds that become infected and open are treated with dressing changes and systemic antibiotic therapy. Depending on the surgeon's prescription, irrigate the wound (e.g., with sterile saline, hydrogen peroxide, povidone-iodine, or acetic acid), loosely pack it with solution-soaked gauze (e.g., neomycin, gentamicin, iodoform, povidone-iodine, saline, or acetic acid), and cover it with dry, sterile dressings. These wet-to-damp dressing changes, done two to three times daily, promote healing from within the wound and débridement (removal of the infected or dead tissue) as the wound heals. Negative-pressure wound-care systems, such as Wound VAC may be prescribed to help close the wound. [Chapter 25](#) discusses these systems.

### **Surgical Management.**

Poorly healing, infected, or complicated wounds may require surgical intervention.

### **Management of Dehiscence.**

*If dehiscence (wound opening) occurs, apply a sterile nonadherent (e.g., Telfa) or saline dressing to the wound and notify the surgeon.* Instruct the patient to bend the knees and avoid coughing. A wound that becomes infected dehisces by itself, or it may be opened by the surgeon through an incision and drainage (I&D) procedure. In either case the wound is left open and is treated as described previously.

### **Management of Evisceration.**

An **evisceration** (a wound opening with protrusion of internal organs) is a surgical emergency. [Chart 16-6](#) lists best practices for emergency care of the patient with surgical wound evisceration. Provide support by explaining what happened and reassuring the patient that the emergency will be handled competently.

## **Chart 16-6**

### **Best Practice for Patient Safety & Quality Care** QSEN

#### **Emergency Care of the Patient With Surgical Wound Evisceration**

1. Contact surgeon immediately or Rapid Response Team to bring any needed supplies into the patient's room.
2. Provide reassurance and support to ease the patient's anxiety. If possible, stay with the patient and instruct him or her to remain in bed.
3. Using sterile technique, unfold a sterile towel to create a sterile field.
4. Open an irrigation set and place the basin and syringe on the sterile field.
5. Open several large abdominal dressings and place them on the sterile field.
6. Put on the sterile gloves and place one or two of the large abdominal dressings into the basin to saturate them with warm saline solution.
7. Place the moistened dressings over the exposed viscera. Then place a sterile, waterproof drape over the dressings to prevent the sheets from getting wet.
8. If saline is not immediately available, cover the wound with gauze and moisten with sterile saline when available.

9. Do not attempt to reinsert the protruding organ or viscera.
- . Assess for manifestations of shock and document vital signs.
  - . Place the patient in a supine position with the hips and knees bent.
  - . Raise the head of the bed 15 to 20 degrees.
  - . Continue assessing the patient, including vital signs assessment every 5 to 10 minutes until the surgeon arrives.
  - . Keep dressings continuously moist by adding warmed sterile saline to the dressing as often as necessary. Do not let the dressing become dry.
  - . When the surgeon arrives, report finding and interventions.
  - . Document the incident, the activity in which the patient was engaged at the time of the incident, assessment, and interventions taken.
  - . If necessary, prepare the patient for emergency surgery; start an IV infusion as ordered.
  - . Don't allow the patient to have anything by mouth to decrease the risk of aspiration if surgery is planned.

**Special Consideration:** Best treatment is prevention. If a postoperative patient is at risk for poor healing, encourage adequate supply of protein, vitamins, and calories. Monitor dietary intake, identify deficiencies, and discuss with the surgeon and the dietitian.

## Nursing Safety Priority QSEN

### Critical Rescue

Monitor surgical incisions at least every 8 hours to recognize an impending evisceration. When a surgical wound evisceration occurs, respond by attending to the patient while another nurse immediately notifies the surgeon.

The surgeon may prescribe a nasogastric (NG) tube to decompress the stomach and relieve internal pressure or to remove the stomach's contents if the patient has been eating and general anesthesia is needed. Prepare the patient for surgery (see [Chapter 14](#)) to close the wound. Regional or local anesthesia may be used, depending on the location and type of wound. Nausea and vomiting, which stress the already fragile incision, are reduced when regional or local anesthesia is used. To increase the incision's integrity, stay or retention sutures of wire or nylon are used along with standard sutures or staples (see [Fig. 15-10](#)).

### Prevention.

Patients also are at risk for developing pressure injuries from positioning during surgery, contact with damp surgical linens, and unpadded surfaces. Pressure injuries acquired during the surgical

period prolong stays and increase the risk for complications. Early intervention of pressure injuries can prevent progression and complications.

Examine the patient's skin for areas of redness or open areas. Document and report any abnormalities. Use padding and positioning to relieve pressure. Treat any open areas according to facility guidelines and the surgeon's prescription. Ensure that information about the patient's skin condition in the PACU is communicated to the medical-surgical nurse. For patients at high risk, collaborate with a certified Wound, Ostomy, and Continence Registered Nurse (WOCRN) to plan preventive or interventional skin care.

## Managing Pain

### Planning: Expected Outcomes.

The postoperative patient is expected to attain or maintain optimal COMFORT levels. Indicators include:

- Patient report that pain is controlled
- Absence of physiologic indicators of acute pain (increased heart rate and blood pressure)
- Absence of behavioral indicators of pain (e.g., facial grimacing, teeth clenching, guarding, rubbing the painful area)
- Willingness to ambulate and participate in self-care

### Interventions.

Pain management after surgery includes drug therapy and other methods of management such as positioning, massage, relaxation techniques, and diversion. Often the patient has better pain relief from a combination of approaches. Assess the patient's comfort level and the effectiveness of the therapies. See [Chapter 4](#) for discussion of pain assessment and management. The patient who has optimal pain control is better able to cooperate with the therapies and exercises to prevent complications and promote rehabilitation.

### Drug Therapy.

*The use of opioids or other analgesics for pain management may mask or increase the severity of symptoms of an anesthesia reaction. Therefore give these drugs with caution, especially in the PACU when the patient's condition is not stable.* In the PACU pain drugs are usually given IV in small doses. After receiving any drug for pain, the patient remains in the PACU for a defined period (often 45 to 60 minutes). Assess for hypotension, respiratory depression, and other side effects. Within 5 to 10 minutes after an IV pain drug is given, assess the effectiveness of the drug (i.e., on a rating scale) in relieving pain and document the patient's response.

Opioid analgesics are given during the first 24 to 48 hours after surgery to control acute pain. Around-the-clock scheduling or the use of patient-controlled analgesia (PCA) systems is more effective and allows consistent blood levels more than does “on demand” scheduling. Common drugs include morphine (Statex ) , hydromorphone (Dilaudid; Hydromorph Contin ; Journista ), ketorolac (Toradol), codeine, butorphanol (Stadol), and oxycodone with aspirin (Percodan) or oxycodone with acetaminophen (Percocet).

## Nursing Safety Priority QSEN

### Drug Alert

The usual dosage for hydromorphone is much smaller (about one-fifth to one-tenth) that of morphine.

Assess the type, location, and intensity of the pain before and after giving pain medication. Monitor the patient's vital signs for hypotension and hypoventilation after giving opioid drugs. [Chart 16-7](#) lists more information about analgesics used after surgery.

### Chart 16-7

## Common Examples of Drug Therapy

### Management of Postoperative Pain

DRUG	NURSING IMPLICATIONS
Opioids	
Morphine sulfate (Epimorph, Stalex), and Hydromorphone hydrochloride (Dilaudid)	Monitor respiratory rate and blood pressure because respiratory depression can be severe and require medical intervention. Monitor GI motility and urine output because constipation and urinary retention can occur.
Codeine sulfate, codeine phosphate (Paveral)	Monitor respiratory status because respiratory depression can occur. Monitor GI motility because constipation when taking this drug is common and interventions may be indicated.
Butorphanol tartrate (Stadol)	Monitor neurologic status and for changes in level of consciousness because this medication can cause increased intracranial pressure. Monitor for respiratory depression.
Oxycodone hydrochloride and aspirin (Percodan, Endodan, Oxycodan)	Monitor for GI tolerance and function because the aspirin component of this drug can irritate the stomach. Constipation and GI bleeding can occur. Monitor coagulation studies (PT, aPTT) because the aspirin component of this drug may influence bleeding times and other coagulation study results.
Oxycodone hydrochloride and acetaminophen (Percocet, Endocet, Oxycocet)	Monitor blood pressure and respiratory status because hypotension and respiratory depression can occur. Monitor GI motility because constipation when taking this drug is common and interventions may be indicated.
NSAIDs	
Ketorolac tromethamine (Toradol)	Monitor for GI tolerance. GI bleeding, ulceration, and perforation can occur while taking this drug. Monitor for kidney effects, especially in older adult, because decreased urine output, increased serum creatinine, hematuria, and proteinuria can occur.
Ibuprofen (Motrin, Amersol, Novoprofen)	Monitor upper GI tolerance of medication; this drug can be given with food or milk to decrease irritation of the stomach. Monitor coagulation studies (PT, aPTT) and assess for signs of bleeding or delayed clotting so early detection can lead to avoidance of complications.

*aPTT*, Activated partial thromboplastin time; *PT*, prothrombin time.

Patient-controlled analgesia (PCA) by IV infusion or internal pump (the catheter is sutured into or near the surgical area) and epidural analgesia are often used for better pain control. In PCA the patient adjusts the dosage of the analgesic based on the pain level and response to the drug. This method allows more consistent pain relief and more control by the patient. The maximum dose per hour is “locked in” to the pump so the patient cannot accidentally overdose. Common drugs used in PCA include morphine and hydromorphone.

## Considerations for Older Adults

### Patient-Centered Care QSEN

Special care is needed when using PCA with older adults to prevent undertreating pain. Assess the patient's level of understanding of the delivery system and his or her comfort with the self-medication process. Reassure the patient that the system prevents accidental overdose.

Epidural analgesia can be given intermittently by the anesthesia provider or by continuous infusion through an epidural catheter left in place after epidural anesthesia. Common drugs given by epidural catheter include the opioids fentanyl (Sublimaze), preservative-free morphine (Duramorph), and bupivacaine (Marcaine).

Take care not to overmedicate or undermedicate, especially with older patients. In assessing for overmedication, monitor vital signs, especially blood pressure and respiratory rate, and level of consciousness. Complications from the use of opioid analgesics include respiratory depression, hypotension, nausea, vomiting, and constipation. An opioid antagonist such as naloxone (Narcan) may be needed to reverse the acute effects of opioid depression. Because of the short effect of the opioid antagonist, monitor the patient's blood pressure and respirations every 15 to 30 minutes until the full effect of the opioid analgesic has passed. More doses of the antagonist may need to be given during this time because it is eliminated from the body more quickly than is the opioid. (See [Chart 16-8](#) for more information on using opioid antagonists to reverse opioid overdose.) In addition, the patient may experience breakthrough pain after the opioid antagonist is given; therefore other interventions to achieve COMFORT are needed.

### Chart 16-8

## Best Practice for Patient Safety & Quality Care QSEN

### Emergency Care of the Patient Experiencing an Opioid Overdose

- Prepare to administer naloxone hydrochloride (Narcan)\* in an initial dose of 0.4 mg-2 mg IV.
- If the desired degree of improvement in respiratory functions is not obtained, it may be repeated at 2- to 3-minute intervals up to 10 mg as needed, depending on the patient's response.
- Naloxone may be administered IV, IM, subcutaneously or intranasal spray. IV is most rapid onset and is recommended in emergency situations.
- Maintain an open airway.
- Give oxygen if hypoxia is present or if respirations are below 10 breaths/min.
- Have suction equipment available because naloxone can trigger vomiting and a drowsy patient is at risk for aspiration.
- Continuously monitor vital signs and level of consciousness for opioid reversal every 10-15 minutes for the first hour. Naloxone is eliminated from the body more quickly than is the opioid; and it may induce side effects, including blood pressure changes, tachycardia, and dysrhythmias.
- Do not leave the patient until he or she is fully responsive.
- Assess the patient for pain because reversal of the opioid also reverses the analgesic effects.
- Determine the need for additional antagonist therapy 1 hour after the patient initially becomes fully responsive.

\*There are other opioid antagonists; however, naloxone hydrochloride is most often indicated for complete or partial reversal of opioid depression induced by natural and synthetic opioids. It is also indicated for suspected or known adult and opioid overdose in the postoperative period.

Assess for undermedication by asking the patient about degree of pain relief and observing for nonverbal cues of discomfort (e.g., restlessness, increased confusion, "picking" at bedcovers). Offer prescribed drug(s) after checking for hypotension and respiratory depression.

As recovery progresses, reduce the doses and frequency of drugs for pain control. Drugs are changed from injectable or PCA to oral as soon as the patient can tolerate oral agents. Nonopioid analgesics such as acetaminophen (Tylenol, Atasol ♣) and NSAIDs such as ibuprofen (Motrin, Novo-Profen ♣) and ketorolac (Toradol) are used alone or with an opioid analgesic. Antianxiety drugs may be given with an opioid analgesic to decrease pain-related anxiety, reduce muscle tension, and control nausea.

## Nursing Safety Priority QSEN

### Drug Alert

Do not confuse Toradol (an NSAID used for short-term, acute-to-moderate pain) with Tramadol (an opioid drug used for central analgesia).

### Complementary and Integrative Health.

Other COMFORT measures that may lower the amount of pain drugs needed are provided in conjunction with drug therapy for pain control. Measures such as positioning, massage, relaxation, and diversion reduce anxiety and allow the patient to relax and rest.

In positioning the patient, consider the position during surgery, the location of the surgical incision and drains, and problems such as arthritis and chronic lung disease. Assist the patient to a position of comfort. Support the extremities with pillows. Turn or help the patient turn at least every 2 hours while he or she is bedridden to prevent complications of immobility.

## Nursing Safety Priority QSEN

### Action Alert

Unless pillow support is ordered, do not place pillows under the knees and do not raise the knee gatch because this position could restrict circulation and increase the risk for venous thromboembolism.

Based on orders for ambulation and assessment of the patient's tolerance, encourage the patient to increase activity progressively to prevent complications. When the patient first gets out of bed, assistance will be required to move him or her to the side of the bed and into a chair. Teach the patient to splint the surgical wound for support and comfort during the transfer.

Use gentle massage on stiff joints or a sore back to decrease discomfort. Assist the patient to a side-lying position and apply lotion with smooth, gentle strokes to increase blood flow to the area and promote relaxation. *Do not massage the calves because of the risk for loosening a clot and causing a life-threatening pulmonary embolus.*

Relaxation and diversion are also used to control acute episodes of pain during dressing changes and injections. (See [Chapter 4](#) for how to instruct and guide the patient through these pain control methods.) Music and noise reduction may help decrease awareness of discomfort. [Chart 16-9](#) lists other interventions that may help reduce pain and promote comfort.

### Chart 16-9

## Best Practice for Patient Safety & Quality Care QSEN

### Nonpharmacologic Interventions to Reduce Postoperative Pain and Promote Comfort

- Find a general position of comfort for the patient.
- Use ice to reduce and prevent swelling as indicated.
- Cushion and elevate painful areas; avoid tension or pressure on these areas.
- Control or remove noxious stimuli.
- Provide adequate rest to increase pain tolerance.
- Encourage the patient's participation in diversional activities.
- Instruct the patient in relaxation techniques; use audio recordings or CDs and breathing exercises.
- Provide opportunities for meditation.
- Help the patient stimulate sensory nerve endings near the painful areas to inhibit ascending pain impulses.
- Help the patient stimulate the area contralateral (opposite) to the painful area.

### Promoting Peristalsis.

Decreased intestinal peristalsis with the possible development of a postoperative ileus (POI) can occur as a result of drug therapy, anesthesia/analgesia, operative manipulation, and increased sympathetic nervous system excitation from stress after any surgery but is most common after open abdominal procedures. Thus all postoperative patients are at some risk for POI. This complication is unpleasant for the patient, increases lengths of stay ([Katrancha et al., 2014](#)), and can lead to other avoidable complications such as wound dehiscence, nausea, vomiting, and deconditioning.

### Planning: Expected Outcomes.

The patient is expected to have return of intestinal peristalsis after surgery as indicated by:

- Presence of active bowel sounds in all four abdominal quadrants
- Passage of flatus and/or stool
- No abdominal distention or rigidity

### Interventions.

Nursing intervention to promote peristalsis include monitoring, ensuring adequate hydration, promotion of mobility, managing pain with nonopioid interventions, and when appropriate, pharmacologic management.

*Monitoring* with accurate assessment of the abdomen is key to determining recovery of intestinal peristalsis and recognizing possible POI early. Assess the abdomen for the presence and quality of bowel sounds, degree of distention, and firmness whenever vital signs are taken. First observe for distention and document whether this has increased or decreased since the last observation. Auscultate for bowel sounds in all four abdominal quadrants for up to 1 minute in each quadrant. Gently palpate the abdomen to determine degree of softness or whether any rigidity is present. Although the presence of bowel sounds, especially lower in the tract, does not indicate full peristalsis, the absence of sound does correlate with hypomotility. Ask the patient whether he or she has passed any flatus or stool. Although passage of either indicates some intestinal motility, it does not rule out POI.

*Ensuring adequate hydration* helps promote peristalsis because dehydration, fluid loss, and crystalloid excess can potentially decrease intestinal motility, leading to POI. Monitor IV fluid volume compared with urine output. Fluid volumes infused should be sufficient (for the adult without known kidney or cardiac problems) to maintain adequate urine output that is dilute in appearance.

*Increased mobility*, especially early ambulation, assists in return of peristalsis. Help the patient ambulate at least once per shift and increase the distance and time spent ambulating with each intervention. Document both the time and distance of each ambulation so progression can be continued by other caregivers.

*Nonopioid pain management* strategies can help reduce the amount of opioids needed to manage pain adequately. Opioids bind to GI receptors and contribute to decreased peristalsis and POI development. Work with the interprofessional team to use alternative pain control measures in addition to opioids in the postoperative period. See [Chapter 4](#) for more discussion of nonopioid and nonpharmacologic pain management strategies.

*Gum chewing* in the early postoperative period has been suggested to promote intestinal peristalsis. Chewing gum stimulates digestive secretions, including gastric hormones that trigger increased motility without adding bulk to the GI system. A variety of nursing studies report this strategy to be acceptable to patients, low-cost, and successful in returning intestinal peristalsis after abdominal surgery ([Katrancha et al., 2014](#)).

*Drug therapy* can be useful both in preventing reduced peristalsis and promoting increased intestinal peristalsis. The opioid analgesics used for pain control work by binding to mu opioid receptors in the brain. Similar mu receptors in the GI system also are bound by opioids, which results in decreased peristalsis. Drugs known as peripherally acting mu opioid receptor antagonists (PAM-OR antagonists) can be given to prevent opioids from binding to mu receptors in the GI tract without interfering with the effectiveness of opioid pain relief. Thus the action of these drugs facilitates return to peristalsis after surgery. Two drugs approved for this purpose are alvimopan (Entereg) and methylnaltrexone (Relistor).

Other drugs that have been tried to promote peristalsis by directly stimulating GI motility are prokinetic agents. A common drug in this class is metoclopramide (Reglan, Maxeran). Because there is no evidence supporting its effectiveness in preventing POI, it is used less often today.

## NCLEX Examination Challenge 16-3

### Psychosocial Integrity

The nurse is caring for an older-adult client who reports being “afraid to get hooked” on opioid pain medication after surgery. What is the appropriate nursing response? **Select all that apply.**

A. “Why do you think you’re going to get hooked?”

- B. "Don't worry, I won't give you any opioid medications."
- C. "Have you had concerns with drug dependence in the past?"
- D. "Tell me what makes you most fearful about taking opioid medication."
- E. "There are ways we can keep you from becoming dependent on these drugs."
- F. "Older adults are much less likely to rely on pain medications than younger people."

### Care Coordination and Transition Management

Many patients are discharged after a brief hospital stay or directly from the PACU (phase III level) to home. Because of the shortened length of hospital stays and the increase in ambulatory surgery, discharge planning, teaching, and referrals begin before surgery and continue after surgery.

#### Home Care Management.

If the patient is discharged directly to home, assess information about the home environment for SAFETY and the availability of caregivers. Use the data obtained on admission before surgery to determine the patient's needs. For example, if the patient is unable or not allowed to climb stairs and lives in a two-story house with only one bathroom, advise him or her to rent a bedside commode. Other assistive devices may be needed such as a shower chair, walker, or recliner, based on assessment of the patient's living arrangements. Collaborate with the social worker or discharge planner to identify needs related to care after surgery, including meal preparation, dressing changes, drain management, drug administration, physical therapy, and personal hygiene. A referral to a home care nursing or physical therapy agency may be indicated.

The patient is usually concerned about complications, pain, changes in the usual activity level, or payment of the hospital bill. The more extensive the surgical procedure is, the more fearful the patient may be of assuming self-care. Support the patient and family members as they make discharge plans. The patient with visible scars after surgery may need more emotional support from and acceptance by his or her family. The patient may be angry about the surgical outcome or about role changes. He or she may be concerned about financial matters and work. The surgical outcome may not have met the patient's expectations, and further interventions may be needed to assist in the process of resolving his or her feelings. Ensure that referrals are made for additional counseling as indicated.

## NCLEX Examination Challenge 16-4

### Health Promotion and Maintenance

Which client statement regarding appropriate pain control requires nursing intervention?

- A. "I'll listen to music when I feel pain."
- B. "Before exercise or physical therapy, I'll be sure I've taken my medication."
- C. "If the prescribed dose of medication doesn't help my pain, I'll take an extra dose."
- D. "I plan to keep a pain diary so I can see trends about when my pain worsens."

#### Self-Management Education.

The teaching plan for the patient and family after surgery includes:

- Pain management
- Drug therapy with reconciliation of postoperative drugs
- SAFETY (e.g., understanding who to contact in case of complications, progressive increase in activity, needed assistive devices)
- Prevention of infection with care and assessment of the surgical wound

- Management of drains or catheters
- Nutrition therapy
- Follow-up with the surgeon

If dressing changes and drain or catheter care are needed, instruct the patient and family members on the importance of proper handwashing to prevent infection. Explain and demonstrate wound care to the patient and family, who then perform a return demonstration. During teaching sessions evaluate learning and promote adherence after discharge. At the same time, teach about the symptoms of complications such as wound infection. Also instruct the patient and family about what to do if complications occur.

Perform a drug reconciliation with the patient before discharge. Ensure that drugs for other health problems are resumed, as needed. Also ensure that drugs specific for the surgical procedure (and its complications) are available to the patient and that he or she understands how they are to be used, any side effects, and when they are to be discontinued. Teach the patient about drugs for pain, especially the proper dosage and frequency. Instruct the patient to notify the surgeon if pain is not controlled or if it suddenly increases. If antibiotics or other drugs are prescribed, stress the importance of completing the entire prescription.

A diet high in protein, calories, and vitamin C promotes wound healing. Supplemental vitamin C, iron, zinc, and other vitamins are often prescribed after surgery to aid in wound healing and red blood cell formation. Instruct the patient who needs dietary restrictions about the importance of following the prescribed diet while recovering from surgery. Encourage the older adult or weakened patient to continue using dietary supplements, if prescribed, between meals until the wound is completely healed and the energy levels are restored.

Surgery stresses the body, and time and rest are needed for healing. Teach the patient to increase activity level slowly, rest often, and avoid straining the wound or the surrounding area. The surgeon decides when the patient may climb stairs, return to work, drive, and resume other usual ADLs (e.g., housekeeping, gardening, and sexual activity). The surgeon will determine the amount of weight that the patient can lift safely after surgery (i.e., in pounds or kilograms). Instruct the patient in the use of proper lifting techniques and remind him or her about weights of frequently used items such as grocery bags, handbags, and common household items. A patient whose work involves a moderate amount of physical labor may return to work about 6 weeks after abdominal surgery. Stress the importance of adherence to prevent complications or disability.

### Health Care Resources.

A referral for a home care nurse may be needed for follow-up. This nurse provides nursing assessments, dressing supplies, education in self-care, and referrals for other services as needed. Such referrals may include Meals on Wheels, support groups, and homemaker services for housekeeping or food shopping.

## Nursing Safety Priority QSEN

### Action Alert

Always ensure that the patient and family receive written discharge instructions (including medication education sheets) to follow at home. Always ensure that the patient and family understand the instructions by having them explain them in their own words.

### ◆ Evaluation: Reflecting

Evaluate the care of the patient after surgery based on the identified priority patient problems. The expected outcomes include that the patient:

- Attains and maintains adequate lung expansion and respiratory function
- Has appropriate wound healing without complications
- Has acceptable pain management
- Has return of peristalsis

# Get Ready for NCLEX® Examination

## Key Points

Review the following key points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Examine individual patient factors for potential risks to SAFETY, especially risk for surgical site infection, hypoventilation, hypotension, venous thromboembolism, or injury during initial ambulation after surgery. **QSEN: Safety**
- Use aseptic technique during all dressing changes. **QSEN: Safety**
- Use established criteria to determine when a patient is ready to leave the postanesthesia care unit (PACU) for discharge to home or a medical-surgical nursing unit.
- Keep suction equipment, oxygen, and artificial breathing equipment near each patient bedside in the PACU. **QSEN: Safety**

### Health Promotion and Maintenance

- Reinforce to the patient and family after surgery the specific interventions to use to prevent complications (e.g., hand hygiene, incision splinting, deep-breathing exercises, range-of-motion exercises—as described in [Charts 14-4](#) and [14-5](#)). **QSEN: Evidence-Based Practice**
- Encourage early ambulation.
- Stress the importance of following activity restrictions prescribed by the surgeon.
- Teach the patient and family about any drugs to be continued after discharge from the facility. **QSEN: Patient-Centered Care**
- Instruct the patient and family about the clinical signs and symptoms of complications and when to seek assistance. **QSEN: Patient-Centered Care**

### Psychosocial Integrity

- Keep family members informed of the patient's progress during the time that he or she is in the postanesthesia recovery area. **Ethics**
- Reassure patients and family members that taking pain medication when needed, even opioids, does not make them drug abusers. **QSEN: Patient-Centered Care**

### Physiological Integrity

- Begin every assessment of the patient after surgery by checking the airway and breathing effectiveness. **QSEN: Safety**
- Assess the incision site each shift (on the medical-surgical nursing unit).
- Offer alternative therapies for relaxation, pain reduction, and distraction such as massage, music therapy, and guided imagery.
- In the event of wound dehiscence or evisceration, have the patient lie flat (supine) with knees bent to reduce intra-abdominal pressure; apply sterile, nonadherent dressing materials to the wound; and follow the steps outlined in [Chart 16-6](#). **QSEN: Evidence-Based Practice**

## CHAPTER 17

# Principles of Inflammation and Immunity

---

*M. Linda Workman*

## PRIORITY AND INTERRELATED CONCEPTS

*The priority concept for this chapter is IMMUNITY.*

## LEARNING OUTCOMES

### **Health Promotion and Maintenance**

1. Explain how physiologic aging affects IMMUNITY and the associated care of older adults.

### **Physiological Integrity**

2. Interpret laboratory findings to assess the patient's risk for an IMMUNITY problem.
3. Explain how drug therapy alters IMMUNITY to interfere with transplant rejection.

## Overview

As described in [Chapter 2](#), IMMUNITY is protection from illness or disease that is maintained by the body's physiologic defense mechanisms. This protection requires the interaction of immunity and inflammation working together to control infection and other problems caused by harmful microorganisms or altered cells. Components of immunity include intact skin and mucous membranes and many different white blood cells (WBCs) and their products. In addition to protection, immunity plays a role in repair of damaged tissues.

Infectious diseases are common, but most adults are healthy more often than they are ill. IMMUNITY with inflammation is critical to maintaining health and preventing disease. When all the different parts and functions of immunity are working well, the adult is **immunocompetent** and has maximum protection against infection.

IMMUNITY is reduced by many diseases, injuries, and medical therapies. *Whether immunity is reduced temporarily or permanently, this reduction always endangers the patient's health.* [Chapter 19](#) discusses reduced and inadequate immunity. Other problems occur when immunity is excessive or if some of its processes occur at inappropriate times. [Chapters 18](#) and [20](#) discuss issues related to excess or inappropriate immunity responses such as hypersensitivity and autoimmune disease.

IMMUNITY uses many cells and their functions to fight against the effects of injury or invasion. Adults interact with many other large and small living organisms (bacteria, viruses, molds, spores, pollens, protozoa, and cells from other people or animals). As long as organisms do not enter the body, they pose no health threat. Body defenses to prevent organisms from entering include intact skin and mucous membranes, the microbiome, and natural chemicals that inhibit bacterial growth. These defenses are not perfect, and invasion can occur. However, most invasions do not result in disease or illness because of proper immunity.

IMMUNITY and the immune system stimulate processes that neutralize, eliminate, or destroy invading organisms. To protect without causing harm, immune system cells exert actions only against non-self proteins and cells. Immune system cells can distinguish between the body's own healthy self cells and non-self proteins and cells.

## Self Versus Non-Self

Non-self proteins and cells include infected body cells, cancer cells, cells from other people, and invading organisms. Recognizing self versus non-self is called **self-tolerance**. This action prevents IMMUNITY from harming healthy body cells. Self-tolerance is possible because of the different proteins present on cell membranes.

Cells are surrounded by plasma membranes with different proteins on or through the surface ([Fig. 17-1](#)). For example, many different protein types are present on the liver cell membranes. Each of these protein types differs from that of all other protein types. Some protein types are specific markers for human tissues and are found only on human cells. In addition, each person's cells have unique surface proteins that are specific to that person known as **human leukocyte antigens (HLAs)**. These HLAs serve as a "universal product code" for that person and are identical only to the HLAs of an identical sibling. One adult's HLAs are recognized as "foreign," or non-self, by the immune system of another adult. Because the cell-surface proteins are non-self to another adult's immune system, they are **antigens**, which are proteins capable of stimulating an IMMUNITY response.

**FIG. 17-1** Proteins on human cell plasma membranes.

Human leukocyte antigens are on the surfaces of most body cells—not just leukocytes. They are a normal part of the person and determine the *tissue type* of a person, which is coded for by the specific genes he or she inherits from both parents. Other names for these HLAs are *human histocompatibility antigens* and *class I antigens*.

The HLAs are key for recognition and self-tolerance. The immune system cells constantly come into contact with other body cells and with any invader that enters the body. At each encounter the immune system cells compare the surface protein HLAs to determine whether the encountered cell belongs in the body (Fig. 17-2). If the encountered cell's HLAs match the HLAs of the immune system cell, the encountered cell is “self” and is not attacked. If the encountered cell's HLAs do not perfectly match the HLAs of the immune system cell, the encountered cell is non-self, or foreign. The immune system cell then takes action to neutralize, destroy, or eliminate this foreign invader.

**FIG. 17-2** Determination by immune system cell of self versus non-self cells.

A key element for recognition of non-self by cells involved in general immunity and those involved in specific immunity is the presence of **toll-like receptors (TLRs)** on these cells. Toll receptors were first discovered in fruit flies as a way that this insect recognizes and rids itself of pathogenic (disease-causing) microorganisms. TLRs, which closely resemble the toll receptors, are known to be present on immune system cells of humans and other animals, as well as on defensive cells of insects and plants (Abbas et al., 2015). Their protective purpose is to interact with the surface of any invading organism and allow recognition that it is non-self so actions are taken to rid the body of this invader. TLRs also help immune system cells recognize damaged or unhealthy self cells.

IMMUNITY changes during an adult's life as a result of nutrition status, environmental conditions, drugs, disease, and age. Immunity is most efficient in adults who are in their 20s and 30s and slowly declines with increasing age (Touhy & Jett, 2016). Older adults have decreased immune function, increasing their risk for many health problems (Chart 17-1).

**Chart 17-1**

## Nursing Focus on the Older Adult

### Changes in Immune Function Related to Aging

IMMUNE COMPONENT	FUNCTIONAL CHANGE	NURSING IMPLICATIONS
Inflammation	Reduced neutrophil function.	Neutrophil counts may be normal, but activity is reduced, increasing the risk for infection.
	Leukocytosis does not occur during acute infection.	Patients may have an infection but not show expected changes in white blood cell counts.
	Older adults may not have a fever during inflammatory or infectious episodes.	Not only is there potential loss of protection through inflammation, but also minor infections may be overlooked until the patient becomes severely infected or septic.
Antibody-mediated immunity	The total number of colony-forming B-lymphocytes and the ability of these cells to mature into antibody-secreting cells are diminished.	Older adults are less able to make new antibodies in response to the presence of new antigens. Thus they should receive immunizations such as "flu shots," the pneumococcal vaccination, and the shingles vaccination.
	There is a decline in natural antibodies, decreased response to antigens, and reduction in the amount of time the antibody response is maintained.	Older adults may not have sufficient antibodies present to provide protection when they are re-exposed to microorganisms against which they have already generated antibodies. Thus older patients need to avoid people with viral infections and receive "booster" shots for old vaccinations and immunizations, especially tetanus and pertussis (whooping cough).
Cell-mediated immunity	The number of circulating T-lymphocytes decreases.	Skin tests for tuberculosis may be falsely negative.
		Older patients are more at risk for bacterial and fungal infections, especially on the skin and mucous membranes, in the respiratory tract, and in the genitourinary tract.

## Organization of the Immune System

The immune system is present throughout the body. Most immune system cells come from the bone marrow. Some cells mature in the bone marrow; others leave the bone marrow and mature in different body sites. When mature, many immune system cells are released into the blood, where they circulate to most body areas and have specific effects.

The bone marrow is the source of all blood cells, including most immune system cells. The bone marrow produces immature, undifferentiated cells called **stem cells**. Stem cells are **pluripotent**, meaning that each cell has more than one potential outcome. When the stem cell is first generated in the bone marrow, it is undifferentiated, not yet committed to maturing into a specific blood cell type. This stem cell is flexible (pluripotent) and could become any one of many mature blood cells. Fig. 17-3 shows the possible outcomes for maturation of stem cells. The type of mature cell that the stem cell becomes depends on which pathway it follows.

**FIG. 17-3** Stem cell differentiation and maturation. (Modified from Goldman, L., & Schafer, A. (Eds.). (2012). *Goldman's Cecil medicine* (24th ed.). Philadelphia: Saunders.)

The maturational pathway of any stem cell depends on body needs and the presence of specific growth factors that direct the cell to a pathway. For example, erythropoietin is a growth factor for red blood cells (**erythrocytes [RBCs]**). When immature stem cells are exposed to erythropoietin, they commit to the erythrocyte pathway and eventually become mature RBCs.

White blood cells (**leukocytes [WBCs]**) are the immune system cells that use a variety of actions to provide **IMMUNITY**. Table 17-1 lists the functions of different immune system cells. The leukocytes provide protection through these defensive actions:

**TABLE 17-1**

### Immune Functions of Specific Leukocytes

VARIABLE	LEUKOCYTE	FUNCTION
Inflammation	Neutrophil	Nonspecific ingestion and phagocytosis of microorganisms and foreign protein
	Macrophage	Nonspecific recognition of foreign proteins and microorganisms; ingestion and phagocytosis
	Monocyte	Assists with antibody-mediated immunity and cell-mediated immunity
	Eosinophil	Destruction of bacteria and cellular debris; matures into macrophage
	Basophil	Releases vasoactive amines during allergic reactions to limit these reactions
Antibody-mediated immunity	Plasma cell	Releases histamine and heparin in areas of tissue damage
	B-lymphocyte	Becomes sensitized to foreign cells and proteins with the assistance of macrophages and helper/inducer T-cells
	Memory cell	Secretes immunoglobulins in response to the presence of a specific antigen
Cell-mediated immunity	Helper/inducer T-cell	Remains sensitized to a specific antigen and can secrete increased amounts of immunoglobulins specific to the antigen on re-exposure
	Cytotoxic/cytolytic T-cell	Enhances immune activity of all parts of general and specific immunity through secretion of various factors, cytokines, and lymphokines
	Natural killer cell	Selectively attacks and destroys non-self cells, including virally infected cells, grafts, and transplanted organs
	Natural killer cell	Nonselectively attacks non-self cells, especially body cells that have undergone mutation and become malignant; also attacks grafts and transplanted organs

- Recognition of self versus non-self
- Destruction of foreign invaders, cellular debris, and unhealthy or abnormal self cells
- Production of antibodies directed against invaders
- Complement activation
- Production of cytokines that stimulate increased formation of leukocytes in bone marrow and increase specific leukocyte activity

The three processes needed for human protection through IMMUNITY are (1) inflammation, (2) antibody-mediated immunity (AMI), and (3) cell-mediated immunity (CMI). Each process uses different defensive actions, and each influences or requires assistance from the other two processes (Fig. 17-4). Therefore full immunity (immunocompetence) requires the function and interaction of all three processes.

**FIG. 17-4** The three divisions of immunity: inflammation, antibody-mediated immunity, and cell-mediated immunity. Optimal function of all three divisions is necessary for complete immunity.

