

# Maternal & Child Health Nursing

Care of the Childbearing  
& Childrearing Family

Eighth Edition

JoAnne Silbert-Flagg  
Adele Pillitteri

## Brief Contents

### **UNIT 1**

#### **Maternal and Child Health Nursing Practice**

- 1 A Framework for Maternal and Child Health Nursing
- 2 Diversity and Maternal Child Nursing
- 3 The Childbearing and Childrearing Family in the Community
- 4 Home Care and the Childbearing and Childrearing Family

### **UNIT 2**

#### **The Nursing Role in Preparing Families for Childbearing and Childrearing**

- 5 The Nursing Role in Reproductive and Sexual Health
- 6 Nursing Care for the Family in Need of Reproductive Life Planning
- 7 Nursing Care of the Family Having Difficulty Conceiving a Child
- 8 The Nursing Role in Genetic Assessment and Counseling

### **UNIT 3**

#### **The Nursing Role in Caring for Families During Normal Pregnancy, Birth, the Postpartum, and Newborn Period**

- 9 Nursing Care During Normal Pregnancy and Care of the Developing Fetus
- 10 Nursing Care Related to Psychological and Physiologic Changes of Pregnancy
- 11 Nursing Care Related to Assessment of a Pregnant Family
- 12 Nursing Care to Promote Fetal and Maternal Health
- 13 The Nursing Role in Promoting Nutritional Health During Pregnancy
- 14 Preparing a Family for Childbirth and Parenting

- 15 Nursing Care of a Family During Labor and Birth
- 16 The Nursing Role in Providing Comfort During Labor and Birth
- 17 Nursing Care of a Postpartal Family
- 18 Nursing Care of a Family With a Newborn
- 19 Nutritional Needs of a Newborn

#### **UNIT 4**

##### **The Nursing Role in Caring for a Family During Complications of Pregnancy, Birth, or the Postpartal Period**

- 20 Nursing Care of a Family Experiencing a Pregnancy Complication From a Preexisting or Newly Acquired Illness
- 21 Nursing Care of a Family Experiencing a Sudden Pregnancy Complication
- 22 Nursing Care of a Pregnant Family With Special Needs
- 23 Nursing Care of a Family Experiencing a Complication of Labor or Birth
- 24 Nursing Care of a Family During a Surgical Intervention for Birth
- 25 Nursing Care of a Family Experiencing a Postpartum Complication
- 26 Nursing Care of a Family With a High-Risk Newborn
- 27 Nursing Care of the Child Born With a Physical or Developmental Challenge

#### **UNIT 5**

##### **The Nursing Role in Health Promotion for Childrearing Family**

- 28 Principles of Growth and Development
- 29 Nursing Care of a Family With an Infant
- 30 Nursing Care of a Family With a Toddler
- 31 Nursing Care of a Family With a Preschool Child
- 32 Nursing Care of a Family With a School-Age Child
- 33 Nursing Care of a Family With an Adolescent
- 34 Child Health Assessment
- 35 Communication and Teaching With Children and Families

#### **UNIT 6**

##### **The Nursing Role in Supporting the Health of Ill Children and Their Families**

- 36 Nursing Care of a Family With an Ill Child
- 37 Nursing Care of a Family When a Child Needs Diagnostic or Therapeutic Modalities
- 38 Nursing Care of a Family When a Child Needs Medication Administration or Intravenous Therapy
- 39 Pain Management in Children

## **UNIT 7**

### **The Nursing Role in Restoring and Maintaining the Health of Children and Families With Physiologic Disorders**

- 40 Nursing Care of a Family When a Child Has a Respiratory Disorder
- 41 Nursing Care of a Family When a Child Has a Cardiovascular Disorder
- 42 Nursing Care of a Family When a Child Has an Immune Disorder
- 43 Nursing Care of a Family When a Child Has an Infectious Disorder
- 44 Nursing Care of a Family When a Child Has a Hematologic Disorder
- 45 Nursing Care of a Family When a Child Has a Gastrointestinal Disorder
- 46 Nursing Care of a Family When a Child Has a Renal or Urinary Tract Disorder
- 47 Nursing Care of a Family When a Child Has a Reproductive Disorder
- 48 Nursing Care of a Family When a Child Has an Endocrine or a Metabolic Disorder
- 49 Nursing Care of a Family When a Child Has a Neurologic Disorder
- 50 Nursing Care of a Family When a Child Has a Vision or Hearing Disorder
- 51 Nursing Care of a Family When a Child Has a Musculoskeletal Disorder
- 52 Nursing Care of a Family When a Child Has an Unintentional Injury
- 53 Nursing Care of a Family When a Child Has a Malignancy

## **UNIT 8**

### **The Nursing Role in Restoring and Maintaining the Mental Health of Children and Families**

- 54 Nursing Care of a Family When a Child Has an Intellectual or Mental Health Disorder
- 55 Nursing Care of a Family in Crisis: Maltreatment and Violence in the Family

56 Nursing Care of a Family When a Child Has a Long-Term or Terminal Illness

**JoAnne Silbert-Flagg, DNP, CPNP, IBCLC, FAAN**

Assistant Professor  
Clinical Coordinator for the MSN (Entry into Nursing) Program  
Coordinator, Pediatric Nurse Practitioner Track  
Johns Hopkins University School of Nursing  
Baltimore, Maryland

**Adele Pillitteri, PhD, RN, PNP**

Former Associate Professor  
University of Southern California  
Los Angeles, California

Saddleback College  
Mission Viejo, California

I am honored that Adele Pillitteri has entrusted me to continue her legacy with the eighth edition of this textbook. As the author of the previous editions, she was committed to a high-quality and student-friendly combined maternal and child health nursing textbook for prelicensure nursing students.

I have provided pediatric health care to a generation of patients as a pediatric nurse practitioner (PNP) at Columbia Medical Practice in Columbia, Maryland. When I joined the faculty of Johns Hopkins University School of Nursing 16 years ago, I was asked to offer hospital clinical instruction to maternal child and pediatric nursing students. In providing maternity instruction, I realized I was not providing adequate breastfeeding support to the mothers in my pediatric practice. I became an International Board Certified Lactation Consultant (IBCLC) to ensure expert breastfeeding support for the parents in my pediatric primary care practice. I have practiced as both a PNP and an IBCLC for over 10 years, and this has been a rewarding part of my practice. These experiences opened my eyes to the importance of understanding the influence of maternal health care on child health nursing, and I am now dedicated to a combined approach to educate nursing students.

Together with the content experts who assisted in the revision of this edition, I have tried to ensure it is accurate and relevant for the prelicensure nursing student. Based on the recommendation of reviewers, many of the features that have evolved over previous editions continue to appear here with some new changes. As an instructor in the classroom of the content in this textbook, I am acutely aware of the pressure on faculty to present relevant and engaging information to their students. The instructor resources that accompany this edition have been expanded and will promote the acquisition of knowledge for the students and promote their critical thinking and lessen the time required for faculty preparation.

*Maternal & Child Health Nursing: Care of the Childbearing and Childrearing Family*, Eighth Edition, continues to present maternal–child health care not as two separate disciplines but as a continuum of knowledge. Care has been taken to eliminate redundant content. The book is designed for prelicensure nursing students to use either in a combined maternal–child health course or in two separate courses, regardless of the

order of the content. It discusses current evidence-based practice related to family-centered maternal child and pediatric care while also promoting a sensitive, holistic outlook on nursing practice. Basic themes include the experience of wellness and illness as family-centered events, the perception of pregnancy and childbirth as periods of wellness, and the importance of knowing normal child development in the planning of nursing care. Themes also reflect changes in healthcare delivery and the importance of meeting the needs of culturally diverse populations.

## The Changing Healthcare Scene

As this book is being published, Americans face many unknowns in health care as legislative changes are debated. Preventive health care during pregnancy and throughout childhood is crucial for our nation to survive and prosper. Many diseases and disabilities of adulthood are influenced by the care that pregnant women and their children receive. As health care in the United States continues to evolve and change, nurses will retain an integral role in ensuring preventive needs are addressed.

The 2020 National Health Goals are referenced throughout this book, but it was written with the 2030 National Health Goals in mind. Care has been taken to include content that represents the diversity of the population with regard to race, ethnicity, sexual orientation, and gender identity. National Health Goals for lesbian, gay, bisexual, and transgender (LGBT) persons were added for the first time in 2020. This edition sought to respond by addressing recommendations from The Joint Commission for cultural competency when caring for this population. Nurses are taking an ever-increasing role in the provision of health care for the maternal and child health population. As the population becomes more diverse, it is imperative that nurses understand the cultural beliefs of all individuals. Nursing care requires a greater focus on care planning, communication, evidence-based therapeutic interventions, and critical thinking.

Nursing issues that grow out of the current climate of change include:

- The accentuation of Nursing Care Planning and the Nursing Process: The care planning process provides the structuring framework for coordinating communication that will result in safe and effective care. By structuring the text to reflect this process, students can begin to conceptualize how they will use textbook knowledge in nursing practice to diagnose, plan, deliver, and monitor patients to maximize optimal outcomes. In addition, Nursing Process Overview boxes included at the beginning of each chapter provide a strong theoretical underpinning for nursing process and ways to use the nursing process in clinical practice.
- An emphasis on 2020 National Health Goals: As a way to focus care and research, National Health Goals have gained wider attention at a time when there is a greater need than ever to be wise in the choice of how dollars are spent. Students can familiarize themselves with how these goals can be applied directly to maternal and child health care by referring to the Nursing Care Planning Based on 2020

National Health Goals displays that appear in each chapter.

- Incorporation of the Centers for Disease Control and Prevention (CDC) Maternity Practices in Infant Nutrition and Care (mPINC) Survey which supports hospital practices that create a supportive environment for breastfeeding prenatally and continue through discharge
- The necessity for nurses to be active participants in redefining quality in health care: A major way nurses can do this is by joining with the Institute of Medicine to help define required competencies for practice. Included in each chapter are multiple-choice questions based on the Quality and Safety Education for Nurses (QSEN) competencies, so students can better envision how these competencies can be applied to practice.
- The importance of basing nursing care on evidence-based practice: The variety of new care settings, as well as the diversity of roles in which nurses practice, is reflected both in the proliferation of community-based nursing facilities and also in the increase in the numbers of nurse-midwives, women's health, pediatric, and neonatal nurse practitioners. This new edition places emphasis on the need for nurses to read and apply research to practice by demonstrating how recent research applies directly to a patient scenario woven throughout each chapter. In addition, boxes on Nursing Care Planning Using Assessment, Nursing Care Planning Based on Responsibility for Pharmacology, and Nursing Care Planning Using Procedures illustrate how medical science is applied to care.
- The need to coordinate care: With a growing ambulatory population, nurses assume the increasingly important role as coordinators for healthcare teams. Interprofessional Care Maps in each chapter demonstrate how the nursing process works for a specific patient throughout the care cycle.
- The responsibility of health teaching with families as a cornerstone of nursing: The teaching role of the nurse has greater significance in the new healthcare milieu as the emphasis on preventive care and short stays in acute care settings create the need for families to be better educated in their own care. Nursing Care Planning Based on Family Teaching displays present detailed health information for the family, emphasizing the importance of a partnership between nurses and patients in the management of health and illness. Nursing Care Planning to Empower a Family boxes provide students with the type of information families need to learn how to participate in and improve both family and individual health.
- The obligation to individualize care according to sociocultural uniqueness: This is a reflection of both greater cultural sensitivity and an increasingly diverse population of caregivers and care recipients. Greater emphasis is being placed on the implications of multiple sociocultural factors in how they affect responses to health and illness. Nursing Care Planning Tips for Effective Communication boxes give examples of ways to improve nurse-patient communication. Nursing Care Planning to Respect Cultural Diversity displays demonstrate solutions in areas of caregiving that differs among patients of various cultures.

## Organization of the Text

*Maternal & Child Health Nursing* follows the family from prepregnancy through pregnancy, labor, birth, and the postpartal period; it then follows the child and the family from birth through adolescence. Coverage includes ambulatory and inpatient care and focuses on primary as well as secondary and tertiary care.

The book is organized in eight units:

Unit 1 provides an introduction to maternal and child health nursing. A framework for practice is presented as well as current trends and the importance of considering childbearing and childrearing within a diverse sociodemographic and family/community context. This focus includes attention to health disparities and the provision of care in the home as well as the hospital setting.

Unit 2 examines the nursing role in preparing families for childbearing and childrearing and discusses reproductive and sexual health, the role of the nurse in genetic counseling, reproductive life planning, and the concerns of the subfertile family.

Unit 3 presents the nursing role in caring for a pregnant family during pregnancy, birth, and the postpartal period and serving as a fetal advocate. A separate chapter details the role of the nurse in providing comfort during labor and birth.

Unit 4 addresses the nursing role when a woman develops a complication of pregnancy, labor or birth, or has a complication during the postpartal period. Separate chapters address the role of the nurse when a woman has a preexisting illness, develops a complication during pregnancy or the postpartal period, has a unique concern, or chooses or needs a cesarean birth. A final chapter details care of the high-risk newborn or a child born with a physical or a developmental challenge.

Unit 5 discusses the nursing role in health promotion during childhood. The chapters in this unit cover principles of growth and development and care of the child from infancy through adolescence, including child health assessment and communication and health teaching with children and families.

Unit 6 presents the nursing role in supporting the health of children and their families. The effects of illness on children and their families, diagnostic and therapeutic procedures, medication administration, and pain management are addressed, with respect to care of the child and family in hospital, home, and ambulatory settings.

Unit 7 examines the nursing role in restoring and maintaining the health of children and families when illness occurs. Disorders are presented according to body systems so that students have a ready orientation for locating content.

Unit 8 discusses the nursing role in restoring and maintaining the mental health of children and families. Separate chapters discuss the role of the nurse when intimate partner violence or child maltreatment or mental, long-term, or fatal illness is present.

## Pedagogic Features

Each chapter in the text is organized to provide a complete learning experience for the student. Numerous pedagogic features are included to help a student understand and increase retention. Important elements include:

- **Chapter Objectives:** Learning objectives are included at the beginning of each chapter to identify outcomes expected after the material in the chapter has been mastered.
- **Key Terms:** Terms that would be new to a student are listed at the beginning of each chapter in a ready reference list. Terms are shown in boldface type where they are defined in the text. Definitions also appear online in the Glossary.
- **Chapter-Opening Scenarios:** Short scenarios appear at the beginning of each chapter. These vignettes are designed to help students appreciate that nursing care is always individualized and provide a taste of what is to come in the chapter. Throughout the chapter, open-ended and multiple-choice questions related to the scenario connect learning with patient care.
- **Nursing Process Overview:** Each chapter begins with a review of nursing process in which specific suggestions, such as examples of nursing diagnoses and outcome criteria helpful to modifying care in the area under discussion, are presented. These reviews are designed to improve students' preparation in clinical areas, so they can focus their care planning and apply principles to practice.
- **Nursing Diagnoses and Related Interventions:** A consistent format highlights the nursing diagnoses and related interventions throughout the text. A special heading draws the students' attention to these sections where individual nursing diagnoses and outcome evaluation are detailed for the major conditions and disorders discussed.
- **QSEN Checkpoint Questions:** Throughout the text, NCLEX-style multiple-choice QSEN Checkpoint Questions appear to help students check their progress and reward them for their comprehension. They relate the chapter-opening scenario to the six QSEN competencies: safety, quality improvement, evidence-based practice, team work and collaboration, informatics, and patient-centered care. Students can check their work by reading the answers provided in the Appendix.
- **What If . . . Questions:** These critical thinking questions, formatted to reflect NCLEX style, also appear throughout each chapter in the text. They ask readers to apply the information just acquired in the patient scenario presented in the chapter opening, thus maximizing learning and emphasizing critical thinking. Suggested solutions are supplied on thePoint.
- **Tables and Displays:** Numerous tables and displays summarize important information or provide extra detail on topics so that a student has ready references to this information.
  - **Nursing Care Planning Based on 2020 National Health Goals:** To

emphasize the nursing role in accomplishing the healthcare goals of our nation, these displays state specific ways in which maternal and child health nursing can provide better outcomes for families. They help the student to appreciate the importance of national healthcare planning and the influence that nurses can have in creating a healthier nation.

- **Nursing Care Planning Tips for Effective Communication:** This feature presents tips to apply communication skills in practice and provides case examples of effective communication, illustrating for the student how an awareness of communication can improve the patient's understanding and positively impact outcomes.
- **Nursing Care Planning Based on Family Teaching:** These boxes present detailed health teaching information for the family, emphasizing the importance of a partnership between nurses and patients in the management of health and illness.
- **Nursing Care Planning Based on Responsibility for Pharmacology:** These boxes provide quick reference for medications that are commonly used for the health problems described in the text. They give the drug name (brand and generic, if applicable), dosage, pregnancy category, side effects, and nursing implications.
- **Nursing Care Planning Using Procedures:** Techniques of procedures specific to maternal and child health care are boxed in an easy-to-follow two-column format, often enhanced with color figures.
- **Nursing Care Planning Using Assessment:** These visual guides provide head-to-toe assessment information for overall health status or specific disorders or conditions.
- **Nursing Care Planning: Interprofessional Care Maps:** Because nurses rarely work in isolation, but rather as a member of a healthcare team or unit, interprofessional care maps written for specific patients are included in each chapter to demonstrate the use of the nursing process, provide examples of critical thinking, and clarify nursing care for specific patient needs. These Interprofessional Care Maps not only demonstrate nursing process but also accentuate the increasingly important role of the nurse as a coordinator of patient care.
- **Nursing Care Planning to Respect Cultural Diversity:** These boxes help students appreciate how care delivery should alter to meet the needs of each patient in a country that continually attracts immigrants from throughout the world.
- **Nursing Care Planning to Empower a Family:** Because patient education is an important nursing responsibility, these boxes provide students with the type of information families need to learn how to participate in improving their health.
- **NEW! Unfolding Patient Stories:** Written by the National League for Nursing,

these Unfolding Patient Stories are an engaging way to begin meaningful conversations in the classroom. These vignettes, which appear in relevant chapters, feature patients from Wolters Kluwer's *vSim for Nursing: Maternity and Pediatric* (co-developed with Laerdal Medical) and DocuCare products; however, each Unfolding Patient Story in the book stands alone, not requiring purchase of these products.

- **NEW! Concept Mastery Alerts:** These Concept Mastery Alerts clarify common misconceptions as identified by Lippincott's Adaptive Learning Powered by PrepU.
- **Key Points:** A review of important points is highlighted at the end of each chapter to help students monitor their own comprehension.
- **Critical Thinking Care Studies:** To involve a student in the decision-making realities of the clinical setting, each chapter ends with an additional case scenario, followed by several thought-provoking questions. These could also serve as a basis for conference or class discussion. Suggested answers are supplied on thePoint.

## Teaching and Learning Package

### RESOURCES FOR INSTRUCTORS

Tools to assist you with teaching your course are available upon adoption of this text at <http://thepoint.lww.com/Flagg8e>.

- **Pre-Lecture Quizzes:** These exercises ask students to recall information. Based on the main points of the chapter, each of the five true/false statements and five fill-in-the-blank questions will help you determine whether students have read the chapters. Answers are provided.
- **Assignments:** Grouped into Written Assignments, Group Assignments, Clinical Assignments, and Web Assignments, the Assignments package will give you a means to gauge students' understanding of the textbook material. The Assignments give students many chances to test their own knowledge of the chapter concepts as well as their developing critical thinking skills. Suggested Answers are provided.
- **Discussion Topics:** With these topics, you can initiate and foster classroom discussion or assign them for use outside the classroom. Each Discussion Topic is designed to help students make a connection between the textbook and application. Suggested Answers are provided.
- **E-Book:** Online access to the book's full text and images gives you an easy-to-transport format.
- **PowerPoint Presentations With Guided Lecture Notes:** The PowerPoint presentations provide you with visual aids to support your lectures or classroom lessons. The accompanying Guided Lecture Notes offer brief talking points you can use along with the presentations.
- **Test Generator:** The Test Generator lets you put together exclusive new tests from a bank containing hundreds of questions to help you in assessing your

students' understanding of the material. Test questions link to chapter learning objectives. This test generator comes with a bank of more than 1,100 questions.

- **Image Bank:** Access to downloadable photographs and illustrations from this textbook offer you the ability to use them in your PowerPoint slides or as you see fit throughout your course.

## RESOURCES FOR STUDENTS

Students can access all these learning tools using the code printed in the front of their textbooks by visiting <http://thepoint.lww.com/Flagg8e>.

- **NCLEX-Style Review Questions:** These *application-level* questions provide students the opportunity to test themselves on their ability to apply specific nursing actions based on what a nurse should know and what a nurse should do in a specific situation related to the chapter content. They also give students experience in answering questions of the type that will appear on the NCLEX.
- **Suggested Readings:** This list of journal articles provides students with the information needed to do more in-depth reading relevant to the topics included in the chapter.
- **Answers and Rationales:** Suggested Answers to the each chapter's What If . . . and Critical Thinking Care Study questions allow students to gauge whether they are on the right track by providing the main points that they are expected to address in answering these questions.
- **Patient Scenarios:** A patient care scenario details a full health history and examination findings pertinent to each chapter's content. Each scenario includes 25 related NCLEX-style questions to help students sharpen their skills and grow more familiar with NCLEX-type questions. Completing these exercises serve as an excellent review of the chapter content.
- **Journal Articles:** Updated for the new edition, online articles offer students the opportunity to read current research related to each chapter's material as available in Lippincott Williams & Wilkins journals.
- **Watch & Learn Video Clips:** These audiovisual aides cover both maternal and child care topics:
  - Developmental Tasks of Pregnancy: 1st Trimester, Accepting the Pregnancy
  - Developmental Tasks of Pregnancy: 2nd Trimester, Accepting the Baby
  - Developmental Tasks of Pregnancy: 3rd Trimester, Preparing for Parenthood
  - Vaginal Birth
  - Scheduled Cesarean Birth
  - Assisting the Patient With Breastfeeding
  - Developmental Considerations in Caring for Children: Infants
  - Developmental Considerations in Caring for Children: Toddlers
  - Developmental Considerations in Caring for Children: Preschoolers
  - Developmental Considerations in Caring for Children: School Agers
  - Developmental Considerations in Caring for Children: Adolescents

- Care of the Hospitalized Child: Introduction
- Care of the Hospitalized Child: Medication Administration
- Care of the Hospitalized Child: Play
- Care of the Hospitalized Child: Pain Management
- Care of the Hospitalized Child: Parent and Family Participation
- **Spanish–English Audio Glossary:** This auditory aide provides helpful terms and phrases for communicating with patients who speak Spanish.

## A Fully Integrated Course Experience

We are pleased to offer an expanded suite of digital solutions and ancillaries to support instructors and students using *Maternal & Child Health Nursing*, Eighth Edition. To learn more about any solution, please contact your local Wolters Kluwer representative.

### LIPPINCOTT COURSEPOINT+

*Lippincott CoursePoint+* is an integrated digital learning solution designed for the way students learn. It is the only nursing education solution that integrates:

- **Leading content in context:** Content provided in the context of the student learning path engages students and encourages interaction and learning on a deeper level.
- **Powerful tools to maximize class performance:** Course-specific tools, such as adaptive learning powered by PrepU, provide a personalized learning experience for every student.
- **Real-time data to measure students' progress:** Student performance data provided in an intuitive display lets you quickly spot which students are having difficulty or which concepts the class as a whole is struggling to grasp.
- **Preparation for practice:** Integrated virtual simulation and evidence-based resources improve student competence, confidence, and success in transitioning to practice.
  - **vSim for Nursing :** Codeveloped by Laerdal Medical and Wolters Kluwer, vSim for Nursing simulates real nursing scenarios and allows students to interact with virtual patients in a safe, online environment.
  - **Lippincott Advisor for Education :** With over 8,500 entries covering the latest evidence-based content and drug information, Lippincott Advisor for Education provides students with the most up-to-date information possible while giving them valuable experience with the same point-of-care content they will encounter in practice.
- **Training services and personalized support:** To ensure your success, our dedicated educational consultants and training coaches will provide expert guidance every step of the way.

thePoint® is a trademark of Wolters Kluwer.

## Acknowledgments

I would like to express my appreciation to the contributors of this edition. All of them have very busy personal and professional lives, yet they took the time and effort to update the content in their area of expertise through many revisions. I especially want to thank one contributor, Colleen Kennedy, who was referred to me by a colleague. When I contacted her about possible chapters, she volunteered for 13 chapters. I was hesitant, as this was much more than any other contributor. She not only completed all of her chapters on time but also volunteered to assist with additional chapters and contributed heavily to the diversity and maternal child nursing chapter.

I want to thank my family for their support and encouragement: my husband Jon, for never complaining about my editing late into the night; my daughter Jennifer, for contributing to the mental health disorder chapter; my son Chris; my daughter-in-law Melissa; and my 1-year-old grandson, Andrew. Sharing the pregnancy and birth of my grandson kept me focused on why maternal child nursing is such a special and personal field of nursing practice. To my stepchildren Sarah, Daniel, Lauren, and Anna, even though I didn't give birth to you and wasn't in your lives in your early years, I have enjoyed watching you grow into responsible young adults these past 5 years. Lastly, I want to thank Victoria White, the Developmental Editor, and Heather A. Rybacki, the Supervising Development Editor, of this edition. I was fortunate to have a professional team who provided expert guidance during every step of this journey.

***JoAnne Silbert-Flagg, DNP, CPNP, IBCLC, FAAN***

## **UNIT 1    Maternal and Child Health Nursing Practice**

- 1    **A Framework for Maternal and Child Health Nursing**  
Goals and Philosophies of Maternal and Child Health Nursing  
Maternal and Child Health Goals and Standards  
A Framework for Maternal and Child Health Nursing Care  
A Changing Discipline  
Legal Considerations of Maternal–Child Practice  
Ethical Considerations of Practice
  
- 2    **Diversity and Maternal Child Nursing**  
**Nursing Process Overview for Care That Respects Cultural Diversity**  
Methods to Respect Diversity in Maternal and Child Health Nursing  
Understanding Cultural Diversity in Maternal and Child Health Nursing  
Understanding Sexual Orientation in Maternal and Child Health Nursing  
Understanding Gender Identity in Maternal and Child Health Nursing
  
- 3    **The Childbearing and Childrearing Family in the Community**  
**Nursing Process Overview for Promotion of Family Health**  
Maternal–Child Nursing Care and the Community  
Family Structures  
Family Functions and Roles  
Assessment of Family Structure and Function
  
- 4    **Home Care and the Childbearing and Childrearing Family**  
**Nursing Process Overview for the Pregnant Woman or Child on Home Care**  
Understanding Home Care

Assessing a Family for Home Care  
Beginning Home Care

## **UNIT 2    The Nursing Role in Preparing Families for Childbearing and Childrearing**

- 5    **The Nursing Role in Reproductive and Sexual Health**  
**Nursing Process Overview for Promotion of Reproductive and Sexual Health**
  - Assessing and Meeting Reproductive Concerns
  - Reproductive Development
  - The Male Reproductive System
  - The Female Reproductive System
  - Sexual Health
  
- 6    **Nursing Care for the Family in Need of Reproductive Life Planning**  
**Nursing Process Overview for Reproductive Life Planning**
  - Assessment for Contraception Options and Possible Contraindications
  - Natural Family Planning
  - Hormonal Contraception
  - Intrauterine Devices
  - Surgical Methods of Reproductive Life Planning
  - The Couple With Unique Needs
  - Future Trends in Contraception
  - Elective Termination of Pregnancy
  
- 7    **Nursing Care of the Family Having Difficulty Conceiving a Child**  
**Nursing Process Overview for a Couple With Subfertility**
  - Subfertility
  - Fertility Assessment
  - Factors That Cause Male Subfertility
  - Factors That Cause Female Subfertility
  - Unexplained Subfertility
  - Assisted Reproductive Techniques
  - Alternatives to Childbirth
  
- 8    **The Nursing Role in Genetic Assessment and Counseling**  
**Nursing Process Overview for Genetic Assessment and Counseling**
  - Genetic Disorders
  - Genetic Counseling and Testing
  - Common Chromosomal Disorders Resulting in Physical or Cognitive

**UNIT 3    The Nursing Role in Caring for Families During Normal Pregnancy, Birth, the Postpartum, and Newborn Period**

- 9    Nursing Care During Normal Pregnancy and Care of the Developing Fetus  
    **Nursing Process Overview to Help Ensure Fetal Health**  
    The Nursing Role and Nursing Care During Normal Pregnancy and Birth  
    Stages of Fetal Development  
    Embryonic and Fetal Structures  
    Origin and Development of Organ Systems  
    Assessment of Fetal Growth and Development  
    Women With Unique Needs or Concerns
- 10    Nursing Care Related to Psychological and Physiologic Changes of Pregnancy  
    **Nursing Process Overview for Healthy Adaptation to Pregnancy**  
    Psychological Changes of Pregnancy  
    The Psychological Tasks of Pregnancy  
    The Confirmation of Pregnancy  
    Physiologic Changes of Pregnancy  
    Patients With Unique Concerns in Pregnancy
- 11    Nursing Care Related to Assessment of a Pregnant Family  
    **Nursing Process Overview for Prenatal Care**  
    Health Promotion and Assessment Before and During Pregnancy  
    The Initial Interview  
    Physical Examination  
    Laboratory Assessment  
    Risk Assessment  
    Signs Indicating Possible Complications of Pregnancy
- 12    Nursing Care to Promote Fetal and Maternal Health  
    **Nursing Process Overview for Health Promotion of a Fetus and Mother**  
    Health Promotion During Pregnancy  
    Preventing Fetal Exposure to Teratogens  
    Preparation for Labor

- 13    **The Nursing Role in Promoting Nutritional Health During Pregnancy**  
      **Nursing Process Overview for Promoting Nutritional Health During Pregnancy**  
          Relationship of Maternal Nutrition and Fetal Health  
          Assessing Nutritional Health  
          Promoting Nutritional Health During Pregnancy  
          Women With Unique Needs
- 14    **Preparing a Family for Childbirth and Parenting**  
      **Nursing Process Overview for Childbirth and Parenting Education**  
          Childbirth Education  
          The Childbirth Plan  
          Preconception Visits  
          Expectant Parenting Classes  
          Methods to Manage Pain in Childbirth  
          The Birth Setting  
          Alternative Methods of Birth  
          Women With Unique Needs
- 15    **Nursing Care of a Family During Labor and Birth**  
      **Nursing Process Overview for the Woman in Labor**  
          Theories of Why Labor Begins  
          The Components of Labor  
          The Stages of Labor  
          Maternal and Fetal Responses to Labor  
          Measuring Progress in Labor  
          Maternal and Fetal Assessments During Labor  
          The Care of a Woman During the First Stage of Labor  
          The Care of a Woman During the Second Stage of Labor

          The Woman With Unique Concerns in Labor
- 16    **The Nursing Role in Providing Comfort During Labor and Birth**  
      **Nursing Process Overview for Pain Relief During Labor and Childbirth**  
          Experience of Pain During Childbirth  
          Comfort and Nonpharmacologic Pain Relief Measures  
          The Woman With Unique Needs
- 17    **Nursing Care of a Postpartal Family**  
      **Nursing Process Overview for a Postpartal Woman and Family**  
          Psychological Changes of the Postpartal Period

Physiologic Changes of the Postpartal Period  
Nursing Care of a Woman and Family During the First 24 Hours  
After Birth  
Nursing Care of a Woman and Family in Preparation for Health  
Agency Discharge  
Nursing Care of a Postpartal Woman and Family With Unique Needs

- 18 **Nursing Care of a Family With a Newborn**  
**Nursing Process Overview for Health Promotion of the Term  
Newborn**  
The Profile of a Newborn  
Assessments for Well-Being  
The Care of a Newborn at Birth  
Nursing Care of a Newborn and Family in the Postpartal Period  
The Assessment of a Family's Readiness to Care for a Newborn at  
Home

- 19 **Nutritional Needs of a Newborn**  
**Nursing Process Overview for Promoting Nutritional Health in a  
Newborn**  
Nutritional Allowances for a Newborn  
Breastfeeding  
Formula Feeding  
Discharge Planning for Newborn Nutrition

## **UNIT 4 The Nursing Role in Caring for a Family During Complications of Pregnancy, Birth, or the Postpartal Period**

- 20 **Nursing Care of a Family Experiencing a Pregnancy Complication  
From a Preexisting or Newly Acquired Illness**  
**Nursing Process Overview for Care of a Woman With a Preexisting  
or Newly Acquired Illness**  
The Nursing Role and Nursing Care During Pregnancy Complications  
Cardiovascular Disorders and Pregnancy  
Hematologic Disorders and Pregnancy  
Renal and Urinary Disorders and Pregnancy  
Respiratory Disorders and Pregnancy  
Rheumatic Disorders and Pregnancy  
Gastrointestinal Disorders and Pregnancy  
Neurologic Disorders and Pregnancy

Musculoskeletal Disorders and Pregnancy  
Endocrine Disorders and Pregnancy  
Mental Illness and Pregnancy  
Cancer and Pregnancy

21 Nursing Care of a Family Experiencing a Sudden Pregnancy  
Complication

**Nursing Process Overview for a Woman Who Develops a  
Complication of Pregnancy**

Bleeding During Pregnancy  
Preterm Labor  
Preterm Rupture of Membranes  
Hypertensive Disorders in Pregnancy  
HELLP Syndrome  
Multiple Pregnancy  
Polyhydramnios  
Oligohydramnios  
Postterm Pregnancy  
Isoimmunization (Rh Incompatibility)  
Fetal Death

22 Nursing Care of a Pregnant Family With Special Needs  
**Nursing Process Overview for Care of a Pregnant Woman With  
Special Needs**

The Pregnant Adolescent  
The Pregnant Woman Over Age 40 Years  
The Pregnant Woman Who Is Physically or Cognitively Challenged  
A Woman Who Is Substance Dependent  
Trauma and Pregnancy

23 Nursing Care of a Family Experiencing a Complication of Labor  
or Birth

**Nursing Process Overview for a Woman With a Labor or Birth  
Complication**

Complications With the Power (The Force of Labor)  
Problems With the Passenger  
Problems With the Passage  
Anomalies of the Placenta and Cord

24 Nursing Care of a Family During a Surgical Intervention for Birth

**Nursing Process Overview for a Woman Having a Surgical  
Intervention for Birth**

Surgical Interventions

Cesarean Birth  
Effects of Surgery on a Woman  
Nursing Care for a Woman Anticipating a Cesarean Birth  
Nursing Care for a Woman Having an Emergent Cesarean Birth  
Intraoperative Care Measures  
Postpartal Care Measures

25 Nursing Care of a Family Experiencing a Postpartum  
Complication

**Nursing Process Overview for a Woman Experiencing a Postpartum  
Complication**

Postpartum Hemorrhages  
Puerperal Infections  
Thrombophlebitis  
Mastitis  
Urinary System Disorders  
Cardiovascular System Disorders  
Reproductive System Disorders  
Emotional and Psychological Complications of the Puerperium

26 Nursing Care of a Family With a High-Risk Newborn

**Nursing Process Overview**

Newborn Priorities in the First Days of Life  
The Newborn at Risk Because of Altered Gestational Age or Birth  
Weight  
Illnesses That Occur in Newborns  
The Newborn at Risk Because of a Maternal Infection  
The Newborn at Risk Because of a Maternal Illnesses

27 Nursing Care of the Child Born With a Physical or Developmental  
Challenge

**Nursing Process Overview for Care of a Newborn Who Is Physically  
or Developmentally Challenged**

Care at Birth of the Newborn Who Is Physically or Developmentally  
Challenged  
Physical and Developmental Disorders of the Skeletal System  
Physical and Developmental Disorders of the Gastrointestinal System  
Physical and Developmental Disorders of the Nervous System

**UNIT 5 The Nursing Role in Health Promotion for  
Childrearing Family**

- 28 **Principles of Growth and Development**  
**Nursing Process Overview for Promotion of Normal Growth and Development**  
Growth and Development and the Role of the Nurse  
Principles of Growth and Development  
Factors Influencing Growth and Development  
Theories of Child Development  
Using Growth and Development in Practice
- 29 **Nursing Care of a Family With an Infant**  
**Nursing Process Overview for Healthy Development of an Infant**  
Growth and Development of an Infant  
The Nursing Role in Health Promotion of an Infant and Family
- 30 **Nursing Care of a Family With a Toddler**  
**Nursing Process Overview for Healthy Development of a Toddler**  
Nursing Assessment of a Toddler's Growth and Development  
Planning and Implementation for Health Promotion of a Toddler and Family
- 31 **Nursing Care of a Family With a Preschool Child**  
**Nursing Process Overview for Healthy Development of a Preschooler**  
Nursing Assessment of a Preschooler's Growth and Development  
Planning and Implementation for the Health Promotion of a Preschooler and Family
- 32 **Nursing Care of a Family With a School-Age Child**  
**Nursing Process Overview for Healthy Development of a School-Age Child**  
Growth and Development of a School-Age Child  
Health Promotion for a School-Age Child and Family
- 33 **Nursing Care of a Family With an Adolescent**  
**Nursing Process Overview for Healthy Development of an Adolescent**  
Growth and Development of an Adolescent  
Health Promotion for an Adolescent and Family
- 34 **Child Health Assessment**  
**Nursing Process Overview for Health Assessment of the Child and Family**  
Health History: Establishing a Database

Physical Assessment  
Vision Assessment  
Hearing Assessment  
Speech Assessment  
Developmental Appraisal  
Intelligence  
Temperament  
Immunizations  
Concluding a Health Assessment

- 35    **Communication and Teaching With Children and Families**  
      **Nursing Process Overview for Health Teaching With Children**  
      Communication  
      Health Teaching in a Changing Healthcare Environment  
      Developing and Implementing a Teaching Plan  
      Health Teaching for a Surgical Experience

## **UNIT 6    The Nursing Role in Supporting the Health of Ill Children and Their Families**

- 36    **Nursing Care of a Family With an Ill Child**  
      **Nursing Process Overview for an Ill Child**  
      The Meaning of Illness to Children  
      Care of the Ill Child and Family in the Hospital  
      Nursing Responsibilities for Care of the Ill Child and Family  
      Promoting Safety for the Ill Child  
      Promoting Adequate Sleep for the Ill Child  
      Promoting Adequate Stimulation for the Ill Child  
      Promoting Play for the Ill Child
- 37    **Nursing Care of a Family When a Child Needs Diagnostic or Therapeutic Modalities**  
      **Nursing Process Overview for a Child Who Needs Diagnostic or Therapeutic Procedures**  
      Nursing Responsibilities With Diagnostic and Therapeutic Techniques  
      Measuring Vital Signs  
      Reducing Elevated Temperature in Children  
      Common Diagnostic Procedures  
      Collecting Specimens for Analysis  
      Assistance With Elimination

Nutritional Care  
Hot and Cold Therapy  
Wound Care

- 38 Nursing Care of a Family When a Child Needs Medication Administration or Intravenous Therapy  
**Nursing Process Overview for a Child Needing Medication/Intravenous Therapy**  
Medication Administration  
Intravenous Therapy

- 39 Pain Management in Children  
**Nursing Process Overview for a Child in Pain**  
The Physiology of Pain  
Assessing the Type and Degree of Pain  
Pain Assessment  
Pain Management  
Pharmacologic Pain Relief  
Nonpharmacologic Pain Management for Children  
Ongoing Pain Relief

## **UNIT 7 The Nursing Role in Restoring and Maintaining the Health of Children and Families With Physiologic Disorders**

- 40 Nursing Care of a Family When a Child Has a Respiratory Disorder  
**Nursing Process Overview for a Child With a Respiratory Disorder**  
Anatomy and Physiology of the Respiratory System  
Assessing Respiratory Illness in Children  
Health Promotion and Risk Management  
Therapeutic Techniques Used in the Treatment of Respiratory Illness in Children  
Disorders of the Upper Respiratory Tract  
Disorders of the Lower Respiratory Tract
- 41 Nursing Care of a Family When a Child Has a Cardiovascular Disorder  
**Nursing Process Overview for Care of a Child With Cardiovascular Disorder**  
Health Promotion and Risk Management

- Nursing Care of the Child With a Cardiac Disorder
  - The Cardiovascular System
  - Congestive Heart Failure
  - Congenital Heart Defects
  - Cardiac Surgery
  - Cardiac Catheterization
  - Cardiac Transplantation
  - Dysrhythmias
  - Acquired Heart Disease
  - Preventive Heart Disease
  
- 42 Nursing Care of a Family When a Child Has an Immune Disorder
  - Nursing Process Overview for a Child With an Immune Disorder**
    - The Immune System
    - Immunodeficiency Disorders
    - Allergy
      - Common Allergic Reactions
      - Atopic Disorders
      - Drug and Food Allergies
      - Stinging Insect Hypersensitivity
      - Contact Dermatitis
  
- 43 Nursing Care of a Family When a Child Has an Infectious Disorder
  - Nursing Process Overview for a Child With an Infectious Disorder**
    - The Infectious Process
    - Health Promotion and Risk Management
    - Caring for the Child With an Infectious Disease
    - Viral Infections
    - Bacterial Infections
    - Other Infectious Pathogens
  
- 44 Nursing Care of a Family When a Child Has a Hematologic Disorder
  - Nursing Process Overview for a Child With a Hematologic Disorder**
    - Anatomy and Physiology of the Hematopoietic System
    - Assessment and Therapeutic Techniques for Hematologic Disorders
    - Health Promotion and Risk Management
    - Disorders of the Red Blood Cells
    - Disorders of Blood Coagulation
  
- 45 Nursing Care of a Family When a Child Has a Gastrointestinal

## Disorder

### **Nursing Process Overview for a Child With a Gastrointestinal Disorder**

- Anatomy and Physiology of the Gastrointestinal System
- Diagnostic and Therapeutic Techniques
- Health Promotion and Risk Management
- Fluid, Electrolyte, and Acid–Base Imbalances
- Common Gastrointestinal Symptoms of Illness in Children
- Common Disorders of the Stomach and Duodenum
- Hepatic Disorders
- Intestinal Disorders
- Disorders of the Lower Bowel
- Disorders Caused by Food, Vitamin, and Mineral Deficiencies

## 46 Nursing Care of a Family When a Child Has a Renal or Urinary Tract Disorder

### **Nursing Process Overview for Care of a Child With a Renal or Urinary Tract Disorder**

- Anatomy and Physiology of the Kidneys
- Assessment of Renal and Urinary Tract Dysfunction
- Therapeutic Measures for the Management of Renal Disease
- Health Promotion and Risk Management
- Structural Abnormalities of the Urinary Tract
- Infections of the Urinary System and Related Disorders
- Disorders Affecting Normal Urinary Elimination
- Kidney Transplantation

## 47 Nursing Care of a Family When a Child Has a Reproductive Disorder

### **Nursing Process Overview for Care of a Child With a Reproductive Disorder**

- Assessing Reproductive Disorders in Children
- Health Promotion and Risk Management
- Disorders Caused by Altered Reproductive Development
- Reproductive Disorders in Males
- Reproductive Disorders in Females
- Breast Disorders
- Sexually Transmitted Infections

## 48 Nursing Care of a Family When a Child Has an Endocrine or a Metabolic Disorder

### **Nursing Process Overview for Care of a Child With an Endocrine or**

## **Metabolic Disorder**

- Health Promotion and Risk Management
- The Pituitary Gland
- Pituitary Gland Disorders
- The Thyroid Gland
- Thyroid Gland Disorders
- The Adrenal Gland
- Adrenal Gland Disorders
- The Pancreas
- The Parathyroid Glands
- Metabolic Disorders (Inborn Errors of Metabolism)

## 49 **Nursing Care of a Family When a Child Has a Neurologic Disorder**

### **Nursing Process Overview for Care of a Child With a Neurologic System Disorder**

- Anatomy and Physiology of the Nervous System
- Assessing the Child With a Neurologic Disorder
- Health Promotion and Risk Management
- Increased Intracranial Pressure
- Neural Tube Disorders
- Neurocutaneous Syndromes
- Cerebral Palsy
- Infection
- Inflammatory Disorders
- Paroxysmal Disorders
- Spinal Cord Injury
- Ataxic Disorders

## 50 **Nursing Care of a Family When a Child Has a Vision or Hearing Disorder**

### **Nursing Process Overview for Care of a Child With a Vision or Hearing Disorder**

- Health Promotion and Risk Management
- Vision
- Disorders That Interfere With Vision
- Structural Problems of the Eye
- Infection or Inflammation of the Eye
- Traumatic Injury to the Eye
- Inner Eye Conditions
- The Child Scheduled for Eye Surgery
- The Hospitalized Child With a Visual Impairment

Structure and Function of the Ears  
Disorders of the Ear  
The Hospitalized Child With a Hearing Impairment

51 Nursing Care of a Family When a Child Has a Musculoskeletal Disorder

**Nursing Process Overview for Care of a Child With a Musculoskeletal Disorder**

The Musculoskeletal System  
Assessment of Musculoskeletal Function  
Health Promotion and Risk Management  
Therapeutic Management of Musculoskeletal Disorders in Children  
Disorders of Bone Development  
Infectious and Inflammatory Disorders of the Bones and Joints  
Disorders of Skeletal Structure  
Disorders of the Joints and Tendons: Collagen Vascular Disease  
Disorders of the Skeletal Muscles

52 Nursing Care of a Family When a Child Has an Unintentional Injury

**Nursing Process Overview for Care of a Child With an Unintentional Injury**

Health Promotion and Risk Management  
The Injured Child  
Head Trauma  
Abdominal Trauma  
Dental Trauma  
Drowning  
Poisoning  
Foreign Body Obstruction  
Bites  
Athletic Injuries  
Injuries of the Extremities  
Thermal Injuries

53 Nursing Care of a Family When a Child Has a Malignancy

**Nursing Process Overview for Care of a Child With a Malignancy**

Health Promotion and Risk Management  
Neoplasia  
Assessing Children With Cancer  
Overview of Cancer Treatment Measures Used With Children  
The Leukemias

The Lymphomas  
Neoplasms of the Brain  
Bone Tumors  
Other Childhood Neoplasms

## **UNIT 8     The Nursing Role in Restoring and Maintaining the Mental Health of Children and Families**

- 54**     Nursing Care of a Family When a Child Has an Intellectual or Mental Health Disorder  
      **Nursing Process Overview for Care of a Child With an Intellectual Challenge or Mental Illness**  
      Health Promotion and Risk Management  
      Classification of Mental Health Disorders  
      Neurodevelopmental Disorders  
      Attention Deficit and Disruptive Behavior Disorders  
      Anxiety Disorders  
      Eating Disorders  
      Tic Disorders  
      Depression, Psychiatric, and Bipolar and Related Disorders Affecting Children  
      Elimination Disorders
- 55**     Nursing Care of a Family in Crisis: Maltreatment and Violence in the Family  
      **Nursing Process Overview for Care of a Family That Has Experienced Child Maltreatment or Intimate Partner Violence**  
      Health Promotion and Risk Management  
      Child Maltreatment  
      Sexual Maltreatment  
      Rape  
      Intimate Partner Violence
- 56**     Nursing Care of a Family When a Child Has a Long-Term or Terminal Illness  
      **Nursing Process Overview for Care of a Family With a Child Who Has a Long-Term or Terminal Illness**  
      The Child With a Long-Term Illness  
      The Child Who Is Terminally Ill

Appendix A    Answers to QSEN Checkpoint Questions

UNIT 1

Maternal and Child Health Nursing  
Practice

# A Framework for Maternal and Child Health Nursing

*Anna Chung is an early premature neonate who will be transported to a regional center for care about 30 miles from the community where she was born. Her parents, Melissa and Robert, tell you they are worried about their tiny daughter being cared for by strangers so many miles away. They're also concerned how they will be able to pay for or give informed consent for this special level of care. Melissa, 42 years old, feels too exhausted to leave the hospital only 2 days after having a cesarean birth. She wonders how she and her husband will be able to visit the new baby because of her exhaustion and because their first child, Miecko, 6 years old, is on home care for pneumonia. Robert wonders how Miecko will react to having an ill rather than a healthy sister.*

*This chapter discusses competencies, philosophies, challenges, and new roles for nurses in maternal–child health care and how these challenges and changes mold and affect care.*

**What are some healthcare issues evident in the previous scenario? What would be your nursing role with Mrs. Chung? With her two children?**

## KEY TERMS

evidence-based practice  
fertility rate  
infant mortality rate  
maternal and child health nursing  
nursing research  
patient advocacy  
Quality & Safety Education for Nurses (QSEN)  
scope of practice

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. View the areas of maternal and child health as a continuum with a seamless flow between the two areas.
  2. Identify the specific goals and philosophies of maternal and child health nursing and apply these to nursing practice.
  3. Identify 2020 National Health Goals as an important guide to understanding the health of the nation and goals that nurses can help the nation achieve.
  4. Describe the evolution, scope, competencies, and professional roles of nurses in maternal and child health nursing.
  5. Describe family-centered care and ways maternal and child health nursing could be made both more family centered and respectful of diversity.
  6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
  7. Define and use common statistical terms used in the field, such as infant and maternal mortality.
  8. Use critical thinking to identify areas of nursing care that could benefit from additional research or application of evidence-based practice.
  9. Integrate knowledge of maternal and child health nursing with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to achieve quality maternal and child health nursing care.
- 

## Goals and Philosophies of Maternal and Child Health Nursing

The area of childbearing and childrearing families is a major focus of nursing practice in promoting health for the next generation. Comprehensive preconception and prenatal care is essential in ensuring a healthy outcome for mother and child. Although childbearing and childrearing are often viewed as two separate entities, they are interrelated, and a deeper understanding is achieved when they are viewed as a continuum (Fig. 1.1) (Burkhard, 2013).

**Figure 1.1** Maternal and child health nursing includes care of the pregnant woman, child, and family. **(A)** During a prenatal visit, a nurse assesses that a pregnant woman’s uterus is expanding normally. **(B)** During a health maintenance visit, a nurse assesses a child’s growth and development. (© Barbara Proud.)

The primary goal of both **maternal and child health nursing** is the promotion and maintenance of optimal family health. Major philosophical assumptions about combined maternal and child health nursing are listed in [Box 1.1](#). Maternal and child health nursing extends from preconception to menopause with an expansive array of health issues and healthcare providers. Examples of the scope of practice include:

- Preconception health care
- Care of women during three trimesters of pregnancy and the puerperium (the 6 weeks after childbirth, sometimes termed the fourth trimester of pregnancy)
- Care of infants during the perinatal period (the time span beginning at 20 weeks of pregnancy to 4 weeks [28 days] after birth)
- Care of children from birth through late adolescent
- Care in a variety of hospital and home care settings

**Maternal and child health nursing is:**

- Family centered; assessment should always include the family as well as an individual.
- Community centered; the health of families is both affected by and influences the health of communities.
- Evidence based; this is the means whereby critical knowledge increases.
- A challenging role for nurses and a major factor in keeping families well and optimally functioning.

**A maternal and child health nurse:**

- Considers the family as a whole and as a partner in care when planning or implementing or evaluating the effectiveness of care.
- Serves as an advocate to protect the rights of all family members, including the fetus.
- Demonstrates a high degree of independent nursing functions because teaching and counseling are major interventions.
- Promotes health and disease prevention because these protect the health of the next generation.
- Serves as an important resource for families during childbearing and childrearing as these can be extremely stressful times in a life cycle.
- Respects personal, cultural, and spiritual attitudes and beliefs as these so strongly influence the meaning and impact of childbearing and childrearing.
- Encourages developmental stimulation during both health and illness so children can reach their ultimate capacity in adult life.
- Assesses families for strengths as well as specific needs or challenges.
- Encourages family bonding through rooming-in and family visiting in maternal and child healthcare settings.
- Encourages early hospital discharge options to reunite families as soon as possible in order to create a seamless, helpful transition process.
- Encourages families to reach out to their community so the family can develop a wealth of support people they can call on in a time of family crisis.

Regardless of the setting, a family-centered approach is the preferred focus of nursing care (Papp, 2012). The health of an individual and his or her ability to function as a member of a family can strongly influence and improve overall family functioning.

Family-centered care enables nurses to better understand individuals and their effect on others and, in turn, to provide more holistic care (Hedges, Nichols, & Filoteo, 2012). It includes encouraging rooming-in with the mother by the mother's partner or support

person and with the child by their caregiver. Family members are encouraged to provide physical and emotional care based on the individual situation and their comfort level. Nurses provide guidance and monitor the interaction between family members to promote the health and well-being of the family unit. (Fig. 1.2).

**Figure 1.2** A nurse involves the mother in a physical exam to promote family-centered care.

**Box 1.2** provides guidance on how to assist a family choose a healthcare setting that is family-centered. Family teaching boxes of this kind are found in all chapters as examples of the type of health teaching important in maternal and child health care.

## BOX 1.2

### Nursing Care Planning Based on Family Teaching

#### TIPS FOR SELECTING A FAMILY-CENTERED HEALTHCARE SETTING

**Q.** Melissa Chung asks you, “With so many healthcare settings available, how do we know which one to choose?”

**A.** When selecting a setting, asking the following questions can help you decide what is best for your family:

- If the setting is for child care, are personnel interested in you as well as your child? If the setting is a maternal care site, do they ask about family concerns as well as individual ones?
- Can the setting be reached easily? (Going for preventive care when well or for continuing care when ill should not be a chore.)

- Will the staff provide continuity of care so you'll always see the same primary care provider if possible?
- Does the physical setup of the facility provide for a sense of privacy, yet a sense that healthcare providers share pertinent information so you do not have to repeat your history at each visit?
- Is the cost of care and the number of referrals to specialists explained clearly?
- Are preventive care and health education stressed? (Keeping well is as important as recovering from illness.)
- Is health education done at your learning level?
- Do healthcare providers respect your opinion and ask for your input on healthcare decisions?
- Will the facility still be accessible if a family member becomes disabled?

## Maternal and Child Health Goals and Standards

Healthcare technology has contributed to a number of important advances in maternal and child health care. Through immunization, childhood diseases such as measles and poliomyelitis almost have been eradicated. New fertility drugs and fertility techniques allow more couples to conceive. The ability to prevent preterm birth and improve the quality of life for both preterm and late preterm infants has increased dramatically. As specific genes responsible for children's health disorders are identified, stem cell therapy may make it possible to replace diseased cells with new growth cells and cure these illnesses. In addition, a growing trend toward healthcare consumerism, or self-care, has made childbearing and childrearing families active participants in their own health monitoring.

Access to health care and social determinants of health impact the role of the nurse and the health of the patient. These factors have expanded the roles of nurses in maternal and child health and, at the same time, have made the delivery of quality maternal and child health nursing care a challenge.

### 2020 NATIONAL HEALTH GOALS

The importance a society assigns to human life can best be measured by the concern a nation places on its most vulnerable members—its elderly, its disadvantaged, and its youngest citizens. In light of this, in 1979, the U.S. Public Health Service first formulated healthcare objectives for the nation. Healthcare goals are reviewed every 10 years. In 2010, new goals to be achieved by 2020 were set ([U.S. Department of Health and Human Services \[DHHS\], 2010](#)). The 2030 goals are scheduled for presentation in 2020. Many of these objectives directly involve maternal and child health care because improving the health of these age groups will have long-term effects on the population. The two main overarching national health goals are:

- To increase quality and years of healthy life.

- To eliminate health disparities.

A new objective added in 2010 recommends that 100% of prelicensure programs in nursing include core content on counseling for health promotion and disease prevention, cultural diversity including for lesbian, gay, bisexual, and transgender (LGBT) populations, evaluation of health sciences literature, environmental health, public health systems, and global health, all important areas for maternal and child health and discussed throughout this text (DHHS, 2010).

The 2020 National Health Goals are intended to help citizens more easily understand the importance of health promotion and disease prevention and to encourage wide participation in improving health in the next decade. It's important for maternal and child health nurses to be familiar with these goals because nurses play such a vital role in helping the nation achieve these objectives through both practice and research (see [www.healthypeople.gov](http://www.healthypeople.gov)). The goals also serve as the basis for grant funding and financing of evidence-based practice. Each of the following sections highlights goals as they relate to that specific area of care.

## GLOBAL HEALTH GOALS

The United Nations (UN) and the World Health Organization established millennium health goals in 2000 in an effort to improve health worldwide. As with 2020 National Health Goals, these concentrate on improving the health of women and children because increasing the health in these two populations can have such long-ranging effects on general health. These Global Health Goals are:

- To end poverty and hunger.
- To achieve universal primary education.
- To promote gender equality and empower women.
- To reduce child mortality.
- To improve maternal health.
- To combat HIV/AIDS, malaria, and other diseases.
- To ensure environmental sustainability.
- To develop a global partnership for development.

The establishment of global health goals is a major step forward in improving the health of all people, as contagious diseases, poverty, and gender inequality do not respect national boundaries but follow people across the world and into all nations (UN, 2000).

## Health Setting Magnet Status

*Magnet status* is a credential furnished by the American Nurses Credentialing Center (ANCC), an affiliate of the American Nurses Association, to hospitals that meet a rigorous set of criteria designed to improve the strength and quality of nursing care. Hospitals who achieve Magnet status meet criteria in five major categories:

- *Transformational leadership*. This is the ability of nurses in the designated

organization to convert their organization's values, beliefs, and behaviors in order to create a high professional level of nursing care.

- *Structural empowerment.* This refers to the ability to provide an innovative environment where strong professional practice can flourish with regard to the hospital's mission, vision, and values.
- *Exemplary professional practice.* The setting demonstrates a comprehensive understanding of the role of nursing; the application of that role with patients, families, communities, and the interdisciplinary team is clear, so new knowledge and evidence can be applied to nursing care.
- *New knowledge, innovation, and improvements.* The organization demonstrates strong nursing leadership, empowered professionals, and exemplary practice while contributing to patient care.
- *Empirical quality results.* The hospital demonstrates solid structure and processes where strong professional practice can flourish and where the mission, vision, and values come to life as the organization achieves the outcomes believed to be important for the organization (ANCC, 2012).

Magnet hospitals typically demonstrate a high level of nursing job satisfaction and a low staff nurse turnover rate and have policies in place that include nurses in data collection and decision making about patient care. These hospitals demonstrate they value staff nurses, involve them in research-based practice, and encourage and reward them for obtaining additional degrees in nursing. All nurse managers and nurse leaders in Magnet-designated hospitals must have either a baccalaureate or master's degree in nursing.

Not all hospitals can qualify for Magnet status; the desirability of being named a Magnet hospital, however, has encouraged all hospitals to examine their nursing environment and bring about changes that improve working conditions, stress evidence-based practice, and improve the education level of their nurses (Hess, Desroches, Donelan, et al., 2011). According to the ANCC, "Magnet hospitals attract and maintain top talent; improve patient care, safety and satisfaction; foster a collaborative culture; advance nursing standards and practice; and grow business and financial success" (ANCC, n.d.).

## A Framework for Maternal and Child Health Nursing Care

Maternal and child health nursing can be visualized within a framework in which nurses use nursing process, nursing theory, and Quality & Safety Education for Nurses (QSEN) competencies to care for families during childbearing and childrearing years and through the four phases of health care:

- Health promotion
- Health maintenance

- Health restoration
- Health rehabilitation

Examples of these phases of health care as they relate to maternal and child health are shown in [Table 1.1](#).

**TABLE 1.1 DEFINITIONS AND EXAMPLES OF PHASES OF HEALTH CARE**

<b>Term</b>	<b>Definition</b>	<b>Examples</b>
Health promotion	Educating parents and children to follow sound health practices through teaching and role modeling	Teaching women the importance of rubella immunization before pregnancy; providing preteens with information about safer sex practices well before they are likely to become sexually active
Health maintenance	Intervening to maintain health when risk of illness is present	Encouraging women to be partners in prenatal care; teaching parents the importance of safeguarding their home by childproofing against poisoning
Health restoration	Using conscientious assessment to be certain that symptoms of illness are identified and interventions are begun to return patient to wellness most rapidly	Caring for a woman during a complication of pregnancy such as gestational diabetes or a child during an acute illness such as pneumonia
Health rehabilitation	Helping prevent complications from illness; helping a patient with residual effects achieve an optimal state of wellness and independence; helping a patient to accept inevitable death	Encouraging a woman with gestational trophoblastic disease (abnormal placenta growth) to continue therapy or a child with a renal transplant to continue to take necessary medications

## **NURSING PROCESS**

Nursing care, at its best, is designed and implemented in a thorough manner, using an organized series of steps, to ensure quality and consistency of care ([Carpenito, 2012](#)). The nursing process, a scientific form of problem solving, serves as the basis for assessing, making a nursing diagnosis, planning, implementing, and evaluating care. It is a process broad enough to serve as the basis for modern nursing care because it is applicable to all healthcare settings, from the home to ambulatory clinics to intensive care units.

Because nurses rarely work in isolation but rather as a member of an interprofessional team, interprofessional care maps and checkpoint questions on teamwork and collaboration are included throughout the text to demonstrate the use of the nursing process as well as to provide examples of critical thinking, clarify nursing care for specific patient needs, and accentuate the increasingly important role of nurses as coordinators of care for a collaborative team.

## NURSING THEORY

One of the requirements of a profession (together with other critical determinants, such as members who set their own standards, self-monitor their practice quality, and participate in research) is that a discipline's knowledge flows from a base of established theory.

### Concept Mastery Alert

Make note of the differences between health *promotion* and health *maintenance*: Health maintenance involves intervening to maintain health *when risk of disease is present*, for example, teaching a group of sexually active adolescents about contraception and prevention of sexually transmitted infections. Health promotion involves education when no specific risk is present.

Nursing theories are designed to offer helpful ways to view patients so nursing activities can be created to best meet patient needs—for example, Calistra Roy's theory stresses that an important role of the nurse is to help patients adapt to change caused by illness or other stressors (Roy, 2011); Dorothea Orem's theory concentrates on examining patients' ability to perform self-care (Orem & Taylor, 2011); Patricia Benner's theory describes the way nurses move from novice to expert as they become more experienced and prepared to give interprofessional care (Benner, 2011). Using a theoretical basis such as these can help you appreciate the significant effect of a child's illness or the introduction of a new member on the total family.

Other issues most nursing theorists address include how nurses should be viewed or what the goals of nursing care should be. Extensive changes in the scope of maternal and child health nursing have occurred as health promotion (teaching, counseling, supporting, and advocacy, or keeping parents and children well) has become a greater priority in care (Salsman, Grunberg, Beaumont, et al., 2012). As promoting healthy pregnancies and keeping children well protects not only patients at present but also the health of the next generation, maternal–child health nurses fill these expanded roles to a unique and special degree.

## QSEN: QUALITY & SAFETY EDUCATION FOR NURSES

In 2007, the Robert Wood Johnson Foundation challenged nursing leaders to improve the quality of nursing care and to build the knowledge, skills, and attitudes necessary to

help achieve that level of care into prelicensure and graduate programs (Disch, 2012).

Because of this challenge, the QSEN Learning Collaborative created six competencies deemed necessary for quality care (Cronenwett, Sherwood, & Gelmon, 2009). These competencies included five competencies that originated from a study by the Institute of Medicine: (a) patient-centered care, (b) teamwork and collaboration, (c) quality improvement, (d) informatics, and (e) evidence-based practice. The QSEN Learning Collaborative added safety as the sixth competency.

Throughout all phases of QSEN, the overall goal is to address the challenge of preparing future nurses with the abilities necessary to continuously improve the quality and safety of the healthcare systems in which they work. Definitions for each of the six competencies along with examples of the knowledge, skills, and attitudes necessary to achieve quality maternal and child health care are shown in Box 1.3.

### BOX 1.3

#### QSEN Competencies in Relation to the Chung Family

Competency	Knowledge	Skills	Attitudes
<i>Patient-Centered Care</i>			
The patient or designee is thought of as the source of control and full partner in the provision of compassionate and coordinated care based on respect for the patient's preferences, values, and needs.	Take an admission history detailing the Chung family's composition. Document the roles of family members and who will be the chief childcare provider.	Encourage Anna's family to spend as much time as possible with her while she is hospitalized; assess that she will have family support on transition to home.	Don't think of admitting Anna to the neonatal care nursery as a single patient but rather as admitting her family to the setting.
<i>Teamwork and Collaboration</i>			
Nurses function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making as they achieve quality	Familiarize yourself with how many other healthcare providers will be interacting with Anna (e.g., neonatologist, nurse practitioner, nutritionist) to help appreciate how frightening having to meet so many people could be to a family.	Discuss with Anna's parents what problems, if any, they will have visiting so other team members can help reassure and support them when they visit.	Consider and respect Anna's parents as integrative members of her healthcare team.

patient care.

---

*Evidence-Based Practice*

---

Nurses integrate the best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care.	Read journal articles related to new evidence about healthy families or neonatal care to be better prepared to help Anna seamlessly transition from one setting to the next.	Implement evidence-based practice so Anna's family are confident that care is based on credible research.	Value the need for change based on new evidence so you can explain to Anna's family with confidence any need for change in care.
---	--	---	--

---

*Quality Improvement (QI)*

---

Nurses use data to monitor the outcomes of care and use improvement methods to design and test changes to continuously improve the quality and safety of healthcare systems.	View QI as an important role for all healthcare professionals beginning with prelicensure students.	Use whatever aids, such as checklists, flow sheets, or patient information forms, necessary in order to provide seamless nursing care from nursery admission to home.	Appreciate that continuous QI is an essential part of successful working with and respecting families.
--	---	---	--

---

*Safety*

---

Nurses minimize the risk of harm to patients and providers through both system effectiveness and individual performance.	Learn the requirements for a safe healthcare setting for a vulnerable preterm infant.	Be certain Anna receives developmental stimuli as well as is cared for in an environment that promotes a sense of security and is as free from pain as possible.	Recognize families under stress do not "hear" instructions well and so may need these repeated or provided in a written form as well as orally.
--	---	--	---

---

*Informatics*

---

Nurses use information and technology to	Keep records and documentation current so various healthcare	Document care in an electronic health record so it	Recognize that documentation must be
--	--	--	--------------------------------------

communicate, manage knowledge, mitigate error, and support decision making.	providers can keep informed in order to provide seamless care shifts and setting shifts in care.	can be available to various healthcare providers.	complete to be valuable (in audit reviews, what wasn't documented as being done is considered as not done).
---	--	---	---

## EVIDENCE-BASED PRACTICE

Evidence-based practice existed as an important element of nursing practice prior to the development of QSEN; it has since been incorporated into QSEN as one of its competencies. **Evidence-based practice** is the conscientious, explicit, and judicious use of current best evidence to make decisions about the care of patients (Falk, Wongsu, Dang, et al., 2012). Evidence can be a combination of research, clinical expertise, and patient preferences or values.

Use of evidence such as that obtained from randomized controlled trials helps to move healthcare actions from “just tradition” to a more solid and therefore safer, scientific basis. The Cochrane Database (listed in PubMed, Ovid, and MEDLINE) is a good source for discovering evidence-based practices as the organization consistently reviews, evaluates, and reports the strength of health-related research (Dong, Chen, & Yu, 2012).

QSEN Checkpoint Questions: Evidence-Based Practice are included in chapters throughout the text and contain summaries of current maternal and child health research followed by questions to assist you in developing a questioning attitude regarding current nursing practice or in thinking of ways to incorporate research findings into care.

## NURSING RESEARCH

**Nursing research** (the systematic investigation of problems that have implications for nursing practice usually carried out by nurses) plays an important role in evidence-based practice as bodies of professional knowledge only grow and expand to the extent people in that profession are able to carry out research (Christian, 2012). Examining nursing care in this way results in improved and cost-effective patient care as it provides evidence for action and justification for implementing activities.

A classic example of how the results of nursing research can influence nursing practice is the application of research carried out by Rubin (1963) concerning mothers' initial approaches to their newborns. Before the publication of this study, nurses assumed a woman who did not immediately hold and cuddle her infant at birth was a “cold” or unfeeling mother. After observing a multitude of new mothers, Rubin concluded attachment is not a spontaneous procedure; rather, it more commonly begins

with only fingertip touching, then over the next few days, moves to “motherly” actions such as hugging and kissing. Armed with Rubin’s findings, nurses today are better able to differentiate healthy from unhealthy bonding behavior in new mothers. Additional nursing research in this area (see [Chapter 17](#)) has provided further substantiation regarding the importance of this original investigation.

Some examples of current questions that warrant nursing investigation in the area of maternal and child health nursing include:

- What is the most effective stimulus to encourage women to come for prenatal care or parents to bring children for health maintenance visits?
- How can nurses be instrumental in fostering diversity and inclusion in care?
- How much self-care should young children be expected (or encouraged) to provide during an illness?
- What is the effect of market-driven health care on the quality of maternal–child nursing care?
- What active measures can nurses take to reduce the incidence of child or intimate partner violence?
- How can nurses best help families cope with the stress of a complication of pregnancy or a child’s long-term illness?
- How can nurses help prevent violence such as homicide in communities and modify the effects of violence on families?
- What information do maternal and child health nurses need to know about alternative therapies, such as herbal remedies, so their practices remain current?

### *QSEN Checkpoint Question 1.1*

#### **TEAMWORK & COLLABORATION**

A nursing assistant informed the nurse that Mr. Chung asked why the hospital where his baby is being cared for is termed a “Magnet hospital.” The nurse would want team members to know which rationale?

- a. Magnet hospitals are those who care for the most acutely ill patients.
- b. The designation is one assigned by the American Medical Association.
- c. The hospital has met high standards for nursing competency.
- d. The term refers to hospitals that only admit a limited number of patients.

*Look in [Appendix A](#) for the best answer and rationale.*

## **A Changing Discipline**

Maternal and child health is an ever-changing area of nursing. This happens because childhood infections, such as pertussis (whooping cough) and measles (Rubeola), can now be prevented so children do not usually require care for these conditions. At the same time, illnesses that could not be treated before, such as cystic fibrosis or hypertension of pregnancy, can now be treated, so the number of settings and critical

aspects of care increases.

## TRENDS IN THE MATERNAL AND CHILD HEALTH NURSING POPULATION

Not only patterns of illness but also variations in social structure, family lifestyle (a way of living in which families cope with social, physical, psychological, and economic variables in their life), and responsibilities continue to constantly change. [Table 1.2](#) summarizes some of these changes that have directly altered assessment and planning care for maternal and child health nurses.

**TABLE 1.2 TRENDS IN MATERNAL AND CHILD HEALTH CARE AND IMPLICATIONS FOR NURSING**

Trend	Implications for Nursing
Families are not as extended as in previous generations, so contain fewer members.	Fewer family members are available as support people in a time of crisis. Nurses are called on to fulfill this role more than ever before.
The number of single-parent families is increasing so rapidly it now equals the number of nuclear families in the United States.	A single parent may have fewer financial resources than dual-employed parents. Nurses need to be aware of alternative care options and available to provide a backup opinion as needed.
Ninety percent of women in the United States work outside their home at least part time; many women are the main wage earner for their family.	Health care must be scheduled at times a working parent can come for care for herself or can bring a child for care. Problems of latchkey (self-care) children and the number and safety of child care centers need to be addressed.
Families are more mobile than previously; there is an increase in the number of homeless women and children.	Good interviewing and health monitoring are necessary with mobile families so a health database can be established and there can be continuity of care.

Both child and intimate partner violence is increasing in incidence.	Screening for child or intimate partner violence should be included in all family assessments. Nurses must be aware of the legal responsibilities for reporting violence.
Families are more health conscious than ever before; the use of websites to monitor their health or ask health questions is rapidly increasing.	Families are ripe for health education; providing evidence-based information can be a major nursing role.
Health care must respect cost containment by creating “healthcare homes” or “medical homes.”	Comprehensive care is necessary in primary care settings because referral to specialists may not be an option depending on a family’s type or lack of health insurance.
Patient advocacy is necessary as it is easy for families to feel lost in the healthcare system.	<b>Patient advocacy</b> is safeguarding and advancing the interests of patients and their families. Familiarity with the healthcare services available in a community, establishing and maintaining a relationship with families, as well as helping them make informed choices about what course of action to take or what services would be best to use are important nursing roles.

## MEASURING MATERNAL AND CHILD HEALTH

Measuring what constitutes the area of maternal and child health is not as simple as defining whether patients are ill or well because individual patients and healthcare practitioners can maintain different perspectives on illness and wellness. A more objective view of health can be provided by using national or regional health statistics to describe degrees of illness ([Box 1.4](#)).

### BOX 1.4

#### Common Statistical Terms Used to Report Maternal and Child Health

*Birth rate:* The number of births per 1,000 population.

*Fertility rate:* The number of pregnancies per 1,000 women of childbearing age.

*Fetal death rate:* The number of fetal deaths (over 500 g) per 1,000 live births.

*Neonatal death rate:* The number of deaths per 1,000 live births occurring at birth or

in the first 28 days of life.

*Perinatal death rate:* The number of deaths during the perinatal time period (beginning when a fetus reaches 500 g, about week 20 of pregnancy, and ending about 4 to 6 weeks after birth); it is the sum of the fetal and neonatal rates.

*Maternal mortality rate:* The number of maternal deaths per 100,000 live births that occur as a direct result of the reproductive process.

*Infant mortality rate:* The number of deaths per 1,000 live births occurring at birth or in the first 12 months of life.

*Childhood mortality rate:* The number of deaths per 1,000 population in children aged 1 to 14 years.

## Birth Rate

The birth rate in the United States has continued to gradually decrease in recent years to 13.4 per 1,000 population in 2014 (Fig. 1.3). It has substantially decreased from a high of 30.2 per 1,000 population in 1909 (Hamilton et al., 2015).

**Figure 1.3** Birth rates by age of mother: United States, 1990–2014. (Hamilton, B. E., Martin, J. A., Osterman, M. J., et al. [2015]. Births: Final data for 2014. *National Vital Statistics Report*, 64[12], 6.)

Early in the century, births to teenage girls were steadily increasing; however, due to additional counseling and increased availability of contraception, particularly long-acting, reversible contraception such as the intrauterine device, this rate is now steadily declining (presently at 24.2/1,000 from a high of 618/1,000 in 1961) (Finer & Zolna, 2016; Hamilton et al., 2015).

The birth rate for women 20 to 24 years of age (79.0/1,000) is gradually declining as well, as women choose to postpone having children until past college age. In contrast, the number of children born to women older than 40 years of age is steadily increasing (presently at 10.6/1,000 from a low of almost no births in this age group in 1901 (Hamilton et al., 2015).

### **Fertility Rate**

The **fertility rate** tends to be low in countries where there are fewer nutritional resources because poor nutrition makes conceiving difficult, as well as in countries where the proportion of young adult men is low because of war or disease. This rate tends to be high in countries where the average woman has access to good nutrition and feels safe to begin a family. The U.S. fertility rate is currently at 62.9%, a rate typical of a healthy, high-resource country (Hamilton et al., 2015).

### **Fetal Death Rate**

Fetal deaths before birth but greater than 20 weeks gestation occur because of maternal factors (such as premature cervical dilation and maternal hypertension) and also because of fetal factors (such as chromosomal abnormalities or poor placental attachment). The cause of many fetal deaths cannot be documented or occur for unknown reasons. Fetal death rate is important in evaluating the health of a nation because it reflects the overall quality of maternal health and whether common services such as prenatal care are available. A renewed emphasis on both preconception and prenatal care has helped to reduce the U.S. rate from a number as high as 18% in 1950 to 5.96% in 2013 (Hamilton et al., 2015).

### **Neonatal Death Rate**

This rate reflects not only the quality of care available to women during pregnancy and childbirth but also the quality of care available to infants during the first month of life. According to the Centers for Disease Control and Prevention (CDC's) most recent data, the number of infant deaths per 100,000 live births in 2014 was 582.1. The leading causes of death during this time are prematurity with associated low birth weight or congenital malformations, maternal complications of pregnancy, sudden infant death syndrome (SIDS), and injuries (Hamilton et al., 2015).

The proportion of infants born with low birth weight is about 11.39% of all births. The number of low-birth-weight infants has declined after steadily increasing since 2006 and was 8.02% in 2013. Infants born to women under the age of 20 years and

between the ages of 40 and 54 years had the highest rate of neonatal and infant deaths.

## Infant Mortality Rate

The **infant mortality rate** of a country is a good index of its general health because it measures the quality of pregnancy care, overall nutrition, and sanitation, as well as infant health and available care. This rate is the traditional standard used to compare the health of a nation with previous years or with other countries.

Thanks to the introduction of prenatal care and other community health measures (such as efforts to encourage breastfeeding, require immunizations, initiate better unintentional injury prevention measures [e.g., requiring car seats], and reduce SIDS or the sudden death of an infant less than 1 year of age that cannot be explained after a thorough investigation of the cause of death), in combination with the many technologic advances available for care, the U.S. infant mortality rate has decreased by 86%, from 47.0 in 1940 to 5.96 per 1,000 live births in 2013 (Heron, Hoyert, Murphy, et al., 2009; Matthews, MacDorman, & Thoma, 2015) (Fig. 1.4).

**Figure 1.4** Infant mortality rates by race and Hispanic origin of mother: United States, 2005 and 2013. (Matthews, T. J., MacDorman, M. F., & Thoma, M. E. [2015]. Infant mortality statistics from the 2013 period linked birth/infant death data set. *National Vital Statistics Report*, 64[9], 5.)

Unfortunately, infant mortality is not equal among all Americans. For example, the rate is higher among Native Alaskan, Native American, and Black infants than it is for White, Asian or Pacific Islander, or non-Hispanic newborns. These differences are thought to be related to a combination of factors, including an unequal provision of and access to health care in different communities (Hamilton et al., 2015).

The infant mortality rate also varies greatly from state to state within the United

States (Table 1.3). For example, in the state of Mississippi, the area with the highest infant mortality (9.25), the rate is over twice that of Massachusetts, the state with the lowest rate (4.21) (Matthews et al., 2015).

**TABLE 1.3** INFANT MORTALITY RATES PERCENTAGE CHANGE, BY STATE: 2005 AND 2013

State	Rate
Alabama	8.60
Alaska	5.77
Arizona	5.25
Arkansas	7.85
California	4.76
Colorado	5.12
Connecticut	4.79
Delaware	6.37
District of Columbia	6.68
Florida	6.14
Georgia	6.98
Hawaii	6.37
Idaho	5.63
Illinois	5.97
Indiana	7.24
Iowa	4.25
Kansas	6.49
Kentucky	6.39
Louisiana	8.69

Matthews, T. J., MacDorman, M. F., & Thoma, M. E. (2015). Infant mortality statistics from the 2013 period linked birth/infant death data set. *National Vital Statistics Report*, 64(9), 5.

Worldwide, one would expect the United States, which has one of the highest gross national products in the world and is known for its technologic capabilities, to have the lowest infant mortality rate of all countries. The United States has a higher infant mortality rate, however, than 25 European countries as shown in [Table 1.4](#) ([MacDorman, Matthews, Mohangoo, et al., 2014](#)).

**TABLE 1.4 INFANT MORTALITY RATE (DEATHS PER 1,000 LIVE BIRTHS)**

## FOR SELECTED COUNTRIES, 2010

Country	Rate
1. Finland	2.3
2. Japan	2.3
3. Portugal	2.5
4. Sweden	2.5

24. New Zealand	5.5
25. Slovakia	5.7
26. United States	6.1

MacDorman, M. F., Matthews, T. J., Mohangoo, A. D., et al. (2014). International comparisons of infant mortality and related factors: United States and Europe, 2010. *National Vital Statistics Reports*, 63(5), 1–6.

Factors that may contribute to national variances in infant mortality are differences in reporting capability as well as the type of health insurance and care available. In Sweden, for example, a comprehensive healthcare program provides state-sponsored maternal and child health care to all residents. Women who attend prenatal clinics early

in pregnancy receive a monetary award, a practice that almost guarantees women will come for prenatal care. This type of healthcare policy contrasts sharply with the availability of health care in an occupation-linked insurance system such as the one in the United States.

Fortunately, the proportion of pregnant women who receive prenatal care, which has the potential to identify risks and allow preventive strategies against complications of pregnancy, is increasing (about 70% of women now begin care in the first 3 months of their pregnancy).

The main causes of infant mortality in the United States are problems that occur at birth or shortly thereafter, such as prematurity, low birth weight, congenital malformations, and SIDS.

Although other factors that contribute to SIDS are yet to be identified, the recommendations made by the American Academy of Pediatrics (AAP) to place infants on their back to sleep, use room sharing but not bed sharing, avoid exposure to overheating or cigarette smoke, and possible use of pacifiers, have led to an almost 50% decrease in its incidence (Moon, 2016). Nurses have been instrumental in reducing the number of these deaths, as they are the healthcare professionals who most often discuss newborn care and make recommendations for new parents.

### **Maternal Mortality Rate**

Early in the 20th century, the maternal mortality rate in the United States reached levels as high as 600 per 100,000 live births. As of 2012, the U.S. maternal mortality rate was 15.9 per 100,000 live births (Fig. 1.5). General improvements in the rates of maternal mortality can be attributed to improved preconception, prenatal, labor and birth, and postnatal care such as:

- Increased participation of women in prenatal care
- Greater detection of disorders such as ectopic pregnancy or placenta previa and prevention of related complications through the use of ultrasound
- Increased control of complications associated with hypertension of pregnancy
- Decreased use of anesthesia with childbirth
- Ability to better prevent or control hemorrhage and infection

**Figure 1.5** Trends in pregnancy-related mortality in the United States 1987–2012. (Centers for Disease Control and Prevention. [2016]. *Pregnancy Mortality Surveillance System*. Atlanta, GA: Author.)

This dramatic overall decrease is not a cause for celebration, however. Although the rates of maternal mortality had begun to increase again in 2011 to 17.8% and in some areas to as high as 24 per 100,000 live births, it showed a decline in 2012 to 15.8%. The increasing rate was associated with more cesarean births, more gestational hypertension related to preexisting hypertensive disorders, and a lack of health insurance for many Americans. Nurses who are alert to the signs and symptoms of hypertension are invaluable guardians of the health of pregnant women and newborns (Clark, 2012). Although some of the causes for maternal mortality remain unclear, known causes include:

- Noncardiovascular disease
- Cardiovascular disease
- Infection or sepsis
- Hemorrhage
- Cardiomyopathy
- Pulmonary embolism
- Hypertensive disorders of pregnancy
- Stroke
- Amniotic fluid embolism
- Anesthesia complications (CDC, 2016b)

**QSEN Checkpoint Question 1.2**

**INFORMATICS**

Mrs. Chung's doctor has told her that her baby's most dangerous time will be until the perinatal period ends. When does the perinatal period take place?

- a. From the day of birth until 1 month afterward
- b. During the time the infant will be on ventilator support
- c. From the 20th week of pregnancy to 4 to 6 weeks after birth
- d. Until the infant's body temperature stabilizes following birth

Look in [Appendix A](#) for the best answer and rationale.

## Child Mortality Rate

Like the infant mortality rate, the child mortality rate in the United States is also declining, although about 25 countries have better rates (UNICEF, 2016). In 1980, for example, the mortality rate was about 6.4% for children aged 1 to 4 years. In 2014, it was 25.5 per 100,000. Children in the prepubescent period (age 5 to 14 years) have the lowest mortality rate of any child age group, at 13 per 100,000. Between 15 and 24 years of age, the rate increases to 64.8 per 100,000 (NCHS, 2016).

The most frequent causes of childhood death are shown in [Box 1.5](#). Notice unintentional injuries are the leading cause of death in children, although many of these accidents are largely preventable through education about the value of car seats and seat belt use, the dangers of drinking/drug abuse and driving, and the importance of pedestrian safety.

### BOX 1.5

#### Major Causes of Death in Childhood

##### UNDER 1 YEAR

1. Congenital malformations and chromosomal abnormalities
2. Disorders related to short gestation age and low birth weight
3. Maternal complications of pregnancy
4. Sudden infant death syndrome
5. Unintentional injuries (accidents)

##### 1 TO 4 YEARS

1. Unintentional injuries (accidents)
2. Congenital malformations and chromosomal abnormalities
3. Homicide
4. Malignant neoplasms
5. Diseases of the heart

##### 5 TO 9 YEARS

1. Unintentional injuries (accidents)
2. Malignant neoplasms
3. Congenital anomalies
4. Homicide

4. Congenital anomalies
5. Homicide

#### 15 TO 24 YEARS

1. Unintentional injuries (accidents)
2. Suicide
3. Homicide
4. Malignant neoplasm
5. Diseases of the heart

Center for Disease Control and Prevention. (2016). *10 Leading causes of death by age group United States–2014*. Atlanta, GA: Author.

A particularly disturbing mortality statistic is the high incidence of homicide and suicide in the 10- to 19-year-old age group (more girls than boys attempt suicide, but boys are more successful). Although school-age children and adolescents may not voice feelings of depression or anger during a healthcare visit, such underlying feelings may actually be a primary concern (Bridge, McBee-Strayer, Cannon, et al., 2012; CDC, 2016c). Nurses who are alert to cues of depression or anger can be instrumental in detecting these emotions and lowering the risk of self-injury.

### Childhood Morbidity Rate

Health problems commonly occurring in large proportions of children today include respiratory disorders (including asthma and tuberculosis), gastrointestinal disturbances, and consequences of injuries. Obesity rates for children aged 2 to 19 years now average 17% (CDC, 2016a). Obesity in school-age children can lead to cardiovascular disorders, self-esteem issues, and type 2 diabetes, so counseling children about maintaining a healthy weight is an important nursing responsibility (Junnila, Aromaa, Heinonen, et al., 2012). Morbid obesity in pregnant women can lead to complications during pregnancy, at birth, and following birth (Machado, 2012).

As more immunizations for childhood diseases become available, fewer children in the United States are affected by common childhood communicable diseases. Continued education about the benefits of immunization against rubella (German measles) is still needed because if a woman contracts this form of measles during pregnancy, her infant can be born with severe congenital malformations.

In 2014, vaccination coverage achieved the 90% coverage target for Healthy People 2020 for children aged 19 to 35 months. These targets include vaccination against measles, mumps, rubella, hepatitis B, polio, and varicella. Although the decline in the overall incidence of preventable childhood diseases is encouraging and most regions of the country report strong adherence to recommended vaccination schedules, many

children are still not fully immunized. Reasons cited include religious, philosophical, and medical exemptions, as well as limited access to care. A 2015 outbreak of measles in the state of California revealed that 68 of the infected children had not received their MMR vaccination. There is a potential for childhood infectious diseases to increase again if immunization is not maintained as a high national priority (Hill, Elam-Evans, Yankey, et al., 2015).

The advent of the HIV has changed care in all areas of nursing but has particular implications for maternal and child health nursing. Sexually active teenagers are at risk for becoming infected with HIV through sexual contact. Infected women may transmit the virus to a fetus during pregnancy through placental exchange or at birth through body secretions (Owen, 2012).

Nurses play a vital role in helping to prevent the spread of HIV by educating adolescents and late adolescents about safer sexual practices (Nachman, Chernoff, Williams, et al., 2012) (see Chapter 5). Follow standard infectious precautions in all areas of nursing practice to safeguard yourself, other healthcare providers, and patients from the spread of this and other infections.

A number of infectious diseases that are increasing in incidence include syphilis; genital herpes; hepatitis A, B, and C; and tuberculosis. The rise in syphilis, hepatitis C, and genital herpes probably stems from an increase in nonmonogamous sexual relationships and lack of safer sex practices. The increase in hepatitis B is due largely to drug abuse and the use of infected injection equipment. One reason for the increase in hepatitis A is shared diaper-changing facilities in day care centers. Tuberculosis, once considered close to eradication, has experienced such a resurgence that one form occurs as an opportunistic disease in HIV-positive persons and is particularly resistant to usual therapy (Hesseling, Kim, Madhi, et al., 2012). Methicillin-resistant *Staphylococcus aureus* is an infection that often occurs in hospitals, causes skin infections or pneumonia, and is also growing in incidence (Moran, Krishnadasan, Gorwitz, et al., 2012).

The incidence of social concerns, such as intimate partner violence and child maltreatment, remains high. Twelve million adults report experiencing intimate partner violence and 10 million children under the age of 18 years experience maltreatment at the hands of a caregiver ranging from neglect to sexual abuse (Sumner, Mercy, Dahlberg, et al., 2015). Pregnant women are at increased risk for adverse maternal and fetal outcomes as a result of intimate partner violence (James, Brody, & Hamilton, 2013):

- 28.4% of pregnant women report experiencing emotional abuse.
- 13.8% of pregnant women report experiencing physical abuse.
- 8% of pregnant women report experiencing sexual abuse.

Also increasing in incidence is autism spectrum disorder, a range of complex neurodevelopment disorders characterized by social impairment, communication difficulty, and repetitive stereotyped patterns of behavior (Dworzynski, Ronald, Bolton, et al., 2012). The estimated prevalence of ASD based on 2014 data was 2.24%, a

significant increase from the estimated annualized prevalence of 1.25% based on 2011–2013 data (Zablotsky, Black, Maenner, et al., 2015).

## **TRENDS IN THE HEALTHCARE ENVIRONMENT**

The settings for health care as well as nursing roles are changing, with the goal of being able to better meet the needs of increasingly well-informed and vocal consumers.

### **Initiating Cost Containment**

Cost containment refers to reducing the cost of health care by closely monitoring the costs of personnel, use and brands of supplies, length of hospital stays, inpatient to outpatient ratios as is clinically appropriate, number of procedures carried out, and number of referrals requested while maintaining quality care (Dolopoulous, 2016). Examples of delegation responsibility or teamwork to make care more cost-effective or family centered are highlighted in “Interprofessional Care Maps” throughout this text. Examples of effective communication are shown in “Effective Communication” boxes throughout chapters.

### **Changes in Health Insurance Coverage**

Prior to the Affordable Care Act (ACA) in 2010, the United States was unique among developed countries in that its healthcare system was privately financed or controlled by work sites. This contrasts with other countries where national health insurance has been available to everyone and with no connection to a person’s employment. Because of this unique system, the United States spent about 17.5% of its gross national product on health care, whereas other countries, for example, Switzerland, spent less yet had healthier citizens (A. B. Martin, Hartman, Benson, et al., 2016). The increase in expenditure is related to the increase in numbers of individuals who have health insurance and obtain healthcare services as a result of the ACA. In the United States, populations most likely to not have health insurance both prior to and after the ACA include late adolescents, individuals who have moved recently or are unemployed, and those who have low incomes. Nurses have important roles at healthcare agencies to ensure people receive comprehensive care and encourage more children and women to receive preventive care.

### **Increasing Alternative Settings and Styles for Health Care**

The past 100 years have seen several major shifts in settings for maternity and child care. At the turn of the 20th century, for example, most births took place in the home, with only the very poor or ill giving birth in “lying-in” hospitals. By 1940, about 40% of live births occurred in hospitals. By 2014, the figure has risen to 98.5%. Out-of-hospital births account for a total of 1.5% of births, with 68% of those occurring in the home and 30.9% occurring in a freestanding birth center. This is the highest rate of home births since 1989 (Hamilton et al., 2015).

This statistic is predicted to increase in the future because increasing numbers of women are choosing home birth or birthing in freestanding alternative birth centers. Women who give birth in these alternative settings feel they have a greater control of their birth experience and their family can be more involved in the birth. Alternative settings also allow more practice opportunities for nurses in advanced practice roles, such as nurse-midwives (Osborne & Hanson, 2012).

An important outcome of this movement is that hospitals have responded to consumers' demands for more natural childbirth environments by refitting labor and delivery suites as homelike birthing rooms, often called labor-delivery-recovery (LDR) or labor-delivery-recovery-postpartum (LDRP) rooms (Fig. 1.6). Partners, family members, and other support people can stay with the woman in labor as if they were home and so can feel a part of the childbirth. Couplet care—care for both the mother and newborn by a primary nurse—is encouraged after the birth. Whether childbirth takes place at home, in a birthing center, or in a hospital, the goal is to keep it as natural as possible while ensuring the protection experienced healthcare providers offer.

**Figure 1.6** A couple, soon to be parents, share a close moment in a birthing room.

Healthcare settings for children are also changing. Patients' homes, community centers, or school-based or retail setting emergent care clinics are examples of places in which comprehensive health care may be administered. Retail clinics or emergent care clinics located in shopping malls are often staffed by nurse practitioners, so nurses play a vital role in seeing such healthcare settings do not limit continuity of care (Rohrer, Garrison, & Angstman, 2012).

In ambulatory settings of this nature, a nurse practitioner may provide immunizations, screenings, health and safety education, counseling, crisis intervention,

or parenting classes. This form of community-based care has the potential to provide cost-effective health promotion, disease prevention, and patient care to large numbers of children and families in an environment familiar to them.

More and more, children and women experiencing a pregnancy complication or an acute illness, who might otherwise have been admitted to a hospital, are now being cared for in ambulatory clinics or at home. Separating a child from his or her family during a long hospitalization has been shown to be potentially harmful to the child's development, so any effort to reduce the incidence of separation has a positive effect (see [Chapter 36](#)). Avoiding long hospital stays for women during pregnancy is also a preferable method of care because it helps to maintain family integrity.

Ambulatory or non-hospital-based care requires intensive health teaching by the nursing staff and follow-up by home care or community health nurses to ensure a smooth transition to and from this setting. Teaching parents of an ill child or a woman with a complication of pregnancy what danger signs to watch for that will warrant immediate attention includes not only imparting self-care information but also providing support and reassurance that the patient or parents are capable of accomplishing this level of care.

### **Increasing Use of Technology**

The use of technology is increasing in all healthcare settings. The field of assisted reproduction technology such as in vitro fertilization and the possibility of stem cell research are forging new pathways ([Palermo, Neri, Monahan, et al., 2012](#)). Charting by computer into electronic health records and monitoring fetal heart rates by Doppler ultrasonography are other examples ([Stewart, Letourneau, Masuda, et al., 2011](#)). Using an electronic charting system has the ability to allow different healthcare providers to share information (e.g., an X-ray taken at one site can be reviewed at another, a caregiver can be alerted to all the medicines a pregnant woman has been prescribed). As long as privacy is maintained, the system allows for a coordination of care never before possible.

To protect patient privacy, the DHHS has established a privacy rule (the Health Insurance Portability and Accountability Act, commonly referred to as HIPAA) that creates national standards to protect individuals' medical records and other personal health information and applies to healthcare providers who conduct healthcare transactions electronically. The rule requires appropriate safeguards be put into place to protect the privacy of personal health information and sets limits and conditions on the uses and disclosures that may be made of such information without patient authorization. The rule also gives patients rights over their health information, including the rights to examine and obtain a copy of their health record and to request corrections ([DHHS, Office of Civil Rights, 2007](#)).

In addition to learning these technologies and rules, maternal and child health nurses must be able to explain their use and their advantages to patients. Otherwise, patients may find new technologies more frightening than helpful to them.

### **QSEN Checkpoint Question 1.3**

#### **QUALITY IMPROVEMENT**

Nurses must always be aware of quality improvement because as society changes with new situations, nursing care must make responding adjustments. Which of the following is a trend that will influence the care that the Chung family's new baby is likely to receive?

- a. More and more children are treated in ambulatory, not hospital, settings so nurses will be less significant in the future.
- b. Immunizations are available for all childhood infectious diseases so the Chungs' baby will never need treatment for these.
- c. The use of multiple technologies can make parents feel overwhelmed unless they receive nursing support.
- d. Prematurely born infants, assuming their mother received prenatal care, rarely need long-term or follow-up care.

*Look in [Appendix A](#) for the best answer and rationale.*

### **Meeting Work Needs of Pregnant and Breastfeeding Women**

As many as 90% of women work at least part time outside their home, and many pregnant women want to continue to work during a pregnancy (in many families, women earn more than their spouse or partner, making them the primary wage earner in the family). Following the birth of their child, however, women may want or need a leave from work to care for their newborn.

The Family Medical Leave Act of 1993 is a federal law that requires employers with 50 or more employees to provide a minimum of 12 weeks of unpaid, job-protected leave to employees under four circumstances crucial to family life:

- Birth of the employee's child
- Adoption or foster placement of a child with the employee
- Need for the employee to care for a parent, spouse, or child with a serious health condition
- Inability of the employee to perform his or her functions because of a serious health condition

A serious health condition is defined as "an illness, injury, impairment, or physical or mental condition involving such circumstances as inpatient care or incapacity requiring 3 workdays' absence" ([U.S. Department of Labor, 1995](#)). Specifically mentioned in the law is any period of incapacity due to pregnancy or for prenatal care with or without treatment. Illness must be documented by a healthcare provider. Nurse practitioners and nurse-midwives are specifically listed as those who can document a health condition, so they have an equal role with physicians in alerting women to this benefit. Although not as generous a program as many other developed countries, paid leave helps appreciably with the care of an ill child or a woman who is ill during

pregnancy.

Whether women should be able to breastfeed at work is a controversial subject for many people (Hojnacki, Bolton, Fulmer, et al., 2012). In 2010, President Obama signed into law the Patient Protection and Affordable Care Act (PPACA), which mandates work settings with more than 50 employees to provide “reasonable break time for a woman to express breast milk for her nursing child for 1 year after the child’s birth each time such employee has need to express milk.” Employers are also required to provide “a place, other than a bathroom, that is shielded from view and free from intrusion for a setting to express breast milk.”

This law has had a major impact on allowing women to continue breastfeeding while working full-time. To support the aim of the law, many employers are now also allowing women to breastfeed at work if doing so does not disrupt their work schedule or work outcome.

### **Regionalizing Intensive Care**

To avoid duplication of care sites, communities are establishing centralized maternal or pediatric health services. Such planning creates one site that is properly staffed and equipped for potential problems rather than a number of lesser equipped sites. When a newborn, older child, or parent is hospitalized in a regional center, the family members who have been left behind need a great deal of support. They may feel they have “lost” their infant, child, or parent unless healthcare personnel can keep them abreast of the ill family member’s progress by means of phone calls or snapshots and by encouraging the family to visit as soon as possible.

When regionalization concepts of newborn care were first introduced, transporting the ill or premature newborn to the regional care facility was the method of choice (Fig. 1.7). Today, if it is known in advance that a child may be born with a life-threatening condition, it may be safer to transport the mother to the regional center at the time of birth because the uterus has advantages as a transport incubator that far exceed those of any commercial incubator yet designed.

**Figure 1.7** A nurse prepares an infant transport incubator to move a premature infant to a regional hospital. Helping with the safe movement of pregnant women and ill newborns to regional centers is an important nursing responsibility. (© Caroline Brown, RNC, MS, DEd.)

Important arguments against regionalization for pediatric care include children will feel homesick in strange settings, become overwhelmed by the number of sick children they see, and grow frightened because they are miles from home. An important argument against regionalization of maternal care is that being away from her community and support network places a great deal of stress on the woman and her family and limits her primary care provider's participation in her care. These are important considerations. Because nurses more than any other healthcare group set the tone for hospitals, they are responsible for ensuring patients and families feel as welcome in a regional center as they would have been in a small hospital. Staffing should be adequate to allow sufficient time for nurses to comfort frightened children and prepare them for new experiences or to support a frightened pregnant woman and her family. Documenting the importance of such actions allows them to be incorporated in critical pathways and preserves the importance of the nurse's role (LeFlore, Thomas,

Zielke, et al., 2011).

### *What If . . . 1.1*

**Melissa Chung has to remain in her local hospital after the birth of her new baby for an extended time while her baby is cared for at a regional center. How could the nurse at the regional center help her keep in touch with her new baby?**

## **Increasing Use of Alternative Treatment Modalities**

There is a growing tendency for families to use alternative forms of therapy, such as acupuncture or therapeutic touch, in addition to or instead of traditional healthcare measures. Nurses have an increasing obligation to be aware of complementary or alternative therapies as they have the potential to either enhance or detract from the effectiveness of traditional therapy (D. Adams, Cheng, Jou, et al., 2011). Unfortunately, many nurses (47% to 52%) do not feel comfortable discussing these therapies with their patients (Chang & Chang, 2015).

Healthcare providers who are unaware of the existence of some alternative forms of therapy may lose an important opportunity to capitalize on the positive features of that particular therapy. For instance, it would be important to know that an adolescent who is about to undergo a painful procedure is experienced at meditation because asking the adolescent if she wants to meditate before the procedure could help her relax. Not only could this increase her comfort, but it could also offer her a feeling of control over a difficult situation. People are using an increasing number of herbal remedies, such as drinking herbal teas during pregnancy to relieve morning sickness. Asking about these at a health assessment is important to prevent drug interactions (Dennehy, 2011). Boxes which highlight the importance of both nursing responsibility for pharmacology and respecting cultural diversity are shown in chapters throughout the text to accent these areas of care (Box 1.6).

### ***QSEN Checkpoint Question 1.4***

#### **EVIDENCE-BASED PRACTICE**

A growing body of knowledge suggests skin-to-skin contact between mother and baby immediately after birth provides numerous benefits, including regulating heartbeat and temperature for the baby and promoting feelings of calm and well-being in both mother and baby. To see if fathers were interested in participating in this form of care (often called kangaroo care), researchers interviewed seven new fathers who had spent time in skin-to-skin interaction with their newborn. Findings showed kangaroo care allowed fathers to feel more in control and also that they were doing something good for their infant (Blomqvist, Rubertsson, Kylberg, et al., 2012).

Based on the previous study, what action would the nurse take?

- a. Assess whether Mr. Chung is willing to try skin-to-skin care.
- b. Suggest neither parent use skin-to-skin care to prevent infection.
- c. Encourage Mr. Chung to praise his wife when she provides skin-to-skin care.
- d. Apologize to his wife because men do skin-to-skin care more effectively than women.

Look in [Appendix A](#) for the best answer and rationale.

## BOX 1.6

### Nursing Care Planning to Respect Cultural Diversity

The term *alternative healthcare practices* refers to therapy such as acupuncture, homeopathy, therapeutic touch, herbalism, and chiropractic care, or nontraditional sources of care such as tribal medicine or Hispanic herbalists such as *yerberos* or *curanderos*. Some people seek out these types of therapy or alternative providers before consulting a traditional healthcare provider; others consult with them after they perceive they have received inadequate care by a traditional provider. Still, others rely on these methods as their major form of health care and therapy.

Respect for these forms of care can be instrumental in showing families their sociocultural traditions are important in their plan of care. Assessing what alternative measures are being used is also important because the action of an herb can interfere with prescribed medications. For example, the consumption of traditional ethnic remedies such as *Jin Bu Huan*, a Chinese herbal medicine to relieve pain, can cause adverse effects such as life-threatening bradycardia and respiratory depression. Lead poisoning has resulted from ingestion of *greta*, a traditional Hispanic remedy used as a laxative.

## Increasing Reliance on Home Care

Shortened hospital stays have resulted in a transition from hospital to home of many women and children before they are optimally ready to care for themselves. In some instances, ill children and women with complications of pregnancy may choose to remain at home for care rather than be hospitalized. This has created a “second system” of care requiring many additional care providers (Turnbull & Osborn, 2012).

Nurses can be instrumental in assessing women and children at hospital discharge and help them plan the best type of continuing care, devise and modify procedures for home care, and sustain patients’ morale so a transition to home is seamless. Home care as a unique and expanding area in maternal and child health nursing is discussed in [Chapter 4](#).

### What If... 1.2

**Melissa Chung demands her 6-year-old, diagnosed with pneumonia, be**

**hospitalized even though it is the clinic's policy to have such children cared for at home by their parents. Would the nurse advocate for hospitalization?**

## **HEALTHCARE CONCERNS AND ATTITUDES**

As we progress through the 21st century, there are likely to be even more changes as the United States actively works toward effective health goals and improved health care for all citizens. These steps can create new concerns.

### **Increasing Concern for Quality of Life**

In the past, health care of women and children was focused on maintaining physical health. Today, many patients view quality of life to be as important as physical health, so the scope of health care has expanded to include the assessment of psychosocial facets of life in such areas as self-esteem and independence. Good interviewing skills are necessary to elicit this information at healthcare visits. Nurses can not only help obtain such information but also plan ways to improve quality of life in the areas the patient considers most important.

One way in which quality of life is being improved for children with chronic illness is the national mandate to allow them to attend regular schools, guaranteeing entrance despite severe illness or use of medical equipment such as a ventilator ([Public Law 99-452, U.S. 99th Congress, 1986](#)). Under this same law, adolescents who are pregnant cannot be excluded from school. School nurses or nurses asked to be consultants to schools play important roles in honoring these children's rights and making these changes possible.

### **Increasing Awareness of the Individuality and Diversity of Patients**

Maternal and child patients do not fit easily into any set mold. Varying family structures, cultural backgrounds, socioeconomic levels, and individual circumstances lead to unique and diverse patients. Women having children may range in age from 12 or 13 years to women having their first pregnancy after the age of 40 ([Johnson & Tough, 2012](#)).

Family structure varies; about 43.9% of babies are born to women outside of marriage. LGBT couples raise families, conceiving children through alternative insemination or adoption. As a result of advances in research and therapy, women who were once unable to have children, such as those with cystic fibrosis, are now able to manage a full-term pregnancy. Individuals with cognitive and physical challenges who once would have been isolated from childbearing are now able to establish families and rear children.

Many families who have emigrated from other countries enter the U.S. healthcare system for the first time during a pregnancy or with a sick child. This requires sensitivity to sociocultural aspects of care on the part of healthcare providers, as people

not used to non-government-sponsored health care can easily be lost in the U.S. system. They may have different cultural beliefs about health and illness than their healthcare provider. Some families may live in unsafe neighborhoods and so may not feel safe with home care. All of these concerns require increased nursing attention (see [Chapter 2](#)).

### *What If . . . 1.3*

**Melissa Chung is concerned because she's already 42 years old and wants to have a third child in a few years. Are many women delaying childbirth until their 40s? Does the nurse anticipate this trend will continue into the future?**

## **Empowerment of Healthcare Consumers**

In part because of the influence of market-driven care and a strengthened focus on health promotion and disease prevention, individuals and families have recently begun to take increased responsibility for their own health. For most families, this means learning preventive measures such as following a more nutritious diet and planning regular exercise; for some families, this means adopting an entirely new lifestyle. When a family member is ill, learning more about the illness, participating in the treatment plan, and preventing the illness from returning can offer a sense of empowerment. Parents want to stay with their ill child in the hospital and are eager for information about their child's health and ways they can contribute to the decision-making process. They may question a treatment or care plan if they believe it is not in their child's best interest. If healthcare providers do not provide answers to a patient's questions or are insensitive to needs, many healthcare consumers are willing to take their business to another healthcare setting or rely totally on therapies or information they find from websites ([Gallagher, Bell, Waddell, et al., 2012](#)).

Nurses can promote empowerment of parents and children by respecting their views and concerns, regarding parents as important participants in their own or in their child's health, keeping them informed, and helping and supporting them to make decisions about care. Although a nurse may have seen 25 patients already in a particular day, he or she can make each patient feel as important as the first by showing a warm manner and keen interest. Boxes on ways to help empower families at home or at healthcare facilities are shown in following chapters.

### ***QSEN Checkpoint Question 1.5***

#### **SAFETY**

Mrs. Chung waited until she was 42 years old to have her second baby. She asks the nurse if that is the reason her baby was born prematurely. Which statement would be the most reassuring for her?

- a. "It's hard to say because so few women over 40 years are having babies today."

- b. “No one can say for certain. You did all you could to ensure a healthy pregnancy.”
- c. “It’s good to see you taking responsibility for your child’s prematurity.”
- d. “You should ideally have had your children as a teenager as that’s the safest time.”

---

Look in *Appendix A* for the best answer and rationale.

---

## Legal Considerations of Maternal–Child Practice

Legal concerns arise in all areas of health care. Maternal and child health nursing carries some legal concerns above and beyond other areas of nursing because care is often given to patients who are not of legal age for giving consent. Additionally, reproductive healthcare rights and laws are complex and vary from state to state. These issues require specific attention when caring for expectant families. New technologies (e.g., assisted reproduction, surrogate motherhood, umbilical cord sampling, safety of new medicines with children, and end-of-life decisions) can lead to potential legal action, especially if patients are uninformed about the reason or medical necessity for these procedures.

Nurses are legally responsible for protecting the rights of their patients, including confidentiality, and are accountable for the quality of their individual nursing care and that of other healthcare team members. New regulations on patient confidentiality guarantee patients can see their medical record if they choose, but health information must be kept confidential from others (Duffy, 2011). Unfortunately, although nurses recognize the need for patient privacy, it is not practiced at the same rates. Patients are also not aware of the importance for their own medical record privacy (Kim, Han, & Kim, 2016).

Understanding the **scope of practice** (the range of services and care that may be provided by a nurse based on state requirements) and standards of care can help nurses practice within appropriate legal parameters.

Documentation is essential for justifying actions. This concern is long lasting because children who feel they were wronged by healthcare personnel can bring a lawsuit at the time they reach legal age. This means a nursing note written today may need to be defended as many as 21 years into the future. The specific legal ramifications of procedures or care are discussed in later chapters as procedures or treatment modalities are described. Personal liability insurance is strongly recommended for all nurses, so they do not incur great financial losses during a malpractice or professional negligence lawsuit.

Nurses need to be conscientious about obtaining informed consent for invasive procedures in children and determining if pregnant women are aware of any risk to the fetus associated with a procedure or test. A parent can be contacted by phone or e-mail if not present with the child at the time the consent is needed.

In divorced or blended families (those in which two adults with children from

previous relationships now live together), it is important to establish who has the right to give consent for health care. Adolescents who support themselves or who are pregnant are frequently termed “emancipated minors” or “mature minors” and have the right to sign for their own health care.

The term “wrongful birth” is the birth of a disabled child whose pregnancy the parents would have chosen to end if they had been informed about the disability during pregnancy. “Wrongful life” is a claim that negligent prenatal testing on the part of a healthcare provider resulted in the birth of a disabled child. “Wrongful conception” denotes that a contraceptive measure failed, allowing an unwanted child to be conceived and born. As many genetic disorders can be identified prenatally, the scope of both “wrongful birth” and “wrongful life” grows yearly (Whitney & Rosenbaum, 2011).

If a nurse knows the care provided by another practitioner was inappropriate or insufficient, he or she is legally responsible for reporting the incident. Failure to do so can lead to a charge of negligence or breach of duty.

### *QSEN Checkpoint Question 1.6*

#### **PATIENT-CENTERED CARE**

Melissa Chung is concerned as to how she will give consent for procedures for her newborn baby because the baby is hospitalized so far away. Which statement would be best to reassure her?

- a. “Informed consent is not needed for newborn care as newborns are underage.”
- b. “Newborn care requires parental consent only for procedures that will involve pain.”
- c. “Healthcare providers can omit informed consent if the parent is not present with the child.”
- d. “Consent is required: you can be contacted by telephone or e-mail for long distance consultation.”

*Look in Appendix A for the best answer and rationale.*

## **Ethical Considerations of Practice**

Some of the most difficult ethical quandaries in health care today are those that involve children and their families. Examples include:

- Conception issues, especially those related to in vitro fertilization, embryo transfer, ownership of frozen oocytes or sperm, and surrogate motherhood
- Pregnancy termination
- Fetal rights versus rights of the mother
- Stem cell research
- Resuscitation (and length of its continuation)
- Number of procedures or degree of pain a child should be asked to endure to achieve a degree of better health

- Balance between modern technology and quality of life
- Difficulty maintaining confidentiality of records when there are multiple caregivers

Legal and ethical aspects of issues are often intertwined, which makes the decision-making process in this area complex. Because maternal and child health nursing is so strongly family centered, it is common to encounter some situations in which the interests of one family member are in conflict with those of another or the goals of a healthcare provider are different from the family's. Maintaining privacy yet aiding problem solving in these instances can be difficult but is a central nursing role (Kim et al., 2016). Nurses can help patients by providing factual information and supportive listening, and helping the family and healthcare providers clarify their values.

The Pregnant Woman's Bill of Rights and the UN Declaration of Rights of the Child (available at <http://thePoint.lww.com/Flagg8e>) provide guidelines for determining the rights of women and children with regard to maternal and child health care.

#### *What If... 1.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals with respect to maternal and child health (see p. 5). What would be a possible research topic to explore, pertinent to these goals, that would be applicable to the Chung family and could also advance evidence-based practice?**

## KEY POINTS FOR REVIEW

- Standards of maternal and child health nursing practice have been formulated by the American Nurses Association to serve as guidelines for practice.
- QSEN competencies, combined with the nursing process, provide a sound method of care for expanding areas of practice.
- Nursing research and use of evidence-based practice are methods by which maternal and child health nursing expands and improves.
- The most meaningful and important measure of maternal and child health is the infant mortality rate, which is the number of deaths among infants from birth to 1 year of age per 1,000 live births. This rate is declining steadily, but in the United States, it is still higher than in 25 European countries.
- Trends in maternal and child health nursing include changes in the settings of care, increased concern about healthcare costs, improved preventive care, and family-centered care.
- Practice roles in maternal and child health nursing are expanding rapidly as nurses become more versed in evidence-based practice and technologic skills.
- Maternal and child health care have both legal and ethical considerations and responsibilities over and above those in other areas of practice because of the role of

the fetus and child.

### CRITICAL THINKING CARE STUDY

Tommy is a 10-year-old who has asthma. He is home schooled after having two serious asthma attacks at school because he is allergic to the cleaning product used in his primary school classroom. His mother is pregnant with a new brother or sister but hasn't come for prenatal care because she noticed the clinic uses the same cleaning solution and doesn't want her new baby to develop an allergy to it. At the same time, she wants a sonogram so she can see if she's having a girl or boy.

1. Nurses work in a wide range of settings in maternal and child health. What actions could you take to help Tommy get back to school and his mother begin to come for prenatal care?
2. Cost containment along with limitations of health insurance make it important for nurses to be aware of the cost of supplies and procedures. Is having a sonogram just to know the sex of a fetus a good use of healthcare funds?
3. Homelessness is becoming an increasing concern in modern society. Suppose Tommy's family became homeless? How do you anticipate this will affect their overall health?

## Diversity and Maternal Child Nursing

*Maria Rodriques is a 12-year-old child who is hospitalized for surgical repair of a broken tibia, which was fractured when she rode her bicycle into a busy street.*

*In planning care for Maria, you assume, because her culture is Hispanic, her family orientation will be male dominant, her time focus will be on the present, and her nutrition preferences will be Mexican American.*

*You are surprised on the second day of her hospital stay to hear Maria tell you she feels “second class.” Her father has been asked for more input about her care than she has. She hasn’t been given any milk to drink so is worried her bone will not heal. She’s concerned she won’t be able to play soccer by next month, but no one else seems worried about that.*

*The previous chapters described the standards and philosophy of maternal and child health nursing. This chapter adds information on caring for families from diverse cultures as well as sexual and gender identities. Such information can both enrich care and help improve the health of childbearing and childrearing families.*

**If you had really planned care in this way, of what would you have been guilty? What would have been a better approach for determining Maria’s cultural preferences?**

### KEY TERMS

**acculturation**

**assimilation**

**bisexual**

**cisgender**

**cultural awareness**

**cultural competence**

**cultural humility**

**cultural values**

**culture**

**culture-specific values**

**culture universal values**

**discrimination**  
**diversity**  
**ethnicity**  
**ethnocentrism**  
**gay**  
**gender dysphoria**  
**gender expression**  
**gender identity**  
**heterosexual**  
**homosexual**  
**lesbian**  
**minority**  
**mores**  
**norms**  
**prejudice**  
**race**  
**sex assigned at birth**  
**stereotyping**  
**taboos**  
**transcultural nursing**  
**transgender**  
**transition**

## **OBJECTIVES**

**After mastering the contents of this chapter, you should be able to:**

1. Identify common areas or concerns relating to cultural diversity, sexual orientation, and gender identity and apply these to nursing practice.
2. Identify 2020 National Health Goals related to diversity considerations and specific ways nurses can help the nation achieve these goals.
3. Assess a family for aspects of cultural diversity that might influence the way the family responds to childbearing and childrearing.
4. Assess a family for the ways in which sexual orientation or gender identity may affect how a family responds to childbearing and childrearing.
5. Formulate nursing diagnoses related to culturally influenced aspects of nursing care.
6. Develop outcomes to assist families who have specific cultural and sociodemographic needs so they can thrive in their community as well as manage seamless transitions across different healthcare settings.
7. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork

& Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.

8. Implement nursing care to assist a family adapt to today's changing sociocultural environment.
  9. Evaluate expected outcomes for achievement and effectiveness of care to be certain that expected outcomes have been achieved.
  10. Integrate aspects of cultural diversity with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to achieve quality maternal and child health nursing care.
- 

**Diversity** in a population means there is a mixture or variety of sociodemographic groups, experiences, and beliefs in the population. **Culture** is a view of the world and a set of traditions a specific social group uses and transmits to the next generation. The United States is an example of a country with varied ethnic and racial backgrounds, cultural groups, sexual orientations and gender identities, and socioeconomic conditions, so you are likely to see a wide range of behaviors and family structures exhibited in any healthcare setting.

Families have evolved dramatically from a nuclear family with male and female parents with children. Families can be multigenerational or single parent, and they can have same-sex parents or friends of parents as parental figures. Families can be recombined through divorce. Children can be adopted, fostered, or biologically related to the parental figures ([Fig. 2.1](#)).

**Figure 2.1** Various cultural preferences are evident in childrearing. Many extended family members, such as grandparents, are the primary caregivers today.

Cultural differences occur across not only different ethnic backgrounds but also different sociodemographic groups (Gagné, Frohlich, & Abel, 2015). Adolescents, urban youth, those with hearing impairment, and gay, or lesbian, or transgender couples have separate cultures from the mainstream, and respecting these cultures is just as important as respecting ethnic differences. A parent who has been deaf since birth, for example, expects her deaf culture to be respected by having healthcare professionals locate a sign language interpreter for her while she is in labor. A lesbian mother will want to be asked, “Is your partner or wife here?” rather than, “Is your husband here?” at a well-child visit.

Assessing for diverse backgrounds and beliefs of families and patients can reveal why people choose the type of preventive health measures they do or why they seek a particular type of care. Nurses also need to be mindful when doing research to include all cultural and sociodemographic groups in research samples, so more can be learned about cultural preferences in relation to nursing interventions and care. [Box 2.1](#) shows

2020 National Health Goals that reference cultural and sociodemographic influences on health care.

## BOX 2.1

### Nursing Care Planning Based on 2020 National Health Goals

A number of 2020 National Health Goals are directly concerned with health practices that can be influenced by cultural diversity and lesbian, gay, bisexual, and transgender (LGBT) health:

- Increase the proportion of pregnant women who receive early and adequate prenatal care from a baseline of 70.5% to a target of 77.6%.
- Increase the proportion of mothers who breastfeed their babies in the early postpartum period from a baseline of 43.5% to a target of 60.6%.
- Increase the proportion of healthy full-term infants who are put down to sleep on their backs from a baseline of 69.0% to a target of 75.9%.
- Increase the proportion of young children who receive all vaccines that have been recommended for universal administration from a baseline of 68% to a target of 80%.
- Reduce the rate of suicide from 11.3 per 100,000 to 10.2 per 100,000, a 10 % decrease.
- Reduce the adolescent suicide attempt rate from 1.9 per 100 to 1.7 per 100, a 10% decrease.
- Increase the proportion of homeless people who suffer with mental illness who are able to receive mental health services from 37% to 41% ([U.S. Department of Health and Human Services, 2010](#); see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these goals by helping design prenatal and childcare services that take into account cultural diversity and LGBT health and by promoting the nutritional and immunologic advantages of breastfeeding in a culturally competent manner.

#### *What If... 2.1*

**When the nurse talks to Mrs. Anna Rodrigues, the nurse determines she is pregnant but hasn't gone for prenatal care yet. She states before coming to the clinic she wants to visit a *yerbero* who will both predict her child's sex and guarantee a safe birth. Would recommending she have a sonogram (which also could predict the fetal sex) likely be as satisfying for her?**

#### *Nursing Process Overview*

FOR CARE THAT RESPECTS CULTURAL DIVERSITY

## ASSESSMENT

An assessment of cultural diversity factors is important so care can be planned based not on predetermined assumptions but on the actual preferences of a family.

Remember, poverty is a major problem for many minority ethnic groups. Many characteristic responses described as cultural limitations are actually the consequences of poverty (e.g., parents seeking medical care for their children late in the course of an illness or a woman not taking prenatal vitamins during pregnancy). Solving these problems may be a question of locating adequate financial resources and may not be related to cultural differences.

To assess patients for aspects of diversity, assess them as individuals, not as one of a group. Note particularly any cultural characteristic that differs from the usual expectations of your care setting, so potential conflicts can be acknowledged and culturally competent care can be planned. Specific areas to assess, along with suggested questions to help explore these areas, are shown in [Table 2.1](#). Sexual orientation and gender identity content are discussed later in this chapter.

**TABLE 2.1 ASSESSING FOR CULTURAL VALUES**

<b>Area of Assessment</b>	<b>Questions to Ask or Observations to Make</b>
Ethnicity	Where were the parents and grandparents born? What ethnicity does the family state is theirs?
Communication	What's the main language used in the home?
Touch	Does the family typically touch or hug each other? Do they mainly use intimate or conversational space?
Time	Is being on time important? Is planning for the future important?
Pain	Do family members express pain or remain stoic in the face of it? What do family members believe best relieves pain?
Family structure	Is the family nuclear? Extended? Single parent? Are the parents same sex? Are family roles clear?
Male and female roles	Is the family male or female dominant? What is the patient's gender identity and what pronouns does he or she use?
Religion	What is the family's religion? Do members actively practice? Will any of their beliefs directly affect your care or their treatment?
Health beliefs	What does the family believe makes one healthy? Causes illness? Makes illness better? Do members use alternative therapies or traditional medical practices?
Nutrition	Does the family mainly eat ethnic foods? Are the foods they enjoy easily available in their community?
Community	Is the predominant culture in the community the same as the family's? Can members name a neighbor they could call on in a crisis?

## NURSING DIAGNOSIS

Several nursing diagnoses speak to the consequences of ignoring cultural preferences in care, including:

- Powerlessness related to expectations of care not being respected
- Impaired verbal communication related to limited English proficiency
- Imbalanced nutrition, less than daily requirements, related to unmet cultural food preferences
- Anxiety related to a cultural preference for not wanting to bathe while ill
- Fear related to possible ethnic discrimination

## OUTCOME IDENTIFICATION AND PLANNING

Planning needs to be very specific for individual families because cultural diversity preferences tend to be very personal. You might want to begin care with an in-service education for team members who are unfamiliar with a particular cultural practice and its importance to a specific family involved. You also might want to ask if your agency could change a policy to accommodate a family's cultural preferences, such as the length of visiting hours, types of food served, or type of hospital clothing provided (e.g., women from the Middle East may only feel comfortable in long-sleeved gowns and with head scarves).

This type of planning can be beneficial not only because it makes health care more acceptable to families but also because it can motivate providers to examine policies, question the rationale behind them, and initiate more diverse care.

World Professional Association for Transgender Health	<a href="http://www.wpath.org/">http://www.wpath.org/</a>

## IMPLEMENTATION

When implementing care, be certain not to force your cultural values on others. Appreciate that such values are ingrained and usually very difficult to change (in

yourself as well as in others). An example of implementing care might be to make arrangements for a new Native American mother to take home the placenta after birth of her child if that is important to her, or planning home care for a Chinese American child whose family uses herbal medicine. It might be to establish a network of healthcare agency personnel or personnel from a nearby university or importing firm to serve as interpreters. It might be educating a child, family, or community about the reason for a hospital practice. Don't feel that you or your healthcare agency are always the ones who must adapt; however, a particular situation may call for both sides to adjust (cultural negotiation).

### OUTCOME EVALUATION

Assessing whether expected outcomes have been met should reveal that a family's diversity preferences have been considered and respected during care. If this was not achieved, procedures or policies may need to be modified until this can be realized.

Examples of expected outcomes that might be established include:

- Parents list three ways they are attempting to preserve cultural traditions in their children.
- Child states she no longer feels socially isolated because of her family's differences.
- Family members state they have learned to substitute easily purchased foods for traditional but unavailable foods to obtain adequate nutrition.
- Child with severe hearing impairment writes that he feels communication with ambulatory care staff has been adequate.
- Adolescent patient states he is ready to tell family about gender identity or sexual orientation.

## Methods to Respect Diversity in Maternal and Child Health Nursing

Almost all nations have a set of people who are its dominant or advantaged group. They hold the greater share of wealth in the nation and hold the majority of political offices. Almost all nations also have **minority** or disadvantaged groups, groups not necessarily fewer in number but who hold less power and wealth.

It's important to avoid stereotyping and assumptions rooted in accepting the dominant group as the norm; it can prevent you from planning care that is accurate, individualized, and valued. At the same time, it is important not to ignore cultural characteristics in an attempt to not stereotype, because most people take pride in their cultural heritage.

- **Stereotyping** is expecting a person to act in a characteristic way without regard to his or her individual traits.
- **Prejudice** is a negative attitude toward members of a group or is an intellectual act.

- **Discrimination** is the action of treating people differently based on their physical or cultural traits or is a doing act.

Cultural differences cause behavior to vary widely from one community to another. Given the multicultural mix in large communities, almost any behavior can be considered appropriate for some individuals at some time and place. The way people respond to pain is another example of a trait that is heavily influenced by culture. Some women and children scream with pain; others remain stoic and quiet. Both are “proper” responses, just culturally different.

Stereotyping is generally derogatory in nature such as “Men never diaper babies well” or “Japanese women are never assertive.” The phenomenon usually occurs because of lack of exposure to people in a particular group and, consequently, a lack of understanding of the wide range of differences among people. Traditionally, a person whose culture differs most drastically from the dominant culture suffers the greatest amount of rejection or prejudice because they are least able to assimilate (Bergsieker, Leslie, Constantine, et al., 2012). In the previous examples, the first speaker, having seen one man change diapers poorly, assumes he represents the entire male population. The second speaker demonstrates lack of knowledge of a changing culture.

You can acknowledge and celebrate a patient’s culture without stereotyping by such actions as respecting a patient’s cultural needs when completing a nutrition assessment or ensuring a patient has the opportunity to perform her cultural traditions during labor, such as reciting a Hispanic lullaby to “call her child outside.”

It is also important to acknowledge sexual- and gender-based diversity. Assessing for sexual orientation is not appropriate as a routine part of every health assessment. However, it should be included when relevant, such as when discussing adolescent development or before providing reproductive life planning information, during pregnancy, and after childbirth. Gender identity can greatly impact how a person feels during a standard health assessment. Therefore, it is a good idea to assess for these needs as a routine part of providing care.

When scanning a list of characteristics typically seen with people of a specific culture or sociodemographic group, the key is to remember those behaviors may not apply at all to your patient. *Ask* what things are important to the individual.

## Understanding Cultural Diversity in Maternal and Child Health Nursing

In the past, the United States was viewed as a giant cultural “melting pot,” where all new arrivals gave up their native country’s traditions and values and became Americans. Today, many people question the idea that America was ever a melting pot; instead, the preferred concept is of a “salad bowl,” in which cultural traditions and values are tossed together but with all their individual crispness and flavor retained.

Maintaining ethnic traditions this way strengthens and enriches family life. It

provides security to younger family members as they realize they are one of a continuing line of people who have a past and will have a future (Fig. 2.2 and Box 2.2). Women are often called the “keepers of the culture” or the people most influential in passing on cultural traditions from one generation to another and in honoring the many cultural traditions of childbirth and childrearing (Lauderdale, 2015).

**Figure 2.2** Cultural traditions passed from one generation to the next offer a sense of security to children.

## BOX 2.2

### Nursing Care Planning Based on Family Teaching

#### PRESERVING A FAMILY'S CULTURAL HERITAGE

**Q.** Mrs. Rodriques tells you, “I’m proud of my family’s ethnic traditions. What are good ways to help my family preserve these?”

**A.** Preserving individual heritage traditions while living in another culture calls for creative planning. Some common suggestions for doing this include:

- Plan an “ethnic night” once per week when only ethnic food is served. Encourage children to invite friends for the meal and discuss the traditions behind the various foods.
- Reserve one night per week when family members speak only the native language, if a foreign language is part of your tradition, so children come to value both languages.
- Choose books for children written by authors from your culture or that positively describe your culture. Read them together as a family and discuss the story.
- Monitor television for programs that focus positively on your culture. Watch them with your children and comment on how such traditions enrich family life.
- Speak to your children about your childhood and traditions and values at bedtime or “talk time,” so they can appreciate how long these values have been revered by your family.

- Celebrate holidays in your traditional manner. Including cultural influences in holiday celebrations adds a rich ingredient and feeling of security to these occasions.

## CULTURAL COMPETENCY FOR NURSES

**Transcultural nursing** is care guided by cultural aspects and respects individual differences (Darnell & Hickson, 2015). Nursing care is about improving the health of individuals and populations. Developing cultural competency is an important aspect of complete care for patients. **Box 2.3** addresses cultural competency terminology for nurses.

### BOX 2.3

#### Cultural Competency Terminology for Nurses

- **Culture-specific values** are norms and patterns of behavior unique to one particular culture.
- **Culture universal values** refers to values, norms, and patterns shared across almost all cultures.
- **Ethnicity** refers to the cultural group into which a person was born, although the term is sometimes used in a narrower context to mean only race.
- **Race**, a social construct, refers to a category of people who share a socially recognized physical characteristic, often skin color or facial features. It can also refer to a group of people who share the same ancestry.
- **Acculturation** refers to the loss of ethnic traditions because of disuse.
  - Cultural **assimilation** means people blend into the general population or adopt the values of the dominant culture.
  - **Ethnocentrism** is the belief one's own culture is superior to all others.
  - **Cultural awareness** is being aware cultural differences exist.
  - **Cultural competence** is respecting cultural differences or diversity.
  - **Cultural humility** is a lifelong process of self-reflection and self-critique that begins, not with an assessment of a patient's beliefs, but rather with an assessment of your own.