## General Immunity: Inflammation

General immunity is nonspecific and is also called *innate-native immunity* or *natural immunity*. With inflammation, general immunity provides immediate protection against the effects of tissue injury and invading foreign proteins. Innate-native immunity is any natural protective feature of a human. It is a barrier to prevent organisms from entering the body and can attack organisms that have already entered the body. This type of IMMUNITY cannot be transferred from one adult to another and is not an adaptive response.

The inflammatory responses, the skin, mucosa, antimicrobial chemicals on the skin, complement, and natural killer cells compose general immunity. Inflammation is critical for health. General immunity and inflammation differ from specific immunity in two ways:

- Inflammatory protection is immediate but short term. It does not provide true immunity on repeated exposure to the same organisms.
- Inflammation is a *nonspecific* body defense to invasion or injury and can be started quickly by almost any event, regardless of where it occurs or what causes it.

So inflammation triggered by a scald burn to the hand is the same as inflammation triggered by bacteria in the middle ear. How widespread the symptoms of inflammation are depends on the intensity, severity, and duration of exposure to the initiating event. For example, a splinter in the finger triggers inflammation only at the splinter site, whereas a burn injuring 50% of the skin leads to an inflammatory response involving the entire body.

Inflammation starts tissue actions that cause visible and uncomfortable symptoms that are important in ridding the body of harmful organisms. However, if the inflammatory response is excessive, tissue damage may result. Inflammation also helps start both antibody-mediated and cell-mediated actions to activate full IMMUNITY.

## Infection

Inflammation occurs in response to tissue injury as well as to infection by organisms. *Infection is usually accompanied by inflammation; however, inflammation can occur without infection.* Inflammation without infection includes joint sprains, myocardial infarction, and blister formation. Inflammation caused by noninfectious invasion includes allergic rhinitis, contact dermatitis, and other allergic reactions. Inflammations from infection include otitis media, appendicitis, and viral hepatitis, among many others. *Inflammation does not always mean that an infection is present.*

## Cell Types Involved in Inflammation

The leukocytes (white blood cells [WBCs]) involved in inflammation are neutrophils, macrophages, eosinophils, and basophils. An additional cell type important in inflammation is the tissue mast cell. Neutrophils and macrophages destroy and eliminate foreign invaders. Basophils, eosinophils, and mast cells release chemicals that act on blood vessels to cause tissue-level responses that help neutrophil and macrophage actions.

### Neutrophils

*Mature neutrophils* make up between 55% and 70% of the normal total WBC count. Neutrophils come from the stem cells and complete the maturation process in the bone marrow (Fig. 17-5). They are also called *granulocytes* because of the large number of granules present inside each cell. Other names for neutrophils are based on their appearance and maturity. Mature neutrophils are also called *segmented neutrophils* (“segs”) or *polymorphonuclear cells* (“polys,” PMNs) because of their segmented nucleus. Less mature neutrophils are called *band neutrophils* (“bands” or “stabs”) because of their nuclear shape.

**FIG. 17-5** Stem cell maturation into fully functional segmented neutrophils.

Usually growth of a stem cell into a mature neutrophil requires 12 to 14 days. This time can be shortened by the presence of specific growth factors (cytokines) such as granulocyte-macrophage colony-stimulating factor (GM-CSF) and granulocyte colony-stimulating factor (G-CSF). The purpose and action of cytokines are described in the Cytokines section. In the healthy adult with full IMMUNITY, more than 100 billion fresh, mature neutrophils are released from the bone marrow into the circulation daily. This huge production is needed because the life span of each neutrophil is short—about 12 to 18 hours.

*Neutrophil function* provides protection after invaders, especially bacteria, enter the body. This powerful army of small cells destroys invaders by phagocytosis and enzymatic digestion, although each cell is small and can take part in only one episode of phagocytosis.

Mature neutrophils are the only stage of this cell capable of phagocytosis. Because this cell type causes continuous, instant, nonspecific protection against organisms, the percentage and actual number of mature circulating neutrophils are used to measure a patient's risk for infection: the higher the numbers, the greater the resistance to infection. This measurement is the **absolute neutrophil count (ANC)**.

The differential of a normal WBC cell count shows the number and percent of the different types of circulating leukocytes (Table 17-2). Most circulating neutrophils are segmented neutrophils; only a small percentage are band neutrophils or less mature forms. Problems such as sepsis cause the circulating neutrophils to change from being mostly segmented neutrophils to being less mature forms. This situation is a **left shift** or *bandemia* because the segmented neutrophil (at the far right of the neutrophil pathway in Fig. 17-5) is no longer the most numerous type in circulation. Instead more of the circulating cells are bands—the less mature cell type found farther left on the neutrophil pathway.

**TABLE 17-2**

**Values of a White Blood Cell Differential for Peripheral Blood Representing a Normal Count**

WBC TYPE	%	/MM <sup>3</sup>	$\times 10^9/L$
Total WBC	100	10,000	5-10
Segs	50-62	5000-6200	5-6.2
Bands	5	500	0.5
Monos	2-8	100-700	0.1-0.7
Lymphs	20-40	1000-4000	1.0-4.0
Eosins	1-4	50-500	0.0-0.3
Basos	0.5-1.0	15-50	0.02-0.05

WBC, White blood cell.

A left shift indicates that the patient's bone marrow cannot produce enough mature neutrophils to keep pace with the continuing infection and is releasing immature neutrophils into the blood. These immature cells are of minimal benefit because they are not capable of phagocytosis.

## Macrophages

*Macrophages* come from the committed myeloid stem cells in the bone marrow and form the mononuclear-phagocyte system. The stem cells first form monocytes, which are released into the blood at this stage. Until they mature, monocytes have limited activity. Most monocytes move from the blood into body tissues, where they mature into macrophages. Some macrophages become “fixed” in position within the tissues, whereas others can move within and between tissues. Macrophages in various tissues have slightly different appearances and names. The liver, spleen, and intestinal tract contain large numbers of these cells.

*Macrophage function* helps stimulate immediate inflammatory responses and also stimulates the longer-lasting immune responses of antibody-mediated IMMUNITY (AMI) and cell-mediated immunity (CMI). Macrophage functions include phagocytosis, repair, antigen presenting/processing, and secretion of cytokines for immune system control.

The inflammatory function of macrophages is phagocytosis. Macrophages can easily distinguish between self and non-self, and their large size makes them very effective at trapping invading cells. They have long life spans, and each cell can take part in many phagocytic events.

## Basophils

*Basophils* come from myeloid stem cells and make up only about 1% of the total circulating WBC count. These cells cause the signs and symptoms of inflammation.

*Basophil function* acts on blood vessels with basophil chemicals (vasoactive amines), which include heparin, histamine, serotonin, kinins, and leukotrienes. Basophils have sites that bind the stem part of immunoglobulin E (IgE) molecules, which binds to and is activated by allergens. When allergens bind to the IgE on the basophil, the basophil membrane opens and releases the vasoactive amines into the blood, where most of them act on smooth muscle and blood vessel walls. Heparin inhibits blood and protein clotting. Histamine dilates arterioles and constricts small veins, slowing blood flow and decreasing venous return. This effect causes blood to collect in capillaries and arterioles. Kinins dilate arterioles and increase capillary permeability, causing blood plasma to leak into the interstitial space (*vascular leak syndrome*). Basophils stimulate both general inflammation and the inflammation of allergic reactions.

## Eosinophils

*Eosinophils* come from the myeloid line and contain many vasoactive chemicals. Only 1% to 2% of the total WBC count normally is composed of eosinophils.

*Eosinophil function* is most active against infestations of parasitic larvae and also limits inflammatory reactions. Some eosinophil granules contain enzymes that degrade the vasoactive chemicals released by other leukocytes. This is why the number of circulating eosinophils increases during an allergic response.

## Tissue Mast Cells

*Tissue mast cells* look like and have functions very similar to basophils and eosinophils. Although mast cells do originate in the bone marrow, they come from a different parent cell than leukocytes and do not circulate as mature cells (Abbas et al., 2015). Instead they differentiate and mature in tissues, especially those near blood vessels, lung tissue, skin, and mucous membranes. Mast cells have binding sites for the stems of IgE molecules and are involved in allergic reactions. They also respond to the inflammatory products released by T-lymphocytes. Tissue mast cells maintain and prolong inflammation and allergic reactions.

## Complement

The complement system is a part of innate immunity. It is composed of a system of 20 different types of inactive plasma proteins that, when activated, act as enzymes and attract agents to enhance (or “complement”) cell actions of innate immunity. When stimulated, each type of complement protein is activated, joins other activated complement proteins, surrounds an antigen, and “fixes” or sticks to the antigen. This action makes immune cell attachment to antigens more efficient. Complement fixation occurs quickly as a cascade.

## Phagocytosis

A key process of inflammation is **phagocytosis**, the engulfing and destruction of invaders, which

also rids the body of debris after tissue injury. Neutrophils and macrophages are most efficient at phagocytosis. Phagocytosis involves the seven steps shown in Fig. 17-6.

**FIG. 17-6** Steps of phagocytosis. *M*, Macrophage.

- *Exposure and invasion* occur as the first step in response to injury or invasion. Leukocytes that engage in phagocytosis and stimulate inflammation are present in the blood and extracellular fluids. Phagocytosis starts with invasion by organisms or foreign proteins.
- *Attraction* is the second step and brings the WBC into direct contact with the target (antigen, invader, or foreign protein). Damaged tissues secrete chemotaxins that attract neutrophils and macrophages and release debris that binds to the surface of invading proteins.
- *Adherence* binds the phagocytic cell to the surface of the target. *Opsinins* are substances that increase contact of the cell with its target by coating the target cell (antigen or organism). During inflammation coating the target makes it easier for phagocytic cells to stick to it. Substances that are opsonins are dead neutrophils, antibodies, and activated (fixated) complement components.
- *Recognition* occurs when the phagocytic cell sticks to the target cell and “recognizes” it as non-self. The phagocytic cells examine the universal product codes (human leukocyte antigens [HLAs]) of whatever they encounter. Recognition of non-self is made easier by opsonins on the target cell surface. Phagocytic cells start phagocytosis only when the target cell is recognized as non-self or debris.
- *Cellular ingestion* occurs when the target cell is brought inside the phagocytic cell by phagocytosis (engulfment).
- *Phagosome formation* occurs when the phagocyte's granules break and release enzymes that attack the ingested target.
- *Degradation* is the final step. The enzymes in the phagosome digest the engulfed target.

## Sequence of Inflammation

Inflammation (inflammatory responses) occurs in a predictable three-stage sequence. The sequence is the same, regardless of the triggering event. Responses at the tissue level cause the **five cardinal symptoms of inflammation**: warmth, redness, swelling, pain, and decreased function. The timing of the stages may overlap.

*Stage I* is a vascular response that starts changes in blood vessels. Injured tissues and the leukocytes and tissue mast cells in this area secrete histamine, serotonin, and kinins that constrict the small veins and dilate the arterioles. These changes cause redness and warmth of the tissues. This increased blood flow increases delivery of nutrients to injured tissues.

Blood flow to the area increases (**hyperemia**), and edema forms at the site of injury or invasion. Capillary leak also occurs, allowing blood plasma to leak into the tissues. This response causes swelling and pain. Edema protects the area from further injury by creating a cushion of fluid. The duration of these responses depends on the severity of the initiating event, but usually they subside within 24 to 72 hours.

The macrophage is the major cell involved in stage I of inflammation. The action is rapid because macrophages are already in place at the site of injury or invasion. This action is limited because the number of macrophages is so small. To enhance the response, tissue macrophages secrete several cytokines. One is colony-stimulating factor (CSF), which triggers the bone marrow to shorten the time needed to produce white blood cells (WBCs) from 14 days to a matter of hours. Some cytokines cause neutrophils from the bone marrow to move to the site of injury or invasion, which leads to the next stage of inflammation.

*Stage II* is the cellular exudate part of the response. In this stage **neutrophilia** (an increased number of circulating neutrophils) occurs. Exudate in the form of pus occurs, containing dead WBCs, necrotic tissue, and fluids that escape from damaged cells.

Neutrophils, basophils, and tissue mast cells are active in this stage. Under the influence of cytokines, the neutrophil count can increase hugely within 12 hours after inflammation starts. Neutrophils attack and destroy organisms and remove dead tissue through phagocytosis. Basophils and tissue mast cells continue or sustain the initial responses

In acute inflammation the healthy adult produces enough mature neutrophils to keep pace with invasion and prevent the organisms from growing. At the same time the WBCs and inflamed tissues secrete cytokines, which allow tissue macrophages to increase and trigger bone marrow production of monocytes.

During this phase the arachidonic acid cascade starts to increase inflammation. This action begins by the conversion of fatty acids in plasma membranes into arachidonic acid (AA). The enzyme *cyclooxygenase* (COX) converts AA into chemicals that are further processed into the substances (mediators) that promote continued inflammation. Mediators include histamine, leukotrienes, prostaglandins, serotonin, and kinins. Anti-inflammatory drugs stop this cascade by preventing cyclooxygenase from converting AA into inflammatory mediators.

When an infection stimulating inflammation lasts longer than just a few days, the bone marrow begins to release immature neutrophils, reducing the number of circulating mature neutrophils. This problem limits helpful effects of inflammation and increases the risk for sepsis.

*Stage III* features tissue repair and replacement. Although this stage is completed last, it begins at the time of injury and is critical to the final function of the inflamed area.

WBCs involved in inflammation start the replacement of lost tissues or repair of damaged tissues by inducing the remaining healthy cells to divide. In tissues that cannot divide, WBCs trigger new blood vessel growth and scar tissue formation. Because scar tissue does not act like the tissue it replaces, function is lost wherever scar tissue forms. For example, when heart muscles are destroyed by a myocardial infarction (heart attack), scar tissue forms in the area to prevent a hole from forming in the heart wall as the ischemic cells die. The scar tissue serves only as a patch; it does not contract or act in any way like heart muscle. So if 20% of the left ventricle is replaced with scar tissue, the effectiveness of left ventricular contraction is reduced by 20%.

Inflammation alone cannot provide long-lasting IMMUNITY. Lymphocytes are the cells needed for long-lasting antibody-mediated immunity (AMI) and cell-mediated immunity (CMI).

## Specific Immunity

Specific IMMUNITY is an *adaptive* protection that results in long-term resistance to the effects of invading microorganisms. This means that the responses are not automatic, which is why specific immunity is also known as *acquired immunity*. The body has to learn to generate specific immune responses when it is infected by or exposed to specific organisms. Lymphocytes develop actions and products that provide true immunity. These cells develop specific actions in response to specific invasion (Fig. 17-7). The two divisions of specific immunity are antibody-mediated immunity and cell-mediated immunity. As indicated by Fig. 17-4, activation of both types of specific immunity require interactions with actions and cells of innate immunity.

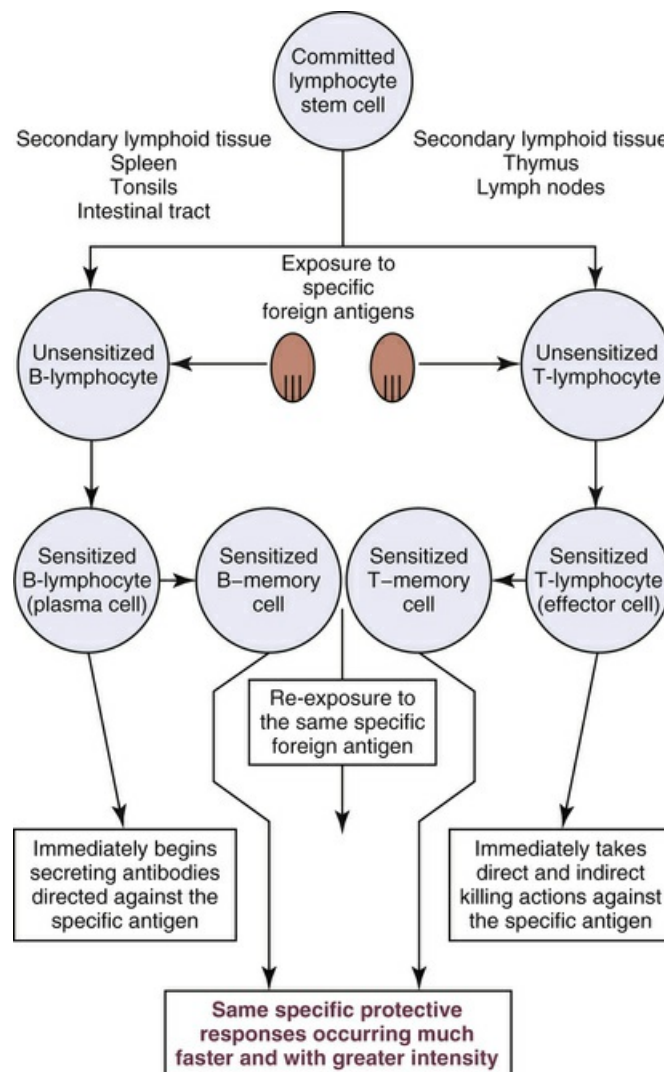

FIG. 17-7 B-lymphocyte and T-lymphocyte differentiation, maturation, and function.

## Antibody-Mediated Immunity

**Antibody-mediated immunity (AMI)**, also known as *humoral immunity*, uses antigen-antibody interactions to neutralize, eliminate, or destroy foreign proteins. Antibodies are produced by sensitized B-lymphocytes (B-cells).

B-cells become sensitized to a specific foreign protein (antigen) and produce antibodies directed specifically against that protein. The antibody, rather than the B-cell, then causes actions to neutralize, eliminate, or destroy that antigen. B-cells have the most direct role in AMI.

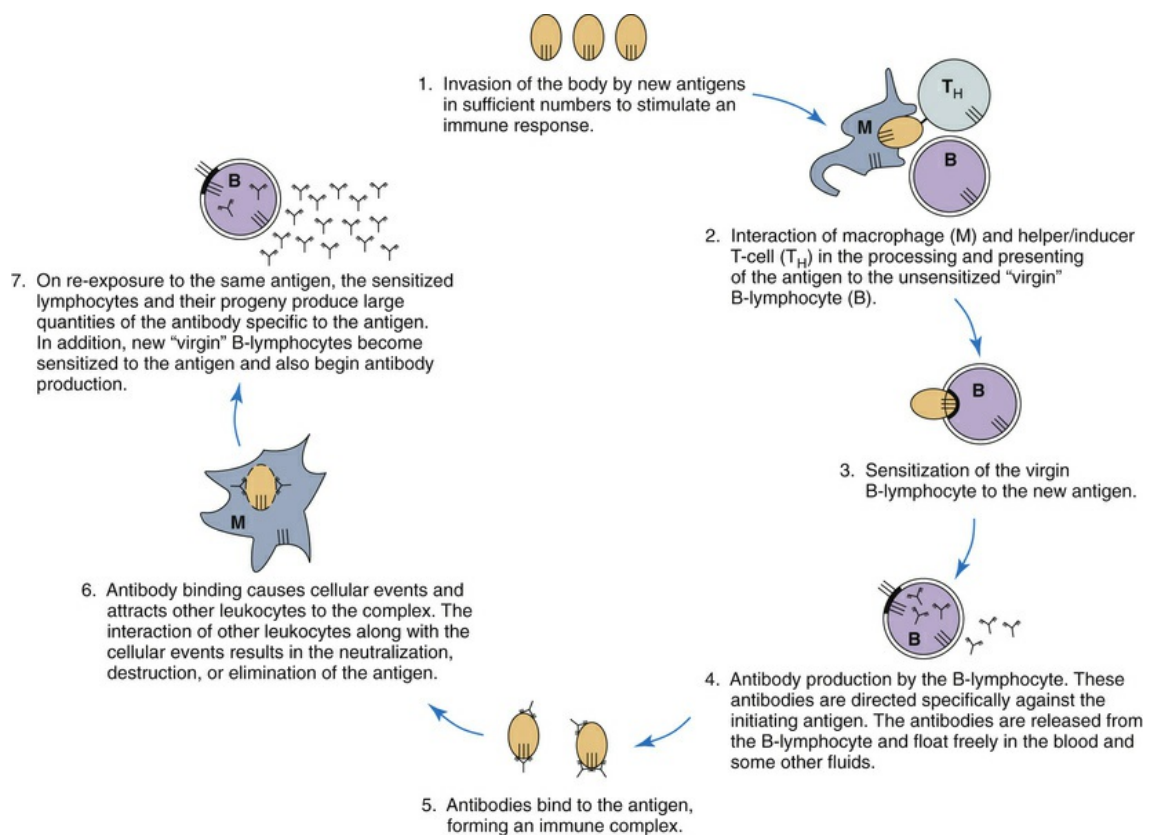

Macrophages and T-lymphocytes (discussed in the Cell-Mediated Immunity section) work with B-cells to generate antigen-antibody interactions. *For optimal AMI the entire immune system must function adequately.*

B-cells start as stem cells in the bone marrow, the primary lymphoid tissue, that commit to the lymphocyte pathway (see Fig. 17-3) and are then restricted in development. The lymphocyte stem cells released into the blood then migrate into many secondary lymphoid tissues to mature. The secondary lymphoid tissues for B-cells are the spleen, parts of lymph nodes, tonsils, and the mucosa of the intestinal tract (McCance et al., 2014).

## Antigen-Antibody Interactions

The body learns to make enough of any specific antibody to provide long-lasting IMMUNITY against specific organisms or toxins. The seven steps for specific antibody production against a specific antigen are shown in Fig. 17-8 and described in the following paragraphs.

**FIG. 17-8** Sequence of the seven steps required to stimulate antibody-mediated immunity.

*Exposure or invasion* is needed for the antigen to enter the adult to generate an antibody, although not all exposures result in antibody production. Invasion by the antigen must occur in such large numbers that some of the antigen evades detection by the body's natural nonspecific defenses or overwhelms the ability of the inflammatory response to get rid of the invader.

For example, an adult who has never been exposed to the viral disease *influenza A* now baby-sits for three children who develop influenza symptoms within the next 10 hours. These children, in the presymptomatic stage, shed many millions of live influenza A virus particles by droplets from the upper respiratory tract. They expose the baby-sitter by drinking out of the baby-sitter's cup, kissing him or her on the lips, and sneezing and coughing into his or her face. During the 5 hours spent with the children, the baby-sitter is heavily invaded by the influenza A virus and will become sick with this disease within 2 to 4 days. While the virus is growing and the disease is developing, the baby-sitter's white blood cells (WBCs) are taking part in antibody-antigen actions to prevent him or her from having influenza A more than once.

*Antigen recognition* is the recognition of the antigen by unsensitized B-cells. This action requires

the help of macrophages and helper/inducer T-cells.

Recognition is started by the macrophages of innate immunity. After the antigen surface has been altered by opsonization (see discussion of “adherence” in the [Phagocytosis](#) section), macrophages recognize the invading antigen as non-self and attach to the antigen. This attachment allows macrophages to “present” the attached antigen to the helper/inducer T-cell. Then the helper/inducer T-cell and the macrophages together process the antigen to expose the antigen's recognition sites (universal product code). After processing the antigen, the helper/inducer T-cells bring the antigen into contact with the B-cell so the B-cell can recognize the antigen as non-self.

*Sensitization* occurs when the B-cell recognizes the antigen as non-self and is now “sensitized” to this antigen. A single unsensitized B-cell can become sensitized only once. *So each B-cell can be sensitized to only one type of antigen.*

Sensitizing allows this B-cell to respond to any substance that carries the same antigens (codes) as the original antigen. The sensitized B-cell always remains sensitized to that specific antigen. In addition, all cells produced by that sensitized B-cell also are already pre-sensitized to that same specific antigen.

Immediately after it is sensitized, the B-cell divides and forms two types of B-lymphocytes, each one remaining sensitized to that specific antigen (see [Fig. 17-7](#)). One new cell becomes a **plasma cell**, which starts immediately to produce antibodies against the sensitizing antigen. The other new cell becomes a memory cell. The **memory cell** is a sensitized B-cell but does not produce antibodies until the next exposure to the same antigen (see discussion of sustained immunity [memory] later as an antigen-antibody interaction).

*Antibody production and release* allow the antibodies to search out specific antigens. Antibodies are produced by plasma cells; each plasma cell can make as many as 300 molecules of antibody per second. A plasma cell produces antibodies specific only to the antigen that originally sensitized the parent B-cell. For example, in the case of the baby-sitter who was invaded by the influenza A virus, the plasma cells from those B-cells sensitized to the influenza A virus can make only anti-influenza A antibodies. The antibody class (e.g., immunoglobulin G [IgG] or immunoglobulin M [IgM]) that the plasma cell produces may vary, but the antibody can be forever directed only against the influenza A virus.

Antibody molecules from plasma cells are released into the blood and body fluids (body “humors”) as free antibodies that are separate from the B-cells. So this type of IMMUNITY may be called **humoral immunity**. *Circulating antibodies can be transferred from one adult to another and provide the receiving adult with immediate short-term immunity.*

*Antibody-antigen binding* is needed for anti-antigen actions. Antibodies are Y-shaped molecules ([Fig. 17-9](#)). The tips of the short arms of the Y recognize the specific antigen and bind to it. Because each antibody molecule has two tips (Fab fragments, or arms), each antibody can bind either to two separate antigens or to two areas of the same antigen.

**FIG. 17-9** Antibody structure and the Fc receptors on leukocytes.

The stem of the **Y** is the “Fc fragment.” This area can bind to Fc receptor sites on white blood cells (WBCs). The WBC then not only has its own means of attacking antigens but also has the added power of having surface antibodies that can stick to antigens (see Fig. 17-9).

The binding of antibody to antigen may not be lethal to the antigen. Instead antibody-antigen binding starts other actions that neutralize, eliminate, or destroy the antigen.

*Antibody-binding actions* are triggered when an antibody binds to an antigen. The resulting actions of agglutination, lysis, complement fixation, precipitation, and inactivation can then neutralize, eliminate, or destroy the bound antigen.

**Agglutination** is a clumping action occurring when the antibodies link antigens together, forming large and small immune complexes (Fig. 17-10). The irregular shape of the antigen-antibody complex (see Fig. 17-10) increases the actions of macrophages and neutrophils.

**FIG. 17-10** Formation of large and small antigen-antibody complexes (immune complexes).

**Lysis** is cell membrane destruction, and it occurs when antibodies bind to membrane-bound antigens of some invaders. Antibody binding makes holes in the invader's membrane, weakening the invader, especially bacteria and viruses. This response usually requires that complement be activated and “fixed” to the immune complex.

**Complement activation and fixation** are actions triggered by the IgG and IgM classes of antibodies that can remove or destroy antigen. (See discussion of complement in the General Immunity and Inflammation section for an explanation of how complement assists in immunity.) Binding of either IgG or IgM to an antigen provides a binding site for the first component of complement. Once the first complement molecule is activated, other proteins of the complement system are activated in a cascade.

**Precipitation** is similar to agglutination but has a larger response. With precipitation, antibody molecules bind so much antigen that large antigen-antibody complexes are formed. These complexes cannot stay in suspension in the blood. Instead they form a large precipitate, which then can be acted on and removed by neutrophils and macrophages.

**Inactivation (neutralization)** makes an antigen harmless without destroying it. Usually only a small area of the antigen, the *active site*, causes the harmful effects. When an antibody binds to an antigen's active site, covering it, the antigen is made harmless without destroying it.

*Sustained immunity (memory)* provides us with long-lasting, true IMMUNITY to a specific antigen. This immunity results from memory B-cells made during lymphocyte sensitization. These memory cells remain sensitized to the specific antigen to which they were originally exposed. On re-exposure to the same antigen, the memory cells rapidly respond by dividing and forming new sensitized blast cells and plasma cells. The blast cells continue to divide, producing many more sensitized plasma cells. These new sensitized plasma cells rapidly make large amounts of the antibody specific for the sensitizing antigen.

Having memory cells respond on re-exposure to the same antigen that originally sensitized the B-cell allows a rapid and large immune response (*anamnestic response*) to the antigen. When so much antibody is made, the invading organisms may be removed completely, and illness does not result. This process prevents adults from becoming ill with any infectious disease more than once, even though they are exposed many times to the causative organism. Without immunologic memory,

adults would be susceptible to diseases at every exposure to the organisms, and no long-term IMMUNITY would be generated (Abbas et al., 2015).

## Antibody Classification

All antibodies are immunoglobulins, also called *gamma globulins*. A globulin is a protein that is globular rather than straight. Because antibodies are globular proteins, they are “globulins.” The term **immunoglobulin** is used because they are globular proteins that provide IMMUNITY. Antibodies also are called **gamma globulins** because all free antibodies in the plasma separate out in the gamma fraction of plasma proteins during electrophoresis. The five antibody types are classified by differences in size, location, amount, and function (Table 17-3).

**TABLE 17-3**  
**Antibody Classification**

ANTIBODY FUNCTION	
IgA	“Secretory” antibody that is present in high concentrations in the secretions of mucous membranes and the intestinal mucosa Very low circulating levels Most responsible for preventing infection in the upper and lower respiratory tracts, the GI tract, and the genitourinary tract
IgD	Present in low blood concentrations in conjunction with IgM
IgE	Variable concentration in blood Associated with antibody-mediated hypersensitivity reactions Binds to mast cells and causes their degranulation when an allergen (antigen) binds to IgE antigen recognition sites
IgG	Composes at least 75% of circulating antibody population Is heavily expressed on second and subsequent exposures to antigens to provide sustained, long-term immunity against invading microorganisms Activates classic complement pathway and enhances neutrophil and macrophage actions
IgM	First antibody formed by a newly sensitized B-lymphocyte plasma cell Composes about 10% to 15% of circulating antibody population Especially effective at the antibody actions of agglutination and precipitation because of having 10 potential binding sites per molecule Activates complement pathway

On first exposure to an antigen, the newly sensitized B-cell produces the IgM antibody type against the antigen. IgM is special because it forms itself into a five-member group with ten antigen binding sites. So even though antibody production is slow on first exposure, IgM is very efficient at antigen binding. This process ensures that the initial illness (e.g., influenza A) lasts only 5 to 10 days. On re-exposure to the same antigen, the already sensitized B-cell makes large amounts of the IgG type of antibody against that antigen. Although IgG does not form groups of five, the enormous amounts produced make IgG antibodies efficient at clearing the antigen and protecting the patient from becoming ill with the disease again.

## Acquiring Antibody-Mediated Immunity

Antibody-mediated IMMUNITY (AMI) is **adaptive immunity** in which a person's body learns to make as an adaptive response to invasion by organisms or foreign proteins. Thus antibody-mediated immunity is an *acquired immunity*. Adaptive immunity occurs either naturally or artificially through lymphocyte responses and can be either active or passive.

*Active immunity* occurs when antigens enter a human and he or she responds by making specific antibodies against the antigen. This type of IMMUNITY is *active* because the body takes an active part in making antibodies.

Natural active IMMUNITY occurs when an antigen enters your body naturally without human assistance and your body responds by actively making antibodies against that antigen (e.g., influenza A virus). Usually the invasion that triggers antibody production also causes the disease. However, processes occurring in your body at the same time as infection create immunity to that antigen so illness does not occur again after a second exposure to the same antigen. *Natural active immunity is the most effective and the longest lasting.*

Artificial active IMMUNITY is the protection developed by vaccination or immunization (Hogue & Meador, 2016). This type of immunity is used to prevent serious and potentially deadly illnesses (e.g., tetanus, diphtheria, polio). Small amounts of specific antigens are placed as a vaccination into your body. Your immune system then responds by actively making antibodies against the antigen. Because antigens used for this procedure have been specially processed to make them less likely to grow in the body (**attenuated**), this exposure usually does not cause the disease. Artificial active immunity lasts many years, although repeated but smaller doses of the original antigen are required as a “booster” to retain the protection.

*Passive IMMUNITY* occurs when the antibodies against an antigen are transferred to a human after first being made in the body of another human or animal. Because these antibodies are foreign to the receiving human, they are recognized as non-self and eliminated quickly. For this reason

passive immunity provides only immediate, short-term protection against a specific antigen. It is used when an adult is exposed to a serious disease for which he or she has little or no actively acquired immunity. Instead the injected antibodies are expected to inactivate the antigen. Artificial passive immunity may be used to prevent disease or death for patients exposed to rabies, tetanus, and poisonous snake bites.

Natural passive IMMUNITY occurs when antibodies are passed from the mother to the fetus via the placenta or to the infant through colostrum and breast milk.

AMI works with inflammation to protect against infection. It provides effective long-lasting IMMUNITY only when its actions are combined with those of cell-mediated immunity.

## NCLEX Examination Challenge 17-1

### Physiological Integrity

Which white blood cell types are involved in the development of antibody-mediated immunity?  
**Select all that apply.**

- A. Basophils
- B. B-lymphocytes
- C. Cytotoxic/cytolytic T-cells
- D. Helper/inducer T-cells
- E. Macrophages
- F. Natural killer cells
- G. Neutrophils

## Cell-Mediated Immunity

Cell-mediated IMMUNITY (CMI), or cellular immunity, involves many white blood cell (WBC) actions and interactions. CMI also is adaptive or acquired true immunity that is provided by lymphocyte stem cells that mature in the secondary lymphoid tissues of the thymus and pericortical areas of lymph nodes (see Fig. 17-7). Certain CMI responses influence and regulate the activities of antibody-mediated immunity (AMI) and innate immunity (inflammation) by producing and releasing cytokines. For total or full immunity, CMI must function optimally.

### Cell Types Involved in Cell-Mediated Immunity

The WBCs with the most important known roles in CMI include several specific T-lymphocytes (T-cells) along with a special population of cells known as *natural killer (NK) cells*. T-cells have a variety of subsets, each of which has a specific function.

Different T-cell subsets can be identified by the presence of “marker proteins” (antigens) on the cell membrane's surface. More than 200 different T-cell proteins have been identified on the cell membrane, and some of these are commonly used clinically to identify specific cells (Abbas et al., 2015). Most T-cells have more than one antigen on their cell membrane. For example, all mature T-cells contain T1, T3, T10, and T11 proteins.

The names that identify specific T-cell subsets include the specific membrane antigen and the overall actions of the cells in a subset. The three T-lymphocyte subsets that are critically important for the development and continuation of CMI are helper/inducer T-cells, suppressor T-cells, and cytotoxic/cytolytic T-cells. The natural killer cell (NK cell) also contributes to CMI.

*Helper/inducer T-cells* have the T4 protein on their membranes. These cells are usually called *T4+ cells* or *T<sub>H</sub> cells*. The most correct name for helper/inducer T-cells is *CD4+* (cluster of differentiation 4).

Helper/inducer T-cells easily recognize self cells versus non-self cells. When they recognize non-self (antigen), helper/inducer T-cells secrete cytokines that can enhance the activity of other WBCs

and increase overall immune function. These cytokines increase bone marrow production of stem cells and speed up their maturation. Thus helper/inducer T-cells act as organizers in “calling to arms” various squads of WBCs involved in inflammatory, antibody, and cellular protective actions.

*Suppressor T-cells* have the T8-lymphocyte antigen on membrane surfaces. These cells are commonly called *T8+ cells*, *CD8+ cells*, or *T<sub>S</sub>-cells*. Suppressor T-cells help regulate CMI.

Suppressor T-cells prevent **hypersensitivity** (IMMUNITY *overreactions*) on exposure to non-self cells or proteins. This action prevents the formation of antibodies directed against normal, healthy self cells, which is the basis for many autoimmune diseases. The suppressor T-cells secrete cytokines that have an overall *inhibitory* action on most cells of the immune system.

Suppressor T-cells have the opposite action of helper/inducer T-cells. For optimal CMI, then, a balance between helper/inducer T-cell activity and suppressor T-cell activity must be maintained. This balance occurs when the helper/inducer T-cells outnumber the suppressor T-cells by a ratio of 2 : 1. When this ratio increases, indicating that helper/inducer T-cells vastly outnumber the suppressor cells, overreactions can occur, some of which are both tissue damaging and unpleasant. When the helper/suppressor ratio decreases, indicating fewer-than-normal helper/inducer T-cells, IMMUNITY is suppressed, and the person's risk for infections increases.

*Cytotoxic/cytolytic T-cells* are also called *T<sub>C</sub>-cells*. Because they have the T8 protein present on their surfaces, they are a subset of suppressor cells. Cytotoxic/cytolytic T-cells destroy cells that contain a processed antigen's human leukocyte antigens (HLAs). This activity is most effective against self cells infected by parasites such as viruses or protozoa.

Parasite-infected self cells have both self HLA proteins (universal product code) and the parasite's antigens on the cell surface. This allows immune system cells to recognize the infected self cell as abnormal; and the cytotoxic/cytolytic T-cell can bind to it, punch a hole, and deliver a “lethal hit” of enzymes to the infected cell, causing it to lyse and die.