(2015). A meta-analysis of educational interventions designed to enhance cultural competence in professional nurses and nursing students. *Nurse Education Today*, 35(2), 333–340.

### QSEN Checkpoint Question 2.1

#### QUALITY IMPROVEMENT

While she is in the hospital, Maria Rodrigues, 12 years old, makes the following statements. The nurse determines which statement most clearly suggests she received culturally competent care?

- a. “My doctor is funny; he tells jokes and makes me laugh.”
- b. “The nurses keep asking me who makes decisions in my family.”
- c. “I’m sure my leg will heal quickly; the nurse said I’m an overall healthy person.”
- d. “The nurse asked me what I like to eat and then brought me the taco I wanted.”

*Look in [Appendix A](#) for the best answer and rationale.*

The way people react to health care is a cultural value (Chen, Wei, Yeh, et al., 2013). **Cultural values** are preferred ways of acting based on cultural traditions (Giger, 2016). They often arise from environmental conditions (in a country where water is scarce, daily bathing is not valued; in a country where meat is scarce, ethnic recipes use little meat). They form early in life and strongly influence the manner in which people plan for childbearing and childrearing as well as the way they respond to health and illness (Mireles-Rios & Romo, 2014). Differing cultural values can be a major source of conflict between parents and children because children learn opposing values from friends and school peers. Nurses can be instrumental in helping relieve this type of conflict by always including a cultural assessment at a healthcare visit (Yang, Kuo, Wang, et al., 2014).

The usual values of a group are termed **mores** or **norms**. Expecting women to come for prenatal care and parents to bring children for immunizations are examples of norms in the United States, but these are not beliefs worldwide or even among all Americans (Tangherlini, Roychowdhury, Glenn, et al., 2016).

Actions not acceptable to a culture are called **taboos**. Three universal taboos are murder, incest, and cannibalism. Issues such as abortion, robbery, and lying are controversial taboos because these are taboos only to some people, not everyone. For instance, some cultures do not put emphasis on individual property ownership and therefore would not understand the concept of robbery. Other cultures will put social harmony, appeasing the other person, at a higher priority than the absolute truth.

A great deal of ethnocentrism has existed because of intolerance toward any behavior that was not like white, middle-class Americans, and a belief that the American way (which actually was the Northern European way) was the “best” way. A more modern philosophy is that the world is large enough to accommodate a diversity of ideas and behaviors, and that there is probably no “best” way to accomplish anything.

Numerous levels of cultural intolerance or acceptance persist because people hold different beliefs along a cultural competence continuum (Fig. 2.3). When planning nursing care, try to not only respect these cultural differences but also help people share their cultural beliefs with their entire care team so that their preferences will be considered and respected.

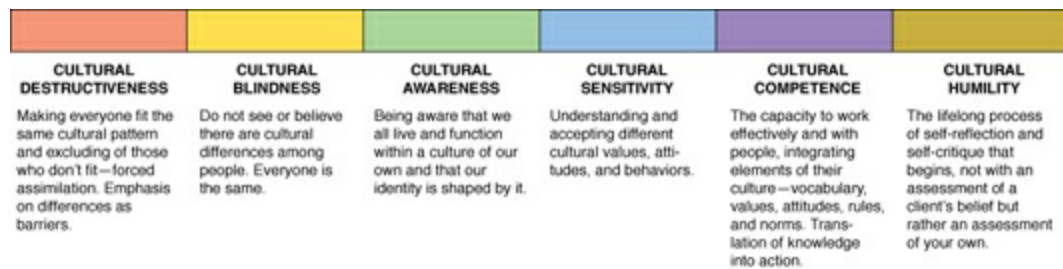

Figure 2.3 A cultural competence continuum.

## COMMUNICATION PATTERNS

Communication patterns (not only what people say but also how they say it) are influenced strongly by culture.

### Language

Communication problems can arise from both translation difficulties and from dialect differences within a country. Something as simple as a New Englander adding an “r” sound to the end of words (saying “idear” instead of “idea”) can make an explanation difficult to follow for a non–New Englander. The slow cadence of a person from the South may seem strange to someone who is used to the rapid speech pattern of New York City residents. African American Vernacular English may be used by Black patients who often have a dialect unique to their area. To care for such patients, learn their dialect’s cadence and common words but don’t attempt to use them yourself, unless that is your dialect. Trying to speak in a dialect not your own could be misinterpreted as mockery.

When caring for patients who speak a different dialect or language than your own, always ask them to repeat your instruction to be certain it was interpreted correctly. Repeat what the patient said so he or she can confirm you understood correctly. Don’t be reluctant to ask for an interpreter to help clarify forms, such as informed consent for surgery or wishes regarding right-to-life care, as necessary.

People who ordinarily associate only with members of their own culture, and therefore always speak their native language, can have great difficulty detailing a health history in English when they are or their child is ill because their ability to cope and to express themselves in any language when they are stressed may be at a low point (Meuter, Gallois, Segalowitz, et al., 2015). Some patients prefer to consult a Chinese herbalist or a Hispanic *yerbero* or *curandero* rather than or in connection with other healthcare providers because they can relate health problems with no language barrier.

Children who are embarrassed or bashful about speaking another language may simply not talk at a healthcare visit or have a great deal of difficulty recalling the English words for symptoms such as nausea or dizziness, words not commonly taught in English as a second language class. Unless you appear receptive as a listener, a patient might omit mentioning a symptom rather than try to pantomime it or describe it in a different way.

Listening to English instructions and translating them into another language is another area that can cause confusion. The statement “I need you to wait,” for example, is easy to translate as “I need your weight.”

Working with an interpreter also can cause miscommunication. General tips for working with interpreters are shown in [Box 2.4](#). It is unacceptable to have a family member serve as an interpreter. There may be cultural limitations that change how the information you are stating is being interpreted for a parent or partner. Additionally, the medical terminology used in the healthcare system is best translated by a trained professional interpreter.

#### BOX 2.4

### Nursing Care Planning to Empower a Family

#### WHEN A FAMILY HAS LIMITED ENGLISH PROFICIENCY

1. Many people can speak a second language better than they can read it. Assess each patient’s reading level as well as speaking level and rewrite information at an easier level if necessary.
2. Ask an interpreter to translate and copy material into the family’s primary language as necessary so it can be clearly understood.
3. Be certain rooms in your healthcare agency, such as bathrooms, are labeled with international symbols that do not require reading ability.
4. Learn a few phrases, such as “Good morning” or “This won’t hurt,” from other languages and use them in interactions with patients to show you’re receptive to participating in solving language difficulties.
5. Use hand gestures or draw a figure, if need be, to help ensure productive communication. Imparting health information is what is important for safe care, not worrying how you look.
6. When using an interpreter, do not ignore the person seeking health care in preference to the interpreter. Observe facial expressions for confirmation that a person understands instructions. Use short sentences; avoid slang words that don’t interpret accurately.

Be certain cultural variations are as respected in written communications as they are in oral communications. In many instances, written communication is even more problematic than oral communication because many people can speak a second language but cannot write or read it. Using short, easy sentences and being certain not to use words with double meanings when writing instructions for patients are important techniques ([Box 2.5](#)).

#### BOX 2.5

### Nursing Care Planning Tips for Effective Communication

Anna Rodriques, Maria’s mother, brings her 4-year-old son to your pediatric clinic because she thinks he has an ear problem. She speaks minimal English, and a neighbor, who speaks English and Spanish has accompanied her to provide assistance.

*Tip:* It is not appropriate to use a family member or friend to provide interpretation for a non-English-speaking patient/parent. A medical interpreter is used because a family member or friend may not understand medical words well enough to interpret them correctly. In this scenario, the nurse should call the hospital interpreter line to assist with communication. Effectively using an interpreter adds additional responsibility to history taking.

**Nurse:** [addressing the neighbor] I appreciate your taking the time to assist Mrs. Rodriques with her visit today. To ensure I get all the information correct and she understands our instructions, I am going to call a medical interpreter who will assist us by phone.

**Neighbor:** That would be helpful.

**Nurse:** [addressing the medical interpreter on the phone line] Would you ask Mrs. Rodriques what concerns she has about her son?

**Mrs. Rodriques:** [through the interpreter] I saw him sticking something in his ear and now it hurts.

**Nurse:** [through the interpreter] When did this happen?

**Mrs. Rodriques:** [through the interpreter] Yesterday; there was some blood on his pillow this morning. I hope he didn’t damage his ear.

**Nurse:** [through the interpreter] I will let the nurse practitioner know. Let me take his temperature and get his weight. Are there any other concerns that you have?

**Mrs. Rodriques:** [through the interpreter] No, he seems fine otherwise. I just want his ear checked.

**Neighbor:** I am glad you got the interpreter as she told me there was blood on the pillow this morning, but I didn’t know he stuck something in his ear. I thought he may have an ear infection.

## *QSEN Checkpoint Question 2.2*

### **TEAMWORK & COLLABORATION**

Maria Rodriques is a 12-year-old student. What advice should the nurse provide to an unlicensed care provider about communicating effectively with Maria?

- “Speak in a clear and natural tone when you’re talking with Maria.”
- “Maria is Hispanic, so avoid talking about current children’s movies.”
- “Maria’s first language is Spanish, so avoid talking about difficult topics.”
- “If possible, try to speak to Maria in an accent that’s similar to hers.”

## Nonverbal Communication

Some people gesture wildly to express any topic; others rarely raise their hands. Whether people look at one another when talking is also culturally determined. Chinese Americans, for example, may not make eye contact during a conversation. This social custom shows respect for the position of the healthcare professional and is a compliment, not an avoidance issue.

Touch, such as whether to greet another person with a kiss or a hug, is a form of communication and thus is culturally determined. Some people don't like to be hugged. Some prefer to bow in contrast to shaking hands. Some Asian Americans feel rumpling the hair or palpating fontanelles is an intrusive gesture because they believe the head is the seat of the body's spirit and should not be touched ([Andrews, 2015](#)).

Tattoos are becoming more commonplace in the United States and therefore more accepted. Tattoos are often meaningful for the patient. It is important that nursing care reflects respect for individual differences in body modification ([Liszewski, Kream, Helland, et al., 2015](#)).

## Use of Conversational Space

People of different cultures use the space around them differently:

- *Intimate space* is the space closely surrounding a person. Physical examinations are conducted in this very tight space because palpation and auscultation are parts of the examination.
- Conversational space is usually 18 in. to 4 ft away.
- Beyond 4 ft is *business space*, as this amount of distance allows room for a desk between parties.
- *Public space* is any distance beyond business space such as shouting across a parking lot. Use of the Internet or telephone can vary from private space ("I have a secret to tell you") to public space (conversation in a chat room).

Everyone has had the uncomfortable experience of speaking to someone who moves closer to him or her than expected or invades his or her intimate space while talking. Likewise, everyone has had someone shout something he or she wanted to be kept confidential (violation of public space). Being aware that the use of space can vary from person to person helps you to respect the use of space for patients when giving health instructions.

Respect for modesty is another way to respect a patient's space. Be aware that women from Middle Eastern cultures adhere to a level of modesty exceeding what you may appreciate, so it's a courtesy to add additional modesty sheets for physical examinations.

## TIME ORIENTATION

The cultural pattern in the United States is geared toward punctuality regarding appointments. “Time is money” is an often-quoted axiom. In some South Asian cultures, however, the use of time contrasts greatly—being late for appointments is a sign of respect (giving the person you are meeting time to organize and be prepared for your arrival). Other cultures believe time is to be enjoyed. For such a person, there is no such thing as wasted time.

Women who do not have a strict time orientation may have difficulty following a strict medical regimen. If they are told, for example, to give a child a medication at 8 AM, noon, and 6 PM daily and to return for another appointment at 2 PM in a week’s time, you may need to stress that the medication should be taken three times a day, not necessarily at the specific times, but returning for a checkup at a set time is important because their primary healthcare provider is only available at that time.

Another way time orientation differs is in whether a culture concentrates on the past, the present, or the future. The dominant U.S. culture is oriented to the present and future. People are expected to not only take care of themselves in the present but also make plans for the future. Other cultures are oriented toward the past: They carefully preserve traditions, allowing only the slightest changes or variations in practices. Still, others are oriented toward the present; saving money for college (a future-oriented action) might seem important to you but would not be a high priority in these cultures.

If a family’s orientation is for the present or the past, members may have difficulty accepting a long-term rehabilitation plan. They may need to be motivated by indications of progress (e.g., last week, all their child could do was sit up; today, he was able to walk two or three steps).

People with strong religious convictions may be future oriented (looking forward to a future existence better than their present one on Earth). The Amish and some Native Americans are examples of past-oriented cultures: They adhere to time-honored traditions that do not include technologic advances. People from lower socioeconomic groups tend to be present oriented because the struggle just to get through each day limits them to the present. People with different time orientations tend to make different healthcare decisions based on their outlook (Boyle, 2015).

## **FAMILY STRUCTURE**

The way families structure themselves and the roles family members play are yet a further area that is culturally determined. In most cultures, the nuclear family is most common. In other cultures, extended families and single-parent families may be more desired or common (see [Chapter 3](#) for family structures).

Some cultures stress that family boundaries should be carefully guarded or information about a family should not be given freely at healthcare visits (a way of keeping the family intact and unique and perhaps also as a reflection of mistrust of outside influences). Other families willingly share the same information. When caring for children, be certain to identify a child’s primary caregiver before asking what the child likes or giving healthcare instructions because which family member cares for the

child can vary by culture.

## CONCEPTS OF MALE AND FEMALE ROLES

In many cultures, the man is the dominant figure. In a strongly male-dominant culture, if approval for hospital admission or therapy is needed, the man would prefer to give this approval. A woman might be unable to offer an opinion of her own health or be too embarrassed to submit to a physical examination from a male healthcare provider unless a female nurse was also present. Some women insist on female-only providers for all aspects of care. A woman's pregnancy may have resulted not from a mutual decision but from sexual relations she felt she could not refuse (Martin-de-las-Heras, Velasco, de Dios Luna, et al., 2015). The incidence of intimate partner violence may be higher in male-dominant cultures and may rise even higher with pregnancy (Donovan, Spracklen, Schweizer, et al., 2016). See Chapter 55 for an in-depth discussion of intimate partner violence and how it increases with any type of stress situation.

As a contrast, in some cultures, women are the dominant person in their family. The oldest woman in the home may be the one to give consent for treatment or hospital admission.

Evaluating male and female roles this way can help you understand the impact of illness on a family. If a woman is the family's dominant person and can no longer make her usual decisions because she is ill during pregnancy, for example, the entire family can be thrown into confusion. If the woman is a nondominant member, you may have to act as an advocate for her with a more dominant partner (Darnell & Hickson, 2015).

### *What If . . . 2.2*

**Mr. Rodriques says he wants no role in labor when his wife, Anna, has her new baby. Would the nurse encourage him to time contractions (a typical role for fathers) or allow him to sit quietly in a corner of the room as he prefers?**

## RELIGION AND SPIRITUALITY

There are wide variations in religious and spiritual practices, and many of these are culturally determined. Because religion guides a person's overall life philosophy, it influences how people feel about health and illness, what foods they eat, and their preferences about birth and death rituals (Whitley, 2016). Knowing which religion a family practices can help you locate the correct religious support person if one is needed. It helps in planning care if you know a woman or adolescent wants a time or times set aside daily for private prayer or if they intend to fast, such as during Ramadan. It guides implementation because many practices, such as whether the family eats meat, what and when holidays are celebrated, whether ill newborns should be baptized, and what clothing is proper to wear in public, are all dictated by religious beliefs. It also can have important implications for decision making during a difficult pregnancy or for

childhood terminal care.

## HEALTH BELIEFS

Even health beliefs are not universal. For example, most people are familiar with the current controversy about whether male circumcision is necessary. More surprising to many people is the belief that, in some cultures, female genital cutting (amputation of the clitoris and perhaps a portion of the vulva) is practiced. Although, as outsiders, this practice seems like a poor health decision, there is often acceptance of it and an expectation that it will be done for all females in the culture (Farage, Miller, Tzeghai, et al., 2015).

The cause of illness is another area strongly culturally influenced. People in developed countries, for example, understand that illness is caused by documented factors such as bacteria, viruses, or trauma. In other cultures, illness may be viewed primarily as a punishment from God, the effect of an evil spirit, or as the work of a person who wishes harm to the sick person.

People who believe their own sins caused an illness may not be highly motivated to take medication or other measures to get well again since they do not believe penicillin can cure them. People with such beliefs may receive more comfort from a spiritualist or counselor than from their primary healthcare provider. Another consequence may be reluctant to ask for pain medication if they believe the pain is necessary to be rid of the illness. Understanding different beliefs of this kind allows you to better work out mutual goals even when opposing beliefs are present. Box 2.6 shows an interprofessional care map illustrating how compromise may be necessary in both nursing and team planning in order to respect cultural diversity.

### BOX 2.6

#### Nursing Care Planning

##### AN INTERPROFESSIONAL CARE MAP FOR A CHILD NEEDING CULTURAL DIVERSITY CONSIDERATIONS

Maria Rodriques is a 12-year-old child who is hospitalized following surgical repair of a broken tibia, which was fractured when she rode her bicycle into a busy street. She has a cast on her right leg, bruising on her body, and is being evaluated for a concussion. She will be on bed rest for 3 days and then allowed to learn crutch walking.

**Family-Centered Assessment:** Maria lives with her mother, Anna; her father, Carlos; and a 4-year-old brother, Jose. She attends a local grade school and enjoys playing video games and reading Harry Potter books. Her mother is 4 months pregnant.

**Patient-Centered Assessment:** Temperature, 99.4°F; pulse, 86 beats/min; respirations, 24 breaths/min. Observed lying on side, gritting teeth as if in pain.

Hands clenched and eyes tearing. When asked if she has pain, she stated, “No. I’m okay.” Father patted her arm and said to her, “We’re proud you’re so brave.” Cast on right leg dry and intact. Toes warm to touch. Intravenous fluid infusing without difficulty. Oral intake primarily tea and soup. Patient’s mother states, “She needs ‘hot’ foods to get better. Can’t she have some mangos?”

**Nursing Diagnosis:** Pain related to tissue trauma of surgery, with cultural belief to not voice pain

**Outcome Criteria:** Patient accepts pain medication when offered; nonverbal expressions of pain are minimal to absent. Patient begins to eat and manage self-care.

Team Member Responsible	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse/physical therapist	Assess what self-care activities child feels ready to begin.	Plan a program of self-care possible within constraints of limited ambulation.	Ability to complete self-care can add to self-esteem and supply physiologic benefits.	Patient feeds self, is out of bed in 3 days, and completes hygiene measures at 12-year-old level.
<i>Teamwork and Collaboration</i>				
Nurse/pain management team	Assess pain level on a 1–10 scale. Determine what child feels would relieve pain best.	Consult with pain management team to establish a pain management plan for patient.	Optimal health care is a collaborative practice.	Child states pain management plan is acceptable to her. Rates her pain level as below 2 on a 1–10 scale.
<i>Procedures/Medications for Quality Improvement</i>				
Nurse	Assess for both verbal and nonverbal indicators of pain.	Offer pain medication as prescribed before pain becomes acute.	Offering medication relieves the patient of the responsibility to ask for relief. It also allows her to have some choice and control in her	Child’s chart documents pain medication was offered every 4 hours during waking hours.

care.

*Nutrition*

Nurse/nutritionist	Assess whether the child has food preferences that are not being met by hospital service.	Encourage the family to bring in foods from home that meet child's cultural preferences.	Allowing the family to bring in foods demonstrates respect for their culture and increases the child's sense of security and being cared for.	Patient increases nutrient intake by including foods brought from home.
--------------------	---	--	---	---

*Patient-Centered Care*

Nurse	Assess the child's knowledge of broken bones and bruising and why trauma leads to head concussions.	Explain the physiology of injuries to child so she understands why she has pain.	Explanations help a child of this age minimize fear.	Patient states she understands her injuries and why hospitalization is necessary; states asking for something to relieve pain is expected and acceptable.
-------	---	--	--	---

*Spiritual/Psychosocial/Emotional Needs*

Nurse	Assess whether child has unmet needs other than pain relief.	Explain to child you want to help, but she needs to verbally express her needs to enable you to do so.	Children may imagine healthcare providers are all knowing.	Child agrees to participate in expressing the presence of other factors, such as loneliness or fear.
-------	--	--	--	--

*Informatics for Seamless Healthcare Planning*

Nurse	Assess with child what modifications she thinks she will need to make to adjust to cast after	Help parents plan adjustments their child may need in order to return to school (transportation, etc.).	Well-informed parents and children are able to make informed decisions.	Child attends school daily because of modifications she has made in usual lifestyle.
-------	---	---	---	--

returning home.

**QSEN Checkpoint Question 2.3**

**SAFETY**

Maria tells the nurse she rates the pain she has from bruising as 5 on a 10-point scale. The nurse offers to bring her a tablet of acetaminophen (Tylenol). Her grandmother produces a packet of herbs from her purse and says, “Good. I’ll give her a family remedy along with that.” The nurse recognizes which statement is the most culturally respectful response?

- a. “Wonderful. I’m sure herbs will complement what your doctor prescribed.”
- b. “I wouldn’t bother with that. Drugs are much more likely to be effective.”
- c. “Good. I understand you people often use home cures for many things.”
- d. “Let’s check first to be certain the herbs won’t cause an interaction.”

Look in [Appendix A](#) for the best answer and rationale.

Pregnancy is an area where illness concepts vary widely, as women’s concepts of whether pregnancy is a time of wellness or illness and whether breastfeeding is a desired choice differ a great deal across the world (Jones, Power, Queenan, et al., 2015). Most American women, for example, visit healthcare facilities early in pregnancy, follow prenatal directives, and at birth, allow a healthcare provider to supervise the birth. In other cultures, pregnancy and childbearing are considered such natural processes that a healthcare provider is unnecessary. The woman knows the special rules and taboos she must follow to ensure a safe birth and depends on close friends rather than healthcare providers to guide her safely through labor and birth. She may plan to breastfeed until the next child is born or for as long as 5 years. Unless differences such as these are respected, it is difficult to plan prenatal or newborn care that meets individual women’s needs.

The type of therapy people choose to restore health is also dependent on culture. When a parent notices a child has an upper respiratory infection, for example, he or she may immediately call a healthcare provider for a formal prescription. Another parent will depend on an herbal or “natural” self-help method. Be aware when taking health histories that many people today from all cultures rely on complementary or alternative therapies. Knowing about these is a way to be certain a medication that has been prescribed will not counteract or be synergistic with what herbs are being used (Pallivalappila, Stewart, Shetty, et al., 2014).

**What If . . . 2.3**

**The Rodrigues family tells the nurse they believe the accident that caused Maria’s broken leg was “God’s will,” not Maria’s fault. How would the nurse address patient education about street safety without interfering with the**

family's cultural beliefs?

*QSEN Checkpoint Question 2.4*

**INFORMATICS**

The nurse is including Maria's nursing care plan with her discharge instructions so a visiting community nurse can make her change from reduced activity to full sports participation as seamless as possible. Which aspect of her care planning could be regarded as an act of discrimination?

- a. Documenting the fact that Maria's mother is responsible for making most of the family's decisions.
- b. Cautioning against Maria's participation in the local soccer league because she is unlikely to fit in.
- c. Adding to her electronic health record a list of foods Maria does not eat because of her preference for Mexican American dishes.
- d. Documenting the fact that Maria's priest plays an important role in the family's spiritual life.

*Look in Appendix A for the best answer and rationale.*

**NUTRITION PRACTICES**

Foods and their methods of preparation are yet another area strongly related to culture. In many instances, children cannot find any food on a hospital menu that appeals to them because of cultural likes or dislikes. A typical Japanese diet, for example, includes many vegetables such as bean sprouts, broccoli, mushrooms, water chestnuts, and alfalfa. Both children and adults with this preference tire quickly of the macaroni and cheese that is common to a middle-class American menu. Fortunately, in most instances, a family member can provide food that is appealing culturally and is still within prescribed dietary limitations.

When counseling a woman about nutrition during pregnancy, remember that respect for culturally preferred foods is important (Brunst, Wright, DiGioia, et al., 2014). People from other cultures, for example, tend to eat much less meat than those from the United States. Adequate protein is ingested, however, by mixing sources of incomplete protein such as beans and rice. Some women may omit various foods during pregnancy because they believe a particular food will mark a baby (eating strawberries will cause birthmarks, eating raisins will cause brown spots) or they believe it is necessary to eat "hot" or "cold" foods to ensure optimal fetal growth. Pregnancy is usually considered a "hot" condition, so it may be difficult for a woman who is trying to eat only "cold" foods to agree to increase her intake of meat, usually considered a "hot" food. Asian women may believe in a similar pattern of required balances (yin and yang).

Before beginning nutrition counseling, try to learn what the dominant type of food that is stocked in stores in the community of your healthcare agency because women

who cannot buy the foods you recommend in their own neighborhood may not eat well because of the inconvenience (and increased cost) involved in shopping elsewhere (Fig. 2.4).

**Figure 2.4** Families select different foods and family customs because of cultural diversity preferences.

### **QSEN Checkpoint Question 2.5**

#### **PATIENT-CENTERED CARE**

Maria, 12 years old, tells the nurse she never eats peanut butter because her mother has warned her against it. Because peanut butter can be a good source of protein, how should the nurse best respond to her?

- a. “Almost everyone in America eats peanut butter when they’re young.”
- b. “Your mother’s wrong; at 12, you should learn the truth about foods.”
- c. “I understand. I don’t like the taste of peanut butter either.”
- d. “Let’s look at your menu and pick out something you would like to eat.”

*Look in Appendix A for the best answer and rationale.*

## **PAIN RESPONSES**

A person’s response to pain is both individually and culturally determined (Boissoneault, Bunch, & Robinson, 2015). Although people may all have the same *threshold sensation* (the amount of stimulus that results in pain), their *pain threshold* (the point at which the individual reports a stimulus is painful) and *pain tolerance* (the point at which an individual withdraws from a stimulus) vary greatly.

These differences are so great, one woman in labor might report her contractions as “agonizing” each time she feels one, whereas a woman in the room next to her, experiencing the same degree of sensation, might barely change her facial expression and report her pain as tolerable. It is important to assess each person individually because there are so many possible responses to pain. Strategies to help recognize cultural influences on pain management or degree of pain include:

- Appreciate that the meaning of pain varies among people and cultures.
- Appreciate that people do not all communicate or express their level of pain in the same way.
- Recognize that the communication of pain may not be acceptable within a culture.
- Develop an awareness of your personal values and beliefs as they may affect how you respond to people in pain.
- Use an assessment tool, such as a 1-to-10 scale, to assist in measuring pain so you are certain you are being as objective as possible (Giger, 2016).

Assessing differing responses to pain that occur because of cultural differences is an important nursing role. Further assessment of pain and its meaning to people is discussed in [Chapters 16](#) and [39](#).

### What If . . . 2.4

The nurse is particularly interested in exploring one of the 2020 National Health Goals with respect to cultural diversity (see [Box 2.1](#)). What would be a possible research topic to explore, pertinent to this goal that would be applicable to Maria's family and also would advance evidence-based practice?

## Unfolding Patient Stories: Fatime Sanogo • Part 1

**Fatime Sanogo**, a 23-year-old, is being seen by the nurse in the prenatal clinic. The nurse learns that this is her first pregnancy, she is Muslim, and she recently moved to the United States from Mali, West Africa, with her husband. What cultural factors are important for the nurse to assess that guide culturally competent care during her pregnancy and preparation for delivery? (Fatime Sanogo's story continues in [Chapter 23](#).)

Care for Fatime and other patients in a realistic virtual environment: *vSim for Nursing* ([thepoint.lww.com/vSimMaternityPed](http://thepoint.lww.com/vSimMaternityPed)). Practice documenting these patients' care in DocuCare ([thepoint.lww.com/DocuCareEHR](http://thepoint.lww.com/DocuCareEHR)).

## Understanding Sexual Orientation in Maternal and Child Health Nursing

There are some major barriers for healthcare providers when caring for individuals who are different from them. One of these barriers is the potential for personal bias. This barrier can only be addressed through self-reflection, trying to understand why these differences might bother you, and setting those feelings aside while taking care of patients. The other major barrier is language. Nurses need to know the right words to describe patients and to discuss their differences with them so that they don't feel

threatened. These two issues, self-reflection and expanding knowledge and vocabulary, are key parts of becoming a culturally competent nurse.

Understanding sexual orientation is part of providing culturally competent health care. There are three main types of sexual orientation: heterosexual, homosexual, and bisexual. See [Box 2.7](#) for important terminology for nurses.

## BOX 2.7

### Sexual Orientation Terminology for Nurses

**Heterosexual:** A heterosexual person is someone who finds sexual fulfillment with a member of the opposite gender. Straight is often used in place of heterosexual.

**Homosexual:** A homosexual person is someone who finds sexual fulfillment with a member of his or her own sex. This term is often disparaged in the LGB community. Same-sex partner and gay (for men or women) can be umbrella terms to use instead of homosexual.

**Gay:** Male-identified individuals who are sexually attracted to male partners. This term is also sometimes used to refer to both men and women who have same-sex partners.

**Lesbian:** Female-identified individuals who are sexually attracted to female partners.

**MSM\*:** Men who have sex with men.

**WSW\*:** Women who have sex with women.

**Bisexual:** People are bisexual if they achieve sexual satisfaction from both same-sex and heterosexual relationships.

\*Both men who have sex with men (MSM) and women who have sex with women (WSW) include individuals who may not self-identify as gay or homosexual but who may have sex with people of the same gender. They are also terms used in medical or public health publications instead of the terms *homosexual*, *gay*, or *lesbian*.

## DEVELOPMENT OF SEXUAL ORIENTATION

It is not yet known how sexual orientation develops, although there is evidence that sexual orientation is genetically determined or develops due to the effect of estrogen or testosterone in utero. Even before puberty, most individuals attracted to the same gender realize they are “different” in that they are not interested in opposite-sex classmates.

It is during adolescence, in seeking a sense of identity, that they realize the reason they feel “different” is because they are lesbian, gay, or bisexual (LGB). This can cause additional stress during adolescent development because revealing their sexual orientation to family and friends or “coming out” may be difficult. There are high rates of homelessness (22% of homeless youth are LGB) and suicide (suicide attempts were present in up to 70% of surveyed LGB individuals) among LGB adolescents (Flentje, Leon, Carrico, et al., 2016; Miranda-Mendizábal, Castellví, Parés-Badell, et al., 2017). Part of the reason these high rates occur may be because LGB teenagers don’t know where to turn for help in a heterosexual-dominant culture (Castellanos, 2016;

McDermott, 2015). Although attitudes are changing, some people refuse to associate with LGB people to such an extent that the fear-based term *homophobia* exists (Herek, 2015).

## HEALTHCARE BARRIERS BASED ON SEXUAL ORIENTATION

Although LGB people often have demonstrated behaviors consistent with an LGB identity from early childhood, late adolescence is the time most persons begin to identify as LGB and when they are ready to reveal this to healthcare providers. LGB patients may be hesitant to reveal their sexual orientation to healthcare providers because they are often the victims of bullying, family rejection, and sexual assault.

In one study, 30% of LGB patients had a negative experience with a healthcare provider because of their sexual orientation (Macapagal, Bhatia, & Greene, 2016). Because of expected or actual discrimination in the healthcare setting, LGB individuals may enter care late and may be at increased risk for adverse health conditions, including sexually transmitted infections (STIs), unwanted pregnancy, and mental health issues (Knight & Jarrett, 2017). They may also need help or suggestions for communicating with friends or family who are having difficulty accepting their sexual orientation. It is important for healthcare providers to be extremely sensitive to these needs.

Men who have sex with men (MSM) may need counseling to help them avoid acquiring HIV and other STIs because issues such as avoiding contact through anal intercourse or vaccination against hepatitis A and human papillomavirus (HPV) may not be routinely covered in sex education classes (King, Gilson, Beddows, et al., 2015).

There is also a belief that women who have sex with women (WSW) are at much lower risk for contracting STIs. Although there may be a lower incidence of HIV in this population, there is still risk for HPV and herpes simplex virus (HSV) as these are transmitted via skin-to-skin contact. Additionally, WSW may use sex toys that can transmit infection between partners. WSW are inadequately screened for STIs and pap smears because of this inaccurate belief (Agénor, Muzny, Schick, et al., 2017).

Growing a family as an LGB patient is common and is accomplished through multiple routes. Female partners may use sperm donation from a known or unknown partner to achieve pregnancy. They can use intrauterine insemination at home or with a fertility specialist. They may also achieve pregnancy through in vitro fertilization. Sometimes, only one partner carries the fetus; other times each partner has one or more pregnancies to complete their families (Yeshua, Lee, Witkin, et al., 2015). Male partners may use their own sperm and an egg donor. Sometimes, that egg donor carries the pregnancy as well; other times, a third person is involved called a gestational carrier, or surrogate, who shares none of her genetic material with the baby but carries and delivers the baby (Fig. 2.5) (Blake, Carone, Raffanello, et al., 2017). Additionally, adoption is a common course of action couples use to grow their families.

**Figure 2.5** Some couples seek a surrogate to assist with childbearing. (iStock.com/oscarhdez.)

Additional barriers exist for LGB families. Many couples will pursue a second parent adoption. This means an extra cost in the form of legal fees are required to ensure that each parent will have rights to custody and care of the child. Birth certificates vary by state with regard to who is listed as parent to the child. Same-sex couples may face stigma from healthcare professionals, their family, or the public as they try to grow their family, attend prenatal care, and deliver or attend the delivery of their babies. Although rare, there have been instances of doctors refusing to care for the children of same-sex parents (Phillip, 2015). A meta-analysis of Nordic women’s experience as same-sex couples seeking prenatal care found that they had anxiety about discussing their sexual orientation for fear of change in the quality of care they would receive from their provider (Wells & Lang, 2016).

**QSEN Checkpoint Question 2.6**

**EVIDENCE-BASED PRACTICE**

Parenting by same-sex couples and child outcomes has often been questioned. A study looked at 43 female same-sex couples, 52 male same-sex couples, and 95 different-sex couples who were all parents. The couples were matched for demographic qualities. No differences were found in the children’s well-being, the parent–child relationships, or use of professional or informal support by the parents (Bos, Kuyper, & Gartrell, 2017). Sofia Garcia, who is a 28-year-old lesbian and Maria’s aunt, presents for prenatal care with her mother. Her mother states that the baby will have problems because there is no man in the house.

Based on this study, which statement helps the nurse address Sofia’s mother’s concerns?

- a. “The child will have male influence through his or her grandfathers.”
- b. “Children raised in same-sex parent houses do just as well as children raised

- with different sex parents.”
- c. “Every family faces challenges in raising their children. This will just be another challenge that they will encounter.”
  - d. “Do you feel Sofia will not do a good job raising her child?”

*Look in [Appendix A](#) for the best answer and rationale.*

## COMMUNICATION RELATED TO SEXUAL ORIENTATION

Assuming anything about patients is a barrier to good communication. When asking about a patient’s needs, ask about the patient’s partner or partners. Once information is gathered about the gender of the patient’s partner or partners, make sure to tailor education to the patient’s specific needs. A nurse can build trust and ensure the individual will return for care as needed by using neutral terminology and asking what the patient needs. It is important to address mental and social healthcare needs in this population given the incidence of bullying, victimization, and mental health issues ([Knight & Jarrett, 2017](#)).

The Joint Commission has recommendations for changes that can be made across organizations to increase effective communication with LGB patients. Rewriting policy to include LGB populations or incorporating new language into existing policy is an important step. Adopting a nondiscrimination policy and having that policy posted clearly for employees and visitors can help ease the anxiety LGB families may feel. Visiting policies should reflect changing families, and a patient should be able to name his or her support people, independent of his or her support person’s legal status as a spouse or adoptive parent. There should also be clear pathways to report any discrimination against LGB families ([The Joint Commission, 2011](#)).

## Understanding Gender Identity in Maternal and Child Health Nursing

A person has both a sexual orientation and a gender identity. There are multiple terms related to gender identity that are important for nurses to know, see [Box 2.8](#).

### BOX 2.8

#### Gender Identity Terminology for Nurses

**Cisgender:** when an individual feels their gender and their sex match

**Transgender:** when an individual feels their gender and their sex do not match

**MTF:** male-to-female transition; usually prefers female pronouns

**FTM:** female-to-male transition; usually prefers male pronouns

**Hormone replacement therapy:** use of estrogens and antiandrogens for MTF individuals and testosterone for FTM individuals to gain characteristics of their

gender identity

Gender affirmation surgery: surgical procedures to change body characteristics to match an individual's gender identity

**Gender identity** is the inner sense a person has of being male or female, which may be the same as or different from sex assigned at birth. **Sex assigned at birth** is usually based on a person's chromosomal sex: male (XY) or female (XX). There have been cases of individuals born intersex, with ambiguous genitalia, where sex was assigned based on a provider's assessment of the genitalia alone. **Gender expression** refers to the behavior a person exhibits, which may or may not be the same as the person's gender identity or sex assigned at birth. Sexual orientation and gender identity are separate from each other. Just like a cisgender man could be attracted to women (heterosexual) or men (gay), a transgender man could also be attracted to women (heterosexual) or men (gay).

## DEVELOPMENT OF GENDER IDENTITY

A **transgender** person is an individual whose gender identity does not match the sex assigned at birth (Unger, 2015). There is not much information about the development of gender identity. **Gender dysphoria** is the realization one's physical sex and gender are mismatched, which can cause a lot of stress and anxiety.

Young children may start to notice they feel different from others, especially in the cultural context of gendered toys and clothes (Rodgers, 2017). An important way to increase open communication with children who are transitioning is to discuss what gender they identify with and which pronouns they would like the nurse to use when addressing them. They also may choose a new name that feels more in line with their gender. Addressing them by their preferred name and preferred pronouns will build trust.

Parents of transgender children often need support and guidance as they struggle with changes in their family. They may benefit from family therapy and support groups. Children who are transgender may do better with social pressure and bullying if they have a supportive family who affirms their gender. Families can find support through organizations like PFLAG ([www.pflag.org](http://www.pflag.org)) and the Human Rights Campaign ([www.hrc.org](http://www.hrc.org)) (Human Rights Campaign, 2016).

Transgender people will often go through **transition**, where they begin to live as the gender they feel they are. Many will seek a provider who can provide them with hormone replacement therapy to attain the characteristics of their gender.

Some may also choose to have gender affirmation surgery (previously termed *sex change operations*) so they appear cosmetically as the sex they feel they really are. They may have top and bottom surgery or just top surgery. Top surgery refers to having the breasts removed or breast implants placed. Bottom surgery refers to having a vagina or penis created. A person may choose to only have top surgery because bottom surgery

can complicate the ability to enjoy sex. Others may choose bottom surgery because having the genitalia of the wrong sex can interfere with their ability to enjoy sex or enjoy life (Gorton & Erickson-Schroth, 2017). Surgical options may also be limited by the cost of care as not all insurance companies will cover these procedures. A female-to-male (FTM) transgender individual who decides not to have bottom surgery will still need regular gynecologic care, such as pap smears, and he may be able to carry a pregnancy.

## HEALTHCARE BARRIERS BASED ON GENDER IDENTITY

Just as LGB individuals are the victims of bullying, sexual assault, and societal isolation, transgender individuals are often more marginalized. Transgender women face twice the victimization rates that cisgender women do (Sterzing, Ratliff, Gartner, et al., 2017). Transgender individuals have higher rates of negative experiences in healthcare settings than their LGB or heterosexual counterparts (Macapagal et al., 2016).

FTM transgender individuals may seek pregnancy and find it difficult to obtain an understanding provider, one who they can trust and who can care for their specific needs related to pregnancy, gender dysphoria, and lactation (MacDonald, Noel-Weiss, West, et al., 2016). It is necessary to stop testosterone hormone therapy to successfully carry a pregnancy. The cessation of testosterone and the changes that occur with pregnancy (growing belly, increased mammary tissue if still present) can cause huge shifts in an individual's mental wellbeing and can lead to increased gender dysphoria (Obedin-Maliver & Makadon, 2016). Although pregnancy progression and delivery are essentially the same for FTM transgender patients as for any other pregnant patient, there are more considerations related to mental health, chest (breast) feeding, and when to reinstate testosterone therapy after delivery. Listing of gender on birth certificates and legal protections for partners may be additional barriers to consider for transgender patients (Tornello & Bos, 2017).

## COMMUNICATION RELATED TO GENDER IDENTITY

With transgender patients, just as with any other patient, it is important not to make assumptions. A patient may be listed as a sex that they don't agree with on their medical chart. It is best to ask which pronouns (he, she, his, her) to use. A partner's gender should not be assumed either. It is crucial for a nurse to ask these questions to show sensitivity to this population's needs and to build trust with the patient.

## KEY POINTS FOR REVIEW

- Culture is an organized structure that guides behavior into acceptable ways for a group of people. Usual customs are termed *mores* or *norms*. Actions that are not acceptable to a culture are termed *taboos*.
- *Stereotyping* is expecting a person to act in a characteristic way without regard to his

or her individual traits. *Prejudice* is *thinking* people are different in some way. *Discrimination* involves *treating* people differently based on their physical or cultural traits.

- Each culture differs to some degree from every other. Most people are proud of these differences or cultural traits.
- Cultural practices usually arise from environmental conditions and are transmitted by both formal and informal ways from generation to generation.
- Although cultural concepts adapt from time to time, they tend to remain constant among tight-knit populations.
- There is wide variation within a culture concerning values and actions because individuals make up the group and individually express their cultural heritage.
- People bring cultural values and beliefs to nursing interactions, and these affect nursing and health care.
- Cultural aspects that are important to assess are communication patterns; use of conversational space; response to pain; time, work, and family orientation; and social organization including nutrition, family roles, and health beliefs.
- LGB individuals can experience discrimination because of their sexual orientation. They are less likely to receive adequate health care because of perceived or actual bias by the healthcare profession.
- Transgender individuals often face social stressors and healthcare barriers. Transgender individuals will benefit from gender-affirming behaviors from family and healthcare providers.
- Because of social stigma surrounding sexual orientation and gender identity, lesbian, gay, bisexual, and transgender (LGBT) individuals have much higher rates of homelessness, suicide attempts, and victimization.
- Parents of LGBT children will need extra support to adapt to their children's changing needs.
- Considering cultural diversity when caring for a family not only meets QSEN competencies but also best meets the family's total needs.

### CRITICAL THINKING CARE STUDY

Rhea Bhaskar is a 32-year-old woman, 20 weeks pregnant, whom you meet at a prenatal clinic. She works as a computer programmer for a wicker import company. She has a 12-year-old daughter from a previous marriage. She has been married to Siddharth, who sells real estate for 6 months. Rhea is concerned because they have just moved to a new community and her daughter (whose father was Black) “hates” their new house and her new school; she also feels as if she “doesn’t fit in.” She no longer likes to eat at home because Rhea has begun using Indian spices, such as curry, when she cooks to please her new husband. Rhea asks you if cooking more “soul food” the way she used to would make her daughter feel more like part of her family and new community. Rhea is also not pleased with her prenatal clinic; when

she said she wanted rhubarb tea as her only fluid to drink during labor, wanted silence during the birth, and to keep her placenta to be turned into capsules for her to take afterward, the charge nurse told her she could not give her the placenta as that would be against infection rules and rhubarb tea wasn't on their list of approved beverages.

1. Rhea is trying to integrate two cultures. Will changing only one thing, such as preparing food differently, make a difference in how her 12-year-old feels about fitting in with their new lifestyle? What are other suggestions you might make to help her daughter adapt to a new family lifestyle?
2. Was the nurse accurate when she said taking a placenta home would be against infection guidelines? Were Rhea's other requests so difficult to carry out that a birth center couldn't adapt to meet them?
3. Rhea's daughter feels she's different than other children at her school. What ideas could you suggest to Rhea to help her daughter better adjust to her new school and community?

### 3

## The Childbearing and Childrearing Family in the Community

*Marlo Hanovan is a 32-year-old woman with a 12-year-old child, Charles, from a first marriage. She is presently married to Stone, 35 years old, who has two children from a first marriage: James, 17 years old, and Brian, 2 years old. James and Brian are both well, but Charles has been sick since birth with cystic fibrosis, a genetic disease that compromises his gastrointestinal and respiratory function. Mrs. Hanovan, a full-time bookkeeper, also attends a community college to study photography. She is 4 months pregnant with a new baby. Because Stone is unemployed, she tells the nurse on many days her income is stretched so far, she's forced to choose between routine health care for her family and groceries.*

*The previous chapters discussed the philosophy of maternal and child health nursing and how cultural traditions affect families. This chapter adds information about healthy communities and the structure of families and how nurses can help ensure healthy family outcomes.*

**Are the Hanovans a well or a dysfunctional family? How typical is their structure? What are some concerns they may need help in resolving?**

### KEY TERMS

**blended family**

**community**

**ecomap**

**family**

**family-centered nursing**

**family of orientation**

**family of procreation**

**genogram**

### OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe what constitutes a healthy community.
  2. Identify common family structures and functions and the roles within families; use critical thinking to analyze ways families are changing in modern society.
  3. Identify 2020 National Health Goals related to the family and specific ways nurses can help the nation achieve these goals.
  4. Assess a family for structure and healthy function.
  5. Formulate nursing diagnoses related to family health.
  6. Develop expected outcomes to help a family achieve optimal health as well as manage seamless transitions across differing healthcare settings.
  7. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
  8. Implement nursing care to teach a family more effective wellness behaviors or to help a family modify its lifestyle to adjust to a pregnancy or accommodate an ill child.
  9. Evaluate outcome criteria for achievement and effectiveness of care to be certain expected outcomes have been achieved.
  10. Integrate knowledge of families with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.
- 

Humans have always tended to live in groups, such as families and communities, but the types of families and communities formed and the goals established have changed as technology has changed and life has become more complicated ([Lavoie-Tremblay, Bonin, Bonneville-Roussy, et al., 2012](#)). For example, when families lived on farms, they were extended or had a wealth of relatives and friends or a community close by to provide both physical and psychological support. As more people moved into cities, families became typically nuclear with only two parents and children present. Less support in terms of family members was available.

In 2015, 35% of children younger than 18 years of age live in a single-family household ([Kids Count Data Center, 2015](#)). This has important implications when planning nursing care because parents in these types of families may not have even one other adult to offer them support. This causes families to look more and more to healthcare providers, especially nurses, for guidance when a problem with pregnancy or childrearing occurs.

Families are important to children's growth because no other social group has the potential to provide the depth of support and long-lasting emotional ties as a person's own family. What people learn in their family determines how they relate to people, what moral values they follow, and the molding of their basic perspectives on both the

present and the future (Parker, Mandelco, Olsen Roper, et al., 2011).

Maintaining healthy family life is so important to the health and welfare of the nation: Several 2020 National Health Goals speak directly to maintaining healthy family and community life (Box 3.1). Because families have such influence on individuals and individuals on families, nursing care that considers not only a single patient but also his or her family is defined as **family-centered nursing**. It has a strong focus in modern nursing practice.

### BOX 3.1

#### Nursing Care Planning Based on 2020 National Health Goals

The 2020 National Health Goals are goals set in place by the [U.S. Department of Health and Human Services \(DHHS, 2010\)](#) to improve the health of the nation for the next millennium and are kept current by updates every 10 years. A number of 2020 National Health Goals focus on ways to improve the quality of families or community life. Representative of these include:

- Increase the percentage of adult smokers aged 18 years and older attempting to stop smoking from 48.3% to 80%.
- Increase the proportion of young children who are screened for an autism spectrum disorder (ASD) and other developmental delays by 24 months of age from a present level of 19.5% to 21.5%.
- Reduce postpartum relapse of smoking among women who quit smoking during pregnancy.
- Increase the proportion of children with special healthcare needs who receive their care in family-centered, comprehensive, and coordinated environments from a present level of 20.4% to 22.4%.
- Increase the rate of infants who are breastfed until 6 months from 43.5% to 60.6%.
- Reduce physical violence directed at women by male partners to no more than 27 per 1,000 couples from a current baseline of 30 per 1,000 couples ([DHHS, 2010](#); see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation meet these goals for healthier family living by assessing families and their environment to identify families at risk, assisting with counseling, and maintaining contact with families to ensure that as a family grows, its changing needs can be recognized and met. Intimate partner violence and child maltreatment are further discussed in [Chapter 55](#).

For a family to adjust to a dramatic change, such as a new family member or an ill child, a family must have structure and roles flexible enough to be able to adjust to the changes pregnancy or a long-term medicine or nutrition regimen for a child bring. The roles individuals assume in the family and their ability to adjust to new roles as their family's structure or situation changes play a major factor in whether a family can adjust to and work through difficult times to achieve a positive family outcome.

Because families do not live in isolation, the family's ability to thrive in and gain strength from a community is equally important. Always consider the strengths, vulnerabilities, and patterns of both a patient's family and the surrounding community to encourage healthy coping mechanisms and to improve overall family health (Fig. 3.1).

**Figure 3.1** Families are a universal among almost all civilizations.

### *Nursing Process Overview*

#### FOR PROMOTION OF FAMILY HEALTH

##### **ASSESSMENT**

Assessment of the structure and function, as well as the strengths and challenges, of families provides information on the ability of a family to remain well during either calm or stressful times. It can reveal the meaning of a current health situation for a family as well as the emotional support an individual family member can expect from other family members or the community. This can be vital to understanding what a pregnancy or childhood illness will mean to different family members, especially if not all members appear to be in agreement.

##### **NURSING DIAGNOSIS**

Nursing diagnoses formulated for families and the community generally relate to the family's ability to handle stress and to provide a positive environment for the growth and development of the members. Examples include:

- Impaired parenting related to unplanned pregnancy

- Parental role conflict related to prolonged separation from the child during a long hospital stay
- Interrupted family processes related to emergency hospital admission of the oldest child
- Ineffective family coping mechanisms related to an inability to adjust to the mother's illness during pregnancy
- Readiness for enhanced family coping mechanisms related to improved perceptions of the child's capabilities
- Health-seeking behaviors related to the birth of a first child
- Inadequate community support for family related to pregnancy

### **OUTCOME IDENTIFICATION AND PLANNING**

Planning for nursing care is most effective if it includes a design that is both family- and community-centered and also both appropriate and desired by the majority of family members; otherwise, opposing family members can resist following the plan.

It would not be helpful, for example, to suggest a mother quit work to better supervise a child's medication regimen if she is the sole wage earner for her family. Helping all family members assume a portion of the responsibility for safe medicine administration might be a more workable solution. To help parents keep up to date on health insurance issues, family leave, and family rights, an interesting website to recommend is the National Partnership for Women & Families ([www.nationalpartnership.org](http://www.nationalpartnership.org)). In addition, the National Safety Council ([www.nsc.org](http://www.nsc.org)) discusses what families can do to help make their home and community safer. The Nurse-Family Partnership ([www.nursefamilypartnership.org](http://www.nursefamilypartnership.org)) offers useful information on helping first-time parents effectively succeed.

### **IMPLEMENTATION**

Implementations to improve family health should flow smoothly if family members have agreed on a plan of action in support of one another. It may be necessary in some instances, however, to encourage family members to agree to a plan or to abide by a chosen plan. Otherwise, they can expend needless energy carrying out activities counterproductive or in direct opposition to their major goal.

### **OUTCOME EVALUATION**

An evaluation should reveal not only that a goal has been achieved but also that the family feels more cohesive after working together toward the goal. If the evaluation does not reveal these two factors, reassess the goal as necessary to determine whether further interventions are required or whether the goal was inadequate. Examples of expected outcomes that might be established include:

- Family members state they are adapting well to a newborn joining the family.
- The mother states she feels prepared to manage home care for her ill child.
- Parents state they have arranged the family finances to accommodate new healthcare expenses for the family.
- The grandmother states she will omit trans-fatty acids from cooking to better

safeguard the health of her family.

## Maternal–Child Nursing Care and the Community

Nursing a community refers to nurses' ability and responsibility to help make communities safer by participating in community activities and organizations with the goal of strengthening the community. Nursing activities originate out of the family assessment. Identified community nursing issues can include:

- Families feeling unsafe walking outside because of broken street lights
- Multiple automobile accidents occurring at a particular street corner due to a malfunctioning traffic light
- Need for better signage at a nearby park to indicate a duck pond is over 3 ft deep

It is easy to fall into the mindset that a single telephone call or an e-mail about a problem won't make a difference. But if all nurses took on their neighborhoods as clients, the number of telephone calls or e-mails could become far too many to be ignored by city officials or others in charge of community design and safety. Examples of nursing activities in the community include:

- Participating in fundraising charity events such as a walkathon
- Encouraging a block of homeowners to form a block parent association to ensure safe passage for students to and from school or activities
- Organizing adolescents from a local high school to begin a reading program at a grade school to increase interest in reading and improve the literacy rate in their neighborhood

Knowing the individual aspects of a community also helps you understand why some people reach the illness level they do before they seek health care (e.g., a woman living in a rural area has no transportation to prenatal care until her partner comes home from work, a 5-year-old child develops measles because there are no free immunization services in his community).

## THE FAMILY AS PART OF A COMMUNITY

Because the health of individuals and their families are influenced by the health of their community, it is important to become acquainted with the community in which you practice or where a specific patient lives. Families rarely live alone on islands; instead, they are a part of and interact with their surrounding community to buy food, use transportation, and receive wages for work (Jilcott, Vu, Morgan, et al., 2012).

A **community** can be defined in many ways, but it is generally understood to be a group of individuals interacting within a limited geographic area (Allender, 2013). When asked what community they are from, people may mention an entire city, a school district, a geographic district (e.g., “the East Side”), a street name (e.g., “Pine Street area”), or a natural marking (e.g., “the Lower Creek area”). A community assessment can reveal if there are aspects about the community that contributed to a

person’s illness (and therefore need to be corrected). It also helps determine whether a person will be able to return to their community without extra help and counseling after recovering from an illness (Fig. 3.2).

**Figure 3.2** Community assessment reveals unsafe conditions that can lead to illness, such as mold. (© [fotosearch.com](http://fotosearch.com).)

Community assessment consists of examining the various systems that are present in almost all communities to see whether they are functioning adequately. For example, it is easier for you to prepare a woman or child for return to a community after childbirth or a hospital stay if you know specific features such as information about the water supply whether the area consists of apartments or homes, or if there is public transportation.

Table 3.1 summarizes common areas to assess in relation to communities. Drawing an **ecomap** or a diagram of a family’s relationship to its community can help identify what community resources are being used by a family or the family’s “fit” into the community.

**TABLE 3.1 ASSESSING A COMMUNITY**

Area of Assessment	Questions to Ask
Age span	Is the community a “young,” a “settled-in,” or a “retired” one? Is the family within the usual age span of residents in the community and thereby assured of support people?

Education	If the family has school-age children, are there schools nearby? Is there a public library for self-education? Is there easy access to such places if the person becomes physically challenged? If a special program such as diet counseling is needed, does it exist?
Environment	Are environmental risks present, such as air pollution? Busy highways? Train yards? Pools of water where drowning could occur? Could hypothermia be a problem?
Financial status	Is there a high rate of unemployment in the community, which could increase the crime rate? What is the average occupation? Will this family have adequate finances to manage comfortably in this neighborhood? Are supplemental aid programs available?
Health care	Is there a healthcare agency the family can use for comprehensive care? Is it convenient in terms of finances, time, and transportation? Is it accessible for people with disability?
Housing	Are houses mainly privately owned or apartments or condos? Are homes close enough together to afford easy contact? Are they in good repair? Will new construction or deteriorated housing be a safety problem?
Politics	Is the community active politically? Can adults reach a local polling place to vote, or do they know how to apply for absentee ballots?
Recreation	Are recreational activities of interest available? Are they economically feasible? Are there some sites that are apt to create health problems such as ski resorts (broken bones), a lake (drowning), or horse racing tracks (smoke-filled air)?
Spirituality	Is there a facility where the family can worship as they choose? Is there a mixture of worship centers to show the community accepts cultural diversity?
Safety	Is there adequate protection so family members can feel safe to hike or jog? Do they feel safe to remain home alone? Do they know about available hotlines and local police and fire department numbers? Do houses have smoke and carbon monoxide alarms in the bedrooms and near the kitchen?
Culture	What is the dominant culture in the community? Does the family fit into this environment? Are foods that are culturally significant available?
Transportation	Is there public transportation? Will family members have access to it if they become physically challenged?

## Family Structures

How well a family works together when times are good and how well it can organize itself against potential threats depends on both its structure (who its members are) and its function (the activities or roles family members carry out). Recognizing different family structures can help you better focus on family-centered care as well as provide a family-friendly environment for health care.

### THE CONCEPT OF FAMILY

A **family** is defined by the [U.S. Census Bureau \(USCB, 2015\)](#) as “a householder and one or more other people living in the same household who are related by birth, marriage, or adoption.”

This definition is workable for gathering comparative statistics but has limitations when assessing a family for its health concerns or support people available because some families are made up of unrelated couples, and at points in life, not all family members live together.

[Allender \(2013\)](#) defines the family in a much broader context as “two or more people who live in the same household [usually], share a common emotional bond, and perform certain interrelated social tasks.” This is a better working definition for healthcare providers because it addresses the broad range of types of families apt to be encountered in healthcare settings.

### FAMILY TYPES

What type of family a person belongs to changes over time, as a family is affected by birth, death, possibly divorce, and the growth of family members. For the purposes of assessing families, two basic family types can be described:

- **Family of orientation** (the family one is born into; or oneself, parents, and siblings, if any)
- **Family of procreation** (a family one establishes; or oneself, spouse or significant other, and children, if any)

Almost all families, regardless of their type, share common activities, and those activities influence the health and activities of their members ([Chapman, Watkins, Zappia, et al., 2012](#)). Specific descriptions of types vary greatly depending on how many members are present, people’s roles, generational issues, means of family support, and sociocultural influences ([Box 3.2](#)).

#### BOX 3.2

#### Nursing Care Planning to Respect Cultural Diversity

Although families are more mobile today than in the past, cultural values and characteristics tend to remain constant. Knowing some of the basic norms and taboos

of different cultural groups allows you to understand the differences behind varying practices, a family's value system, and the degree of support family members are able to provide.

Some cultures, for example, respect elderly family members, depend on them for advice, and ensure they receive health care; other families are more oriented to the present and so treat older family members with less respect. Some cultures have extended families; others have a high number of single-parent families. Whether families are headed by men or women is also culturally determined.

Poverty tends to be a problem for nondominant (minority) ethnic groups. Some characteristic responses sometimes described as cultural limitations are actually the consequences of poverty—for example, a mother seeking medical care for her child late in the course of an illness or late in pregnancy is just as apt to be a financial influence as a cultural one. Solving this type of problem may be a question of locating financial resources rather than modifying care to respect cultural patterns.

### The Childfree or Childless Family

A childfree or childless family is composed of two people living together without children. This category refers to a growing trend of a voluntary choice to not have children and be childfree. With the many opportunities that are offered to women, there may be a delay in marriage and in planning for a family. The increased choice and availability of contraception also assists to prevent pregnancy, allowing a couple to plan for a family. The couple who experiences issues with infertility and is childless may also be included in this type of family (Davidson, London, & Ladewig, 2016).

- **Positive aspects:** companionship, possibly shared resources
- **Potential negative aspects:** feelings of guilt for the couple who decided to delay a family and who then may experience infertility issues

### The Cohabitation Family

Cohabitation families are composed of couples, perhaps with children, who live together but remain unmarried. Although such a relationship may be temporary, it may also be as long-lasting as a legal marriage. Couples may choose cohabitation for a variety of personal or financial reasons. Statistically, however, couples who cohabit before marriage have a higher divorce rate than those who do not (Cherlin, 2012).

- Cohabitation provides the same benefits as a legal marriage and included companionship and financial security while the couple is together. It does not always provide for long-term financial security or additional legal benefits if the couple ends the relationship. When children are involved in the relationship, determining custody and financial care may be an issue.

### The Nuclear Family

The traditional nuclear family is composed of two parents and children. In the past, it

was the most common family structure seen worldwide. Today, however, in the United States, the number of nuclear families has declined to about 46% of families due to the increase in divorce, acceptance of single parenthood, and remarriage (Pew Research Center, 2015). The biggest advantage of a nuclear family is its ability to provide support to family members because, with its small size, people know each other well and can feel genuine affection and support for and from each other. Unfortunately, in a time of crisis, this same characteristic may become a challenge to a family because there are few family members to share the burden or look at a problem objectively. Helping nuclear families locate and reach out to support people in their extended family or community during a crisis can be an important nursing responsibility.

The binuclear family is a family created by divorce when the child is raised in two families. Joint custody allows both the biologic mother and father to spend varying amounts of time with the child(ren) in a joint venture. The children may alternate between two homes with each parent co-parenting (Davidson et al., 2016).

- **Positive aspects:** support for family members; sense of security
- **Possible negative aspects:** may lack support people in a crisis situation

### The Extended (Multigenerational) Family

An extended family includes not only a nuclear family but also other family members such as grandmothers, grandfathers, aunts, uncles, cousins, and grandchildren. An advantage of such a family is it contains more people to serve as resources during crises and provides more role models for behavior or values (Keene, Prokos, & Held, 2012). In a typical extended family, however, there is usually only one main income provider, a situation which can strain the family's resources, and to include all family members in shared decisions may be difficult. When assessing such families, remember that, because many members are present, a parent's strongest support person may not be the spouse, and a child's primary caregiver may not be his or her biologic parent. The grandmother, an aunt, or another sibling, for example, may provide the largest amount of support or child care, so may be the person best prepared to talk about a child's health. Helping the family maintain meaningful communication between all members is an important nursing responsibility (Box 3.3).

- **Positive aspects:** many people for child care and member support
- **Possible negative aspects:** Resources may be stretched thin because of few wage earners.

#### BOX 3.3

#### Nursing Care Planning to Empower a Family

#### TIPS TO IMPROVE FAMILY COMMUNICATION

**Q.** Suppose Mrs. Hanovan says to you, “My family doesn’t communicate well. How can I improve this?”

A. Traditionally, families gathered for an evening meal, and this practice allowed a set period of time each day for interaction, problem solving, and conflict resolution while problems were still small. If sit-down-together meals aren't possible because of busy work or school schedules, suggestions for better communication could include:

- Plan a time (even 15 minutes) daily when all family members “touch base” with each other.
- Have all members check in daily by e-mail or a text message.
- Use a telephone answering machine to leave daily messages.
- Set up a bulletin or chalkboard that family members can check each day for messages.
- Plan an earlier wake-up time two or three mornings per week so all family members can sit and have breakfast together.
- Reserve one night a week as “family night,” when the family plans a special activity to do together such as play a board game or watch a favorite movie.
- Agree family night is off limits for cell phones, television, computers, iPods, etc., so family members are not distracted by outside sources.
- Limit the amount of time children work on their computers in their own bedrooms or spend in sedentary activities such as television watching; encourage more time in creative activities, discussing the day's events, or participating in an activity where all family members are brought together.
- Plan special activities for holidays or weekends that involve the whole family such as a hike or picnic or visiting a museum or park.
- Participate in each other's activities (e.g., if one member is playing in a ball game, all family members come and watch).

## **The Single-Parent Family**

Single-parent families play a large role in childrearing. Unfortunately, low income is often a problem encountered by single-parent families, especially if a woman is the head of the household. Women's incomes for the same jobs are lower than men's by about 28% ([U.S. Bureau of Labor Statistics, 2014](#)). Single parents have difficulty working full-time plus taking total care of young children. Trying to fulfill several central roles (mother and father) is not only time-consuming but also mentally and physically exhausting and, in many instances, not rewarded.

Such a parent may develop low self-esteem if things are not going well, especially if a spouse left them for another or if the other parent refuses to help with child support or shared custody. Single-parent fathers may have difficulty with home management or child care if they had little experience with those roles before the separation. It's important to identify low self-esteem because it has the potential to interfere with decision making and impede daily functioning.

Single-parent families have a special strength, however, as such a family can offer a child a rich parent–child relationship as well as increased opportunities for self-reliance and independence.

If there has been a divorce, one parent may have been given legal custody of the children or both parents may share custody (Carlsund, Eriksson, Löfstedt, et al., 2013). Either way, both parents often participate in decision making. At a time of illness, both may stay with an ill child in the hospital and be eager to receive reports of the child’s progress. Identifying who is the custodial parent is especially important when consent forms for care need to be signed, so be certain this is clearly marked in the child’s healthcare records.

Another type of single-parent family that has emerged is the single-mother family. The single-mother family is typically designed by choice as a woman desires a family. Her desire for a family then guides her choice to enter motherhood by a variety of methods including adoption or donor insemination (Davidson et al., 2016). Women who choose to be a single parent are often financially secure with their education completed, but they may have no desire to marry or have not met someone they wish to marry or with whom they want to have children.