*Natural killer (NK) cells* are also known as *CD16+ cells* and are very important in providing CMI. These cells have direct cytotoxic effects on some non-self cells without first being sensitized. They conduct “seek and destroy” missions in the body to eliminate non-self cells. The NK cells are most effective in destroying unhealthy or abnormal self cells such as cancer cells and virally infected body cells (Kannan et al., 2014).

## Cytokines

Cell-mediated IMMUNITY (CMI) regulates the immune system by producing cytokines. **Cytokines** are small protein hormones produced by the many WBCs (and some other tissues). Cytokines made by the macrophages, neutrophils, eosinophils, and monocytes are called **monokines**. Those produced by T-cells are called **lymphokines**. In addition, many other body cell types can produce and respond to cytokines.

Cytokines work like hormones: one cell produces a cytokine, which in turn exerts its effects on other cells of the immune system and on other body cells. The cells responding to the cytokine may be located close to or remote from the cytokine-secreting cell. Thus cytokines act like “messengers” that tell specific cells how and when to respond. The cells that change their activity when a cytokine is present are “responder” cells. For a responder cell to respond to the presence of a cytokine, the responder cell must have a specific receptor to which the cytokine can bind. Once the cytokine binds to its receptor, the responder cell changes its activity.

Cytokines control many inflammatory and immune responses and are controlled by interactions with other systems. Cytokines include the interleukins (ILs), interferons (INFs), colony-stimulating factors, tumor necrosis factor (TNFs), and transforming growth factors (TGFs). The interleukins are the largest group of cytokines, with interleukin-33 (IL-33) being the most recently defined (Abbas et al., 2015). Some cytokines have families and other classifications. Some cytokines are “proinflammatory” and increase the actions of natural immunity (inflammation). These currently include TNF- $\alpha$ , IL-1, IL-10, IL-12, and interferons ( $\alpha$  [alpha],  $\beta$  [beta], and  $\gamma$  [gamma]). Other cytokines have a major influence on AMI and CMI activities. These include IL-2, IL-4, IL-5, IL-10, TGF- $\beta$ , and INF- $\gamma$ . Although there are many cytokines, not all functions are known or clinically useful at this time. Table 17-4 lists the cytokines that have current clinical importance. Chapters discussing specific diseases (e.g., lymphoma, rheumatoid arthritis) caused by or treated with certain cytokines have more information about the role of specific cytokines in the disease and its treatment.

**TABLE 17-4****Activity of Selected Cytokines**

CYTOKINE	ACTIONS
<b>Pro-inflammatory Cytokines</b>	
Interleukin-1 (IL-1)	Induces fever Stimulates production of prostaglandins Increases growth of CD4 <sup>+</sup> T-cells
Interleukin-2 (IL-2)	Increases growth and differentiation of T-lymphocytes Enhances natural killer cell activity against cancer cells
Interleukin-6 (IL-6)	Stimulates liver to produce fibrinogen and protein C Increases rate of bone marrow production of stem cells Increases numbers of sensitized B-lymphocytes
Tumor necrosis factor (TNF)	Induces fever Major cytokine involved in rheumatoid arthritis damage Major cytokine involved in the acute inflammatory response to infectious bacteria and starts many of the systemic complications of severe infection or sepsis Participates in graft rejection Induces cell death Stimulates delayed hypersensitivity reactions and allergy
<b>Growth Factors</b>	
Granulocyte colony-stimulating factor (G-CSF)	Increases numbers and maturity of neutrophils
Granulocyte-macrophage colony-stimulating factor (GM-CSF)	Increases growth and maturation of myeloid stem cells
Erythropoietin	Increases growth and differentiation of erythrocytes
Thrombopoietin	Increases growth and differentiation of platelets

**Protection Provided by Cell-Mediated Immunity**

Cell-mediated IMMUNITY (CMI) helps protect the body through the ability to differentiate self from non-self. The non-self cells most easily recognized by CMI are cancer cells and self cells infected by organisms that live within host cells, especially viruses. CMI watches for and rids the body of self cells that might potentially harm the body. *CMI is important in preventing the development of cancer and metastasis after exposure to carcinogens.*

**NCLEX Examination Challenge 17-2****Health Promotion and Maintenance**

A client has a white blood cell change in which the number of suppressor T-cells is way below normal and asks the nurse which type of health problem(s) could be expected as a result of this deficiency. What is the nurse's **best** response?

- "You will need to receive booster vaccinations more often because your ability to make antibodies is reduced."
- "Try to avoid crowds and people who are ill because you are now more susceptible to bacterial and viral infections."
- "You will be more prone to allergic reactions when exposed to allergens or drugs."
- "Your risk for cancer development is increased."

## Age-Related Changes in Immunity

Many IMMUNITY changes occur in older adults that reduce protection and increase risk for infection and the development of autoimmune diseases. These changes occur in both general immunity and in specific immunity. Review [Chart 17-1](#) for nursing implications related to reduced immunity in the older adult.

Normal flora (microbiome) of skin, mucous membranes, and the GI tract change; and overgrowth of more pathogenic organisms occurs ([Touhy & Jett, 2016](#)). The number of neutrophils and macrophages are reduced, as are their functions. As a result, some of the normal responses to infection and injury are reduced. The older adult may not have a fever or any temperature elevation even with severe infection. The usual response of an increased white blood cell (WBC) count is delayed or absent. The number of toll-like receptors (TLRs) decreases ([McCance et al., 2014](#)). These changes result in less recognition of pathogens and an increase in the risk for infections of all types. In addition, because some of the usual responses are absent, identification and management of infection may be delayed until sepsis is present.

Changes in specific immune function include lower T-cell function (although lymphocyte numbers do not decrease). B-lymphocytes take longer to become sensitized and begin to make antibodies to new antigen exposures. Memory cells are much slower to respond to re-exposure of antigens. For these reasons repeat vaccinations to boost specific immunities developed in childhood are needed for older adults. With the loss of recognition of self, the amount of circulating autoantibodies increases, increasing the risk for autoimmune diseases in older adults ([McCance et al., 2014](#)).

### Clinical Judgment Challenge 17-1

#### Safety; Patient-Centered Care QSEN

When reviewing the vaccination record of a 74-year-old patient who has a chronic pulmonary disease, you note that, although he gets a flu shot every year and received the pneumonia vaccination 3 years ago, he has not received the pertussis (whooping cough) booster since he was 10 years old. When you recommend that he receive one now, he asks why.

1. Which type of immunity was provided by his previous pertussis vaccinations? Explain your choice.
2. What would another pertussis vaccination do for him now?
3. How will you answer his question? Provide a rationale for your response.

## Transplant Rejection

Transplant rejection is caused by general and specific immunity functions of a host directed against tissues and organs transplanted from other people. Host natural killer (NK) cells and cytotoxic/cytolytic T-cells are the major cells responsible for the destructive attacks on transplanted organs (*grafts*) leading to host rejection of these helpful tissues. Because the solid organ transplanted into the recipient (host) is seldom a perfectly identical match of human leukocyte antigens (HLAs) (unless the organ is obtained from an identical sibling) between the donated organ and the recipient host, the patient's immune system cells recognize a newly transplanted organ as non-self. Without intervention, the recipient's immune system starts immunologic actions that destroy these non-self cells, leading to rejection of the transplanted organ. Rejection is a complex series of responses that change over time and involve different components of IMMUNITY. Rejection can be hyperacute, acute, or chronic.

### Hyperacute Rejection

*Hyperacute rejection* begins immediately on transplantation and is a result of antigen-antibody complexes that form in the blood vessels of the transplanted organ (Abbas et al., 2015). The recipient's blood has pre-existing antibodies to the antigens (including blood group antigens) present in the donated organ. The antigen-antibody complexes adhere to the lining of blood vessels and activate complement, which triggers small blood clots to form throughout the new organ. Widespread clotting occludes blood vessels and leads to ischemic necrosis, inflammation with phagocytosis of the necrotic blood vessels, and release of enzymes into the new organ. The enzymes cause massive cellular destruction within the transplanted organ.

Hyperacute rejection occurs mostly in transplanted kidneys but is less common now with better HLA matching. Symptoms of rejection are apparent within minutes of attachment of the donated organ to the recipient's blood supply. The process usually cannot be stopped once it has started, and the rejected organ is removed as soon as hyperacute rejection is diagnosed.

### Acute Rejection

*Acute rejection* first occurs within 1 week to 3 months after transplantation and sporadically after that as a result of two mechanisms. The first mechanism is antibody mediated and results in vasculitis within the transplanted organ. This reaction differs from hyperacute rejection in that blood vessel necrosis (not occlusion) leads to organ destruction.

The second mechanism is cellular. The recipient's cytotoxic/cytolytic T-cells and NK cells enter the transplanted organ through the blood, penetrate the organ cells, start an inflammatory response, and cause lysis of the organ cells.

Diagnosis of acute rejection is made by laboratory tests that show impaired function of the donated organ and by biopsy of the donated organ. Symptoms of acute rejection vary with each patient and with the specific organ transplanted. For example, when acute rejection occurs in a transplanted kidney, the patient usually has some tenderness in the kidney area and may have other general symptoms of inflammation.

*An episode of acute rejection after solid organ transplantation does not automatically mean that the patient will lose the new organ.* Drug management of the recipient's immune responses at this time may limit the damage to the organ and allow the graft to be maintained.

### Chronic Rejection

The origin of *chronic rejection* is related to chronic inflammation and scarring. The smooth muscles of arteries overgrow and occlude these vessels (Abbas et al., 2015). The organ tissues are replaced with fibrotic, scarlike tissue, and function is reduced in proportion to the amount of scarring. This type of reaction is long-standing and occurs continuously as a response to chronic ischemia caused by blood vessel injury. The results of chronic rejection are unique to different transplanted organs. For example, in transplanted lungs chronic rejection thickens small airways. In transplanted livers chronic rejection destroys bile ducts. In transplanted hearts this process is called *accelerated graft atherosclerosis (AGA)* and is the major cause of death in patients who have survived 1 or more years

after heart transplantation.

Although good control over the recipient's immune function can delay this type of rejection, the process probably occurs to some degree with all transplanted solid organs obtained from donors who are not identical siblings of the recipients. Because the fibrotic changes are permanent, there is no cure for chronic graft rejection. When the fibrosis increases to the extent that the transplanted organ can no longer function, the only recourse is retransplantation.

## Management of Transplant Rejection

Rejection of transplanted solid organs involves all three components of IMMUNITY, although cell-mediated immune (CMI) responses contribute the most to the rejection process. Approved drugs used to manage transplant rejection are listed in [Chart 17-2](#).

**Chart 17-2**

### Common Examples of Drug Therapy

#### Drugs to Prevent Transplant Rejection

DRUG/CLASS	ROUTE	SIDE EFFECTS
<b>Corticosteroids</b> —Broadly inhibit cytokine production in most leukocytes, resulting in generalized immunosuppression		
Prednisone (Deltasone)	Oral	Hypertension Hyperlipidemia Osteoporosis Weight gain Cushingoid appearance Opportunistic infection Glaucoma GI ulcer formation Hyperglycemia
Prednisolone (Millipred, Orapred, Veripred)	Oral	Same as for prednisone
<b>Calcineurin Inhibitors</b> —The inhibition of calcineurin stops the production and secretion of IL-2, which then prevents the activation of lymphocytes involved in transplant rejection		
Cyclosporine (Sandimmune, Neoral, Gengraf)	Oral	Nephrotoxic Hypertension Tremor Coronary artery disease Hirsutism Gingival hyperplasia Opportunistic infections Malignancies Hyperuricemia Hepatotoxicity
Tacrolimus (Astagraf XL, HECORIA, Prograf)	Oral	Nephrotoxic Hypertension Hyperkalemia Hypomagnesemia Hyperglycemia Opportunistic infections Malignancies
<b>Antiproliferatives</b> —The main action of all antiproliferatives is to inhibit something essential to DNA synthesis, which prevents cell division in activated lymphocytes. Some have additional immune suppressive actions		
Azathioprine (Azasan, Imuran)	Oral	Bone marrow suppression Thrombocytopenia Anemia Pancreatitis Hepatotoxicity Malignancies
Mycophenolate (CellCept, Myfortic)	Oral	Leucopenia Thrombocytopenia Nausea Opportunistic infection Malignancies
Sirolimus (Rapamune)	Oral	Leucopenia Thrombocytopenia Hypercholesterolemia Hypertriglyceridemia
Everolimus (Afinitor, Zortress)	Oral	Acne GI upsets Hepatotoxicity Cushingoid appearance Gingival hyperplasia Hyperglycemia Hyperlipidemia Hypertension Leucopenia
<b>Monoclonal Antibodies</b> —Specifically target the activation sites of T-lymphocytes, increasing their elimination from circulation		
Muromonab-CD3 (Orthoclone OKT3)	IV	Systemic inflammatory responses Aseptic meningitis Opportunistic infections Malignancies Hypersensitivity reactions
Basiliximab (Simulect)	IV	GI disturbances
Daclizumab (Zenapax)	IV	GI disturbances
<b>Polyclonal Antibodies</b> —Antibodies derived from other animals (horses, rabbits, rats) that bind to and eliminate most T-lymphocytes, thus stopping a transplant rejection episode		
Antithymocyte globulin—equine (Atgam)	IV	Leukopenia Serum sickness Thrombocytopenia Pruritus Fever Arthralgias Opportunistic infections Malignancies
Antithymocyte globulin—rabbit (RATG, Thymoglobulin)	IV	Same as for antithymocyte globulin—equine

*Maintenance therapy* is the continuous immunosuppression used after a solid organ transplant. The drugs used for routine therapy after solid organ transplantation are combinations of a calcineurin inhibitor, a corticosteroid, and an antiproliferative agent (Allison, 2016). Corticosteroids cause a general immunosuppression, which leave the patient at greater risk for infection. Although corticosteroids remain a part of therapy, the dosages are lower than in the past. Calcineurin inhibitors and antiproliferative agents are part of “selective immunosuppressant” therapy (Allison, 2016; Burchum & Rosenthal, 2016). These drugs more specifically target immunity components that are responsible for rejection. Which drugs are used depends on the transplant type and other patient-specific conditions. These are all oral agents and must be taken for the life of the transplanted organ. All are immunosuppressive to some degree, and the dosage is adjusted to the immune response of each patient. Treatment with these agents increases the risk for bacterial and fungal infections and for cancer development.

*Rescue therapy* is used to treat acute rejection episodes. The drug categories for this purpose are the monoclonal and polyclonal antibodies (see Chart 17-2). The drugs used for maintenance are often also used during rejection episodes at much higher dosages than for maintenance (Allison, 2016; Burchum & Rosenthal, 2016).

# Get Ready for the NCLEX® Examination!

## Key Points

Review the following key points for each NCLEX Examination Client Needs Category.

### Health Promotion and Maintenance

- Remind adults, especially older adults, that vaccinations providing artificial active IMMUNITY require periodic “boosting” for best long-term effects.
- Remember that older adults may not have typical symptoms of infection or responses to tests as a result of reduced IMMUNITY.

### Physiological Integrity

- Use the differential of the WBC count to determine the patient's risk for infection, the presence or absence of infection, the presence or absence of an allergic reaction, and whether an infection is bacterial or viral.
- Remind patients who receive transplanted organs (unless from an identical sibling) about the need to take immunosuppressive drugs daily to prevent transplant rejection.
- Teach patients who take immunosuppressive drugs long term that they have an increased risk for infection and cancer development.

## CHAPTER 18

# Care of Patients With Arthritis and Other Connective Tissue Diseases

Roberta Goff, Kathy Vanderbeck

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concepts for this chapter are:**

- MOBILITY
- IMMUNITY

✚ The MOBILITY concept exemplar for this chapter is Osteoarthritis, p. 305.

✚ The IMMUNITY concept exemplar for this chapter is Rheumatoid Arthritis, p. 318.

**The interrelated concepts for this chapter are:**

- COMFORT
- CLOTTING

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with members of the interprofessional team to ensure quality care for patients with arthritis and other connective tissue diseases (CTDs).
2. Use clinical judgment to prioritize evidence-based interventions for patients with osteoarthritis (OA) and rheumatoid arthritis (RA) to promote MOBILITY.
3. Prioritize nursing interventions to help prevent and monitor for postoperative complications of total joint arthroplasty, including impaired CLOTTING, joint dislocation, and infection.

### Health Promotion and Maintenance

4. Identify community resources to help patients achieve or maintain ADL independence and MOBILITY.
5. Teach patients evidence-based strategies for how to prevent osteoarthritis.
6. Teach patients how to prevent Lyme disease and detect it early if it occurs.

### Psychosocial Integrity

7. Assess the patient's and family's response to arthritis or other CTD, their support systems, and available resources.
8. Assess the patient's and family's sources of stress and coping mechanisms when living with arthritis or other CTD.

### Physiological Integrity

9. Interpret laboratory findings for patients with RA and other CTDs that affect IMMUNITY.
0. Assess presence and extent of pain and suffering in patients with arthritis.
1. Teach patients and their families about the postoperative care required after a total joint arthroplasty, including promotion of COMFORT.
2. Describe the nursing implications associated with drug therapy for patients with RA and other CTDs.
3. Select nursing interventions for patients who have systemic sclerosis.
4. Apply knowledge of pathophysiology to plan patient-centered collaborative care of patients

with gout.

5. Outline current treatment strategies for patients with fibromyalgia syndrome and psoriatic arthritis.

**Connective tissue disease (CTD)** is the major focus of *rheumatology*, the study of rheumatic disease. A **rheumatic disease** is any disease or condition involving the musculoskeletal system. In this text CTDs are discussed separately from other musculoskeletal conditions because most CTDs are classified as autoimmune disorders. In autoimmune disease, antibodies attack healthy normal cells and tissues. For reasons that are unclear, the immune system does not recognize body cells as self and therefore triggers an immune response. The usual *protective* nature of the immune system does not function properly in patients with autoimmune CTDs.

Most common CTDs are characterized by chronic pain and progressive joint deterioration, which results in decreased functional ability and impaired MOBILITY. Some of these disorders have additional localized signs and symptoms, whereas others are systemic. The economic and social costs of these diseases are staggering and will increase steadily as “baby boomers” continue to age. Patient care usually requires an interprofessional approach, including medicine, nursing, rehabilitation therapy, pharmacy, case management, and/or surgery.

**Arthritis** means inflammation of one or more joints. However, in clinical practice arthritis is categorized as either noninflammatory or inflammatory. The major exemplar for the concept of MOBILITY is osteoarthritis (OA), a noninflammatory, localized disorder. OA is not an autoimmune disease. The major exemplar for IMMUNITY is rheumatoid arthritis (RA), a systemic, inflammatory disorder. These priority concepts are reviewed briefly in [Chapter 2](#).

## ▣ Mobility Concept Exemplar Osteoarthritis

### ❖ Pathophysiology

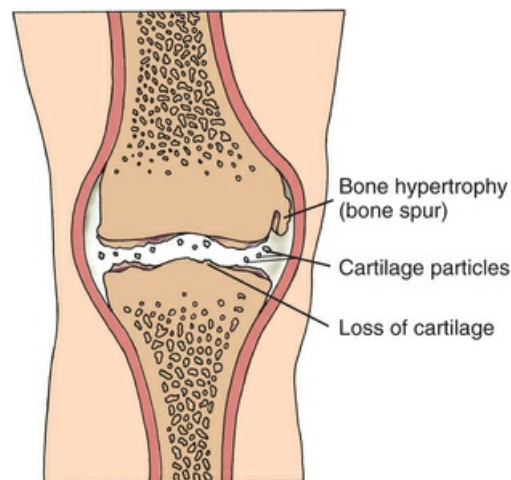

Osteoarthritis is the most common arthritis and a major cause of impaired MOBILITY and disability among adults in the United States and the world. It is sometimes referred to as *osteoarthrosis* or *degenerative joint disease (DJD)*, although osteoarthritis is not always degenerative.

**Osteoarthritis** is the progressive deterioration and loss of cartilage and bone in one or more joints. Articular cartilage, also known as *hyaline cartilage*, contains water and a matrix of:

- Proteoglycans (glycoproteins containing chondroitin, keratin sulfate, and other substances)
- Collagen (elastic substance)
- Chondrocytes (cartilage-forming cells)

As people age or experience joint injury, proteoglycans and water decrease in the joint. The production of synovial fluid, which provides joint lubrication and nutrition, also declines because of the decreased synthesis of hyaluronic acid and less body fluid in the older adult (McCance et al., 2014).

In patients of any age with OA, enzymes such as stromelysin break down the articular matrix. In early disease the cartilage changes from its normal bluish white, translucent color to an opaque and yellowish brown appearance. As cartilage and the bone beneath the cartilage begin to erode, the joint space narrows, and **osteophytes** (bone spurs) form (Fig. 18-1). As the disease progresses, fissures, calcifications, and ulcerations develop; and the cartilage thins. Inflammatory cytokines (enzymes) such as interleukin-1 (IL-1) enhance this deterioration. The body's normal repair process cannot overcome the rapid process of degeneration (McCance et al., 2014). Secondary joint inflammation can occur when joint involvement is severe.

**FIG. 18-1** Joint changes in osteoarthritis.

Eventually the cartilage disintegrates, and pieces of bone and cartilage “float” in the diseased joint, causing **crepitus**, a grating sound caused by the loosened bone and cartilage. The resulting joint pain and stiffness can lead to decreased MOBILITY and muscle atrophy. Muscle tissue helps support joints, particularly those that bear weight (e.g., hips, knees).

### **Etiology and Genetic Risk**

The cause of OA is a combination of many factors. For patients with *primary* OA, the disease is caused by aging and genetic factors. Weight-bearing joints (hips and knees), the shoulders, the vertebral column, and the hands are most commonly affected, probably because they are used most often or bear the mechanical stress of body weight and many years of use.

*Secondary* OA occurs less often than primary disease and results from joint injury and obesity. Injury to the joints from excessive use, trauma, or other joint disease (e.g., rheumatoid arthritis)

predisposes a person to OA. Heavy manual occupations (e.g., carpet laying, construction, farming) cause high-intensity or repetitive stress to the joints. The risk for hip and knee OA is increased in professional and amateur athletes, especially football players, runners, and gymnasts. Fractures or other joint tissue injuries can lead to OA years after the trauma. Certain metabolic diseases (e.g., diabetes mellitus, Paget's disease of the bone) and blood disorders (e.g., hemophilia, sickle cell disease) can also cause joint degeneration.

Obesity is a common contributing factor to OA. Weight-bearing joints such as hips and knees are most often affected in obese people.

## Incidence and Prevalence

The prevalence of OA varies among different populations but is a universal problem. Most people older than 60 years have joint changes that can be seen on x-ray examination, although not all of these adults actually develop the disease. According to the [Arthritis Foundation \(2016a\)](#) estimates, 27 million people in the United States have symptomatic OA.

## Gender Health Considerations

### Patient-Centered Care QSEN

More men than women younger than 55 years have OA caused by athletic injuries. After age 55 women have the disease more often than men. Although the cause for this difference is not known, contributing factors may include increased obesity in women after having children and broader hips in women than men (Arthritis Foundation, 2016a).

Lesbian women have a high risk for OA because they are more likely to be overweight or obese when compared with other groups of women. Although the reason for this difference is not known, it is possible that lesbian women use food as a coping strategy because many have fears and concerns about “coming out” about their sexual orientation, especially to health care professionals and family members (Pettinato, 2012). Be sure to assess all patients in the hospital or community-based setting, particularly those who are older and obese, for signs and symptoms of OA.

## Health Promotion and Maintenance

Based on the etiology of OA, teach patients to:

- Maintain proper nutrition to prevent obesity.
- Take care to avoid injuries, especially those that can occur from professional or amateur sports.
- Take adequate work breaks to rest joints in jobs where repetitive motion is common.
- Stay active and maintain a healthy lifestyle.

## Interprofessional Collaborative Care

### Assessment: Noticing

#### History.

Patients with OA usually seek medical attention in ambulatory care settings for their joint pain. However, you will also care for those who have OA as a secondary diagnosis in acute and chronic care facilities. Ask the patient about the course of the disease. Collect information specifically related to OA such as the nature and location of joint pain and how much pain and suffering he or she is experiencing. *Remember that older patients may underreport pain, resulting in inadequate management.* Use a 0-to-10 scale or other assessment tool to assess pain intensity. [Chapter 4](#) discusses pain assessment in detail.

Other questions to ask include:

- If joint stiffness has occurred, where and for how long?
- When and where has any joint swelling occurred?
- How much discomfort are you having?

- How much is your impaired COMFORT disrupting your daily life?
- What do you do to control the discomfort, pain, or stiffness?
- Do you have any loss of MOBILITY or difficulty in performing ADLs?

Because this disease occurs more often in older women, age and gender are important factors for the nursing history. Ask patients about their occupation, nature of work, history of injury (including falls), weight history, and current or previous involvement in sports. A history of obesity is significant, even for those currently within the ideal range for body weight. Document any family history of arthritis. Determine whether the patient has a current or previous medical condition that may cause joint symptoms.

### Physical Assessment/Signs and Symptoms.

In the early stage of the disease the signs and symptoms of OA may appear similar to those of rheumatoid arthritis (RA). The distinction between OA and RA becomes more evident as the disease progresses. Table 18-1 compares the major characteristics of both diseases and their common drug therapy.

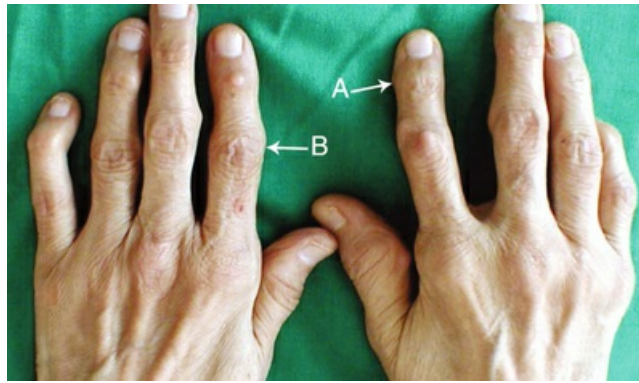

**TABLE 18-1**  
**Differential Features of Rheumatoid Arthritis and Osteoarthritis**

CHARACTERISTIC	RHEUMATOID ARTHRITIS	OSTEOARTHRITIS
Typical onset (age)	35-45 yr	Older than 60 yr
Gender affected	Female (3 : 1)	Female (2 : 1)
Risk factors or cause	Autoimmune (genetic basis) Emotional stress (triggers exacerbation) Environmental factors	Aging Genetic factor (possible) Obesity Trauma Occupation
Disease process	Inflammatory	Likely degenerative with secondary inflammation
Disease pattern	Bilateral, symmetric, multiple joints Usually affects upper extremities first Distal interphalangeal joints of hands spared Systemic	May be unilateral, single joint Affects weight-bearing joints and hands, spine Metacarpophalangeal joints spared Nonsystemic
Laboratory findings	Elevated rheumatoid factor, antinuclear antibody, and ESR	Normal or slightly elevated ESR
Common drug therapy	NSAIDs (short-term use) Methotrexate Leflunomide (Arava) Corticosteroids Biological response modifiers Other immunosuppressive agents	NSAIDs (short-term use) Acetaminophen Other analgesics

ESR, Erythrocyte sedimentation rate.

The typical patient with OA is a middle-age or older woman who reports *chronic joint pain and stiffness*. Early in the course of the disease, the pain diminishes after rest and worsens after activity. Later, impaired COMFORT occurs with slight motion or even when at rest. Because cartilage has no nerve supply, the pain is caused by joint and soft-tissue involvement and spasms of the surrounding muscles. During the joint examination the patient may have tenderness on palpation or when putting the joint through range of motion. **Crepitus** may be felt or heard as the joint goes through range of motion. One or more joints may be affected. The patient may also report joint stiffness that usually lasts *less than 30 minutes* after a period of inactivity.

On inspection the joint is often enlarged because of bony hypertrophy. The joint feels hard on palpation. The presence of inflammation in patients with OA indicates a secondary synovitis. About half of patients with hand involvement have **Heberden's nodes** (bony nodules at the distal interphalangeal [DIP] joints) and **Bouchard's nodes** (bony nodules at the proximal interphalangeal [PIP] joints) (Fig. 18-2). Although OA is *not* typically a bilateral, symmetric disease, these large bony nodes appear on both hands, especially in women. The nodes may be painful and red. Some patients experience impaired COMFORT when developing nodes or when nodes are palpated. These deformities tend to be familial and are often a cosmetic concern to patients.

**FIG. 18-2** Heberden's and Bouchard's nodes are enlarged bony nodules affecting the joints of the hand.  
(From Sainani, G. S. [2010]. *Manual of clinical and practical medicine*. New Delhi: Elsevier India.)

*Joint effusions* (excess joint fluid) are common when the knees are inflamed. Observe any *atrophy of skeletal muscle* from disuse. The vicious cycle of the disease discourages the movement of painful joints, which may result in contractures, muscle atrophy, and further pain. *Loss of function* or decreased MOBILITY may result, depending on which joints are involved. Hip or knee pain may cause the patient to limp and restrict walking distance.

OA can affect the spine, especially the lumbar region at the L3-4 level or the cervical region at C4-6 (neck). Compression of spinal nerve roots may occur as a result of vertebral facet bone spurs. The patient typically reports radiating pain, stiffness, and muscle spasms in one or both extremities.

Severe pain and deformity interfere with ambulation and self-care. In addition to performing a musculoskeletal assessment, collaborate with the physical and occupational therapists to conduct a functional assessment. Assess the patient's MOBILITY and ability to perform ADLs. [Chapter 6](#) describes functional assessment.

### Psychosocial Assessment.

OA is a chronic condition that may cause permanent changes in lifestyle. An inability to care for oneself in advanced disease can result in role changes and other losses. Constant pain interferes with quality of life, including sexuality. Patients may not have the energy for sexual intercourse or may find positioning uncomfortable.

Patients with continuous pain from arthritis may develop depression or anxiety. The patient may also have a role change in the family, workplace, or both. To identify changes that have been or need to be made, ask about his or her roles before the disease developed. Identify coping strategies to help live with the disease. Ask the patient about his or her expectations regarding treatment for OA.

In addition to role changes, joint deformities and bony nodules often alter body image and self-esteem. Observe the patient's response to body changes. Does he or she ignore them or seem overly occupied with them? Ask patients directly how they perceive their body image. Document your assessment findings in the interprofessional health record per agency policy.

### Laboratory Assessment.

The primary health care provider uses the history and physical examination to make the diagnosis of OA. The results of routine laboratory tests are usually normal but can be helpful in screening for associated conditions. The erythrocyte sedimentation rate (ESR) and high-sensitivity C-reactive protein (hsCRP) may be slightly elevated when secondary synovitis occurs. The ESR also tends to rise with age, infection, and other inflammatory disorders.

### Imaging Assessment.

Routine x-rays are useful in determining structural joint changes. Specialized views are obtained when the disease cannot be visualized on standard x-ray film but is suspected. Magnetic resonance imaging (MRI) and computed tomography (CT) may be used to determine vertebral or knee involvement.

### ◆Analysis: Interpreting

The priority collaborative problems for patients with osteoarthritis (OA) include:

1. Chronic pain due to joint swelling and deterioration
2. Potential for decreased MOBILITY due to joint pain and muscle atrophy

### ◆ **Planning and Implementation: Responding**

In 2010 the Osteoarthritis Research Society International (OARSI) committee updated its evidence-based expert consensus guidelines for patients with knee, hand, and hip OA (Zhang et al., 2010). These interprofessional best practice guidelines remain the most current except for nonsurgical management for OA of the knee, which were updated in 2014 (McAlindon et al., 2014). The OARSI clinical guidelines have major implications for nursing care as described in the following section.

## **Managing Chronic Pain**

### **Planning: Expected Outcomes.**

The patient with OA is expected to have a COMFORT level that is acceptable to the patient (e.g., at a 3 or less on a pain intensity scale of 0 to 10).

### **Interventions.**

No drug therapy can influence the course of OA. Optimal management of patients with OA requires a multimodal approach (combination of therapies) to manage pain. Perform a pain assessment before and after implementing interventions.

### **Nonsurgical Management.**

Management of chronic joint pain can be challenging for both the patient and the health care professional. Drug therapy and a variety of nonpharmacologic therapies are used to manage the patient with OA. Chapter 4 elaborates on interventions for chronic noncancer pain.

### **Drug Therapy.**

The purpose of drug therapy is to reduce pain and inflammation caused by cartilage destruction, muscle spasm, and/or synovitis. The American Pain Society, American Geriatrics Society, and OARSI committee recommend regular *acetaminophen* (Tylenol, Atasol) as the primary drug of choice because OA is not a primary anti-inflammatory disorder (Lilley et al., 2014).

## **Nursing Safety Priority** QSEN

### **Drug Alert**

The standard ceiling dose of acetaminophen is 4000 mg each day. However, patients may be at risk for liver damage if they take more than 3000 mg daily, have alcoholism, or have liver disease. *Older adults are particularly at risk because of normal changes of aging such as slowed excretion of drug metabolites.* Remind patients to read the labels of over-the-counter (OTC) or prescription drugs that could contain acetaminophen before taking them. Teach them that their liver enzyme levels may be monitored while taking this drug.

*Topical drug applications* may help with temporary relief of impaired COMFORT. Prescription lidocaine 5% patches (Lidoderm) have been approved by the Federal Drug Administration (FDA) for postherpetic neuralgia (nerve pain) but may also relieve joint pain (especially the knee) for some patients. Teach the patient to apply the patch on clean, intact skin for 12 hours each day. Up to three patches may be applied to painful joints at one time. Remind him or her that Lidoderm can cause skin irritation. Teach the patient that the lidocaine patch is contraindicated in patients taking class I antidysrhythmics. Topical salicylates such as OTC Aspercreme patch, gel, or cream, are useful for some patients as a temporary pain reliever, especially for knee pain. Buspirone HCl (Buspar) topical cream may also relieve local joint pain for some patients.

If acetaminophen or topical agents do not relieve discomfort, the analgesic drug class of choice is NSAIDs if the patient can tolerate them. These traditional drugs supported by OARSI guidelines

include oral COX-2 nonselective and selective NSAIDs and topical NSAIDs.

Before beginning oral NSAID therapy, baseline laboratory information is obtained, including a complete blood count (CBC) and kidney and liver function tests. Celecoxib (Celebrex), a COX-2 inhibitor, is usually the first choice unless the patient has hypertension, kidney disease, or cardiovascular disease.

## Nursing Safety Priority QSEN

### Drug Alert

All of the COX-2 inhibiting drugs are thought to cause cardiovascular disease such as myocardial infarction and kidney problems. Older NSAIDs such as ibuprofen can cause severe GI side effects, bleeding, and acute kidney failure. Therefore they are prescribed at the lowest effective dose for a short period of time. Teach your patient about adverse effects from NSAIDs and the need to report them to his or her primary health care provider. Examples include having dark, tarry stools; shortness of breath; edema; frequent dyspepsia (indigestion); **hematemesis** (bloody vomitus); and changes in urinary output.

*Topical NSAIDs* are considered to be safe and effective nonsystemic drugs for pain relief. For example, the diclofenac-epolamine patch and diclofenac solution are used for patients with signs and symptoms associated with knee OA.

When topical or systemic drugs are not effective and for temporary relief of pain in a single joint, the primary health care provider may inject an individual joint with *cortisone*, a commonly used steroid. Patients may have the same joint injected up to four times a year, or once every 3 months. Frequently injected joints include the knee, base of the thumb, shoulder, and trochanteric bursa, which people often call the *hip*.

*Hyaluronic acid (HA)* is an alternative injection for knee and hip pain associated with OA. This lubricating synthetic joint fluid replaces or supplements the body's natural hyaluronic acid, which is broken down by inflammation and aging. The effectiveness of these agents varies, depending on the patient. Current evidence supporting the use of HA is controversial but suggests that it is *least* likely to help patients who are obese, have severe OA, are over 65, and/or have had previous knee injections ([Arthritis Foundation, 2016a](#)).

Other oral drugs that can be given to patients with OA include muscle relaxants and weak opioids. Muscle relaxants such as cyclobenzaprine hydrochloride (Flexeril) are sometimes given for painful muscle spasms, especially those occurring in the back from OA of the vertebral column. *These drugs should be used with caution in older adults because they can cause acute confusion. Remind any patient not to drive or operate dangerous machinery when taking muscle relaxants.* Weak opioid drugs such as tramadol (Ultram or Ultram ER) may also be given for patients with OA. [Chapter 4](#) discusses drug therapy for pain relief in more detail.

## NCLEX Examination Challenge 18-1

### Physiological Integrity

The primary health care provider prescribes acetaminophen for a client with osteoarthritis. Which health teaching will the nurse provide for the client regarding this drug? **Select all that apply.**

- A. "Don't take more than 3000-4000 mg of this drug each day."
- B. "Stop taking the drug if unusual bleeding occurs and call your primary health care provider."
- C. "Tell your primary health care provider if you notice any yellowing of your skin or eyes."
- D. "Expect fluid accumulation in your legs and feet that usually gets worse during the day."
- E. "Check over-the-counter drugs to see if they contain acetaminophen."