- **Positive aspects:** ability to offer a unique and strong parent–child bond
- **Possible negative aspects:** Resources may/may not be limited.

### *QSEN Checkpoint Question 3.1*

#### **PATIENT-CENTERED CARE**

It’s important that care extends to include the concerns of a patient’s family. Mrs. Hanovan and Charles were a single-parent family before Mrs. Hanovan remarried. What is the most common challenge among single-parent families that nurses must address when planning care?

- a. Education is frequently compromised.
- b. Finances can be extremely limited.
- c. Communication is often limited.
- d. Emotional engagement is often lacking.

*Look in Appendix A for the best answer and rationale.*

### **The Blended Family**

In a **blended family** (a remarriage or reconstituted family), a divorced or widowed person with children marries someone who also has children. Although the arrangement is apt to be a positive one because it creates a nuclear family, childrearing problems can arise in this type of family from rivalry among the children for the attention of a parent. In addition, each spouse may encounter difficulties in helping rear the other’s children if their philosophy of childrearing differs from the biologic parent’s, particularly in terms of discipline. Children may not welcome a stepparent because they have not yet

resolved their feelings about the separation of their biologic parents (through either divorce or death); they may believe the stepparent threatens their relationship with their biologic parent. They may become extremely distressed at seeing their other biologic parent move into another home and become a stepparent to other children.

Children also may have heard so many stories about evil stepparents from children's books that they come into the new family already prejudiced against their new parent.

Although blended families usually lessen financial difficulties, finances can be severely limited, especially if one or both parents are obligated to pay child support for children from a previous relationship while supporting the children of the current marriage. If there is economic disparity between what a biologic parent earns and a stepparent earns, conflicts and distorted expectations can occur between parents. Nurses can be instrumental in offering emotional support to members of a blended family until these adjustments for mutual living can be resolved (Box 3.4).

#### BOX 3.4

### Nursing Care Planning Based on Family Teaching

#### TIPS FOR REDUCING FAMILY STRESS

**Q.** Suppose Mr. Hanovan tells you he is worried because the tension level in his family is growing so bad he fears his wife will leave him. He asks you, “How can my family better manage stress?”

**A.** Managing stress calls for interventions specific to each family, but some general suggestions include:

- Try to describe why you and family members feel so stressed. Almost nothing limits the extent of a threat more than being able to describe it accurately (put a fence around it). Detailing a problem is the beginning of problem solving.
- Recognize stress levels differ from person to person. Because one person is not upset by some condition does not mean another person will not be. On the other hand, if a situation does not annoy a person, that person should not feel he or she has to react to it just because someone else does.
- Anticipate life events and plan for them to the extent possible. Anticipatory guidance will not totally prepare you for a coming event but will at least assist you in preparing for the event.
- Try to reduce the number of stressors coming at you by turning off television, dimming the lights, and spending time with just your inner self.
- Ask yourself if you really need to accomplish all the tasks piling up around you. Do you need to volunteer to be a schoolroom helper this month? Does the garage really need to be cleaned this week?
- Face a situation as honestly as possible. As a rule, knowing the exact nature of a threat is less stressful than a “something-is-out-there” feeling. On the other hand, do not feel compelled to face intense threats, such as a serious complication of

pregnancy or a fatal illness in a child, until you have had time to mobilize your defenses, or you may feel overwhelmed.

- Learn to change those things you cannot accept and accepting those things you cannot change. Trial and error is often required to determine the difference.
- Consider that a total change may be unnecessary; a simple modification in one thing will create a cascade or be enough to make a difference.
- Reach out for support. When you are under stress, it's easy to become so involved in the problem you don't realize people around you want to help. Sometimes, people closest to you are under the same threat and so are no longer able to offer support. When this happens, you might have to call on second- or third-level support people (extended family or the community) for help.
- Remind family members that unintentional injuries increase when people are under stress. A person worrying about a complication of pregnancy, for example, is more apt to have an automobile accident than a person who is stress free. Children are more apt to poison themselves when the family is under stress as parents are more apt to leave pills on counters during this time.
- Remember that action feels good during stress. Doing something brings a sense of control over feelings of helplessness and disorganization. Action often is so satisfying that people write threatening letters or shout harmful remarks they later regret. Channel your energy into therapeutic action (such as going for a long walk and quietly reflecting) instead.
- Do not rush decisions or make final adaptive outcomes to a stressful situation. As a rule, major decisions should be delayed at least 6 weeks after a stressful event; 6 months is even better.
- Reach out to give support when others are being threatened. Survival is a collaborative effort of social groups; a favor offered now can be called in when you are in need at a later date.

- **Positive aspects:** increased security and resources; exposure to different customs or culture may help children become more adaptable to new situations
- **Possible negative aspects:** rivalry or competition among children; difficulty adjusting to a stepparent

## The LGBT Family

Lesbian, gay, bisexual, and transgender (LGBT) couples live together as partners for companionship, financial security, and sexual fulfillment, or form the same structure as a nuclear family. Now that laws in the United States have changed to legally sanction gay marriage, this type of family has increased in number. Such a relationship offers support in times of crisis comparable to that offered by a traditional nuclear or cohabitation family.

Some LGBT families include children from previous heterosexual marriages or through the use of alternative insemination, adoption, or surrogate motherhood. On June

26, 2015, the Supreme Court ruled that states cannot ban same sex marriage. However, lack of understanding by healthcare providers of the strength and richness of these unions can further impede healthcare response (Chapman et al., 2012).

### *What If... 3.1*

**The Hanovan family identifies their main family problems as a poor financial base, a serious family illness, and limited family communication. Would this change if they were an extended family? A single-parent family? A cohabitation family?**

## **The Foster Family**

Children whose parents can no longer care for them may be placed in a foster or substitute home by a child protection agency (Kubiak, Kasiborski, Karim, et al., 2012). Foster parents may have children of their own; they receive remuneration for care of the foster child. Theoretically, foster home placement is temporary until children can be returned to their own parents. Unfortunately, if return does not become possible, children may be raised to adulthood in a series of foster care families. Such children can experience a high level of insecurity, concerned that they will have to soon move again. In addition, they may have some emotional difficulties related to the reason they were removed from their original home (Taussig, Culhane, Garrido, et al., 2012).

Most foster parents are as concerned with health care as biologic parents and can be depended on to follow healthcare instructions conscientiously. When caring for children from foster homes, be certain to determine who has legal responsibility to sign for health care for the child (a foster parent may or may not have this responsibility).

- **Positive aspects:** prevents children from being raised in large orphanage settings
- **Possible negative aspects:** insecurity and inability to establish meaningful relationships because of frequent moves

## **The Adoptive Family**

Families of a great many types (nuclear, extended, cohabitation, blended, single parent, gay, and lesbian) adopt children today. No matter what the family structure is, adopting brings joy and fulfillment to a family. Adoption can also offer a number of challenges for both the adopting parents and the child as well as for any other children in the family (Jones, 2012).

Regardless of whether the adoption was arranged privately or through an adoption agency, new parents should visit a healthcare facility shortly after a child is placed in their home, so a baseline of health information on the child can be established, potential problems can be discussed, and solutions can be explored (Niemann & Weiss, 2012). If the birth mother of an adopted child ate inadequately or received little prenatal care, for example, the adopted child is at a higher risk for abnormal neurologic development than

usual. Children from war-torn or poverty-stricken countries have a greater risk of having illnesses such as hepatitis B, intestinal parasites, and growth restriction. They may lack routine immunizations or have delayed motor development from having been raised in a restricted institutional setting (Roeber, Tober, Bolt, et al., 2012).

When assessing a family with a newly adopted child, be certain to determine the stage of parenting the parents have reached. Nonadopting parents have 9 months to prepare physically and emotionally for a coming child. Adoptive parents may be asked to make the mental steps toward parenthood in as little as 24 hours.

If partners have low self-esteem because they were unable to conceive, they may need reassurance at healthcare visits that they are functioning as well as other parents. With the increase in foreign adoptions, parents often express a conflict between trying to preserve the child's native culture and socializing the child into the community and so appreciate having this problem addressed as well.

Also, be certain to assess siblings' responses to an adopted child. Biologic children (whether born before or after the adoption) may feel inferior to the adopted child because they were "just born," not "chosen." They may, however, feel superior because they are the "real" children of the parents. These feelings can interfere with their relationship with the adopted child as well as their parents if not discussed and resolved.

It is generally accepted that adopted children should be told as early as they can understand they are adopted (at about 2 or 3 years). Knowing this from early childhood is not nearly as stressful as accidentally stumbling onto the information when they are school-age or adolescents. At least by 4 years, children are old enough to fully understand the story of their adoption: They grew inside the body of another woman who, because she could not care for them after they were born, gave them to the adopting parent to raise and love. It's important for parents not to criticize a birth mother as part of the explanation as children need to know for their own self-esteem their birth parents were good people and they were capable of being loved by them. Things just didn't work out that way.

When children are first told they are adopted, they may exhibit "honeymoon behavior" or may try to behave perfectly for fear of being given away again. After this honeymoon period, children may deliberately test their parents to see whether, despite bad behavior such as disobeying a house rule or even shoplifting, the parents will still keep them. It helps parents to put this behavior in perspective if they are aware it may happen. Nonadopted children may also use the same testing strategies on some occasions.

Counseling an adopted child or forming a relationship with one as a healthcare provider carries additional responsibility: making certain the relationship is not ended abruptly or thoughtlessly. When ending a relationship, try to introduce the person who will continue health supervision to the child, so the child doesn't feel abandoned for a second time.

When hospitalized, all preschoolers worry about being abandoned and left in the hospital. Preschoolers who have just been told they were adopted or were chosen by

their adoptive parents “from all the babies in the hospital nursery” may be terribly afraid they are now being returned to the hospital to be given back. Parents of an adopted child may need additional help in preparing the child for the hospital experience and also should be encouraged to stay with the child in the hospital as much as possible to reduce this type of postadoption fear.

As adopted children enter puberty and begin to think about having children of their own, they may begin to worry if they will make good parents or fail at parenthood as did their birth mother. Some children of this age feel a lack of a sense of identity because they do not know who their birth parents are. It’s common for them to spend time tracing records to try to locate their birth parents. Counsel adopting parents that this is not a criticism of their care but a normal consequence of being adopted. Children seek their birth parents not because they do not love their adoptive parents but because they need information to know where they fit into the eternal scheme of life.

- **Positive aspects:** Children grow up well cared for and experiencing a sense of love; a woman who relinquishes her child for adoption can feel a sense of relief her baby will have a lifestyle better than what she could provide.
- **Possible negative aspects:** Divorce of the adopting parents can be devastating if the child views himself as the cause of the separation or as a child unable to find a secure family for a second time.

## Family Functions and Roles

A family is a small community group and, as such, works best if it can designate certain people to complete necessary tasks. Otherwise, it is easy for work in a family to be duplicated or never completed. The roles family members view as appropriate for themselves are usually the ones they saw their own parents fulfilling. As each new generation takes on the values of the previous generation, family traditions and culture pass to the next generation.

Because family roles tend to be more flexible and often not as well defined as in the past, an important part of a family assessment is to identify what roles family members have assumed. Most families, for example, can identify an individual who serves as the *wage earner* or who supplies the bulk of the income for the family. In the past, this was typically the father. Today, it may just as easily be both mother and father. In dual-earner families, the mother contributes as much as 40% of the total family income (Smith, 2015). Also usually identified can be the *financial manager* (the person who determines how money will be spent), the *problem solver*, the *decision maker*, the *nurturer*, the *health manager*, the *environmentalist*, the *culture bearer*, and the *gatekeeper* or the person who allows information into and out of the family (Table 3.2). Identifying what these roles consist of and who fulfills these roles in a family allows you to work with a specific person and for assessment or counseling to be most effective (Fig. 3.3). If a hospitalized child will need continued care after he or she returns home, for example, it would be important to identify and contact the nurturing

member of the family because this person is probably the one who will supervise or give the needed care at home so it can continue seamlessly. Be careful not to make assumptions about which family members play which roles based on gender or stereotyping because every family operates differently. Although nurturing has typically been thought of as a female characteristic, many men best fill this role today.

**TABLE 3.2 PLANNING NURSING CARE BASED ON ASSESSMENT**

Area of Assessment	Questions to Ask
Type of family	How many family members live in the home? What are their ages and relationships?
Financial support	Who is responsible for the family’s income? Are finances adequate? Is money divided evenly among family members?
Safety	Is the home safe from fire or unintentional injuries? (Are smoke alarms present and police and fire numbers posted?) If there are small children, are poisons put on high shelves or in locked cabinets? Are prescription medicines and alcohol in safe places?
Environment	Is there adequate space? Heat? Hot water? Adequate plumbing?
Health	What is a typical breakfast? Lunch? Dinner? Do members monitor the amount of saturated fat and trans-fatty acids in their diet? Do they receive adequate sleep? Do they have a primary care health provider? Are immunizations current? Is there a balance between work and recreation? Does the family feel it copes with problems adequately?
Emotional support within family	Do members eat together or spend an equal amount of time with each other daily? Do they band together to defend each other from outsiders?
Emotional support outside family	Is the family active in community organizations or activities? Do they visit (or are they visited by) friends and relatives? Can the family name at least one outside person they can always rely on for help in a time of crisis?
Cultural diversity	Are there specific customs or traditions that will affect health care? Can they obtain favorite foods locally? What holidays do they celebrate?
Spirituality	Does the family have a religious affiliation? Do members attend religious services? Are there foods or activities restricted in relation to this that might influence care planning?
Family roles	
Nurturer	Who is the primary caregiver to children or a physically or

	cognitively challenged member?
Provider	Who brings in the bulk of the family's income?
Decision maker	Who makes decisions, particularly in the area of lifestyle, and how leisure time is spent?
Financial manager	Who supervises the family finances (pays the bills, provides savings for the future)?
Problem solver	Who does the family depend on to provide a solution to problems?
Health manager	Who makes healthcare decisions, ensures family members keep health appointments, immunizations are kept current, and preventive care such as a mammogram for the mother is scheduled?
Culture bearer	Who maintains family and community customs so children can develop a sense of where they belong in history?
Environmentalist	Who is responsible for recycling and not wasting electricity or water?
Gatekeeper	Who determines what information will be released from the family, or what new information can be introduced?

**Figure 3.3** A healthy family supports each member and performs roles flexibly. Here, a father and daughter help fix dinner.

### **TEAMWORK & COLLABORATION**

The nurse notices Mrs. Hanovan serves many roles in her family. If, while the nurse is talking to Charles, her 12-year-old son, she interrupts and says to him, “Don’t tell our family secrets,” the nurse would want the team members to appreciate she is fulfilling what family role?

- a. Decision maker
- b. Gatekeeper
- c. Problem solver
- d. Safety officer

Look in [Appendix A](#) for the best answer and rationale.

### **FAMILY TASKS**

In addition to family roles, [Duvall and Miller \(1990\)](#) identified eight tasks essential for a family to perform to survive as a healthy unit. These tasks differ in degree from family to family and depend on the growth stage of the family, but they are usually present to some extent in all families. Wellness behaviors such as these may decrease during periods of heightened stress. Therefore, assessing families for these characteristics is helpful to better establish the extent of stress on a family as well as to empower the family to move toward healthier family behaviors.

- *Physical maintenance*: A healthy family provides food, shelter, clothing, and health care for its members. Being certain a family has enough resources to provide for a new or ill member is an important assessment. [Box 3.5](#) shows an example of using effective communication to assess for a family’s unique needs.
- *Socialization of family members*: This task includes being certain that children feel part of the family and learning appropriate ways to interact with people outside the family such as teachers, neighbors, or police. It means the family has an open communication system among family members and outward to the community.
- *Allocation of resources*: This involves determining which family needs will be met and their order of priority, including not only material goods but also affection and space. In healthy families, there is justification, consistency, and fairness in the distribution. In many families, resources are limited, so for example, no one has new shoes. A danger sign would be a family in which one child is barefoot, whereas the others wear \$100 sneakers.
- *Maintenance of order*: This task includes establishing family values, establishing rules about expected family responsibilities and roles, and enforcing common regulations for family members such as using “time out” for toddlers. In healthy families, members know the family rules and respect and follow them; in dysfunctional families, you may see a flagrant disregard of rules.

- *Division of labor*: Healthy families not only evenly divide the workload among members but are also flexible enough to interchange workloads as needed.
- *Reproduction, recruitment, and release of family members*: Often, not a great deal of thought is given to who lives in a family; membership often happens more by changing circumstances than by true choice. Having to accept a new infant into an already crowded household may make a pregnancy a less-than-welcome event; allowing a late adolescent to move to a college dorm may be viewed as abandonment by a close-knit family.
- *Placement of members into the larger society*: Healthy families realize they do not have to operate alone but can reach out to other families or their community for help as needed. They are able to select community resources, such as schools, affiliations, a place to worship, a birth setting, a hospital, hospice, or a political group, that correlate with the family's beliefs and values. A family that lives in a community with a culture or values different from its own may find this a difficult task.
- *Maintenance of motivation and morale*: Healthy families are able to maintain a sense of unity and pride in their family. When this is present, it helps members defend the family against threats as well as allows them to support each other during a crisis. It means parents are growing with and through the experience of their children the same as children grow through contact with their parents. Assessing whether a feeling of loyalty to other family members is present tells you a lot about the overall health of a family.

### BOX 3.5

#### Nursing Care Planning Tips for Effective Communication

The Hanovan family consists of Mr. and Mrs. Hanovan and three children: James, 17 years old; Charles, 12 years old; and Brian, 2 years old. You notice Brian has missed many health maintenance visits, and he is underimmunized.

*Tip:* Assess for the unique needs of a family prior to providing patient education. In our zeal to educate people about good health practices, it is easy to rush in and teach. Unless a family's needs are met, people may agree to comply with a better health regimen but then be unable to do so because their original need was not met.

**Nurse:** It's good to see you in clinic today, Mrs. Hanovan. I know money is a problem, but you've got to start coming more until Brian gets caught up with his immunizations.

**Mrs. Hanovan:** It's hard with a 2-year-old.

**Nurse:** Is there anything I could do to make coming to the clinic easier?

**Mrs. Hanovan:** I should never come. Brian's outgrown his car seat so it's illegal for me to drive him here.

**Nurse:** Let me give you the number of an agency you can call to borrow a seat, not

only so you can come to the clinic more often but so you can take him out safely at other times as well.

### *What If... 3.2*

**Charles complains to the nurse he has to do more than his share of the work in his family because he's expected to keep his own room clean and his 2-year-old brother doesn't have to do that. How would the nurse respond to him?**

## DEVELOPMENTAL STAGES

Families, like individuals, not only have specific tasks to carry out but also pass through predictable developmental stages (Duvall & Miller, 1990). To assess whether a family is using stage-appropriate health promotion activities, it is helpful to first determine what stage the family is experiencing. The age of the oldest child is used to mark the stage. Because families are delaying the age at which they marry and have a first child and parents are living longer, the lengths of stages 7 and 8 are growing longer, whereas stage 1 is growing shorter (Table 3.3).

**TABLE 3.3 DEVELOPMENTAL STAGES AND GOALS FOR FAMILIES**

Developmental Stages	Goal
Marriage (stage 1)	<ul style="list-style-type: none"><li>• Establish a mutually satisfying relationship.</li><li>• Learn to relate well to their families of orientation.</li><li>• Engage in reproductive life planning, if applicable.</li></ul>
The early childbearing family (stage 2)	<ul style="list-style-type: none"><li>• Integrate the new member into the family.</li><li>• Make whatever financial and social adjustments are necessary to meet the needs of the new member while continuing to meet the needs of the parents.</li></ul>
The family with a preschool child (stage 3)	<ul style="list-style-type: none"><li>• Prevent unintentional injuries (accidents) such as poisoning or falls.</li><li>• Begin socialization through play dates, child care, or nursery school settings.</li></ul>
The family with a school-age child (stage 4)	<ul style="list-style-type: none"><li>• Promote children's health through immunizations, dental care, and routine health assessments.</li><li>• Promote child safety related to home and automobiles.</li><li>• Encourage socialization experiences outside the home such as sports participation, music lessons, or hobby activities.</li><li>• Encourage a meaningful school experience to make</li></ul>

	learning a lifetime concern, not one of merely 12 years.
The family with an adolescent (oldest child is between 13 and 20 years of age) (stage 5)	<ul style="list-style-type: none"> <li>• Loosen ties enough to allow an adolescent more freedom while still remaining safe.</li> <li>• Begin to prepare adolescents for life on their own.</li> </ul>
The launching stage family: the family with a late adolescent (stage 6)	<ul style="list-style-type: none"> <li>• Change their role from mother or father to once-removed support persons or guideposts.</li> <li>• Encourage independent thinking and adult-level decision skills in their child.</li> </ul>
The family of middle-aged parents (stage 7)	<ul style="list-style-type: none"> <li>• Adjust to “empty nest” syndrome by reawakening their relationship with their supportive partner.</li> <li>• Prepare for retirement so when they reach that stage they will not be unprepared socially or financially.</li> </ul>
The family in retirement or older age (stage 8)	<ul style="list-style-type: none"> <li>• Maintain health by preventive care in light of aging.</li> <li>• Participate in social, political, and neighborhood activities to keep active and enjoy this stage of life.</li> </ul>

### ***QSEN Checkpoint Question 3.3***

#### **QUALITY IMPROVEMENT**

The Hanovan family consists of two parents plus James, 17 years old; Charles, 12 years old; and Brian, 2 years old. Mrs. Hanovan is 4 months pregnant. When examining how to improve the quality of the nurse’s health teaching with the Hanovan family, which of Duvall’s family life stages would the nurse consider the family currently experiencing?

- Pregnancy stage
- Preschool stage
- Launching stage
- Adolescent stage

*Look in [Appendix A](#) for the best answer and rationale.*

## **Assessment of Family Structure and Function**

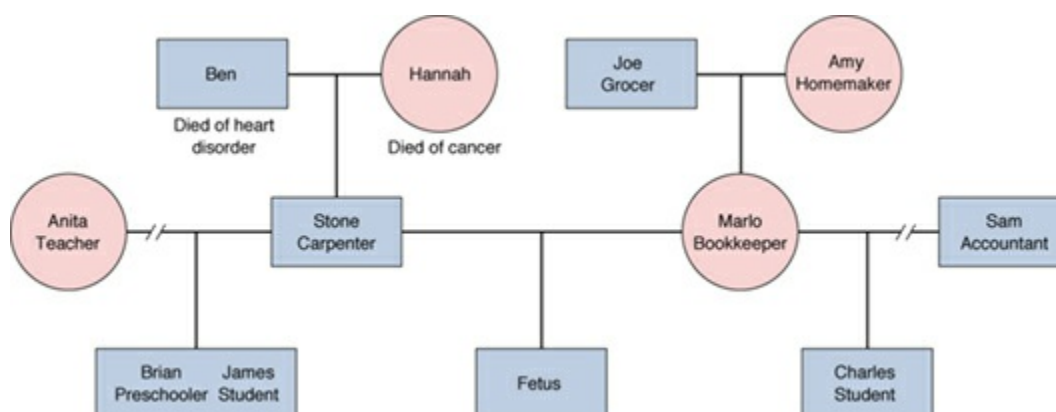

Family characteristics can be assessed on a variety of levels and in varying degrees of detail. The type of family data collected and the method of collection should match the way in which the assessment data will be used.

General characteristics of family type and functioning can be assessed using observation and general history questions (see [Table 3.2](#)). If more detailed information about family environment and roles is required, using an assessment tool specifically developed for that purpose can be most effective.

## THE WELL FAMILY

Assessment of psychosocial family wellness requires a measurement of how the family relates and interacts as a unit, including communication patterns, bonding, roles and role relationships, division of tasks and activities, governance, decision making, problem solving, and leadership within the family unit. Assessment also looks at how the family relates to the outside community.

A **genogram** is a diagram that details family structure and provides information about the family's health history and the roles of various family members across several generations. It can provide a basis for discussion and analysis of family interaction at healthcare visits (Fig. 3.4).

**Figure 3.4** A genogram of the Hanovan family showing three generations. Males are shown by squares, females by circles.

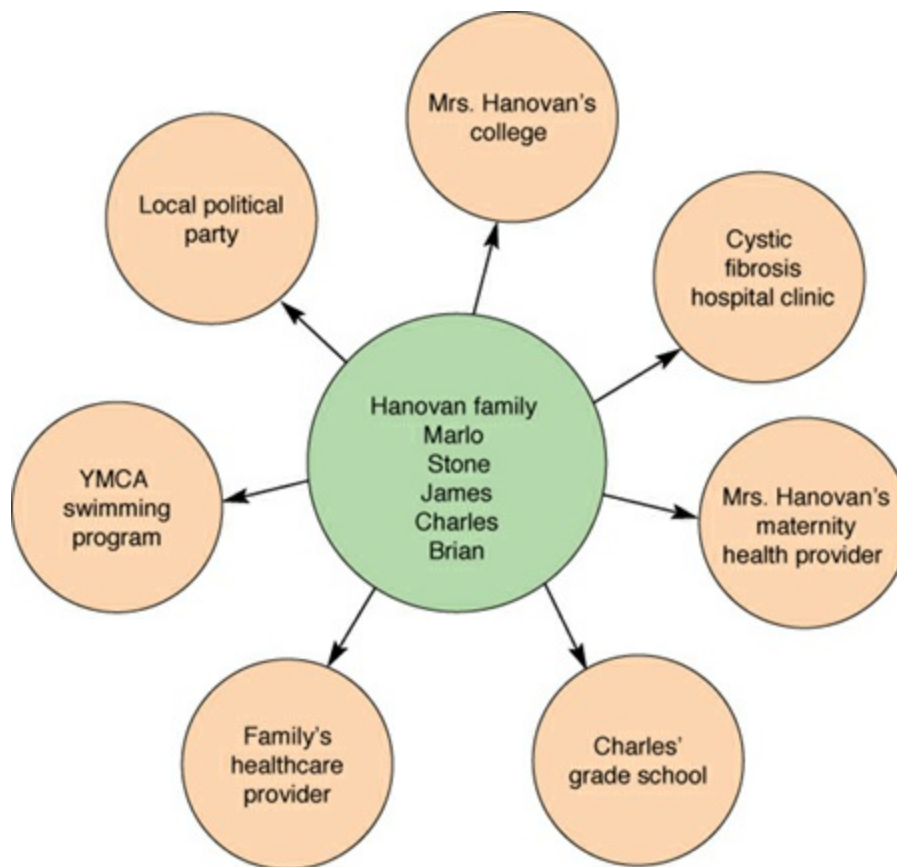

### Concept Mastery Alert

A genogram provides details about family structure and health rather than specifics about an individual patient.

Another aspect of family assessment is to document the “fit” of a family into their community. This is done by means of an ecomap, a diagram of family and community relationships (Fig. 3.5). To construct such a map, first draw a circle in the center to represent the family. Around the outside, draw circles that represent the family's community contacts such as church, school, neighbors, or other organizations. Families who “fit” well into their community usually have many outside circles or community contacts. A mark of families who are new to a community is that they have few community contacts because they have not formed these as of yet. This pattern is also the mark of an abusive or dysfunctional family if such a family deliberately keeps outside people separate from them. Constructing such a map helps you assess the emotional support that will be available to a family in a time of crisis. A family whom you assess as having few connecting lines between its members and the community may need increased nursing contact and support to remain a well family. Box 3.6 shows an interprofessional care map illustrating both nursing and team planning for the Hanovan

family.

**Figure 3.5** An ecomap of the Hanovan family’s relationship to its community. The family members are shown in the center circle; the outer circles show community contacts.

### BOX 3.6

#### Nursing Care Planning

#### AN INTERPROFESSIONAL CARE MAP FOR A FAMILY WITH AN ILL CHILD

Charles Hanovan is a 12-year-old child with cystic fibrosis whom you care for in the hospital. As you prepare him for discharge, his mother tells you, “He refuses to do his afternoon chores assigned to him and has been ‘acting out’ in school for the past month. He refuses to speak to family members and argues about what to eat. He’s supposed to independently take his medicine and do chest expansion exercises after school but refuses to do them.”

Charles states, “I’m tired of being nagged all the time, and of being so different from everyone else. And I want to get out of the house, not stay home alone. Imagine how much worse things will get when the new baby comes.”

**Family Assessment:** Blended middle-class family, which lives in an older three-bedroom home in the central city. Father is disabled from an on-the-job accident 1

year ago; does not participate in any community activities. Mother works as a bookkeeper and also attends a community college; she is 4 months pregnant and active in local political party. Patient is a middle child with two stepbrothers, age 17 years and age 2 years. Mother swims weekly at the local YMCA; the rest of family refuses to go with her. Charles is responsible for homework and cleaning kitchen after school while he is home alone (father is at physical therapy visits). Admits to having few close friends. Two neighbors are available in case of emergency during his alone time.

**Patient Assessment:** Respiratory rate: 26 breaths/min. Appears thin and pale. Productive cough with tenacious sputum. Lungs with fine bilateral rales.

**Nursing Diagnosis:** Interrupted family processes related to effect of child's illness and situational stressors limiting communication

**Outcome Criteria:** Family demonstrates greater participation in family activities, interaction with ill child, and positive methods of communication by 3 months' time.

Charles states he feels more family attachment and increased self-esteem by 3 months' time.

Team Member Responsible	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Interview family about family structure and roles.	Complete a family genogram and ecogram. Prioritize needs for each family member.	Family interview, genogram, and ecogram profile will show how family members relate and interact with each other and community and should help prioritize and focus care.	Family structure interview genogram ecogram inform follow-up visits per the family needs to identify
Nurse	Help family select a common activity that can be enjoyed by all members to help decrease sense of loneliness.	Encourage participation in this activity, initially once per month, then twice per month, and then weekly.	Participation in a group activity fosters bonding. Gradually increasing the frequency of the activity promotes integration into	Patient motivation a schedule document his participation the selected family activity

the family routine.

---

*Teamwork and Collaborations*

---

Nurse/social worker	Assess which community agencies have after-school programs that Charles could attend.	Contact local community organizations with patient and set up a visit. Ask the school nurse or guidance counselor to provide contacts, if needed.	Contacting the organization with the patient offers support and helps reduce any possible anxiety with new situations. School personnel provide additional support and reassurance.	Patient vi least or scho agency healthc visit.
---------------------	---	---	---	--

---

*Procedures/Medications for Quality Improvement*

---

Nurse	Assess and list all of child's required exercises, therapy, and medications.	Demonstrate procedures, if necessary, and ask patient to return demonstrations. Help patient incorporate regimens into usual routine.	Review and redemonstration help to reinforce measures and ensure patient is doing them correctly. Incorporating them into patient's routine helps to promote positive adjustment and decreases feelings of being different.	Patient redemo proced with 90 accurat Incorporat least on exercis medica into us routine Taking respon for the: should enhanc patient of "groc up" an decreas for ren
-------	--	---	---	---

Nurse/physical or respiratory therapist	Help family assess which family member could serve as backup support for child's exercise and medication regimens.	Meet with family and plan a schedule that will allow a backup family member to participate in child's exercise and therapy regimens so he isn't alone.	Family involvement divides the responsibility and minimizes the risk of added stress on the family system.	Family member state the checkli ensure them is availab cooper and en patient follow treatme regime Patient he is ac to treat regime of time
---	--	--	--	---

*Nutrition*

Nurse/nutritionist	Assess nutrition needs based on medical prescription.	Review special diet needed by patient with father (food preparer). Brainstorm foods patient would like to eat.	Both the food preparer and the patient need to be well informed about a special diet.	Both pati father s they unders special necess: describ breakfa lunch, dinner that ad the die
Nurse/nutritionist	Assess family's eating habits.	Encourage family to eat together as a family unit at least two times per week.	Eating together should help patient comply with nutrition plan and also provide a time for family sharing and communication.	Family re they ea least tv meals j week t or, if n possibl arrang alterna "sharir time."

*Patient-Centered Care*

Nurse	Assess patient's and family's present knowledge of his illness.	Review with patient and parents the cause and therapy for illness based on their present knowledge base.	Building on a patient's knowledge base facilitates teaching and learning and minimizes repetition.	Patient and family they understand underlying cause of illness important treatment
Nurse	Assess with patient what a typical school day consists of; how many friends he can identify.	Brainstorm with patient ways he could make a new friend or "fit in" at school better.	A feeling of "being different" can be detrimental to self-esteem.	Patient still has made least one friend in months feels a "fit" at school

*Psychosocial/Spiritual/Emotional Needs*

Nurse	Help each family member identify his or her greatest stressor.	Help family members reduce stress by teaching better problem-solving techniques such as time or anger management.	Identifying problems is the first step in effective problem solving. Use of therapeutic measures such as time management can reduce stress.	Family members identify greatest stressor their family and techniques they are to decrease stress to health care visit.
-------	--	---	---	---

*Informatics for Seamless Healthcare Planning*

Nurse/case manager	Assess home rules and delegation of responsibilities. Meet with family to identify where support may be needed when	Encourage joint cooperation in household tasks so patient doesn't feel so isolated when home alone.	Joint ownership of household tasks encourages a sense of family.	Family members demonstrate they have family schedule events and involve all members
--------------------	---	---	--	---

	child returns home.			
Nurse/case manager	Assess what community resources are available to support the Hanovans, such as the Cystic Fibrosis Foundation.	Meet with family to gauge their interest in using identified community organizations as resources.	Community resources can provide additional support in areas of need.	Family members state that attendees least one Parents Cystic Childre similar meetin months

### What If . . . 3.3

**The nurse discovers the Hanovan family is “out of sync” with its community (they are the only family on their block who does not work at the local factory, they attend a different church than many, they are having a new baby when many neighbors have college-age children). How could the nurse help them fit into their community better?**

## CHANGING PATTERNS OF FAMILY LIFE

Family life has changed significantly across the world during the past 50 years due to many complex and interrelated factors, such as an increase in divorce, families in which both parents work outside the home (dual-earner families), the legalization of marriage for LGBT couples, single-parent families, and shared childrearing responsibilities. Many more couples delay marriage and childrearing today until they are completely finished with school and established in their careers. This delay has implications for fertility and the need for assisted reproduction technology.

Understanding the impact these changes have on family structure and family life can help you create care plans that are realistic and better meet the needs of today’s families.

### QSEN Checkpoint Question 3.4

#### SAFETY

Because of smaller families, the supervision of children may be delegated to many different caregivers during a day’s time. What age group has the most automobile-related unintentional injuries if not supervised conscientiously?

- Infants, because child car seats are often installed incorrectly
- Toddlers, because they walk in front of cars in parking lots
- School-age children, because they ride school buses almost daily

d. Adolescents, because of alcohol or distraction while driving

*Look in Appendix A for the best answer and rationale.*

### Increased Divorce Rate

Divorce is rarely easy for either children or adults. Because parents are so emotionally entangled and their roles change so dramatically after divorce, they may be unable to give their children the support they need during this time (Vélez, Wolchik, Tein, et al., 2011). This can leave long-term, negative effects on children because the loss of a parent or favorite grandparent through divorce is little different from the loss of a parent through death.

Children react in differing ways to divorce depending on their age and understanding of what is happening and the explanations their parents give them. Divorce, as a rule, has three separate phases in which children follow a course similar to grief.

- The first phase is apt to be an antagonistic time as parents realize they are no longer compatible, marked by quarreling, hurt feelings, and whispered conversations. This phase can be particularly upsetting for children because they usually haven't been told what is happening as yet. They may assume the quarreling is their fault (i.e., if they had behaved better, this wouldn't be happening).
- The second phase is the actual separation stage. Everyone in the family is forced to take on an unfamiliar role, perhaps move to a new home, and probably realize a marked difference in finances. Although it is comforting to be free from a house filled with tension and arguing, most children wish they had their old life back as they grieve for the missing parent.
- The third phase involves reshaping lives. The family becomes a single-parent family or, if the custodial parent remarries, a blended one. Financial arrangements, whether higher or lower, stabilize. Children realize their lives are permanently changed, and they cannot go back to the time before the divorce and so must move forward.

Although there are thoughts that boys generally have more emotional trauma from divorce than girls, boys and girls react differently to the divorce of their parents. All children may manifest their feelings with physical symptoms or by a change in behavior. Their school performance may suffer. Most children report that when the noncustodial parent remarries, it is one of the hardest moments for them because at that point they have no choice but to accept the finality of the divorce (Angarne-Lindberg & Wadsby, 2012).

Although all three stages of divorce are stressful for children, following a divorce, a redeeming feature may be that children may actually feel less stress than they experienced living in a home where there was a high level of conflict between parents. To help them adjust to their changing situation, children need an explanation of why the

divorce occurred and assurance that it was not their fault. The parent who will now be raising them may need help in avoiding playing the role of the injured party or portraying the former partner as dishonorable, selfish, or unreliable. Although a former spouse was not a good marriage partner, he or she may have been a good parent and may be well loved and missed by the children (Sigal, Wolchik, Tein, et al., 2012).

### ***QSEN Checkpoint Question 3.5***

#### **EVIDENCE-BASED PRACTICE**

In previous years, few parents asked for shared or joint custody of their children following a divorce. Today, this type of custody is seen in as many as 30% of custody arrangements. To investigate whether joint custody of this type—where a child spends some time in both parents' homes following a divorce—poses behavioral risks such as increased smoking or drug use, researchers interviewed a cohort of 15-year-old Swedish teenagers.

Findings revealed adolescents living in shared physical custody had higher rates of health risk behaviors such as beginning smoking or drinking alcohol compared with adolescents from two-parent families (60% and 50% higher, respectively). At the same time, adolescents in this study had significantly lower rates of these health risk behaviors than their counterparts in single-parent families (Carlsund et al., 2013).

Suppose Mr. and Mrs. Hanovan divorce. Based on this study, what would be an important responsibility when the nurse is discharging James, an adolescent, from a hospital stay to his homecare setting?

- a. The nurse should suggest his mother, who will be his primary caregiver, to quit work so he will be able to have a stay-at-home mother for his care.
- b. The nurse should assess the parent's custodial pattern to be certain a responsible adult will be available no matter which home James returns to.
- c. The nurse should assure his parents that shared custody is a common pattern today and therefore does not pose a risk to teenagers; otherwise, no one would choose it.
- d. The nurse should assume the parents are responsible adults and will sensibly solve any problems that arise according to their custodial agreement.

*Look in Appendix A for the best answer and rationale.*

### **Decreased Family Size**

The U.S. birth rate has declined steadily from 1900 to the present, putting the United States at a rate of almost zero population growth or with fewer births each year than deaths. The average number of children in families has decreased from 4 or 5 at the beginning of the last century to 2.1 children today (National Center for Health Statistics, 2012). Because parents in small families spend less total time providing direct child care, this limits parents' experience in childrearing so the amount of childrearing counseling time by nurses needed per parent increases. As children have fewer older sibling role models than before, they may need more counseling in behaviors such as how to manage stress, how to survive a failing grade at school, or how to deal with a sports team's loss.

### **Increased Dual-Parent Employment**

As many as 60% of women of childbearing age work full-time outside their home, and

as many as 90% work at least part-time (Cherlin, 2012). The implication of this trend for healthcare providers is that healthcare facilities need to schedule appointments at times when parents are free to come (parents will willingly miss work if their child is sick but not necessarily for a health maintenance or a routine prenatal visit). Instructions about how to give medication must take into account both the child's and the parents' schedules. For instance, help parents tailor administration of medicine to the times they will be with the child to supervise the administration (perhaps before breakfast, following after-school child care, and at bedtime) rather than suggesting the more traditional 10 AM, 2 PM, and 6 PM schedule.

The amount of time spent watching television and what websites are being visited are important for parents to monitor with self-care school-age children. It is important for children to learn to live in a fast-paced world, but parents need to be certain children understand news of world events are reported over and over. Otherwise, serial repetition of that type can frighten children because it may seem as if 100 airplanes have crashed instead of one airplane crash being reported over and over.

To avoid exposure to excessive violence on television, the American Academy of Pediatrics (AAP) recommends children's television viewing time be limited until they reach 2 years of age (AAP, 2012). Many parents restrict this through school age so children have adequate time to spend with friends and on required homework. Caution parents that they need to monitor time spent on the Internet because of the misinformation posted and the risk from Internet predators.

Dual-parent employment has increased the number of children attending day care centers or after-school programs (Copeland, Sherman, Kendeigh, et al., 2012). This high attendance rate may have an impact on health care as well because children attending day care centers have an increased incidence of infections such as acute diarrhea and upper respiratory infections. They may engage in less gross motor activities than children playing at home. Helping parents choose a quality day care center or after-school program that takes the necessary precautions against infections and includes physical as well as academic activities can be a nursing responsibility (see Chapter 31).

Dual working parents may also require school-age children to spend some time alone after school before their parents return from work. Helping parents prevent loneliness in these "latchkey" or "self-care" children as well as helping children make good use of their time alone can be another important nursing responsibility (see Chapter 32).

### *QSEN Checkpoint Question 3.6*

#### **INFORMATICS**

The amount of technology and media that children are exposed to increases yearly. What is the youngest age the nurse would suggest the Hanovan family introduce their new baby to television viewing based on the recommendation of the AAP?

- a. 1 year

- b. 18 months
- c. 2 years
- d. 4 years

Look in *Appendix A* for the best answer and rationale.

## HIGH LEVELS OF VIOLENCE IN FAMILIES

An alarming statistic in today's families is that the incidence and reports of intimate partner violence and child maltreatment remain high ([Centers for Disease Control and Prevention, 2016](#)). This is apparently related to high stress levels in families and better reporting of violence and maltreatment. Detecting these behaviors begins with the awareness that they occur. Both intimate partner violence and child maltreatment are discussed in detail in [Chapter 55](#).

### *What If . . . 3.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals with respect to healthy families (see [Box 3.1](#)). What would be a possible research topic to explore pertinent to this goal that would be applicable to the Hanovan family and also would advance evidence-based practice?**

## KEY POINTS FOR REVIEW

- Families exist within communities; assessment of the community and the family's place in the community yields important information on family functioning and abilities.
- A family is a group of people who share a common emotional bond and perform certain interrelated social tasks.
- Because families work as a unit, the unmet needs of any member can spread to become the unmet needs of all family members.
- Common types of families include nuclear, extended, single-parent, blended, cohabitation, LGBT, foster, and adopted families.
- Common family tasks are physical maintenance, socialization of family members, allocation of resources, maintenance of order, division of labor, reproduction, recruitment and release of members, placement of members into the larger society, and maintenance of motivation and morale.
- Common life stages of families are marriage; early childbearing; families with preschool, school-age, and adolescent children; launching stage; middle-years families; and the family in retirement.
- Changes in patterns of family life that are occurring include dual-parent employment, increased divorce rates, reduced family size, and social problems such as intimate partner violence.

- Considering a family as a unit (a single patient) helps in planning nursing care that not only meets QSEN competencies but also best meets the family's total needs.
- Because families exist within communities, assessment of the community and the family's place in the community yields further information on family functioning and abilities.

### CRITICAL THINKING CARE STUDY

The Garcia family consists of Mr. Garcia, 42 years old; Mrs. Garcia, 36 years old; Mrs. Garcia's mother, 62 years old; Jose, 14 years old; Anna, 12 years old; and Carlos, 4 years old. Mr. Garcia works as a city bus driver. All six members live in a crowded apartment in the center of the city. Mrs. Garcia recently solved the problem of someone needing to care for her mother who has Alzheimer disease by quitting her job as a secretary to care for her. She tells the nurse she used to enjoy entertaining her children's friends but now asks them not to visit because her mother needs quiet.

1. What type of family do the Garcia's represent? Who do you think is the family problem solver? The health supervisor? The gatekeeper?
2. What is the stage of the Garcia family? Would their situation be different if the children were other ages?
3. Carlos was adopted because his mother, Mrs. Garcia's sister, died in a car accident. What are special concerns of adopted children you need to consider when giving nursing care?

## 4

# Home Care and the Childbearing and Childrearing Family

*Lisa Puente, a 16-year-old, is 20 weeks pregnant. She was admitted to the hospital for 3 days at week 14 of her pregnancy. Due to excessive vomiting and weight loss, she was placed on a nutritional supplement regimen that included gastrostomy feedings. Her condition improved over a 6-week time period, but at 20 weeks gestation, her blood pressure increased to 160/90 mmHg and she was diagnosed with gestational hypertension. She was placed on bed rest with fetal and uterine surveillance at home. She reports difficulty resting at home: boredom with school assignments and decreased visits from friends (and boyfriend). You notice she's missed at least three doses of her antihypertensive agent. She requests her care be provided in the hospital instead of at home.*

*Previous chapters discussed healthy communities, family structure, and how cultural traditions affect families. This chapter adds information about families and their community as they prepare to care for themselves or an ill family member at home.*

**Is Lisa a good candidate for home care? What additional interventions would she need to make home care more successful?**

## KEY TERMS

**direct care**

**home care**

**hospice care**

**indirect care**

**skilled home nursing care**

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe the usual nursing and patient concerns when home care is required during pregnancy or childhood.

2. Identify 2020 National Health Goals related to home care during pregnancy and childhood that nurses can help the nation achieve.
3. Assess a pregnant woman or child and their community for likely success with home care.
4. Formulate nursing diagnoses related to care of a child or pregnant patient at home.
5. Identify expected outcomes for a family requiring home care as well as help manage seamless transitions across differing healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care to meet the needs of a pregnant woman or child on home care such as teaching techniques of intravenous therapy or suggesting ways to keep in contact with significant others.
8. Evaluate outcome criteria for achievement and effectiveness of nursing care to be certain expected outcomes have been achieved.
9. Integrate knowledge of home care with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

**Home care**, as the name suggests, is care of persons in their homes, provided by employees of a certified home healthcare or community healthcare agency. In recent years, hospital stays have decreased, and the need for home care has increased.

Postsurgical children or those recovering from an acute illness are often appropriate patients for home care. Women who receive comprehensive prenatal care during the entire course of their pregnancy have more positive birth and postpartum outcomes (Bernstein & VanBuren, 2013). Home care can be a means of promoting personalized prenatal surveillance and initiating specific health teaching for high-risk pregnancies. Pregnant women who require these additional resources are appropriate for home care (Olander, Atkinson, Edmunds, et al., 2012). Many children in terminal stages of disease are also cared for at home (**hospice care** or palliative care).

Assessing and orienting families to home care, home visiting supervising and coordinating home health personnel, providing health teaching, and evaluating the appropriateness of continuing home care are important nursing responsibilities. [Box 4.1](#) shows 2020 National Health Goals that speak to home care.

#### BOX 4.1

### Nursing Care Planning Based on 2020 National Health Goals

National Health Goals are concerned with eliminating common infectious diseases of

childhood and reducing complications of pregnancy. These measures are important because both eliminating common infections and complications of pregnancy could reduce the hours spent in home care.

- Increase to at least 77% the proportion of all pregnant women who receive early and adequate prenatal care, from a baseline of 70.5%.
- Reduce the rate of preterm births, from a baseline of 12.7% to a target of 11.4%.
- Reduce or eliminate vaccine-preventable diseases such as measles (from 115 to 30 cases per year), pertussis (from 2,777 to 2,500 cases per year), and varicella (chickenpox) (from 482,535 to 100,000 cases per year) and keep poliomyelitis at zero cases per year (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these goals by helping women better accept and adhere to home care if it is advised during pregnancy. They can remind parents how important it is to have children routinely immunized so children no longer contract “childhood infections.”

### *Nursing Process Overview*

## FOR THE PREGNANT WOMAN OR CHILD ON HOME CARE

### **ASSESSMENT**

Being able to assess communities and families is an important role for the nurse in home care. The shorter length of hospital stays has resulted in an increase in the need for expanded home care for pregnant women and ill children. Patients who are candidates for home care are seen and evaluated initially in an ambulatory or acute healthcare setting. After this treatment, they are discharged to a home care program. A family assessment will ensure that care is congruent with the family’s usual self-care or childrearing practices.

### **NURSING DIAGNOSIS**

Nursing diagnoses for home care may address the physiologic reason for supervised home care or the effect of the experience on the family, such as:

- Deficient knowledge related to complication of pregnancy and necessary procedures and treatments needed
- Interrupted family processes related to need for home care
- Ineffective role performance related to bed rest at home
- Social isolation related to the need for home care
- Anxiety related to complication of pregnancy, which has required home care

Home care of a child can place a heavy burden on a family as the stress of being responsible for an ill child’s daily health status can have a negative impact on a parent’s self-esteem or a couple’s marriage; it can prevent parents from spending time with their other children or each other. Examples of possible nursing diagnoses that arise out of these factors include:

- Readiness for enhanced family coping related to increased time together because of home care
- Health-seeking behaviors related to skills needed to continue home care
- Risk for delayed growth and development related to lack of usual childhood activities
- Interrupted family processes related to dependence of ill child
- Disabled family coping related to changes in family routine brought about by home care needs of ill child

## **OUTCOME IDENTIFICATION AND PLANNING**

Both outcome identification and planning for home care require close collaboration between the healthcare providers supervising care at home and the family experiencing home care. Reviewing the family's needs and expectations and their congruency with the nursing expectations are an important aspect of nursing care. Local organizations can provide assistance to families on home care. Women, Infants, and Children (WIC) supplies food for qualifying children as well as women during pregnancy, and Literacy Volunteers offers help to increase reading levels so families can better understand healthcare directions or increase their health literacy. Several national and international organizations also have online resources available to families.

## **ONLINE RESOURCES**

Home Healthcare Nurses Association	<a href="http://www.hhna.org">www.hhna.org</a>
International Association for Hospice & Palliative Care	<a href="http://www.hospicecare.com">www.hospicecare.com</a>
National Association for Home Care & Hospice	<a href="http://www.nahc.org">www.nahc.org</a>

## **IMPLEMENTATION**

Interventions performed for a patient at home range from patient and family teaching and counseling to hands-on nursing care.

The home care nurse assists with the patient and family's psychological well-being and provides patients and families with resources for coping with stress from the caregiving responsibilities. If a child has a terminal illness, parents may require support to express their grief. Nursing care is similar to those performed in an acute care facility. Home care nurses need to have the same background and level of expertise as acute care nurses. They are usually required to have previous acute care experience as they are functioning with more independence and less supervision than nurses in the hospital setting.

## **OUTCOME EVALUATION**

A home setting is less structured than a healthcare facility. Goals may need to be adjusted to reflect this aspect, and goals may need to be adjusted based on individual and/or family circumstances.

The outcome evaluation for the pregnant woman receiving home care includes determining whether the woman and her fetus are stable and progressing as expected

in the home environment and whether, with the woman's input, home care is acceptable. For many women, successful home care will mean the difference between a premature birth and a successful term pregnancy.

Examples of outcome criteria for pregnant women could include:

- Patient demonstrates adequate skill at performing home monitoring procedures.
- Patient verbalizes changes in condition she will need to report to her healthcare provider.
- Patient participates as a member of the family within limitations imposed by pregnancy complication.
- Family members state they have adjusted to home care of mother.
- Patient states she is able to maintain contact with friends and family despite complete bed rest at home.

Examples of outcome criteria for an ill child might include:

- Parents state they have been able to make adjustments to accommodate care of an ill child at home.
- Child states he or she enjoys respite care in hospice setting one weekend per month.
- Parents state they are actively trying to supply adequate growth experiences for siblings in light of home care of oldest child.

## Understanding Home Care

Home care is possible because parenteral nutrition, fetal monitoring, pharmacy care, mental health care, and laboratory analysis are now available in the home setting. Voluntary agencies may assist with transportation to and from healthcare facilities for specialized testing, such as X-rays. Home care educators may provide individual instruction (Clark, Gates, McKiernan, et al., 2016; Miller-Matero, Dykuis, Albujoq, et al., 2016; Vivian-Taylor, Roberts, Chen, et al., 2012).

Pregnant women with complications such as preterm labor that has been halted, hyperemesis gravidarum (a severe manifestation of nausea and vomiting of pregnancy), and gestational hypertension are examples of conditions that can be managed at home with supervision and periodic visits by a community or home care nurse (Theilla, Ławiński, Cohen, et al., 2015). Frequent home visits are also helpful to monitor the health of newborns who were born at low birth weights or who arrived prematurely. These visits are met with high levels of family satisfaction (Awindaogo, Smith, & Litt, 2015).

Advantages of home care include:

- It prevents extensive disruption of the family. For children who are acutely but not terminally ill, this extra emotional support may not be as immediately important as physical care. For those who are chronically ill or dying, being close to their family and friends may be the most important aspect of their care. For these children, home care is ideal (Ergün, Sülü, & Başbakkal, 2011).

- It is less costly for the healthcare delivery system. It is less costly to care for pregnant women or children at home rather than in a hospital setting largely because the number of healthcare personnel needed is reduced. Home care can also reduce the cost of care when monitoring is the main type of care needed.
- Technologic advances have made it possible for potentially complicated procedures, such as ventilator therapy, to be performed safely at home.
- It presents the opportunity to focus not only on a specific health problem but also on promoting healthy behaviors for the entire family. For example, to prevent a child or woman from being exposed to secondary smoke, family members should agree to establish a “smoke-free” home, allowing a family illness to improve the lifestyle of a whole family (Ashford & Westneat, 2012).
- It can increase a woman’s or child’s self-confidence and self-efficacy because it allows for more self-care and often more control of circumstances.
- Families can be better assessed in their own environment than in an agency environment because family interactions, values, and priorities are more obvious at home than in a healthcare setting.
- Home visits provide a private, one-on-one opportunity for health teaching.

Disadvantages of home care include:

- Cost containment has to be weighed against the safety and quality of care. Not all home settings are safe for care, and not all families have the commitment necessary, so it is not an alternative for all families. In addition, although home care is cost-effective for healthcare agencies, it may not be cost-effective for the family. Costs that health insurance would have paid for had the patient been hospitalized, such as dressings and medications, may no longer be covered once the person is transferred to home care. This means it can actually increase the cost for an individual family if the family’s insurance does not cover the cost of nursing visits or necessary supplies.
- The physical care required (e.g., tracheal suctioning or a complicated medication regimen) can be overwhelming for family caregivers.
- A financial strain can arise if at least one parent or a spouse has to quit work and, therefore, cannot earn an income.
- Bed rest at home can cause social isolation and a disruption of normal family life.

#### *What If . . . 4.1*

**Lisa’s mother is concerned she will become exhausted because of the need for Lisa’s around-the-clock care. What suggestions could the nurse offer to make home care more successful?**

## **FEATURES OF HOME CARE**

Home care visits vary in frequency depending on a patient’s condition and the ability of

the patient or family to learn and maintain specific procedures. In some settings, telephone, e-mail, and chat room contacts are set up to link healthcare providers with families so questions can be answered immediately even when the healthcare provider isn't physically present in the home.

Home care is not a level of care adequate for everyone or every situation, so evaluating whether a family is a good candidate for home care is the first assessment needed. Based on this evaluation, the number of home care visits and which provider would be best for home visits can be determined.

### *Concept Mastery Alert*

Home nursing care is deemed “skilled” when a specific provider-prescribed procedure is indicated, such as medication administration, monitoring, or dressing changes.

Care at home may include:

- **Direct care**, in which a nurse remains in continual attendance or visits frequently and actually administers care
- **Indirect care**, in which a nurse plans and supervises care given by others, such as home care assistants

Nursing care is considered **skilled home nursing care** if it includes primary healthcare provider-prescribed procedures such as dressing changes, administration of medication, health teaching, or observation of a woman's or child's progress or status through such activities as monitoring vital signs or fetal heart rate. Whether nursing care is categorized as skilled or not can determine whether it will be paid for by third-party payers.

Frequency of visits varies with individual factors. For example:

- Those patients whose conditions are categorized as low risk probably need only weekly visits; a home healthcare aide may make the majority of visits.
- Those at intermediate risk need one to three visits per week; a nurse is necessary for the level of care needed.
- Those at high risk may need as many as seven visits per week; a nurse combined with other team members such as a nursing assistant, physical therapist, or a respiratory therapist will be needed for this complex level of care.

## **Assessing a Family for Home Care**

The initial assessment includes an interview with the patient and family; a thorough health history and physical examination to document a woman's or child's current status; and an environmental, community, and social assessment. Family motivation and preparation are factors that contribute to successful home care.

## THE INTERVIEW

Assessment begins with an interview to determine the current structure and function of the family. Identifying family roles (see [Chapter 3](#)), such as who are the wage earner(s), the decision maker(s), the nurturer(s), or the problem solver(s), is an important component of the interview. Incorporating the current structure and function of the family to support the new activities of home care are addressed ([Box 4.2](#)).

### BOX 4.2

#### Nursing Care Planning Based on Respect for Cultural Diversity

Whether home care is successful is strongly influenced by cultural expectations ([Hines, 2012](#)). This may be especially true with regard to male–female roles in a home. In a family in which men and women share responsibilities, care tasks as well as time away from the stress of home care can be distributed equally. In contrast, in cultures in which the male is dominant and child care is strictly delegated to women, a woman can become exhausted from trying to keep her house clean, prepare meals, care for her husband and other children, and also care for a medically fragile child. In male-dominant cultures, the idea of a man giving care to his wife or an ill child contradicts a usual pattern. If a woman is the dominant member of the household, becoming a passive, cared-for partner may be extremely difficult for her.

Because the structure of families is culturally determined, home care may be easier in some cultures than in others. If the family is extended, for example, a mother may be so involved in the care of other family members, such as an older adult, she is unable to rest adequately at home or add enough time to care for an ill child to her other responsibilities. In such a family, however, there may be many people to offer care and support, so home care will be ideal.

Some cultures stress women must be active during pregnancy to help ensure a small baby and therefore an easier birth. That can make bed rest difficult if a woman wants to be active rather than resting. The culture of a particular community might oppose the use of technology, so a family living there might not like having a van to supply needed oxygen or intravenous equipment parked outside. Assessing each family individually helps determine how cultural diversity may affect that particular family and how to individual plans.

### *QSEN Checkpoint Question 4.1*

#### EVIDENCE-BASED PRACTICE

Adolescents may spend hours each day on social media websites or talking with friends. To determine if adolescents on home care experience depression from lack of social interaction, researchers conducted an online survey of 422 adolescents on home care. Findings from the survey revealed adolescents voiced positive aspects to

solitude, but they also strongly rejected wanting or liking spending time alone. They expressed feelings such as fear, boredom, and separation anxiety. Those who reported feeling lonely were significantly less likely to enjoy being home alone during the day than those who weren't experiencing loneliness (Ruiz-Casares, 2012).

Lisa Puente is alone all day at home because both of her parents work. Based on the study, the nurse would make which recommendation to help Lisa prevent loneliness?

- a. She could arrange to go on brief outings with her friends.
- b. She could begin keeping a reflective diary of her thoughts and feelings.
- c. She and friends could all download a book to their e-readers and then discuss it by phone or online.
- d. She could keep up with her cheerleading squad by cheering along with them on Skype.

---

Look in [Appendix A](#) for the best answer and rationale.

---

After assessing present family structure and function, the nurse identifies ways family members think the illness and care at home will change their lives. This could include a wide range of changes such as increased expenses, the need for a parent or spouse to take a leave from work, the need for family members to help with frequent ambulatory healthcare visits, and the need to arrange for child care for other children. Because these needs change as the course of an illness changes, assessment must be ongoing.

Other assessments focus on likely adherence to medical, preventive, or medication regimens and whether the family will be able to safely monitor the patient's health at home. Additional assessment regarding other services or resources the family will need, such as the services of a home healthcare assistant or further nursing visits to ensure home care, is optimal. Future visits focus on continuing the assessment and evaluation of patient progress and readiness to help the woman or child move to another level of health care.

The term *resources* refers not only to material objects (such as a hospital bed, oxygen, fetal home monitor) but also whether a family is ready to deal with the chronic stress of home care. For example, pregnant parents may have to quit work to become home care patients. One parent of an ill child usually has to do the same. This automatically reduces a family's income, which can lead to severe financial problems.

## HEALTH HISTORY AND PHYSICAL EXAM

A home care plan is developed based on the health history and physical exam. This plan may include teaching the patient or family how to obtain required health parameters. Teaching may also include ensuring the family has received cardiopulmonary resuscitation (CPR) instruction.

Typically, women receiving home care are taught how to self-assess various health

parameters such as blood pressure, temperature, pulse, protein in the urine, serum glucose (with the use of a glucometer), fundal height, fetal movement, fetal heart rate, and uterine contractions. Parents or other family members of ill children invariably need to assess vital signs, comfort level, oxygenation (by means of an oximeter), and side effects of medications. When teaching these assessments, be certain to spend enough time with the patient and/or family so they thoroughly understand both the reason for the assessment and the procedure for doing it.

At subsequent home care visits, assess not only the results of the measurements but also whether they are being done correctly and consistently.

## ENVIRONMENTAL ASSESSMENT

An assessment of the family’s environment ascertains whether the home’s physical surroundings will be adequate for home care (Table 4.1). Table 4.2 lists additional important assessments to make depending on the age of a child.

**TABLE 4.1 ASSESSING A HOME FOR SAFE HOME CARE**

Category of Information	Conditions to Note
Safety	Is there a smoke and carbon monoxide detector in the patient’s bedroom? Do caregivers know the emergency call system procedure in their community? Does the primary caregiver know what steps to take if the patient is suddenly worse?
Oxygen therapy	If oxygen will be used, is there a sign to omit smoking in the room? Is the oxygen away from a fireplace, gas space heater, or gas stove? Does the family know not to light candles near oxygen in a power failure or for a birthday?
Space	Is there a bathroom in easy proximity to the patient’s bedroom? Is there a working refrigerator if medicine needs to be kept cold? Is there adequate storage space for supplies? Does the family know how to reorder supplies?
Patient support	Is there a family member who will be the consistent caregiver? Does this person understand the importance of this role? Identify the roles of family members such as who are the wage earner(s), the decision maker(s), the nurturer(s), or the problem solver(s).
Electricity	Is the home well lit? Are there adequate three-pronged plugs needed for the care equipment available? Has the power company been notified if an electrical appliance is necessary for life support? What would be the caregiver’s actions in a power failure? Do they need to purchase a battery power source?
Environment	Is the home a house or an apartment? Will the bedroom used for care be upstairs or downstairs? Is the home smoke-free? Is there evidence of

Nutrition	roaches, rats, mice, or fleas? Are food preparation areas in the kitchen clean? If a special diet is necessary, does the person who will do the cooking have adequate knowledge of food preparation?
-----------	---

**TABLE 4.2 ASSESSING A HOME FOR HOME CARE OF CHILDREN BY AGE GROUP**

Age	Points to Assess
Newborn or infant	Is there a suitable sleeping place? Do side rails of a crib lock securely? Are safe sleeping practices being used? Is there a freezer if stored breast milk will be used? Is there protection from mosquitoes? Is the home free of rodents that might attack a small infant? Is the infant kept safe from secondary smoking?
Toddler and preschooler	Is there a safe area for play free from stairs and poisoning possibilities? Are there screens or locks on windows to prevent a child from crawling out onto a ledge? Is there provision for stimulation and learning activities?
School-age child and adolescent	What is the provision for schooling (possibly an intercom with a regular classroom or home tutor)? Is peer interaction possible? If adolescent is self-medicating, will reminder sheets or some other reminder system be necessary?

## Beginning Home Care

Discharge planners in acute care settings can be instrumental in helping set the stage for home care by discussing the need for continued health supervision as well as helping patients begin to establish personal goals for home care. A number of steps are then necessary for an actual home visit to be successful. These steps can be divided into previsit, visit, and postvisit phases.

### PREPARING FOR A HOME VISIT

Typically, a first home visit is made within 24 hours of discharge or notice from an acute care or ambulatory care facility. A patient's referral form will inform the nurse of the patient's plan of care and treatment, and the nurse can generate a list of supplies needed for the visit. During a home visit, it is crucial to demonstrate respect for the patient's and family's privacy, beliefs, lifestyles, routines, culture, and requests.

As a part of individualizing care, telephone a patient or family in advance to verify the address and arrange a mutually convenient time for a visit. Ethical and legal aspects of nursing care, such as confidentiality, informed consent, Health Insurance Portability and Accountability Act (HIPAA) requirements, decision making, and patient rights commonly associated with acute care nursing, are applicable to home care.

## ENSURING PERSONAL SAFETY

Home care visits are often made by an individual nurse. Steps to assure personal safety during the visit are crucial. Safety tips for traveling in an unfamiliar community are shown in [Box 4.3](#).