### Nonpharmacologic Interventions.

In addition to analgesics, many nonpharmacologic measures can be used for patients with OA such as rest balanced with exercise, joint positioning, heat or cold applications, weight control, and a variety of complementary and integrative therapies. In addition, *stem cell therapy* is being used for knee OA to repair damaged cartilage.

Teach the patient to *position joints in their functional position*. For example, when in a supine position (recumbent), he or she should use a small pillow under the head or neck but avoid the use of other pillows. The use of large pillows under the knees or head may result in flexion contractures. Remind him or her to use proper posture when standing and sitting to reduce undue strain on the vertebral column. Teach the patient to wear supportive shoes; foot insoles may help relieve pressure on painful metatarsal joints. Collaborate with the physical therapist (PT) to plan a program for muscle-strengthening exercises to better support the joints.

Many patients apply *heat or cold* for temporary relief of pain. Heat may help decrease the muscle tension around the tender joint and thereby decrease pain and stiffness. Suggest hot showers and baths, hot packs or compresses, and moist heating pads. *Regardless of treatment, teach him or her to check that the heat source is not too heavy or so hot that it causes burns*. A temperature just above body temperature is adequate to promote COMFORT.

If needed, collaborate with the PT to provide special heat treatments such as paraffin dips, diathermy (using electrical current), and ultrasonography (using sound waves). A 15- to 20-minute application usually is sufficient to temporarily reduce pain, spasm, and stiffness. Cold packs or gels that feel hot and cold at the same time may also be used.

Cold therapy has limited use for most patients in promoting COMFORT. Cold works by numbing nerve endings and decreasing secondary joint inflammation, if present.

## Nursing Safety Priority QSEN

### Action Alert

Teach the patient to use ice packs that are not too heavy. Do not place them directly on skin; instead wrap them in a towel or soft cloth and apply for a maximum of 20 minutes at a time.

Gradual *weight loss* for obese patients may lessen the stress on weight-bearing joints, decrease pain, and perhaps slow joint degeneration. If needed, collaborate with the registered dietitian to provide more in-depth teaching and meal planning or make referrals to community resources.

### Complementary and Integrative Health.

Some patients with OA have reported that a variety of integrative therapies are useful. However, the evidence supporting their effectiveness is often inconsistent and inconclusive.

Topical *capsaicin* products are safe over-the-counter (OTC) drugs. They work by blocking or modifying substance P and other neurotransmitters for pain. Tell the patient using capsaicin to expect a burning sensation for a short time after applying it. Recommend the use of plastic gloves for application. To prevent burning of eyes or other body areas, wash hands immediately after applying the substance.

Dietary supplements may complement traditional drug therapies. Glucosamine and chondroitin are widely used and are the most effective nonprescription supplements taken to decrease pain and improve functional ability. However, the evidence to support their use is inconsistent (Fouladbakhsh, 2012). These natural products are found in and around bone cartilage for repair and maintenance. **Glucosamine** may decrease inflammation, and **chondroitin** may play a role in strengthening cartilage. These supplements are used topically or taken in oral form. [Chart 18-1](#) summarizes what you should teach your patients about glucosamine, with or without chondroitin.

### Chart 18-1

## Patient and Family Education: Preparing for Self-Management

## Considerations for Taking Glucosamine Supplements

- Tell your primary health care provider if you decide to take glucosamine.
- Do not take glucosamine if you have hypertension.
- Do not take glucosamine if you are pregnant or breast-feeding.
- Monitor for bleeding if you take chondroitin with glucosamine or chondroitin alone if you are on anticoagulant therapy.
- If you have diabetes, monitor your blood glucose levels carefully because taking glucosamine for a prolonged time can increase them.
- Be aware that glucosamine can cause adverse effects such as a rash; GI disturbances, especially diarrhea; drowsiness; and headache.
- Be sure to take the recommended dosage based on your weight.
- Read drug labels to ensure that you do not take too much glucosamine for your weight; some drug names may not indicate they contain glucosamine (e.g., Bioflex, Arth-X Plus, Nutri-Joint).

### Surgical Management.

Surgery may be indicated when conservative measures and/or drug therapy no longer provide pain control, when MOBILITY becomes so restricted that the patient cannot participate in activities he or she enjoys, and when he or she cannot maintain the desired quality of life. The most common surgical procedure for OA is **total joint arthroplasty (TJA)** (surgical creation of a functional joint), also known as **total joint replacement (TJR)**. Almost any synovial joint of the body can be replaced with a prosthetic system that consists of at least two parts—one for each joint surface. The hip and knee are most often replaced, but shoulder arthroplasty is becoming increasingly common as a result of advances in technology. TJAs are expected to increase as baby boomers age over the next 20 years.

TJA is a procedure used most often to manage the pain of OA and improve MOBILITY, although other conditions causing cartilage destruction may require the surgery. These disorders include rheumatoid arthritis (RA), congenital anomalies, trauma, and osteonecrosis. **Osteonecrosis** is bone death secondary to lack of or disruption in blood supply to the affected bone, usually from trauma or chronic steroid therapy. The affected bone site is most commonly the femoral or humeral head, distal femur, and proximal tibia.

The *contraindications* for TJA are active infection anywhere in the body, advanced osteoporosis, and rapidly progressive inflammation. An active infection elsewhere in the body or from the joint being replaced can result in an infected TJA and subsequent prosthetic failure. Advanced osteoporosis can cause bone fracture during insertion of the prosthetic device. Severe medical problems such as uncontrolled diabetes or hypertension put the patient at risk for major postoperative complications and possible death.

### Total Hip Arthroplasty.

The number of total hip arthroplasty (THA) procedures (also known as *total hip replacement [THR]*) has steadily increased over the past 35 years. If the patient has a joint replacement for the first time, it is referred to as **primary arthroplasty**. If the implant loosens or fails for any reason, **revision arthroplasty** may be performed. Availability of improved joint implant materials and better custom design features allow longer life of a replaced hip. Although patients of any age can undergo THA, the procedure is performed most often in those older than 60 years. *The special needs and normal physiologic changes of older adults often complicate the perioperative period and may result in additional postoperative complications.*

### Preoperative Care.

As with any surgery, preoperative care begins with assessing the patient's level of understanding about the surgery and his or her ability to participate in the postoperative plan of care. The surgeon

explains the procedure and postoperative expectations (including possible complications) during the office visit, but this patient education may have occurred weeks or months before the scheduled surgery. Some patients may not know which questions to ask or may forget the important information that was taught. Information may be provided in a notebook or DVD format that the patient can take home to review and share with family. This is particularly useful to patients with poor reading skills or poor memory.

## Cultural/Spiritual Considerations

### Patient-Centered Care

Written materials or other media provided in the language appropriate for the patient's educational level and culture are essential. If an interpreter is needed to be sure that the information is understood, one needs to be provided at each appointment, while in the hospital, and when discharged with home or inpatient rehabilitation services.

Additional preoperative education may be provided, depending on office, hospital, or Joint Replacement Center protocols. In some settings the physical therapist (PT) may teach the patient transfers, positioning, and ambulation and/or assist in building muscle strength before surgery. An occupational therapist (OT) may assess needs for assistive/adaptive equipment that will be needed after surgery. The cost of durable medical equipment (DME) is usually covered by most insurance companies, both Medicare and commercial. The items usually paid for following THA to prevent hip dislocation and promote recovery are a walker and a commode chair. Younger patients may be taught the use of crutches for gait assistance. Any additional equipment such as shower chairs and grab bars is usually not covered by third-party payers but can be privately purchased in medical supply stores or most pharmacies.

Patients need to have any necessary dental procedures done at least 2 weeks before surgery. Once the new joint has been inserted, the patient must take extreme care to avoid or receive immediate care for an infection that could migrate to the surgical area and cause prosthetic failure. *Remind the patient to tell any future health care provider that he or she has had any total joint arthroplasty.*

In addition to usual preoperative laboratory tests, the surgeon may ask the patient with RA to have a cervical spine x-ray if he or she is having general anesthesia. Those with RA often have cervical spine disease that can lead to subluxation during intubation. Hip x-rays, CT scan, and/or MRI may be done to assess the operative joint and surrounding soft tissues, especially if the patient is undergoing a robotic-assisted THA.

Because venous thromboembolism (VTE) is a serious postoperative complication, especially after hip surgery, assess the patient's risk factors for CLOTTING problems, including history of previous clotting, obesity, smoking, limited preoperative MOBILITY, and advanced age. *Teach patients that drugs that increase the risks for clotting and bleeding such as NSAIDs and vitamins C be discontinued 5 to 10 days before surgery, depending on surgeon instructions.* The concept of CLOTTING is reviewed in [Chapter 2](#) of this text.

Current blood bank standards do not recommend either donor or autologous blood storage before surgery unless the patient's blood type or antibody profile is difficult to crossmatch. Devices such as intraoperative cell savers and postoperative reinfusion blood collection systems can be used to assist in maintaining acceptable hemoglobin and hematocrit levels. A **cell saver system** allows for collection of the person's own red blood cells during surgery, which is then reinfused directly back to the patient via a closed system. A **reinfusion system** allows for collection of red blood cells from a joint drain over a specific time frame, which then can be reinfused directly back into the patient's systemic circulation.

For some patients who have a tendency for anemia or who have a low blood count before surgery, the surgeon may prescribe several weeks of epoetin alfa (Epoen, Procrit, Eprex) with or without iron to prevent anemia that can occur after hip or knee replacement. Epoetin alfa is recombinant human erythropoietin, a substance that is essential for developing red blood cells. This drug is particularly useful for older adults who frequently have mild anemia before surgery or for patients who for religious or personal reasons would not accept a blood transfusion.

Remind patients that they will likely be instructed to take a shower with special antiseptic soap 1 to 3 nights before and the morning of surgery, based on hospital or provider policy, to decrease

bacteria that could cause infection. Teach them to wear clean nightwear after their shower and sleep on clean linen. Review which drugs are safe to take or necessary the morning of the operation such as antihypertensives and which ones should be avoided. Medication should be taken with a very small amount of water to prevent vomiting and aspiration during surgery. If an insulin pump is part of the drug therapy for the patient with diabetes, remind him or her to check with his or her primary health care provider about adjusting the insulin dosage on the morning of surgery. See [Chapter 14](#) for additional preoperative care for any type of surgery.

### **Operative Procedures.**

Similar to other orthopedic surgeries, the patient receives an IV antibiotic, usually a cephalosporin such as cefazolin (Ancef), within an hour before the initial surgical incision per the Surgical Care Improvement Project (SCIP) Core Measures to help prevent infection. [Chapter 14](#) discusses these measures in detail.

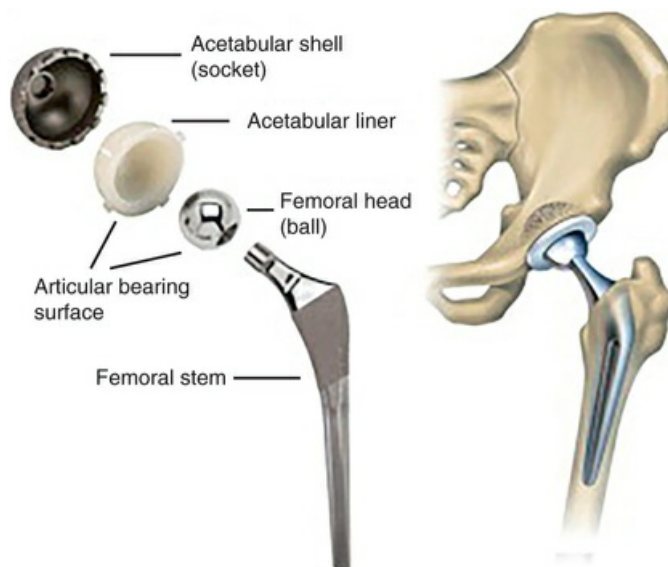

Several different types of anesthesia are used for THA surgeries and are administered by an anesthesiologist or nurse anesthetist. These options include general anesthesia, neuraxial (spinal) anesthesia, regional nerve blocks, or a combination of these agents. Patients receiving neuraxial or regional anesthetics may also be given IV moderate sedation to keep them unaware of their environment during the procedure. The benefit of a regional block is that the patient may receive extended pain relief, often up to 24 hours after surgery.

Some patients are candidates for *minimally invasive surgery* (MIS) using a smaller incision with special instruments to reduce muscle cutting and stretching. This newer technique cannot be used for patients who are obese or those with osteoporosis. It is done only for primary THAs, not for revision surgeries. Like those of any MIS, the benefits of minimally invasive THA are decreased soft tissue damage and postoperative pain. Patients often have a shorter hospital stay and quicker recovery. They are generally satisfied with the cosmetic appearance of the incision because there is less scarring. Postoperative complications are not as common in patients having minimally invasive (“mini”) hip replacements when compared with those having the traditional technique.

*Hip resurfacing* is an alternative to total hip replacement surgery. This procedure is most often performed for younger patients or for those with early-stage cartilage loss of the weight-bearing surface of the femoral head. Instead of completely removing the femoral head and inserting the stem into the femoral canal, the surgeon removes the cartilage from the surface, and a metal cap is placed over the existing natural femoral head.

Two components are used in the THA—the acetabular component and the femoral component ([Fig. 18-3](#)). A noncemented prosthesis is most often used. Bone surfaces are smoothed as they are prepared to receive the artificial components. The noncemented components are press-fitted into the prepared bone. The acetabular cup may be placed using computer- or robotic-assisted guidance. If the prosthesis is cemented, polymethyl methacrylate (an acrylic fixating substance) is used. The hybrid technique usually involves a cemented femoral component and a noncemented acetabular component. A closed wound drainage system may be placed alongside the wound before the surgeon closes the incision.

**FIG. 18-3** Two major components of total hip arthroplasty. From Zhang, Y., Zhu, J., Wang, Z., Zhou, Y., & Zhang, X. [2015]. Constructing a 3D-printable, bioceramic sheathed articular spacer assembly for infected hip arthroplasty. *Journal of Medical Hypotheses and Ideas*, 9(1), 13-19.)

Considerations of a noncemented prosthesis include protection of weight-bearing status to allow bone to grow into the prosthesis and decreased problems with loosening of the prosthesis. With a cemented prosthesis, cement can fracture or deteriorate over time, leading to loosening of the prosthesis, which causes pain and can lead to the need for a revision arthroplasty. In revision arthroplasty the old prosthesis is removed, and new components are replaced. Bone graft may be placed if bone loss is significant. Outcomes from revision arthroplasty may not be as positive as with primary arthroplasty.

### Postoperative Care.

In addition to providing the routine postoperative care discussed in [Chapter 16](#), assess for and help prevent possible postoperative complications. [Table 18-2](#) summarizes these complications, including nursing measures for prevention, assessment, and intervention. [Chart 18-2](#) highlights special concerns for the care of older adults in the postoperative period. Collaborate with your patient and his or her family to become safety partners to prevent “failure to rescue” events.

**TABLE 18-2**

### Nursing Interventions to Prevent Major Complications of Lower-Extremity Total Joint Arthroplasty

COMPLICATION	PREVENTION/INTERVENTION
Dislocation (hip)	Position correctly. Keep legs slightly abducted ( <i>for posterior surgical approach</i> ). Prevent hip flexion beyond 90 degrees ( <i>for posterior surgical approach</i> ). Prevent hip hyperextension ( <i>for anterior surgical approach</i> ). Assess for acute pain, rotation, and extremity shortening. Perform frequent neurovascular assessments, at least every 4 hours for the first 24 hours or per agency protocol. Report dislocation immediately to the surgeon.
Infection	Use aseptic technique for wound care and emptying of drains. Wash hands thoroughly when caring for patient. Culture drainage fluid, if change. Monitor temperature. Report excessive inflammation or drainage to surgeon.
Venous thromboembolism	Have patient wear elastic stockings and/or sequential compression device per agency policy. Teach leg exercises to patient. Encourage fluid intake. Observe for signs of deep vein thrombosis (redness, swelling, or pain). Observe patient for changes in mental status. Administer anticoagulant as prescribed. Do not massage legs. Do not flex knees for a prolonged period of time.
Hypotension, bleeding, or infection	Take vital signs at least every 4 hours for the first 24 hours or per agency protocol. Observe patient for bleeding. Report excessively low blood pressure or bleeding to physician.

### Chart 18-2

## Nursing Focus on the Older Adult

## Postoperative Care of the Older Adult With a Total Hip Arthroplasty

- For patients who had a *posterior surgical approach*, use an abduction pillow or splint to prevent adduction after surgery if the patient is very restless or has an altered mental state. For patients with an *anterior surgical approach*, no abduction pillow is needed.
- Keep the patient's heels off the bed to prevent pressure injuries.
- Do not rely on fever as a sign of infection; older patients often have infection without fever. Be alert to decreasing mental status and/or elevated white blood cell count as indicators of infection.
- When assisting the patient out of bed, move him or her slowly to prevent orthostatic (postural) hypotension. Allow the patient to sit on the side of the bed for a brief period of time before standing; have him or her stand for a brief period before beginning ambulation.
- Encourage the patient to deep breathe and cough and to use the incentive spirometer every 2 hours to prevent atelectasis and pneumonia.
- As soon as permitted, get the patient out of bed to a recliner chair to prevent complications of immobility.
- Anticipate the patient's need for pain medication, especially if he or she cannot verbalize the need for pain control. For patients on a multimodal pain protocol, assess the need to medicate for breakthrough pain (see Chapter 4).
- Expect a temporary change in mental state immediately after surgery as a result of the anesthetic and unfamiliar sensory stimuli. Reorient the patient frequently.

## Nursing Safety Priority QSEN

### Action Alert

Teach patients to maintain correct positioning of the hip joint and leg at all times. When the patient returns from the postanesthesia care unit (PACU), place him or her in a supine position with the head slightly elevated. For the patient who had a *posterior surgical approach*, place a regular or abduction pillow between the legs to prevent adduction beyond the midline of the body according to agency policy or surgeon preference.

In some hospitals abduction devices with straps are placed on patients who are restless or cannot follow instructions, especially older adults with delirium or dementia. One or two regular bed pillows are used in most cases to remind patients to keep their legs abducted. For devices with straps, be sure to loosen the straps every 2 hours and check the patient's skin for irritation or breakdown. Patients having the *anterior surgical approach* do not require the use of the abduction pillow.

Place and support the affected leg in neutral rotation. *Keep the patient's heels, particularly those of older adults, off the bed to prevent skin breakdown.* The procedure for postoperative turning is not universal and is specified by agency policy or surgeon preference. Turning the patient to the operative side provides “splinting” of the operative hip but may be too painful for some patients. If the patient is turned to the nonoperative side, the operative leg needs to be fully supported with pillows to prevent slipping of the leg into a position that can lead to dislocation.

Teach the patient and family about other precautions to prevent dislocation as outlined in [Chart 18-3](#). In addition to preventing adduction, remind them that the patient who had a *posterior approach* should avoid flexing the hips more than 90 degrees at all times. For patients having the *anterior approach*, teach them to avoid hyperextension of the operative hip and external rotation of the leg. Use diagrams or demonstrate correct positioning to help reinforce this information before the patient gets out of bed ([Fig. 18-4](#)).

### Chart 18-3

## Patient and Family Education: Preparing for Self-Management

### Care of Patients With Total Hip Arthroplasty After Hospital Discharge

#### Hip Precautions

- Do not sit or stand for prolonged periods.
- Do not cross your legs beyond the midline of your body.
- For *posterior surgical approach* patients: Do not bend your hips more than 90 degrees.
- For *anterior surgical approach* patients: Do not hyperextend your operative leg behind you.
- Do not twist your body when standing.
- Use the prescribed ambulatory aid such as a walker when walking.
- Use assistive/adaptive devices as needed (e.g., sock aids, shoehorns, dressing sticks, reachers [also see Chapter 6]).
- Do not put more weight on your affected leg than allowed and instructed.
- Resume sexual intercourse as usual on the advice of your surgeon.

#### Pain Management

- Report increased hip or anterior thigh pain to the surgeon immediately.
- Take oral analgesics as prescribed and only as needed.
- Do not overexert yourself; take frequent rests.
- Use ice as needed to operative hip to decrease or prevent swelling and minimize pain.

#### Incisional Care

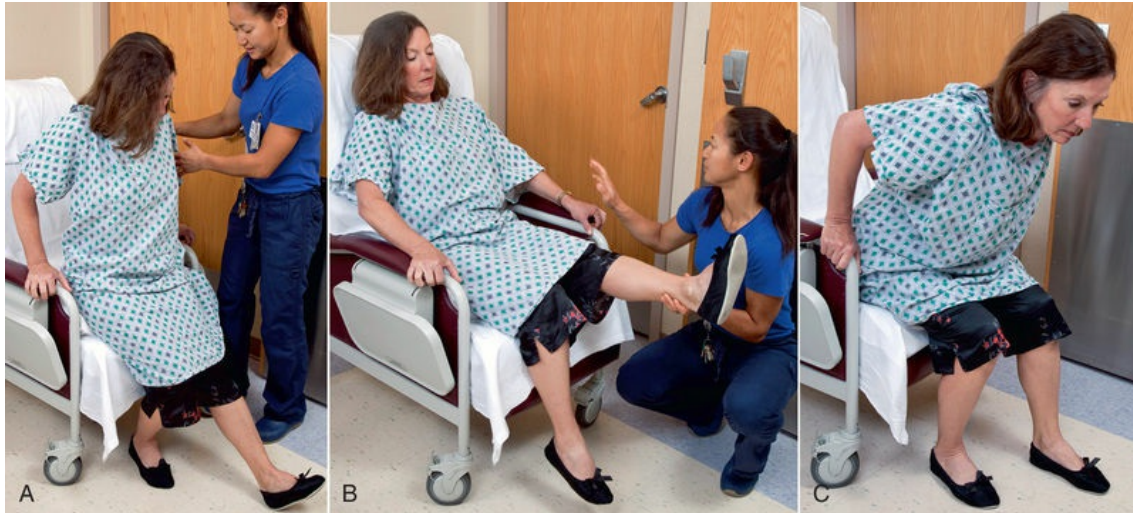

- Follow the instructions provided regarding dressing changes. Some surgeons use specialty dressings that do not need to be changed. No dressing may be needed if a skin sealant was used.
- Inspect your hip incision every day for redness, heat, or drainage; if any of these are present, call your surgeon immediately.
- Do not bathe the incision or apply anything directly to the incision unless instructed to do so. Shower according to the surgeon's instructions.

#### Other Care

- Continue walking and performing the leg exercises as you learned them in the hospital. Do not increase the amount of activity unless instructed to do so by the therapist or surgeon.
- Do not cross your legs to help prevent blood clots.
- Report pain, redness, or swelling in your legs to your surgeon immediately.
- Call 911 for acute chest pain or shortness of breath (could indicate pulmonary embolus).
- If you are taking an anticoagulant, follow the precautions learned in the hospital to prevent

bleeding; avoid using a straight razor, avoid injuries, and report bleeding or excessive bruising to your surgeon immediately.

- Follow up with visits to the surgeon's office as instructed.

**FIG. 18-4** Correct (A, B) and incorrect (C) hip flexion after a total hip replacement.

If the hip is dislocated, the surgeon may be able to manipulate and relocate it after the patient receives moderate sedation. If the hip does not reduce into position, the patient may have surgical reduction in the operating room (OR). Following reduction, the hip is usually immobilized by an abduction splint or other device until healing occurs—usually in about 6 weeks.

As with other musculoskeletal surgery, *monitor neurovascular assessments* frequently for a possible compromise in circulation to the affected distal extremity.

## **Nursing Safety Priority** QSEN

### **Action Alert**

Check and document color, temperature, distal pulses, capillary refill, movement, and sensation.

The procedure for performing a thorough lower-extremity neurovascular assessment is described in detail in [Chapter 51](#). Remember to compare the operative leg with the nonoperative leg. These assessments are performed at the same time the vital signs are checked. Report any changes in neurovascular assessment to the surgeon and carefully monitor for changes. Early detection of changes in neurovascular status can prevent permanent tissue damage.

The most potentially life-threatening complication after THA is venous thromboembolism (VTE), which includes deep venous thrombosis (DVT) and pulmonary embolism (PE). *Older patients are especially at increased risk for VTE because of age and decreased circulation before surgery. Obese patients and those with a history of VTE are also at high risk for thrombi.*

Preventive postoperative measures include applying bilateral sequential compression devices (SCDs) and/or antiembolism stockings and anticoagulant therapy. Anticoagulants such as warfarin (Coumadin, Warfilone ) , subcutaneous low-molecular-weight heparin (LMWH), or factor Xa inhibitors are effective in preventing VTE to patients having a THA. Patients are usually on anticoagulants for 10 days to several weeks after surgery, depending on surgeon preference and the patient's response and risk factors. Patients on warfarin require frequent monitoring of prothrombin time (PT) and international normalized ratio (INR).

The use of subcutaneous LMWH has markedly increased for patients with total hip replacements. Examples include enoxaparin (Lovenox) and dalteparin (Fragmin). As an alternative to LMWH, subcutaneous fondaparinux (Arixtra), a factor Xa inhibiting agent, may be prescribed for some patients undergoing hip and knee arthroplasty. A newer Xa inhibitor, rivaroxaban (Xarelto), is

given orally once a day. Recently oral apixaban (Eliquis) has received FDA approval for VTE prophylaxis in patients having a THA. You do not need to monitor the PT or INR for patients receiving these drugs because they do not affect coagulation values. However, for other anticoagulants, patients are at risk for bleeding due to impaired CLOTTING. A complete discussion of nursing care associated with patients taking anticoagulants and who have VTE is found in [Chapter 36](#). The Joint Commission's *VTE Core Measures* are also discussed in that chapter.

Early ambulation and exercise help prevent VTE. Teach the patient about leg exercises, which should begin in the immediate postoperative period and continue through the rehabilitation period. These exercises include plantar flexion and dorsiflexion (heel pumping), circumduction (circles) of the feet, gluteal and quadriceps muscle setting, and straight-leg raises (SLRs). Teach the patient to perform gluteal exercises by pushing the heels into the bed and achieve [quadriceps-setting exercises](#) (“quad sets”) by straightening the legs and pushing the back of the knees into the bed. In addition to preventing clots, these exercises improve muscle tone, which helps restore the function of the extremity.

Monitor the surgical incision and vital signs carefully—every 4 hours for the first 24 hours and every 8 to 12 hours thereafter, following facility and surgeon protocols. Observe for signs of infection such as an elevated temperature, increased redness around the incision, and excessive or foul-smelling drainage from the incision. *An older patient may not have a fever with infection but instead may experience an altered mental state.* If you suspect this problem, obtain a sample of any drainage for culture and sensitivity to determine the causative organisms and the antibiotics that may be needed for treatment.

### Managing Postoperative Pain.

Although hip arthroplasty is performed to relieve joint pain, patients experience varying levels of pain related to the surgical procedure. Many state that their pain is different and less severe than before surgery. Pain control protocols vary, depending on the region of the country, anesthesiologist/nurse anesthetist, and surgeon. Immediate pain control may be achieved by extended-release epidural morphine (EREM), regional blocks, patient-controlled analgesia (PCA), or IV push, typically with morphine or hydrocodone. Acetaminophen, ketorolac, and/or celecoxib are usually given as adjunct analgesics. For some patients, IV acetaminophen (Ofirmev) may be the *only* analgesic required to relieve mild-to-moderate pain, which avoids the risks of side effects from opioids and other NSAIDs. [Chapter 4](#) contains information on the nursing care associated with these acute pain modalities.

Regardless of the pain management method used, most patients do not require parenteral analgesics after the first day. Oral opioids such as hydrocodone plus acetaminophen (Norco) and tramadol (Ultram) are then commonly prescribed until the pain can be controlled by NSAIDs such as celecoxib (Celebrex) or oral acetaminophen.

Nonpharmacologic methods for acute and chronic pain control can also be used to decrease the amount of drug therapy used (see [Chapter 4](#)).

### Promoting Postoperative Mobility and Activity.

Depending on the time of day that the surgery is performed, the patient with a THA gets out of bed with assistance the night of surgery to prevent problems related to impaired MOBILITY (e.g., atelectasis, pneumonia), especially in older adults.

## Nursing Safety Priority QSEN

### Action Alert

Be sure to assist the patient the first time he or she gets out of bed to prevent falls and observe for dizziness. When getting the patient out of bed, put a gait belt on him or her and then stand on the same side of the bed as the affected leg. After the patient sits on the side of the bed, remind him or her to stand on the unaffected leg and pivot to the chair with guidance. If the patient has been instructed by PT to use stretch bands, reinforce the correct use of this device to support and help in proper positioning of the operative leg. *To avoid injury, do not lift the patient!*

Remind the patient who had a *posterior approach for surgery* to avoid flexing the hips beyond 90

degrees as discussed earlier (see Fig. 18-4). Raised toilet seats and reclining chairs help prevent hyperflexion. Remind patients having the *anterior surgical approach* to avoid hyperextension of the operative hip. Be sure to teach all THA patients to also *avoid* twisting the body or crossing their legs to prevent hip dislocation.

The surgeon, type of prosthesis, and surgical procedure determine the amount of weight bearing that can be applied to the affected leg. A patient with a cemented implant is usually allowed immediate weight bearing as tolerated (WBAT). Typically only “toe-touch” or minimal weight bearing is permitted for patients with noncemented prostheses. When x-ray evidence of bony ingrowth can be seen, the patient can progress to partial weight bearing (PWB) and then to full weight bearing (FWB).

In collaboration with the physical therapist (PT), teach the patient how to follow weight-bearing restrictions. Most patients use a walker, but younger adults may use crutches. They are usually advanced to a single cane or crutch if they can walk without a severe limp 4 to 6 weeks after surgery. When the limp disappears, they no longer need an ambulatory/assistive device and may be permitted to sit in chairs of normal height, use regular toilets, and drive a car. Timing of driving may be slightly longer in a patient who has had surgery on the right hip because of patient safety concerns.

## NCLEX Examination Challenge 18-2

### Physiological Integrity

A client had a left anterior total hip arthroplasty 2 days ago. Which precautions will the nurse teach the client to prevent surgical complications? **Select all that apply.**

- A. “Avoid extending your left hip behind you when you sit.”
- B. “Do not flex your hips more than 90 degrees when toileting.”
- C. “You may cross your legs to be more comfortable in a chair.”
- D. “Avoid twisting your body when moving or performing ADLs.”
- E. “Stand on your right leg and pivot into the chair when getting out of bed.”

### Promoting Postoperative Self-Management.

The hospital's occupational therapy department may supply assistive/adaptive devices to help with ADLs, especially for those having traditional surgery. Particularly important are devices designed for reaching to prevent patients from bending or stooping and flexing the hips more than 90 degrees. Extended handles on shoehorns and dressing sticks may be very useful to achieve ADL independence. Third-party payers may or may not pay for these devices, depending on the patient's status.

With the increase in Joint Replacement Center programs that emphasize a structured approach and recovery, the length of stay in the acute care hospital is typically 3 days or fewer if there are no postoperative complications. McCann-Spry et al. (2016) reported a quality improvement project in which the patient's length of stay was reduced to 2.5 days for a 2-night stay rather than the typical 3-night stay (see the [Quality Improvement](#) box). Patients experiencing postoperative complications often stay longer. Medicare patients need a 3-day qualifying hospital stay to receive rehabilitation in a skilled inpatient unit. Discharge from the acute care facility may be to the home, a rehabilitation unit, a transitional care unit, or a skilled unit or long-term care facility for continued rehabilitation before discharge to home. The interprofessional team provides written instructions for posthospital care and reviews them with patients and their family members (see [Chart 18-3](#)). Be sure to provide a copy of these instructions for the patient.

## Quality Improvement QSEN

### Can Hospital Length of Stay Be Shortened for Patients Having Joint Replacements?

McCann-Spry, L., Pelton, J., Grandy, G., & Newell, D. (2016). An interdisciplinary approach to reducing length of stay in joint replacement patients. *Orthopaedic Nursing, 35*(5), 279–300.

Demand for total joint replacement surgeries is increasing as baby boomers become older adults. One large hospital in a northern U.S. state developed a process for decreasing postoperative hospital length of stay (LOS) using an interprofessional collaborative approach. Four interventions were implemented: (1) improve communication for primary health care providers (surgeons), including a letter explaining the goal of reducing LOS from 3 nights to 2 nights; (2) develop a script for staff conversations with the patient and family for each hospital day; (3) standardize the risk assessment and prediction for reducing LOS; and (4) initiate physical therapy the day of surgery. As a result of this quality improvement project, patient LOS was reduced an average of 0.5 days per patient for primary hip and knee replacement surgeries. This reduction was very cost-effective without negatively affecting patient and family satisfaction.

### Commentary: Implications for Research and Practice

This QI project was very successful at improving financial outcomes and increasing collaboration and communication among interprofessional health care team members and improving staff-patient communication. Nurses play a major role in care coordination and discharge teaching for patients and their families. More QI projects and interventions are needed in additional joint replacement centers to achieve these positive outcomes.

Acute rehabilitation usually takes several weeks, depending on the patient's age and progress and the type of prosthesis used. However, it often takes 6 weeks or longer for complete recovery. Some patients who are discharged to their home are able to attend physical therapy sessions in an office or ambulatory care setting. Others have no means or cannot use community resources and need physical therapy in the home, depending on their health insurance coverage. *Collaborate with the case manager to determine which option is best for your patient.*

### Total Knee Arthroplasty.

As the population ages, more adults are undergoing total knee arthroplasty (TKA, also known as *total knee replacement [TKR]*). Continued improvements in total knee implants have increased the expected life of a TKA to 20 years or more, depending on the age and activity level of the patient. Options for *total* knee replacements include medial compartment replacement and robotic-assisted partial knee replacement. Partial knee replacements are used most often in patients with minimal cartilage loss in specified areas of the involved knee and are typically done more often in younger patients. Minimally invasive surgery (MIS) is also an option for either partial or total knee replacements. Severe bone loss, obesity, and previous knee surgeries are contraindications for this type of surgery. Patients who have MIS procedures have less pain and blood loss and greater range of motion to promote a faster postoperative recovery.

### Preoperative Care.

TKA, like hip replacement, is performed when joint pain cannot be managed by conservative measures. When limited MOBILITY severely prevents patients from participating in work or activities they enjoy, this procedure can restore a high quality of life. The preoperative care and teaching for patients undergoing a TKA are similar to that for total hip replacement. However, precautions for positioning are not the same because joint dislocation is not a common complication. Differences in patient and family teaching depend on the procedure used by the orthopedic surgeon.

All patients are given verbal and either written or video preoperative instructions, which include the activity protocol to follow after surgery. The PT and OT provide information about transfers, ambulation, postoperative exercises, and ADL assistance. Patients may practice walking with walkers or crutches to prepare them for ambulation after TKA. Teach patients about the possible need for assistive/adaptive devices to assist with ADLs, including an elevated toilet seat, safety handrails, and dressing devices like a long-handled shoehorn. Some third-party payers cover these devices, depending on the patient's condition and age; however, other insurers may not pay for them. Teach the patient and family how and where this equipment can be obtained to have it available after surgery. Case managers or social workers may arrange for needed items to be delivered to the patient's room before discharge.

Routine diagnostic testing is requested and any additional tests such as cervical spine x-rays for

patients with rheumatoid arthritis (RA) to determine if the patient can be intubated for anesthesia. Knee x-rays, CT scan, and/or MRI may be done to assess the joint and surrounding soft tissues.

Teach patients that they will need to shower with a special antiseptic soap 1 to 3 nights before surgery and the morning of surgery to decrease bacteria on the skin that could cause infection. Remind them to wear clean nightwear and sleep on clean linen. Ask them to check with their surgeon about which medications they can take the morning of surgery with a small amount of water, including antihypertensives, thyroid hormone supplements, and corticosteroids (taken by many patients with RA). Some medications such as NSAIDs are discontinued 5 to 10 days before surgery to prevent surgical bleeding. See [Chapter 14](#) for additional preoperative care for any type of surgery.

### Operative Procedures.

As with the hip, the knee can be replaced with the patient under a variety of anesthetic agents, including general or neuraxial (epidural or spinal) anesthesia. One of the more recent advances in postoperative pain management for knee joint replacements is the use of peripheral nerve blocks (PNB), most commonly sciatic, femoral, or adductor canal blocks using a local anesthetic. An IV moderate sedation agent is used in addition to the neuraxial or PNB drug. PNB may be either a single injection or continuous infusion by a portable pump (e.g., **continuous femoral nerve blockade** or CFNB). In addition, other local medications may be injected into the knee or surrounding tissues to assist in the reduction of severe pain that usually occurs after knee surgery and to minimize perioperative bleeding.

An antibiotic, usually an IV cephalosporin or vancomycin, is given shortly before the surgical incision per the SCIP Core Measures to aid in the prevention of infection. In the *traditional surgery* the surgeon makes a central longitudinal incision about 6 to 8 inches (15 to 20 cm) long. Osteotomies of the femoral and tibial condyles and of the posterior patella are performed, and the surfaces are prepared for the prosthesis. The femoral component is often noncemented (using a press-fit) with the tibial component being cemented. The surgeon may insert a surgical drain, depending on the amount of expected postoperative bleeding. A compression (pressure) dressing is applied from the toes to the thigh to decrease edema and bleeding.

*Minimally invasive* TKA may be performed using a shorter incision and special instruments to spare muscle and other soft tissue. Computer-guided or robotic equipment may be used to ensure accurate positioning of the knee implants.

### Postoperative Care.

Provide the usual postoperative care needed for any patient who has surgery (see [Chapter 16](#)). Specific nursing care of the patient with a TKA is similar to that for the patient with a total hip arthroplasty as described in the previous section.

## Nursing Safety Priority QSEN

### Critical Rescue

If the patient has a continuous femoral nerve blockade (CFNB), perform and document neurovascular assessment every 2 to 4 hours, or according to hospital protocol. Be sure that patients can perform dorsiflexion and plantar flexion motions of the affected foot without pain in the lower leg. In addition, monitor these patients for signs and symptoms that indicate absorption of the local anesthetic into the patient's system, including:

- Metallic taste
- Tinnitus
- Nervousness
- Slurred speech
- Bradycardia

- Hypotension
- Decreased respirations
- Seizures

Document and report these new-onset signs and symptoms to the surgeon and anesthesiologist/nurse anesthetist immediately and carefully continue to monitor the patient for any changes.

Since joint dislocation is rare after TKA, there are no special positioning precautions required to prevent adduction. Maintain the operative leg in a neutral position, avoiding both internal and external rotation. Do not place a pillow under the replaced knee or hyperextend the knee.

Although not as commonly used today, the surgeon may prescribe a continuous passive motion (CPM) machine, which can be applied in the postanesthesia care unit (PACU) or soon after the patient is admitted to the postoperative unit (Fig. 18-5). The CPM machine keeps the prosthetic knee in motion and may prevent the formation of scar tissue, which could decrease knee MOBILITY and increase postoperative pain. Observe and document the patient's response to the device and follow the surgeon's protocol for settings. Chart 18-4 outlines your responsibility when caring for a patient using the CPM machine. This device may also be used for other types of orthopedic surgery.

**FIG. 18-5** A continuous passive motion (CPM) machine in use.

#### Chart 18-4

### Best Practice for Patient Safety & Quality Care QSEN

#### The Patient Using a Continuous Passive Motion (CPM) Machine

- Ensure that the machine is well padded.
- Check the cycle and range-of-motion settings at least once every 8 hours.
- Ensure that the joint being moved is properly positioned on the machine.
- If the patient is confused, place the controls to the machine out of his or her reach.
- Assess the patient's response to the machine.
- Turn off the machine while the patient is having a meal in bed.

- When the machine is not in use, do not store it on the floor.

In the immediate postoperative period, the surgeon also typically prescribes some form of cryotherapy (cold application) to decrease swelling, hematoma formation, and pain at the surgical site. These problems are more common with this type of surgery than with hip surgery. Several types of cryotherapy are used, including ice/gel pack compression and circulating cold water cryotherapy devices. A recent study comparing these two cryotherapy methods for 100 randomized subjects found that the less expensive ice-gel packs were as effective as the circulating cold water devices in managing pain and swelling. Patient satisfaction was the same for both study groups (Schinsky, et al., 2016).

In general, pain control measures for patients with TKA are similar to those with total hip arthroplasty. Many patients report high ratings on the pain intensity scale and require opioid medications longer than patients with THA, particularly if they have had bilateral surgery. However, for other patients, IV acetaminophen is very effective in managing TKA pain. *Be sure to manage your patient's pain to provide comfort, increase his or her participation in physical therapy, and improve joint mobility.*

Some complications that affect patients with THA may also affect those having TKA such as venous thromboembolism, infection, anemia, and neurovascular compromise. Assessments and interventions associated with these complications are described in the [Postoperative Care](#) section of the discussion of [Total Hip Arthroplasty](#).

The desired outcome for discharge from the acute hospital unit is that the patient can walk with crutches or a walker and has adequate flexion in the operative knee for ambulation, including walking up and down stairs. Patients are able to bear weight as tolerated unless the prosthesis is not cemented. Patients may be discharged to their home or to an acute rehabilitation unit, transitional care unit, or skilled unit in a long-term care facility for therapy. For many patients home care services can provide physical therapy and nursing care for 1 to 2 weeks followed by outpatient therapy only if their insurance approves this plan and they have family support. *Collaborate with the case manager to determine which option is best for your patient.*

During the home rehabilitation phase, the use of a stationary bicycle or CPM machine may help gain flexion. These patients can return to work and other usual activities in 6 weeks, depending on their age, type of surgery, and other health status factors. Total recovery from a TKA surgery takes 6 weeks or longer, especially for those older than 75 years.

## **NCLEX Examination Challenge 18-3**

### **Safe and Effective Care Environment**

A nursing assistant (NA) is assigned to care for a client who had a cemented total knee arthroplasty. Which statement by the NA indicates a need for further teaching and supervision by the nurse?

- A. "I'll keep an abduction pillow in place at all times."
- B. "I'll tell the client not to place a pillow under the surgical knee."
- C. "I'll apply ice packs to decrease swelling in the knee as ordered."
- D. "I'll check to make sure the client's leg is not rotated."

### **Other Joint Arthroplasties.**

The shoulder and other upper-extremity joints do not bear weight and therefore tend to have less degeneration and subsequent pain. Preoperative teaching for patients having any of these surgeries depends on the surgeon's technique and postoperative protocols.

*Total shoulder arthroplasty (TSA)* has gained popularity as newer prostheses and technology have been developed. This procedure usually decreases arthritic or traumatic pain and increases the patient's ability to perform ADLs. Because the shoulder joint is complex and has many **articulations** (joint surfaces), **subluxation** (partial dislocation) or complete dislocation is a major potential

complication. Usually the glenohumeral joint, created by the glenoid cavity of the shoulder blade (scapula) and the head of the humerus, is replaced because it moves the most and is therefore most affected by arthritis. A cemented or noncemented **hemiarthroplasty** (replacement of part of the joint), typically the humeral component, may be performed as an alternative to TSA.

After surgery the patient is placed in an abduction immobilizer or pillow device to protect the joint from excessive motion until rehabilitation therapy begins. *Do not remove these devices unless instructed to do so by the surgeon.*

In addition to the potential for dislocation, postoperative complications are similar to those for other total joint replacements and include infection and neurovascular compromise. *As for any other total joint arthroplasty, perform frequent neurovascular assessments at least every 4 to 8 hours.* The procedure for performing a thorough upper-extremity neurovascular assessment is described in detail in [Chapter 51](#). Document and report any significant changes to the surgeon immediately. The hospital stay for TSA is shorter than for a total hip or knee replacement. Rehabilitation with an OT generally takes several months.

## Improving Mobility

### Planning: Expected Outcomes.

The patient with osteoarthritis (OA) is expected to maintain or improve a level of MOBILITY and activity that allows him or her to function independently with or without an assistive ambulatory device.

### Interventions.

Management of the patient with OA often requires an interprofessional health team effort. If needed, consult and collaborate with the physical therapist (PT) and occupational therapist (OT) to meet the outcome of independent function and MOBILITY. Major interventions include therapeutic exercise and the promotion of ADLs and ambulation by teaching about health and the use of assistive devices.

Certain recreational activities may also be therapeutic such as swimming to enhance chest and arm muscles. Aerobic exercises (e.g., walking, biking, swimming, aerobic dance) are also recommended. Exercises may be prescribed by rehabilitation therapists for the patient with OA, but you will need to reinforce their techniques and principles. The ideal time for exercise is immediately after the application of heat. To prevent further joint damage, teach patients to carefully follow the instructions for exercise outlined in [Chart 18-5](#).

### Chart 18-5

## Patient and Family Education: Preparing for Self-Management

### Exercises for Patients With Osteoarthritis or Rheumatoid Arthritis

- Follow the exercise instructions that have been prescribed specifically for you. There are no universal exercises; your exercises have been specifically tailored to your needs.
- Do your exercises on both “good” and “bad” days. Consistency is important.
- Respect pain. Reduce the number of repetitions when the inflammation is severe and you have more pain.
- Use active rather than active-assist or passive exercise whenever possible.
- Do not substitute your normal activities or household tasks for the prescribed exercises.
- Avoid resistive exercises when your joints are severely inflamed.

Collaborate with the PT to evaluate the patient's need for ambulatory aids such as canes, walkers,

or platform crutches. Although some patients do not like to use these aids or may forget how to use them, they can help prevent further joint deterioration and pain. Collaborate with the OT, if needed, to provide suggestions and devices for assistance for ADLs. [Chapter 6](#) discusses rehabilitation therapies in more detail.

### Care Coordination and Transition Management

The patient with OA is not usually hospitalized for the disease itself but is admitted for surgical management. Expect that any patient older than 60 years will have some degree of arthritis and possibly chronic pain that need to be managed.

### Home Care Management.

If weight-bearing joints are severely involved, the patient may have difficulty going up or down stairs. Making arrangements to live on one floor with accessibility to all rooms is often the best solution. A home care nurse or case manager may collaborate with a rehabilitation therapist to assess the need for structural alterations to the home to accommodate ambulatory aids and enable the patient to perform ADLs. For example, a kitchen counter may need to be lowered, or a seat and handrails may need to be installed in the shower. If the patient has undergone a total hip replacement, an elevated toilet seat is necessary for several weeks after surgery to prevent excessive hip flexion. Patients who have TKAs may also find elevated toilet seats easier to use. Throw rugs and other environmental hazards should be removed to prevent tripping and falls.

### Self-Management Education.

Self-management education (SME) is an effective psychosocially focused nonpharmacologic intervention. Learning how to protect joints is the most important part of patient and family education. Preventing further damage to joints slows the progression of OA and minimizes pain. Explain the general principles of joint protection and give practical examples ([Chart 18-6](#)).

#### Chart 18-6

### Patient and Family Education: Preparing for Self-Management

#### Evidence-Based Instructions for Joint Protection

- Use large joints instead of small ones; for example, place your purse strap over your shoulder instead of grasping the purse with your hand.
- Do not turn a doorknob clockwise. Turn it counterclockwise to avoid twisting your arm and promoting ulnar deviation.
- Use two hands instead of one to hold objects.
- Sit in a chair that has a high, straight back.
- When getting out of bed, do not push off with your fingers; use the entire palm of both hands.
- Do not bend at your waist; instead bend your knees while keeping your back straight.
- Use long-handled devices such as a hairbrush with an extended handle.
- Use assistive/adaptive devices such as Velcro closures and built-up utensil handles to protect your joints.
- Do not use pillows in bed except a small one under your head.
- Avoid twisting or wringing your hands.

As with other diseases in which drugs and nutritional therapy are used, teach the patient and family the drug therapy protocol, desired effects and potential side effects, and toxic effects. Emphasize the importance of reducing weight and eating a well-balanced diet to promote tissue healing.

Many patients with arthritis look for a cure after becoming frustrated and desperate about the course of the disease and treatment. Better control of arthritis is possible, but cure is not yet available. Unfortunately tabloids, books, media, and the Internet often report “curative” remedies. People spend billions of dollars each year on quackery, including liniments, special diets, and copper bracelets. More hazardous substances such as snake venom and industrial cleaners are also advertised as remedies. Refer the patient to the Arthritis Foundation for up-to-date information about these “cures.” The practice of wearing a copper bracelet will not cure arthritis, but it will not cause harm. However, if the patient is using a potentially harmful substance or method, reinforce the need to avoid the unproven remedy and explain why it should not be used. Respect the patient's preferences, values, and beliefs for using benign remedies that do not cause harm.

With most types of arthritis and connective tissue disease (CTD), patients must live with a chronic, unpredictable, and painful disorder. Their roles, self-esteem, and body image may be affected by these diseases. Body image is often not as devastating in OA as in the inflammatory arthritic diseases such as RA. The psychosocial component associated with having arthritis is discussed in more detail later in this chapter in the [Rheumatoid Arthritis](#) section.

### Health Care Resources.

The patient who has undergone surgery may need help from community resources. After an arthroplasty, he or she may need assistance with MOBILITY. The patient may be discharged to home or an inpatient unit. Collaborate with the case manager and surgeon to determine the best placement. If the patient is discharged to home, home care nurses may be approved for third-party payment for several visits, depending on the presence of any existing systemic diseases. A home care aide may visit the home to help with hygiene-related needs, and a PT may work with ambulatory and MOBILITY skills. For older patients, a family member, significant other, or other caregiver should be in the home for at least the first few weeks when the patient needs the most assistance. Emphasize the need for patient safety, especially interventions to prevent falls as described in [Chapter 3](#).

Provide written instructions about the required care, regardless of whether the patient goes home or to another inpatient facility. As required by The Joint Commission's National Patient Safety Goals (NPSGs) and other health care accrediting organizations, hand-off communication with the new care provider is essential for seamless continuity of care and care coordination.

The Arthritis Foundation ([www.arthritis.org](http://www.arthritis.org)) is an important community resource for all patients with arthritis and other CTDs. This organization provides information to lay people and health care professionals and refers patients and their families to other resources as needed. Local support groups can help them cope with these diseases.

### ◆Evaluation: Reflecting

Evaluate the care of the patient with OA on the basis of the identified priority problems. The expected outcomes are that he or she:

- Achieves pain control to a pain intensity level of 3 to 4 on a scale of 0 to 10 or at a level that is acceptable to the patient
- Moves and functions in his or her own environment independently with or without assistive devices

## Immunity Concept Exemplar Rheumatoid Arthritis

### Pathophysiology

**Rheumatoid arthritis (RA)** is a chronic, progressive, systemic inflammatory autoimmune disease process that affects primarily the synovial joints. **Systemic** means this disease affects the body system, affecting many joints and other tissues.

In RA transformed autoantibodies (rheumatoid factors [RFs]) are formed that attack healthy tissue, especially synovium, causing inflammation. The disease then begins to involve the articular cartilage, joint capsule, and surrounding ligaments and tendons. IMMUNITY and inflammatory factors cause cartilage damage in patients with RA (Crawford & Harris, 2015; McCance et al., 2014):

- CD4 T-helper cells and other immune cells in synovial fluid promote cytokine release, especially interleukin-1 (IL-1) and tumor necrosis factor- $\alpha$  (TNF $\alpha$ ), which attack cartilage.
- Neutrophils and other inflammatory cells in the joint are activated and break down the cartilage.
- Immune complexes deposit in synovium, and osteoclasts are activated.
- B- and T-lymphocytes of the immune system are stimulated and increase the inflammatory response. (Also see Chapter 17 for a complete discussion of the inflammatory response.)

The synovium then thickens and becomes hyperemic, fluid accumulates in the joint space, and a pannus forms. The pannus is vascular granulation tissue composed of inflammatory cells; it erodes articular cartilage and eventually destroys bone. As a result, in late disease fibrous adhesions, bony ankyloses (abnormal fusion of bones in the joint), and calcifications occur; bone loses density, and secondary osteoporosis occurs.

Permanent joint changes may be avoided if RA is diagnosed early. Early and aggressive treatment to suppress synovitis may lead to a remission. RA is a disease characterized by natural remissions and exacerbations. Interprofessional health care team management helps control the disease to decrease the intensity and number of exacerbations. Preventing flares helps prevent joint erosion and permanent joint damage.

Because RA is a systemic disease, areas of the body besides the synovial joints can be affected. Inflammatory responses similar to those occurring in synovial tissue may occur in any organ or body system in which connective tissue is prevalent. If blood vessel involvement (**vasculitis**) occurs, the organ supplied by that vessel can be affected, leading to eventual failure of the organ or system in late disease.

### Etiology and Genetic Risk

The etiology of RA remains unclear, but research suggests a *combination of environmental and genetic factors*. Some researchers also suspect that female reproductive hormones influence the development of RA because it affects women more often than men—usually young to middle-age women. Others suspect that infectious organisms may play a role, particularly the Epstein-Barr virus (McCance et al., 2014). Physical and emotional stresses have been linked to exacerbations of the disorder and may be contributing factors or “triggers” to its development.

## Genetic/Genomic Considerations

### Patient-Centered Care QSEN

Research has shown that there is a strong association between RA and several human leukocyte antigen (HLA)–*DR* alleles. The cause of this association is not clear, but most HLA diseases are autoimmune (McCance et al., 2014). *DR* alleles, especially *DR4* and *DRB1*, are the primary genetic factors contributing to the development of RA. *DR4* is associated with more severe forms of the disease. Other contributing factors are being researched.

### Incidence and Prevalence

RA affects over 1.3 million people, and Euro-Americans have the disease more often than other groups (Arthritis Foundation, 2016b). The cause for this trend is not known.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

The onset of rheumatoid arthritis (RA) may be acute and severe or slow and progressive; patients may have vague symptoms that last for several months before diagnosis. The onset of the disease is more common in the winter months than in the warmer months. The manifestations of RA can be categorized as early or late disease and as articular (joint) or extra-articular (Chart 18-7).

#### ▶ Chart 18-7

### Key Features

#### The Patient With Rheumatoid Arthritis

Early Signs and Symptoms	Late Signs and Symptoms
<b>Joint</b> <ul style="list-style-type: none"><li>• Inflammation</li></ul>	<b>Joint</b> <ul style="list-style-type: none"><li>• Deformities (e.g., swan neck or ulnar deviation)</li><li>• Moderate-to-severe pain and morning stiffness</li></ul>
<b>Systemic</b> <ul style="list-style-type: none"><li>• Low-grade fever</li><li>• Fatigue</li><li>• Weakness</li><li>• Anorexia</li><li>• Paresthesias</li></ul>	<b>Systemic</b> <ul style="list-style-type: none"><li>• Osteoporosis</li><li>• Severe fatigue</li><li>• Anemia</li><li>• Weight loss</li><li>• Subcutaneous nodules</li><li>• Peripheral neuropathy</li><li>• Vasculitis</li><li>• Pericarditis</li><li>• Fibrotic lung disease</li><li>• Sjögren's syndrome</li><li>• Kidney disease</li><li>• Felty's syndrome</li></ul>

### Physical Assessment/Signs and Symptoms

#### Early Signs and Symptoms.

In the early stage of RA the patient typically reports joint inflammation, generalized weakness, and fatigue. Anorexia, weight loss of about 2 to 3 lb (1 kg), and persistent low-grade fever are common. In patients with early disease, the upper-extremity joints are involved initially—often the proximal interphalangeal (PIP) and metacarpophalangeal (MCP) joints of the hands. These joints may be slightly reddened, warm, stiff, swollen, and tender or painful, particularly on palpation (caused by synovitis). The typical pattern of joint involvement in RA is bilateral and symmetric (e.g., both wrists). The number of joints involved usually increases as the disease progresses. In early disease the patient may report migrating symptoms known as **migratory arthritis**.

The presence of only *one* hot, swollen, painful joint (out of proportion to the other joints) may mean that the joint is infected. *Refer the patient to the primary health care provider (generally the rheumatologist) immediately if this is the case.* Single hot, swollen joints are considered infected until proven otherwise and require immediate long-term antibiotic treatment.

#### Late Signs and Symptoms.

As the disease worsens, the joints become progressively inflamed and very painful. The patient usually has frequent morning stiffness (also called the **gel phenomenon**), which can last for several hours after awakening. On palpation the joints feel soft and look puffy because of synovitis and **effusions** (joint swelling with fluid, especially the knees). The fingers often appear spindle-like. Note any muscle atrophy (which can result from disuse secondary to joint pain) and a decreased range of motion in the affected joints.

Most or all synovial joints are eventually affected. The temporomandibular joint (TMJ) may be involved in severe disease, but such involvement is uncommon. When the TMJ is affected, the patient may have pain when chewing or opening the mouth.

When the spinal column is involved, the cervical joints are most likely to be affected. During clinical examination gently palpate the posterior cervical spine and identify it as cervical pain, tenderness, or loss of motion.

### 📌 Nursing Safety Priority **QSEN**

## Critical Rescue

Cervical RA may result in subluxation (partial joint dislocation), especially of the first and second vertebrae. This complication may be life threatening because branches of the phrenic nerve that supply the diaphragm are restricted and respiratory function may be compromised. The patient is also in danger of becoming quadriparetic (weak in all extremities) or quadriplegic (paralyzed in all extremities). If cervical pain (may radiate down one arm) or loss of range of motion is present in the cervical spine, keep the neck straight in a neutral position to prevent permanent damage to the spinal cord or spinal nerves. *Notify the primary health care provider immediately about these neurologic changes!*

*Joint deformity* occurs as a late, articular manifestation, and secondary osteoporosis can cause bone fractures. Observe common deformities, especially in the hands and feet (Fig. 18-6). Extensive wrist involvement can result in carpal tunnel syndrome (see Chapter 51 for assessment and management of carpal tunnel syndrome).

**FIG. 18-6** Common joint deformities seen in rheumatoid arthritis. (From Damjanov I. [2006]. *Pathophysiology for the health professions* [3rd ed.]. Philadelphia: Saunders.)

Gently palpate the tissues around the joints to elicit pain or tenderness associated with other rheumatoid complications, unless the patient is having severe joint pain. For example, **Baker's cysts** (enlarged popliteal bursae behind the knee) may occur and cause tissue compression and pain. Tendon rupture is also possible, particularly rupture of the Achilles tendon.

Numerous extra-articular signs and symptoms are associated with advanced disease. Assess the patient to ascertain systemic involvement. In addition to increased joint swelling and tenderness, *moderate-to-severe weight loss, fever, and extreme fatigue* are common in late disease **exacerbations**, often called *flare-ups*. Some patients have the characteristic round, movable, nontender **subcutaneous nodules**, which usually appear on the ulnar surface of the arm, on the fingers, or along the Achilles tendon. These nodules can disappear and reappear at any time and are associated with severe, destructive disease. Rheumatoid nodules usually are not a problem themselves; however, they occasionally open and become infected and may interfere with ADLs. Accidentally bumping the nodules may cause discomfort. Occasionally nodules occur in the lungs.

Inflammation of the blood vessels results in *vasculitis*, particularly of small to medium-size vessels. When arterial involvement occurs, major organs can become ischemic and malfunction. Assess for ischemic skin lesions that appear in groups as small, brownish spots, most commonly around the nail bed (**periungual lesions**). Monitor the number of lesions, note their location each day, and report vascular changes to the health care provider. Increased lesions indicate increased vasculitis, and a decreased number indicates decreased vasculitis. Also carefully assess any larger lesions that appear on the lower extremities. These lesions can lead to ulcerations, which heal slowly as a result of decreased circulation. Peripheral neuropathy associated with decreased circulation can cause footdrop and **paresthesias** (burning and tingling sensations), usually in older adults.

Respiratory complications may manifest as *pleurisy, pneumonitis, diffuse interstitial fibrosis*, and

*pulmonary hypertension*. Cardiac complications include *pericarditis* and *myocarditis*. These health problems are discussed elsewhere in this text. Assess for eye involvement, which typically manifests as *iritis* and *scleritis*. If either of these complications is present, the sclera of one or both eyes is reddened, and the pupils have an irregular shape. Visual disturbances may occur.

Several syndromes are seen in patients with advanced RA. The most common is **Sjögren's syndrome**, which includes a triad of:

- Dry eyes (keratoconjunctivitis sicca [KCS], or the sicca syndrome)
- Dry mouth (**xerostomia**)
- Dry vagina (in some cases)

Note the patient's report of dry mouth or dry eyes. Some patients state that their eyes feel "gritty," as if sand is in their eyes. Inspect the mouth for dry, sticky membranes and the eyes for redness and lack of tearing.

### Psychosocial Assessment.

Rheumatoid arthritis (RA) and other inflammatory types of arthritis are chronic diseases that can be disabling if not well controlled. Fear of becoming dependent, uncertainty about the disease process, altered body image, devaluation of self, frustration, and depression are common psychosocial problems. Physical limitations and chronic pain may limit MOBILITY. These limitations can result in role changes in the family and society. For example, the person may not be able to cook for the family or be an active sexual partner. In addition, extreme fatigue often causes patients to desire an early bedtime and may result in a reluctance to socialize.

Body changes caused by joint changes and drug therapy (if used) may also cause poor self-esteem and body image. Because many societies value people with physically fit, attractive bodies, the patient with RA may be embarrassed to be seen in public places. The patient may grieve or experience degrees of depression. He or she may have feelings of helplessness caused by a loss of control over a disease that can "consume" the body. Fortunately newer drugs have improved the treatment of RA and provide the patient with hope and better disease control. Only a small percentage of patients with RA become wheelchair dependent.

Living with a chronic disease and its associated impaired COMFORT is difficult for the patient and family. Chronic suffering and pain affect quality of life. Assess the patient's emotional and mental status in relation to the disease and its problems. Evaluate his or her support systems and resources. Patients who are knowledgeable about their disease and treatment options feel emotionally stronger to cope with their disease and better able to discuss treatment options with their primary health care provider.

### Laboratory Assessment.

Laboratory tests help support a diagnosis of RA, but no single test or group of tests can confirm it. [Chart 18-8](#) summarizes the most common laboratory tests that the primary health care provider may use for diagnosing connective tissue diseases.

#### Chart 18-8

## Laboratory Profile

### Connective Tissue Disease

TEST	NORMAL RANGE FOR ADULTS	SIGNIFICANCE OF ABNORMAL FINDINGS
Rheumatoid factor	Negative	Positive or increase indicative of possible RA or other CTD; may also be elevated in leukemia, liver disease, and kidney disease
ANA (total)	Negative (if positive, types of ANA identified [e.g., anti-ENA, anti-Smith, anti-SS-a (Ro)] to indicate what parts of cells are involved)	Elevations common in SLE, SSC, RA, and other inflammatory CTDs (5% of healthy adults have positive ANA results)
Serum complement	Total: 30-75 units/mL (75-160 kU/L) (C3: 75-175 mg/dL; C4: 22-45 mg/dL)	Decreased values indicative of active autoimmune disease such as SLE and other problems such as anemia, infection, and malnutrition
Erythrocyte sedimentation rate (ESR)	Male: up to 15 mm/hr Female: up to 20 mm/hr	Increased in inflammatory diseases such as RA, SLE, PMR, temporal arteritis; also elevated in patients with bacterial infections or severe anemias
SPEP	Total: 6.4-8.3 g/dL (64-83 g/L)	
Albumin	3.5-5.0 g/dL (35-50 g/L)	Decreased level occurs with chronic inflammation or infection; also decreased in malnutrition and advanced cirrhosis
Globulin	2.3-3.4 g/dL (23-34 g/L)	
Alpha <sub>1</sub> globulin	0.1-0.3 g/dL (1-3 g/L)	Increased level possible in RA
Alpha <sub>2</sub> globulin	0.6-1.0 g/dL (6-10 g/L)	
Beta globulin	0.7-1.1 g/dL (7-11 g/L)	
Gamma globulin	0.8-1.6 g/dL (8-16 g/L)	Increased levels indicative of CTD (inflammatory type)
HLA testing (HLA-)	None	Presence of HLA-B27 indicative of Reiter's syndrome or ankylosing spondylitis

ANA, Antinuclear antibody; CTD, connective tissue disease; ENA, extractable nuclear antigens; HLA, human leukocyte antigen; PMR, polymyalgia rheumatica; RA, rheumatoid arthritis; SLE, systemic lupus erythematosus; SPEP, serum protein electrophoresis; SSc, systemic sclerosis.

The test for *rheumatoid factor (RF)* measures the presence of unusual antibodies of the immunoglobulins G (IgG) and M (IgM) types that develop in a number of connective tissue diseases. Many patients with RA have a positive titer (greater than 1 : 80), *especially in older adults* (Pagana et al., 2017). However, the presence of RF is not diagnostic for RA.

The newest laboratory test called the *anti-cyclic citrullinated peptide (anti-CCP)* is very specific and sensitive in detecting early RA. The presence of anti-CCP is also a marker for aggressive and erosive late-stage disease.

The *antinuclear antibody (ANA)* test measures the titer of a group of antibodies that destroy the nuclei of cells and cause tissue death in patients with autoimmune disease. The fluorescent method is sometimes referred to as *FANA*. If this test result is positive (a value higher than 1 : 40), various subtypes of this antibody are identified and measured.

When RA patients also have Sjögren's syndrome (SS) or if the syndrome occurs as a separate disease, several unusual anti-SS antibody types may be present. In particular, *anti-SS-a (Ro)* and *anti-SS-b (La)* antibodies are present in about 60% to 70% of those with Sjögren's syndrome or those with secondary Sjögren's and RA (Pagana et al., 2017).

An elevated *erythrocyte sedimentation rate (ESR)*, or "sed rate," can confirm inflammation or infection anywhere in the body. An elevated ESR helps support a diagnosis of an unspecified inflammatory disease. The test is most useful to monitor the course of a disease, especially for inflammatory autoimmune diseases. In general the more severe the disease gets, the higher the ESR rises; as the disease improves or goes into remission, the ESR level decreases.

The *high-sensitivity C-reactive protein*, or *hsCRP*, is another useful test to measure inflammation and may be done with or instead of the ESR. As the name implies, it is more sensitive to inflammatory changes than the ESR. It is also very useful for detecting infection anywhere in the body.

The presence of most chronic diseases usually causes mild-to-moderate anemia, which contributes to the patient's fatigue. Therefore monitor the patient's complete blood count (CBC) for a low hemoglobin, hematocrit, and red blood cell (RBC) count. An increase in white blood cell (WBC) count is consistent with an inflammatory response. A decrease in the WBC count may indicate Felty's syndrome, a complication associated with late RA. Thrombocytosis (increased platelets) can also occur in patients with late RA. Additional laboratory tests may be performed, depending on the body systems and organs that may be affected by the disease. For example, if heart involvement is suspected, the primary health care provider may request cardiac enzymes.

### Other Diagnostic Assessment.

A standard x-ray is used to visualize the joint changes and deformities typical of RA. A CT scan may help determine the presence and degree of cervical spine involvement.

An *arthrocentesis* is an invasive procedure that may be used for patients with joint swelling caused by excess synovial fluid (effusion). It may be performed at the bedside or in a health care provider's office or clinic. After administering a local anesthetic, the provider inserts a large-gauge needle into the joint (usually the knee) to aspirate a sample of synovial fluid to relieve pressure. The fluid is analyzed for inflammatory cells and immune complexes, including RF. Fluid from patients with RA typically reveals increased WBCs, cloudiness, and volume.

Teach the patient to use ice and rest the affected joint for 24 hours after arthrocentesis. Often the primary health care provider will recommend acetaminophen as needed for discomfort. If increased pain or swelling occurs, teach the patient or family to notify the primary health care provider immediately.

## Nursing Safety Priority QSEN

### Action Alert

After an arthrocentesis, monitor the insertion site for bleeding or leakage of synovial fluid. Notify

the health care provider if either of these problems occurs.

A bone scan or joint scan can also assess the extent of joint involvement. MRI may be performed to assess spinal column disease or other joint involvement.

Because RA can affect multiple body systems, tests to diagnose specific systemic manifestations are performed as necessary. For example, nerve conduction studies help confirm peripheral neuropathy. Pulmonary function tests help determine the presence of lung involvement.

## NCLEX Examination Challenge 18-4

### Physiological Integrity

Which assessment findings will the nurse expect for the client with late-stage rheumatoid arthritis? **Select all that apply.**

- A. Bony nodes in finger joints
- B. Subcutaneous nodules
- C. Severe weight loss
- D. Joint deformity
- E. Thrombocytosis

#### ◆ Analysis: Interpreting

The priority collaborative problems for patients with rheumatoid arthritis (RA) include:

1. Chronic inflammation and pain due to systemic autoimmune disease process
2. Potential for decreased mobility due to joint deformity, muscle atrophy, and fatigue
3. Potential for decreased self-esteem image due to joint deformity

#### ◆ Planning and Implementation: Responding

Patients who have RA are managed in the community under the supervision of a qualified health care provider. The goal of management is that the disease goes into remission and its progression slows to decrease pain, prevent joint destruction, and increase MOBILITY. When patients with RA are admitted to the inpatient acute care or long-term care facility, it is usually for health problems other than for complications of arthritis. Whether the patient is in a facility or community, be sure to plan interventions to manage his or her chronic pain and inflammation and the potential for decreased mobility and decreased self-esteem.

### Managing Chronic Inflammation and Pain

#### Planning: Expected Outcomes.

The patient with RA is expected to have a COMFORT level that is acceptable to the patient (e.g., at a 3 on a pain intensity scale of 0 to 10). A major focus of pain management is drug therapy to modify or prevent the progression of the disease, thereby decreasing joint and systemic inflammation.

#### Interventions.

As in other types of arthritis, the interprofessional health care team manages pain by using a combination of pharmacologic and nonpharmacologic measures. A **synovectomy** to remove inflamed synovium may be needed for joints such as the knee or elbow. Total joint arthroplasty (TJA) may be indicated when other measures fail to relieve pain. TJA is discussed in the **Osteoarthritis** section of this chapter.

#### Drug Therapy.

Some drugs prescribed for RA have anti-inflammatory and/or analgesic actions. For example, NSAIDs are sometimes used for RA to help promote COMFORT and decrease inflammation. The choice of which one to prescribe depends on the patient's needs and tolerance and the scientific evidence supporting the drug therapy. To decrease GI problems, the NSAID may be given with an H<sub>2</sub>-blocking agent such as ranitidine (Zantac) or misoprostol (Cytotec). If there is no clinical change after 6 to 8 weeks, the health care provider may discontinue the current NSAID and try another one or change to a different drug class.

It was once thought that celecoxib (Celebrex), a COX-2 inhibiting NSAID, should be given rather than the older NSAIDs such as ibuprofen. However, all COX-2 inhibiting drugs have recently been associated with cardiovascular disease such as myocardial infarction, and some have been taken off the market. The risk for GI bleeding is also high in patients taking Celebrex, and the drug cannot be given to those who have had recent open-heart surgery.

Other drugs are immunosuppressive and disease modifying, which may cause remission of the illness and prevent erosive joint changes. Biological response modifiers make up the newest class of disease-modifying drugs that help reduce signals for the immune system to cause inflammation. Patients with inflammatory diseases other than RA are also using various biological response-modifying drugs successfully. Although RA is a chronic disease and no cure is yet available, drugs now used can better control the disease and prevent further deterioration. Adjustments in drug therapy are recommended every 3 to 6 months until the expected outcome or disease remission is met.

The primary health care provider, often a rheumatologist, makes decisions about appropriate drug therapy for patients with rheumatoid disease based on the severity of the disease. Initially most patients are managed with **disease-modifying antirheumatic drugs (DMARDs)**. As the name implies, these drugs are given to slow the progression of the disease. For best results, they should be started early in the disease process.

### First-Line Disease-Modifying Antirheumatic Drugs.

Methotrexate (MTX) (Rheumatrex), an immunosuppressive medication, in a low, once-a-week dose (generally 25 mg or less per week orally) is the mainstay of therapy for RA because it is effective and relatively inexpensive. It is a slow-acting drug, taking 4 to 6 weeks to begin to control joint inflammation. Observe for desired therapeutic drug effects such as a decrease in joint discomfort and swelling.

Monitor patients for potential adverse effects such as decreasing WBCs and platelets (as a result of bone marrow suppression) or elevations in liver enzymes or serum creatinine.

## Nursing Safety Priority QSEN

### Drug Alert

Patients taking MTX are at risk for infection caused by impaired or decreased drug-induced IMMUNITY. Teach them to avoid crowds and people who are ill. Remind patients to avoid alcoholic beverages while taking MTX to prevent liver toxicity. Teach them to observe and report other side and toxic effects, which include mouth sores and acute dyspnea from pneumonitis. Although not commonly occurring, lymph node tumor (lymphoma) and pneumonitis (lung inflammation) have been associated in those who have RA and are taking MTX. Folic acid, one of the B vitamins, is often given to those who are taking MTX to help decrease some of the drug's side effects.

Pregnancy is not recommended while taking methotrexate because birth defects are possible. *Strict birth control is recommended for childbearing women who are in need of MTX to control their RA.* If pregnancy is ever desired, instruct the patient to consult the rheumatologist and an obstetric/gynecologic (OB/GYN) health care provider. Generally the health care provider will discontinue the drug at least 3 months before planned pregnancy. MTX may be restarted after birth if the patient does not breast-feed (Lilley et al., 2014).