### BOX 4.3

#### Safety Tips for Home Healthcare Travel and Visits

- Plan your trip in advance using a reliable map of the area, a navigation system, or a computer mapping program so you don't become lost in a strange neighborhood.
- Let an agency member know where you are going and when you expect to return.
- Keep your automobile in good repair and filled with gasoline or electrically charged so you don't run out of gas and can avoid having to make stops at unfamiliar service stations.
- Park your car in a well-lit, busy area. Lock the car door.
- Lock any valuables in the trunk of your car before you leave the healthcare agency, not after you park in front of a home so no one sees you do this.
- Do not leave valuable objects such as expensive electronic equipment in your car or a briefcase on the seat that someone might think contains drugs, so the car is not a target for car thieves.
- Learn the location of public phones in the area or keep a cellular phone with you.
- If you suspect someone is following you in your car, drive to the nearest police or fire station.
- Do not carry a purse or backpack that suggests you are carrying a large sum of money, drugs, or valuables. If you suspect someone is following you while you are walking, walk into a business establishment.
- Carry only minimal supplies so your hands are free to defend yourself. Walk determinedly, as if you have a purpose and are in charge of your environment and situation.
- Avoid shortcuts through alleys or unoccupied areas; drive or walk on main or busy streets.
- Avoid approaching homes by a dark, back alley; use the front door or a busy hallway.
- Use special caution in stairwells and elevators. Leave a stairwell or elevator if a potentially threatening person enters.
- When you first enter a home, assess it for personal safety. Ask who is at home. If there are animals in the house, ask if they are friendly.
- If there are animals, take precautions to avoid getting bitten by fleas (sit on a kitchen chair, not an upholstered one).
- Be cautious about accepting food or drink if you are not certain about the hygiene of the dishes or food. Decline it gracefully with an excuse such as "I'm trying to cut down on the amount of coffee I drink" or "It's against my agency's rules."

- Look under your car when approaching it and in the back seat before entering it to be certain no one is there. Relock your car door immediately once inside.
- Have your car keys in your hand when you leave the house so you can unlock and enter your car quickly.
- If either you or your patient is in personal danger, call 911 for help. Leave a home immediately if you feel threatened or unsafe.

### ***QSEN Checkpoint Question 4.2***

#### **PATIENT-CENTERED CARE**

The nurse needs to make a first home visit with Lisa, 16 years old, following a hospital stay. Which action by the nurse is best?

- a. Telephoning her home to establish a time both she and a parent will be present.
- b. Dropping in unannounced so the nurse can obtain a true picture of Lisa's home conditions.
- c. Visiting at a time Lisa will be there by herself so she can better express her feelings.
- d. E-mailing Lisa the 10 am arrival time; the nurse can expect a parent to also be home at that time.

*Look in [Appendix A](#) for the best answer and rationale.*

## **LOGISTICS OF THE VISIT**

Home visits may occur in a variety of settings from a house, an apartment, a mobile home, or a shelter. You need to determine the route to the visit prior to departing for the visit. Upon arrival at the home, knock or ring the bell and wait for someone to physically or verbally invite you to enter (even though you don't want the patient to get out of bed to let you in, walking in without permission could be interpreted as a home invasion). Greet the patient, any other family members present, and pets if they come to greet you. Dogs typically serve a guard function, and you want them to view you as a friendly, not a threatening, visitor. Occasionally, advance arrangements, such as having a neighbor let you in, may be necessary if a woman lives alone and cannot walk down a stairway or a long hallway to answer the door.

As in any healthcare setting, hand washing following universal precautions prior to patient contact and an assessment is required. Most home care nurses carry antibacterial gel or disposable wipes with them for hand washing, as these facilities in a home may not be convenient or available. Consent for care may need to be obtained.

## **ASSESSING THE PATIENT**

At the initial home visit, you are going to conduct a thorough health assessment, including a social history, a current health history, and a focused physical examination.

Provide privacy and confidentiality when obtaining the health history and performing a physical examination. Despite the informality of the setting, appropriate interviewing and physical assessment skills are indicated (Box 4.4) (Polat, Bayrak Kahraman, Kaynak, et al., 2015).

#### BOX 4.4

### Nursing Care Planning Tips for Effective Communication

Lisa is receiving home care because of hyperemesis of pregnancy and elevated blood pressure. She lost 15 lb at the beginning of pregnancy but now, at 20 weeks, has gained back the lost pounds, plus 2 lb extra, since beginning supplemental gastrostomy feedings every day. A home healthcare assistant visits her three times per week to supervise her nutrition. She always seems pleased to be visited by a home care nurse once per week.

*Tip:* Because home settings are more informal than those of healthcare agencies, it is easy to forget a home is a healthcare setting. Be careful to maintain therapeutic and structured communication during the health interview. Avoid overly relaxed communication with potentially leading questions.

**Nurse:** Hello, Lisa. How is everything?

**Lisa:** Great.

**Nurse:** Are you doing your own gastrostomy feedings?

**Lisa:** Right.

**Nurse:** Do you have any concerns about those?

**Lisa:** They make me throw up once—maybe twice—a day.

**Nurse:** I need to do a more thorough assessment.

Throughout the assessment, evaluate the patient's needs and provide instructions and reinforcement on any specific areas that are necessary. Assess compliance with the instructions for activity orders. If bed rest is required, ask how this is being achieved to ensure it is congruent with the medical orders. At the conclusion of the visit, ensure the family has a realistic understanding of the medical diagnosis and prescription instructions as well as knowledge of when to seek immediate care for particular signs and symptoms. Prescription instructions include the family's ability to obtain the prescription, and instructions on when to seek immediate care include knowing who to contact based on the time and presentation of signs and symptoms.

Plans for a follow-up visit should be provided prior to the end of the visit.

#### *What If... 4.2*

**Lisa's family lives in a trailer park. Their nearest neighbor stops the nurse at every visit to ask how Lisa is doing. How would the nurse answer her?**

---

## ASSESSING THE HOME ENVIRONMENT

During the home visit, it is important to assess the home environment to assure basic safety needs are met (Fig. 4.1). This means verifying and answering the following:

**Figure 4.1** Procedures need to be incorporated into the family routine. Here, a young boy gets his gastrostomy tube feeding prior to leaving for school. A nurse assists the family with this new procedure.

- Are the water, electricity, heat, and refrigeration in good working order?
- Are there working smoke alarms?
- Is the structure adequate, including functional windows and doors?
- Is the home free of rodents, insects, and lead-based paint?
- Is the bathroom accessible to the patient?
- Is the telephone within reach of the patient?
- If medical equipment, such as a hospital bed, wheelchair, or oxygen, is required, is the house suitable for the equipment?
- Is the flooring and layout of the room appropriate for a wheelchair?
- Are shelves and cabinets accessible if the person is using a wheelchair?
- Are bathing facilities appropriate and accessible?

### *QSEN Checkpoint Question 4.3*

#### **SAFETY**

In the middle of a visit to Lisa's home, her former boyfriend arrives and threatens he will "punch" both Lisa and the nurse if the nurse doesn't leave. What action by the nurse is best?

- a. Telling him threatening someone is not mature behavior and he should stop
- b. Suggesting Lisa have her parents change their locks so this man can't visit again

- c. Leaving the home and notify the agency of the unsafe circumstances for the nurse
- d. Telephoning 911 and reporting that both the patient and the nurse are being threatened

*Look in Appendix A for the best answer and rationale.*

## HOME CARE ASSISTANTS

Effective home care requires a team of healthcare providers, including a supervising primary healthcare provider, home care nurses, and other persons such as health equipment suppliers and home care assistants. Home health assistants can supply the bulk of personal care services such as assisting with or providing hygiene, assisting with ambulation, or helping to feed patients. Home care assistants have varied levels of preparation depending on their home health or community healthcare agency policies and the level of care they are being asked to provide.

When working with unlicensed assistive personnel, be certain you are familiar with their level of ability and education, so you assign care that is appropriate to their level of certification.

### *What If . . . 4.3*

**When visiting Lisa, the nurse discovers large mouse holes in the bedroom that will be used by her new baby. What would the nurse do next?**

## POSTVISIT PLANNING

Postvisit planning consists of completing all required documentation identified in the assessment, care provided, evaluation of care, and planning for future care. Billing information as required by the agency is to be completed. Any changes in health status, needs for prescriptions renewals, or requests for updating and revising the plan of care should be communicated to the primary healthcare provider. Privacy rules (HIPAA regulations) apply the same as in hospital or ambulatory care settings.

## FOLLOW-UP VISITS

Subsequent home visits are planned depending on the patient's circumstances. A second visit could be scheduled as often as the next day or as infrequently as once per month depending on the level of supervision required.

### *QSEN Checkpoint Question 4.4*

## INFORMATICS

Lisa says one reason she doesn't like home care is because private things about her

won't be respected. The nurse could assure her of which of the following?

- a. Privacy rules (HIPAA) apply to home care health records the same as hospital records.
- b. It is a problem, but the nurse will do try to respect her privacy and gain her confidence as much as possible.
- c. The nurse won't keep a record of home care procedures so she doesn't need to worry.
- d. Electronic home care records are protected by copyright rules the same as all records.

Look in [Appendix A](#) for the best answer and rationale.

## Nursing Diagnoses and Related Interventions

**Nursing Diagnosis:** The family process is interrupted related to the stress of caring for ill family member at home.

**Outcome Evaluation:** Family members state they feel able to manage home care; family meets weekly to discuss problems and share accomplishments.

### HEALTH PROMOTION

Nursing responsibilities for birthing parents and children receiving home care vary greatly because the reason for home care and the actions needed vary so greatly. Typical interventions carried out in homes are concerned with promoting both a healthy environment and healthy family function.

#### Identify a Child's Primary Caregiver

Although traditionally the primary caregiver for an ill child is the mother, in today's families, if another parent works more flexible hours, they may be the parent best able to give the bulk of care. In some homes, a grandparent or an older sibling will be the person primarily responsible for care. Arrange to include this person in planning and problem solving because this person knows best what strategy of care will be most effective with the child as well as what strategy will be most appropriate in light of the physical layout of the home and the family's financial ability and lifestyle.

#### Determine Knowledge (Health Literacy) Level of Family

Before anyone can be cared for at home, teaching will be required so the family understands the illness and principles of care. Include in teaching both the things that must be learned immediately and additional care measures that will need to be taught as the patient's condition changes. [Box 4.5](#) shows an interprofessional care map

illustrating both nursing and team planning and education for a family cared for in their community.

## BOX 4.5

### Nursing Care Planning

#### AN INTERPROFESSIONAL CARE MAP FOR A PREGNANT ADOLESCENT AT HOME ON BED REST

Lisa Puente is a 16-year-old who is 20 weeks pregnant. Since the beginning of her pregnancy, she had been vomiting at least four times daily and was losing weight. At 14 weeks, she was admitted to the hospital for 3 days and placed on a program of gastrostomy feedings. She managed well until last week when she was also diagnosed with gestational hypertension and placed on bed rest with fetal and uterine surveillance at home. She tells you it's impossible for her to rest at home: She's bored with school assignments and her friends (and boyfriend) no longer visit. You notice she's missed at least three doses of her antihypertensive agent. She asks to be hospitalized again for care.

**Family Assessment:** Patient lives with parents in a two-story home. Patient's bedroom is on second floor with bathroom located approximately 20 ft from patient's bed. Patient's mother is primary wage earner in the family; works full-time as a travel agent. Husband drives a delivery van; is home until noon daily.

**Patient Assessment:** Vital signs: temperature, 98.4°F; pulse, 76 beats/min; respirations, 22 breaths/min; blood pressure (BP), 144/94 mmHg; fetal heart rate (FHR), 148 beats/min. Mild facial edema, +1 protein in urine, 2-lb weight gain in last week.

**Nursing Diagnosis:** Ineffective coping related to need for bed rest secondary to nausea and gestational hypertension.

**Outcome Criteria:** Patient identifies methods to continue in school while maintaining bed rest, expresses increased satisfaction with imposed bed rest, and is able to maintain bed rest until fetal maturity. BP remains 140/80 mmHg or less, FHR within acceptable parameters, urine for protein remains +1 or less, weight gain limited to 1 lb/week, edema limited and without increase for the duration of pregnancy.

Team Member	Responsible	Assessment	Intervention Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Assess vital signs, including heart rate,	Instruct patient how to take own vital signs. Review	Assessment of vital signs and fetal activity provides a	Patient demonstrates she is able to accurately

	BP, and FHR at every visit.	how to do a “count-to-10” assessment daily to assess fetal movement.	baseline for future comparison and evidence of the patient’s and fetus’s status.	obtain own pulse, BP, and fetal activity. Findings compare with nurse’s weekly findings.
--	-----------------------------	--	--	--

*Teamwork and Collaboration*

Nurse/primary healthcare provider	Assess what care services are most appropriate for an adolescent patient.	Arrange for home care visits by hospital home care team. Care assistant: daily; registered nurse: once a week.	Home care functions best when it is part of a “seamless” service.	Patient agrees to services of hospital home care team.
-----------------------------------	---	--	---	--

*Procedures/Medications for Quality Improvement*

Nurse	Assess random urine specimen for protein at each home visit.	Instruct patient to assess urine specimen and weigh herself every day.	Proteinuria +1 suggests potentially limited kidney function or infection.	Patient voices an understanding of need for bed rest and adheres to restriction.
	Assess what patient interprets home bed rest to mean.	Review concept of complete bed rest. Arrange for a bedside commode if necessary.	Weight gain suggests fluid retention. Bed rest will reduce symptoms of gestational hypertension.	Patient demonstrates ability to carry out procedures accurately.

*Nutrition*

Nurse/nutritionist	Obtain a 24-hour recall of	Ensure patient is using the prescribed	An adequate nutritional intake is	Patient describes a 24-hour
--------------------	----------------------------	--	-----------------------------------	-----------------------------

	gastrostomy feeding pattern to determine if nutritional intake is adequate.	liquid feeding; encourage additional fluid intake.	needed for fetal growth.	intake of gastrostomy feedings adequate for pregnancy.
--	---	--	--------------------------	--

*Patient-Centered Care*

Nurse/social worker	Assess what patient feels are her chief needs that could make her more agreeable to remaining on bed rest at home.	Assist patient with planning effective bed rest; discuss possible sources of help from friends and family.	Planning concrete methods to make bed rest more tolerable alleviates stress.	Patient demonstrates ways she has adapted to bed rest restrictions.
	Assess what measures would make her more agreeable to continuing school work.	Urge parents to speak to school for more creative arrangements.	Collaboration with school officials should help teenager to remain in school.	Patient voices plan for creative measures taken so she can remain in contact with school.

*Psychosocial/Spiritual/Emotional Needs*

Nurse	Discuss usual activities with patient and how lack of these has led to boredom.	Encourage patient to plan activities such as reading and listening to music that are both enjoyable and compatible with bed rest.	Discussion provides baseline information to identify patient's needs, beliefs, and responsibilities.	Patient lists at least three restful activities she can use to occupy her day so she feels less boredom.
-------	---	---	--	--

*Informatics for Seamless Healthcare Planning*

Nurse	Assess for readiness to continue with home care.	Instruct patient and family to report increased blood pressure or sharp headache to primary care provider.	Knowledge of danger signs allows for early identification and prompt intervention.	Patient lists signs and symptoms she will report to primary care provider if they should occur.
-------	--	--	--	---

### Identify Available Resources

Assess where the nearest fire and rescue company are located in relation to the home in case CPR is necessary, whether a backup resource is available to power needed equipment if a blackout should occur, and if the patient can be evacuated easily in case of a fire.

### Promote Healthy Family Functioning

A family that is supportive of all family members and provides an environment conducive to each member's continued growth and development is more likely to be able to manage home care than a family with a history of ineffective or destructive coping strategies (e.g., a family in which parents have unrealistic expectations of family members, a family with a history of abusive relationships, or members who do not cope effectively with stressors). A careful assessment is necessary because even a family that appears to be functioning well may become so adversely affected by factors such as the loss of employment income, resentment over missed promotions, or cramped living space all caused by home care that its members' ability to be successful can fail. Remember, every family operates differently and handles stress in different ways. This means events that may seem overwhelming for a visiting healthcare provider may actually be easy for the family to handle. Conversely, problems that seem minor could be disruptive enough to affect the family's ability to continue adequate care at home.

Many women fulfill multiple roles in their family, such as financial manager, peacemaker, problem solver, nurturer, and decision maker. Even when a woman is on bed rest, help her to continue in these roles to ensure the family's usual functioning because support people often have great difficulty assuming these roles in her place. In some families, the ill child may fill one of these roles and so needs to be encouraged to continue in the role as well.

As a general rule, support people can only be supportive if they understand the need for and importance of their role. Arranging for a homemaker service to help care for children or an aging parent or to help with light housework may be necessary to prevent support people from feeling stretched so thin when the usual manager of the home is ill.

At home visits, ask a woman how her support people are coping and if there are ways this experience could be made easier for them as well as for her. The ability to be allowed to make decisions about her own care can make a significant difference in whether a woman thinks her home care experience is satisfactory.

## HEALTH MAINTENANCE

Health maintenance actions are a step beyond health promotion or are taken when a specific risk of ill health is present.

### Maintain Skin Integrity

Both adults and children who are on long-term home care can develop skin ulcers the same as hospital patients if their caretakers don't use preventive measures against this (e.g., good nutrition, position changes, cleaning skin, and promoting mobility) (Kottner, Boronat, Blume-Peytavi, et al., 2015).

### Promote Elimination

Constipation occurs at a high rate during pregnancy and can occur in children on bed rest from lack of exercise. Encourage a diet high in fiber and fluid to minimize this problem.

### Ensure Bed Rest

One solution to help both adults and children cope with the stress of bed rest is for them to keep busy in some way, such as using their time to learn a new skill. Most women can name activities they would like to do but have never had time before to begin. For example, bed rest could provide an ideal time for an individual to catch up on reading previously neglected for a long time (Fig. 4.2).

**Figure 4.2** Bed rest can be stressful. Helping a woman who is on bed rest identify enjoyable and productive activities to pass the time can help ease stress.

Electronic readers make it possible for women and children to download reading material immediately. If a woman has children, she could spend part of her time reading to them. She could also use the time to take a home-study course, learn to knit, write a short story, or study for a certifying examination related to her work. In any event, helping her plan meaningful activities such as these can help her view home care not as wasted time but as time invested in her family or career (Box 4.6).

#### BOX 4.6

#### Nursing Care Planning Based on Empowering a Family

**Q.** Lisa tells you, “I feel like I’m wasting my time being home all the time this way. Tell me what to do to keep busy.”

**A.** Try these suggestions:

- Concentrate on school work; make this a time to really delve into a subject.
- Ask your teacher if there is a special project you could work on from home while on bed rest for extra credit.
- Renew an old hobby or begin a new one such as solving crossword puzzles.
- Ask someone to bring you books on newborn care from the library or download them on an electronic reader (you’ll be an expert on newborn care by the time your baby is born).
- Telephone your friends. Rest next to a telephone so friends know they won’t be disturbing you when they return calls.
- Catch up on your correspondence. Friends and family will be surprised and delighted to receive a letter as so few people write them anymore.
- Investigate whether there is a local community project (such as telephoning for a political campaign, urging neighbors to write letters of support for a new playground) you could work on while on bed rest.
- E-mail friends or join a social media site (if you have a limited data plan, be conscious of the extra charges that might result). If you have a Skype connection, invite friends to show you what is new with them.
- Learn a second language; many books and websites are available on this.
- Take a mail-order or Internet course on something you want to learn more about (such as creative writing, learning to be a paralegal, how to cook French sauces).
- Ask your home care nurse about preparation-for-childbirth information or download a book on this. By conscientiously practicing breathing exercises while on bed rest, you can become well prepared for labor and birth.

Children need to involve themselves in schoolwork or play, perhaps by learning a new game or solving sudoku or crossword puzzles. Otherwise, they may spend their time simply watching television or napping.

Although play is a universal activity of children, not all parents realize how

important it is to children, so nurses can play an important role in teaching this. When a child is not proficient in English and English is the language of the healthcare provider, games such as stacking blocks or building with Tinkertoys can be played despite communication difficulty. Playing recordings of well-loved children's songs can also be effective because the child doesn't need to be able to understand the words to enjoy the music or clap with the rhythm.

### **Teach Monitoring of Vital Signs**

Monitoring vital signs in the home does not differ from monitoring them in a healthcare agency. Although the mercury thermometer has been banned in many states due to concerns about poisoning, there may be a rare few in the home setting still. The family should be advised to properly dispose of the mercury thermometer and obtain an electronic one.

Blood pressure is best measured on the same arm and when the person is in the same position (lying down or sitting up) each time. Using an automated cuff simplifies taking blood pressure. These can be purchased for a low cost from pharmacies or from home care agencies.

### **Teach Self-Monitoring of Uterine Height, Contractions, and Fetal Heart Rate**

Uterine (fundal) height during pregnancy is measured by using a paper tape measure according to McDonald's rule (see [Chapter 9](#)). If a woman is asked to record weekly fundal height measurements, demonstrate the correct technique and have her give a return demonstration, as this measurement varies greatly depending on where the tape measure is placed. Be sure a woman is measuring the height in the same manner each time.

Many women conduct fetal movement counts (also called kick counts) daily (see [Chapter 9](#)) to help assess fetal well-being ([Hantoushzadeh, Sheikh, Shariat, et al., 2015](#)).

Fetal heart rate (FHR) is usually recorded by the home care nurse at each home visit. In addition, a patient may be taught how to obtain this herself. FHR can be recorded by listening with a Doppler, a fetoscope, or an electronic monitoring device supplied as part of her home care program.

The patient can self-monitor uterine contractions using a uterine monitor, the same as in a healthcare facility, or by palpation (see [Chapter 15](#)). A nonstress test can be conducted using a portable monitor no bigger than 3 × 4 in. in size. A birthing parent straps this device to the abdomen for 20 to 30 minutes at a set time every day or at any time they feel contractions or are concerned about the lack of fetal movement ([Fig. 4.3](#)). The monitor records both uterine contractions and FHR. At the conclusion of the monitoring period, the tracing is transmitted to a central facility for evaluation.

**Figure 4.3** Fetal heart rate and uterine contractions can be recorded successfully by women at home. (Kzenon/Shutterstock.com)

If you discover a woman is omitting something such as counting fetal movement, spend some time asking why she's omitting it. It may be because she's unsure she's doing it correctly, or it may be because she's afraid it will reveal her fetus is not doing well (the philosophy of what she doesn't know won't hurt her). It's helpful to try to turn her fear into positive action; discovering decreased fetal movement will allow a healthcare provider to initiate an action to save her baby and so is a helpful step, not one to fear.

**QSEN Checkpoint Question 4.5**

**TEAMWORK & COLLABORATION**

Since Lisa has begun eating oral food after gastrostomy feedings were discontinued, she has begun to develop constipation. What measure would the nurse want the team members to suggest she take to help prevent this?

- a. Drink more milk, as increased calcium prevents constipation.
- b. Walk for at least half an hour daily to stimulate peristalsis.
- c. Drink at least eight full glasses of a fluid, such as water, daily.
- d. Eat more frequent small meals instead of three large ones daily.

*Look in [Appendix A](#) for the best answer and rationale.*

**HEALTH INTERVENTION**

Health intervention begins when illness is present so that symptoms are not allowed to progress to a more serious state.

**Explain Advances in Technology**

A family may assume one advantage of home care is that their child will no longer be held captive by so much monitoring or oxygen equipment as surrounded the child in a

hospital. Because so much of equipment is portable, however, a child on home care can receive the same level of monitoring as in a hospital. Parents may also need to adjust to receiving instructions over the Internet. Webcasting or telemedicine by a healthcare agency can be used to supply them information, treat patient conditions, lend encouragement, and answer questions they have about care (Given, Bunting, O’Kane, et al., 2015).

Caution adolescents there are some downsides to too much Internet use as there is an apparent association between depression and spending excessive amounts of time on social media chat rooms, so much so, a syndrome termed “Facebook depression” has been identified (Blachnio, Przepiórka, & Pantic, 2015).

Parents also need to alert children and adolescents that not all websites are safe to visit because of the possibility that sexual predators also visit such sites, putting them at risk (Khurana, Bleakley, Jordan, et al., 2015).

### Provide Health Teaching

Because the home setting is private, a home care visit can provide many more opportunities for one-on-one health teaching than a healthcare agency setting. An important aspect of teaching for a pregnant parent might be providing childbirth education because a woman on bed rest will not be able to attend formal classes. For a child, it could be teaching the whole family about the child’s illness and why the current therapy is needed.

### Provide for Safe Medicine Administration

Most people receiving home care are prescribed some type of medicine, such as a tocolytic for pregnant women to halt preterm labor or chemotherapy for children because of cancer (Ewen, Combs, Popelas, et al., 2012). Review the rules of safe medication administration with the family to minimize mistakes such as taking the medicine more frequently than prescribed or forgetting to take it (Box 4.7).

#### BOX 4.7

#### Nursing Care Planning Based on Family Teaching

##### SAFETY TIPS FOR SAFELY TAKING MEDICINE AT HOME

- Keep drugs in a safe place. In most homes, this is in a locked medicine cabinet or drawer above the height a child could reach.
- Keep alert that most childhood poisonings occur when a family is under stress; that is, because during these times, the family can forget usual procedures such as locking away medicine. Families need to take more and more precautions the higher the stress level rises in the home.
- Never take medicine in front of children (children can imitate this action with the parent’s medication).
- Don’t pour or prepare medicine in the dark. Because almost all medicine bottles

dispensed from local pharmacies look and feel the same, it is easy to pour the wrong liquid, extract the wrong pills, or read the bottle instructions incorrectly without adequate light.

- Read instructions as to whether medicine should be taken with food or not and whether pills can be chewed or not. Try and drink a full glass of water with pills to ensure they reach the stomach.
- Create a reminder sheet and hang it in a prominent place. Cross off each time the medication is taken.
- Purchase a medicine box with an individual compartment for each day of the week. Such boxes help to eliminate confusion over whether medicine was taken or not.

### **Provide for Adequate Nutrition and Hydration**

A pregnant parent who is on home care often needs help maintaining adequate nutrition. If ordinarily she is the person who plans menus, shops for food, and cooks for the family, other family members must assume these roles. If other family members are inexperienced at cooking, the entire family, including the pregnant woman, may not eat enough healthy foods.

As ill children don't get as much activity as usual, they may not be as hungry at mealtime as usual. You may need to make suggestions for healthy snacks so a child's total daily intake is adequate even if not a lot of food is eaten at formal meals.

All women during pregnancy should drink six to eight full glasses of fluid a day to obtain adequate fluid for effective kidney function and placental exchange (Harnisch, Harnisch, & Harnisch, 2012). Be certain women on bed rest have a supply of fluid close to their bed, such as a bottle of water, so they can do this easily.

Many pregnant women or children on home care receive intravenous therapy as a route of medication or fluid administration. Women with hyperemesis gravidarum (uncontrolled vomiting during pregnancy) or an isolated incidence oligohydramnios (less than normal amount of amniotic fluid) receive it as a means of hydration (Gizzo, Noventa, Vitagliano, et al., 2015). Women and children with blood dyscrasias may receive blood transfusions in the home (Marouf, 2011).

Because peripheral intravenous lines frequently become dislodged, in the home setting, intravenous fluid is often administered by a central line or a peripherally inserted central catheter (PICC) line threaded to a central blood vessel. Many drugs, especially antibiotics, are given through bagged "piggyback" infusions kept frozen until the time of administration. Specially pressurized fluid containers allow for fast and easy administration of special solutions. To be certain fluid infuses slowly and accurately, an intravenous infusion pump is strongly recommended. Be certain a woman or a family member knows how to operate a pump, how to monitor intravenous insertion sites for inflammation and infiltration, how to protect the site from becoming infected (e.g., cover it with plastic rather than letting it get wet), when to remind a healthcare provider

the site should be changed, and how to monitor the amount and kind of fluid or medication infused.

### **Home Enteral Nutrition**

Chronically ill children and women who have hyperemesis gravidarum may receive nutrition by a gastrostomy or nasogastric tube. The supplies necessary for enteral feedings, such as feeding tubes and enteral pumps, are available for rent or purchase through pharmacies, medical supply houses, or the home care agency. Such tubes are usually changed every 2 to 4 weeks. The home care nurse will most likely be the person responsible for changing the tube, but this depends on the home care agency's policies. In addition to assessing the amount of formula infused by this route, be certain the woman or a family member is familiar with all aspects of care for the tube, equipment, and administration of the feeding. Caution the family to monitor the amount of formula for the feedings they have on hand so they don't run out, especially over weekends or holidays when their supplier may be closed. Patients on enteral feedings probably will need to weigh themselves periodically and record their weight. They may need to test blood serum for glucose with a glucometer. Be certain they use the same scale, wear consistent clothing, and know when to call for advice if they are unsure if their weight is remaining adequate.

### **Total Parenteral Nutrition**

Total parenteral nutrition (TPN) is yet another way to supply complete nutrition and fluid to patients on home care. The home care agency or a separate vendor will furnish and deliver the formula, tubing, clean dressings, and an infusion pump. The formula, which consists of amino acids, hypertonic glucose, vitamins, and minerals in solution, needs to be stored in the patient's refrigerator until 1 to 2 hours before use; it is then removed from the refrigerator and allowed to warm to room temperature. Women and children requiring this type of intravenous nutritional therapy usually have a central venous access device such as a central venous catheter or PICC line inserted. The home care nurse plays a key role in teaching family members about the therapy and also in assessing the woman's or child's response to therapy.

Throughout therapy, be certain the patient or a family member knows how to monitor the infusion of the solution and the patency of the tube, how to change dressings (if that will be their responsibility), how to observe the insertion site for redness or inflammation, and how to assess body temperature for a possible infection. They also must be aware of any restrictions that should be adhered to (such as no baths if the water level will rise above the catheter insertion site) and the interval at which blood should be drawn for monitoring. Because TPN solutions are hypertonic, a woman or a family member needs to obtain blood glucose levels as necessary, test them with a glucometer, and keep a record of these. Be sure the family knows what findings they should report immediately to a healthcare provider.

## Teach Self-Monitoring by Serum or Urine Testing

Women who develop gestational diabetes will be required to self-monitor their serum glucose level using a glucometer at least once daily, some three or four times daily (Evensen, 2012). Children with diabetes need to do these actions as well (Garg & Hirsch, 2012). Both women and children need support to be conscientious about continuing to do these actions when home care extends for a long time. A nurse can be instrumental in being the person to supply this support.

## Manage Pain

Children who are on home care after surgery or those with a chronic or terminal illness may need efficient pain management for long periods of time. Be certain parents understand the principles of pain management such as to give medication before pain becomes acute. A detailed discussion with other pain management philosophies is discussed in Chapter 39.

### QSEN Checkpoint Question 4.6

#### QUALITY IMPROVEMENT

Lisa has been on home care for a long time. Which of her following statements would worry the nurse most about whether her home is a safe place for home care?

- “My mother is trying to quit smoking; she usually goes outside to smoke.”
- “If the lights go out, I know the circuit breaker is located in the garage.”
- “A police report says there’s never been a robbery in this neighborhood.”
- “My father had the paint in the bathroom tested last year and it is lead-free.”

Look in *Appendix A* for the best answer and rationale.

## Health Rehabilitation

Health rehabilitation begins at the point complications have arisen and a patient is learning to adapt to chronic illness or take active steps toward restoring function. It can also mean accepting end-of-life care.

## LONG-TERM HOME CARE

Although many families are good candidates for home care in the beginning, they have difficulty maintaining this high level of commitment as home care becomes long term. They may need both advice and support to continue to adapt constructively to the changing phases of an illness. They can develop low self-esteem and depression, feelings which can harm a marital relationship or prevent parents from spending time with other children (Fig. 4.4).

**Figure 4.4** Home care of a child is family care. Here, a brother helps his sister transfer to a wheelchair.

Help families maintain healthy functioning by promoting communication with each other and encouraging family members to identify and share their feelings about the situation at home. Encourage members to voice the frustration they can feel at being constantly confined at home or what they perceive to be a lack of progress in the ill person's condition. If a child has a terminal illness, support parents to express their grief and not grow discouraged because the work they are accomplishing is making the child comfortable. Continued successful coping will require the family to acknowledge and take seriously the impact of home care on each family member and work together to solve identified problems. To do this effectively, they may need to renegotiate roles and responsibilities within the family or seek outside help.

Children on home care need to continue with school if at all possible so they can maintain contact with friends, so they don't fall behind a grade level, and so they can continue the stimulation of learning. This means parents should make some sort of arrangement for schooling either through their local school district (many schools can establish a telecommunication setup for children ill at home) or investigate their ability to home school.

When a family has difficulty functioning well at the beginning of home care or does not adjust readily to continued care, nursing measures to support family functioning become even more important. A family whose coping strategies are maladaptive may not be able to care for a sick family member at home for long without strong nursing and other healthcare professional support.

#### *What If . . . 4.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals with respect to home care (see [Box 4.1](#)). What would be a possible research topic to explore pertinent to this goal that would be applicable to Lisa's family and also advance evidence-based practice?**

## Unfolding Patient Stories: Olivia Jones • Part 1

**Olivia Jones**, a 23-year-old gravida 1 para 0 at 30 weeks gestation, is being seen for a routine prenatal visit. She presents with mild edema and elevation in blood pressure requiring placement on bed rest at home. She is active in the local Baptist church and lives with her mother, who works during the day. What home care and community resources can the nurse consider to help her with symptom monitoring and maintenance of bed rest at home? (Olivia Jones's story continues in [Chapter 13](#).)

Care for Olivia and other patients in a realistic virtual environment: *vSim for Nursing* ([thepoint.lww.com/vSimMaternityPed](http://thepoint.lww.com/vSimMaternityPed)). Practice documenting these patients' care in DocuCare ([thepoint.lww.com/DocuCareEHR](http://thepoint.lww.com/DocuCareEHR)).

### KEY POINTS FOR REVIEW

- Advantages of home care include the ability to provide care to chronically ill children and women with a complication of pregnancy in a cost-effective manner while keeping families intact and encouraging them to provide meaningful comfort and support.
- Disadvantages of home care include possible fatigue for families, possible financial hardship if there is a loss of job for the primary caregiver, and social isolation and disruption of normal home life.
- Home care requires careful planning and a combined effort between healthcare providers and the family to ensure collaboration and continuity of care.
- Not all homes are ideal for home care. Assessing that a primary family care provider is present; that the family is knowledgeable about the care necessary; necessary resources are available; and safety features such as a smoke detector, a safe area for oxygen storage, and a working refrigerator for food or medicine are present are important nursing actions.
- Parents may need respite care to continue to be effective care providers for children just as professionals need time off. Help family members take turns giving care so each has some free time during the week.
- Considering a family as both a single patient and as part of a community helps in planning nursing care that meets not only QSEN competencies but also the family's total needs.

### CRITICAL THINKING CARE STUDY

Kimi Toi Hackett is a 23-year-old who just gave birth to a baby boy named Harding. She lives in a high-rise condo that was recently converted into apartments from an unused warehouse in the center of the city. Harding weighs 5.5 lb, has congenital heart disease, and will be cared for at home until he gains 5 more pounds and can

have his heart repaired. He's being breastfed; his care instructions include never letting him cry, keeping him away from people with infections, and being certain he gets adequate sleep. Kimi Toi used to be a nanny for two school-age children before she quit work to take care of Harding. Her husband works nights at the post office. Kimi calls you for advice because she doesn't know any of her neighbors and so has no one to help her keep Harding from crying. Harding sleeps instantly if she puts him in his car seat and drives around the block, but she's afraid to go into the underground parking garage at night because there's no night guard. She feels she has moved into a totally wrong community; all of her neighbors are well-to-do businessmen or retired older adults.

1. Kimi Toi feels she and her husband have made a poor choice when they chose to move into a loft. Moving to any new community can be a major adjustment for a family. What are community features this family should have investigated before they bought a loft?
2. Kimi Toi is afraid to walk down to the parking garage at night to get her car. What suggestions could you make to help Harding stop crying in place of driving him around the block?
3. The Hacketts' building was just redone so it's easy to assume their condo has all the qualities needed for home care. To be certain, what questions would you want to ask Kimi Toi about the loft?

UNIT 2

The Nursing Role in Preparing  
Families for Childbearing and  
Childrearing

## The Nursing Role in Reproductive and Sexual Health

*Suzanne and Kevin Matthews, a young adult couple, planned to have a baby as soon as they married; however, it took Suzanne 1 year before she conceived. Now, 12 weeks pregnant, she comes to your clinic for a prenatal visit. In tears, she states, “My husband isn’t interested in me anymore. We haven’t had sex since I became pregnant.” Kevin states, “I’m afraid I’ll hurt the baby.”*

*Previous chapters presented the scope of maternal and child health nursing and how the structure, function, and culture of families can have a significant impact on health. This chapter adds information about how to educate patients and their families about anatomy, physiology, and sexual health to better prepare them for childbearing and childrearing.*

**How would you counsel Suzanne and Kevin Matthews?**

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe anatomy and physiology pertinent to reproductive and sexual health.
2. Discuss 2020 National Health Goals that nurses can help the nation achieve related to reproductive health.
3. Assess a couple for anatomic and physiologic health and readiness for childbearing.
4. Assess a couple for reproductive planning and sexual health needs related to sexual orientation and gender identity if pertinent.
5. Formulate nursing diagnoses related to reproductive and sexual health.
6. Develop expected outcomes for reproductive and sexual health education to manage seamless transitions across differing healthcare settings.
7. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
8. Implement nursing care related to reproductive and sexual health, such as educating middle school children about menstruation.
9. Evaluate expected outcomes for achievement and effectiveness of care.
10. Integrate knowledge of preparation for childbearing with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

Whether or not someone is planning on childbearing, everyone is wiser for being familiar with reproductive anatomy and physiology and his or her own body's reproductive and sexual health. Patients and their partners who are planning on childbearing may become curious about reproductive physiology and the changes they will undergo during pregnancy. Patients who are pregnant are also often interested about physiologic changes, so nurses are frequently asked by both patients and their partners about reproductive and gynecologic health ([Callegari, Ma, & Schwarz, 2015](#)).

Although the general public is becoming increasingly sophisticated about their bodies because of courses in school on sexual health, misunderstandings about sexual health, conception (preventing or promoting), and childbearing still abound. When caring for children of school age or adolescence, they may ask you a variety of detailed questions about sexual or reproductive health they heard about in class but didn't really understand. For instance, many adolescents want to know more about what is a

“normal” menstrual period; late adolescents may want to know what the “normal” expected frequency is for sexual relations.

A general rule in answering a question about sexual relations is normal sexual behavior includes any act mutually satisfying to both sexual partners. Actual frequency and type of sexual activity vary widely. According to a definition by the Centers for Disease Control and Prevention (CDC, 2014), sexual health is not just an absence of disease, dysfunction, or infirmity but a condition of physical, emotional, and psychosocial well-being.

Encouraging patients to ask questions about sexual health is one of the most important contributions nurses can make. With this attitude, sexual and reproductive health problems can be openly discussed and made as solvable as other health concern. If this is an area that you were raised to not discuss freely, learning to be comfortable with the topic and your own sexuality can be the first step needed (Johnson & Williams, 2015).

A sample of 2020 National Health Goals that speak directly to improving reproductive or sexual health are shown in Box 5.1.

#### BOX 5.1

#### Nursing Care Planning Based on 2020 National Health Goals

A number of 2020 National Health Goals speak directly to reproductive and sexual health:

- Increase the proportion of adolescents who, by age 15 years, have never engaged in sexual intercourse to 80.2% of girls and 79.2% of boys from baselines 72.9% and 72.0%.
- Increase to at least 91.3% the proportion of sexually active 15- to 19-year-olds at risk for unintended pregnancy who used contraception at last sexual intercourse from a baseline of 83.0%.
- Reduce deaths from cancer of the uterine cervix to no more than 2.2 per 100,000 women, from a baseline rate of 2.4 per 100,000.
- Reduce breast cancer deaths to no more than 20.6 per 100,000 women, from a baseline rate of 22.9 per 100,000.
- Improve the health, safety, and well-being of lesbian, gay, bisexual, and transgender (LGBT) individuals (developmental goal) (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses help the nation achieve these goals by educating adolescents about abstinence as well as refusal skills, safer sex practices, and the advantage of obtaining a vaccine against human papillomavirus (HPV), the virus associated with cervical cancer. The need to participate in screening activities such as vulvar and testicular self-examination are also important to teach.

## FOR PROMOTION OF REPRODUCTIVE AND SEXUAL HEALTH

### ASSESSMENT

Problems of sexual or reproductive health may not be evident on first meeting with patients because it may be difficult for people to bring up the topic until they feel more secure with your relationship. This makes good follow-through and planning important because even if people find the courage to discuss a problem once, they may be unable to do so again. If the problem is ignored or forgotten through a change in caregivers, the problem can go unsolved.

Any change in physical appearance (such as occurs with puberty or with pregnancy) can intensify or create a sexual or reproductive concern. The person with a sexually transmitted infection (STI); excessive weight loss or gain; a disfiguring scar from surgery or an unintentional injury; hair loss such as occurs with chemotherapy; surgery, inflammation, or infection of reproductive organs; chronic fatigue or pain; spinal cord injury; or the presence of a retention catheter needs to be assessed for problems regarding sexual role as well as other important areas of reproductive functioning.

### NURSING DIAGNOSIS

Common nursing diagnoses used with regard to reproductive health include:

- Health-seeking behaviors related to reproductive functioning
- Anxiety related to inability to conceive after 6 months without contraception
- Pain related to uterine cramping from menstruation
- Disturbance in body image related to early development of secondary sex characteristics
- Risk for infection related to high-risk sexual behaviors

Diagnoses relevant to sexual health may include:

- Sexual dysfunction related to as yet unknown cause
- Altered sexuality patterns related to chronic illness
- Self-esteem disturbance related to recent reproductive tract surgery
- Altered sexuality patterns related to fear of harming a fetus
- Anxiety related to fear of contracting an STI
- Health-seeking behavior related to learning responsible sexual practices

### OUTCOME IDENTIFICATION AND PLANNING

A major part of nursing care in this area is to empower patients to feel control over their bodies. Plan health teaching to provide patients with knowledge about their reproductive system and specific information about ways to alleviate discomfort or prevent reproductive disease. It is also essential to design care that demonstrates acceptance of all sexual orientations and gender identities equally.

Turner Syndrome Society	<a href="http://www.turnersyndrome.org">www.turnersyndrome.org</a>

## **IMPLEMENTATION**

A primary nursing role concerning reproductive anatomy and physiology is education because both female and male patients may feel more comfortable asking questions of nurses rather than other healthcare providers. For example, nurses may be asked about contraception or fertility needs, STI prevention, or concerns related to congenital health conditions.

It is important to address potential concerns of patients of all sexual orientations and gender identities when providing reproductive and sexual health education. For example, include a discussion about anal or oral–genital sex practices when presenting information on safer sex.

## **OUTCOME EVALUATION**

The evaluation must be ongoing in the area of reproductive health because health education needs to change with circumstances and increased maturity. For example, the needs of a woman at the beginning of a pregnancy may be different from her needs at

the end.

How people feel about themselves sexually also changes. Their concept of themselves may have a great deal to do with how quickly they recover from an illness, how quickly they are ready to begin self-care after childbirth, or even how motivated they are as an adolescent to accomplish activities in life phases that depend on being sure of their sexuality or gender.

Examples of expected outcomes include:

- Patient states he is taking precautions to prevent contracting an STI.
- Patient states she is better able to manage symptoms of premenstrual dysphoric syndrome.
- Couple state they have achieved a mutually satisfying sexual relationship.

## Assessing and Meeting Reproductive Concerns

An assessment in the area of reproductive health begins with interviewing to determine a patient's knowledge level of the reproductive process, STIs, concerns about his or her reproductive functioning, or safer sex practices (Box 5.2). This area of health interviewing takes practice, and the conviction that exploring sexual health is as important as exploring less emotionally involved areas of health, such as dietary intake or activity level. The 14-year-old girl, who is not yet menstruating, for instance, may be anxious about that fact but may be reluctant to say so unless asked directly.

### BOX 5.2

#### Nursing Care Planning Tips for Effective Communication

Kevin brings his 16-year-old nephew, Mark, into your healthcare clinic because Mark has had painful urination for 2 days. A culture is taken to determine whether he has contracted a sexually transmitted infection (STI).

*Tip:* Ask specific, open-ended follow-up questions to ensure a positive exchange of information and effective health teaching. Remain nonjudgmental to encourage the individual to continue to elaborate. Adolescents are often so concerned about protecting their privacy from adults they may initially offer as little information as possible at a healthcare visit, especially in regard to sexual issues.

**Nurse:** Mark, because you're sexually active, your symptoms suggest you may have contracted a sexually transmitted infection.

**Mark:** Uh-huh.

**Nurse:** Do you practice safer sex?

**Mark:** Uh, yeah.

**Nurse:** What measures do you take?

**Mark:** My girlfriend's on the pill, so that's all we need to know, isn't it?

**Nurse:** Let's talk about the different kinds of protection needed to prevent pregnancy

and STIs.

A statement such as the following invites discussion: “Although many of your friends at school may be menstruating, it’s not at all uncommon for some girls not to begin their periods until age 15 or 16 years. How do you feel about not yet having your period?” This combination of providing information and while interviewing may encourage an adolescent to discuss not only her possible concern about delayed **menarche** (the beginning of menstruation) but also other areas that will reveal her knowledge or lack of knowledge about reproductive health. Specific questions to include in a sexual history are shown in [Box 5.3](#).

### BOX 5.3

#### Specific Questions to Include in a Sexual History

- Are you sexually active?
- Is your sexual partner of the same or a different gender?
- How many sexual partners have you had in the past 6 months?
- Are you satisfied with your sex life? If not, why not?
- Do you have any concerns about your sex life? If so, what are they? What would you like to change?
- What measures do you take to practice safer sex?
- For those at high risk of contracting HIV: Are you using pre-exposure prophylaxis (PrEP) to reduce your chances of HIV infection?
- Have you ever contracted a sexually transmitted infection or are you worried you have one now?
- Have you ever experienced a problem such as maintaining an erection, erectile dysfunction, failure to achieve orgasm, or pain during intercourse?
- If you’re sexually active, are you using a method to prevent pregnancy?
- Are you satisfied with your current reproductive planning method? Do you have any questions about it?
- For adolescents and women under the age of 27 years: Are you vaccinated against human papillomavirus (HPV)?

During a physical examination, it’s important to include observation for normal distribution of body hair such as triangle-shaped pubic hair in women and diamond-shaped pubic hair in men, normal genital and breast development, and signs and symptoms of STIs. Many STIs are asymptomatic, so it is important to assess whether the patient is at risk for contracting such an infection (see [Chapters 33](#) and [47](#) for documentation of stages of sexual development and signs of STIs).

To help patients better understand reproductive functioning and sexual health, specific teaching might include:

- Explaining to a school-age boy that nocturnal emissions are normal

- Teaching an early adolescent about normal anatomy and physiology and the process of reproduction
- Teaching a young adolescent safer sex practices
- Explaining reproductive physiology to a couple who wish to become pregnant

Teaching may be in response to a direct question posed by a parent (Box 5.4). It is often enhanced by the use of illustrations from books or journals, video clips, or models of internal and external reproductive organs. Nursing interventions in this area, however, should include much more than just distributing educational materials. You need to follow up by asking if the education material answered the patient's questions. In addition, offer empathy for a patient's concerns, such as a woman's worry that increased tension before menstruation is a symptom of premenstrual dysphoric syndrome, to help her validate her suspicions. Websites set up by health professionals can be an ideal method for adolescents to learn more about their bodies and safer sex practices because they can do this in a private, nonjudgmental setting (Guilamo-Ramos, Lee, Kantor, et al., 2015). Again, follow-up is important to be certain the content was understood and the adolescent didn't also visit websites with misleading information.

#### BOX 5.4

### Nursing Care Planning Based on Family Teaching

#### COMMUNICATING GENDER AND SEXUALITY TO CHILDREN

**Q.** Suzanne asks you, “Is it all right to call body parts by nicknames, such as ‘peter’ for penis, when we talk to children? Or should we use the anatomic name?”

**A.** Although this decision is strictly up to parents, using anatomic names is usually advised. This prevents children from thinking of one part of their body as so different from others (and perhaps dirty or suspect) it can't be called by its real name. Additionally, using correct names for genitalia can help the child to communicate if he or she has been a victim of sexual assault.

**Q.** Kevin asks you, “Will it be important to give our child unisex toys?”

**A.** Gender involves more than the toys children use for play. If parents are concerned about coercing children into particular gender roles through play, they need to begin by monitoring their own perspective. Once they project a feeling, roles are interchangeable, such as both genders participate in sports and both parents cook and do dishes, the general home milieu does more than any one action to teach this principle to children.

Discussing the subject of reproduction in a matter-of-fact way, or treating menstruation as a positive sign of growth in a woman rather than as a burden, can help patients assume a positive attitude about these subjects and can serve as a valuable intervention.

# Reproductive Development

Reproductive development begins at the moment of conception and continues through life.

## INTRAUTERINE DEVELOPMENT

Sex assigned at birth is generally determined at the moment of conception by chromosome information, which is supplied by the sperm that joins with the ovum to create the new life. A **gonad** is a body organ that produces the cells necessary for reproduction (the ovary in females, the testis in males). At approximately week 5 of intrauterine life, mesonephric (wolffian) and paramesonephric (müllerian) ducts, the tissue that will become ovaries and testes, have already formed. By week 7 or 8, in chromosomal males, this early gonadal tissue begins formation of testosterone. Under the influence of testosterone, the mesonephric duct develops into male reproductive organs and the paramesonephric duct regresses. If testosterone is not present by week 10, the paramesonephric duct becomes dominant and develops into female reproductive organs. When ovaries form, all of the **oocytes** (cells that will develop into eggs throughout the woman's mature years) are already present (Edmonds, 2012).

At about week 12 of intrauterine life, the external genitals begin to develop. In males, penile tissue elongates and the ventral surface of the penis closes to form a urethra. In females, with no testosterone present, the uterus, labia minora, and labia majora form. If, for some reason, testosterone secretion is halted in utero, a chromosomal male could be born with female-appearing genitalia (ambiguous genitalia). If a pregnant woman should be prescribed a form of testosterone or, because of a metabolic abnormality, she produces a high level of testosterone, a chromosomal female could be born with male-appearing genitalia (Kumar, 2012).

## PUBERTAL DEVELOPMENT

**Puberty** is the stage of life at which secondary sex changes begin. In most girls, these changes are stimulated when the hypothalamus synthesizes and releases gonadotropin-releasing hormone (GnRH), which then triggers the anterior pituitary to release follicle-stimulating hormone (FSH) and luteinizing hormone (LH). FSH and LH are termed gonadotropin (*gonad* = "ovary"; *tropin* = "growth") hormones not only because they begin the production of androgen and estrogen, which in turn initiate secondary sex characteristics, but also because they continue to cause the production of eggs and influence menstrual cycles throughout women's lives (Eggers, Ohnesorg, & Sinclair, 2014).

The mechanism that initiates this pubertal change is not well understood, but the hypothalamus apparently serves as a gonadostat or regulation mechanism to "turn on" gonad functioning. Although it is not proven, the general consensus is a girl must reach a critical weight of approximately 95 lb (43 kg) or develop a critical mass of body fat before the hypothalamus is triggered to send initial stimulation to the anterior pituitary

gland to begin the formation of FSH and LH. Probably because of the combination of better nutrition and increased obesity, girls are beginning puberty at earlier ages than ever before (8 to 11 years of age) (Maron, 2015). Studies of female athletes and girls with anorexia nervosa demonstrate that delays or halts in menstruation are related to the lack of body fat or energy expenditure (Mountjoy, Sundgot-Borgen, Burke, et al., 2014). The phenomenon of what triggers puberty is even less understood in boys but is probably also related to body weight.

There may be different needs and developmental routes for transgender individuals, whose sex assigned at birth, and gender do not match. Although this section uses gendered pronouns, it is important for nurses to be aware of resources that address transgender patient health and development needs such as [The Joint Commission's \(2011\) \*Advancing Effective Communication, Cultural Competence, and Patient- and Family-Centered Care for the Lesbian, Gay, Bisexual, and Transgender\(LGBT\) Community: A Field Guide\*](#).

### **The Role of Androgen**

Androgenic hormones are the hormones responsible for muscular development, physical growth, and the increase in sebaceous gland secretions that cause typical acne in both boys and girls during adolescence. In males, androgenic hormones are produced by the adrenal cortex and the testes and, in females, by the adrenal cortex and the ovaries.

The level of the primary androgenic hormone, testosterone, is low in males until puberty (between ages 12 and 14 years) when it rises to influence pubertal changes in the testes, scrotum, penis, prostate, and seminal vesicles; the appearance of male pubic, axillary, and facial hair; laryngeal enlargement with its accompanying voice change; maturation of spermatozoa; and closure of growth plates in long bones (termed **adrenarche**). In girls, testosterone influences enlargement of the labia majora and clitoris and the formation of axillary and pubic hair.

### **The Role of Estrogen**

When triggered at puberty by FSH, ovarian follicles in females begin to excrete a high level of the hormone estrogen. This increase influences the development of the uterus, fallopian tubes, and vagina; typical female fat distribution; hair patterns; and breast development. It also closes the epiphyses of long bones in girls the same way testosterone closes the growth plate in boys. The beginning of breast development is termed thelarche, which usually starts 1 to 2 years before menstruation.

### **Secondary Sex Characteristics**

Adolescent sexual development has been categorized into stages (Tanner, 1990). There is wide variation in the time required for adolescents to move through these developmental stages; however, the sequential order is fairly constant. In girls, pubertal

changes typically occur as:

- Growth spurt
- Increase in the transverse diameter of the pelvis
- Breast development
- Growth of pubic hair
- Onset of menstruation
- Growth of axillary hair
- Vaginal secretions

The average age at which menarche (the first menstrual period) occurs is 12.4 years of age (Ledger, 2012). It may occur as early as age 9 years or as late as age 17 years, however, and still be within a normal age range. Irregular menstrual periods are the rule rather than the exception for the first year or two. Menstrual periods do not become regular until ovulation occurs consistently, and this does not tend to happen until 1 to 2 years after menarche (see Chapter 33 for a discussion of the use of oral estrogen-based contraceptives to help regulate menstrual periods in girls). Unlike the production of ova in girls, spermatozoa in boys do not begin in intrauterine life and is not produced in a cyclic pattern; rather, they are produced in a continuous process. The production of ova stops at menopause. In contrast, sperm production continues from puberty throughout the male's life.

Secondary sex characteristics of boys usually occur in the order of:

- Increase in weight
- Growth of testes
- Growth of face, axillary, and pubic hair
- Voice changes
- Penile growth
- Increase in height
- Spermatogenesis (production of sperm)

### *QSEN Checkpoint Question 5.1*

#### **PATIENT-CENTERED CARE**

Suzanne Matthews tells the nurse she's worried she might be subfertile because both breast development and her first menstrual period occurred later than most of her friends. To increase her self-esteem and meet her learning needs, the nurse could assure her of what fact?

- a. Adrenarche, the development of breasts, typically occurs before the first menstrual period.
- b. Breast development, termed mamarche, is not fully complete until about age 25 years.
- c. The time for development of breasts varies a great deal and is termed thelarche.
- d. Menarche, the term for breast development, typically occurs before 12 years

of age.

Look in [Appendix A](#) for the best answer and rationale.

## The Male Reproductive System

Although the structures of the female and male reproductive systems differ greatly in both appearance and function, they are homologues; that is, they arise from the same or matched embryonic origin. **Andrology** is the study of the male reproductive organs. The male reproductive system consists of both external and internal divisions ([Fig. 5.1](#)).

**Figure 5.1** The male internal and external reproductive organs.

### MALE EXTERNAL STRUCTURES

External genital organs of the male include the testes (which are encased in the scrotal sac) and the penis.

#### The Scrotum

The scrotum is a rugated, skin-covered, muscular pouch suspended from the perineum. Its functions are to support the testes and help regulate the temperature of sperm. In very cold weather, the scrotal muscle contracts to bring the testes closer to the body. In very hot weather, or in the presence of fever, the muscle relaxes, allowing the testes to fall away from the body. In this way, the temperature of the testes can remain as even as possible to promote the production and viability of sperm.

## The Testes

The testes are two ovoid glands, 2 to 3 cm wide, that rest in the scrotum. Each testis is encased by a protective white fibrous capsule and is composed of a number of lobules. Each lobule contains interstitial cells (Leydig cells) that produce testosterone and a seminiferous tubule that produces spermatozoa.

Testes in a fetus first form in the pelvic cavity and then descend late in intrauterine life (about the 34th to 38th week of pregnancy) into the scrotal sac. Because this descent occurs so late in pregnancy, many male infants born preterm still have undescended testes. These infants need to be monitored closely to be certain their testes do descend at what would have been the 34th to 38th week of gestational age because testicular descent does not occur as readily in extrauterine life as it does in utero. Testes that remain in the pelvic cavity (cryptorchidism) may not produce viable sperm and have a four to seven times increased rate of testicular cancer ([Fantasia, Aidlen, Lathrop, et al., 2015](#)).

Although spermatozoa are produced in the testes, they reach maturity through a complex sequence of events. First, the hypothalamus releases GnRH, which in turn influences the anterior pituitary gland to release FSH and LH, the same as in women. FSH in men is responsible for the release of androgen-binding protein (ABP). LH is responsible for the release of testosterone from the testes. ABP and testosterone then combine to promote sperm formation. When the production of testosterone reaches a peak amount, a feedback effect on the hypothalamus and anterior pituitary gland is created, which slows the production of FSH and LH and ultimately decreases or regulates sperm production.

In most males, one testis is slightly larger than the other and is suspended slightly lower in the scrotum than the other (usually the left one). Because of this, testes tend to slide past each other more readily on sitting or muscular activity, and there is less possibility of trauma to them. Most body structures of importance are more protected than the testes (e.g., the heart is surrounded by ribs of hard bone). However, spermatozoa do not survive at a temperature as high as that of the internal body, so the location of the testes outside the body, where the temperature is about 1°F lower than body temperature, provides protection for sperm survival ([Huether & McCance, 2012](#)).

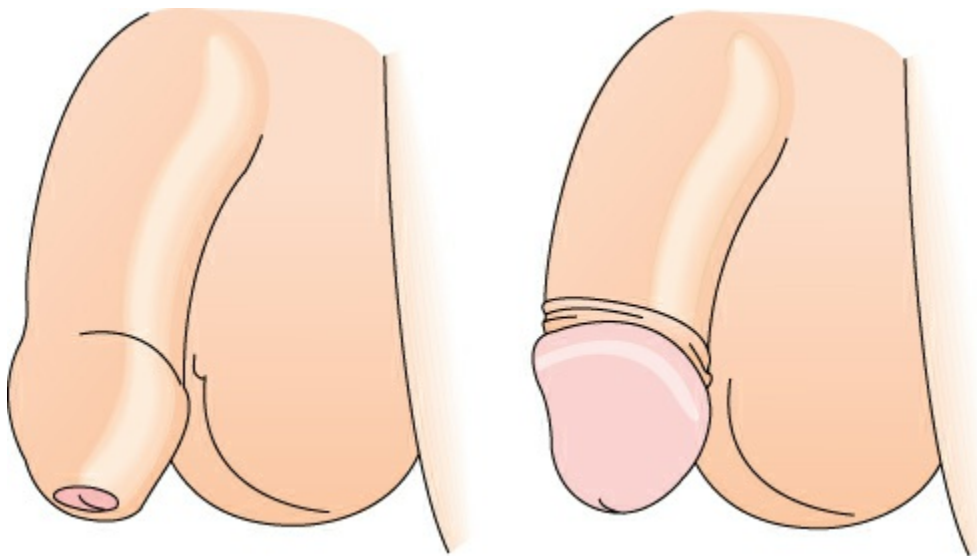

Normal testes feel firm and smooth and are egg shaped. Beginning in early adolescence, boys need to learn testicular self-examination so they can detect tenderness or any abnormal growth in testes (see [Chapter 34](#)).

## The Penis

The penis is composed of three cylindrical masses of erectile tissue in the penis shaft. The urethra passes through these layers of tissue, allowing the penis to serve as both the outlet for the urinary and reproductive tracts in men. With sexual excitement, nitric oxide is released from the endothelium of blood vessels. This causes dilation and an increase in blood flow to the arteries of the penis (engorgement). The ischiocavernosus

muscle at the base of the penis, under stimulation of the parasympathetic nervous system, then contracts, trapping both venous and arterial blood in the three sections of erectile tissue. This leads to distention (and erection) of the penis.

At the distal end of the organ is a bulging, sensitive ridge of tissue called the glans. A retractable casing of skin, the prepuce, protects the nerve-sensitive glans at birth. Based on religious or cultural beliefs, many male infants have the prepuce tissue removed surgically (circumcision) shortly after birth (Fig. 5.2). Although controversial to some, the American Academy of Pediatrics (AAP) advises that the health benefits of male circumcision outweigh its medical risks; however, the benefits are not strong enough to recommend every male newborn be circumcised. The AAP advises that circumcision decisions should be made in consultation with parents with consideration of their cultural or religious beliefs. Its advantages allow for lower rates of urinary tract infections, HIV, STIs, and penile cancer. Its disadvantages include surgical complications, such as bleeding and pain, and reduction of sensation with sexual stimulation (AAP, 2012; Bossio, Pukall, & Steele, 2014).

**Figure 5.2** An uncircumcised and a circumcised penis.

## MALE INTERNAL STRUCTURES

The male internal reproductive organs are the epididymis, the vas deferens, the seminal vesicles, the ejaculatory ducts, the prostate gland, the urethra, and the bulbourethral glands (see Fig. 5.1).

### The Epididymis

The seminiferous tubule of each testis leads to a tightly coiled tube, the epididymis, which is responsible for conducting sperm from the tubule to the vas deferens, the next step in the passage to the outside. Because each epididymis is so tightly coiled, its length is extremely deceptive: It is actually over 20 ft long. Some sperm are stored in the epididymis, and a part of the alkaline fluid (semen, or seminal fluid that contains a

basic sugar and protein) that will surround sperm at maturity is produced by the cells lining the epididymis.

Sperm are immobile and incapable of fertilization as they pass through or are stored at the epididymis level. It takes at least 12 to 20 days for them to travel the length of the tube and a total of 65 to 75 days for them to reach full maturity. This is one reason that **aspermia** (absence of sperm) and oligospermia (fewer than 20 million sperm per milliliter) do not appear to respond immediately to therapy but do respond after 2 months of treatment (Tortora & Derrickson, 2014).

### **The Vas Deferens (Ductus Deferens)**

The vas deferens is an additional hollow tube surrounded by arteries and veins and protected by a thick fibrous coating. Altogether, these structures are referred to as the **spermatic cord**. It carries sperm from the epididymis through the inguinal canal into the abdominal cavity, where it ends at the seminal vesicles and the ejaculatory ducts below the bladder. Sperm complete maturation as they pass through the vas deferens. They are still not mobile at this point, however, probably because of the fairly acidic medium of semen.

### **The Seminal Vesicles**

The seminal vesicles are two convoluted pouches that lie along the lower portion of the bladder and empty into the urethra by ejaculatory ducts. These glands secrete a viscous alkaline liquid with a high sugar, protein, and prostaglandin content. Sperm become increasingly motile because this added fluid surrounds them with a more favorable pH environment.

### **The Prostate Gland**

The prostate is a chestnut-sized gland that lies just below the bladder and allows the urethra to pass through the center of it, like the hole in a doughnut. The gland's purpose is to secrete a thin, alkaline fluid, which, when added to the secretion from the seminal vesicles, further protects sperm by increasing the naturally low pH level of the urethra.

### **The Bulbourethral Glands**

Two bulbourethral, or Cowper's, glands lie beside the prostate gland and empty by short ducts into the urethra. They supply one more source of alkaline fluid to help ensure the safe passage of spermatozoa. Semen, therefore, is derived from the prostate gland (60%), the seminal vesicles (30%), the epididymis (5%), and the bulbourethral glands (5%).

### **The Urethra**

The urethra is a hollow tube leading from the base of the bladder, which, after passing

through the prostate gland, continues to the outside through the shaft and glans of the penis. It is about 8 in. (18 to 20 cm) long. Like other urinary tract structures, it is lined with mucous membrane.

### *QSEN Checkpoint Question 5.2*

#### **QUALITY IMPROVEMENT**

Suppose Kevin Matthews tells the nurse he is planning on having a vasectomy after the birth of his new child but is worried about having his testes removed this way. The nurse would want the clinic's educational material on vasectomy to clearly state that this procedure involves which of the following structures?

- The seminal vesicles
- The epididymis
- The vas deferens
- The ducts of the bulbourethral glands

*Look in [Appendix A](#) for the best answer and rationale.*

## **The Female Reproductive System**

The female reproductive system, like the male, has both external and internal components. The study of the female reproductive organs is **gynecology**.

### **FEMALE EXTERNAL STRUCTURES**

The structures that form the female external genitalia are termed the vulva (from the Latin word for “covering”) and are illustrated in [Figure 5.3](#).