*Leflunomide (Arava)* may be prescribed for some patients. It is a slow-acting immune-modulating medication that helps diminish inflammatory symptoms of joint swelling and stiffness and improves MOBILITY. The drug is generally prescribed as a loading dose of 100 mg orally daily for 3 days followed by 20 mg orally daily thereafter. Inform the patient that Arava takes 4 to 6 weeks and

sometimes up to 3 months before maximum benefit is realized.

Arava is a potent medication that is generally tolerated; but side effects of hair loss, diarrhea, decreased WBCs and platelets, or increased liver enzymes have been reported. *Teach patients to report these changes and monitor laboratory results carefully. Remind them to avoid alcohol. Inform them that Arava can cause birth defects; therefore recommend strict birth control to women of childbearing age. Tell patients to contact their primary health care provider immediately if pregnancy occurs while taking the drug.*

Another DMARD sometimes used for RA is hydroxychloroquine. This drug slows the progression of mild rheumatoid disease before it worsens. It is an antimalarial drug that helps decrease joint and muscle pain. Patients generally tolerate hydroxychloroquine quite well. In a few cases mild stomach discomfort, light-headedness, or headache has been reported.

## Nursing Safety Priority QSEN

### Drug Alert

The most serious adverse effect of hydroxychloroquine is retinal damage. Teach patients to report blurred vision or headache. Remind them to have an eye examination before taking the drug and every 6 months to detect changes in the cornea, lens, or retina. If this rare complication occurs, the primary health care provider discontinues the drug (Lilley et al., 2014).

### Biological Response Modifiers.

As a group, **biological response modifiers (BRMs)**, sometimes called **biologics**, are one of the newest classes of DMARDs. Most BRMs neutralize the biologic activity of tumor necrosis factor–alpha (TNFA) by inhibiting its binding with TNF receptors. Any one of the BRMs may be tried. If one drug is not effective, the health care provider prescribes another drug in the same class. All these drugs are extremely expensive at this time, and insurance companies may not completely pay for their use. Some patients receive one of these drugs in addition to the drugs in this [Drug Therapy](#) section.

Teach patients receiving any one of the BRMs that they are at a high risk for developing impaired IMMUNITY and subsequent infection. Instruct them to stay away from people with infections and to avoid large crowds if possible. Remind patients with multiple sclerosis (MS), tuberculosis (TB), or a positive TB test that they should not receive TNF inhibitors because they make patients susceptible to flare-ups of these diseases. Determine whether the patient has had a recent negative purified protein derivative (PPD) test for TB. If not, a PPD skin test is typically administered, and the selected BRM is not started until a negative test result is confirmed. Collaborate with the health care provider to ensure that this process is complete. [Chart 18-9](#) provides specific examples of BRMs and associated nursing implications. Most of these medications are given parenterally and require health teaching for self-administration.

## Chart 18-9

### Common Examples of Drug Therapy

#### Biological Response Modifiers Used for Rheumatoid Arthritis and Other Connective Tissue Diseases\*

COMMON DRUGS	PURPOSE OF DRUG/DRUG CLASSIFICATION	NURSING IMPLICATIONS
For all biological response modifiers (BRMs) (also called <i>biologics</i> )	Neutralize biologic activity of tumor necrosis factor–alpha (TNFA), interleukins (IL), T-lymphocytes, or tyrosine kinase (TK) to decrease immune response and inflammation	Do not give BRMs if patient has a serious infection, TB, or MS because they may exacerbate these health problems. Teach patients taking BRMs to avoid getting live vaccines. Teach patient to avoid crowds and people with infections because serious infections, especially respiratory infections, can lead to hospitalization or cause death.
Etanercept (Enbrel)	TNFA inhibitor	Teach patient to report site reaction, which may indicate a local allergic response and cause pain. Teach patient how to self-administer drug.
Infliximab (Remicade)	TNFA inhibitor	Refrigerate all BRMs, except infliximab, to prevent drug decomposition. Teach patient to report chest pain or difficulty breathing during infusion, which could indicate a severe allergic response; monitor blood pressure and infusion site.
Adalimumab (Humira)	TNFA inhibitor	Teach patient to report site reaction, which may indicate local allergic response.
Anakinra (Kineret)	IL-1 receptor antagonist	Teach patient to monitor site for reaction (occurs more commonly when compared with other BRMs). Monitor WBC count because the drug can cause a severe decrease in WBC count and make the patient very susceptible to infection. Teach the patient to report respiratory symptoms such as cough and fever. Teach him or her that malignancies can result from taking this drug.
Abatacept (Orencia)	Selective T-lymphocyte co-stimulator modulator (T-cell inhibitor)	Report cough, dizziness, and sore throat; do not receive live vaccines while taking the drug.

		Monitor for dyspnea, wheezing, flushing, itching, which may indicate a mild-to-moderate allergic reaction.
Rituximab (Rituxan)	Monoclonal antibody	Observe for infusion reaction as for etanercept. Drug has a <b>black box warning</b> about serious infections from opportunistic pathogens that can lead to hospitalizations or death.
Golimumab (Simponi)	TNFA inhibitor	Teach patient to report signs and symptoms of infection, including fever and malaise; teach patient to avoid live vaccines while taking drug. Teach patient about adverse drug effects, including hypertension, GI distress, and infection from opportunistic pathogens; report signs and symptoms of these problems to the health care provider.
Tocilizumab (Actemra)	IL-6 inhibitor	Teach patient the importance of having frequent WBC, platelet, and liver enzyme testing. This drug can cause decreased WBCs and platelets and liver dysfunction.

MS, Multiple sclerosis; TB, tuberculosis; TNF, tumor necrosis factor; WBC, white blood cell.

\*This is not a comprehensive list; this chart lists only the common biological response modifiers (BRMs) used for rheumatoid arthritis and other connective tissue diseases.

### Other Drugs.

A few drugs may be given as adjuncts to or instead of the previously described drugs. It is not unusual for a patient to be taking several disease-modifying drugs such as methotrexate, a BRM, and an adjunct medication. Each drug works differently to relieve symptoms and slow the progression of the disease.

*Glucocorticoids (steroids)*—usually prednisone (Deltasone)—are given for their fast-acting anti-inflammatory and immunosuppressive effects. Prednisone may be given in high dose for short duration (**pulse therapy**) or as a low chronic dose. Moderate-dose short-term tapering bridge therapy may be used when inflammation is symptomatic and other RA medications are insufficient or have not yet had an effect.

Chronic steroid therapy can result in numerous complications such as:

- Diabetes mellitus
- Impaired or decreased IMMUNITY
- Fluid and electrolyte imbalances
- Hypertension
- Osteoporosis
- Glaucoma

Some drug effects are dose related, whereas others are not. Observe the patient for complications associated with chronic steroid therapy and report them to the primary health care provider. For example, if blood pressure becomes elevated or significant laboratory values change, notify the primary health care provider.

Instruct patients taking chronic steroids to take calcium, 1200 to 1500 mg daily, plus vitamin D, 400 mg daily, to help prevent osteoporosis. Bisphosphonate drugs may also be prescribed. Bone-density measurements (DEXA [dual-energy x-ray absorptiometry] scans) are done every 2 to 3 years to monitor for bone loss.

Patients with RA may experience one or a few joints that have more pain and inflammation than the others. Cortisone injections in single joints may be used to relieve local pain and inflammation. Have the patient ice and rest the joint for 24 hours after the procedure. Oral analgesics also are sometimes needed during that time.

### Nonpharmacologic Interventions.

Adequate rest, proper positioning, and ice and heat applications are important in pain management. If acute inflammation is present, ice packs may be applied to “hot” joints for pain relief until the inflammation lessens. The ice pack should not be too heavy. At home the patient can use a small bag of frozen peas or corn as an ice pack.

Heated paraffin (wax) dips may help increase COMFORT of arthritic hands. Finger and hand exercises are often done more easily after paraffin treatment. To relieve morning stiffness or the pain of late-stage disease, recommend a hot shower rather than a sponge bath or a tub bath. It is often difficult for the patient with RA to get into and out of a bathtub, although special hydraulic lifts and tub chairs are available to allow him or her to bathe. Safety (grab) bars and nonskid tread in the tub or shower floor are important safety features to discuss with all patients. Some older adults prefer using shower chairs and a walk-in shower that does not have a ledge that could cause falls.

Hot packs applied directly to involved joints may be beneficial. Most physical therapy departments have machines that keep hot packs ready anytime they are needed. Teach patients to use the microwave or stovetop heating instructions to warm heat packs at home. Remind them to follow the instructions given with each heating device used.

*Plasmapheresis* (sometimes called *plasma exchange*) is an in-hospital procedure prescribed by a health care provider in which the patient's plasma is treated to remove the antibodies causing the disease. Although not commonly done, this procedure may be combined with steroid pulse therapy for patients with severe, life-threatening disease.

### Complementary and Integrative Health.

Some patients may have pain relief from hypnosis, acupuncture, imagery, music therapy, or other techniques. Stress management is also popular as a pain relief intervention. [Chapter 4](#) discusses these therapies in more detail.

Adequate nutrition is an important part of the management of RA. Obesity should be avoided or treated if present. The inflammatory state may place a greater burden on the metabolism of some essential nutrients. This catabolic state may be related to increased cytokine production, specifically tumor necrosis factor.

According to the [Arthritis Foundation \(2016b\)](#), no one food causes or cures RA; however, healthy nutrition in general is important. Refer the patient to the Arthritis Foundation's pamphlet regarding diet and arthritis. Refer him or her to the dietitian for vitamin- and nutrition-specific questions or recommendations. Teach patients to take any herbal or nutrition supplement under the supervision of a qualified health care provider to prevent adverse events and drug-food or drug-drug interactions.

Other integrative therapies are safe and have been scientifically proven to be effective to help control RA pain for most people. Examples include mind-body therapies such as relaxation techniques, imagery, and spiritual practices. For information about these techniques, see [Chapter 4](#).

### Promoting Mobility

#### Planning: Expected Outcomes.

Patients with RA often have decreased MOBILITY related to multiple joint deformities and muscle atrophy. Fatigue and generalized weakness also contribute to decreased mobility. The expected outcome is that the patient will be able to independently perform ADLs with or without ambulatory and assistive devices.

#### Interventions.

Although the physical appearance of a patient with severe RA may create the image that ADL independence is not possible, a number of alternative and creative methods can be used to perform these activities. *Do not perform these activities for the patient unless asked. Those with RA do not want to be dependent.* For example, hand deformities often prevent a patient from opening packages of food such as a box of crackers; however, he or she may prefer to use the teeth to open the crackers rather than depend on someone else.

In the hospital or long-term care facility, a patient may not eat because of the barriers of heavy plate covers, milk cartons, small packages of condiments, and heavy containers. Styrofoam or paper cups may bend and collapse as he or she attempts to hold them. A china or heavy plastic cup with handles may be easier to manipulate. Collaborate with the dietitian to help with access to food and total independence in eating.

When fine-motor activities (e.g., squeezing a tube of toothpaste) become impossible, larger joints or body surfaces can substitute for smaller ones. For example, teach how to use the palm of the hand to press the paste onto the brush. Devices such as long-handled brushes can help patients brush their hair; dressing sticks can assist with putting on pants. These examples illustrate the need to assess the problem area, suggest alternative methods, and refer the patient to an OT or PT for special assistive and adaptive devices if necessary.

Additional nursing interventions depend in part on identifying the factors contributing to fatigue. For example, decreased or impaired COMFORT, sleep disturbances, and weakness are associated with increased fatigue. Anemia may also be a contributing factor and may be treated with iron (if an iron deficiency anemia is present), folic acid, or vitamin supplements prescribed by the health care

provider. Chronic normochromic or chronic hypochromic anemia often occurs in most chronic systemic diseases. Assess for drug-related blood loss such as that caused by NSAIDs by checking the stool for gross or occult blood. *Older white women are the most likely to experience GI bleeding as a result of taking these medications. The reason for this trend is not known.*

If fatigue and decreased MOBILITY result from muscle atrophy, the health care provider prescribes an aggressive physical therapy program to strengthen muscles and prevent further atrophy. Patients also experience increased fatigue when pain prevents them from getting adequate rest and sleep. Measures to facilitate sleep include promoting a quiet environment, giving warm beverages, and administering hypnotics or relaxants as prescribed if necessary.

In addition to identifying and managing specific reasons for fatigue, determine the patient's usual daily activities and teach principles of **energy conservation**, including:

- Pacing activities
- Allowing rest periods
- Setting priorities
- Obtaining assistance when needed

**Chart 18-10** lists specific suggestions for conserving energy and thus increasing activity tolerance and mobility.

### **Chart 18-10**

## **Patient and Family Education: Preparing for Self-Management**

### **Energy Conservation for the Patient With Arthritis**

- Balance activity with rest. Take one or two naps each day.
- Pace yourself; do not plan too much for one day.
- Set priorities. Determine which activities are most important and do them first.
- Delegate responsibilities and tasks to your family and friends.
- Plan ahead to prevent last-minute rushing and stress.
- Learn your own activity tolerance and do not exceed it.

### **Enhancing Self Esteem**

#### **Planning: Expected Outcome.**

The patient with RA often has multiple joints that are inflamed or deformed, causing a potential for decreased self-esteem. Therefore the expected outcome is that the patient will verbalize a positive perception of self as a result of interprofessional interventions.

#### **Interventions.**

Body image and self-esteem may be affected by both the disease process and drug therapy. Steroids can cause a moonfaced appearance, acne, striae, "buffalo humps," and weight gain. Determine the patient's perception of these changes and the impact of the reactions of family and significant others. The most important intervention is communicating acceptance of the patient. When a trusting relationship is established, encourage him or her to express personal feelings.

As a reaction to body changes and joint deformity and the presence of a chronic, painful disease, some patients display behaviors indicative of loss. They may use coping strategies that range from denial or fear to anger or depression. In an attempt to regain control over the effects of the disease process, they may appear to be "manipulative and demanding" and sometimes may be referred to as having an "arthritis personality." *This personality, which represents a negative label, is a myth; avoid using these terms.* Patients are trying to cope with the effects of their illness and should be treated

with patience and understanding. Continually assess and accept these behaviors but remain realistic in discussing goals to improve self-esteem and body image. Emphasize their strengths and help them identify previously successful coping strategies. If needed, consult with mental health professionals or religious/spiritual leaders to help patients cope with this potentially debilitating chronic disease.

### Care Coordination and Transition Management

Patients with rheumatoid arthritis (RA) are usually managed at home but in a few cases may be institutionalized in a long-term care facility if they become restricted to bed or a wheelchair. Some patients may be transferred to a rehabilitation facility for several weeks to help develop strategies, techniques, and skills for independent living at home. Chapter 6 discusses the rehabilitation process in detail.

### Home Care Management.

The amount of home care preparation depends on the severity of the disease. Structural changes may be necessary if there are deficits in performing ADLs or MOBILITY. Doors must be wide enough to accommodate a wheelchair or walker if one is used. Ramps are needed to prevent the patient in a wheelchair from becoming homebound. If the person cannot use stairs, he or she must have access to facilities for all ADLs on one floor. Handrails should be available in the bathroom and halls.

To promote continued homemaking functions, countertops and appliances may require structural changes. The patient may also require handrails and elevated chairs and toilet seats, which facilitate transfers (Fig. 18-7). *These devices are especially important for older adults with arthritis.*

FIG. 18-7 Handrails and an elevated toilet seat make transfers easier for the patient.

### Self-Management Education.

Self-management education (SME) is a vital role for nurses in collaborative management of arthritis. Many people have signs and symptoms of joint inflammation but do not seek medical attention. Teach them to seek professional health care to reduce pain and prevent disability.

Teach patients to discuss any questions with their health care provider before trying any over-the-counter or home remedies. Some remedies may be harmful. Check with the Arthritis Foundation for the latest information on arthritis myths and quackery ([www.arthritis.org](http://www.arthritis.org)).

Provide information to the patient and family about drug therapy, joint protection, energy conservation, rest, and exercise. This SME is summarized in Charts 18-5, 18-6, and 18-10.

Assess the patient's coping strategies. The patient with RA often reports being on an "emotional roller coaster" from coping with a chronic illness every day. Control over one's life is an important human need. The patient with an unpredictable chronic disease may lose this control, and this lowers self-esteem. Health care providers must allow the patient to make decisions about care. Families and significant others must also include him or her in decision making. Although the patient's behavior may be perceived as demanding or manipulative, his or her self-esteem cannot be improved without this important aspect of interpersonal relationships.

Increased dependency also affects a sense of control and self-esteem. Some people ignore their health needs and portray a tough image for others by insisting that they need no assistance. Emphasize to the patient and family that asking for help may be the best decision at times to prevent further joint damage and disease progression.

RA may also affect work and social roles. The patient may have physical difficulty doing tasks that require lifting, climbing, grasp, or gross- or fine-motor activities. The severity of RA disease may cause difficulty with total number of hours worked. Some people with RA can do their jobs well without problem; others may have varying degrees of difficulty. Those who can no longer do their job at work may need to discuss with their employer having a lighter workload, but some may need to file for disability with their company and Social Security office.

### Health Care Resources.

The need for health care resources for the patient with RA is similar to that for the patient with osteoarthritis. A home care nurse or aide, physical therapist, or occupational therapist may be needed during severe exacerbations or as the disease progresses. In collaboration with the case manager, identify these resources and make sure that they are available as needed. The Arthritis Foundation is an excellent source of information and support.

Arthritis support groups and self-help courses provide the education and support that patients, families, and friends need. Refer the patient to a psychological counselor or religious or spiritual leader for emotional support and guidance during times of crisis or as needed. Identify and recommend other support systems within the family and community when necessary.

## Clinical Judgment Challenge 18-1

### Teamwork and Collaboration; Safety QSEN

An 83-year-old woman with RA has been controlled with methotrexate (MTX) and prednisone for many years. Recently she was admitted to the acute care hospital for difficulty breathing and extreme weakness. She walked with a walker at home and rarely left her apartment. After a 9-day stay in the hospital for treatment of pneumonitis and congestive heart failure, she was transferred to a rehabilitation unit in a long-term care facility to regain her strength and ambulation ability. She was not ambulated during her entire hospital stay. Both medications being used to manage her long-term RA were discontinued.

1. What problems do you anticipate the patient will have and why?
2. Why do you think her medications were discontinued?
3. With which members of the health care team might you collaborate as part of her plan of care in rehabilitation and why?
4. Which home and community assessment might be needed to ensure her safety and provide continuity of care?
5. Which self-management education will she need before discharge from the rehabilitation setting? Will the patient be able to return to her apartment to live independently as she did before her hospital admission?

### ◆ Evaluation: Reflecting

Evaluate the care of the patient with RA on the basis of the identified priority problems. The expected outcomes are that he or she:

- Achieves pain control to a pain intensity level of 3 to 4 or less on a scale of 0 to 10 or at a level that is acceptable to the patient
- Moves and functions in his or her own environment independently with or without assistive devices
- Verbalizes increased self-esteem and positive perception of self

# Lupus Erythematosus

## ❖ Pathophysiology

The two main classifications of lupus are discoid lupus erythematosus (DLE) and systemic lupus erythematosus (SLE). A small percentage of patients with lupus have the DLE type, which affects only the skin.

Unlike DLE, **systemic lupus erythematosus** is a chronic, progressive, inflammatory connective tissue disorder that can cause major body organs and systems to fail. Like RA, it is characterized by spontaneous remissions and **exacerbations** (“flare-ups”), and the onset may be acute or insidious (slow). The condition is potentially fatal, but most patients with SLE live many years after diagnosis and lead productive lives. Improvements in determining the cause, diagnosis, and treatment of lupus account for the prolonged survival.

Lupus is thought to be an autoimmune process. Antinuclear antibodies (ANAs) primarily affect the DNA, ribonucleic acid (RNA), and other components within the cell nuclei. As a result, immune complexes form in the serum and organ tissues, which cause inflammation, damage, and destruction (McCance et al., 2014). These complexes invade organs directly or cause **vasculitis** (vessel inflammation), which deprives the organs of arterial blood and oxygen.

Autoimmune complexes in SLE tend to be most attracted to the glomeruli of the kidneys. Therefore many of these patients have some degree of kidney involvement, called *lupus nephritis* —the leading cause of death from the disease. Other causes of death are cardiac and central nervous system involvement.

## 🏠 Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Lupus affects women 10 times more often than men; women of color are affected far more often than Euro-Americans. The reason for this difference is unknown (McCance et al., 2014). The disease also occurs among American Indians, Asian Americans, and Hispanics (Lupus Foundation of America, 2016).

The onset of the disease occurs most often during the childbearing years (ages 20 to 40 years), but it has been reported in young children and older adults. A genetic predisposition is based on the trend to develop the disease in some twins and the occurrence of autoimmune disease in some families of patients who have lupus. However, it is not the only basis of the disease. Like RA, lupus is probably caused by a complex *combination of genetic and environmental factors*.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

It is impossible to describe a typical textbook picture of a patient with lupus because of the extreme range of symptoms. There is no classic presentation of this disease. When lupus is in remission, the patient may appear healthy and have few or no activity limitations. When the disease flares, some patients may be so ill that admission to a critical care unit is needed. [Chart 18-11](#) highlights the signs and symptoms that can occur with systemic lupus.

### ▶ Chart 18-11

## Key Features

### Systemic Lupus Erythematosus (SLE) and Systemic Sclerosis (SSc)

SYSTEMIC LUPUS ERYTHEMATOSUS	SYSTEMIC SCLEROSIS
Skin Manifestations	
Inflamed, red rash Discoid lesions	Inflamed Fibrotic Sclerotic

	Edematous
Renal Manifestations	
Nephritis	Kidney failure
Cardiovascular Manifestations	
Pericarditis	Myocardial fibrosis
Raynaud's phenomenon	Raynaud's phenomenon Deep vein thrombosis
Pulmonary Manifestations	
Pleural effusions	Interstitial fibrosis
Pneumonia	Pulmonary hypertension
Neurologic Manifestations	
CNS lupus	Not common
GI Manifestations	
Abdominal pain	Esophagitis Ulcers GERD
Musculoskeletal Manifestations	
Joint inflammation (polyarthritis)	Arthralgia
Myositis	Myositis
Other Manifestations	
Fever (indicates exacerbations)	Fever
Fatigue	Fatigue
Anorexia	Anorexia
Weight loss	Vasculitis
Generalized weakness	
Vasculitis	

CNS, Central nervous system; GERD, gastroesophageal reflux disease.

## Physical Assessment/Signs and Symptoms

### Skin Involvement.

The major skin manifestation of DLE and SLE is a dry, scaly, raised rash on the face (“butterfly” rash) (Fig. 18-8). This rash may also appear on other sun-exposed areas. It is initially nonscarring and may increase in a lupus flare and disappear when the disease is in remission.

**FIG. 18-8** The characteristic “butterfly” rash of systemic lupus erythematosus.

Individual round **discoid** (coinlike) **lesions** are the scarring lesions of discoid lupus. The lesions are especially evident when the patient is exposed to sunlight or ultraviolet light. Alopecia is also common in lupus. Observe and document all skin changes and monitor them daily while the patient is in an acute care setting or during an ambulatory care or home visit. Mouth ulcers are not uncommon.

### Other Signs and Symptoms.

In addition to skin changes, *polyarthritis* occurs in most patients with SLE. The early joint changes are similar to those seen in rheumatoid arthritis (RA), but severe deformities are not common even in late disease. Small joints and the knees are most commonly inflamed. **Osteonecrosis** (bone

necrosis from lack of oxygen) is often seen in those who have been treated for at least 5 years with steroids like prednisone. Chronic steroid therapy may cause the constriction of small blood vessels supplying the joint, which causes the tissue to die. The hip is most commonly affected, and reports of pain and decreased MOBILITY result. As a result, a total hip arthroplasty may be done.

Because SLE is an inflammatory condition, *fever* and *fatigue* are common findings. *Fever is the classic sign of a flare, or exacerbation.* Various degrees of generalized weakness, fatigue, anorexia, and weight loss may occur. These signs may be the only evidence of disease, which makes diagnosis by the health care provider difficult. Therefore some patients have a diagnosis of “probable SLE.” Additional signs and symptoms of SLE are listed in [Chart 18-11](#).

### Psychosocial Assessment.

The psychosocial results of lupus can be devastating. With either DLE or SLE, the rash can be disfiguring and embarrassing. Young adult women who never had a blemish are confronted with a rash that cannot be completely covered with makeup. If chronic steroid therapy is used, side effects such as acne, striae, fat pads, and weight gain intensify the problem of an already altered body image.

Chronic fatigue and generalized weakness may prevent the patient from being as active as in the past. He or she may avoid social gatherings and may withdraw from family activities. The unpredictability and chronicity of SLE can cause fear and anxiety. Fear may increase if the patient knows another person with the disease, particularly if the other person has more advanced severe disease. Unfortunately the myth that lupus is fatal is still common. Inform the patient and family that control of lupus is generally possible with regular medical monitoring, medications, and healthy practices such as limiting sun exposure to prevent exacerbation of the disease.

Assess the patient's and family's feelings about the illness to identify areas requiring intervention. Determine their usual coping mechanisms and support systems before developing a plan of care. See the [Psychosocial Assessment](#) section of the [Rheumatoid Arthritis](#) section for additional information.

### Laboratory Assessment.

Because discoid lupus erythematosus (DLE) is not a systemic condition, the only significant test is a *skin biopsy*. The physician gently scrapes skin cells from the rash for microscopic evaluation. The characteristic lupus cell and a number of inflammatory cells confirm the diagnosis.

Some of the immunologic-based laboratory tests used to diagnose SLE are the same as those performed for rheumatoid arthritis (RA): rheumatoid factor, antinuclear antibody, erythrocyte sedimentation rate, serum protein electrophoresis, serum complement (especially C3 and C4), and immunoglobulins (see [Chart 18-8](#)). A false-positive Venereal Disease Research Laboratory (VDRL) syphilis test is common with lupus ([Pagana et al., 2017](#)).

More specific immunologic tests such as anti-SS-a (Ro), anti-SS-b (La), anti-Smith (anti-Sm), anti-DNA, and extractable nuclear antigens (ENAs) are also performed ([Pagana et al., 2017](#)). High titers of some of these antibodies are associated with lupus.

A complete blood count (CBC) commonly shows **pancytopenia** (a decrease of all cell types), probably caused by direct attack of the blood cells or bone marrow by immune complexes. Serum electrolyte levels, kidney function, cardiac and liver enzymes, and CLOTTING factors are also routinely assessed to determine other body system functioning.

### ◆Interventions: Responding

The primary health care provider often prescribes potent drugs that are used topically and systemically. In addition, precautions are taken to prevent further skin impairment and exacerbations. Many of the skin lesions do not disappear, even with treatment, but they usually fade when the disease is in remission.

### Managing Lupus With Drug Therapy.

With DLE the patient's major concern is the rash or discoid lesions. Patients with SLE are also concerned about skin changes. Topical cortisone preparations help reduce inflammation and promote fading of the skin lesions. Acetaminophen (Tylenol) or NSAIDs may be used to treat joint and muscle pain and inflammation.

In addition, the health care provider may prescribe the anti-malarial agent *hydroxychloroquine* for some patients. Hydroxychloroquine decreases the absorption of ultraviolet light by the skin and therefore decreases the risk for skin lesions. *Teach patients to have frequent eye examinations (before starting the drug and every 6 months thereafter) if they are receiving hydroxychloroquine.*

The primary health care provider often prescribes chronic steroid therapy to treat the systemic disease process. For renal or central nervous system lupus, he or she may also prescribe immunosuppressive agents such as methotrexate (Rheumatrex) or azathioprine (Imuran). Although signs and symptoms typically improve during remission, maintenance doses of these drugs are usually continued to prevent further exacerbations of the disease. These drugs make patients susceptible to decreased IMMUNITY.

## Nursing Safety Priority QSEN

### Drug Alert

When patients are taking steroids and/or immunosuppressants, stress the importance of avoiding large crowds and people who are ill. Teach patients to report any early sign of infection to their health care provider. Observe for side effects and toxic effects of these drugs and report their occurrence immediately. Remind patients to take their medication early in the morning before breakfast because that is the time when the body's natural corticosteroid level is the lowest.

For severe renal involvement, immunosuppressants may be given in combination with steroids. For patients who do not respond to this regimen, a high-dose IV bolus of glucocorticoids, cyclophosphamide, and plasmapheresis may be tried for 3 consecutive days. Kidney transplantation has been successful for some patients.

The first drug approved for SLE in 60 years is *belimumab* (*Benlysta*). In SLE abnormal B-cells contribute to autoantibodies. Belimumab is an IV human monoclonal antibody (mAb) that prevents B-lymphocyte stimulator protein from binding to B-cell receptor sites, thus decreasing B-cell survival. It is given with other drugs to treat SLE. Like for other biologics, teach patients that the drug increases their risk for serious infections. Teach them not to receive live vaccines for 30 days before treatment.

### Protecting the Skin.

Teach patients to protect their skin to prevent an exacerbation of the disease.

## Nursing Safety Priority QSEN

### Action Alert

Instruct patients to avoid prolonged exposure to sunlight and other forms of ultraviolet lighting, including certain types of fluorescent light. Remind them to wear long sleeves and a large-brimmed hat when outdoors. Patients should use sun-blocking agents with a sun protection factor (SPF) of 30 or higher on exposed skin surfaces.

In addition, teach patients to clean the skin with mild soap (e.g., Ivory) and to avoid harsh, perfumed substances. The skin should be rinsed and dried well and lotion applied. Excess powder and other drying substances should be avoided. Cosmetics must be selected carefully and should include moisturizers and sun protectors. If desired, refer the patient to a medical cosmetologist who specializes in applying makeup for skin lesions of all types.

Patients' hair should receive special attention because alopecia (hair loss) is common. Recommend the use of mild protein shampoos and the avoidance of harsh treatments (e.g., permanents or highlights) until the hair regrows during remission.

### Care Coordination and Transition Management

Community-based and continuing care for the patient with lupus is similar to that for RA. In general the patient is home but may need repeated hospitalizations during exacerbations of disease.

He or she usually does not need rehabilitation unless having surgery, because severe joint deformity and prolonged immobility are not common in lupus.

Two major differences exist between SLE and RA in terms of education of the patient and family or significant others. First, instruct patients with SLE how to protect the skin (Chart 18-12). Second, teach them to monitor body temperature. Fever is the major sign of an exacerbation, during which they can become seriously ill. Teach the importance of reporting any other unusual or new signs and symptoms to the primary health care provider immediately.

### Chart 18-12

## Patient and Family Education: Preparing for Self-Management

### Evidence-Based Practice for Skin Protection in Patients With Lupus Erythematosus

- Cleanse your skin with a mild soap such as Ivory.
- Dry your skin thoroughly by patting rather than rubbing.
- Apply lotion liberally to dry skin areas.
- Avoid powder and other drying agents such as rubbing alcohol.
- Use cosmetics that contain moisturizers.
- Avoid direct sunlight and any other type of ultraviolet lighting, including tanning beds.
- Wear a large-brimmed hat, long sleeves, and long pants when in the sun.
- Use a sun-blocking agent with a sun protection factor (SPF) of at least 30.
- Inspect your skin daily for open areas and rashes.

Many patients become frustrated that family members, significant others, and lay people do not have a thorough understanding of lupus. When lupus is in complete remission, patients appear to be healthy; however, an exacerbation can lead to a critical care admission. This unpredictability disrupts the patient's life and can cause fear and anxiety. Help him or her identify coping strategies and support systems that can help with functioning in the community.

Teach the possible effects of the disease, including fatigue, on lifestyle. Women of childbearing age need to know that pregnancy can be a stressor and can cause an exacerbation of the disease, either during pregnancy or after delivery. The pregnant woman also has an increased risk for miscarriage, stillbirth, or premature birth. Pregnancy is not recommended for those with cardiac, renal, or central nervous system involvement.

The Arthritis Foundation is a general resource for all patients with connective tissue disease. The Lupus Foundation ([www.lupus.org](http://www.lupus.org)) is a resource specific for patients with lupus. It is a national organization and has chapters in every state to provide information and assistance for patients with lupus and their families. Local support groups and services are offered free of charge.

### NCLEX Examination Challenge 18-5

#### Health Promotion and Maintenance

Which health teaching by the nurse is important for clients diagnosed with systemic lupus erythematosus? **Select all that apply.**

- A. "Take frequent rest periods to prevent fatigue."
- B. "Avoid green leafy vegetables to prevent bleeding."

- C. "Avoid sun exposure to prevent disease flare-ups."
- D. "Report fever to your health care provider immediately"
- E. "Use a mild soap for bathing to prevent skin irritation."

# Systemic Sclerosis

## ❖ Pathophysiology

**Systemic sclerosis (SSc)**, also called *scleroderma*, is another chronic, inflammatory, autoimmune connective tissue disease. Systemic sclerosis has been described in people of all races and in all geographic areas and affects over 300,000 people in the United States. Women are affected more often than men. The onset of the disease is usually between 25 and 55 years of age, with most women getting it in their 40s ([Scleroderma Foundation, 2016](#)).

Formerly called *progressive systemic disease*, or *PSS*, this illness is not always progressive.

**Scleroderma** means hardening of the skin, which is only one sign of the problem. Some patients, often children, have only skin involvement, or localized scleroderma (also called *linear scleroderma*). However, adults usually have skin and other body system involvement. SSc is less common than systemic lupus erythematosus (SLE) but is associated with a higher mortality rate. See [Chart 18-11](#) for a comparison of the key features of these two diseases. The signs and symptoms for both diseases vary widely from person to person.

Patients with the *limited* form of the disease often have the CREST syndrome:

- Calcinosis (calcium deposits)
- Raynaud's phenomenon (first symptom that occurs)
- Esophageal dysmotility
- Sclerodactyly (scleroderma of the digits)
- Telangiectasia (spider-like hemangiomas)

Little is known about the cause of SSc, but autoimmunity is suspected. The occurrence of more than one case per family is uncommon, but other connective tissue diseases may be noted in the family history. At this time specific genetic causes have not been confirmed.

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

#### Physical Assessment/Signs and Symptoms.

**Arthralgia** (joint pain) and stiffness are common manifestations that you can assess during the musculoskeletal examination. The acute joint inflammation that occurs with rheumatoid arthritis (RA) is not common, and deformities are rare.

Findings on inspection of the skin depend on the stage of the scleroderma. Typically a painless, symmetric, pitting edema of the hands and fingers is present, especially in patients with the diffuse form of the disease. The edema may progress to include the entire upper and lower extremities and face. In this phase the fingers are described as *sausage-like*. The skin is taut, shiny, and free of wrinkles. If diffuse scleroderma occurs, swelling is replaced by tightening, hardening, and thickening of skin tissue; this phase is sometimes called the *indurative phase* ([Fig. 18-9](#)). The skin loses its elasticity, and range of motion is markedly decreased; ulcerations may occur. Joint contractures may develop, and the patient may be unable to perform ADLs independently.

**FIG. 18-9** Late-stage skin changes seen in patients with systemic sclerosis. (From Goldman, L., & Ausiello, D. [2007]. *Cecil medicine* [23rd ed.]. Philadelphia: Saunders.)

Major organ damage is likely to develop with diffuse scleroderma, specifically affecting the renal and cardiopulmonary systems. The initial gastroesophageal reflux disease (GERD) symptoms progress into other problems, especially affecting the esophagus. The esophagus loses its motility, resulting in *dysphagia* (*difficulty swallowing*). *Assess for the ability of the patient to swallow before allowing him or her to drink or eat food!* Reflux of the gastric contents can cause esophagitis and subsequent ulceration, particularly in the lower two thirds of the esophagus. Intestinal changes are similar to those of the esophagus. Peristalsis is diminished, which causes signs and symptoms similar to a partial bowel obstruction. Malabsorption is a common complication, causing malodorous *diarrheal stools*.

In addition to assessing problems of the digestive tract, observe for *cardiovascular manifestations*. *Raynaud's phenomenon* occurs in various degrees in most patients with SSc. On exposure to cold or emotional stress, the small arterioles in the digits of both hands and feet rapidly constrict, which causes decreased blood flow. In severe cases the patient experiences digit necrosis, excruciating pain, and **autoamputation of the distal digits** (the tips of the digits fall off spontaneously). In many patients vasculitic lesions, often around the nail beds (**periungual lesions**), are evident. *Myocardial fibrosis*, another common problem, is evidenced by electrocardiographic (ECG) changes, cardiac dysrhythmias, and chest pain.

*Lung involvement* in the patient with SSc may go undetected until late in the disease or sometimes until autopsy. *Fibrosis of the alveoli and interstitial tissues* is present in almost all cases of the disease, but signs and symptoms may not be present. Patients with scleroderma and *pulmonary arterial hypertension* have a more serious prognosis. *Renal involvement* is an important aspect of the overall disease process and often causes malignant hypertension and death. Assess for signs of impending organ failure such as changes in urine output and increased blood pressure.