**Figure 5.3** The female external genitalia.

### **The Mons Veneris**

The mons veneris is a pad of adipose tissue located over the symphysis pubis, the pubic bone joint. Covered by a triangle of coarse, curly hairs, the purpose of the mons veneris is to protect the junction of the pubic bone from trauma.

### **The Labia Minora**

Immediately posterior to the mons veneris spread two hairless folds of connective tissue, the labia minora. Before menarche, these folds are fairly thin; by childbearing age, they have become firm and full; and after menopause, they atrophy and again become much smaller. Normally, the folds of the labia minora are pink in color; the internal surface is covered with mucous membrane, and the external surface is covered with skin. The area is abundant with sebaceous glands, so localized sebaceous cysts may occur here. Women who perform monthly vulvar examinations are able to detect infection or other abnormalities of the vulva such as sebaceous cysts or herpes lesions.

### **The Labia Majora**

The labia majora are two folds of tissue, fused anteriorly but separated posteriorly, which are positioned lateral to the labia minora and composed of loose connective tissue covered by epithelium and pubic hair. The labia majora serve as protection for the external genitalia; they shield the outlets to the urethra and vagina. Trauma to the area, such as occurs from childbirth or rape, can lead to extensive edema formation because of the looseness of the connective tissue base.

### **Other External Organs**

The *vestibule* is the flattened, smooth surface inside the labia. The openings to the bladder (the urethra) and the uterus (the vagina) both arise from this space. The *clitoris* is a small (approximately 1 to 2 cm), rounded organ of erectile tissue at the forward junction of the labia minora. It's covered by a fold of skin, the prepuce; is sensitive to touch and temperature; and is the center of sexual arousal and orgasm in a woman. Arterial blood supply for the clitoris is plentiful. When the ischiocavernosus muscle surrounding it contracts with sexual arousal, the venous outflow for the clitoris is blocked and this leads to clitoral erection.

In nations which allow it, young girls approaching puberty may be circumcised or have their clitoris removed with the labia minora excised as well. Aside from being a very painful procedure, female circumcision can lead to contractions and scarring of the vulva that make vaginal childbirth difficult because the vagina is unable to expand with birth (Nour, 2015).

Two Skene glands (paraurethral glands) are located on each side of the urinary meatus; their ducts open into the urethra. Bartholin glands (vulvovaginal glands) are located on each side of the vaginal opening with ducts that open into the proximal vagina near the labia minora and hymen. Secretions from both of these glands help to lubricate the external genitalia during coitus. The alkaline pH of their secretions also

helps to improve sperm survival in the vagina. If the Skene glands or the Bartholin glands (the most common site) become infected, they swell, feel tender, and produce a serous discharge.

The *fourchette* is the ridge of tissue formed by the posterior joining of the labia minora and the labia majora. This is the structure that sometimes tears (laceration) or is cut (episiotomy) during childbirth to enlarge the vaginal opening.

Posterior to the fourchette is the perineal muscle (often called the perineal body). Because this is a muscular area, it stretches during childbirth to allow enlargement of the vagina and passage of the fetal head. Many exercises suggested for pregnancy (such as Kegel exercises, squatting, and tailor sitting) are aimed at making the perineal muscle as flexible as it can be to allow for optimal expansion during birth and to prevent tearing of this tissue.

The *hymen* is a tough but elastic semicircle of tissue that covers the opening to the vagina during childhood. It is often torn during the time of first sexual intercourse. However, because of the use of tampons and active sports participation, many girls who have not had sexual relations can also have torn hymens at the time of their first pelvic examination. Occasionally, a girl has an imperforate hymen, or a hymen so complete that it does not allow for the passage of menstrual blood from the vagina (hematocolpometra) or for sexual relations until it is surgically incised (Fischer & Kwan, 2014).

### **The Vulvar Blood Supply**

The blood supply of female external genitalia is mainly from the pudendal artery and a portion is from the inferior rectus artery. Venous return is through the pudendal vein. Pressure on this vein by the fetal head during pregnancy can cause extensive back pressure and development of varicosities (distended veins) in the labia majora and in the legs. A disadvantage of this rich blood supply is that trauma to the area, such as occurs from pressure during childbirth or a bicycle seat injury, can cause large hematomas. An advantage is that it contributes to the rapid healing of any tears in the area after childbirth or other injury (Huether & McCance, 2012).

### **The Vulvar Nerve Supply**

The anterior portion of the vulva derives its nerve supply from the ilioinguinal and genitofemoral nerves (L1 level). The posterior portions of the vulva and vagina are supplied by the pudendal nerve (S3 level). Such a rich nerve supply makes the area extremely sensitive to touch, pressure, pain, and temperature. Luckily, at the time of birth, normal stretching of the perineum causes a temporary loss of sensation to the area, limiting the amount of local pain felt during childbirth.

## **FEMALE INTERNAL STRUCTURES**

Female internal reproductive organs (Fig. 5.4) include the ovaries, the fallopian tubes,

the uterus, and the vagina.

**Figure 5.4** The female internal reproductive organs.

## The Ovaries

The ovaries are approximately 3 cm long by 2 cm in diameter and 1.5 cm thick, or the size and shape of almonds. They are grayish-white and appear pitted, with minute indentations on the surface.

The ovaries are located close to and on both sides of the uterus in the lower abdomen. Normally, they lie so low they cannot be located by abdominal palpation. Only if an abnormality exists, such as an enlarging ovarian cyst, can the resulting tenderness and enlargement be evident on lower left or lower right abdominal palpation.

The function of the two ovaries is to produce, mature, and discharge ova (the egg cells). In the process of producing ova, the ovaries also produce estrogen and progesterone and initiate and regulate menstrual cycles. If the ovaries are removed before puberty (or are nonfunctional), the resulting absence of estrogen normally produced by the ovaries prevents maturation and maintenance of secondary sex characteristics; in addition, pubic hair distribution will assume a more male than female pattern.

The ovaries are held suspended and in close contact with the ends of the fallopian tubes by three strong ligaments that attach both to the uterus and the pelvic wall. Ovaries are unique among pelvic structures in that they are not covered by a layer of peritoneum. Because they are not covered this way, ova can readily escape from them and enter the uterus by way of the fallopian tubes. Because they are suspended in position rather than being firmly fixed, an abnormal tumor or cyst growing on them can enlarge to a size easily twice that of the organ before pressure on surrounding organs or

the ovarian blood supply leads to symptoms of compression. This is the reason ovarian cancer continues to be one of the leading causes of death from cancer in women (the tumor can grow without symptoms for an extended period) (Sundar, Neal, & Kehoe, 2015).

### The Division of Reproductive Cells (Gametes)

At birth, each ovary contains approximately 2 million immature ova (oocytes), which were formed during the first 5 months of intrauterine life. Although these cells have the unique ability to produce a new individual, they basically contain the usual components of cells: a cell membrane, an area of clear cytoplasm, and a nucleus that contains chromosomes.

One way they do differ from all other body cells is in the number of chromosomes their nuclei contain. All other human cells have 46 chromosomes: 22 pairs of autosomes (paired matching chromosomes) and 1 pair of sex chromosomes (two X sex chromosomes in the female and an X and a Y sex chromosome pair in the male). In contrast to this, reproductive cells (both ova and spermatozoa) have only half the usual number of chromosomes. This is so that, when sperm and egg combine (fertilization), the new individual formed will not have twice the needed number but, rather, 46 chromosomes. The manner in which reproductive cells divide causes this change in chromosome number.

Other cells in the body undergo cell division by *mitosis*, or daughter cell division; prior to a point of division, all the chromosomes are duplicated, leaving both new daughter cells with the right number of chromosomes.

In intrauterine life, oocytes divide by one typical mitotic division. Division activity then halts until puberty, when a second type of cell division, *meiosis* (cell reduction division), occurs. In the male, this reduction division occurs just before the spermatozoa mature. In the female, it occurs just before ovulation. After this reduction division, a typical ovum will have 22 autosomes and an X sex chromosome; a spermatozoon will have 22 autosomes and either an X or a Y sex chromosome. A new individual formed from the union of an ovum and the X-carrying spermatozoon will be female (an XX chromosome pattern); an individual formed from the union of an ovum and the Y-carrying spermatozoon will be male (an XY chromosome pattern).

### The Maturation of Oocytes

Between 5 and 7 million ova form in utero. Most never develop beyond a primitive state and then atrophy, so by birth, only about 2 million are still present. By age 7 years, only about 500,000 are present in each ovary; by 22 years of age, the count is down to 300,000; and by menopause, or the end of the fertile period in females, none are left (all have either matured or atrophied).

## The Fallopian Tubes

The fallopian tubes arise from each upper corner of the uterine body and extend outward and backward until each opens at its distal end, next to an ovary. Fallopian tubes are approximately 10 cm long in a mature woman. Their function is to convey the ovum from the ovaries to the uterus and to provide a place for fertilization of the ovum by sperm.

Although a fallopian tube is a smooth, hollow tunnel, it is anatomically divided into four separate parts (Fig. 5.5).

- The most proximal division, the interstitial portion, is the part of the tube that lies within the uterine wall. This portion is only about 1 cm in length; its lumen is only 1 mm in diameter.
- The next distal portion is the isthmus. This is about 2 cm in length and, like the interstitial tube, remains extremely narrow. This is the portion of the tube that is cut or sealed in a tubal ligation, or tubal sterilization procedure.
- The ampulla is the third and also the longest portion of the tube. It is about 5 cm in length and is the portion of the tube where fertilization of an ovum usually occurs.
- The infundibular portion is the most distal segment of the tube. It is about 2 cm long, funnel shaped, and covered by fimbria (small hairs) that help to guide the ovum into the fallopian tube.

**Figure 5.5** An anterior view of female reproductive organs showing the relationship of the fallopian tubes and body of the uterus.

The lining of the fallopian tubes is composed of a mucous membrane, which contains both mucus-secreting and ciliated (hair-covered) cells. Beneath this mucous lining are connective tissue and a circular muscle layer. The muscle layer is important because it is able to produce peristaltic motions that help conduct the ovum the length of

the tube (probably also aided by the action of the ciliated lining and the mucus, which acts as a lubricant). The mucus produced may also serve as a source of nourishment for the fertilized egg because it contains protein, water, and salts.

Because the fallopian tubes are open at their distal ends, a direct pathway exists from the external genital organs, through the vagina to the uterus and tubes, to the peritoneum. This open pathway is what makes conception possible. It also, however, can lead to infection of the peritoneum (peritonitis) if germs spread from the perineum through the uterus and tubes to the pelvic cavity. For this reason, clean technique must be used during pelvic examinations. During labor and birth, vaginal examinations are done with sterile technique to ensure no organisms can enter by this route.

## The Uterus

The uterus is a hollow, muscular, pear-shaped organ located in the lower pelvis, posterior to the bladder and anterior to the rectum. During childhood, it is about the size of an olive; the cervix is the largest portion and the uterine body is the smallest part. When a girl reaches about 8 years of age, an increase in the size of the organ begins. This growth is so slow, however, the young woman is closer to 17 years old before the uterus reaches its adult size and changes its proportions so that the body cavity, not the cervix, is its largest portion. Small uterine size may be a contributing factor to the number of low-birth-weight babies typically born to adolescents younger than this age ([March of Dimes Foundation, 2012](#)).

With maturity, a uterus is about 5 to 7 cm long, 5 cm wide, and, in its widest upper part, 2.5 cm deep. In a nonpregnant state, it weighs approximately 60 g. The function of the uterus is to receive the ovum from the fallopian tube; provide a place for implantation and nourishment; furnish protection to a growing fetus; and, at maturity of the fetus, expel it from a woman's body. After a pregnancy, the uterus never returns to exactly its nonpregnant size but remains approximately 9 cm long, 6 cm wide, 3 cm thick, and 80 g in weight.

Anatomically, the uterus consists of three divisions: the body or corpus, the isthmus, and the cervix.

- The body of the uterus is the uppermost part and forms the bulk of the organ. The lining of the cavity is continuous with the fallopian tubes, which enter at its upper aspects (the cornua). The portion of the uterus between the points of attachment of the fallopian tubes is termed the fundus. During pregnancy, the body of the uterus is the portion of the structure that expands to contain the growing fetus. The fundus is the portion that can be palpated abdominally to determine the amount of uterine growth during pregnancy, to measure the force of uterine contractions during labor, and to assess that the uterus is returning to its nonpregnant state after childbirth.
- The isthmus is a short segment between the body and the cervix. In the nonpregnant uterus, it is only 1 to 2 mm in length. During pregnancy, this portion also enlarges greatly to aid in accommodating the growing fetus. It is the portion

where the incision most commonly is made when a fetus is born by a cesarean birth.

- The cervix is the lowest portion of the uterus. It represents about one third of the total uterine size and is approximately 2 to 5 cm long. About half of it lies above the vagina and half extends into the vagina. Its central cavity is termed the cervical canal. The opening of the canal at the junction of the cervix and isthmus is the internal cervical os; the distal opening to the vagina is the external cervical os. The level of the external os is at the level of the ischial spines (an important relationship in estimating the level of the fetus in the birth canal at the time of birth).

## Uterine and Cervical Coats

The uterine wall consists of three separate coats or layers of tissue:

- The endometrium, an inner layer of mucous membrane
- The myometrium, a middle layer of muscle fibers
- The perimetrium, an outer layer of connective tissue

The endometrium layer of the uterus consists of two layers of cells and is the one important for menstrual function. The cell layer closest to the uterine wall, the basal layer, remains stable, uninfluenced by hormones. In contrast, the inner glandular layer is dramatically influenced by both estrogen and progesterone. It grows and becomes so thick and responsive each month under the influence of estrogen and progesterone that it becomes capable of supporting a pregnancy. If pregnancy does not occur, this is the layer that is shed as the menstrual flow.

The mucous membrane that lines the cervix is termed the endocervix. Continuous with the endometrium, these cells are also affected by hormones, although their changes are more subtle. A responsibility of such cells is to secrete mucus to provide an alkaline, lubricated surface to reduce the acidity of the upper vagina and to aid the passage of spermatozoa through the cervix; the efficiency of this lubrication increases or wanes depending on hormone stimulation. At the point in the menstrual cycle when estrogen production is at its peak, as many as 700 ml of mucus per day are produced; at the point estrogen is at its lowest level, only a few milliliters are produced. During pregnancy, so much mucus is produced, the endocervix becomes plugged with mucus, forming a seal to keep out ascending infections (the operculum).

Both the lower outer surface of the cervix and the internal cervical canal are lined not with a mucous membrane but with a stratified squamous epithelium, similar to that lining the vagina. Locating the point at which this tissue changes from epithelium to mucous membrane (squamocolumnar junction) is important when obtaining a Papanicolaou smear (a test for cervical cancer) because this tissue interface is most dynamic in cellular growth and is often the origin of cervical cancer ([Gueye & Diaz-Montes, 2015](#)).

The myometrium, or muscle layer of the uterus, is composed of three interwoven layers of smooth muscle, the fibers of which are arranged in longitudinal, transverse,

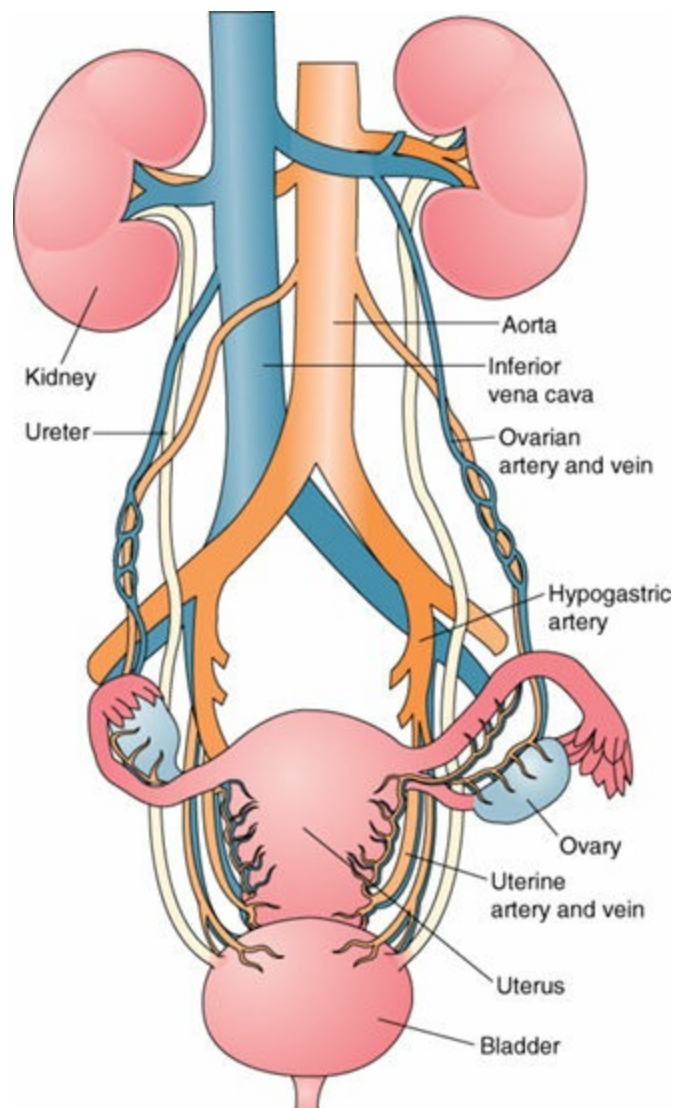

and oblique directions. This intertwining network of fibers is what offers extreme strength to the organ so when the uterus contracts at the end of pregnancy to expel the fetus, equal pressure is exerted at all points throughout the cavity. Another function of the myometrium is to constrict the fallopian tubes at the point they enter the fundus, preventing regurgitation of menstrual blood into the tubes. The myometrium also holds the internal cervical os closed during pregnancy to prevent a preterm birth. After childbirth, the interlacing network of fibers is able to constrict the blood vessels coursing through the layers, thereby limiting the amount of blood loss. Myomas, or benign fibroid (leiomyoma) tumors that can interfere with conception or birth, arise from the myometrium (Huether & McCance, 2012).

The purpose of the perimetrium, the outermost layer of the uterus, is to add further strength and support to the organ.

### Uterine Blood Supply

The large descending abdominal aorta divides to form two iliac arteries; these then form the hypogastric arteries and the uterine arteries, which supply the uterus (Fig. 5.6).

Because the uterine blood supply is not far removed from the aorta this way, it is guaranteed to be copious and adequate to supply the growing needs of a fetus. As an additional guarantee that enough blood will be available, after supplying the ovaries with blood, the ovarian artery (a direct subdivision of the aorta) joins the uterine artery and adds more blood to the uterus.

**Figure 5.6** Blood supply to the uterus.

The blood vessels that supply the cells and lining of the uterus look tortuous against the sides of the uterine body in nonpregnant women. As a uterus enlarges with pregnancy, the vessels “unwind” and stretch as another guarantee that the uterus will maintain an adequate blood supply as the organ grows larger. The uterine veins follow the same twisting course as the arteries; they empty into the internal iliac veins.

An important organ relationship to be aware of is the close proximity of uterine blood vessels and ureters. Ureters pass from the kidneys on their way to the bladder directly behind the ovarian vessels, near the fallopian tubes (see [Fig. 5.5](#)). This close anatomic relationship has implications in procedures such as tubal ligation, cesarean birth, and hysterectomy (removal of the uterus) because a ureter this close to the fallopian tubes can be injured if bleeding during surgery is controlled by clamping of the uterine or ovarian vessels. This is a reason a first voiding after uterine or tubal surgery is measured and assessed carefully for color or the presence of blood.

### Uterine Nerve Supply

The uterus is supplied by both efferent (motor) and afferent (sensory) nerves. The efferent nerves arise from the T5 through T10 spinal ganglia. The afferent nerves join the hypogastric plexus and enter the spinal column at T11 and T12. The fact that sensory innervation from the uterus registers lower in the spinal column than does motor control has implications for controlling pain in labor. An anesthetic solution can be injected to stop the pain of uterine contractions at the T11 and T12 levels without stopping motor control or contractions (which are registered higher, at the T5 to T10 level). This is the principle of both epidural and spinal anesthesia (see [Chapter 16](#)).

## Uterine Supports

The uterus is suspended in the pelvic cavity by a number of ligaments that also help support the bladder; it is further supported by a combination of fascia and muscle. Because the uterus is suspended this way, it is free to enlarge without discomfort during pregnancy. If its ligaments become overstretched during pregnancy, however, they may not support the bladder well afterward, and the bladder can then herniate into the anterior vagina (a **cystocele**), possibly causing frequent urinary infections from status of urine ([Fig. 5.7A](#)). If the rectum pouches into the vaginal wall, a **rectocele** ([Fig. 5.7B](#)) develops, possibly leading to constipation ([Podzemny, Pescatori, & Pescatori, 2015](#)).

**Figure 5.7** (A) A cystocele. The bladder has herniated into the anterior wall of the vagina. (B) A rectocele. The posterior of the vagina is herniated.

A fold of peritoneum behind the uterus is the posterior ligament. This forms a pouch (Douglas cul-de-sac) between the rectum and uterus. Because this is the lowest point of the pelvis, any fluid (such as blood) released from a condition, such as a ruptured tubal (ectopic) pregnancy, tends to collect in this space. The space can be examined for the presence of fluid or blood to help in diagnosis by inserting a culdoscope through the posterior vaginal wall (**culdoscopy**) or a laparoscope through the abdominal wall (**laparoscopy**) ([Sholapurkar, 2015](#)).

The *broad ligaments* are two folds of peritoneum that cover the uterus in the front and back and extend to the pelvic sides to help steady the uterus. The *round ligaments*

are two fibrous, muscular cords that pass from the body of the uterus through the broad ligaments and down into the inguinal canal, inserting into the fascia of the vulva. The round ligaments act as additional “stays” to further steady the uterus. If a pregnant woman moves quickly, she may pull one of these ligaments, causing a quick, sharp pain of frightening intensity in one of her lower abdominal quadrants. Pain of this type calls for conscientious assessment or it can be mistaken for labor or appendicitis pain.

### *What If . . . 5.1*

**Suzanne Matthews decides to have a tubal ligation (clamping of the fallopian tubes) after the birth of her baby. The nurse notices the first time she voids following surgery that her urine looks blood tinged. Would the nurse assume the urine was contaminated by vaginal secretions so its appearance is innocent? Or would the nurse report this as a potentially serious finding (her surgery was on her reproductive, not her urinary, system)?**

## Uterine Deviations

A number of uterine deviations (i.e., shape and position) can interfere with fertility or pregnancy and so are helpful to recognize. When a uterus first forms in intrauterine life, it is split by a longitudinal septum into two portions. As the fetus matures, this septum dissolves, so, typically at birth, no remnant of the division remains. In some women, half of the septum or even the entire septum never atrophies, so the uterus remains as two separate compartments. Still, other women have oddly shaped “horns” at the junction of the fallopian tubes—a **bicornuate uterus**. Any of these malformations may decrease the ability to conceive or to carry a pregnancy to term (Owens & Green, 2015). Some examples of these types of uterine formation are shown in Figure 5.8. The specific effects of these deviations on fertility and pregnancy are discussed in later chapters.

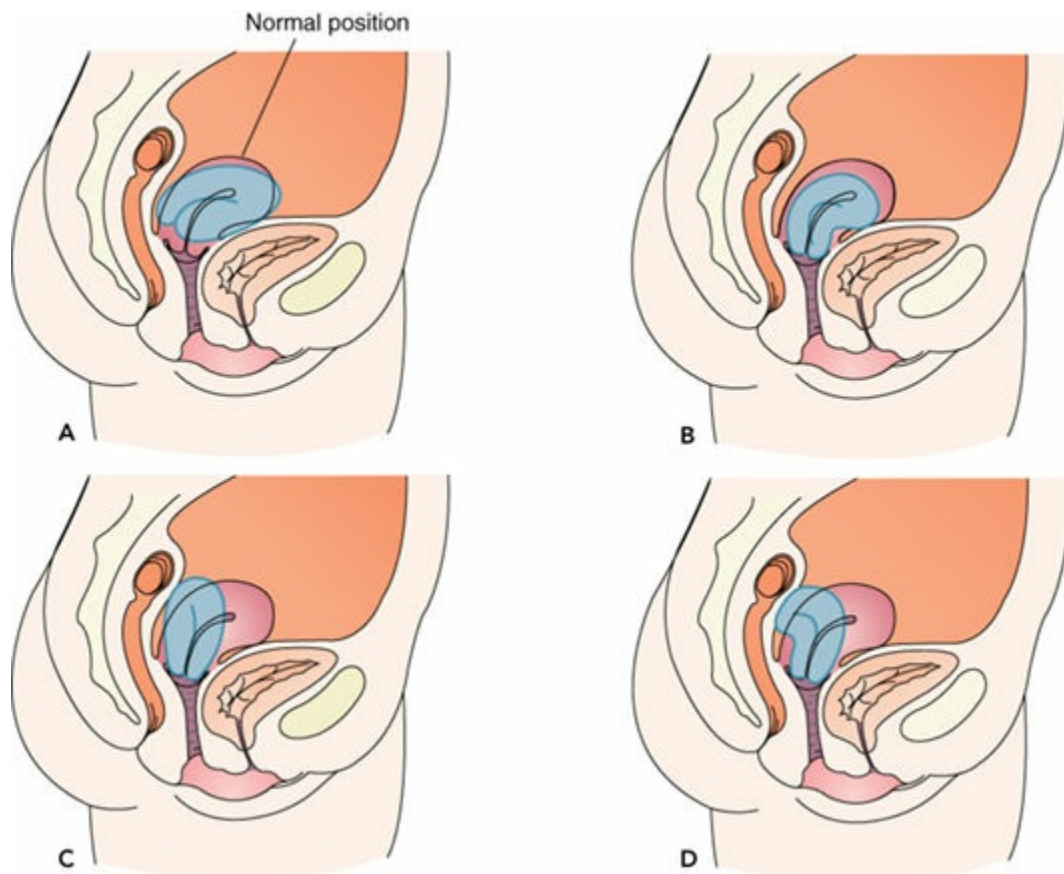

**Figure 5.8** (A) A normal uterus. (B) A bicornuate uterus. (C) A septum-dividing uterus. (D) A double uterus. Abnormal shapes of

uterus allow less placenta implantation space.

Ordinarily, the body of the uterus tips slightly forward. Positional deviations of the uterus that are commonly seen include (Fig. 5.9):

- **Anteversio**n: The entire uterus tips far forward.
- **Retroversio**n: The entire uterus tips far back.
- **Anteflexio**n: The body of the uterus is bent sharply forward at the junction with the cervix.
- **Retroflexio**n: The body of the uterus is bent sharply back just above the cervix.

**Figure 5.9** Uterine flexion and version. (A) Anteversion. (B) Anteflexion. (C) Retroversion. (D) Retroflexion.

Minor variations of these positions do not tend to cause reproductive problems. Extreme abnormal flexion or version positions may interfere with fertility because the sharp bend can block the deposition or migration of sperm.

## The Vagina

The vagina is a hollow, musculomembranous canal located posterior to the bladder and anterior to the rectum. It extends from the cervix of the uterus to the external vulva. Its function is to act as the organ of intercourse and to convey sperm to the cervix. With childbirth, it expands to serve as the birth canal.

### Concept Mastery Alert

Even though the vagina opens to the outside, it is considered an internal reproductive organ.

When a woman lies on her back, as she does for a pelvic examination, the course of the vagina is inward and downward. Because of this downward slant and the angle of the uterine cervix, the length of the anterior wall of the vagina is about 6 to 7 cm and the length of the posterior wall is 8 to 9 cm. At the cervical end of the structure, there are recesses on all sides, termed the posterior, anterior, and lateral fornices. The posterior fornix serves as a place for the pooling of semen after coitus; this allows for a large number of sperm to remain close to the cervix and encourages sperm migration into the cervix.

The vaginal wall is so thin at the fornices that an examiner can palpate the bladder through the anterior fornix, the ovaries through the lateral fornices, and the rectum through the posterior fornix.

The vagina is lined with stratified squamous epithelium similar to that covering the cervix. Under this, it has a middle connective tissue layer and a strong muscular wall. Normally, the walls contain many folds or rugae that lie in close approximation to each other. These folds make the vagina very elastic and able to expand so much that at the end of pregnancy, a full-term baby can pass through without tearing. A circular muscle at the external opening of the vagina, called the bulbocavernosus muscle, acts as a voluntary sphincter. Relaxing and tensing this external vaginal sphincter muscle a set number of times each day (Kegel exercises) makes it more supple for birth and helps maintain tone after birth.

The blood supply to the vagina is furnished by the vaginal artery, a branch of the internal iliac artery. Vaginal tears at childbirth tend to bleed profusely because of this rich blood supply. The same rich blood supply, however, is also the reason any vaginal trauma at birth heals rapidly.

The vagina has both sympathetic and parasympathetic nerve innervations originating at the S1–S3 levels. Despite this dual nerve supply, the vagina is not an extremely sensitive organ. Sexual excitement, often attributed to a vaginal origin, is actually mainly a clitoral function.

Mucus produced by the vaginal lining has a rich glycogen content. When this glycogen is broken down by the lactose-fermenting bacteria that frequent the vagina (*Döderlein bacillus*), lactic acid is formed. This causes the usual pH of the vagina to be acidic, a condition detrimental to the growth of pathologic bacteria, so even though the vagina connects directly to the external surface, infection of the vagina does not readily occur. You can advise women not to use vaginal douches or sprays as a daily hygiene measure so they do not clear away this natural acidic medium because this would invite infection (Sheth & Keller, 2015).

### TEAMWORK & COLLABORATION

On physical examination, Suzanne Matthews is found to have a cystocele. The nurse should confirm that the vocational nurse who is contributing to Suzanne's care knows that a cystocele can cause which of the following?

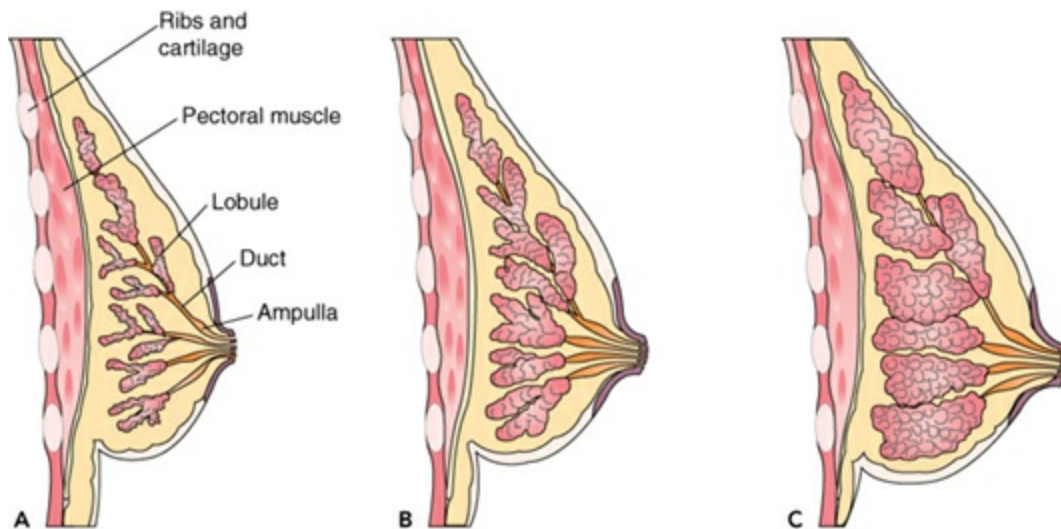

- a. A fear of developing cancer from the sebaceous vulvar cyst that develops
- b. Nagging pain from protrusion of the lower intestine into the posterior vagina
- c. Bleeding from the prolapse of the uterine body and cervix into the distal vagina
- d. Urinary infection from the pocket caused by pressure against the anterior vaginal wall

*Look in [Appendix A](#) for the best answer and rationale.*

### The Breasts

The mammary glands, or breasts, form early in intrauterine life. They then remain in a halted stage of development until a rise in estrogen at puberty causes them to increase in size. This increase occurs mainly because of growth of connective tissue plus deposition of fat. The glandular tissue of the breasts, necessary for successful breastfeeding, remains undeveloped until a first pregnancy begins. Boys, especially those who are obese, may notice a temporary increase in breast size at puberty, termed **gynecomastia** (Narula & Carlson, 2014). If boys are not prepared that this is a normal change of puberty, they may be concerned that they are developing abnormally.

Breasts are located anterior to the pectoral muscle (Fig. 5.10), and, in many women, breast tissue extends well into the axilla. When palpating for breast health, always include the axillary region in the examination, or this breast tissue can be missed. It is not uncommon for women or men to have supernumerary breast tissue along mammary lines on the front of their body. The nipple on these auxiliary sites may look like a mole, so adolescents may report this as a "mole changing in color" or be concerned they have skin cancer. You can assure them supernumerary breast tissue or nipples are not uncommon and are innocent findings.

**Figure 5.10** Anatomy of the breast. **(A)** Nonpregnant. **(B)** Pregnant. **(C)** During lactation.

Women should be aware of the usual appearance of their breasts (breast awareness) so they can report any change in contour or density to their healthcare provider.

Milk glands of the breasts are divided by connective tissue partitions into approximately 20 lobes. All of the glands in each lobe produce milk by acinar cells and deliver it to the nipple via a lactiferous duct. The nipple has approximately 20 small openings through which milk is secreted. An ampulla portion of the duct, located just posterior to the nipple, serves as a reservoir for milk before breastfeeding.

The nipple is composed of smooth muscle capable of erection on manual or sucking stimulation. On stimulation, it transmits sensations to the posterior pituitary gland to release oxytocin, which then acts to constrict milk glands and push milk forward into the ducts that lead to the nipple (a let-down reflex). The skin surrounding the nipples is darkly pigmented out to about 4 cm and termed the *areola*. The area appears rough on the surface because it contains many sebaceous glands, called Montgomery tubercles. Because the milk glands are the structures important for breastfeeding and the size of breasts is associated with fat deposits, the size of breasts has no effect on whether a woman can successfully breastfeed.

The blood supply to the breasts is profuse because it is supplied by large thoracic branches of the axillary, internal mammary, and intercostal arteries. This effective blood supply is necessary so milk glands can be supplied with nutrients and fluid to make possible a plentiful supply of milk for breastfeeding. Unfortunately, this rich blood connection also aids in the metastasis of breast cancer if cancer is not discovered early (Huether & McCance, 2012).

## MENSTRUATION

A menstrual cycle (the female reproductive cycle) is episodic uterine bleeding in response to cyclic hormonal changes. The purpose of a menstrual cycle is to bring an

ovum to maturity and renew a uterine tissue bed that will be necessary for the ova's growth should it be fertilized. Because menarche may occur as early as 9 years of age, it is good to include health teaching information on menstruation to both school-age children and their parents as early as fourth grade as part of routine care. It is a poor introduction to sexuality and womanhood for a girl to begin menstruation unwarned and unprepared for the important internal function it represents.

The length of menstrual cycles differs from woman to woman, but the average length is 28 days (from the beginning of one menstrual flow to the beginning of the next). It is not unusual for cycles to be as short as 23 days or as long as 35 days. The length of the average menstrual flow (termed menses) is 4 to 6 days, although women may have flows as short as 2 days or as long as 9 days (Ledger, 2012).

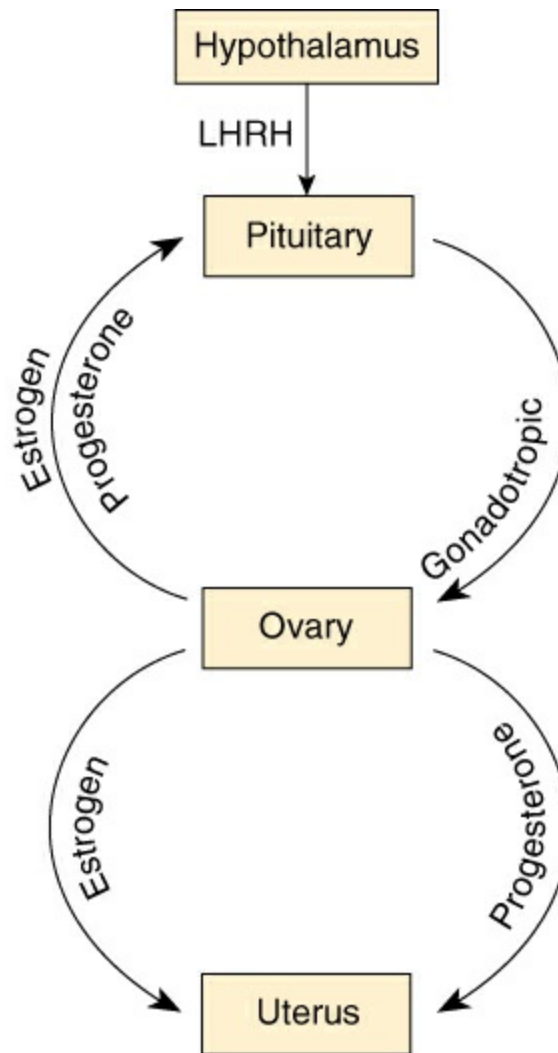

Because there is such variation in length, frequency, and amount of menstrual flow and also in the onset of menarche, many women have questions about what is considered normal. Contact with healthcare personnel during a routine health examination or prenatal visit may be their first opportunity to ask questions they have had for some time. Table 5.1 summarizes the normal characteristics of menstruation for quick reference.

**TABLE 5.1 CHARACTERISTICS OF NORMAL MENSTRUAL CYCLES**

Characteristic	Description
Beginning (menarche)	Average age at onset, 12.4 years; average range, 9–17 years
Interval between cycles	Average, 28 days; cycles of 23–35 days not unusual
Duration of menstrual flow	Average flow, 4–6 days; ranges of 2–9 days not abnormal
Amount of menstrual flow	Difficult to estimate; average 30–80 ml per menstrual period; saturating a pad or tampon in less than 1 hr is heavy bleeding
Color of menstrual flow	Dark red; a combination of blood, mucus, and endometrial cells
Odor	Similar to marigolds

### The Physiology of Menstruation

Four body structures are involved in the physiology of the menstrual cycle: the hypothalamus, the pituitary gland, the ovaries, and the uterus. For a menstrual cycle to be complete, all four organs must contribute their part; inactivity of any part results in an incomplete or ineffective cycle (Fig. 5.11).

**Figure 5.11** The interaction of pituitary–uterine–ovarian functions in a menstrual cycle.

## The Hypothalamus

The release of GnRH (also called luteinizing hormone–releasing hormone [LHRH]) from the hypothalamus initiates the menstrual cycle. GnRH then stimulates the pituitary gland to send the gonadotropic hormone to the ovaries to produce estrogen. When the level of estrogen rises, release of GnRH is repressed and no further menstrual cycles will occur (the principle that birth control pills use to eliminate menstrual flows).

Excessive levels of pituitary hormones can also inhibit release.

During childhood, the hypothalamus is apparently so sensitive to the small amount of estrogen produced by the adrenal glands, release of GnRH is suppressed. Beginning with puberty, the hypothalamus becomes less sensitive to estrogen feedback, so every month in females, the hormone is released in a cyclic pattern.

Diseases of the hypothalamus, which cause deficiency of this releasing factor, can result in delayed puberty. Likewise, a disease that causes early activation of GnRH can lead to abnormally early sexual development or precocious puberty (Neely & Crossen,

2014) (see [Chapter 47](#)).

## The Pituitary Gland

Under the influence of GnRH, the anterior lobe of the pituitary gland (the adenohypophysis) produces two hormones:

- FSH, a hormone active early in the cycle that is responsible for maturation of the ovum
- LH, a hormone that becomes most active at the midpoint of the cycle and is responsible for ovulation, or release of the mature egg cell from the ovary. It also stimulates growth of the uterine lining during the second half of the menstrual cycle.

## The Ovaries

FSH and LH are called gonadotropic hormones because they cause growth (trophy) in the gonads (ovaries). Every month during the fertile period of a woman's life (from menarche to menopause), one of the ovary's oocytes is activated by FSH to begin to grow and mature. As the oocyte grows, its cells produce a clear fluid (follicular fluid) that contains a high degree of estrogen and some progesterone. As the follicle surrounding the oocyte grows, it is propelled toward the surface of the ovary. At full maturity, the follicle is visible on the surface of the ovary as a clear water blister approximately 0.25 to 0.5 in. across. At this stage of maturation, the small ovum (barely visible to the naked eye, about the size of a printed period) with its surrounding follicular membrane and fluid is termed a *graafian follicle*.

By day 14 or the midpoint of a typical 28-day cycle, the ovum has divided by mitotic division into two separate bodies: a primary oocyte, which contains the bulk of the cytoplasm, and a secondary oocyte, which contains so little cytoplasm that it is not functional. The structure also has accomplished its meiotic division, reducing its number of chromosomes to the haploid (having only one member of a pair) number of 23.

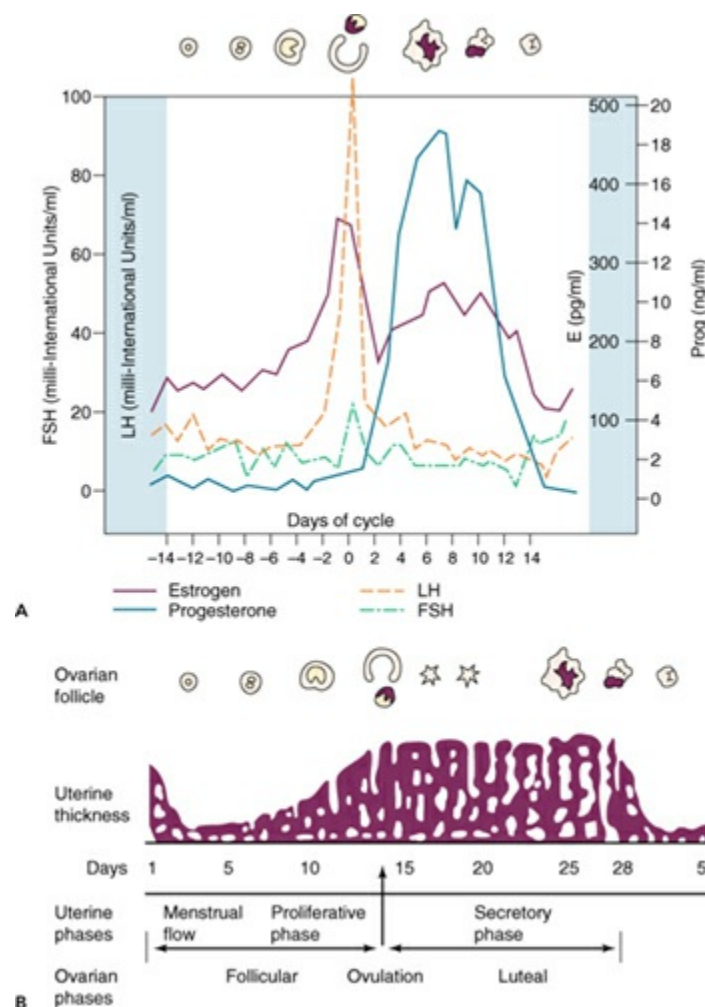

After an upsurge of LH from the pituitary at about day 14, prostaglandins are released and the graafian follicle ruptures. The ovum is set free from the surface of the ovary, a process termed *ovulation*. It is swept into the open end of a fallopian tube. It is important to teach women that ovulation does not necessarily occur on the 14th day of their cycle; it occurs 14 days *before the end of their cycle*. If their menstrual cycle is only 20 days long, for example, their day of ovulation would be day 6 (14 days before the end of the cycle). If their cycle is 44 days long, ovulation would occur on day 30, not at the halfway point—day 22.

After the ovum and the follicular fluid have been discharged from the ovary, the cells of the follicle remain in the form of a hollow, empty pit. The FSH has done its work at this point and now decreases in amount. The second pituitary hormone, LH, continues to rise in amount and directs the follicle cells left behind in the ovary to

produce lutein, a bright-yellow fluid high in progesterone. With lutein production, the follicle is renamed a *corpus luteum* (yellow body).

The basal body temperature of a woman drops slightly (by 0.5° to 1°F) just before the day of ovulation because of the extremely low level of progesterone that is present at that time. It rises by 1°F on the day after ovulation because of the concentration of progesterone, which is thermogenic. The woman’s temperature remains at this elevated level until approximately day 24 of the menstrual cycle, when the progesterone level again decreases (Huether & McCance, 2012). Therefore, taking body temperature daily is one method of assessing if ovulation has occurred.

If conception (fertilization by a spermatozoon) occurs as the ovum proceeds down a fallopian tube and the fertilized ovum implants on the endometrium of the uterus, the corpus luteum remains throughout the major portion of the pregnancy (to about 16 to 20 weeks). If conception does not occur, the unfertilized ovum atrophies after 4 or 5 days, and the corpus luteum (now called a “false” corpus luteum) remains for only 8 to 10 days. As the corpus luteum regresses, it is gradually replaced by white fibrous tissue, and the resulting structure is termed a corpus albicans (white body). Figure 5.12A summarizes the times when ovarian hormones are secreted at peak levels during a typical 28-day menstrual cycle to cause these changes.

**Figure 5.12 (A)** Plasma hormone concentrations in the normal female reproductive cycle. **(B)** Ovarian events and uterine changes during the menstrual cycle.

## The Uterus

**Figure 5.12B** also illustrates uterine changes that occur monthly as a result of stimulation from the estrogen and progesterone produced by the ovaries.

### *The First Phase of the Menstrual Cycle (Proliferative)*

Immediately after a menstrual flow (which occurs during the first 4 or 5 days of a cycle), the endometrium, or lining of the uterus, is very thin, approximately one cell layer in depth. As the ovary begins to produce estrogen (in the follicular fluid, under the direction of the pituitary FSH), the endometrium begins to proliferate so rapidly the thickness of the endometrium increases as much as eightfold from day 5 to day 14. This first half of a menstrual cycle is interchangeably termed the proliferative, estrogenic, follicular, or postmenstrual phase.

### *The Second Phase of the Menstrual Cycle (Secretory)*

After ovulation, the formation of progesterone in the corpus luteum (under the direction of LH) causes the glands of the uterine endometrium to become corkscrew or twisted in appearance and dilated with quantities of glycogen (an elementary sugar) and mucin (a protein). It takes on the appearance of rich, spongy velvet. This second phase of the menstrual cycle is termed the progestational, luteal, premenstrual, or secretory phase.

### *The Third Phase of the Menstrual Cycle (Ischemic)*

If fertilization does not occur, the corpus luteum in the ovary begins to regress after 8 to 10 days, and therefore, the production of progesterone decreases. With the withdrawal of progesterone, the endometrium of the uterus begins to degenerate (at about day 24 or day 25 of the cycle). The capillaries rupture, with minute hemorrhages, and the endometrium sloughs off.

### *The Fourth Phase of the Menstrual Cycle (Menses)*

Menses, or a menstrual flow, is composed of a mixture of blood from the ruptured capillaries; mucin; fragments of endometrial tissue; and the microscopic, atrophied, and unfertilized ovum.

Menses is actually the end of an arbitrarily defined menstrual cycle. Because it is the only external marker of the cycle, however, the first day of menstrual flow is used to mark the beginning day of a new menstrual cycle.

Contrary to common belief, a menstrual flow contains only 30 to 80 ml of blood; if it seems to be more, it is because of the accompanying mucus and endometrial shreds.

The iron loss in a typical menstrual flow is approximately 11 mg. This is enough loss that many adolescent women could benefit from a daily iron supplement to prevent iron depletion during their menstruating years (Bitzer, Sultan, Creatsas, et al., 2014).

### *QSEN Checkpoint Question 5.4*

#### **INFORMATICS**

The nurse documents the fact that Suzanne Matthews typically has a menstrual cycle of 34 days. If she had coitus on days 8, 10, 15, and 20 of her last cycle, which is the day on which she most likely conceived?

- a. The 8th day
- b. The 10th day
- c. Day 15
- d. Day 20

*Look in Appendix A for the best answer and rationale.*

### **Cervical Changes**

The mucus of the uterine cervix also changes in structure and consistency each month during a menstrual cycle. At the beginning of each cycle, when estrogen secretion from the ovary is low, cervical mucus is thick and scant. Sperm survival in this type of mucus is poor. At the time of ovulation, when the estrogen level has risen to a high point, cervical mucus becomes thin, stretchy (spinnbarkeit), and copious. Sperm penetration and survival in this thin mucus are both excellent. Because progesterone becomes the major influencing hormone during the second half of the cycle, cervical mucus again thickens and sperm survival is again poor.

Women can analyze cervical mucus changes to help plan coitus so it coincides with ovulation if they want to increase their chance of becoming pregnant or plan to avoid coitus at the time of ovulation to prevent pregnancy (natural family planning; see [Chapter 6](#)) by analyzing how thick or thin is cervical mucus. During ovulation, the body of the cervix is softer and the os is slightly open compared with the rest of the cycle when it is firm and the os is closed as another indication of ovulation.

#### **The Fern Test**

An interesting property of cervical mucus just before ovulation when estrogen levels are high is the ability to form fernlike patterns on a microscope slide when allowed to dry. This pattern is known as arborization or ferning ([Fig. 5.13](#)). When progesterone is the dominant hormone, as it is just after ovulation, this fern pattern is no longer discernible. Cervical mucus, therefore, can be examined at midcycle for ferning to detect whether a high estrogen surge is present. Women who do not ovulate usually show a ferning pattern throughout their menstrual cycle (progesterone levels never become dominant), or they never demonstrate it because their estrogen levels never rise.

**Figure 5.13** (A) A ferning pattern of cervical mucus occurs with high estrogen levels. (B) Incomplete ferning during secretory phase of cycle. (From Scott, J. R. [1990]. *Danforth's obstetrics and gynecology* [6th ed.]. Philadelphia, PA: J. B. Lippincott.)

### The Spinnbarkeit Test

At the height of estrogen secretion, yet another property of cervical mucus is the ability to stretch into long strands, a contrast to its thick, viscous state when progesterone is the dominant hormone. That means performing this test, known as *spinnbarkeit*, at the midpoint of a menstrual cycle is another way to demonstrate high levels of estrogen are being produced and, by implication, ovulation is about to occur. A woman can do this herself by stretching a mucus sample between thumb and finger, or it can be tested in an examining room by smearing a cervical mucus specimen on a slide and stretching the mucus between the slide and cover slip (Fig. 5.14).

**Figure 5.14** Spinnbarkeit is the property of cervical mucus to stretch a distance before breaking.

## Sexual Health

Sexuality is a multidimensional phenomenon that includes feelings, attitudes, and actions. It has both biologic and cultural diversity components. It encompasses and gives direction to a person's physical, emotional, social, and intellectual responses throughout life.

Sexuality has always been a part of human life, but only in the past few decades has it been studied scientifically. One common finding of researchers has been that feelings and attitudes about sex vary widely across cultures and individuals. Although the sexual experience is unique to each individual, sexual physiology (how the body responds to sexual arousal) has common features ([Resetkova & Rogers, 2015](#)).

### THE SEXUAL RESPONSE CYCLE

Two of the earliest researchers of sexual response were Masters and Johnson. In 1966, they published the results of a major study based on more than 10,000 episodes of sexual activity among more than 600 men and women ([Masters, Johnson, & Kolodny, 1998](#)). In this study, they described the human sexual response as a cycle with four discrete stages: excitement, plateau, orgasm, and resolution. Whether stages are felt as separate steps this way or blended into one smooth process of desire, arousal, and orgasm is individualized.

#### Excitement

Excitement occurs with physical and psychological stimulation (sight, sound, emotion, or thought) that causes parasympathetic nerve stimulation. This leads to arterial dilation

and venous constriction in the genital area. The resulting increased blood supply leads to vasocongestion and increasing muscular tension. In women, this vasocongestion causes the clitoris to increase in size and mucoid fluid to appear on vaginal walls for lubrication. The vagina widens in diameter and increases in length. Breast nipples become erect. In men, penile erection occurs as well as scrotal thickening and elevation of the testes. In both sexes, there is an increase in heart and respiratory rate and blood pressure.

### **Plateau**

The plateau stage is reached just before orgasm. In the woman, the clitoris is drawn forward and retracts under the clitoral prepuce, the lower part of the vagina becomes extremely congested (formation of the orgasmic platform), and there is increased breast nipple elevation.

In men, vasocongestion leads to distention of the penis. Heart rate increases to 100 to 175 beats/min and respiratory rate to about 40 breaths/min.

### **Orgasm**

Orgasm occurs when stimulation proceeds through the plateau stage to a point at which a vigorous contraction of muscles in the pelvic area expels or dissipates blood and fluid from the area of congestion. The average number of contractions for the woman is 8 to 15 contractions at intervals of 1 every 0.8 seconds. In men, muscle contractions surrounding the seminal vessels and prostate project semen into the proximal urethra. These contractions are followed immediately by three to seven propulsive ejaculatory contractions, occurring at the same time interval as in the woman, which force semen from the penis (Masters et al., 1998).

As the shortest stage in the sexual response cycle, orgasm is usually experienced as intense pleasure affecting the whole body, not just the pelvic area. It is also a highly personal experience: Descriptions of orgasms vary greatly from person to person.

### **Resolution**

The resolution is a 30-minute period during which the external and internal genital organs return to an unaroused state. For the male, a refractory period occurs during which further orgasm is impossible. Women do not go through this refractory period, so it is possible for women who are interested and properly stimulated to have additional orgasms immediately after the first.

## **THE INFLUENCE OF THE MENSTRUAL CYCLE ON SEXUAL RESPONSE**

During the second half of the menstrual cycle—the luteal phase—there is increased fluid retention and vasocongestion in the woman's lower pelvis. Because some vasocongestion is already present at the beginning of the excitement stage of the sexual

response, women appear to reach the plateau stage more quickly and achieve orgasm more readily during this time. Women also may be more interested in initiating sexual relations during this time.

## THE INFLUENCE OF PREGNANCY ON SEXUAL RESPONSE

Pregnancy is another time in life when there is vasocongestion of the lower pelvis because of the blood supply needed by a rapidly growing fetus. This causes some women to experience their first orgasm during their first pregnancy. Following a pregnancy, many women continue to experience increased sexual interest because the new growth of blood vessels during pregnancy lasts for some time and continues to facilitate pelvic vasocongestion. These differences in response are why discussing sexual relationships is an important part of health teaching during pregnancy. At a time when a woman may want sexual contact very much, she needs to be free of myths and misconceptions, such as the notion that orgasm will cause a spontaneous miscarriage. Although the level of oxytocin, the hormone that rises with labor, does appear to rise in women after orgasm, this rise is not enough that women should worry that sexual relations will lead to premature labor in the average woman.

For some women, the increased breast engorgement that accompanies pregnancy results in extreme breast sensitivity during coitus. Foreplay that includes sucking or massaging of the breasts may also cause release of oxytocin, but it is not contraindicated unless the woman has a history of premature labor. [Box 5.5](#) shows an interprofessional care map illustrating both nursing and team planning for reproductive and sexual health.

### BOX 5.5

#### Nursing Care Planning

##### AN INTERPROFESSIONAL CARE MAP FOR A COUPLE NEEDING SEXUAL COUNSELING

Suzanne and Kevin Matthews, a young adult couple, 6 months pregnant, come to your antepartal clinic for a routine visit. Suzanne, in tears, states, “My husband isn’t interested in me anymore. We haven’t had sex since I became pregnant.” The couple engaged in coitus two to three times per week prior to this pregnancy. Kevin states, “I’m afraid I’ll hurt the baby.”

**Family Assessment:** Couple has been married for 4 years; lives in two-bedroom apartment in the central city. Husband works as a high school teacher; wife works as a baker in a local coffeehouse.

**Patient Assessment:** A previous pregnancy, 2 years ago, ended at 8 weeks with a spontaneous miscarriage. Blood pressure today is 118/70 mmHg; overall health is “good.”

**Nursing Diagnosis:** Altered sexuality pattern related to pregnancy and fear of harming fetus.

**Outcome Criteria:** Couple states they recognize coitus is not harmful in normal pregnancy; reports engaging in sexual intercourse as well as pleasurable noncoital sexual activities by next visit if desired.

<b>Team Member Responsible</b>	<b>Assessment</b>	<b>Intervention</b>	<b>Rationale</b>	<b>Expected Outcome</b>
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Assess sexual concerns.	Encourage couple to continue routine prenatal care. Discuss alternative sexual activities, such as cuddling or massage.	As pregnancy progresses, discomfort, fatigue, and increasing abdominal size may interfere with a satisfying sexual relationship.	Couple continues prenatal care; describes other means of sexual expression.
<i>Teamwork and Collaboration</i>				
Nurse/primary care provider	Assess signs and symptoms of pregnancy; note any indication of complications.	Consult with team primary care provider to be certain the patient has no contraindications to remaining sexually active during pregnancy.	Sexual relations may be contraindicated in a few women who have had previous miscarriages or if vaginal bleeding is present.	The couple's primary care provider supplies information on if the couple can remain sexually active throughout pregnancy.
<i>Procedures/Medications for Quality Improvement</i>				
Nurse	Assess whether alternative types of sexual activity would fulfill couple's needs.	Review alternative sexual positions for optimal comfort and pleasure, such as side-lying.	Alternative sexual positions may be necessary to provide comfort late in pregnancy, as the woman's abdomen expands.	Couple describes alternative positions or other ways they relate to each other.
<i>Patient-Centered Care</i>				

Nurse/primary care provider	Assess what couple understands about reproductive anatomy and usual sexual response.	Explain sexual relations are allowed during pregnancy until labor begins. Use charts and illustrations to show how the fetus is protected in utero.	Barring complications, couples can engage in sexual intercourse and activity to the extent it is comfortable and desired. Visual aids enhance learning.	Couple states they understand sexual relations are allowed during a normal pregnancy.
-----------------------------	--	---	---	---

*Psychosocial/Spiritual/Emotional Needs*

Nurse	Assess whether couple knows hormones can change sexual desire during pregnancy.	Encourage the couple to talk openly about their feelings, concerns, desires, and changes in interest to each other throughout the pregnancy.	Physical and psychological changes occur in both the pregnant woman and her partner throughout pregnancy. Open communication enhances the relationship.	Couple reports they are able to voice their feelings and concerns during the pregnancy.
Nurse	Assess what communication pattern couple uses to share information with each other.	Teach importance of a couple maintaining good communication.	Beginning a sound communication pattern during pregnancy can lay a foundation for a sound future relationship.	Couple reports they appreciate the importance of good communication for their ongoing relationship.

*Informatics for Seamless Healthcare Planning*

Nurse	Assess whether couple's questions and concerns were answered satisfactorily.	Review concern about sexual relations at each visit as indicated.	Continued interest in a couple's problem allows them to continue to	Patient's electronic health record includes a notation about the questions that were asked
-------	--	---	---	--

voice concerns. and answered at subsequent visits.

## MASTURBATION

Masturbation is self-stimulation for erotic pleasure; it can also be a mutually enjoyable activity for sexual partners. It offers sexual release, which may be interpreted by the person as overall tension or anxiety relief. [Masters et al. \(1998\)](#) reported women may find masturbation to orgasm the most satisfying sexual expression and use it more commonly than men.

## SEXUAL HARASSMENT AND VIOLENCE

Sexual gratification can be experienced in a number of ways. What is considered normal varies greatly among cultures, although general components of accepted sexual activity are that it is an activity of adults with privacy, consent, and lack of force included. Sexual violence or violence in general occurs when one partner does not respect these boundaries. This is a particular concern for maternal and child health nurses because intimate partner violence tends to occur at an increased frequency during pregnancy ([Van Parys, Deschepper, Michielsen, et al., 2015](#)). Young children and adolescents are also persons targeted for sexual maltreatment. All forms of maltreatment or partner violence are discussed in [Chapter 55](#).

Sexual harassment is unwanted, repeated sexual advances, remarks, or behavior toward another that is offensive to the recipient or interferes with job or school performance. It can involve actions as obvious as a job superior demanding sexual favors from an employee, or it could be a man or woman sending sexist jokes by e-mail to another person in the department. In school, it can refer to bullying ([Eom, Restaino, Perkins, et al., 2015](#)).

Two types exist. One is *quid pro quo* (an equal exchange), in which an employer asks for something in return for sexual favors, such as a hiring or promotion preference. The second is a *hostile work environment*, in which an employer creates an environment in which an employee feels uncomfortable and exploited (such as being addressed as “honey” or “babe,” asked to wear revealing clothing, or working where walls are decorated with sexist posters).

Sexual harassment rules apply to same-gender as well as opposite-gender harassment. In addition to causing occupational disruption, sexual harassment may be so distressing that it can lead to short- or long-term psychosocial consequences for victims and their families such as emotional distress (e.g., anxiety, depression, posttraumatic stress disorder, substance abuse), interpersonal conflict, and impaired intimacy and sexual functioning ([Eom et al., 2015](#)).

Sexual harassment has been illegal in the United States since 1964. Patients who report being subjected to harassment should be advised to report the situation to their

personnel supervisor. Nurses should be aware of sexual harassment guidelines in their own work setting and likewise report such behavior to keep their workplace free of this type of strain.

## **INDIVIDUALS WITH UNIQUE NEEDS OR CONCERNS**

A number of individuals have special concerns related to reproductive health.

### **The Individual With a Disability**

Individuals who are physically challenged have sexual desires and needs the same as all others (Chou, Lu, & Pu, 2015). They may, however, have difficulty with sexual identity or sexual fulfillment because of their disability. Males with upper spinal cord injury, for example, may have difficulty with erections and ejaculation because these actions are governed at the spinal level. Manual stimulation of the penis or psychological stimulation can, however, achieve erection in most men with spinal cord lesions, allowing the man a satisfying sexual relationship with his partner. Most women with spinal cord injuries cannot experience orgasm but are able to conceive and have children.

Any person who interprets a procedure such as a colostomy as disfiguring may be reluctant to participate in sexual activities, fearing the sight of an apparatus will diminish their partner's satisfaction. People with chronic pain such as from arthritis may be too uncomfortable to enjoy sexual relations. Individuals with urinary catheters may be concerned about their ability to enjoy coitus with the catheter in place. For women, a retention catheter should not interfere with coitus. Men can be taught how to replace their own catheter, so they can remove it for sexual relations. In all instances in which one sexual partner is disabled in some way, the response of a loving partner does much to enhance body image and feelings of adequacy of a mate. Encouraging these patients to ask questions and work on specific difficulties is a nursing role.

Sexuality is a facet of rehabilitation that has not always received attention. If a person can accomplish activities of daily living such as eating, elimination, and mobility, then he or she is often considered to be leading a normal or near-normal life. However, establishing a satisfying sexual relationship is an important part of living as well and so should be included in assessments of patients in rehabilitation programs.

### **The Individual With a Hypoactive Sexual Desire**

Lessened interest in sexual relations is normal in some circumstances, such as after the death of a family member, a divorce, or a stressful job change. The support of a caring sexual partner or relief of the tension causing the stress allows a return in sexual interest.

Decreased sexual desire can also be a side effect of many medicines. Chronic diseases, such as peptic ulcers or chronic pulmonary disorders that cause frequent pain or discomfort, may interfere with a man's or a woman's overall well-being and interest

in sexual activity. Obese men and women may not feel as much satisfaction from sexual relations as others because they have difficulty achieving deep penetration due to the bulk of their abdomens. An individual with an STI such as genital herpes may choose to forgo sexual relations rather than inform a partner of the disease. Some women experience a decrease in sexual desire during perimenopause. Administration of androgen (testosterone) to women may be helpful at that time because it can improve interest in sexual activity (Wright & O'Connor, 2015).

### *What If... 5.2*

**The nurse is interested in exploring one of the 2020 National Health Goals related to reproductive or sexual health (see Box 5.1). Most government-sponsored money for nursing research is allotted based on these goals. What research topics would be appropriate to explore these goals and advance evidence-based practice?**

## **KEY POINTS FOR REVIEW**

- The reproductive and sexual organs form early in intrauterine life, and full functioning occurs at puberty.
- The female internal organs of reproduction include the ovaries, the fallopian tubes, the uterus, and the vagina.
- The female external organs of reproduction include the mons veneris, the labia minora and majora, the vestibule, the clitoris, the fourchette, the perineal body, the hymen, and the Skene and the Bartholin glands.
- The male external reproductive structures are the penis, scrotum, and testes. Internal organs are the epididymis, the vas deferens, the seminal vesicles, the ejaculatory ducts, the prostate gland, the urethra, and the bulbourethral glands.
- A menstrual cycle is periodic uterine bleeding in response to cyclic hormones. Menarche is the first menstrual period. Menopause is the end of menstruation. Menstrual cycles are possible because of the interplay between the hypothalamus, the pituitary gland, the ovaries, and the uterus.
- [Masters et al. \(1998\)](#) identified a sexual response cycle consisting of excitement, plateau, orgasm, and resolution stages.
- Educating people about reproductive function is an important primary health strategy because it teaches people to better monitor their own health through vulvar or testicular self-examination.
- Considering reproductive and sexual health in a patient assessment helps in planning nursing care that not only meets QSEN competencies but also best meets a family's total needs.

## **CRITICAL THINKING CARE STUDY**

Josephine Rice is 26 years old, works as a nurse on an oncology service, and has been married for 6 years. Her husband, Peter, 28 years of age, is a race car driver. They have been trying to have a child for 4 years. A fertility study revealed that this is probably because Josephine doesn't ovulate every month. A specialist suggested she lose weight (her body mass index is 27.5) and try in vitro fertilization. She confides in you she feels the fault is not ovulation. It's because, unknown to her family, she had a Plan B abortion while in college and this is her "payback."

1. Does Josephine have risk factors because of her work? Are these more apt to be the reason for her subfertility than her former abortion?
2. Does Peter's job also create risk factors?
3. Was Josephine well advised to lose weight?
4. What patient education would you provide regarding Plan B?

## Nursing Care for the Family in Need of Reproductive Life Planning

*Seventeen-year-old Dana Crews has come to your community health clinic for a routine gynecologic exam. She tells you she is sexually active and her boyfriend “sometimes” uses a condom. She trusts he will “stop in time” when they aren’t using one. She doesn’t want to take birth control pills because she can’t afford them and also she’s afraid her parents will find out she’s broken her abstinence pledge if they see the pills.*

*The previous chapter described the anatomy and physiology of the male and female reproductive systems and the importance of sexual health. This chapter adds information about ways to prevent pregnancy or to plan and space children. Such information builds a base for both care and health teaching of families.*

**What additional health teaching does Dana need to be well informed about reproductive life planning?**

### KEY TERMS

**barrier methods**  
**basal body temperature**  
**cervical cap**  
**coitus**  
**coitus interruptus**  
**contraceptive**  
**diaphragm**  
**elective termination of pregnancy**  
**female condom**  
**fertile days**  
**fertility awareness**  
**intrauterine device**  
**laparoscopy**  
**male condom**

natural family planning  
reproductive life planning  
spermicide  
transdermal contraception  
tubal ligation  
vasectomy

## OBJECTIVES

After mastering the contents of this chapter, you should be able to:

1. Describe common methods of reproductive life planning and the advantages, disadvantages, and risk factors associated with each.
2. Identify 2020 National Health Goals related to reproductive life planning that nurses can help the nation achieve.
3. Formulate nursing diagnoses related to reproductive life planning concerns.
4. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
5. Implement nursing care related to reproductive life planning, such as educating adolescents about the use of condoms as a safer sex practice as well as to prevent unintended pregnancy.
6. Evaluate expected outcomes for achievement and effectiveness of care.
7. Integrate knowledge of reproductive life planning with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

**Reproductive life planning** includes all the decisions an individual or couple make about whether and when to have children, how many children to have, and how they are spaced. Some couples you will meet want counseling about how to avoid conception. Others want information on increasing fertility and about their ability to conceive. Others need counseling because a **contraceptive** (a measure to halt conception) has failed (Bond, 2013).

Intentional pregnancies are important for the health of children because when a pregnancy is unintended or mistimed, both short-term and long-term consequences can result. The woman may be less likely or less careful to:

- Seek prenatal care
- Breastfeed
- Protect her fetus from harmful substances

A disproportionate share of women who bear children whose conception was

unintended are adolescents; such women are less apt to complete high school or college and more likely to require public assistance and/or live in poverty than their peers who are not mothers. The child of such a pregnancy is at greater risk for low birth weight, dying in the first year of life, being maltreated, and not receiving sufficient resources for healthy development ([Centers for Disease Control and Prevention \[CDC\], 2015](#)).

Planning for reproductive choices is so important that several 2020 National Health Goals speak directly to this area of care ([Box 6.1](#)).

## BOX 6.1

### Nursing Care Planning Based on 2020 National Health Goals

A number of 2020 National Health Goals speak directly to reproductive life planning:

- Increase the proportion of adolescents who receive formal instruction on abstinence before 18 years of age from a baseline of 87.2% to a target of 95.9%.
- Increase the proportion of females less than 15 years of age who have never had sexual intercourse from a baseline of 82.9% to a target of 91.2%; of males, from 82.0% to 90.2%.
- Reduce the proportion of females experiencing pregnancy despite use of a reversible contraceptive method from a baseline of 12.4% to a target of 9.9%.
- Increase the proportion of intended pregnancies from a baseline of 51% to a target of 56%.
- Decrease the proportion of births occurring within 18 months of a previous birth from a baseline of 35.3% to a target of 31.7% ([U.S. Department of Health and Human Services, 2010](#); see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these objectives by teaching people, especially adolescents, about contraceptive options while being cautious to avoid indirectly encouraging sexual activity among teens.

### *Nursing Process Overview*

#### FOR REPRODUCTIVE LIFE PLANNING

##### **ASSESSMENT**

As a result of changing social values and lifestyles, many people today are able to talk easily about reproductive life planning. Other people, however, may be uncomfortable with this topic and may not voice their interest in the subject independently. For this reason, at health assessments, ask patients if they want more information or need any help with reproductive life planning as part of obtaining a basic health history.

##### **NURSING DIAGNOSIS**

Because reproductive life planning touches so many facets of life, nursing diagnoses can differ greatly depending on the circumstances and individual preferences.

Examples might include:

- Readiness for enhanced knowledge regarding contraception options related to a desire to prevent pregnancy
- Deficient knowledge related to use of a diaphragm
- Spiritual distress related to partner's preferences for contraception
- Decisional conflict regarding choice of birth control because of health concerns
- Decisional conflict related to unintended pregnancy
- Powerlessness related to failure of chosen contraceptive
- Altered sexuality pattern related to fear of pregnancy
- Risk for ineffective health maintenance related to lack of knowledge about natural family planning methods

## **PLANNING AND IMPLEMENTATION**

When establishing expected outcomes for care in this area, be certain plans are realistic for each couple. If a woman has a history of poor compliance with medication, for instance, it might not be realistic for her to plan on taking an oral contraceptive every day. If she only desires temporary contraception, tubal ligation or vasectomy for her partner would certainly be inappropriate. Be certain when counseling to be sensitive to a couple's spiritual, cultural, and moral beliefs before suggesting possible methods. It is equally important to explore your own beliefs and values before counseling. This not only helps develop self-awareness of how these beliefs affect nursing care, but it also allows you to become more sensitive to the beliefs of others.

Patients are required to provide informed consent for surgical contraceptive methods or procedures such as vasectomy or tubal ligation. The risks, benefits, alternatives, and proper use of the method and the patient's understanding of his or her rights and responsibilities should be included in the consent form as this helps ensure patients have weighed their options and know the procedure may be irreversible. If you are helping to obtain a consent signature, always do so in the presence of a witness. It is also helpful to refer patients to online resources for further information (see [Chapter 5](#)).

## **OUTCOME EVALUATION**

Evaluation is important in reproductive life planning because anything that causes patients to discontinue or misuse a particular method will leave them at risk of pregnancy. Reassess early (within 1 to 3 weeks) after a couple begins a new method of contraception to prevent such an occurrence. Evaluate not only whether a chosen method is effective but also whether the woman and her partner are satisfied or have further questions. Examples of expected outcomes include:

- Patient voices confidence in chosen contraceptive method by next visit.
- Patient expresses satisfaction with chosen method at follow-up visit.
- Patient consistently uses chosen method without pregnancy for 1 year.

## Assessment for Contraception Options and Possible Contraindications

As many as 93% of women of childbearing age in the United States use some form of contraception (CDC, 2015). Major benefits of this increase in contraception include decreases in unintended adolescent pregnancies, the need for “morning after” or postcoital medications, and elective terminations of pregnancy (CDC, 2015).

Important things to consider when helping a couple choose a method that will be right for them include:

- Personal values
- Ability to use a method correctly
- If the method will affect sexual enjoyment
- Financial factors
- If a couple’s relationship is short term or long term
- Prior experiences with contraception
- Future plans

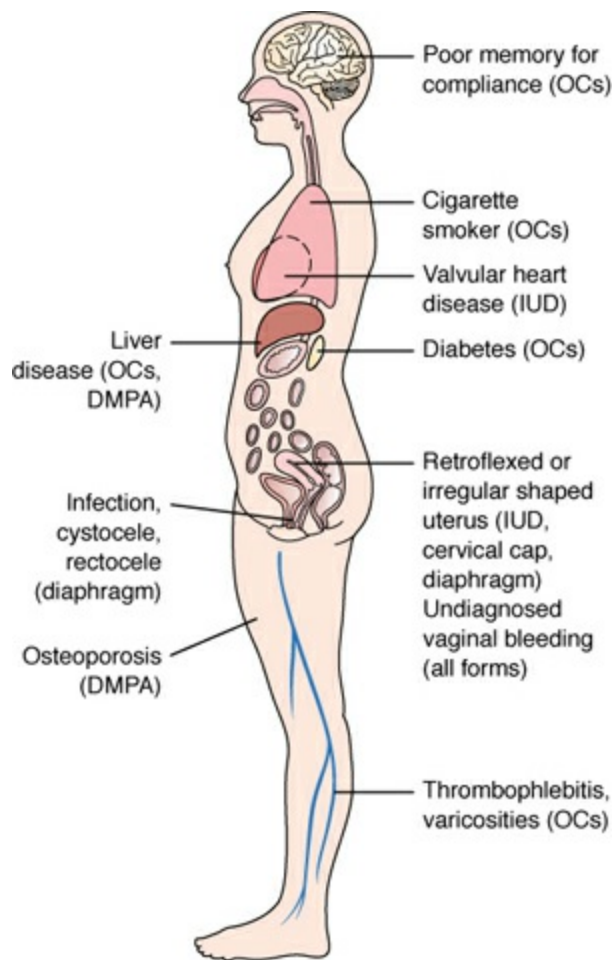

For counseling to be successful, it is necessary to understand how various methods of contraception work and how they compare in terms of benefits and disadvantages (Box 6.2). In addition to assessing to determine the best contraceptive option, be certain to emphasize safer sex practices. Although there are many contraceptive options for reliable pregnancy prevention, only condoms (both male and female) provide protection against sexually transmitted infections (STIs) or HIV—an important concern if a relationship is not a monogamous one.

### BOX 6.2

#### Nursing Care Planning Using Assessment

##### ASSESSING A WOMAN FOR POSSIBLE CONTRAINDICATIONS TO CONTRACEPTIVE USE

DMPA, depot medroxyprogesterone acetate; IUD, intrauterine device; OCs, oral contraceptives.

Many postpartum services distribute printed information on contraception packaging to women at discharge. Women are then invited to ask questions as necessary about the material. Read these materials carefully to be certain they are accurate before distributing them and, if suggestions are needed, make them to the correct healthcare committee. Be certain to make it clear you are available to answer questions about contraception; otherwise, women are in such a hurry to take their newborn home, they tend to postpone questions “until later,” a time when the question may be too late to be effective or a healthcare provider is no longer available.

Consider each person’s lifestyle and overall health, as these influence what type of conception a woman will choose (Box 6.3). Morbidly obese women, for example, may need to choose different types than women with an average body mass index (Mody & Han, 2014). Women in a male-dominant family may have little choice as to what reproductive life planning method they can choose. If their partner does not wish to participate in contraception planning, it would be unhelpful to suggest a type where male cooperation is needed, such as the use of a male condom or natural family planning.

### BOX 6.3

People differ greatly in the way they desire or accept information on reproductive life planning, depending on individual preferences and sociocultural influences. For example, certain religions do not believe a method beyond abstinence or fertility awareness is right to use. People with lower incomes cannot afford surgical procedures or methods such as daily combination pills. Be certain while counseling in this area that you do not impose your own values on people but rather work together to identify a system that your patient will be able to follow consistently.

Because no method of contraception, except abstinence, offers 100% protection against pregnancy, it is important to carefully answer a patient's questions regarding methods of contraception. It is necessary to be prepared to answer questions about postcoital protection if there were unprotected sexual relations as well as elective termination of pregnancy if contraception failed. Only when couples have sufficient information in all these areas and the freedom to discuss specific concerns can they be prepared to make a decision that will be right for them (Loke & Lam, 2014).

An ideal contraceptive should be:

- Safe
- Effective
- Compatible with spiritual and cultural beliefs and personal preferences of both the user and sexual partner
- Free of bothersome side effects
- Convenient to use and easily obtainable
- Affordable and needing few instructions for effective use
- Free of effects (after discontinuation) on future pregnancies

Before a patient begins using a new method of contraception, information that should be obtained includes:

- Vital signs, possibly a Pap smear, pregnancy test, gonococcal and chlamydial screening, and perhaps hemoglobin for detection of anemia
- Obstetric history, including STIs, past pregnancies, previous elective abortions, failure of previously used methods, and compliance history with previously used methods
- Subjective assessment of the patient's desires, needs, feelings, and understanding of conception (a teen may believe she is too young to get pregnant; a woman in the immediate postpartum period may believe she cannot conceive immediately, especially if she is breastfeeding)
- Sexual practices, such as frequency, number of partners, feelings about sex, and body image

How well contraceptive methods meet ideal requirements is discussed with each type. The range of effectiveness of frequently used contraceptive methods is shown in [Table 6.1](#). This table shows the effectiveness of each method by listing the *ideal failure*

*rate* (the number of unintended pregnancies that will occur in 1 year) for couples who use the method consistently and correctly and also the *failure rate* for routine use (less-than-perfect use). A method that shows a large difference between the ideal failure rate and the actual failure rate may not be easy and convenient to use.

**TABLE 6.1 CONTRACEPTION FAILURE RATES**

Type of Contraceptive	Ideal Failure Rate (%) Perfect Use <sup>a</sup>	Failure Rate (%) Typical Use	Advantages	Disadvantages
<i>Natural Family Planning</i>				
Abstinence	100%	85%	Acceptable to all religious groups No cost	Requires high motivation and periods of abstinence
Lactation, amenorrhea	1%–5% (under 6 months)	95% (after 6 months)	Effective while infant is totally breastfed; approved by all religions and cultures	Temporary measure Not reliable if infant takes supplemental feedings
Calendar	1%–9%	25%	No cost	Requires motivation, cooperation
Standard day method: CycleBeads	5%	12%–13%	Visual aid can improve compliance Available as iPhone app	Initial cost May need to mark on a calendar they have moved a bead rather than rely on memory
Basal body temperature (BBT)	3%	25%	Cost of thermometer	Requires motivation and cooperation by male partner
Ovulation method	3%	25%	No cost	Requires motivation and cooperation by male partner
Symptothermal	0.4%	25%	No cost	Requires motivation and cooperation from male partner
Two-day method	3%–4%	13%–14%	No cost	Requires motivation and cooperation

Withdrawal	4%	22%	A male-controlled method	from male partner Sperm may be present in pre-ejaculatory fluid
<i>Barrier Methods</i>				
Spermicide	18%	28%	Easy to use Sold over the counter	May leave an annoying vaginal discharge
Male condom	2%	18%	Protects against STIs Male responsibility No prescription necessary	Requires interruption of sexual activity
Female condom	5%	21%	Protection against STIs	Insertion may be difficult
Sponge (parous woman)	20%	24%	Easy to insert No prescription	May cause leakage Necessary to take measures to avoid danger of TSS
Sponge (nulliparous woman)	9%	12%	Easy to insert No prescription	May cause leakage Necessary to take measures to avoid TSS
Diaphragm	6%	12%	Easy to insert	Prescription needed Necessary to take measures to avoid TSS
Cervical cap (parous woman)	23%	35%	Can leave in place for several days if desired	May be difficult to insert Can irritate cervix Necessary to take measures to avoid TSS
Cervical cap (nulliparous woman)	9%	18%	Can leave in place for several days if desired	May be difficult to insert Can irritate cervix Necessary to take measures to avoid TSS
<i>Hormonal Methods</i>				

Transdermal patch	0.3%	9%	Easy to apply	Irritation at local site
Vaginal ring	0.3%	9%	Easy to insert	May need reminder to insert
Combination oral contraceptives (COCs)	0.3%	9%	Coitus independent	Continual cost Possible side effect of thrombophlebitis
Progestin-only pills (mini-pills)	0.5%	5%–8%	Coitus independent No side effects of COCs	Continual cost
Injectable progesterone (DMPA)	0.2%	6%	Coitus independent Dependable for 12 weeks	Continual cost Continual injections
Intradermal implant (Nexplanon)	0.05%	0.05%	Coitus independent Dependable for 5 years	Initial cost Appearance on arm
IUD (copper T)	0.6%	0.8%	No memory or motivation needed	Cramping, bleeding Expulsion possible
Mirena IUD	0.2%	0.2%	No memory or motivation needed	Cramping, bleeding Expulsion possible
<i>Surgical Methods</i>				
Female sterilization	0.5%	0.5%	Permanent and highly reliable	Initial cost Irreversible
Male sterilization	0.1%	0.15%	Permanent and highly reliable	Initial cost Irreversible
<i>Postcoital (Emergency) Methods</i>				
Postcoital pills	1%–2%	25%	Can be purchased over the counter	May cause nausea
Postcoital IUD	0.1%	0.1%–2%	Can be inserted up to 5 days after unprotected coitus Can be left in place as contraceptive measure	Visit to a healthcare provider is needed within 5 days (120 hr) of unprotected coitus

<sup>a</sup>Couples who use the method consistently and correctly during a year's time.

DMPA, depot medroxyprogesterone acetate; IUD, intrauterine device; STI, sexually transmitted infection; TSS, toxic shock syndrome.

Modified from Centers for Disease Control and Prevention. (2014). Appendix D: Contraceptive effectiveness.

## Natural Family Planning

**Natural family planning** methods, also called periodic abstinence methods, are, as the name implies, methods that involve no introduction of chemical or foreign material into the body (Oman & Burke, 2015).

Many people hold spiritual beliefs that rule out the use of birth control pills or devices. Others simply believe a “natural” way of planning pregnancies is best for them, one that will involve no expense, does not introduce a foreign substance into their body, and has no risk to a fetus should they become pregnant. The effectiveness of these methods varies greatly from a 2% ideal failure rate to about a 25% failure rate, depending mainly on the couple’s ability to refrain from having sexual relations on **fertile days** or days in which a woman is most likely to become pregnant (Rodriguez, Darney, Elman, et al., 2015).

### ABSTINENCE

**Abstinence**, or refraining from sexual relations, has a theoretical 0% failure rate and is also the most effective way to prevent STIs. Due to the natural human sexual drive, patients may find it difficult to adhere to abstinence because they may deny the possibility of sexual activity and fail to plan for pregnancy and STI prevention. Because it is difficult for many couples to adhere to abstinence, the method has a high failure rate (Schalet, Santelli, Russell, et al., 2014).

Many sex education classes for adolescents advocate abstinence as the only contraceptive measure, so teenagers and young adults who take these courses may know little about other options. When discussing abstinence as a contraceptive method, be certain to provide information not only on the method but also suggestions for ways to comply with this method (Box 6.4). A worry is adolescents who make “abstinence pledges” to not have sexual intercourse until they are married may “tune out” not only additional information on contraception but also on safer sex practices. Then, if they break their pledge (about 50% do), that could leave them more vulnerable to STIs and pregnancy than others (Schalet et al., 2014).

#### BOX 6.4

#### Nursing Care Planning to Empower a Family

#### SUGGESTIONS FOR PROMOTING ABSTINENCE

**Q.** Dana, 17 years old, asks you, “How can I avoid being pressured into unwanted sex?”

**A.** A few suggestions are:

- Discuss with your partner in advance which sexual activities you will permit and

which you will not.

- Try to avoid high-pressure situations such as a party with known drug use, excessive alcohol consumption; for teenagers: no adult supervision.
- Be certain your partner understands when you say, “No,” you mean it.
- Make it clear your partner understands you consider being forced into relations against your wishes the same as rape, not simply irresponsible conduct.
- Do not accept any drug to “help you relax” or “be cool,” as such a drug could impair your judgment. The drug could also be the “date rape” drug flunitrazepam (Rohypnol), which causes loss of memory for recent events.

## Periodic Abstinence

Periodic abstinence is a method to avoid pregnancy by avoiding sex on the days a woman may conceive. Methods for determining the days when a woman could conceive are under “Fertility Awareness Methods.”

## LACTATION AMENORRHEA METHOD

When a woman is breastfeeding, there is a natural suppression of both ovulation and menses (Pratts & Lawson, 2015).

Lactation amenorrhea method (LAM) is a safe birth control method (a failure rate of about 1% to 5%) if:

- An infant is:
  - Under 6 months of age
  - Being totally breastfed at least every 4 hours during the day and every 6 hours at night
  - Receives no supplementary feedings, and
- Menses has not returned

After 6 months, or if the infant begins to receive supplemental feedings or isn’t sucking well, the use of LAM as an effective birth control method becomes questionable and the woman probably should be advised to choose another method of contraception (Lopez, Grey, Chen, et al., 2014). A woman should also consider a different method of contraception once her baby begins sleeping through the night, even if this occurs before the child reaches 6 months of age.

## COITUS INTERRUPTUS

**Coitus interruptus** (withdrawal) is one of the oldest known methods of contraception. The couple proceeds with coitus until the moment of ejaculation. Then, the man withdraws and spermatozoa are emitted outside the vagina. Unfortunately, ejaculation may occur before withdrawal is complete and, despite the caution used, some spermatozoa may be deposited in the vagina. Furthermore, because there may be a few spermatozoa present in pre-ejaculation fluid, fertilization may occur even if withdrawal seems controlled (Killick, Leary, Trussell, et al., 2011). For these reasons, coitus

interruptus is only about 82% effective, and the method should be used with caution as it also can lead to STIs (Jones, Lindberg, & Higgins, 2014).

## POSTCOITAL DOUCHING

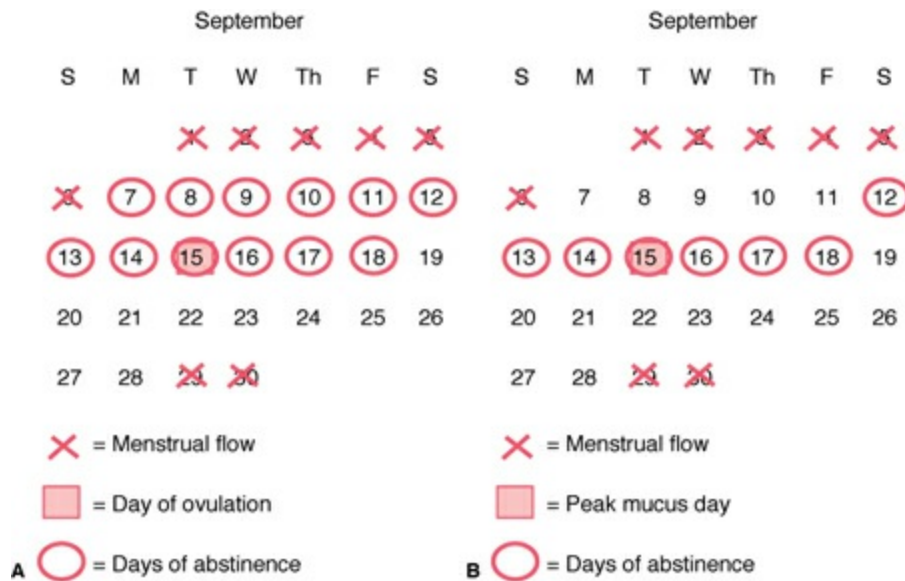

Douching following intercourse, no matter what solution is used, is ineffective as a contraceptive measure as sperm may be present in cervical mucus as quickly as 90 seconds after ejaculation, long before douching could be accomplished.

## FERTILITY AWARENESS METHODS

**Fertility awareness** methods rely on detecting when a woman will be capable of impregnation (fertile) so she can use periods of abstinence during that time. There are a variety of ways to determine a fertile period, such as using a calendar to calculate the period of time based on a set formula, using a visual tool such as “CycleBeads,” measuring the woman’s body temperature, observing the consistency of cervical mucus, or employing a combination of these methods (Taylor, Aldad, McVeigh, et al., 2012). The methods consider the typical length of sperm survival (anywhere from 3 to more than 5 days) and the length of time an ova is ripe for fertilization (about 1 day). Based on this, a fertile period exists from about 5 days before ovulation to 1 day after.

### Calendar (Rhythm) Method

The calendar method requires a couple to abstain from coitus on the days of a menstrual cycle when the woman is most likely to conceive. To plan for this, the woman keeps a diary of about six menstrual cycles. To calculate “safe” days, she subtracts 18 from the shortest cycle she documented. This number predicts her first fertile day. She then subtracts 11 from her longest cycle. This represents her last fertile day. If she had six menstrual cycles ranging from 25 to 29 days, her fertile period would be from the 7th day ( $25$  [the shortest cycle]  $- 18$ ) to the 18th day ( $29$  [the longest cycle]  $- 11$ ). To avoid pregnancy, she would avoid coitus during those days (Fig. 6.1A). When used conscientiously, the method has a low failure rate; in typical use, however, this rate rises substantially because of irregular menstrual cycles, miscalculation, or disregard for predicted fertile days.

**Figure 6.1** (A) A typical month showing predicted fertile days using the calendar method as a natural family planning method. (B) A typical month using the cervical mucus method of natural family planning. Unmarked days are those predicted to be unfertile and therefore safe for sexual relations.

### Basal Body Temperature Method

Just before the day of ovulation, a woman’s **basal body temperature** (BBT), or the temperature of her body at rest, falls about 0.5°F. At the time of ovulation, her BBT rises a full Fahrenheit degree (0.2°C) because of the rise in progesterone with ovulation. This pattern serves as the basis for the BBT method of contraception (Taylor et al., 2012).

To use this method, the woman takes her temperature, either orally or with a tympanic thermometer, each morning immediately after waking before she rises from bed or undertakes any activity; this is her BBT. A woman who works nights should take her temperature after awakening from her longest sleep period, no matter what the time of day. As soon as a woman notices a slight dip in temperature followed by an increase, she knows she has ovulated. She refrains from having **coitus** (sexual relations) for the next 3 days (the possible life of the discharged ovum).

Because sperm can survive from 3 to 5 days and rarely as many as 7 days in the female reproductive tract, it is usually recommended that the couple combine this method with a calendar method, so they abstain for a few days before ovulation as well. The BBT method has an ideal failure rate as low as 3% but a failure rate of 25% (see Table 6.1). For more information on BBT and how it also can be used to aid conception, see Chapter 7 and Figure 7.2.

A problem with assessing BBT for fertility awareness is that many factors can affect BBT. For example, a temperature rise caused by illness could be mistaken as the signal of ovulation. If this happens, a woman could mistake a fertile day for a safe one.

Changes in the woman's daily schedule, such as starting an aerobic program or getting up earlier than usual, could also affect BBT.

### **Cervical Mucus Method (Billing's Method)**

Yet another method to predict ovulation is to use the changes in cervical mucus that occur naturally with ovulation (Fig. 6.1B). Before ovulation each month, the cervical mucus is thick and does not stretch when pulled between the thumb and finger. Just before ovulation, mucus secretion increases. On the day of ovulation (the peak day), it becomes copious, thin, watery, and transparent. It feels slippery (like egg white) and stretches at least 1 inch before the strand breaks, a property known as *spinnbarkeit* (see Chapter 5, Fig. 5.14). In addition, breast tenderness and an anterior tilt to the cervix occur. All the days on which cervical mucus is copious, and for at least 3 to 4 days afterward, are considered to be fertile days, or days on which the woman should abstain from coitus to avoid conception (Oman & Burke, 2015).

A woman using this method must be conscientious about assessing her vaginal secretions every day, or she will miss the change in texture and amount. The feel of vaginal secretions after sexual relations is unreliable because seminal fluid (the fluid containing sperm from the male) has a watery, postovulatory consistency and can be confused with ovulatory mucus. Figure 6.1B shows a hypothetical month using this method. This method has a potentially high failure rate because of difficulty in interpreting mucus status (Blackwell, Vigil, Alliende, et al., 2016). Because sperm have a life span from 3 to more than 5 days, a woman needs to abstain for at least 4 days prior to the appearance of estrogen-influenced mucus; therefore, this method should be combined with a calendar method for best results.

### **Two-Day Method**

To use a 2-day method, a woman assesses for vaginal secretions daily. If she feels secretions for 2 days in a row, she avoids coitus that day and the day following as the presence of secretions suggests fertility. The method requires conscientious daily assessment and results in about 12 days per month in which she should avoid coitus, the same as a calendar method (Aksel, Sinai, & Yee, 2012).

### **Symptothermal Method**

The symptothermal method of birth control combines the cervical mucus and BBT methods (Wettstein & Bourgeois, 2014). The woman takes her temperature daily, watching for the rise in temperature that marks ovulation. She also analyzes her cervical mucus every day and observes for other signs of ovulation such as *mittelschmerz* (midcycle abdominal pain) or if her cervix feels softer than usual. The couple then abstains from intercourse until 3 days after the rise in temperature or the fourth day after the peak of mucus change. The symptothermal method, because it assesses more clues to ovulation, is more effective than either the BBT or the cervical mucus method alone

(ideal failure rate about 2%).

### Standard Days Method: CycleBeads

This method is designed for women who have menstrual cycles between 26 and 32 days (Igras, Sinai, Mukabatsinda, et al., 2014). A woman purchases a circle of beads that helps her predict fertile days (Fig. 6.2). The first bead on the ring is red and marks the first day of her menstrual flow; this is followed by six brown beads which indicate “safe” days. Twelve glow-in-the-dark white beads, which mark fertile days (during which she needs to abstain from coitus), and 13 additional brown “safe” days follow. The woman advances one bead per day during the month. If she reaches a dark brown bead (appears on the 27th day) before she begins her next menses, her cycle is too short for the method to be reliable. If she reaches the end of the string of beads (32 days) before menses, she knows her cycle is too long for the method to be reliable. The system is easy to use, and, if a woman wants a more technology-based system than using a circle of beads, there is an iPhone app available in place of actual beads (iCycleBeads). The system is easy to understand; most women, however, need to use a calendar to check off daily that they have moved a bead or they can lose track of the system.

**Figure 6.2** With CycleBeads, a woman moves one bead every day to predict her fertile days if her menstrual cycles range from 26 to 32 days. (Courtesy of Cycle Technologies, Inc., Washington, DC.)

### Ovulation Detection

Still another method to predict ovulation is by the use of an over-the-counter ovulation detection kit. These kits detect the midcycle surge of luteinizing hormone (LH) that can be detected in urine 12 to 24 hours before ovulation. Such kits are 98% to 100% accurate in predicting ovulation. Although they are fairly expensive and not intended to be used as a contraceptive aid, combining a cervical mucus assessment and the ovulation detector to mark the peak fertile day is becoming the method of choice for

many families. An ovulation detector can be used in the future to help conception when the couple is ready to have children.

### **Marquette Model**

This method combines the use of ovulation detection with other signs of ovulation (cervical mucus, BBT, cervix position and softness) to avoid pregnancy during a woman's fertile period. It was developed in the late 1990s by nurses and doctors at Marquette University in Wisconsin.

### **Side Effects and Contraindications for Natural Family Planning**

Natural family planning methods do not have side effects. If there is a contraindication to their use, it would be for couples who must prevent conception (perhaps because the woman is taking a drug that would be harmful to a fetus or the couple absolutely does not want the responsibility of children) because the failure rate of all forms is about 25%.

### **Natural Family Planning and Effect on Pregnancy**

Natural family planning methods have no effect if a woman should get pregnant while using them as well as no effect on future pregnancies.

### **Natural Family Planning and Effect on Sexual Enjoyment**

Once a couple is certain of a woman's nonfertile days using one of the natural planning methods, more spontaneity in sexual relations is possible than with methods that involve vaginal insertion products. However, the required days of abstinence may make a natural planning method unsatisfactory and unenjoyable for a couple. Coitus interruptus may be unenjoyable because of the need to withdraw before ejaculation.

### **Natural Family Planning and the Adolescent**

Natural methods of family planning (with the exception of abstinence) are usually not the contraceptive method of choice for adolescents as they require a great deal of thought and persistence. Adolescent boys may lack the control or experience to use coitus interruptus effectively. Girls tend to have occasional anovulatory menstrual cycles for several years after menarche and so may not experience definite cervical changes or an elevated body temperature each month. In addition, these methods require adolescents to say "no" to sexual intercourse on fertile days, a task that may be difficult to complete under peer pressure.

### **Natural Family Planning and the Perimenopausal Woman**

Perimenopausal women are good candidates for natural family planning methods because they may not be able to use hormonal methods such as birth control pills

because of risk to them if they have a history of high blood pressure, thromboembolic disease, or cigarette smoking. As menopause approaches, however, they may not have as much cervical mucus as previously, causing the contrast between fertile and nonfertile days more difficult to detect. Additionally, their menstrual cycles could become unpredictable, causing issues with detecting fertile days.

## Natural Family Planning and the Postpartal Woman

After a successful pregnancy, most women are interested in delaying their next pregnancy until their new baby is older. This makes them good candidates for natural family planning as they can breastfeed with these methods without worrying about hormonal contamination or a decrease in breast milk. However, a postpartal woman often ovulates before her first menstrual cycle and should be warned that she could become pregnant even before her return to menses.

### QSEN Checkpoint Question 6.1

#### PATIENT-CENTERED CARE

Suppose Dana, 17 years old, tells the nurse she wants to use a fertility awareness method of contraception. How should the nurse best meet Dana's learning needs?

- The nurse should teach her to record if she feels hot and whether she is perspiring heavily.
- The nurse should teach her to assess whether her cervical mucus is thin and watery.
- The nurse should teach her to monitor her emotions for sudden anger or crying.
- The nurse should teach her to assess whether her breasts feel sensitive to cool air.

Look in [Appendix A](#) for the best answer and rationale.

## BARRIER METHODS OF CONTRACEPTION

**Barrier methods** are forms of birth control that place a chemical or latex barrier between the cervix and advancing sperm so sperm cannot reach and fertilize an ovum.

### Spermicides

A **spermicide** is an agent that causes the death of spermatozoa before they can enter the cervix. It is a chemical barrier method and is often used in combination with other physical barrier methods. Spermicides not only actively kill sperm but also change the vaginal pH to a strong acid level, a condition not conducive to sperm survival. They do not protect against STIs. In addition to the general benefits for barrier contraceptives, the advantages of spermicides include:

- They may be purchased without a prescription or an appointment with a

healthcare provider, so they allow for greater independence and lower costs.

- When used in conjunction with another contraceptive, they increase the other method's effectiveness.
- Various preparations are available, including gels, creams, sponges, films, foams, and vaginal suppositories.

Gels or creams are easily inserted into the vagina before coitus with the provided applicator (Fig. 6.3). The woman should do this no more than 1 hour before coitus. If she chooses to douche to remove the spermicide afterward (no need to do this), she should wait 6 hours after coitus to ensure the agent has completed its spermicidal action.

**Figure 6.3** Vaginal insertion of a spermicidal agent.

Another form of spermicidal protection is a film of glycerin impregnated with a spermicidal agent that is folded and inserted vaginally. On contact with vaginal secretions or precoital penile emissions, the film dissolves and a carbon dioxide foam forms to protect the cervix against invading spermatozoa.

Still, other vaginal products are cocoa butter and glycerin-based vaginal suppositories containing a spermicide. Because it takes about 15 minutes for a suppository to dissolve, it must be inserted 15 minutes before coitus.

Foam-impregnated synthetic sponges are moistened to activate the impregnated spermicide and then inserted vaginally to block sperm access. Well liked by most users, they are easy to insert and have an ideal failure rate of 9% and a typical use failure rate of about 16% to 20% (CDC, 2014). Caution women preparations labeled “feminine hygiene” products are for vaginal cleanliness and are not spermicidal; therefore, they are not effective contraceptives.

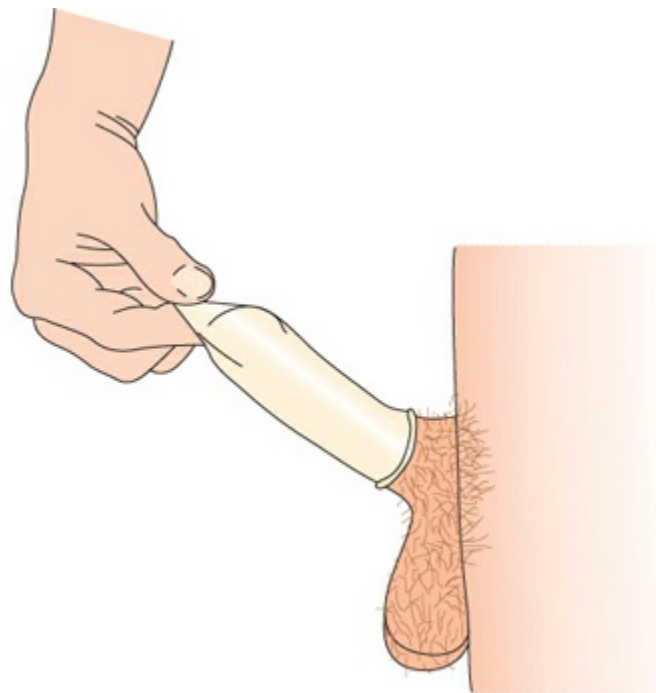

## Side Effects and Contraindications

Vaginally inserted spermicidal products are contraindicated in women with acute cervicitis because they might further irritate the cervix. Some women find the vaginal leakage after use of these products bothersome. Vaginal suppositories, because of the cocoa butter or glycerin base, are the most bothersome in this regard.

## Male and Female Condoms

A **male condom** is a latex rubber or synthetic sheath that is placed over the erect penis before coitus to trap sperm (Fig. 6.4). Male condoms have an ideal failure rate of 2% and a true failure rate of about 15% because breakage or spillage occurs in up to 15% of uses (see Table 6.1). A big advantage of male condoms is they are one of the few “male-responsibility” birth control measures available. In addition, no healthcare visit or prescription is needed. They are recommended for partners who do not maintain a monogamous relationship because although latex condoms do not necessarily offer protection against diseases spread by skin-to-skin contact such as human papillomavirus (HPV), syphilis, or genital herpes, they do prevent the spread of STIs such as gonorrhea and chlamydia; their use has become a major part of the fight to prevent infection from HIV.

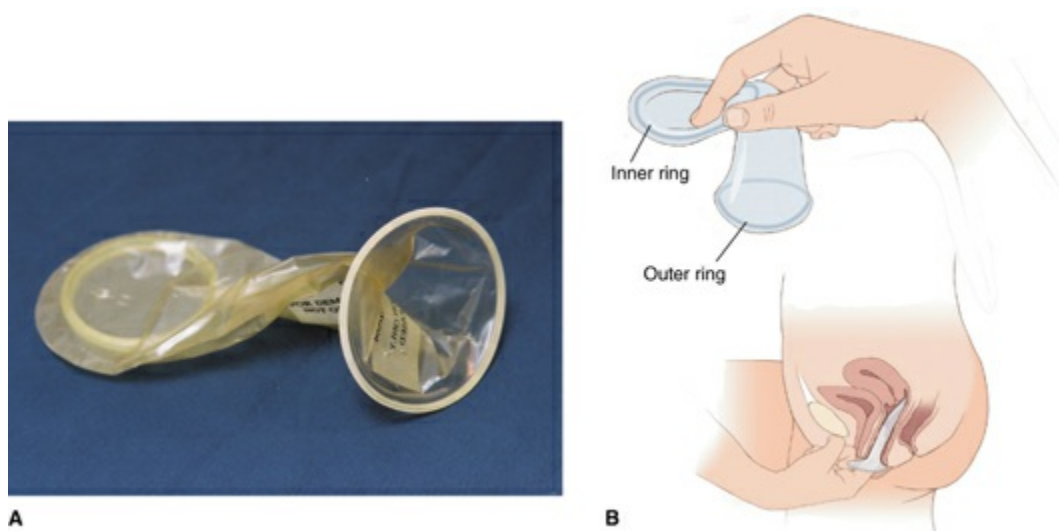

**Figure 6.4** Proper application of a male condom. Being certain space is left at the tip helps to ensure the condom will not break with ejaculation.

To be effective, a condom must be applied before any penile–vulvar contact as even pre-ejaculation fluid may contain some sperm. The condom should be positioned so it is loose enough at the penis tip to collect the ejaculate without placing undue pressure on

the condom. The penis (with the condom held carefully in place) must be withdrawn before it begins to become flaccid after ejaculation to prevent sperm from leaking from the now loosely fitting sheath into the vagina.

**Female condoms** are sheaths made of latex or polyurethane, prelubricated with a spermicide so, similarly to male condoms, they offer protection against conception as well as STIs, including HIV. The inner ring (closed end) covers the cervix, and the outer ring (open end) rests against the vaginal opening. The sheath may be inserted any time before sexual activity begins and then removed after ejaculation occurs. Like male condoms, they are intended for one-time use (Fig. 6.5). They can be purchased without a prescription but are more expensive than male condoms. Male and female condoms should not be used together or there is an increased chance of tearing one or the other. The ideal failure and usual failure rate of female condoms equals those of male condoms, 5% and 15% (CDC, 2014). Because they prevent skin-to-skin contact STIs, they are the only woman-controlled safer sex method available (Brawner, Alexander, Fannin, et al., 2015). Despite these features, they have not gained great popularity, probably because of their bulk and difficulty to use.

**Figure 6.5** (A) A female condom. Such a device is effective protection against both sexually transmitted infections and pregnancy. (B) Insertion technique.

### Side Effects and Contraindications

There are no contraindications to the use of either male or female condoms except for sensitivity or allergy to latex. If either the male or his partner has a sensitivity or allergy to latex, polyurethane or natural membrane types can be used. Couples should be cautioned that these types of condoms do not offer the same level of protection against STIs.

### Diaphragms and Cervical Caps

A **diaphragm** is a circular rubber disk that is placed over the cervix before intercourse to mechanically halt the passage of sperm (Fig. 6.6). Although use of a spermicide to coat a diaphragm is not required, using a spermicidal gel with one combines a barrier and a chemical method of contraception so one is usually added. With the use of a spermicide, the failure rate of the diaphragm is as low as 6% (ideal) to 18% (typical use) (see Table 6.1).

**Figure 6.6** (A) After spermicidal jelly or cream is applied to the rim, the diaphragm is pinched between the fingers and thumb. (B) The folded diaphragm is then inserted into the vagina and pushed backward as far as it will go. (C) To check for proper positioning, the woman should feel the cervix to be certain it is completely covered by the soft rubber dome of the diaphragm. (D) To remove the diaphragm, a finger is hooked under the forward rim and the diaphragm is pulled down and out.

A diaphragm is prescribed and fitted initially by a healthcare provider to ensure a correct fit. Because the shape of a woman's cervix changes with pregnancy, miscarriage, cervical surgery (dilatation and curettage [D&C]), or elective termination of pregnancy, teach women to return for a second fitting if any of these circumstances occur. A woman should also have the fit of the diaphragm checked if she gains or loses more than 15 lb because this could also change her pelvic and vaginal contours.

Before expected coitus, after first coating the inside rim and center portion of the diaphragm with a spermicide gel, the diaphragm is inserted into the vagina, sliding it along the posterior wall and pressing it up against the cervix so it is gripped by the vaginal fornices. A woman should check a diaphragm with a finger after insertion to be certain it is fitted well up over the cervix; she should be able to palpate the cervical os through the center of the diaphragm.

Diaphragms should remain in place for at least 6 hours after coitus because

spermatozoa remain viable in the vagina for that length of time; they may be left in place for as long as 24 hours. Leaving them in place longer than this can cause cervical inflammation (erosion) or urethral irritation from the pressure against the vaginal walls. If coitus is repeated before 6 hours, both a diaphragm or cap should not be removed and replaced; more spermicidal gel should be added to the vagina by an applicator.

A diaphragm is removed by inserting a finger into the vagina and loosening the diaphragm by pressing against the anterior rim and then withdrawing it vaginally. After use, a diaphragm should be washed in mild soap and water, dried gently, and stored in its protective case. With this care, a diaphragm will last for 2 years, after which it should be replaced.

### Side Effects and Contraindications

Diaphragms may not be effective if a uterus is prolapsed, retroflexed, or anteflexed to such a degree the cervix is also displaced in relation to the vagina. Intrusion on the vagina by a cystocele or rectocele where the walls of the vagina are displaced by bladder or bowel may also make insertion of a diaphragm difficult. Users of diaphragms may experience a higher number of urinary tract infections (UTIs) than nonusers probably because of pressure on the urethra. Diaphragms should not be used in the presence of acute cervicitis, herpes virus infection, or a papillomavirus infection because the close contact of the rubber and the use of a spermicide can cause additional irritation. Other contraindications include:

- History of toxic shock syndrome (TSS; a staphylococcal infection introduced through the vagina)
- Allergy to rubber or spermicides
- History of recurrent UTIs

To prevent TSS (see [Chapter 47](#)) while using a diaphragm or cervical cap (discussed in the following), advise women to:

1. Wash their hands thoroughly with soap and water before insertion or removal.
2. Do not use a diaphragm during a menstrual period.
3. Do not leave a diaphragm in place longer than 24 hours.
4. Be aware of the symptoms of TSS, such as elevated temperature, diarrhea, vomiting, muscle aches, and a sunburn-like rash.
5. If symptoms of TSS should occur, immediately remove the diaphragm and telephone a healthcare provider.

### Cervical Caps

A **cervical cap** is made of soft rubber shaped like a thimble, which fits snugly over the uterine cervix ([Fig. 6.7](#)). The failure rate is estimated to be as high as 23% (ideal) to 35% (typical use) because caps tend to dislodge more readily than diaphragms during coitus (see [Table 6.1](#)). The precautions for use are the same as for diaphragm use except caps can be kept in place longer (up to 48 hours) because they do not put pressure on

the vaginal walls or urethra.

**Figure 6.7** A cervical cap is placed over the cervix and used with a spermicidal jelly the same as a diaphragm.

Many women cannot use cervical caps because their cervix is too short for the cap to fit properly. Like diaphragms, they must be fitted individually by a healthcare provider. They include a small strap, which can be grasped for easy removal. They are contraindicated in any woman who has:

- An abnormally short or long cervix
- A current abnormal Pap smear
- A history of TSS
- An allergy to latex or spermicide
- A history of cervicitis or cervical infection
- A history of cervical cancer
- Undiagnosed vaginal bleeding

They may not be as effective in parous women as they are for those who have never had children because the cervix does not conform as well to a thimble shape after childbirth.

***QSEN Checkpoint Question 6.2***

**QUALITY IMPROVEMENT**

Dana, 17 years old, wants to try female condoms as her reproductive planning method. If the nurse was creating a relevant educational handout, it should include which of the following directives?

- a. The hormone that condom use stimulates may cause mild weight gain.
- b. Female condoms should be inserted before any penile penetration.
- c. Women should coat the condom with a spermicide before use.
- d. Female condoms, unlike male condoms, can be reused after being washed.

*Look in Appendix A for the best answer and rationale.*

## Barrier Methods and Effect on Pregnancy

If conception should occur while using a barrier method, there is no reason to think the fetus will be affected. Some women worry a sperm that survived a spermicide must have been weakened by migrating through it and, therefore, will produce a child with problems. They can be assured conception most likely occurred because the product did not completely cover the cervical os, so the sperm that reached the uterus was free of the product and unharmed.

## Barrier Methods and Effect on Sexual Enjoyment

Although barrier methods must be inserted fairly close to the time of coitus, most couples find the inconvenience of insertion only a minor problem. If a couple is concerned the method does not offer enough protection, worrying about becoming pregnant may interfere with sexual enjoyment. Some couples find the foam or moisture irritating to vaginal and penile tissue during coitus and, therefore, are unable to use them.

Some men report that condoms dull their enjoyment of coitus; some couples do not like the fact the man must withdraw promptly after ejaculation (not true for female condoms). For some couples, concern that a condom may break or slip may inhibit sexual pleasure.

Use of a vibrator as a part of foreplay, frequent penile insertion, or the woman-superior position during coitus may dislodge a diaphragm or cap; therefore, these may not be the contraceptive of choice for some couples. Some couples may find the precaution that more spermicidal gel should be added to the vagina if coitus is repeated before 6 hours restricting. An advantage of the diaphragm or cap is they allow sexual relations during menses (although see the earlier precaution on TSS). They may also offer some protection against STIs.

### *What If . . . 6.1*

**Dana, 17 years old, tells the nurse she and a friend intend to share a diaphragm because they don't have enough money to each buy one. Is this good planning?**

---

## Barrier Methods and the Adolescent

Many adolescents use spermicides as their chief method of birth control because no parental permission or extensive expense is involved. Because of the nontraditional settings in which adolescents may engage in coitus (cars or couches), some young women find inserting the product awkward and consequently may not use it, even though they have purchased it and intended to be more cautious.

Adolescents may be fitted for either diaphragms or caps. Because an adolescent girl's vagina will change in size as she matures and begins sexual relations, these devices may not remain as effective as they do with older women and so need refitting more often. Adolescents may need to be reminded that pelvic examinations will be necessary to ensure the diaphragm or cap continues to fit properly. Some adolescents may not know where their cervix is or how to feel for it when checking the placement of a diaphragm. Use an anatomic diagram or model to show them or give them a mirror to use to view their own cervix during a pelvic examination. Caution them not to accidentally tear the diaphragm with long or sharp fingernails.

Male adolescents are showing increased ability to use condoms responsibly. They may need to be cautioned that condoms should never be reused due to concern for infection and wear on the condom itself that could cause STI transmission or pregnancy. Adolescent boys who have infrequent coitus may have condoms they have owned and stored for a long time. The effectiveness of these old condoms, especially if they are carried in a warm pocket, is questionable. For many adolescent couples, use of a dual method, such as a vaginally inserted spermicide by the girl and a condom by her partner, is a preferred method of birth control. These two methods used in conjunction increase effectiveness (Kottke, Whiteman, Kraft, et al., 2015).

## Barrier Methods and the Perimenopausal Woman

Women older than 35 years have a higher incidence of cystocele or rectocele than younger women so diaphragms or cervical caps may not be the ideal contraceptive for them. Spermicide foam can help lubricate the vagina to increase sexual enjoyment in women nearing menopause. The use of vaginal film or suppository is not recommended as lessened vaginal secretions might prevent the film or suppository from dissolving completely.

## Barrier Methods and the Postpartal Woman

Vaginal spermicides are appealing to postpartal women as they can be purchased over the counter and have no effect on breastfeeding and so can be used in the short time period before a postpartal checkup when a more permanent form of contraception can be discussed and prescribed.

As the cervix changes considerably with childbirth, women must be refitted for diaphragms and cervical caps after childbirth. This is usually done at a 4- or 6-week

checkup.

### *What If . . . 6.2*

**Dana asks the nurse to help her choose a barrier contraceptive method. What method of reproductive life planning would the nurse recommend? Would the nurse's recommendation be different if she had a guaranteed monogamous relationship?**

## Hormonal Contraception

Hormonal contraceptives are, as the name implies, hormones that when taken orally, transdermally, intravaginally, or intramuscularly, cause such fluctuations in a normal menstrual cycle that ovulation or sperm transport does not occur.

### ORAL CONTRACEPTIVES

Oral contraceptives, commonly known as the pill, OCs (for oral contraceptive), or COCs (for combination oral contraceptives), are composed of varying amounts of natural estrogen (17 $\beta$ -estradiol, estradiol valerate) or synthetic estrogen (ethinyl estradiol) combined with a small amount of synthetic progesterone (progestin). The estrogen acts to suppress follicle-stimulating hormone (FSH) and LH to suppress ovulation. The progesterone action causes a decrease in the permeability of cervical mucus and so limits sperm motility and access to ova. Progesterone also interferes with tubal transport and endometrial proliferation to such an extent the possibility of implantation is significantly decreased.

### Combination Oral Contraceptives

Popular COCs prescribed in the United States are:

- *Monophasic* pills, which contain fixed doses of both estrogen and progestin throughout a 21-day cycle
- *Biphasic*, or preparations that deliver a constant amount of estrogen throughout the cycle but varying amounts of progestin
- *Triphasic* and *tetraphasic* preparations, which vary in both estrogen and progestin content throughout the cycle

Typical pills are supplied in 28-pill dispensers (21 active pills and 7 placebo pills) labeled with the day of the cycle they should be taken. Newer forms designed to eliminate menses are supplied in 84-day dispensers (see the following). Caution women to always take pills in the order designated by the dispenser or the progesterone level could be inaccurate and ineffective for that day (Fig. 6.8).

**Figure 6.8** Counseling women on how to follow an oral contraceptive schedule and what to do if they miss a day or more is an important nursing responsibility. (© Caroline Brown, RNC, MS, DEd.)

COCs must be prescribed by a healthcare provider after screening for eligibility. If the woman is over the age of 21 years and due for a routine exam, a pelvic exam and Pap smear are usually completed at this visit as well. When used correctly, COCs are 99.9% effective. Because women occasionally forget to take them, however, and because of individual physiologic differences, the typical failure rate is closer to 5% (CDC, 2014).

Oral contraceptives have benefits in addition to preventing pregnancy, such as decreasing incidences of:

- Dysmenorrhea, because of lack of ovulation
- Premenstrual dysphoric syndrome and acne because of the increased progesterone levels
- Iron deficiency anemia because of the reduced amount of menstrual flow
- Acute pelvic inflammatory disease (PID) and resulting tubal scarring
- Endometrial and ovarian cancer, ovarian cysts, and ectopic pregnancies
- Fibrocystic breast disease
- Possibly osteoporosis, endometriosis, uterine myomata (fibroid uterine tumors), and possibly rheumatoid arthritis
- Colon cancer (Bahamondes, Bahamondes, & Shulman, 2015)

Because estrogen interferes with lipid metabolism, it may also lower the concentration of low-density lipoproteins (LDL) and increase the high-density lipoprotein (HDL) level.

Women can set a start date for a cycle of pills in one of four ways:

- Sunday start: Take the first pill on the first Sunday after the beginning of a menstrual flow.
- Quick start: Begin pills as soon as they are prescribed. Beginning pills immediately after a prescription is filled may increase compliance, reducing unintended pregnancies.

- First day start: Begin pills on the first day of menses.
- After childbirth, a woman should start the contraceptive on a day (or Sunday) closest to 2 weeks after birth; after an elective termination of pregnancy, she could begin on a chosen day or the first Sunday after the procedure.

Because COCs are not effective for the first 7 days, advise women to use a second form of contraception during the initial 7 days that they take pills. A woman begins a second dispenser of pills the day after finishing the first dispenser. Menstrual flow will begin during the 7 days on which she is taking the placebo tablets.

If a woman does not want to have menstrual flows, she can eliminate her period by beginning a new cycle of pills immediately after finishing the active pills in a dispenser instead of taking the placebo pills. This can be done routinely or to accommodate special circumstances.

With extended-use pills, pills are taken for 84 days and a woman will have a menstrual flow only every 3 months or 4 times a year. Ethinyl estradiol 20 mcg and levonorgestrel 90 mcg (Lybrel) is a new low-dose combination estrogen and progestin pill that is taken 365 days a year without a placebo or pill-free interval so menstrual periods are completely eliminated for 1 year. Such pills are especially attractive to physically active women or those who have long work schedules such as military deployment (Goyal, Borrero, & Schwarz, 2012). Extensive study documents that suppressing menstrual flows for long periods this way appears to have no long-term effects (Oman & Burke, 2015).

The key to being certain ovulation suppressants are effective is for women to take them consistently and conscientiously. Some women may set an alarm on their phone to alert them it is time to take their pill. Other women may leave them in plain sight on bathroom or kitchen counters so they are reminded to take them. Caution women with young children that this is a potentially dangerous practice. Poisoning with increased blood clotting from the high estrogen content could result if a small child ingested the pills accidentally (urge the woman to use her calendar or some other method to remind her). Women who have difficulty remembering to take a contraceptive in the morning may find it easier to take a daily pill at bedtime or with a meal (the time of day makes no difference; it is the consistency that is important) (Box 6.5). Also, some women find taking pills at bedtime rather than in the morning has the advantage of eliminating any nausea they otherwise may experience.

## BOX 6.5

### Nursing Care Planning Based on Family Teaching

#### SUGGESTIONS ON ORAL CONTRACEPTIVE MANAGEMENT

**Q.** Dana, 17 years old, asks you, “What do I do if I forget to take an oral contraceptive pill?”

**A.** The answer differs, depending on your situation:

1. If the pill omitted was one of the placebo ones, ignore it and just take the next pill on time the next day.
2. If you forgot to take one of the active pills, take it as soon as you remember. Continue the following day with your usual pill schedule. Doing so might mean taking two pills on one day if you don't remember until the second day, but that's all right. *Missing one pill this way should not initiate ovulation.*
3. If you miss two consecutive active pills, take two pills as soon as you remember. Then, continue the following day with your usual schedule. You may experience some breakthrough bleeding (vaginal spotting) with two forgotten pills. Do not mistake this bleeding for your menstrual flow. *Missing two pills may allow ovulation to occur, so an added contraceptive such as a spermicide should be used for the remainder of the month.*
4. If you miss three or more pills in a row, throw out the rest of the pack and start a new pack of pills. *You might not have a period because of this routine and should use extra protection until 7 days after starting a new pack of pills.*
5. If you think you might be pregnant, stop taking pills and notify your healthcare provider.

### **QSEN Checkpoint Question 6.3**

#### **SAFETY**

Suppose Dana, 17 years old, chooses to use a COC as her family planning method. What is a danger sign of COCs the nurse would ask her to report?

- a. A stuffy or runny nose
- b. Arthritis-like symptoms
- c. Weight gain over 5 lb
- d. Severe migraine headache

*Look in [Appendix A](#) for the best answer and rationale.*

### **Progestin-Only Pills (Mini-Pills)**

Oral contraceptives containing only progestins are popularly called mini-pills and, like combination types, must be taken conscientiously every day. Without estrogen content, ovulation may occur, but because the progestins have not allowed the endometrium to develop fully or sperm to freely access the cervix, fertilization and implantation will not take place.

### **Side Effects and Contraindications of All Oral Contraceptives**

The main side effects women may experience with COCs are:

- Nausea
- Weight gain
- Headache

- Breast tenderness
- Breakthrough bleeding (spotting outside the menstrual period)
- Monilia vaginal infections
- Mild hypertension
- Depression

Side effects such as nausea and breakthrough bleeding usually subside after a few months of pill use. They may be lessened by using a different routine or brand of contraceptive.

It is no longer believed the use of COCs leads to an increased risk of myocardial infarction, and the risk of increased clotting or blood pressure elevation is low. Nevertheless, COCs are not routinely prescribed for women with a history of thromboembolic disease or a family history of cerebral or cardiovascular accident, who have migraine with aura, or who smoke because of the increased tendency toward clotting as an effect of the increased estrogen (Karch, 2015).

Advise all women taking COCs to notify their healthcare provider if symptoms of myocardial or thromboembolic complications occur, such as:

- Chest pain (pulmonary embolus or myocardial infarction)
- Shortness of breath (pulmonary embolus)
- Severe headache (cerebrovascular accident)
- Severe leg pain (thrombophlebitis)
- Eye problems, such as blurred vision (hypertension, cerebrovascular accident)

It is also recognized that COCs can interfere with glucose metabolism. For this reason, women with diabetes mellitus or a history of liver disease, including hepatitis, are evaluated individually before COCs are prescribed. The World Health Organization (WHO) recommends women who experience migraines with an aura or those who take certain drugs for seizures avoid the use of oral contraceptives as these women may be at an increased risk for cerebrovascular accident (WHO, 2011). Box 6.6 lists all risk factors and contraindications the WHO has associated with COCs. Oral contraceptives apparently do not increase the risk of breast cancer as was once feared and actually decrease the incidence of ovarian and uterine cancer (Oman & Burke, 2015).

## BOX 6.6

### Estrogen-Based Oral Contraceptive Use

#### Contraindications

- Breastfeeding and less than 6 weeks postpartum
- Aged 35 years or older and smoking 15 or more cigarettes per day
- Multiple risk factors for arterial cardiovascular disease, such as older age, smoking, diabetes, moderate or severe hypertension
- Current or history of deep vein thrombosis or pulmonary embolism
- Major surgery that requires prolonged immobilization
- Current or history of ischemic heart disease or cerebrovascular accident

- Complicated valvular heart disease
- Migraine with focal neurologic symptoms (migraine with aura)
- Current breast cancer or diabetes with nephropathy, retinopathy, neuropathy, vascular disease, or diabetes of more than 20 years' duration
- Severe cirrhosis or liver tumors
- Women taking certain seizure drugs such as phenobarbital or phenytoin (Dilantin) and women taking rifabutin for tuberculosis treatment
- Women prescribed certain broad-spectrum antibiotics such as tetracycline

From World Health Organization. (2015). *Medical eligibility criteria for contraceptive use* (5th ed.). Geneva, Switzerland: Author.

COCs typically increase or strengthen the action of some drugs such as caffeine and corticosteroids. They may also interact with drugs such as acetaminophen, anticoagulants, and some anticonvulsants by reducing their therapeutic effect, so women may be advised to temporarily change their method of birth control while prescribed these drugs. Several drugs, such as barbiturates, griseofulvin, isoniazid, penicillin, and tetracycline, decrease the effectiveness of COCs, so women might want to change their contraceptive method temporarily while taking these drugs (Karch, 2015).

When discussing COCs, be certain to assess both a woman's ability to pay for them and her ability to follow instructions faithfully (Box 6.7). Women using COCs should return for a yearly follow-up visit (for a pelvic examination, Pap smear, and breast examination), as long as they continue to use this form of birth control. Women without risk factors may continue to take low-dose OCs until they reach menopause.

### BOX 6.7

#### Nursing Care Planning Tips for Effective Communication

You notice Dana, 17 years old, is reading a pamphlet on oral contraceptives while she waits to be seen by the nurse practitioner.

*Tip:* Take the time to help a woman assess how particular measures fit her lifestyle, ask follow-up questions, and avoid advice with a “one size fits all” philosophy. Reproductive life planning measures have to be individualized to fit a person's lifestyle; otherwise, they are quickly discontinued.

**Nurse:** Is that pamphlet helpful? Tell you everything you need to know?

**Dana:** Not really. I need a way to remind me to take a pill every day.

**Nurse:** Will that be a problem?

**Dana:** Duh. I think so.

**Nurse:** Your pill dispenser is meant to serve as a daily reminder. If that doesn't work for you, I could help you make out a reminder chart for your mirror. As a long-term solution, though, have you thought about using a method that doesn't require a reminder more than once a month such a vaginal ring? Or not at all such as an

IUD? Why don't I discuss different types with you so you can think about some more options?

Progestin-only pills have the disadvantage of causing more breakthrough bleeding than combination pills, but they are just as effective and do not pose a danger of thromboembolism (WHO, 2011). These pills are taken every day, even through the menstrual flow. Because they do not interfere with milk production, they may be taken during breastfeeding.

### Oral Contraceptives and Effect on Sexual Enjoyment

For the most part, not having to worry about becoming pregnant because of the reliability of the contraceptive can make sexual relations more enjoyable for a couple. Some women appear to lose interest in coitus after taking COCs for about 18 months, possibly because of the long-term effect of altered hormones in their body. Sexual interest increases again after they change to another form of contraception. Some women experience nausea from COCs and find this interferes with sexual enjoyment as well as with other activities. If they are having side effects with one brand, they might be able to take another brand that has a different strength of estrogen without problems.

### ESTROGEN/PROGESTERONE TRANSDERMAL PATCH

**Transdermal contraception** refers to patches that slowly but continuously release a combination of estrogen and progesterone (Fig. 6.9). Patches are applied each week for 3 weeks. No patch is applied the fourth week. During the week on which the woman is patch free, a menstrual flow will occur. After the patch-free week, a new cycle of 3 weeks on, 1 week off begins again. The efficiency of transdermal patches is equal to COCs, although they may be less effective in women who are obese. Because they contain estrogen, they have the same risk for thromboembolic symptoms as COCs.

**Figure 6.9** Estrogen/progesterone-based patches help adherence because they need attention only once a week. They may be applied

on the arms, the trunk, or buttocks.

Patches may be applied to one of four areas: upper outer arm, upper torso (front or back, excluding the breasts), abdomen, or buttocks. They should not be placed on any area where makeup, lotions, or creams will be applied; at the waist where bending might loosen the patch; or anywhere the skin is red, irritated, or has an open lesion.

Patches can be worn in the shower, while bathing, or while swimming. If a patch does come loose, the woman should remove it and immediately replace it with a new patch. No additional contraception is needed if the woman is sure the patch has been loose for less than 24 hours. If the woman is not sure how long the patch has been loose, she should remove it and apply a new patch to start a new 4-week cycle, with a new day 1 and a new week to change the patch. She also should use a backup contraception method, such as a condom or spermicide for the first week of this new cycle.

Although mild breast discomfort as well as irritation at the application site may occur, one reason transdermal patches are so effective is the woman does not need to remember to take a daily pill.