### Laboratory Assessment.

The laboratory findings for SSc are similar to those for SLE. Clinical findings and the patient's response to drug therapy help the health care provider differentiate between the two diseases. Additional tests depend on which organs seem to be affected. Upper and lower GI series are commonly performed because of the frequency of GI signs and symptoms.

### ◆Interventions: Responding

The medical management of SSc aims to force the disease into remission and thus slow disease progression. The primary health care provider prescribes drug therapy primarily for this purpose, but it is often unsuccessful. Systemic steroids and immunosuppressants are used in large doses and often in combination. Another desired outcome of disease management is to identify early organ involvement and treat it before it becomes severe and irreversible. For example, a patient who has lung involvement receives aggressive respiratory therapy and other treatments as the condition requires.

Recently bosentan (Tracleer), the first of a new class of drugs called *endothelin receptor antagonists*, demonstrated improved walk tests for patients with class III or class IV pulmonary arterial hypertension. Various doses improved patients' breathing during exercise, but the potential for

liver injury at the highest dose caused recommended doses to be lowered. Teach the patient the desired and potential adverse effects, including liver toxicity and birth defects. Remind him or her of the importance of follow-up testing for liver enzyme levels.

New oral tyrosine kinase inhibitors (TKIs), including nilotinib (Tasigna) and imatinib mesylate (Gleevec), are being tested in the United States for use for patients with systemic sclerosis, and the results are very promising. These drugs work to decrease inflammation and slow the progression of the disease. They are currently approved in the United States for use in certain types of cancer.

Local skin protective measures can help maintain skin integrity. Teach the patient to use mild soap and lotions and gentle cleaning techniques. Inspect the skin for further changes or open lesions. Skin ulcers are treated according to their type and location.

In addition to drug therapy to control the overall disease process, specific measures can provide COMFORT. The patient with SSc not only experiences chronic joint discomfort but also has severe, acute pain during episodes of Raynaud's phenomenon. Remind unlicensed nursing personnel to use a bed cradle and foot board to keep bed covers away from the skin in severe cases. Adjust the room temperature to prevent chilling, which can precipitate digit vasospasm. The patient who can tolerate touching the affected areas can wear gloves and socks to increase warmth. Because cigarette smoking and extreme emotional stress can also cause symptoms to recur, teach the patient to avoid or minimize these factors as much as possible.

If the patient has esophageal involvement, collaborate with the speech and language pathologist to schedule a swallowing study. The patient may need small, frequent meals rather than the traditional three meals daily. He or she should minimize the intake of foods and liquids that stimulate gastric secretion (e.g., spicy foods, caffeine, alcohol). Teach the patient to keep his or her head elevated for 1 to 2 hours after meals. He or she may need to be in this position continuously. Histamine antagonists and antacids help reduce and neutralize gastric acid. To help prevent choking, collaborate with the dietitian for dietary changes ([Chart 18-13](#)).

### Chart 18-13

## Best Practice for Patient Safety & Quality

### Care of the Patient With Systemic Sclerosis and Esophagitis

- Keep the patient's head elevated at least 60 degrees during meals and for at least 1 hour after each meal.
- Provide small, frequent meals rather than three large meals each day.
- Give the patient small amounts of food for each bite and explain the importance of chewing each bite carefully before swallowing.
- Provide semisoft foods such as mashed potatoes and pudding or custard; liquids are most likely to cause choking.
- Collaborate with the dietitian about the patient's diet.
- Teach the patient to avoid foods that increase gastric secretion such as caffeine, pepper, and other spices.
- Give antacids or histamine antagonists as needed.

Nursing care for the patient with joint pain and decreased MOBILITY is very similar to that for rheumatoid arthritis (see the [Interventions](#) section of the [Rheumatoid Arthritis](#) section).

Continuing and community-based care for the person with SSc is similar to that for lupus. The patient is treated at home but may need frequent hospitalizations if major organ involvement occurs during exacerbations. The Arthritis Foundation ([www.arthritis.org](http://www.arthritis.org)) and Scleroderma Foundation ([www.scleroderma.org](http://www.scleroderma.org)) are excellent resources for more information about the disease and how to manage it.

# Gout

## ❖ Pathophysiology

**Gout**, or gouty arthritis, is a systemic disease in which urate crystals deposit in the joints and other body tissues, causing inflammation. It is the most common acute inflammatory arthritis in older adults. The cause and treatment of gout have been firmly established. The classic case of well-advanced disease is seldom seen today unless the patient does not adhere to the therapeutic regimen. The two major types of gout are primary and secondary.

**Primary gout** is the most common type and results from one of several inborn errors of purine metabolism. An end product of purine metabolism is uric acid, which is usually excreted by the kidneys. In primary gout the production of uric acid exceeds the excretion capability of the kidneys. Sodium urate is deposited in synovium and other tissues, resulting in inflammation. For some patients primary gout is inherited as an X-linked trait; males are affected through female carriers. A number of patients have a family history of gout. Primary gout affects middle-age and older men and postmenopausal women. The peak time of onset in men is between 40 and 50 years of age (McCance et al., 2014).

**Secondary gout** involves **hyperuricemia** (excessive uric acid in the blood) caused by another disease or factor. Secondary gout affects people of all ages. Renal insufficiency, diuretic therapy, “crash” diets, and certain chemotherapeutic agents decrease the normal excretion of uric acid and other waste products. Disorders such as multiple myeloma and certain carcinomas result in increased production of uric acid because of a greater turnover of cellular nucleic acids. Treatment involves management of the underlying disorder.

Hyperuricemia and gout are often seen in older patients with cardiovascular health problems, obese people, and postmenopausal women. The incidence of gout is increasing as the baby boomer generation reaches 65 years of age.

The three clinical stages of the primary disease process are asymptomatic hyperuricemia, acute gouty arthritis, and chronic or tophaceous gout (McCance et al., 2014). The patient is usually unaware of the *asymptomatic hyperuricemic stage* unless he or she has had a serum uric acid level determination. The serum level is elevated, but no obvious signs of the disease are present. No treatment is needed in this stage.

The first “attack” of gouty arthritis begins the *acute stage*. The patient experiences excruciating pain and inflammation in one or more small joints, usually the metatarsophalangeal joint of the great toe, called **podagra**. The erythrocyte sedimentation rate (ESR) is usually increased as a result of the inflammatory process. Months or years may pass before additional attacks occur. The patient is asymptomatic, and no abnormalities are found during examination of the joints.

After repeated episodes of acute gout, deposits of urate crystals develop under the skin and within the major organs, particularly in the renal system. The patient is then classified as having *chronic tophaceous gout*. In chronic gout urate kidney stone formation is more common than renal insufficiency. Chronic gout can begin anywhere between 3 and 40 years after the initial gout symptoms occur (McCance et al., 2014).

## ❖ Interprofessional Collaborative Care

### ◆ Assessment: Noticing

Note the patient's age, gender, and family history of gout. A complete history is needed to determine whether gout has been caused by another problem. Some women overuse diuretics, which can lead to secondary gout.

Overt manifestations are present in the acute and chronic phases of gout. You will likely encounter a patient with acute gout, but chronic gout is not as common in the United States today. *Joint inflammation is the most common finding of acute gout. The joint is usually so painful that the patient seeks medical care immediately.* Inspect the inflamed area; it is usually too painful and swollen to be touched or moved.

The primary health care provider requests a serum uric acid level to check for hyperuricemia. Because the level can be altered by food intake, several measurements may be obtained. A consistent level of more than 6.5 mg/dL is generally considered abnormal, depending on the

laboratory test used. Urinary uric acid levels are also measured; an overproduction of uric acid is confirmed by an excretion of more than 750 mg/24 hr (Pagana et al., 2017).

The primary health care provider may request kidney function tests such as blood urea nitrogen (BUN) and serum creatinine levels to monitor possible kidney involvement. A definitive diagnostic test for the disease is synovial fluid aspiration (arthrocentesis) to detect the needle-like crystals in the affected joint that are characteristic of the disorder.

With *chronic* gout inspect the skin for **tophi**, or deposits of sodium urate crystals (Fig. 18-10). Although tophi are rarely seen today, they may appear on the outer ear, arms, and fingers near the joints. The tophi are hard on palpation and irregular in shape. When the skin over the tophi is irritated, it may break open, and a yellow, gritty substance is discharged. Infection may result.

**FIG. 18-10** Typical appearance of tophi, which may occur in chronic gout on an index finger. (From Currie, G., & Douglas, G. [2011]. *Flesh and bones of medicine*. Edinburgh: Mosby Ltd.)

Other manifestations of chronic gout include signs of renal calculi (stones) or renal dysfunction such as severe pain or changes in urinary output. In some cases urate kidney stones occur before the arthritis is present.

### ◆ **Interventions: Responding**

Gout is one of the easiest diseases for the primary health care provider to diagnose and treat in its early phases. If the patient receives treatment and adheres to drug therapy, he or she should experience no further symptoms and no change in body image or lifestyle. The patient with gout is treated on an ambulatory basis, but hospitalized patients may have a secondary diagnosis of the disease.

### **Drug Therapy.**

Drug therapy is the key to managing patients with gout. In acute gouty “attacks,” the inflammation subsides spontaneously within 3 to 5 days; however, most patients cannot tolerate the pain for that long. The drugs used for acute gout are different from those used for chronic gout. The health care provider typically prescribes a combination of colchicine (Colcrys) and an NSAID such as indomethacin (Indocin, Novomethacin ♣) or ibuprofen (Motrin, Amersol) for acute gout. IV colchicine works within 12 hours. The patient takes oral medications until the inflammation subsides, usually for 4 to 7 days.

For patients with repeated acute episodes or chronic gout, the health care provider prescribes drugs on a continuous, maintenance basis to promote uric acid excretion or reduce its production. Allopurinol (Zyloprim, Purinol) or febuxostat (Uloric) is the drug of choice. Febuxostat may cause a greater risk to cardiovascular health than allopurinol (Lilley et al., 2014). As xanthine oxidase inhibitors, these drugs prevent the conversion of xanthine to uric acid. Teach patients to take them after meals and drink a glass of water with each dose to prevent GI distress. Drinking at least eight glasses of water each day helps prevent renal dysfunction. Remind patients that periodic follow-up laboratory tests, including liver enzymes, kidney function studies, and complete blood count, are important because xanthine oxidase inhibitors cause liver dysfunction and bone marrow suppression.

Probenecid can also be effective as a uricosuric drug in gout because it promotes the excretion of excess uric acid. Combination drugs that contain probenecid and colchicine (e.g., ColBENEMID) are also available. The primary health care provider and nurse monitor serum uric acid levels to determine the effectiveness of these medications. Aspirin should be avoided because it inactivates the effects of the drug.

For patients with severe gout who do not respond to other drugs (refractory gout), pegloticase (Krystexxa) can be prescribed as an IV dose every 2 weeks. This drug is an enzyme that works directly on uric acid and converts it to allantoin, which can be excreted by the kidneys. Monitor patients carefully for allergic reactions, including anaphylaxis, during and immediately after drug administration because pegloticase is a protein that is foreign to the body.

### **Nutrition Therapy and Lifestyle Recommendations.**

The American College of Rheumatology best practice guidelines recommend a strict low-purine diet and suggest that patients avoid foods such as organ meats, shellfish, and oily fish with bones (e.g., sardines). Some primary health care providers and dietitians believe that limiting protein foods, especially red and organ meats, is sufficient. However, it is well known that excessive alcohol intake and fad “starvation” diets can cause a gouty attack. *Teach patients to determine which foods precipitate acute attacks and try to avoid them.*

In addition to food and beverage restrictions, patients with gout should avoid all forms of aspirin and diuretics because they may precipitate an attack. Likewise, excessive physical or emotional stress can exacerbate the disease. Surgery or acute illness such as a myocardial infarction can also trigger an attack. Stress-management techniques may be helpful for the patient with gout.

Teach the patient to drink plenty of fluids to prevent the formation of urinary stones. Increasing fluid intake helps dilute urine and prevents sediment formation.

## **NCLEX Examination Challenge 18-6**

### **Physiological Integrity**

The nurse is preparing to give medications to a group of clients. Which drug is not appropriate to treat the disease with which it is matched?

- A. Rheumatoid arthritis—leflunomide
- B. Osteoarthritis—acetaminophen
- C. Acute gout—allopurinol
- D. Systemic lupus erythematosus—prednisone

## Lyme Disease

**Lyme disease** is a reportable systemic infectious disease caused by the spirochete *Borrelia burgdorferi* and results from the bite of an infected deer tick, also known as the *black-legged tick*. It is the most common vector-borne disease in the United States and Europe. Most cases of the disease in the United States are seen in New England; the mid-Atlantic states, including Maryland and Virginia; the upper Midwest, including Wisconsin and Minnesota; and northern California, especially during the summer months.

In the early and *localized stage I*, the patient appears with *flu-like symptoms*, **erythema migrans** (round or oval, flat or slightly raised rash), and *pain and stiffness in the muscles and joints*. Most patients in the United States tend to have only one lesion, sometimes referred to as a *bull's-eye lesion*. Symptoms begin within 3 to 30 days of the tick bite, but most present in 7 to 14 days. Antibiotic therapy such as doxycycline or amoxicillin is prescribed during this uncomplicated stage for 14 to 21 days. Erythromycin can be used for patients who are allergic to penicillin. Without treatment these symptoms may disappear in about 4 to 5 weeks.

If not treated or if treatment is not successful, the patient may progress to the more serious complications of Lyme disease. *Stage II (early disseminated stage)* occurs 2 to 12 weeks after the tick bite. The patient may develop *carditis* with *dysrhythmias, dyspnea, dizziness, or palpitations* and central nervous system disorders such as *meningitis, facial paralysis* (often misdiagnosed as Bell's palsy), and *peripheral neuritis*. For severe disease, IV antibiotics (e.g., ceftriaxone or cefotaxime) are given for at least 30 days.

If Lyme disease is not diagnosed and treated in the earlier stages, later chronic complications (e.g., *arthritis, chronic fatigue, memory/thinking problems*) can result. This *late stage III (chronic persistent stage)* occurs months to years after the tick bite. *For some patients the first and only sign of Lyme disease is arthritis*. In some cases the disease may not respond to antibiotics in any stage, and the patient develops permanent damage to joints and the nervous system. *Prevention is the best strategy for Lyme disease*. Teach patients to follow the measures outlined in [Chart 18-14](#) to prevent Lyme and other tick-borne diseases. Tell them about community resources such as the Lyme Disease Foundation ([www.lyme.org](http://www.lyme.org)) for more information.

### Chart 18-14

## Patient and Family Education: Preparing for Self-Management

### Prevention and Early Detection of Lyme Disease

- Avoid heavily wooded areas or areas with thick underbrush, especially in the spring and summer months.
- Walk in the center of the trail.
- Avoid dark clothing. Lighter-colored clothing makes spotting ticks easier.
- Use an insect repellent (DEET) on your skin and clothes when in an area where ticks are likely to be found.
- Wear long-sleeved tops and long pants; tuck your shirt into your pants and your pants into your socks or boots.
- Wear closed shoes or boots and a hat or cap.
- Bathe immediately after being in an infested area and inspect your body for ticks (about the size of a pinhead); pay special attention to your arms, legs, and scalp.
- Check your pets for ticks.

- Gently remove with tweezers or fingers covered with tissue or gloves any tick that you find (do not squeeze). Dispose of the tick by flushing it down the toilet (burning a tick could spread infection).
- After removal, clean the tick area with an antiseptic such as rubbing alcohol.
- Wait 4 to 6 weeks after being bitten by a tick before being tested for Lyme disease (testing before this time is not reliable).
- Report symptoms such as a rash or influenza-like illness to your primary health care provider immediately.

## Disease-Associated Arthritis

Arthritis can occur as a symptom of a number of diseases and other health disorders (see [Tables 18-3](#) and [18-4](#)). One of the most common disorders in which arthritis occurs is in patients who have psoriasis. **Psoriatic arthritis (PsA)** affects some people who have psoriasis—a skin condition characterized by a scaly, itchy rash, usually on the elbows, knees, and scalp. Fingernail and toenail lifting and pitting may also occur. The joint pain associated with psoriasis is often associated with stiffness, especially in the morning. Neck and back pain are particularly common, but various forms of the disease can cause small joint arthritis or involvement of the sacroiliac joints of the spine.

**TABLE 18-3**  
**Common Health Disorders Associated With Arthritis**

<ul style="list-style-type: none"> <li>• Psoriasis</li> <li>• Crohn's disease</li> <li>• Ulcerative colitis</li> <li>• Tuberculosis</li> <li>• Hemophilia</li> <li>• Whipple's disease</li> </ul>	<ul style="list-style-type: none"> <li>• Intestinal bypass surgery</li> <li>• Hyperparathyroidism</li> <li>• Hyperthyroidism</li> <li>• Diabetes mellitus</li> <li>• Sickle cell anemia crisis</li> <li>• Infection</li> </ul>
---	--

**TABLE 18-4**  
**Other Less Common Connective Tissue Diseases That Affect Joints**

DISEASE	DESCRIPTION/ PATHOPHYSIOLOGY	ASSESSMENT/SIGNS AND SYMPTOMS	COLLABORATIVE INTERVENTIONS
Polymyositis/dermatomyositis	Autoimmune, inflammatory disease that causes symmetric muscle atrophy; when skin rash is also present, disease is called <i>dermatomyositis (DM)</i> ; women between 30 and 60 years affected most often	Severe muscle weakness Dysphagia (difficulty swallowing) Periorbital edema and lilac eyelid rash (DM) Malignant neoplasms in older patients	Comfort measures Swallowing precautions Nutritional support PT/OT support Immunosuppressant agents and/or chronic steroid therapy (Teach about risk for infection.) Health teaching about progression of disease, comfort measures, and dietary needs
Systemic necrotizing vasculitis	A group of autoimmune diseases that result in arteritis (inflammation of arterial walls) causing ischemia in the tissues or organs that are supplied by the arteries	Peripheral arterial disease causing severe pain and necrosis of toes or fingers Signs and symptoms of organ dysfunction or failure such as kidney or heart failure; also can cause stroke-like symptoms	Chronic steroid therapy and other immunosuppressants Vasodilators, depending on type of vasculitis Management of organ dysfunction or failure
Polymyalgia rheumatica (PMR) and temporal arteritis (TA)	Autoimmune, genetic-based disease affecting middle-age and older women most often that causes proximal muscle weakness (shoulder and pelvic girdles) (PMR) (TA [also known as <i>giant cell arteritis</i> ] may occur as a separate disease or with PMR.)	Shoulder, neck, pelvic, and hip weakness; stiffness; joint aches; low-grade fever; fatigue; and weight loss caused by inflammation (PMR) Headache and visual disturbances (TA)	Responds well to high-dose steroid therapy to cause remission of disease Symptom management Short-term PT/OT as needed Health teaching about medication and pain modalities such as heat application for joints
Ankylosing spondylitis	Autoimmune, inflammatory disease affecting the spine that is thought to be genetic (strongly associated with specific variations in the <i>HLA-27</i> allele on chromosome 6) Can occur in both men and women, but white men younger than 40 years most commonly affected	Chronic back pain Compromised respiratory function caused by rigid chest wall Visual disturbances caused by iritis (inflammation of the iris) Joint pain and aching Malaise Weight loss	Chronic pain management modalities NSAIDs DMARD such as methotrexate and biologic response modifiers Symptom management
Reiter's syndrome	Complex syndrome associated with the <i>HLA-27</i> allele causing a triad of arthritis, conjunctivitis, and urethritis (inflammation of the urethra) Triggered by exposure to infection, especially sexually transmitted disease or intestinal infection	Joint pain Eye infection causing redness, pain, and drainage Pain or burning on urination and changes in urinary pattern	Antibiotic therapy to manage infection Pain management NSAIDs Other symptom management
Marfan syndrome	Autosomal-dominant disorder resulting from mutations in the <i>fibrillin 1</i> gene (FBN1) Fibrillin important in limiting the stretch of elastic connective tissues and allowing them to return to their original resting shape Shortens life expectancy, often with death in the 30s	Excessive height Elongated hands and feet Joint discomfort or pain Scoliosis Visual problems such as decreased visual acuity or glaucoma Cardiovascular problems such as mitral valve prolapse and aortic aneurysm, leading to heart failure or death	Symptom management Frequent echocardiography monitoring and physical examinations to detect heart problems Genetic counseling

DMARDs, Disease-modifying antirheumatic drugs; OT, occupational therapy; PT, physical therapy.

PsA occurs most often in people between 30 and 50 years of age in men and women of all races. Nail symptoms are common in patients who have the associated arthritis. Causes may include genetic and environmental factors, infectious agents, and immune system dysfunction.

Most patients do not experience destructive and deforming arthritis affecting more than three joints; but for those who do, the experience has a major impact on their quality of life. Treatment is focused on managing joint pain and inflammation, controlling skin lesions, and slowing the progression of the disease. Health teaching for skin care is similar to that for lupus. Management of joint inflammation is similar to that for rheumatoid arthritis as described earlier in this chapter.

Methotrexate (Rheumatrex), sulfasalazine (Azulfidine), and biological response modifiers (also called *biologics*) such as etanercept (Enbrel), ustekinumab (Stelara), and golimumab (Simponi) are being used with success.

Teach the patient or family member how to self-administer Enbrel injections. Injection site reactions and infections (especially respiratory) are possible adverse effects. Ice and hydrocortisone 1% cream can be used if a red, itchy rash at the injection site develops.

*Golimumab (Simponi)* is the first biologic that is administered only once each month for psoriatic arthritis. Teach patients that this drug has a black box warning for serious infections that may lead to hospitalization or death from opportunistic pathogens (Lilley et al., 2014).

Several newer types of biologics have also been approved for psoriatic arthritis. Ustekinumab (Stelara) targets the cytokines *interleukin (IL)-12* and *IL-23* to decrease inflammation. Alefacept (Amevive) is an IV immunosuppressive drug (T-cell blocker) that is reserved for moderate-to-severe disease. Teach patients taking these drugs about their risk for decreased IMMUNITY. Remind them to avoid crowds and anyone with an infection.

Acitretin (Soriatane) is an oral retinoid given for patients with severe disease. Teach patients to take the drug once a day with a meal and follow up with laboratory testing for liver enzymes.

The National Psoriasis Foundation ([www.psoriasis.org](http://www.psoriasis.org)) is an excellent community resource for patients and their families.

## Fibromyalgia Syndrome

**Fibromyalgia syndrome (FMS)**, also referred to as simply *fibromyalgia*, is a chronic pain syndrome, not an inflammatory disease. However, arthritis and other comorbidities are commonly present in patients diagnosed with FMS. Pain, stiffness, and tenderness are located at specific sites in the back of the neck, upper chest, trunk, low back, and extremities. These tender points are also known as **trigger points** and can typically be palpated to elicit pain in a predictable, reproducible pattern. The pain is typically described as burning and gnawing. Increased muscle tenderness may be caused by the inability to tolerate pain, possibly related to dysfunction in the brain, especially the thalamus and hypothalamus (McCance et al., 2014).

The pain and tenderness tend to come and go but typically worsen in response to stress, increased activity, and weather conditions. The patient reports mild-to-severe fatigue, and sleep disturbances are common. Some people report numbness or tingling in their extremities; and others are sensitive to noxious odors, loud noises, and bright lights. Headaches and jaw pain are also common. Secondary FMS can accompany any connective tissue disease (CTD), particularly lupus and rheumatoid disease, and may not necessarily be related to sleep patterns.

Other symptoms include:

- GI, including abdominal pain, diarrhea and constipation, and heartburn
- Genitourinary, including dysuria, urinary frequency, urgency, and pelvic pain
- Cardiovascular, including dyspnea, chest pain, and dysrhythmias
- Visual, including blurred vision and dry eyes
- Neurologic, including forgetfulness and concentration problems

Many with these symptoms become frustrated because they are not properly diagnosed and are in constant pain and discomfort (Menzies, 2016).

Most patients are women between 30 and 50 years of age. It is unlikely that the disease is caused by one factor. Possible precipitating factors include CFS, Lyme disease, trauma, and flu-like illness (McCance et al., 2014). FMS may also be aggravated by deep-sleep deprivation. Teach patients to limit caffeine, alcohol, or other unnecessary substances that could interfere with deep sleep.

Establish a regular sleep pattern.

Selected anticonvulsants such as gabapentin (Neurontin) and pregabalin (Lyrica) and selective norepinephrine reuptake inhibitors (SNRIs, a class of antidepressants) such as duloxetine HCl (Cymbalta) and milnacipran (Savella) may improve fibromyalgia nerve pain (Menzies, 2016). Teach the patient that these drugs can cause drowsiness and sleepiness and that alcohol should be avoided while taking them.

Tricyclic antidepressive agents such as amitriptyline (Elavil, Apo-Amitriptyline) or nortriptyline (Pamelor) may promote sleep and reduce pain or muscle spasm. These drugs should be used with caution in older adults because they can cause confusion and orthostatic hypotension. Trazodone (Desyrel) may be preferred for this population because of its minimal side effects. Tramadol (Ultram) is also effective for managing fibromyalgia. This drug has tricyclic effects and opioid properties to help relieve pain (see Chapter 4).

Physical therapy along with NSAIDs and possibly muscle relaxants may also be prescribed to help promote COMFORT. Instruct the patient to exercise regularly. Home exercise should include stretching, strengthening, and low-impact aerobic exercise. Walking, swimming, rowing, biking, and water exercise are good examples of low-impact exercise. Integrative therapies such as tai chi, acupuncture, hypnosis, and stress management may help some patients with symptom relief. Refer patients to the land, water, and walking exercise pamphlets produced by the Arthritis Foundation ([www.arthritis.org](http://www.arthritis.org)). Inform them about the National Fibromyalgia Association for additional information and patient and family support ([www.fmaware.org](http://www.fmaware.org)).

# Get Ready for the NCLEX® Examination!

## Key Points

Review these Key Points for each NCLEX Examination Client Needs Category.

### Safe and Effective Care Environment

- Collaborate with the health care team to manage chronic pain and increase MOBILITY for patients with arthritis and other CTDs. **QSEN: Teamwork and Collaboration**
- Prioritize care for patients with systemic lupus erythematosus (SLE) and systemic sclerosis (SSc) by monitoring for life-threatening complications such as kidney failure.

### Health Promotion and Maintenance

- Provide information about community resources for patients, especially professional organizations such as the Arthritis Foundation and Lupus Foundation.
- Teach patients to prevent joint trauma and reduce weight as needed to help prevent osteoarthritis. **QSEN: Evidence-Based Practice**
- Recall that a combination of environmental, genetic, and immune risk factors can cause arthritis and other connective tissue diseases.
- Reinforce the importance of good health practices such as adequate sleep, proper nutrition, regular exercise, and stress-management techniques for patients with arthritis and other CTDs.
- Teach patients with arthritis which exercises to do ([Chart 18-5](#)), joint protection techniques ([Chart 18-6](#)), and energy conservation guidelines ([Chart 18-10](#)). **QSEN: Evidence-Based Practice**
- Teach patients with SLE to avoid sunlight; exacerbations of the disease may be triggered.
- Remind patients with gout to avoid factors that trigger an attack such as aspirin, organ meats, and alcohol. **QSEN: Evidence-Based Practice**
- Teach people ways to prevent or detect early Lyme disease as listed in [Chart 18-14](#).

### Psychosocial Integrity

- Recognize that patients with rheumatoid arthritis (RA) may have body image disturbance as a result of potentially deforming joint involvement and nodules.
- Encourage patients with arthritis and connective tissue diseases to discuss their chronic illness and identify coping strategies that have previously been successful. **QSEN: Patient-Centered Care**
- Be aware that chronic, painful diseases affect the patient's quality of life and role performance.
- Recognize that patients with fibromyalgia syndrome (FMS) are often frustrated because they have not been diagnosed or have been misdiagnosed.

### Physiological Integrity

- Be aware that most of the connective tissue diseases and arthritic disorders have a genetic basis as part of their etiology; most are also classified as autoimmune diseases and have remissions and exacerbations.
- Differentiate OA as primarily a joint problem that can affect one or more joints and RA as a systemic disease that presents as a bilateral symmetric joint inflammation.
- Realize that older patients have OA more than younger patients; younger patients have RA more than older adults. Other differences between the two diseases are summarized in [Table 18-1](#).
- Teach patients who have osteoarthritis (OA) or are prone to the disease to lose weight (if obese), avoid trauma, and limit strenuous weight-bearing activities. **QSEN: Evidence-Based Practice**

- Instruct patients with arthritic pain to use multiple modalities for pain relief, including ice/heat, rest, positioning, integrative therapies, and drug therapy as prescribed.
- Teach patients to monitor and report side and adverse effects of drugs used to treat OA and other connective tissue diseases. **QSEN: Safety**
- Assess patients with rheumatoid arthritis for early or late signs and symptoms as listed in [Chart 18-7](#).
- Teach patients who are taking hydroxychloroquine to have frequent (every 6 months) eye examinations to monitor for retinal changes. **QSEN: Safety**
- Remind patients to avoid crowds and other possible sources of infection when they are taking drugs that decrease IMMUNITY. **QSEN: Safety**
- Implement interventions for patients having total joint arthroplasty (TJA) to prevent venous thromboembolic complications (e.g., anticoagulants, exercises, sequential compression devices); observe the patient for bleeding when he or she is taking anticoagulants. **Clinical Judgment**
- Be careful when positioning a patient after a total hip arthroplasty (THA) to prevent dislocation; do not hyperflex the hips or adduct the legs (see [Chart 18-3](#)). **QSEN: Safety**
- Be aware that disease-modifying antirheumatic drugs (DMARDs) and biological response modifiers (BRMs) slow the progression of connective tissue diseases, especially RA and SLE.
- Teach patients receiving BRMs and other disease-modifying agents to avoid crowds and people with infections; opportunistic pathogens may cause serious infections or death. Check the patient's PPD test or history of tuberculosis before starting any of these drugs (see [Chart 18-9](#)). **QSEN: Safety**
- Monitor and interpret laboratory test results for patients with autoimmune connective tissue diseases as highlighted in [Chart 18-8](#).
- Differentiate signs and symptoms of patients with systemic lupus erythematosus (SLE) versus systemic sclerosis (SSc) as listed in [Chart 18-11](#).
- Prioritize care by assessing for swallowing ability in patients who have SSc; collaborate with the dietitian for food modifications if needed. **QSEN: Teamwork and Collaboration**
- Monitor for acute joint pain and inflammation in patients with a history of gout; the great toe and other small joints are most typically affected.
- Be aware that arthritis often accompanies other diseases such as psoriasis and Crohn's disease.

## CHAPTER 19

# Care of Patients With Problems of HIV Disease

James G. Sampson, M. Linda Workman

## PRIORITY AND INTERRELATED CONCEPTS

**The priority concept for this chapter is IMMUNITY.**

✚ The IMMUNITY concept exemplar for this chapter is HIV Infection and AIDS, below.

**The interrelated concepts for this chapter are:**

- GAS EXCHANGE
- TISSUE INTEGRITY
- NUTRITION

## LEARNING OUTCOMES

### Safe and Effective Care Environment

1. Collaborate with the interprofessional team to coordinate high-quality care to patients with impaired IMMUNITY.
2. Prevent human immune deficiency virus (HIV) transmission to yourself and others.
3. Teach the patient and caregiver(s) how impaired IMMUNITY affects home safety.

### Health Promotion and Maintenance

4. Identify community resources for patients with impaired IMMUNITY.
5. Assess all adults for high-risk behaviors related to HIV infection.

### Psychosocial Integrity

6. Implement evidence-based nursing interventions to help the patient and family cope with the psychosocial impact caused by impaired IMMUNITY.

### Physiological Integrity

7. Use signs, symptoms, and laboratory data to assess for impaired IMMUNITY and its complications.
8. Teach the patient and caregiver(s) about common drugs used for impaired IMMUNITY, HIV prevention, or HIV disease and its complications.

As described in [Chapter 2](#) and explained in [Chapter 17](#), IMMUNITY is protection from illness or disease that is maintained by the body's physiologic defense mechanisms. Provided by the cells, products, and actions of the immune system, immunity prevents the growth of infectious organisms and disease development, despite exposure to invading organisms. Immunity also detects body cells that undergo changes to become cancer cells. Impaired immunity can result in life-threatening infection and an increased risk for cancer development.

## Immunity Concept Exemplar HIV Infection and AIDS

### Pathophysiology

Human immune deficiency virus (HIV) infection and disease can progress to acquired immune deficiency syndrome (AIDS). This common chronic disorder of impaired immunity is a serious worldwide epidemic (World Health Organization [WHO], 2015).

### Etiology and Genetic Risk

The cause of HIV infection is a virus—the human immune deficiency virus. This virus, just like all other viruses, is an intracellular parasite because it must use the infected cell's resources to reproduce. The HIV can infect a cell and take over its functions to force the cell to make more copies of the virus (viral particles). These new viral particles are able to infect more cells, repeating the cycle as long as there are new host cells to infect.

### The HIV Infectious Process.

*Viral particle features* include an outer envelope with special “docking proteins,” known as gp41 and gp120, which assist in finding a host (Fig. 19-1). Inside, the virus has genetic material along with the enzymes *reverse transcriptase (RT)* and *integrase*. To infect, HIV must first enter the host's bloodstream and then “hijack” certain cells, especially the *CD4+ T-cell*, also known as the *CD4+ cell*, *helper/inducer T-cell*, or *T4-cell* (see Chapter 17). This cell directs IMMUNITY and regulates the activity of all immune system cells. When HIV enters a CD4+ T-cell, it can then create more virus particles (McCance et al., 2014).

**FIG. 19-1** The human immune deficiency virus (HIV). (From Kumar, V., Abbas, A., & Fausto, N. [2010]. *Robbins & Cotran pathologic basis of disease* (8th ed.). Philadelphia: Saunders.)

*Virus-host interactions* are needed after infection for disease development. When an adult is infected with HIV, the virus randomly “bumps” into many cells. The docking proteins on the outside of the virus must find special receptors on a host cell to which the virus can bind and then enter the cell. The CD4+ T-cell has surface receptors known as *CD4*, *CCR5*, and *CXCR4* (Fig. 19-2). The gp120 and gp41 proteins on the HIV particle surface recognize these receptors on the CD4+ T-cell. For the virus to enter this cell, *both* the gp120 and the gp41 must bind to the receptors. The gp120 first binds to the primary CD4 receptor, which changes its shape and allows the gp120 to bind to either the CCR5 co-receptor or the CXCR4 co-receptor. Once co-receptor binding occurs, gp41 inserts a fusion peptide into the T-cell membrane, boring a hole to allow insertion of viral genetic material and enzymes into the host cell. This attachment allows the virus to then enter the

CD4+ T-cell (McCance et al., 2014) (see Fig. 19-2). Viral binding to the CD4 receptor and to either of the co-receptors is needed to enter the cell. (The drug class known as *entry inhibitors* works here to prevent the interaction needed for entry of HIV into the CD4+ T-cell.)

**FIG. 19-2** The HIV “docking” proteins and the successful interaction of these proteins with the CD4+ T-lymphocyte receptors.

After entering a host cell, HIV must insert its genetic material into the host cell's DNA. HIV is a **retrovirus**, which is able to insert its single-stranded ribonucleic acid (ss-RNA) genetic material into the host's DNA. The HIV enzyme *reverse transcriptase* (RT) converts HIV's RNA into DNA, which makes the viral genetic material the same as human DNA. (The drug classes known as *nucleoside reverse transcriptase inhibitors* [NRTIs] and *non-nucleoside reverse transcriptase inhibitors* [NNRTIs] work here to prevent viral replication [Fig. 19-3] by reducing how well reverse transcriptase can convert HIV genetic material into human genetic material.) HIV then uses its enzyme *integrase* to get its DNA into the nucleus of the host's CD4+ T-cell and insert it into the host's DNA (McCance et al., 2014). This action completes the infection of the CD4+ T-cell. (The drug class known as *integrase inhibitors* works here to prevent viral DNA from integrating into the host's DNA.)

**FIG. 19-3** The life cycle of the HIV and sites of action for anti-HIV therapy. (From McCance, K. L., & Huether, S.E. [2002]. *Pathophysiology: The biologic basis for disease in adults and children* [4th ed.]. St. Louis: Mosby.)

HIV particles are made within the infected CD4+ T-cell, using the metabolic machinery of the host cells. The new virus particle is made in the form of one long protein strand. The strand is

clipped by the enzyme *HIV protease* into smaller functional pieces. These pieces are formed into a new finished viral particle. (The drug class known as *protease inhibitors* works here to inhibit HIV protease.) Once the new virus particle is finished, it fuses with the infected cell's membrane and then buds off in search of another CD4+ T-cell to infect (see Fig. 19-3).

## NCLEX Examination Challenge 19-1

### Physiological Integrity

Which part of the HIV infection process is disrupted by the antiretroviral drug class of entry inhibitors?

- A. Activating the viral enzyme “integrase” within the infected host's cells
- B. Binding the virus to the CD4+ receptor and either of the two co-receptors
- C. Clipping the newly generated viral proteins into smaller functional pieces
- D. Fusing the newly created viral particle with the infected cell's membrane

*Effects of HIV infection* are related to the new genetic instructions that now direct CD4+ T-cells to change their role in immune system defenses. The new role is to be an “HIV factory,” making up to 10 billion new viral particles daily. The immune system is made weaker by removing some CD4+ T-cells from circulation. In early HIV infection before HIV disease is evident, the immune system can still attack and destroy most of the newly created virus particles. However, with time the number of HIV particles overwhelms the immune system. Gradually CD4+ T-cell counts fall, viral numbers (*viral load*) rise, and without treatment, the patient eventually dies of opportunistic infection or cancer (McCance et al., 2014).

Everyone who has AIDS has HIV infection; however, not everyone who has HIV infection has AIDS (Centers for Disease Control and Prevention [CDC], 2015b). The distinction is the number of CD4+ T-cells and whether any opportunistic infections have occurred. A healthy adult usually has at least 800 to 1000 CD4+ T-cells per cubic millimeter (mm<sup>3</sup>) of blood. This number is reduced in HIV disease.

Some adults develop an acute infection within 4 weeks of first being infected. Symptoms of this acute HIV infection can be fever, night sweats, chills, headache, and muscle aches, which are similar to those of any viral infection—not just HIV. A sore throat and rash also may be present. With time these symptoms cease, and the patient feels well again, although a “war is going on” between HIV and the immune system. Even in this early phase of the disease, the viral numbers in the bloodstream and genital tract are high, and sexual transmission is possible (Grimes et al., 2016).

As time passes, more CD4+ T-cells are infected and taken out of immune system service. The count decreases, and those that remain function poorly. Poor CD4+ T-cell function leads to these IMMUNITY abnormalities:

- Lymphocytopenia (decreased numbers of lymphocytes)
- Increased production of incomplete and nonfunctional antibodies
- Abnormally functioning macrophages

As the CD4+ T-cell level drops, the patient is at risk for bacterial, fungal, and viral infections, as well as opportunistic cancers. **Opportunistic infections** are those caused by organisms that are present as part of the body's microbiome and usually are kept in check by normal IMMUNITY (see Chapter 5 for an explanation of the microbiome). The profound reduced immunity in the adult with AIDS allows these usually harmless organisms to overgrow and cause infection.

A diagnosis of AIDS requires that the adult be HIV positive and have either a CD4+ T-cell count of less than 200 cells/mm<sup>3</sup> ( $0.2 \times 10^9/L$ ) or less than 14% (even if the total CD4+ count is above 200 cells/mm<sup>3</sup> [ $0.2 \times 10^9/L$ ]) or an opportunistic infection. Once AIDS is diagnosed, even if the patient's T-cell count goes higher than 200 cells/mm<sup>3</sup> ( $0.2 \times 10^9/L$ ), or if the percentage rises above 14%, or the infection is successfully treated, the AIDS diagnosis remains.

### HIV Classification.

The Centers for Disease Control and Prevention (CDC) defines five stages of HIV disease (CDC, 2015b). In this definition laboratory confirmation of HIV infection (by fourth-generation antigen/antibody testing or enzyme-linked immunosorbent assay [ELISA] and Western blot analysis) plus CD4+ T-lymphocyte count or percentage and the presence or absence of the 27 AIDS-defining conditions (Table 19-1) determine the classification (CDC, 2015b). *The adult with HIV infection can transmit the virus to others at all stages of disease, but the recently infected adult with a high viral load and those at end-stage without drug therapy can be particularly infectious.*

**TABLE 19-1**

**Centers for Disease Control and Prevention Classification of AIDS-Defining Conditions in Adults**

<ul style="list-style-type: none"> <li>• Bacterial infections, multiple or recurrent</li> <li>• Candidiasis of bronchi, trachea, or lungs</li> <li>• Candidiasis of esophagus</li> <li>• Cervical cancer, invasive</li> <li>• Coccidioidomycosis, disseminated or extrapulmonary</li> <li>• Cryptococcosis, extrapulmonary</li> <li>• Cryptosporidiosis, chronic intestinal (&gt;1-month duration)</li> <li>• Cytomegalovirus disease (other than liver, spleen, or nodes)</li> <li>• Cytomegalovirus retinitis (with loss of vision)</li> <li>• Encephalopathy, HIV-related</li> <li>• Herpes simplex: chronic ulcers (&gt;1-month duration) or bronchitis, pneumonitis, or esophagitis</li> <li>• Histoplasmosis, disseminated or extrapulmonary</li> <li>• Isosporiasis, chronic intestinal (&gt;1-month duration)</li> <li>• Kaposi's sarcoma</li> <li>• Lymphoid interstitial pneumonia or pulmonary lymphoid hyperplasia complex</li> <li>• Lymphoma, Burkitt's (or equivalent term)</li> <li>• Lymphoma, immunoblastic (or equivalent term)</li> <li>• Lymphoma, primary, of brain</li> <li>• <i>Mycobacterium avium</i> complex or <i>Mycobacterium kansasii</i>, disseminated or extrapulmonary</li> <li>• <i>Mycobacterium tuberculosis</i> of any site, pulmonary, disseminated, or extrapulmonary</li> <li>• <i>Mycobacterium</i>, other species or unidentified species, disseminated or extrapulmonary</li> <li>• <i>Pneumocystis jirovecii</i> pneumonia</li> <li>• Pneumonia, recurrent (two instances within 12 months)</li> <li>• Progressive multifocal leukoencephalopathy</li> <li>• <i>Salmonella</i> septicemia, recurrent</li> <li>• Toxoplasmosis of brain</li> <li>• Wasting syndrome attributed to HIV</li> </ul>
--

From Schneider, E., Whitmore, S., Glynn, K. M., Dominguez, K., Mitsch, A., McKenna, M.T.: Centers for Disease Control and Prevention. (2008). Revised surveillance case definitions for HIV infection among adults, adolescents, and children aged <18 months and for HIV infection and AIDS among children aged 18 months to <13 years—United States, 2008. *Morbidity and Mortality Weekly Report: Recommendations and Reports*, 57(RR-10), 9; [www.cdc.gov/mmwr/preview/mmwrhtml/rr5710a2.htm](http://www.cdc.gov/mmwr/preview/mmwrhtml/rr5710a2.htm).

*Stage 0 CDC Case Definition* describes a patient who develops a first positive HIV test result within 6 months after a negative HIV test result. Changing the patient's status to stage 1, 2, or 3 does not occur until 6 months have elapsed since the stage 0 designation, even when CD4+ T-cell counts decrease or an AIDS-defining condition is present.

*Stage 1 CDC Case Definition* describes a patient with a CD4+ T-cell count of greater than 500 cells/mm<sup>3</sup> ( $0.5 \times 10^9/L$ ) or a percentage of 29% or greater. An adult at this stage has no AIDS-defining illnesses.

*Stage 2 CDC Case Definition* describes a patient with a CD4+ T-cell count between 200 and 499 cells/mm<sup>3</sup> ( $0.2$  to  $0.449 \times 10^9/L$ ) a percentage between 14% and 28%. An adult at this stage has no AIDS-defining illnesses.

*Stage 3 CDC Case Definition* describes any patient with a CD4+ T-cell count of less than 200 cells/mm<sup>3</sup> ( $0.2 \times 10^9/L$ ) or a percentage of less than 14%. An adult who has higher CD4+ T-cell counts or percentages but who also has an AIDS-defining illness meets the Stage 3 CDC Case Definition.

*Stage Unknown CDC Case Definition* is used to describe any patient with a confirmed HIV infection but no information regarding CD4+ T-cell counts, CD4+ T-cell percentages, and AIDS-defining illnesses is available.

### HIV Progression.

The time from the beginning of HIV infection to development of AIDS ranges from months to years. The range depends on how HIV was acquired, which additional health problems the patient has, personal factors, and interventions. For example, for adults who have been transfused with HIV-contaminated blood, AIDS often develops quickly. For those who become HIV positive as a result of a single sexual encounter, progression to AIDS takes much longer. Other personal factors that

influence progression to AIDS include frequency of re-exposure to HIV, presence of other sexually transmitted infections (STIs), NUTRITION status, and stress.

## Genetic/Genomic Considerations

### Patient-Centered Care QSEN

About 1% of adults with HIV infection are *long-term nonprogressors (LTNPs)* who have been infected with HIV for at least 10 years and have remained asymptomatic, with CD4+ T-cell counts within the normal range and a viral load that is either undetectable or very low.

A genetic difference for this group is that their CCR5/CXCR4 co-receptors on the CD4+ T-cells are nonfunctional as a result of gene mutations for these co-receptors. The mutation creates defective co-receptors that do not bind to the HIV docking proteins, and these cells successfully resist the entrance of HIV. Adults who have only one mutated co-receptor gene allele have fewer normal co-receptors and can be infected with HIV, but progression is slow. Remind patients that even with low viral levels, they can still transmit the disease to others.

### Incidence and Prevalence

Since the beginning of the epidemic in the United States, more than 658,507 people have died of AIDS. Currently about 50,000 people are diagnosed annually, and more than 1,200,000 people in the United States are living with HIV/AIDS (CDC, 2015a). Worldwide about 2 million people per year are newly infected with HIV, at least 34 million deaths from AIDS have occurred since the start of the epidemic, and 37 million people are currently living with HIV (World Health Organization [WHO], 2015).

Most AIDS cases in North America occur among men who have sex with men (MSM) or adults of either gender who have used injection drugs (16%) (CDC, 2015a). *However, the perception that HIV/AIDS is only a problem for homosexual white men is false. The highest rates of new infections occur among adults of color.*

## Cultural/Spiritual Considerations

### Patient-Centered Care QSEN

Most new HIV infections reported in the United States and Canada occur in racial and ethnic minorities, particularly among blacks/African Americans and Hispanics (CDC, 2015b). More culturally sensitive efforts targeted at these groups for prevention and treatment are needed.

## Gender Health Considerations

### Patient-Centered Care QSEN

About 25% of newly diagnosed cases are women. In less affluent countries 50% of cases occur in women (WHO, 2015). The largest risk factor is sexual exposure. Women with HIV disease have a poorer outcome, with shorter mean survival time than that of men. This outcome may be the result of late diagnosis and social or economic factors that reduce access to medical care. Encourage all women to monitor their HIV status.

Gynecologic problems, especially persistent or recurrent vaginal candidiasis, may be the first signs of HIV disease in women. Other problems include pelvic inflammatory disease, genital herpes, other sexually transmitted infections (STIs), and cervical dysplasia or cancer.

The effect of HIV on pregnancy outcomes includes higher incidence of premature delivery, low-birth-weight infants, and transmission of the disease to the infant. Appropriate antiretroviral drug therapy during pregnancy reduces the risk for transmitting the infection to the infant. (See the discussion in the [Perinatal Transmission](#) section.)

## Considerations for Older Adults

### Patient-Centered Care QSEN

Infection with HIV can occur at any age. Assess the older patient for risk behaviors, including a sexual and drug use history. Age-related decline in IMMUNITY increases the likelihood that the older adult will develop the infection after an HIV exposure.

## Health Promotion and Maintenance

AIDS has a high morbidity and mortality rate when untreated. Although there is no current cure for HIV/AIDS, the conscientious and continued use of antiretroviral therapy allows HIV patients to live long and healthy lives. The foci for health care worldwide are prevention of HIV infection and antiretroviral treatment for all who are HIV positive (WHO, 2015).

HIV is in the blood, semen, vaginal secretions, breast milk, amniotic fluid, urine, feces, saliva, tears, cerebrospinal fluid, lymph nodes, cervical cells, corneal tissue, and brain tissue of infected patients. The fluids with the highest concentrations of HIV are semen, blood, breast milk, and vaginal secretions. Contact with tears, saliva, and sweat is considered low risk for transmission unless obvious blood is present. HIV is transmitted most often in these three ways:

- Sexual: genital, anal, or oral sexual contact with exposure of mucous membranes to infected semen or vaginal secretions
- Parenteral: sharing of needles or equipment contaminated with infected blood or receiving contaminated blood products
- Perinatal: from the placenta, from contact with maternal blood and body fluids during birth, or from breast milk from an infected mother to child

*Teach all adults about the transmission routes and ways to reduce their exposure (discussed next). Also stress that HIV is not transmitted by casual contact in the home, school, or workplace. Sharing household utensils, towels and linens, and toilet facilities does not transmit HIV. HIV is not spread by mosquitos or other insects.*

## Nursing Safety Priority QSEN

### Action Alert

Teach all adults, regardless of age, gender, ethnicity, or sexual orientation, that they are susceptible to HIV infection.

## HIV Status

About 1.2 million people are currently living with HIV infection in the United States, and about 75,000 are living with HIV infection in Canada (CDC, 2015a; Government of Canada, 2015). In both countries about 20% of those infected are unaware of their HIV infection. Many new transmission events come from those who are HIV positive and unaware of their diagnosis. Early identification and diagnosis allows for early treatment and preventive care. Once an adult is placed on combination antiretroviral therapy (cART), reducing the viral load to undetectable levels significantly reduces the risk that HIV will be transmitted, a concept known as *treatment as prevention (TAP)*.

The recommendations for HIV screening have been expanded to include a one-time screen for all adults between the ages of 15 and 65, an annual screening of those who are at heightened risk for HIV infection, routine prenatal screening, and frequent testing in adults with repeated high-risk exposures.

## Veterans' Health Considerations

### Patient-Centered Care QSEN

The Veteran's Health Administration (VHA) is a major health care provider in the United States and has found that a significant number of veterans have undiagnosed HIV disease. As a result, in 2009 the VHA eliminated the need for written consent for including HIV screening as part of routine testing. Despite the directive, only about 9% of veterans treated annually at VHA facilities have ever been tested (Gant-Clark et al., 2015). When asked, most veterans believed that they were HIV negative because they thought the test had already been done as part of routine testing and that the VHA would have notified them of positive results. This false sense of security has major implications because of the high prevalence of risky behaviors such as substance abuse and unsafe sexual practices among the VHA patient population. When interacting with veterans and discussing the issue of being aware of their HIV status as part of disease prevention, be sure to inform them that HIV screening is available to them through the VHA.

HIV testing requires interpretation, counseling, and confidentiality. Testing plays a role in prevention because tests are a way of diagnosing HIV infection before immune changes or disease symptoms develop. A major health care focus for testing is to teach those who test positive to modify their behaviors to prevent transmission to others. *Therefore all sexually active adults should know their HIV status.* [Chart 19-1](#) lists conditions for which HIV testing is advised.

### **Chart 19-1**

## **Patient and Family Education: Preparing for Self-Management**

### **CDC Recommendations for Annual HIV Testing and One-Time Screening**

You should be tested annually for HIV if you:

- Have a sexually transmitted infection
- Use injection drugs
- Consider yourself at risk
- Are a woman of childbearing age with identifiable risks, including:
  - Used injection drugs
  - Engaged in sex work
  - Had sexual partners who were infected or at risk
  - Had sexual contact with men from countries with high HIV prevalence
- Received a transfusion between 1978 and 1985
- Plan to get married
- Are undergoing medical evaluation or treatment for symptoms that may be HIV related
- Are in correctional institutions such as jails and prisons
- Are a sex worker or have had sex with a sex worker

In the absence of any of the above conditions, you should be tested (screened) once:

- If you are between the ages of 18 and 65 years
- As part of routine prenatal screening when you are pregnant

Modified from CDC, Centers for Disease Control and Prevention, 2015a.

Pretest and post-test counseling must be performed by personnel trained in HIV issues. These counselors may be nurses, physicians, social workers, health educators, or lay educators who have specialized training. Counseling helps the patient make an informed decision about testing and provides an opportunity to teach risk-reduction behaviors. Post-test counseling is needed to interpret the results, discuss risk reduction, provide psychological support, and provide health promotion information for the patient with a positive test result. The newly diagnosed adult should be linked to care within an infectious disease practice or clinics. Adults who test positive should also be counseled on how to inform sexual partners and those with whom they have shared needles. Testing methods are listed in the Laboratory Assessment section.

## Sexual Transmission

Safer sex methods of *A*, abstinence; *B*, be faithful (monogamous); and *C*, condom use can reduce HIV transmission. Abstinence and mutually monogamous sex with a noninfected partner are the *only* absolutely safe methods of preventing HIV infection from sexual contact. Many forms of sexual expression can spread HIV infection if one partner is infected. *The risk for becoming infected from a partner who is HIV positive is always present, although some sexual practices are more risky than others.* Because the virus concentrates in blood and seminal fluid and is also present in vaginal secretions, risk differs by gender, sexual act, and the viral load of the infected partner.

*Gender* affects HIV transmission, and the infection is more easily transmitted from infected male to uninfected female than vice versa. This is because HIV is most easily transmitted when infected body fluids come into contact with mucous membranes or nonintact skin. The vagina has more mucous membrane (surface area) than does the urethra of the penis. Teach women the importance of always either using a vaginal or dental dam or female condom or having their male partners use a condom.

*Sexual acts* or practices that permit infected seminal fluid to come into contact with mucous membranes or nonintact skin are the most risky for sexual transmission of HIV. The practice with the highest risk is anal intercourse with the penis and seminal fluid of an infected adult coming into contact with the mucous membranes of the uninfected partner's rectum. *Anal intercourse in which the semen depositor (inserting or active partner [top]) is infected is a very risky sexual practice, regardless of whether the semen receiver (receiving partner [bottom]) is male or female.* Anal intercourse allows seminal fluid to make contact with the rectal mucous membranes and also tears the mucous membranes, making infection more likely. Teach patients who engage in anal intercourse that the semen depositor needs to wear a condom during this act.

## Cultural and Spiritual Considerations

### Patient-Centered Care QSEN

In certain cultures anal receptive intercourse for male to female intercourse is a form of contraceptive practice. Because this act increases the risk for HIV transmission, instruct such couples to use condoms, regardless of whether intercourse is vaginal or anal.

*Viral load*, or the amount of virus present in blood and other body fluids, affects transmission. The higher the blood level of HIV (**viremia**), the greater the risk for sexual and perinatal transmission. Current combination antiretroviral therapy (cART) (formerly known as HAART-highly active antiretroviral therapy) has caused the viral load of some infected patients to drop below detectable levels. *Although there is less virus in seminal or vaginal fluids of patients receiving cART, the risk for transmission still exists.*

Safer sex practices are those that reduce the risk for nonintact skin or mucous membranes coming in contact with infected body fluids and blood. Teach all adults the importance of consistently using these safer sex practices:

- A latex or polyurethane condom for genital and anal intercourse
- An appropriate water-based lubricant with a latex condom
- A condom or latex barrier (dental dam) over the genitals or anus during oral-genital or oral-anal sexual contact
- Latex gloves for finger or hand contact with the vagina or rectum

### Pre-Exposure Prophylaxis.

Pre-exposure prophylaxis (PrEP) to HIV is the use of HIV-specific anti-retroviral drugs in an HIV-uninfected adult for the purpose of preventing HIV infection. The approved drug combination for PrEP is Truvada (tenofovir 300 mg/emtricitabine 300 mg), one oral tablet daily (Volk et al., 2015).

PrEP is for a select population that is at high risk for acquiring HIV infection. This includes men who have sex with men, heterosexually active men and women, injecting drug users, and those in serodiscordant relationships (one partner HIV positive, one partner HIV negative). Risk assessment is determined by asking focused questions about sexual and drug-injecting activities. After an adult has been identified as at risk (has screened positive for increased risk of acquiring HIV infection), specific blood and urine testing is done to make sure that it is safe to use PrEP. First ensure that the adult is HIV negative (often using a fourth-generation HIV antigen/antibody test and an HIV viral load test). Other necessary tests include renal function tests; estimated glomerular filtration rate (GFR); tests for other sexually transmitted infections such as syphilis, gonorrhea, and chlamydia; and hepatitis A, B, and C serologies. If the adult is found to have active hepatitis B, do not initiate PrEP but refer to an infectious disease specialist, because both tenofovir and emtricitabine have activity against hepatitis B and should be used appropriately.

After starting Truvada, ongoing testing of renal function and HIV infection is performed at specified intervals, usually every 3 months. The person using Truvada for PrEP is not protected until 4 days of consistent dosing leading to a steady-state blood drug level is achieved. Once the initial protection period is completed, one dose can be missed, and protection is still adequate; however, two consecutively missed doses significantly reduce protection. The patient needs to start over (before being exposed to HIV) with another 4 day-lead in period until a new steady state can be achieved. When Truvada is used consistently and correctly, it is very effective in HIV infection prevention (Mayer & Krakower, 2015). However, it has no effect in preventing the contraction of any other sexually transmitted infection (STI).

New studies are testing the efficacy of Truvada using various alternative dosing models; however, at present Truvada is the only drug approved for PrEP, and the once-daily dosing is the only approved dosing regimen. Two new injectable formulations of PrEP (rilpivirine and cabotegravir) administered once every 12 weeks are being explored for effectiveness as an alternative to daily Truvada.

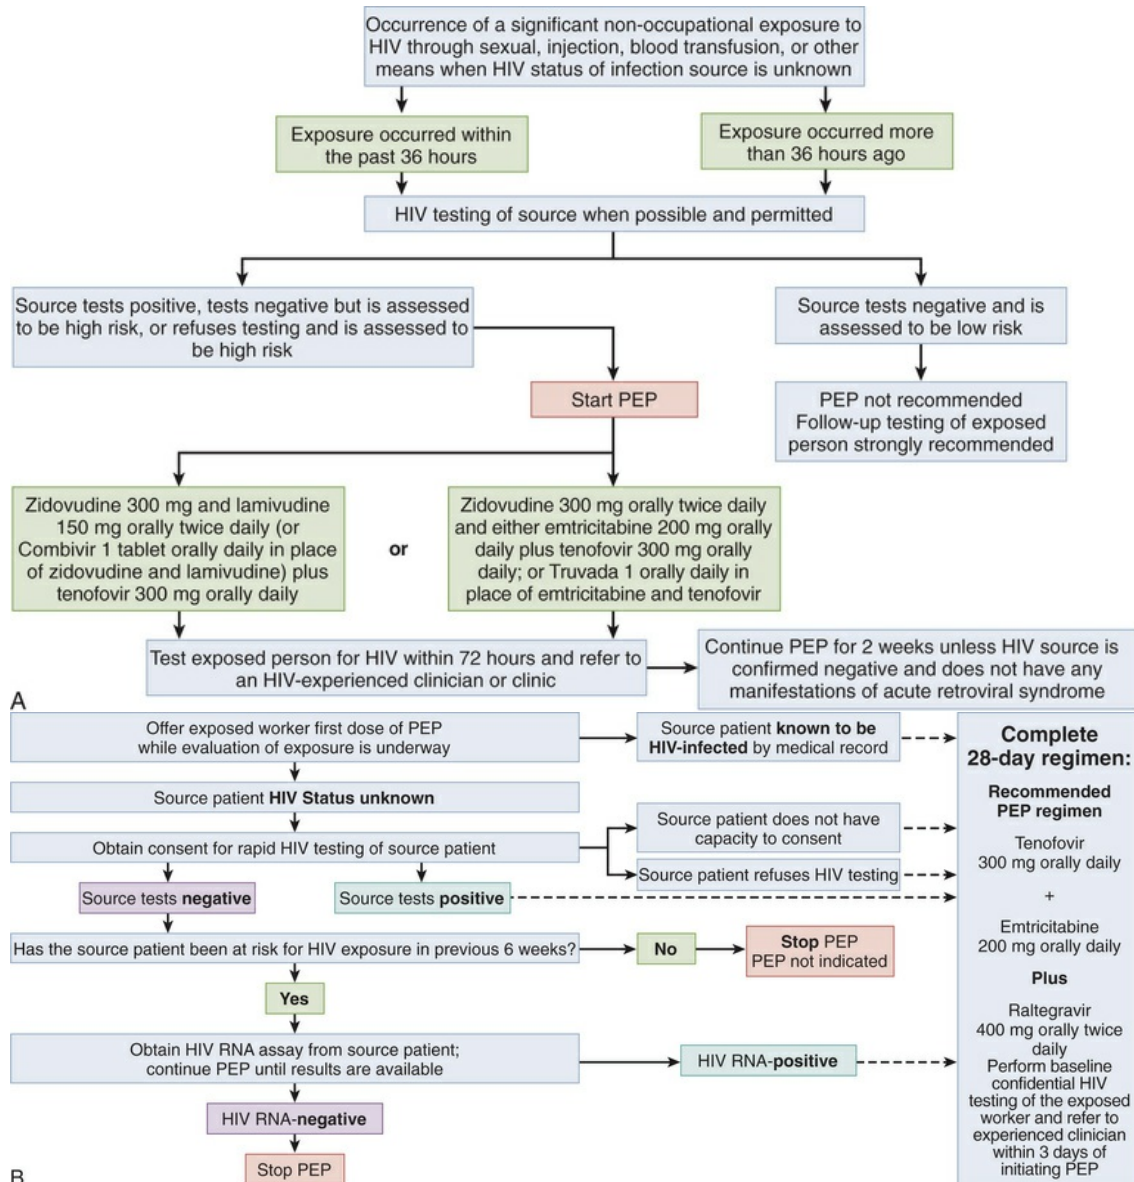

## Nursing Safety Priority QSEN

### Drug Alert

Pre-exposure prophylaxis does not replace the standard safer sex practices recommended to prevent HIV transmission. If this drug therapy is used in patients who become infected with HIV-1, the risk for developing drug resistance greatly increases. Therefore remind adults prescribed Truvada to use the safer sex practices described previously and to adhere to an every-3-month HIV testing schedule along with monitoring for side effects of this drug.

### Postexposure Prophylaxis.

Using cART as postexposure prophylaxis (PEP) generally falls into one of three exposure categories for adults: those who have had an occupational exposure (such as a needlestick injury); those who have had a nonoccupational exposure (such as a consensual sexual exposure with an adult of unknown HIV status); and those who have suffered a sexual assault. In all cases, starting cART as soon as possible (preferably within the first 24 to 36 hours) is critical to preventing HIV infection. The current recommendations are that significant exposures should be treated with the same three-drug regimen for 28 days or until the HIV status of the source has been determined to be negative (Fig. 19-4A).

**FIG. 19-4** New York State Health Department HIV guidelines. PEP, postexposure prophylaxis. **A**, Recommendations for nonoccupational postexposure prophylaxis for HIV infection. **B**, Recommendations for occupational postexposure prophylaxis for HIV infection. (A adapted from New York State Department of Health AIDS Institute. Clinical Guidelines Development Program. [2013]. *Recommendations for non-occupational postexposure prophylaxis for HIV infection*. New York: Author. [www.hivguidelines.org](http://www.hivguidelines.org). B adapted from New York State Department of Health AIDS Institute. Clinical Guidelines Development Program. [2012]. *Recommendations for occupational postexposure prophylaxis for HIV infection*. New York: Author. [www.hivguidelines.org](http://www.hivguidelines.org).)

*Occupational exposure* is defined as contact between blood, tissue, or selected body fluids (e.g., blood, cerebrospinal fluid [CSF], pleural fluid, synovial fluid, peritoneal fluid, pericardial fluid, breast milk, amniotic fluid, semen, and vaginal secretions) from a patient who is positive for HIV (*source patient*) and the blood, broken skin, or mucous membranes of a health care professional. Bodily substances not considered infectious for HIV unless obviously bloody (e.g., feces, nasal secretions, sputum, saliva, sweat, tears, urine, vomit) do not require prophylaxis.

In the case of an occupational exposure, a percutaneous needlestick with a hollow-bore or solid needle is the most common occurrence necessitating PEP. The other common exposure is fluid contact with mucous membranes (e.g., eyes, nose, mouth). For sharps injuries, initial steps include “bleeding” the wound, washing the wound carefully for at least 1 full minute, and immediately contacting employee health (or the emergency department during hours when employee health is not open) to begin the documentation, testing, and prophylaxis process.

Once the exposure has been discovered, three-drug cART within 2 hours of the exposure has the best possible outcome in preventing HIV infection. *The window of opportunity for best outcome closes*

when prophylaxis is started after 72 hours. Thus the exposed health care professional is started on cART before all test results are known. The professional receiving prophylaxis must return for periodic HIV testing at 1, 3, and 6 months and electrolytes, creatinine, and complete blood counts 2 weeks after starting cART.

*Nonoccupational exposure* generally refers to consensual and nonconsensual sexual exposures, involving insertive and receptive types of sex with oral, vaginal, or anal contact. Other types of contact can include the sharing of needles and inadvertent percutaneous or mucosal contact in the home.

Exposure to HIV as a result of sexual assault also includes testing for gonorrhea, chlamydia, and syphilis. For women of childbearing age, emergency contraception is offered.

### Parenteral Transmission

Preventive practices to reduce transmission among injection drug users (IDUs) include the use of proper cleaning of “works” (needles, syringes, other drug paraphernalia). Instruct IDUs to clean a used needle and syringe by first filling and flushing them with clear water. Next the syringe should be filled with ordinary household bleach. The bleach-filled syringe should be shaken for 30 to 60 seconds. Advise IDUs to carry a small container with this solution whenever sharing needles or to participate in community needle-exchange programs, if they are available.

The risk for HIV transmission through transfusion of banked blood and blood products is very low. All donated blood in North America is screened for the HIV antibody, and blood that is positive for HIV antibodies is not used for transfusion purposes. Because of the time lag in antibody production after exposure to HIV, infected blood can test negative for HIV antibodies. Inform patients that there is a small but real possibility of HIV transmission through blood and blood products.

### Perinatal Transmission

HIV transmission can occur across the placenta during pregnancy, with infant exposure to blood and vaginal secretions during birth, or with exposure after birth through breast milk. Inform women of childbearing age with HIV infection about the risks for perinatal transmission. The risk for transmission to infants from pregnant women with HIV infection who are not using HIV drug therapy is about 25%. It is about 8% for women who are using HIV drug therapy. Encourage HIV-positive women who are pregnant to continue the therapy or, if they are not on antiviral therapy, to start the therapy as soon as possible.

### Transmission and Health Care Workers

*Needlestick or “sharps” injuries are the main means of occupation-related HIV infection for health care workers (Mitchell & Parker, 2015b).* In addition, health care workers can be infected through exposure of nonintact skin and mucous membranes to blood and body fluids (Mitchell & Parker, 2015a). **The best prevention for health care professionals is the consistent use of Standard Precautions for all patients as recommended by the CDC and required by The Joint Commission’s (TJC) National Patient Safety Goals (NPSG) (see Chapter 23).** Fig. 19-14B shows the recommended actions for prevention of HIV infection after a needlestick or other occupational exposure (postexposure prophylaxis [PEP]). When the source patient is known to be HIV negative, PEP is not recommended.

To prevent HIV transmission to patients, health care workers should wear gloves when in contact with patients' mucous membranes or nonintact skin. Infected workers with weeping dermatitis or open lesions must wear gloves or not perform direct patient care. The CDC guidelines for preventing HIV transmission by health care workers during exposure-prone invasive procedures are listed in Chart 19-2. These include any procedure in which there is a risk for broken skin injury to the health care worker and the worker's blood is likely to make contact with the patient's body cavity, subcutaneous tissues, or mucous membranes.

#### Chart 19-2

### Best Practice for Patient Safety & Quality Care QSEN

#### Recommendations for Preventing HIV Transmission by Health Care Workers

- Workers should adhere to Standard Precautions.
- Workers with exudative lesions or weeping dermatitis should not perform direct patient care or handle patient care equipment and devices used in invasive procedures.
- Workers must follow guidelines for disinfection and sterilization of reusable equipment used in invasive procedures.
- Workers infected with HIV are not restricted from practice of non-exposure-prone procedures, as long as they comply with Standard Precautions and sterilization and disinfection recommendations.
- Workers should identify exposure-prone procedures by institutions where they are performed.
- Workers who perform exposure-prone procedures should know their HIV antibody status.
- Workers who are infected with HIV should seek advice from an expert review panel before performing exposure-prone procedures to determine under which circumstances they may continue to practice these procedures. These circumstances would include notification of prospective patients of HIV positivity.

Adapted from Centers for Disease Control and Prevention. (1991). Recommendations for preventing transmission of human immunodeficiency virus and hepatitis B virus to patients during exposure-prone invasive procedures. *Morbidity and Mortality Weekly Report: Recommendations and Reports*, 40(RR-8), 1-9.

## NCLEX Examination Challenge 19-2

### Safe and Effective Care Environment

With which activities does the nurse teach unlicensed assistive personnel (UAP) and nursing students caring for a client who is HIV positive to wear gloves to prevent disease transmission? **Select all that apply.**

- A. Applying lotion during a back rub
- B. Brushing the client's teeth
- C. Emptying a Foley catheter reservoir
- D. Feeding the client
- E. Filing the client's fingernails
- F. Providing perineal care

### Interprofessional Collaborative Care

With treatment HIV disease is chronic but manageable (Starr & Bradley-Springer, 2014). The usual disease course includes intermittent acute infections and periods of relative wellness. This period is often followed by chronic, progressive debilitation. Because of the cyclic nature of HIV disease and AIDS, the patient spends long periods at home between hospital admissions. During this time the patient must practice adequate self-care. New techniques and strategies to promote self-care, known as mHealth, include the use of mobile devices for reminders and information. This strategy appears to be helpful for some populations, but more information is needed to determine how to modify it for best use among minority populations (see the Evidence-Based Practice box).

### Evidence-Based Practice OSEN

## mHealth Technology as a Strategy for HIV Self-Management Among African-American Women

Adams-Tufts, K., Johnson, K., Shepherd, J., Lee, J., Bait-Ajzoon, M., Mahan, L., et al. (2015). Novel interventions for HIV self-management in African-American women: A systematic review of mHealth interventions. *Journal of the Association of Nurses in AIDS Care*, 26(2), 139-150.

HIV is now considered a chronic disease when antiretroviral drug therapy is used appropriately, which relies heavily on the very effective intervention of self-management. In addition to drug therapy, self-management includes adhering to scheduled medical visits, healthy diet, regular exercise, stress reduction, and self-monitoring of ongoing health status. However, even though about 45% of Americans newly diagnosed as HIV positive are African-American women, culturally appropriate strategies for promoting HIV self-management among this population are lacking. Without self-management skills, HIV-positive patients live shorter, less healthy lives and may contribute to greater HIV transmission.

mHealth, which is the use of mobile devices with software applications to provide access to health services, manage patient information, provide specific health knowledge, and assist skill development for health promotion and condition management, is now widely used to promote self-management of a variety of chronic conditions. The purpose of this study was to explore the use of mHealth technology for self-management of HIV disease and to determine the existence of culturally appropriate applications for HIV-positive African-American women.

This study was a systematic review of 411 completed analyses and 39 ongoing clinical trials reviewing the effectiveness of all types of mHealth and general self-management education programs for HIV. The majority of studies were conducted with men, and few used true mHealth technologies. Those that did include women who were focused more on HIV prevention rather than the skills needed to successfully live with HIV. No completed studies were found that were specifically designed and culturally tailored for use among African-American women living with HIV/AIDS. The ongoing studies included several mHealth HIV intervention studies that were focused on women of all ethnicities but did not address the unique needs of African-American women.

### Level of Evidence: 1

This study is an exhaustive meta-analysis of previous research studies on the use of electronic media, specifically mHealth, technologies to assist in self-management of HIV as a chronic disease. The methods used were appropriate for the purposes of the study, and the inclusion of results from ongoing randomized clinical trials added credible evidence to support study results.

### Commentary: Implications for Practice and Research

mHealth provides a strategy that has been successfully used for self-management of many chronic diseases. The strategy is most successful when tailored to the specific needs of a population. Its use was previously limited to adults with the financial means to acquire and maintain mobile devices. This limitation has been ameliorated by specific programs providing cell phones and other mobile devices to adults with low incomes. Thus the remaining limitation is designing an mHealth application that addresses the specific needs (including cultural differences) related to African-American women living with HIV/AIDS. Although both qualitative and quantitative studies focused on this topic are needed, nurses caring for adults living with HIV/AIDS can make contributions by asking African-American women with HIV/AIDS specifically what could help them with medication management, keeping clinical appointments, and other aspects of living with this chronic disease.

In the acute care setting, the disease is best managed using an interprofessional team approach. Team members include physicians, nurses, registered dietitians, infectious disease specialists, social workers, mental health professionals, and wound care specialists among others.

### ◆ Assessment: Noticing

The adult who has HIV disease is monitored on a regular basis for changes in IMMUNITY or health status that indicate disease progression and the need for intervention. The frequency of monitoring varies from every 2 to 6 months based on disease progression and responses to treatment.

Continuing assessment is crucial to ensure that the drugs continue to work optimally because the patient may have medication issues or problems related to disease in many organ systems. Assess for subtle changes so any problems can be found early and treated.

### History.