## **VAGINAL ESTROGEN/PROGESTIN RINGS (NUVARING)**

An etonogestrel/ethinyl estradiol vaginal ring (NuvaRing) is a flexible silicone vaginal ring that, when placed in the vagina, continually releases a combination of estrogen and progesterone (Fig. 6.10). The ring is inserted vaginally by the woman and left in place for 3 weeks and then removed for 1 week with menstrual bleeding occurring during the ring-free week (Bitzer, 2012). The hormones released are absorbed directly by the mucous membrane of the vagina, thereby avoiding a “first pass” through the liver, as happens with COCs; this is an advantage for women with liver disease. Rings do not need to be removed for intercourse. The effectiveness is equal to COCs. Women may need to mark a conspicuously posted calendar to remind themselves to remove and replace the ring. Some women may need to be encouraged to use vaginal rings, as introducing a ring vaginally may at first seem more complicated than taking a pill every day. Some women may experience vaginal discomfort or infection, both of which would make the ring an undesirable method of contraception. Women should be counseled that if they should take out the ring for more than 4 hours for any purpose, they should replace it with a new ring and use a form of barrier protection for the next 7 days.

**Figure 6.10** A vaginal ring. Progesterone is gradually released to be absorbed by the vaginal walls.

## SUBDERMAL HORMONE IMPLANTS

A progestin-filled miniature rod no bigger than a matchstick, etonogestrel implant (Nexplanon) can be embedded just under the skin on the inside of the upper arm where it will slowly release progestin over a period of 3 years. Once embedded, the implant is barely noticeable; it appears as an irregular crease on the skin, simulating a small vein. As with oral progestin, the implant is able to effectively suppress ovulation, thicken cervical mucus, and change the endometrium lining, making implantation difficult.

The rod is inserted as an in-office procedure with the use of a local anesthetic during menses or no later than day 7 of a menstrual cycle to be certain a woman is not pregnant at the time of insertion. It can be placed immediately after an elective termination of pregnancy or 6 weeks after the birth of a baby. An implant is so effective, the failure rate is less than 1%, comparable to oral contraception (CDC, 2014).

A major disadvantage of the implant method is its cost, although for most women, the procedure is covered under the regulations of the Affordable Care Act. However, a major advantage of this long-term reversible contraceptive is that compliance issues associated with COCs are eliminated. Rod insertion also offers an effective and reliable alternative to COCs' estrogen-related side effects. Sexual enjoyment is not inhibited, as may happen with condoms, spermicides, diaphragms, and natural family planning methods. An implant can be used during breastfeeding without an effect on milk production. Implants may also be used in adolescents. The rapid return to fertility after removal is an advantage for women when they become ready to begin a family.

### Side Effects and Contradictions

Side effects include weight gain, irregular menstrual cycle (heavy bleeding, spotting, breakthrough bleeding, and amenorrhea), depression, scarring at the insertion site, and need for removal.

Contraindications to a subdermal rod are pregnancy, desire to be pregnant within 1 year, and undiagnosed uterine bleeding. A complication that can occur is an infection at the insertion site, although this is very rare. Most people who ask to have them removed do so because of irregular or heavy menstrual flows (Berenson, Tan, & Hirth, 2015).

## INTRAMUSCULAR INJECTIONS

A single intramuscular injection of depot medroxyprogesterone acetate or DMPA (Depo-Provera), a progesterone given every 12 weeks, inhibits ovulation, alters the endometrium, and thickens the cervical mucus so sperm progress is difficult (Box 6.8). The effectiveness rate of this method is almost 100%, making it an increasingly popular contraceptive method (CDC, 2014). The injection is made deep into a major muscle (buttocks, deltoid, or thigh) before the fifth day after the beginning of a menstrual flow. Be sure the woman does not massage the injection site after administration so the drug can absorb slowly from the muscle.

### BOX 6.8

#### Nursing Care Planning Based on Responsibility for Pharmacology

### DEPOT MEDROXYPROGESTERONE ACETATE

**Classification:** Contraceptive

**Action:** Depot medroxyprogesterone acetate (DMPA) is a progesterone derivative that inhibits the secretion of pituitary gonadotropins, thereby altering the endometrium and preventing follicular maturation and ovulation (Karch, 2015).

**Pregnancy Category:** X

**Dosage:** 150 mg intramuscular injection every 3 months

**Possible Adverse Effects:** Spotting, breakthrough bleeding, amenorrhea, irregular menstrual flow, headaches, weight fluctuations, fluid retention, edema, rash or acne, abdominal discomfort, glucose intolerance, pain at injection site, or osteoporosis (loss of bone density).

#### Nursing Implications

- Advise patient to have a routine physical examination that includes breast examination, pelvic examination, and Pap smear.
- Caution the patient that potential side effects such as weight gain may occur.
- Advise patient to maintain a high calcium intake to reduce development of osteoporosis.
- Advise the patient to report pain or swelling of the legs, acute chest pain, or shortness of breath; tingling or numbness in the extremities; loss of vision; sudden

severe headaches; dizziness; or fainting; these could be signs of potentially serious cardiovascular complications.

Intramuscular injections have the advantage of long-term reliability without many of the side effects and contraindications associated with COCs. There also is no visible sign a birth control measure is being used as with a subdermal implant, making them attractive to adolescents. However, the thought of weight gain may not be appealing (Modesto, de Nazaré Silva dos Santos, Correia, et al., 2015).

Because DMPA contains only progesterone, it can be used during breastfeeding, although women should wait about 6 weeks after birth for the first injection. Advantageous effects are reductions in ectopic pregnancy, endometrial cancer, endometriosis, and, for unknown reasons, the frequency of sickle cell crises (Taylor et al., 2012).

The woman must return to a healthcare provider for a new injection every 12 weeks for the method to remain reliable. A reminder system, such as a postcard mailed by the prescribing agency, may be necessary to be certain women return on time for their next injection. Alternative methods of administration, such as allowing pharmacists to give the injections or selling them over the counter so women can inject themselves, are being investigated and might increase compliance.

### Side Effects and Contraindications

Common side effects include headache, weight gain, depression, irregular or heavy menstrual cycles for 1 year, and no menstrual bleeding after the first year. DMPA may also impair glucose tolerance in women at risk for diabetes so it should be prescribed cautiously for this population. Because there also may be an increase in the risk for osteoporosis from a loss of bone mineral density, women need to include an adequate amount of calcium in their diet (up to 1,200 mg/day) and engage in weight-bearing exercise daily to minimize this risk.

The manufacturer of DMPA has added a “black box” warning for women not to use the method long term (not over 2 years) to protect against bone loss. For this reason, although often prescribed to adolescents, DMPA should be prescribed with caution to this age group, as this is during the time when the bulk of their calcium deposits are being laid down (Modesto, Bahamondes, & Bahamondes, 2015).

### QSEN Checkpoint Question 6.4

#### TEAMWORK AND COLLABORATION

Suppose Dana, 17 years old, chooses intramuscular injections of DMPA as her method of reproductive life planning. What instructions would the nurse want members of the care team to give her with regard to this method?

- a. “Encourage Dana to limit cigarette smoking to no more than one pack per day.”

- b. “Encourage Dana to drink a glass of milk or take a calcium supplement daily.”
- c. “Teach Dana not to swim for longer than an hour at any one time.”
- d. “Teach Dana not to expose the injection site to direct sunlight.”

*Look in Appendix A for the best answer and rationale.*

## HORMONAL CONTRACEPTION AND EFFECT ON PREGNANCY

Different hormonal applications have different effects on pregnancy.

- *Estrogen/progestin combination pills (COCs)*. If a woman taking an estrogen/progestin combination pill suspects she is pregnant, she should discontinue taking any more pills if she intends to continue the pregnancy as high levels of estrogen might be teratogenic to a growing fetus (Karch, 2015). After women stop taking COCs, they may not be able to become pregnant for 1 or 2 months, and possibly 6 to 8 months, because the pituitary gland requires a recovery period to resume cyclic gonadotropin stimulation. If ovulation does not return spontaneously after this time, there is likely an underlying hormonal imbalance and ovulation can be stimulated by administration of FSH, LH, clomiphene citrate (Clomid), or letrozole (Femara) to restore fertility.
- *Progestin-impregnated rings or progestin patches*. If a woman using a progestin ring or patch becomes pregnant, the progestin should have no effect on a developing fetus. After discontinuing both methods, women become fertile again immediately.
- *Subdermal implants*. If a woman becomes pregnant while using a subdermal implant, the rod can be removed; although, because the implant releases only progestin, there should be no effect on the fetus. At the end of 3 years, when the implant is removed (a 5- to 10-minute procedure), the woman will be fertile again almost immediately.
- *DMPA*. DMPA, like other progestin products, should have no effect if a woman becomes pregnant. A worrisome post-use effect for some women, however, is that the return to fertility is often delayed by 6 to 12 months.

## HORMONAL CONTRACEPTION AND THE ADOLESCENT

It is usually recommended that adolescent girls have well-established menstrual cycles for at least 2 years before beginning COCs. This reduces the chance the estrogen content will cause permanent suppression of pituitary-regulating activity. Estrogen has the side effect of causing the epiphyses of long bones to close and growth to halt; therefore, waiting at least 2 years also helps ensure the preadolescent growth spurt will not be halted. Because adolescents' compliance with most medications is low, adolescent girls may not take either combined or progestin-only pills reliably enough to make them effective. COCs have side benefits of improving facial acne in some girls because of the increased estrogen/androgen ratio created and also decreasing

dysmenorrhea, both of which are appealing to most adolescents and may increase their compliance rate. The pill may be prescribed to some adolescents specifically to decrease dysmenorrhea, especially if endometriosis is present (Evans & Sutton, 2015) (see Chapter 47).

## HORMONAL CONTRACEPTION AND THE PERIMENOPAUSAL WOMAN

As women near menopause, they are likely over the age of 35 years and so are less likely to be good candidates for COCs than when they were younger, especially if they smoke. However, most healthy women over the age of 35 years may remain on COCs if they have no other risk factors. If she is not a good candidate, help women in this age group find an alternative method that will meet their personal preferences as well as still be maximally effective for them, such as an intrauterine device, progestin-only patches, or vaginal rings (Brotherston, 2015).

## HORMONAL CONTRACEPTION AND THE POSTPARTAL WOMAN

It has been recommended that women who are lactating should not take estrogen-based contraceptives as a small amount of the hormone will not only be excreted in breast milk but will also reduce the amount of breast milk formed. Due to conflict in recent evidence about whether estrogen-based contraceptives affect milk supply, women who want hormonal contraception are, therefore, usually prescribed progestin-only pills, progesterone-activated vaginal rings, etonogestrel implant (Nexplanon), or IUDs until they are no longer breastfeeding (Pieh Holder, 2015).

## Intrauterine Devices

An **intrauterine device** (IUD) is a small plastic device that is inserted into the uterus through the vagina. IUDs can be either hormonal or nonhormonal. Although a popular choice worldwide because they are almost 100% effective and need no memory aide, IUDs are used by only a relatively small number of U.S. women. That number is increasing in recent years, however (Conti & Shaw, 2015).

Even though the insertion of foreign objects into the uterus for contraceptive purposes dates back thousands of years (ancient camel drivers used uterine stones for their animals), the mechanism of action for the method is still not fully understood. The method is thought, however, to prevent fertilization as well as to create a local sterile inflammatory reaction that prevents implantation. When copper is added to the device, the possibility sperm will not be able to successfully cross the uterine space and reach the ovum increases as well.

IUDs may be used by women who have never had children as well as those who have. The device must be fitted by a healthcare provider who first performs a pelvic examination and, in women with high risk for STIs, a test for gonorrhea and chlamydia.

The device is usually inserted before a woman has had coitus after a menstrual flow, so the healthcare provider can be assured the woman is not pregnant at the time of insertion. The copper IUD can also be used within 5 days of unprotected sex as a form of emergency contraception.

The device is inserted in a collapsed position and then opens to its final shape in the uterus when the inserter is withdrawn. The woman may feel a sharp cramp as the device is passed through the internal cervical os, but she will not feel the IUD after it is in place. Properly fitted, such devices are contained wholly within the uterus, although an attached string protrudes through the cervix into the vagina. Women may continue to use tampons or menstrual cups for menstrual flow with no danger of dislodging an IUD (Wiebe & Trouton, 2012).

Four types are commonly approved for use in the United States, but that number is increasing as companies expand their product line and other companies create generic versions:

- Copper T380 (ParaGard) is a T-shaped plastic device wound with copper. It is effective for 10 years, after which time it should be removed and replaced with a new IUD.
- Levonorgestrel-releasing intrauterine system 52 mg (Mirena or Liletta) IUD, which features a drug reservoir of progesterone in the stem (Fig. 6.11). The progesterone (levonorgestrel) in the drug reservoir gradually diffuses into the uterus through the plastic; it both prevents endometrium proliferation and thickens cervical mucus. Because it reduces endometrium proliferation, it also has the potential to reduce endometrial cancer (Oman & Burke, 2015). It is effective for 5 years (possibly as long as 7 years). Many women using the Mirena will have a cessation of menses or periodic light spotting instead of a normal menses.

**Figure 6.11** Intrauterine devices using copper or levonorgestrel. (From Beckmann, C. R. B., Ling, F. W., Herbert, W. N. P., et al. [2014]. *Obstetrics and gynecology* [7th ed.]. Baltimore, MD: Lippincott Williams & Wilkins.)

- Levonorgestrel-releasing intrauterine system 13.5 mg (Skyla) IUD, which is manufactured by the same company as Mirena, has a lower dose of progesterone in the stem. It works similarly to Mirena and is effective for 3 years. Women are more likely to have unscheduled bleeding with Skyla than with Mirena.
- Levonorgestrel-releasing intrauterine system 19.5 mg (Kyleena) IUD, which is manufactured by the same company as Mirena, has a lower dose of progesterone in the stem as compared to Mirena but higher than that of Skyla. It is approved for 5 years and has a bleeding profile similar to Mirena. Women may choose this over Mirena due to the lower dose of progesterone but the benefits of Mirena in terms of duration of use and lower rates of breakthrough bleeding.

All the IUD types have an ideal failure rate as low as 0.1% (see [Table 6.1](#)). They have several advantages over other contraceptives in that only one insertion is necessary, so there is no continuing expense. They are appropriate for women who are at risk for complications associated with estrogen-based side effects. With the copper IUD, there is little change in the timing of menstrual flows, although monthly flow may be heavier. Teach women to regularly check after each menstrual flow to make sure the IUD string is in place and to obtain a yearly pelvic examination as usual.

## **SIDE EFFECTS AND CONTRAINDICATIONS**

A woman may notice some spotting or uterine cramping the first 2 or 3 weeks after IUD

insertion. Ibuprofen, a prostaglandin inhibitor, is helpful in relieving the pain. Rarely, a woman continues to have cramping and spotting after insertion; in such instances, she may expel the device spontaneously. If this happens, she should use an alternative method of birth control until she can visit her healthcare provider to have a new one inserted (or choose a different type of protection). Nulliparous women may have a higher percentage of spontaneous expulsion than others.

It was once a concern nulliparous women could not be fitted with IUDs and any woman with an IUD in place might have a higher risk for PID than others. Nulliparous women can be fitted (although they may have a slightly higher rate of expulsion); infection is no longer a concern because the vaginal string no longer conducts fluid (Oman & Burke, 2015). The Mirena IUD may actually help resist infection because of the change created in the cervical mucus.

Use of an IUD may be contraindicated for a woman whose uterus is distorted in shape (the device might perforate the uterine wall). The copper IUD use also is not advised for a woman with severe dysmenorrhea (painful menstruation) or menorrhagia (heavy bleeding) because use may increase the incidence of these conditions. Because use of a copper IUD can cause heavier than usual menstrual flow, a woman with anemia also may not be considered a good candidate for a copper IUD.

## **EFFECT ON PREGNANCY**

If a woman with an IUD in place suspects she is pregnant, she should alert her primary healthcare provider. The woman will receive an early sonogram to document placement of the IUD and rule out ectopic pregnancy. Following confirmation of the IUD's location, it may be left in place during the pregnancy, but it is usually removed vaginally to prevent the possibility of infection or spontaneous miscarriage during the pregnancy.

## **INTRAUTERINE DEVICES AND THE ADOLESCENT**

IUDs and etonogestrel implant (Nexplanon), long-acting reversible contraceptives (LARCs), are now recommended for adolescents by the American Academy of Pediatrics (AAP) due to their efficacy and high rates of continuation (Usinger, et al., 2016).

## **INTRAUTERINE DEVICES AND THE PERIMENOPAUSAL WOMAN**

Women who are premenopausal are, overall, good candidates for IUDs.

## **INTRAUTERINE DEVICES AND THE POSTPARTAL WOMAN**

Although postpartum insertion of an IUD is usually done at a 6-week postpartal checkup, it can be done immediately after childbirth (also immediately after a spontaneous or induced abortion or at the time of a cesarean birth (Goldthwaite & Shaw, 2015). An IUD inserted immediately this way does not affect uterine involution

or the uterus's return to its prepregnant uterine size, but it is associated with a higher rate of expulsion (Goldthwaite & Shaw, 2015). Yet another time for the copper IUD insertion is after unprotected sex as postcoital protection (Oman & Burke, 2015).

## Surgical Methods of Reproductive Life Planning

Surgical methods of reproductive life planning, often called sterilization, include tubal ligation for women and vasectomy for men. Tubal ligation is chosen by about 16% of all women in the United States of childbearing age as their contraceptive of choice. Vasectomy is the contraceptive method of choice for about 5% of men, making these two procedures a very popular option for couples older than 30 years of age (Daniels, Daugherty, & Jones, 2014). Many people choose these surgical methods because they are some of the most effective methods of contraception besides abstinence, involve no further costs, and should have no effect on sexual enjoyment. Although both sexes should think of these procedures as permanent before they have them, between 6% and 7% of both men and women in the United States who have had these procedures ask to have the procedures reversed (Herrel, Goodman, Goldstein, et al., 2015).

Reversal techniques may be much more complicated and expensive than the sterilization itself, and success rates are only 70% to 80%. For this reason, surgical methods should be chosen with great thought and care. These procedures may not be recommended for individuals whose fertility is important to their self-esteem. Counseling should be especially intensive for men and women younger than 30 years of age because the possibility of divorce, death of a sexual partner, loss of a child, or remarriage could change a person's philosophy toward childbearing.

### VASECTOMY

In a **vasectomy**, a small puncture wound (referred to as “no-scalpel technique”) is made on the scrotum. The vas deferens on each side are then pulled forward, cut and tied, cauterized, or plugged, blocking the passage of spermatozoa (Cameron & Glasier, 2012) (Fig. 6.12). A vasectomy can be done under local anesthesia in an ambulatory setting, such as in a primary healthcare provider's office or a reproductive life planning clinic. The man may experience a small amount of local pain afterward, which can be managed by taking a mild analgesic and applying ice to the site. Although the procedure is about 99.5% effective, spermatozoa, which were present in the vas deferens at the time of surgery, can remain viable for as long as 6 months. Therefore, although the man can resume sexual intercourse within 1 week, an additional birth control method should be used until two negative sperm reports at about 6 and 10 weeks have been obtained (proof all sperm in the vas deferens have been eliminated, usually requiring 10 to 20 ejaculations).

**Figure 6.12** (A) The left vas deferens being cut with surgical scissors. (B) The cut ends of the vas deferens are cauterized or clamped to completely ensure blockage of the passage of sperm.

Some men resist the concept of vasectomy because they are not sufficiently aware of their anatomy to know exactly what the procedure will involve. They can be assured a vasectomy does not interfere with the production of sperm; the testes continue to produce sperm as always, but the sperm simply do not pass beyond the plugged vas deferens and are absorbed at that point. The man will still have full erection capacity and continue to produce testosterone. Because he also continues to form seminal fluid, he will ejaculate seminal fluid; it will just not contain sperm.

There are very few complications associated with a vasectomy. A hematoma at the surgical site may occur, although this is seen less frequently with “no scalpel” or puncture incisions. The procedure may also be associated with the development of urolithiasis (kidney stones). A few men develop chronic pain after vasectomy (postvasectomy pain syndrome); having the procedure reversed relieves this pain (Horovitz, Tjong, Domes, et al., 2012).

Some men develop autoimmunity or form antibodies against sperm following a vasectomy, so even if reconstruction is successful, sperm may not have good mobility or be incapable of fertilization. Men who want their sperm to be available for the future can have it sperm banked before vasectomy.

### *Concept Mastery Alert*

Vasectomy can be reversed, but the procedure is complicated, expensive, and success rates are low.

## TUBAL LIGATION

Sterilization of women could include removal of the uterus or ovaries (hysterectomy), but it usually refers to a minor surgical procedure, such as **tubal ligation**, where the fallopian tubes are occluded by cautery, crushed, clamped, or blocked, thereby preventing passage of both sperm and ova. A fimbriectomy, or removal of the fimbria at the distal end of the tubes, is another possible but little used technique. Tubal ligation has a 99.5% effectiveness rate (CDC, 2014). It also is associated with a decreased incidence of ovarian cancer.

After a menstrual flow and before ovulation, with the woman under general or local anesthesia, an incision as small as 1 cm is made just under the woman's umbilicus by laparoscopy technique. **Laparoscopy** is a surgical procedure where a small incision is made in the abdomen for the purpose of viewing or performing surgery on the organs of the pelvis or abdomen. During a laparoscopic tubal ligation, a lighted laparoscope is inserted through the incision. Carbon dioxide then may be pumped into the incision to lift the abdominal wall upward and out of the line of vision. A surgeon locates the fallopian tubes by viewing the field through a laparoscope. An electrical current to coagulate tissue is then passed through the instrument for 3 to 5 seconds, or the tubes are clamped by plastic, metal, or rubber rings and then cut; they also may be filled with a silicone gel to seal them. All procedures provide immediate contraception.

The woman is discharged from the hospital a few hours after the procedure. She may notice a day or two of abdominal discomfort caused by local necrosis if clips were used, and she may notice abdominal bloating for the first 24 hours, until the carbon dioxide infused at the beginning of the procedure is absorbed. The presence of carbon dioxide can also cause sharp diaphragmatic or shoulder pain if some of the carbon dioxide escapes under the diaphragm and presses on ascending nerves. Possible complications include bowel perforation, hemorrhage, and the risks of general anesthesia if this was used.

A newer system, Essure, consists of a spring-loaded mechanism that, when inserted through the vagina and uterus into a fallopian tube (a hysteroscopy procedure), releases a soft micro-insert into the tube (Fig. 6.13). This procedure is preferred over the traditional surgical tubal ligation for women who are very obese and would therefore be a difficult surgical case. It is also preferred by patients who would like to avoid a

surgical procedure through their abdomen. The procedure is done as an in-office or operating room procedure. Women must use a second form of contraception afterward until at 3 months, an infusion sonogram, hysterosalpingogram, or magnetic resonance imaging (MRI) is done to confirm the fallopian tubes are firmly blocked (la Chapelle, Veersema, Brölmann, et al., 2015). The U.S. Food and Drug Administration (FDA) held a conference on Essure's safety and effectiveness in September of 2015 after receiving complaints from providers and patients. Although Essure has not been pulled off the market, the FDA is seeking more information related to complications of Essure including persistent pelvic pain, allergic reactions, perforation of the fallopian tubes, and spontaneous expulsion of the device through the vagina (FDA, 2016).

**Figure 6.13** An Essure procedure blocks the fallopian tubes by a coiled spring introduced vaginally.

Women may return to having coitus as soon as 2 to 3 days after the procedure. Be certain they understand tubal ligation, unlike a hysterectomy, does not affect the menstrual cycle, so they will still have a monthly menstrual flow.

### Side Effects and Contraindications

If tubal ligation surgery is done by laparoscopy, an umbilical hernia or ureter or bowel perforation are possible complications. Extensive obesity might require a full laparotomy to allow adequate visualization. A number of women develop vaginal spotting, intermittent vaginal bleeding, and even severe lower abdominal cramping after tubal ligation—symptoms termed *posttubal ligation syndrome*. Removal of the fallopian tubes appears to relieve these symptoms.

Not only is it difficult to reconstruct fallopian tubes after tubal ligation but there is also a possibility that, afterward, the anastomosis site could cause an ectopic (tubal) pregnancy because of its irregular surface. If a silicone gel has been instilled into the tubes as a blocking agent, this can be removed at a later date to reverse the procedure

much more easily. As with a vasectomy, however, woman should view tubal ligation as a permanent, irreversible procedure as the length of their tube may be shortened afterward, interfering with fertilization (Messinger, Alford, Csokmay, et al., 2015); otherwise, they can develop postprocedural regret. However, women could turn to in vitro fertilization (IVF) as a method to have future children (see Chapter 7).

### Effect on Pregnancy

Because both vasectomy and tubal ligation are nearly 100% effective, pregnancy rarely occurs. If it should, there is no effect on the fetus. If sperm were present in a woman's fallopian tube prior to ligation, an ovum could be fertilized in the blocked tube, causing an ectopic pregnancy.

## SURGICAL METHODS AND EFFECT ON SEXUAL ENJOYMENT

Both tubal ligation and vasectomy may lead to increased sexual enjoyment because they largely eliminate the possibility of pregnancy. However, if either partner changes his or her mind about having children, the surgery may become an issue between them that interferes not only with sexual enjoyment but also with their entire relationship.

## SURGICAL METHODS AND THE ADOLESCENT

As a rule, counsel adolescents to use more temporary forms of birth control because their future goals may change so drastically that what they think they want at age 16 or 18 years may not be what they desire at age 30 years. Later, if they still feel a vasectomy or tubal ligation is the method of reproductive life planning for them, the option will still be available.

## SURGICAL METHODS AND THE PERIMENOPAUSAL WOMAN

When a woman realizes childbearing for her is complete, a vasectomy for her partner or tubal ligation for her are the two most frequently requested forms of contraception as they require no further expense or motivation for success.

## SURGICAL METHODS AND THE POSTPARTAL WOMAN

Tubal ligation can be done as soon as 4 to 6 hours after the birth of a baby or after an elective termination of a pregnancy, although it may be more common at 12 to 24 hours after birth. The abdominal distention at this time may make locating the tubes difficult, so a mini-laparotomy may be used. Such procedures can be done in an ambulatory surgery department with the woman under local anesthesia.

### *QSEN Checkpoint Question 6.5*

#### INFORMATICS

Dana, 17 years old, e-mails the nurse to ask how a tubal ligation prevents pregnancy.

To be certain she's fully informed, which would be the nurse's best answer?

- a. Sperm can no longer reach the ova because fallopian tubes are blocked.
- b. Sperm cannot enter the uterus because the cervical entrance is blocked.
- c. Prostaglandins released from the cut fallopian tubes effectively kill sperm.
- d. The ovary no longer releases ova because there is nowhere for them to go.

---

*Look in [Appendix A](#) for the best answer and rationale.*

---

## EMERGENCY POSTCOITAL CONTRACEPTION

A number of regimens, often referred to as “morning-after pills,” are available for emergency postcoital contraception (EC), which is needed after unprotected voluntary coitus or involuntary situations such as rape ([American College of Obstetricians and Gynecologists \[ACOG\], 2015](#)). Two types are most common:

- High-dose progestin-based pills
- Insertion of a copper IUD

It may be important to explain to women postcoital methods such as Plan B One-Step and Next Choice (the most frequently used forms) do not cause abortion; the pills work by inhibiting ovulation and interfering with fertilization by slowing the transport of sperm. An IUD creates changes in the endometrium and cervical mucus to also slow or prevent sperm transport ([ACOG, 2015](#)).

Levonorgestrel 1.5 mg (Plan B One-Step and Next Choice) are available over the counter without a prescription by males or females. Studies show that, despite their age, young adolescents are able to read the pamphlet instructions and take the pills just as independently as adults ([McCarthy, 2013](#)). One or two pills, depending on the brand, containing a high dose of levonorgestrel, a progestin, are taken anytime within 72 hours (3 days) of unprotected coitus to interrupt a pregnancy.

A newer form of pill, ulipristal acetate (known as ella) requires a prescription and may be taken as late as 120 hours (5 days) after unprotected intercourse ([ACOG, 2015](#)). The dose is the same (one pill). Most women expect the pills will begin a menstrual flow; caution them this will not happen, although they may notice some spotting from the change of hormones in their body. Their next menstrual flow may begin either earlier or later than usual.

Overall, the rate of effectiveness for EC if taken within 72 hours is about 75% ([ACOG, 2015](#)). Be certain women know the pills do not protect against STIs and they will not continue to protect against pregnancy should coitus recur. A woman needs to begin a protective measure for this or use a postcoital method again.

An ethical question that was asked when postcoital pills were first approved was whether the availability of EC would encourage risky sexual behavior; this does not seem to be so. It is important women don't think of postcoital contraception as a routine contraceptive method but as a true emergency measure ([Raymond & Cleland, 2015](#)). The chief side effect is nausea; if a woman notices this, she can take an over-the-counter antiemetic. Rh-negative women do not need Rho(D) immune globulin (RhoGAM)

injections after postcoital pills or IUD insertion because a fetus never formed, thus negating isoimmunization (see [Chapter 26](#) for a full discussion of Rh-negative blood, isoimmunization, and pregnancy).

Although EC pills have the potential to greatly reduce the number of unintended pregnancies and abortion, fear of side effects, reluctance to have a pelvic examination (not necessary), lack of knowledge about how to use the pills, and reluctance to ask a family pharmacist for the pills limit the number of these products being sold ([Upadhya, Santelli, Raine-Bennett, et al., 2017](#)). Internet drug companies can serve as a resource for EC as they provide both privacy protection and competitive prices. Such sites are appreciated by young adults and also can supply education on different reproductive life planning methods for the future ([Gawron & Turok, 2015](#)).

A postcoital IUD is inserted by a healthcare provider with the same technique as for routine use. It can then be left in place and continue as the woman's reproductive life planning method so unprotected intercourse will not happen again.

### *What If . . . 6.3*

**Dana does not follow the nurse's advice for reproductive life planning and needs a prescription for Plan B One-Step for EC. Her mother asks the nurse to give her something so painful she'll not want to engage in unprotected coitus again. Would the nurse agree to her philosophy of care?**

## The Couple With Unique Needs

Reproductive life planning can be a greater concern than usual for a couple with a physical or cognitive challenge, as finding a suitable contraceptive may be more difficult for them than for other couples. For example, a man who has unsteady coordination might not have adequate hand coordination to place a condom effectively. A woman with a similar handicap might have difficulty inserting a diaphragm or vaginal ring; a woman who is cognitively challenged might not understand the need to take COCs daily. Morbidly obese patients can also have difficulty with diaphragm insertion and may notice estrogen patches and implants may not supply an adequate dosage of drug to be effective. Women with recurrent convulsions (epilepsy) may be unable to take COCs because of the interaction of estrogen with common seizure medications ([Taylor et al., 2012](#)). For these reasons, subdermal implants, IUDs, or surgical intervention may be the ideal contraceptive for many couples with a disability.

## Future Trends in Contraception

Although COCs contain much less estrogen today than originally, estrogen remains responsible for most of the side effects associated with COCs. Therefore, studies are being conducted using even lower doses and different forms of estrogen. Biodegradable

implants that do not have to be removed or an estrogen-based gel that is rubbed onto the skin may be used in the future. A progesterone-filled vaginal ring that is permanently implanted is yet another possibility. A birth control vaccine consisting of antibodies against human chorionic gonadotropin hormone is a distant possibility. Injections of testosterone for males (which halts sperm production, just as estrogen halts ova production in women) are being tested at major centers. Hormone-related male contraception, however, has inherent problems; because sperm production is continuous, there is not just one event (ovulation) to halt. Administration of FSH and LH to men could stop sperm production through effects on the pituitary and hypothalamus. However, this approach would also decrease production of testosterone, which is necessary for male muscle strength. Until the matter of how to balance the amount of needed testosterone and excessive testosterone (which produces aggression) is solved, hormonal male contraception remains an elusive concept (Zdrojewicz, Konieczny, Papier, et al., 2015).

Until some method is found that satisfies all of the criteria for an ideal contraceptive (completely safe, no side effects, low cost, easy availability, easy reversibility, and user acceptability), both women and men need opportunities to discuss options to find the method right for them. [Box 6.9](#) shows an interprofessional care map illustrating both nursing and team planning for reproductive life planning.

## BOX 6.9

### Nursing Care Planning

#### AN INTERPROFESSIONAL CARE MAP FOR AN ADOLESCENT SEEKING CONTRACEPTIVE INFORMATION

Seventeen-year-old Dana Crews has come to your community health clinic for a pelvic examination and Pap smear. She is sexually active and tells you her boyfriend “sometimes” uses a condom. She trusts he will “stop in time” when they aren’t using one. She doesn’t want to take birth control pills because she can’t afford it and she’s afraid her parents will find out she’s broken her abstinence pledge if they see the dispenser.

**Family Assessment:** Patient lives at home with parents and younger sister, 12 years old. Father works as a Boy Scout administrator. Mother is a stay-at-home mom. Patient states family finances are “good; no problem.”

**Patient Assessment:** Past medical history is negative for major health problems. Menarche at age 12 years. Menstrual cycles range from 28 to 35 days, with a moderately heavy flow lasting 5 to 7 days. She has enough cramping monthly she “has to stay home from school for 1 day.” Last menstrual flow was 1 week ago. Denies history of STIs or other reproductive problems. Weight is appropriate for height. Secondary sex characteristics are present. You notice her smoking a cigarette outside in the parking lot. Following her healthcare visit, she is prescribed Ortho-ovum 7/7/7, a 28-day-cycle triphasic oral contraceptive. Decided against DMPA

because of cost.

**Nursing Diagnosis:** Readiness for enhanced knowledge related to knowledge deficit concerning contraception

**Outcome Criteria:** Patient identifies options available to her; states valid reasons for method chosen; demonstrates correct use of and appropriate follow-up care for chosen method; voices satisfaction with method chosen within 1 month.

Team Member Responsible	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Assess patient's lifestyle.	Discuss when she will take pill and where she will store them. Help make out a reminder sheet. Caution against smoking while taking an estrogen-based pill.	Reviewing lifestyle may reveal potential reasons why the method could be ineffective or not continued.	Patient describes lifestyle healthca provide actively participi devising lifestyle changes will add contrac effective
<i>Teamwork and Collaboration</i>				
Nurse/nurse practitioner	Consult with nurse practitioner to determine whether method patient chooses will be optimal, safe, and effective.	Secure prescription for medication.	Effective health care is a collaborative effort drawing on interdisciplinary expertise.	Consult reveals contrac method has cho be optim safe, an effective patient r prescrip
<i>Procedures/Medications for Quality Improvement</i>				
Nurse/nurse practitioner	Assess what additional information patient needs to use chosen form of contraception	Help complete pre-prescription procedures such as a Pap test and pelvic examination. Review	Medication administration invariably requires discussion to	Procedu necessa prescrip carried o safely w

	effectively. Determine if patient has questions regarding pelvic examination or other procedures scheduled.	method of administration of prescription and steps to take if she forgets to take a pill.	help patients comply. Nurses can be invaluable in lending psychological and physical support during procedures.	optimal for patient privacy concerns states should understand importance of prescription procedure ensure health safety.
--	---	---	---	--

*Nutrition*

Nurse/nutritionist	Determine whether patient commonly eats a dietary source of folic acid such as green vegetables.	Discuss with patient that oral contraceptive use can lead to folic acid deficiency.	Knowledge of side effects is important to create informed consumers.	Patient acknowledge she needs to be conscious of the need for folic acid names to good sources of folic acid food.
--------------------	--	---	--	--

*Patient-Centered Care*

Nurse	Determine whether patient has any further questions regarding chosen contraceptive measure.	Have patient repeat information for return demonstration.	Instruction provides an opportunity for learning to improve compliance.	Patient describe action of contraceptive and the importance of taking the contraceptive conscientiously.
-------	---	---	---	--

*Psychosocial/Spiritual/Emotional Needs*

Nurse	Assess if patient has discussed with boyfriend that contraception is different than safer sex practices.	Review and discuss the need for safer sex practices in addition to contraception.	Safer sex practices promote health, empower the patient, and minimize the risk of STIs.	Patient acknowledge need for safer sex practices to prevent STIs and states will ask partner to use condom.
-------	--	---	---	---

## Informatics for Seamless Healthcare Planning

Nurse	Assess if patient understands she will need continued health supervision while on an oral contraceptive.	Explain the need for routine follow-up in 1 month and yearly pelvic examinations.	Follow-up is essential for evaluating adherence and satisfaction and for reducing the risk of possible complications.	Patient : she will for a fol visit in and eve thereaft
-------	--	---	---	--

STI, sexually transmitted infection.

### QSEN Checkpoint Question 6.6

#### EVIDENCE-BASED PRACTICE

Declines in adolescent pregnancy rates have increased from 2007 to 2012; rates dropped 36% in women 15 to 19 years old. Determinants for the decrease in the pregnancy rate in this group could be related to individual, household, community, or other influences. The decrease in pregnancy rate could also be related to how often adolescents are having sex, how often they are using birth control, or how often they are choosing abortion after unexpected pregnancy occurs. The National Survey of Family Growth surveyed high school students and found a modest decline in sexual activity, a large increase in contraceptive use, and that the use of abortion remained the same from 1995 to 2002. A reexamination of data from the same survey from 2007 to 2012 found there was no change in sexual activity, an increase in contraceptive use, and a stable use of abortion (Lindberg, Santelli, & Desai, 2016).

Assuming Dana is a typical 17-year-old adolescent, her likelihood of giving birth in 2012 is mostly related to which of the following factors?

- Her partner and she decided to choose abstinence.
- She has access to a provider who provides abortion services.
- She has access to a provider who prescribes birth control.
- Her community frowns upon adolescent pregnancy.

Look in [Appendix A](#) for the best answer and rationale.

## Unfolding Patient Stories: Carla Hernandez • Part 1

**Carla Hernandez**, a 32-year-old gravida 2 para 1, is accompanied by her husband during a routine prenatal visit. They want to discuss options for preventing a future pregnancy after delivery of their second child. What information can the nurse prepare to help them make an informed decision? What questions asked by the nurse can help guide the discussion toward methods that correspond with their beliefs and values? (Carla Hernandez's story continues in [Chapter 15](#).)

Care for Carla and other patients in a realistic virtual environment: *vSim* for Nursing ([thepoint.lww.com/vSimMaternityPed](http://thepoint.lww.com/vSimMaternityPed)). Practice documenting these patients' care in DocuCare ([thepoint.lww.com/DocuCareEHR](http://thepoint.lww.com/DocuCareEHR)).

## Elective Termination of Pregnancy

Unsupervised abortions are terminations of pregnancy performed by unskilled people, often under less than sterile conditions at any point in pregnancy. An **elective termination of pregnancy** is a procedure performed by a knowledgeable healthcare provider to end a pregnancy before fetal viability. Such procedures are also referred to as therapeutic, medical, or induced abortions. In 2011, the abortion rate in the United States was 16.9 per 1,000 women aged 15 to 44 years (Jones & Jerman, 2014). Whereas unsupervised abortions carry a high risk for infection or excessive bleeding that can lead to death, the maternal mortality rate for elective terminations is only 0.6 per 100,000 procedures. This rate correlates to elective termination being about 11 times safer for women than childbirth, for which the mortality rate is closer to 6 per 100,000 births (Zane, Creanga, Berg, et al., 2015).

Elective terminations of pregnancy would be needed less often if women were aware of emergency contraception and how to use it within 120 hours of unprotected coitus. Reasons that elective terminations are most often requested are for a pregnancy that:

- Threatens a woman's life, such as pregnancy in a woman with class IV heart disease
- Involves a fetus found on amniocentesis to have a chromosomal defect
- Is unwanted because it is the result of rape or incest
- Is unwanted because a woman chooses not to have a child at this time in her life for such reasons as being too young, not wanting to be a single parent, wanting no more children, having financial difficulties, or from failed contraception

The majority of pregnancy terminations are done for this last reason.

In the United States, although drugs to induce abortion safely are available, elective termination of pregnancy is still mainly a surgical procedure. Nurses employed in healthcare agencies where induced abortions are performed are asked to assist with such procedures as a part of their duties.

Women should be educated that elective termination is not ideal as a method of reproductive life planning but should be used as remediation for failed contraception. In addition, women should be counseled about other options such as adoption or single parenthood before the procedure (Chervenak & McCullough, 2012).

In 1973, the U.S. Supreme Court ruled elective terminations must be legal in all states as long as the pregnancy is less than 12 weeks. Individual states regulate whether termination of second-trimester pregnancies are allowed and can prohibit termination of third-trimester pregnancies that are not life threatening. They can also mandate additional regulations regarding the procedures, such as requiring a 24-hour waiting

period for counseling or requiring parental approval for minors. Whether a particular institution or healthcare provider performs elective termination services depends on the policy and choice of that institution or individual.

## MEDICALLY INDUCED TERMINATION

Mifepristone (RU-486 or Mifeprex) is a progesterone antagonist that blocks the effect of progesterone, preventing implantation of the fertilized ovum and therefore causing the pregnancy to be lost. Mifepristone is not solely used for induced terminations and so may also be prescribed to women for regression of uterine leiomyomas or detoxification in cocaine overdose. When used for a medical termination of pregnancy, the compound is taken as a single oral dose any time before 63 days gestational age followed by buccal or vaginal misoprostol (Cytotec) (a prostaglandin), which causes uterine contractions (Chen & Creinin, 2015). Some women may also be prescribed an antibiotic as prophylactic protection against infection.

Another medical regimen is methotrexate (Trexall) and misoprostol (Cytotec). Methotrexate (also used to end ectopic pregnancies or trophoblastic disease; see Chapter 21) interferes with the DNA synthesis of dividing cells and so prevents growth of the zygote. A mifepristone/misoprostol regimen is about 96% effective; methotrexate/misoprostol is slightly lower (Oman & Burke, 2015).

Because the blood type of the conceptus is unknown with either medical or surgical termination, all women with Rh-negative blood should receive Rho(D) immune globulin (RhoGAM or RHIG) at the time the mifepristone is prescribed or within 72 hours after the procedure to prevent the buildup of antibodies in the event the conceptus was Rh positive (Aitken, 2015). (See Chapter 26 for a full discussion of Rh isoimmunization.)

Medically induced termination of pregnancy is contraindicated if a woman has:

- A confirmed or suspected ectopic pregnancy (only methotrexate is used and the woman needs additional follow-up)
- An IUD in place
- A serious medical condition such as chronic adrenal failure
- A history of current long-term systemic corticosteroid therapy
- A history of allergy to mifepristone, misoprostol, or other prostaglandins
- A hemorrhagic disorder or is taking concurrent anticoagulant therapy

Advantages of medically induced over surgical termination include the decreased risk of damage to the uterus through instrument insertion and decreased use of anesthesia necessary for surgically performed procedures. The complications of medically induced termination include nausea and vomiting, diarrhea, severe uterine cramping, incomplete abortion, and the possibility of prolonged bleeding.

A woman can expect to have mild vaginal spotting and perhaps cramping for 2 weeks postprocedure. Caution her to use sanitary pads rather than tampons and not to douche to help avoid infection. She should not take aspirin for discomfort as this can increase bleeding (advise acetaminophen [Tylenol] instead).

She can resume regular activities but avoid heavy lifting or strenuous exercise for about 3 days. Her usual menstrual period will return in 2 to 4 weeks. It's best if she doesn't have sexual relations until a scheduled checkup to avoid infection, but if she does, she should advise her partner to use a condom to avoid a second pregnancy.

It's important that she notify her healthcare provider if she has heavy vaginal bleeding (more than two pads saturated in 1 hour), passing of clots, abdominal pain or tenderness, oral temperature over 102.4°F, or if she notices severe depression or sadness. As a last measure, she should be certain to keep her follow-up appointment in about 2 weeks for postprocedure ultrasonography or a pregnancy test to ensure the pregnancy has ended and obtain contraceptive counseling so she can avoid a repeat procedure.

## **SURGICAL ELECTIVE TERMINATION PROCEDURES**

Elective surgical terminations involve several different techniques, depending on the gestational age at the time the termination is performed.

*Menstrual extraction* or suction evacuation is performed on an ambulatory basis 5 to 7 weeks after the last menstrual period. A narrow polyethylene catheter is introduced through the vagina into the cervix and uterus; the lining of the uterus that would be shed with a normal menstrual flow is suctioned and removed by the vacuum pressure of a syringe (Fig. 6.14A). The procedure causes only a minimum of discomfort (perhaps slight uterine cramping).

**Figure 6.14** Techniques of surgical elective termination of pregnancy. **(A)** Menstrual extraction. **(B)** Dilatation and curettage (D&C). **(C)** Dilatation and vacuum extraction (D&E). **(D)** Saline induction.

*D&C* is used when the gestational age of a pregnancy is still less than 13 weeks. This is done in an ambulatory setting using a paracervical anesthetic block that does not eliminate all pain but limits what the woman experiences to cramping and a feeling of pressure. The cervix is dilated and the uterus is scraped clean with a curette, removing the zygote and trophoblast cells with the uterine lining (Fig. 6.14B). D&C has a potential risk of uterine perforation from the instruments used and carries an increased risk of uterine infection compared with menstrual extraction because of the greater

cervical dilatation.

*Dilatation and vacuum extraction (D&E)* is used with terminations between 12 and 16 weeks of gestation. They are done in either an inpatient or ambulatory setting. In some centers, dilatation of the cervix is begun the day before the procedure by administration of buccal misoprostol or insertion of a laminaria tent (seaweed that has been dried and sterilized) into the cervix. In a moist body part such as the cervix, the seaweed absorbs fluid and swells in size. Over a 24-hour period, gradually, painlessly, and without trauma, it dilates the cervix enough for a vacuum extraction tip to be inserted. There is some concern that if a woman needs frequent surgical dilatation of the cervix, as would occur from frequent abortion procedures, it could lead to a cervix that dilates so easily it would not remain contracted during a subsequent pregnancy. Therefore, laminaria dilatation is often chosen for young women who may have more than one pregnancy termination in their lifetime as the gradual dilation of a cervix by this method helps to safeguard their childbearing potential. Antibiotic prophylaxis may be initiated at the time of the laminaria insertion, and the woman is cautioned not to have sexual relations until the process is complete to protect against infection.

For the actual procedure, a narrow suction tip is introduced into the cervix ([Fig. 6.14C](#)). A suction pump or vacuum container gently evacuates the uterine contents over a 15-minute period. The woman will feel pain as the cervical dilatation is performed and some pressure and cramping, similar to menstrual cramps, during suction, but it is not a markedly painful procedure.

*Prostaglandin or a saline induction* is used if a pregnancy is between 16 and 24 weeks ([Fig. 6.14D](#)) and is done on an inpatient or same-day surgery basis. Following oral misoprostol or vaginal laminaria to prepare the cervix for dilatation, prostaglandin F2 or E2 is administered followed by a 20% saline injection into the uterus. The saline, because it is hypertonic, causes fluid shifts and sloughing of the placenta and endometrium.

A dilute intravenous solution of oxytocin (Pitocin) to assist the start of contractions may also be used. Pain from the procedure is similar to natural birth but can be controlled by analgesics and breathing exercises.

Oxytocin administration is discussed in [Chapter 23](#). As with the woman receiving oxytocin for term labor, the woman needs to be observed carefully for signs of water intoxication (fluid accumulating in body tissue), such as severe headache and confusion. A serious potential complication of saline administration is hypernatremia from accidental injection of the hypertonic saline solution into a blood vessel within the uterine cavity. This could cause interstitial fluid to shift into the blood vessels in an attempt to equalize osmotic pressure and result in serious hypertension and dehydration of tissue. If an intravascular puncture should occur, the woman immediately experiences an increased pulse rate, a flushed face, and a severe headache. The injection must be stopped immediately and an intravenous solution such as 5% dextrose is begun to dilute the saline solution and restore fluid balance.

After expulsion of the products of conception after about 12 to 36 hours, all the

tissue expelled should be examined to determine whether the entire conceptus (fetus and placenta and membranes) have been expelled. If a woman wishes to see the fetus, wrap it as if it were a full-term infant and allow her to do this to begin effective grieving or closure. Assess for vaginal hemorrhage following the procedure, the same as after a term birth. If a procedure is prolonged, a woman may develop disseminated intravascular coagulation (see [Chapter 21](#)), making her very susceptible to hemorrhage because her blood clotting mechanism has become compromised.

*Hysterotomy*, or removal of the fetus by surgical intervention, is similar to a cesarean birth (see [Chapter 24](#)) and is performed if the gestational age of the pregnancy is more than about 20 to 24 weeks. Surgery is necessary at this point because the uterus becomes resistant to the effect of oxytocin as it reaches this phase of pregnancy and so may not respond to saline induction, even with the assistance of oxytocin. Furthermore, the chance is great at this gestational age that, because the uterus is so enlarged, it will not contract well afterward, leading to hemorrhage. Because this is so late in pregnancy, fewer than 1% of surgical terminations are done using this technique.

*Partial birth abortion* was a surgical technique formerly used during the last 3 months of pregnancy if the fetus was discovered to have a congenital anomaly that would be incompatible with life or would result in a severely compromised child. With the advent of so many reproductive life planning methods and early fetal screening measures, this late-in-pregnancy procedure is no longer needed and is believed to be unethical by many ([Greasley, 2014](#)). For these reasons, this type of termination is no longer legal in the United States.

## PSYCHOLOGICAL ASPECTS OF ELECTIVE TERMINATION OF PREGNANCY

Women of all ages request elective terminations. For such a procedure, the usual profile is a woman who:

- Is young; 18% of women obtaining abortions are teenagers, women in their 20s account for more than 50% of abortions.
- Is unmarried, 45% of all women seeking abortions
- Has had a previous live birth; 61% of abortions are obtained by women who have one or more child.
- Undergoes the procedure to end an unintended pregnancy; 75% of women report economic issues limiting their ability to care for a child.
- Has not taken any or adequate protection against becoming pregnant; however, 51% of women seeking abortion used contraception during the month they got pregnant, either condoms or a hormonal method.
- Abortions are provided to women of all races, 1/3 white women, 1/3 black women, 1/4 Hispanic women, and 9% to women of other races.
- Most women obtaining abortion are low income, 42% below the federal poverty line, and 27% just above the federal poverty line ([Guttmacher Institute, 2014](#)).

Only 1.9% of women seeking elective termination of pregnancy do so for reasons associated with rape. However, around 20% of women are raped at some point in their life (Perry, Zimmerman, Al-Saden, et al., 2015). As many as 4% to 8% of women suffer intimate partner violence that not only leads to pregnancy but also increases in the level of violence experienced during the pregnancy (Wilbur & Dennis, 2015) (see Chapter 55).

Be certain to give women undergoing termination procedures the same kind of explanations and support that women in labor receive (women do not share termination experiences with each other the way they share labor experiences, so women usually have little advance education as to what to expect). Remembering that this is not a decision taken lightly helps in planning nursing care aimed at making an elective termination as nontraumatic as possible.

The majority of women report they are relieved with their decision following an elective termination of pregnancy (Andersson, Christensson, & Gemzell-Danielsson, 2014). Those few who express sadness and guilt may need to be referred for professional counseling so they can integrate and accept this event in their lives.

#### *What If . . . 6.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals in respect to reproductive life planning (see Box 6.1). What possible research topic could the nurse explore that is pertinent to this goal, applicable to Dana, and would advance evidence-based practice?**

### **KEY POINTS FOR REVIEW**

- Reproductive life planning involves personal decisions based on each individual's background, experiences, and sociocultural beliefs. It involves thorough planning to be certain the method chosen is acceptable and can be used effectively.
- Natural family planning (periodic abstinence and fertility awareness) methods are varied but involve determining the fertile period each month and then avoiding sexual relations during that time.
- Oral contraceptives are combinations of estrogen and progesterone or progesterone-only pills. They provide a reliable form of contraception outside of abstinence. Women who are breastfeeding, are older than 40 years of age, and who smoke are not candidates for COCs because the estrogen can reduce breast milk supply as well as lead to cardiovascular complications such as thromboembolism. Progestin-only oral contraceptives do not contain estrogen, so do not have cardiovascular risk; they can be used during breastfeeding.
- A subdermal implant (renewed every 3 years), intramuscular injections of DMPA (renewed every 3 months), transdermal patches, and vaginal rings are also effective family planning methods.

- IUDs are small plastic devices wound with copper or filled with slow-acting progesterone placed in the uterus to prevent fertilization and implantation and are highly effective forms of birth control.
- Barrier methods of contraception include the diaphragm, cervical cap, sponges, vaginal spermicides, and condoms (male and female). Such methods are low in cost but are not as effective as ovulation suppressant methods. Use of diaphragms may be associated with UTIs.
- Postcoital or “Plan B” protection involves administration of a high dose of progesterone that prevents FSH release, which then prevents ovulation. A copper-wound IUD may also be used for postcoital protection; its insertion creates changes in the endometrium and cervical mucus to slow or prevent sperm transport.
- Surgical methods of contraception are tubal ligation in women and vasectomy in men. Counsel individuals who wish to undergo these procedures that they are largely irreversible and should not be considered lightly.
- An elective termination of pregnancy can be accomplished medically by administration of mifepristone and misoprostol or surgically by menstrual extraction, D&C, D&E, or prostaglandin or saline induction. Counsel women not to think of elective termination of pregnancy as a contraceptive method but as a recourse to be used if preventive measures fail. Women who are Rh negative need to receive Rho(D) immune globulin after these procedures.
- When counseling patients about reproductive life planning, nurses have the second responsibility to teach about safer sex practices. Such thoroughness not only helps in planning care that meets QSEN guidelines but also best meets the family’s total needs.

### CRITICAL THINKING CARE STUDY

Eve, 27 years old, and Lamar, 33 years, are a young couple who have just gotten married. They both are heavy smokers. Eve had a miscarriage before marriage when they were using a cervical mucus method of natural planning. It’s important to her now not to become pregnant again for 2 years so she can finish a master’s degree in psychology. Lamar wants a contraceptive that when discontinued will allow fertility to return immediately. He also wants a contraceptive that will prevent sexually transmitted diseases.

1. What contraceptive would you recommend as best for Eve?
2. Lamar has special requests. What contraceptive would best meet his needs?
3. Is it safe to use a contraceptive method for as long as 2 years? What if Eve has another miscarriage, making her over 30 years by the time she’s pregnant for the third time?

## Nursing Care of the Family Having Difficulty Conceiving a Child

*Cheryl and Bob Carl, married when they were both 25 years old, planned to wait 5 years before beginning their family so they could save money for a house. On the day they moved into their new home, Cheryl stopped taking her birth control pills. At the end of a year, however, she still was not pregnant so she began fertility testing. Three years later, they are now undergoing their second cycle of in vitro fertilization and embryo transfer. The Carls have applied for a second mortgage on their house to finance the fertility testing. At a healthcare visit, Mrs. Carl states, "This is my fault because I'm so rigid. Look how I had to buy the house before I could even consider getting pregnant, and now we'll probably lose it. I've made our whole life revolve around trying to get pregnant instead of enjoying life."*

*Previous chapters described normal ovulation and conception and ways to prevent pregnancy. This chapter adds information about care of the couple who is unable to conceive.*

**How could you best help the Carls?**

### KEY TERMS

**alternative insemination**

**anovulation**

**cryptorchidism**

**endometriosis**

**erectile dysfunction**

**in vitro fertilization**

**pelvic inflammatory disease**

**sperm count**

**sperm motility**

**spermatogenesis**

**sterility**

**subfertility**

**varicocele**

## OBJECTIVES

After mastering the contents of this chapter, you should be able to:

1. Describe common causes of difficulty with conception or subfertility in both men and women.
2. Identify 2020 National Health Goals related to subfertility that nurses can help the nation achieve.
3. Describe common assessments necessary to detect subfertility.
4. Formulate nursing diagnoses related to subfertility.
5. Identify expected outcomes for a subfertile couple to help them manage seamless transitions across differing healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care designed to improve subfertility and increase ability to conceive a child, such as health teaching about ovulation and conception.
8. Evaluate outcomes for achievement and effectiveness of nursing care to be certain expected outcomes have been achieved.
9. Integrate knowledge of fertility and subfertility with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

Many marriage customs, such as throwing rice, originate from ancient rituals to promote fertility. The existence of such common rituals is an indication of the importance of having children for most couples and society as a whole.

*Infertility* is a term used to describe the inability to conceive a child or sustain a pregnancy to birth. A couple is said to be *infertile* if they have not become pregnant after at least 1 year of unprotected sex. Because most couples have the potential to conceive but are just less able to conceive without additional help, the term **subfertility** is more often used today. Subfertility affects as many as 8% to 12% of couples who desire children (Kumar & Singh, 2015).

Couples who feel they need fertility testing consist of a wide range of people: many are married couples; some are planning to marry; some desire to remain single but bear a child; and some are lesbian, gay, bisexual, or transgender (LGBT) and want to have a child through an assisted fertility method. Occasionally, others are looking for assurance they are unable to have children so they can discontinue a contraceptive method (although they'll need to be cautioned to maintain safer sex practices if their relationship isn't monogamous). People who are discontinuing using condoms so a woman can become pregnant need this same safer sex caution.

When a couple first begins fertility counseling, they usually have fears and anxieties not only about their ability to conceive but also about what an identified problem will mean to their future lifestyle and family. Without information about the cause of their subfertility, each may blame the other or carry unexpressed anger toward his or her partner. Some couples may strongly desire a child but feel anxious about impending parenthood, which would bring with it a loss of independence. For all these reasons, subfertility screening and counseling can be both an emotionally difficult and a physically demanding process, often creating a high level of strain on a couple's relationship, especially if they don't maintain open communication (Galhardo, Moura-Ramos, Cunha, et al., 2015). The level of stress a couple is experiencing is important because increased family stress can produce a higher than usual level of intimate partner violence (Hasanpoor-Azghdy, Simbar, & Vedadhir, 2015). Having healthy children when they are wanted is such a priority in health care that a 2020 National Health Goal aimed at reducing subfertility was established (Box 7.1).

### BOX 7.1

#### Nursing Care Planning Based on 2020 National Health Goals

One of the 2020 National Health Goals identified by *Healthy People 2020* directly addresses the problem of subfertility:

- Reduce the proportion of woman aged 18 to 44 years who have impaired fecundity (fertility) from 12% to a target of 10.8% (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

To meet this health objective, nurses need to keep active in health promotion, identify and help prevent problems that could lead to subfertility such as poor nutrition early in life, and play active roles in teaching patients about safer sex practices (see Chapter 5) so the incidence of sexually transmitted infections and pelvic inflammatory disease can be reduced.

#### *Nursing Process Overview*

### FOR A COUPLE WITH SUBFERTILITY

#### **ASSESSMENT**

Subfertility assessment used to require many months and many tests, all of which had the potential to interfere with a couple's self-image, self-esteem, and lifestyle. Today, a subfertility investigation is usually limited to only three assessments: semen analysis, ovulation monitoring, and tubal patency. Even with this more directed approach to evaluation, a nursing assessment often reveals that one or both partners feel inadequate or angry and frustrated by what has happened to them and their need to undergo testing. Questions such as "How do you feel about what has happened?" or "How do you think your partner feels about not being able to conceive?" may be

enough to encourage partners to express these concerns.

Talking with both partners together may be advantageous because they may feel more comfortable speaking about their problem together. It is important, however, to spend some time alone with each patient in case there is anything a partner wishes to discuss privately. This might be the only opportunity for one of them to ask that one “silly” question or voice a fear he or she believes is too foolish to ask or bring up in front of his or her partner.

### **NURSING DIAGNOSIS**

Nursing diagnoses related to subfertility are likely to focus on psychosocial issues associated with the inability to conceive and the potentially nerve-wracking process of fertility testing and management. Examples of possible diagnoses include:

- Fear related to possible outcome of subfertility studies
- Situational low self-esteem related to the apparent inability to conceive
- Anxiety related to what the process of fertility testing will entail
- Deficient knowledge related to measures to promote fertility
- Anticipatory grieving related to failure to conceive or sustain a pregnancy
- Powerlessness related to repeated unsuccessful attempts at achieving conception
- Hopelessness related to perception of no viable alternatives to usual conception

If required tests interfere with a couple’s relationship (including sexual patterns), “sexual dysfunction related to command performance of subfertility therapy” might be applicable.

### **EXPECTED OUTCOMES AND PLANNING**

In establishing expected outcomes with a couple undergoing fertility testing and counseling, be certain the couple realizes even after the reason for their subfertility is identified, fertility may not be instantaneous. In some instances, a couple may need to change or modify their goals if tests begin to show what they first wanted—to have a child without medical intervention—is impossible. Participation in a support group may allow a couple to work through the stress fertility testing places on their lives. It is helpful to refer patients to online resources for further information and support (see [Chapter 5](#)).

### **IMPLEMENTATION**

Fertility testing can be costly for a couple because not all health insurance programs provide reimbursement for these procedures. Because of this, be certain couples are informed beforehand of specific estimates of the cost of testing or therapy so they can budget and plan their resources and the next steps they want taken.

Suggesting a couple combine involvement with fertility testing with ongoing activities or beginning new activities together, such as taking a night school course, planting a garden, or learning a new sport or hobby, is a way of helping them reduce the feeling that their entire existence revolves around the testing procedures. It also may help provide them with time for sharing experiences and increasing intimacy, helping to compensate for any decreased enjoyment that comes from “scheduled”

sexual relations.

Throughout testing, couples need thorough education about the various procedures being done. Make sure to review any specific instructions about preprocedural and postprocedural care. Depending on their motivations, a couple's reaction to study results may vary from relief, to stoic acceptance, to grief for children never to be born. Each partner may wonder whether the other will be able to continue the relationship if he or she turns out to be the subfertile one. Couples need the active support of healthcare personnel from the first day they brace themselves to ask "Exactly why are we childless?" until the end, regardless of the results.

### OUTCOME EVALUATION

Examples of expected outcomes in this area include:

- The patient rearranges work plans to manage the schedule of fertility testing by 1 month's time.
- The couple verbalizes they understand their individual subfertility problem after preliminary testing.
- The couple demonstrates a high level of self-esteem after fertility studies, even in the face of disappointing study outcomes.

For a couple with the problem of subfertility, an evaluation is best if it is ongoing because, as circumstances around them change, so may their goals and desires. Until they can accept an alternative method of having children—adoption or an assisted reproductive technique such as **alternative insemination** (deposition of sperm into a woman's cervix or uterus) or **in vitro fertilization** (IVF; the union of sperm and ovum under laboratory conditions)—former plans to have children have been crushed.

Continuing or future evaluations are also important because a couple who decides at age 20 years to choose child-free living may change their minds at a later date. In the same way, a couple who chooses an assisted reproductive technique may decide after a number of unsuccessful attempts that they are no longer interested in this method of conception. Keeping the evaluation as an ongoing process allows such plans to be modified as necessary. Because establishing fertility is an ever changing field of study, encourage couples seen for subfertility who couldn't conceive but are still interested in having a child to contact their subfertility setting every 6 to 12 months to inquire about new discoveries in the field and if any of these might apply to their situation.

## Subfertility

Subfertility is said to exist when a pregnancy has not occurred after at least 1 year of engaging in unprotected coitus (Hamilton, 2012). In *primary subfertility*, there have been no previous conceptions; in *secondary subfertility*, there has been a previous viable pregnancy but the couple is unable to conceive at present. **Sterility** is the inability to

conceive because of a known condition, such as the absence of a uterus.

In about 40% of couples with a subfertility problem, the cause of subfertility is multifactorial; in other words, more than one reason for the loss of full fertility is involved. In about 30% of couples, it is the man who is subfertile; in 70%, it is the woman. Of women seen for a fertility evaluation, 20% to 25% experience ovulatory failure; another 20% experience tubal, vaginal, cervical, or uterine problems. In about 10% of couples, no known cause for the subfertility can be discovered despite all the diagnostic tests currently available. Such couples are categorized as having unexplained subfertility (Oman & Burke, 2015).

Some couples, because they are unaware of the average length of time it takes to achieve a pregnancy, may worry they are subfertile when they are not. On average, if they engage in coitus about four times per week, 65% to 75% of couples will conceive within 6 months; 90% within 12 months. These periods will be longer if sexual relations are less frequent (Ghadir, Ambartsumyan, & Decherny, 2013).

Couples who engage in coitus daily, hoping to cause early impregnation, may actually have more difficulty conceiving than those who space coitus every other day. This is because too-frequent coitus can lower a man's sperm count to a level below optimal fertility. All couples who focus their sexual relations on trying to increase sperm/ovum exposure by scheduling sex may find their lives governed by temperature charts and "good days" and "bad days" to such an extent that their relationship suffers.

Age is related to subfertility. Because of this gradual decline in fertility, women who defer pregnancy into their late 30s are apt to have more difficulty conceiving than their younger counterparts. Women who are using oral, injectable, or implanted hormones for contraception may have difficulty becoming pregnant for several months after discontinuing these medications, although most women return to normal cycles within 1 month. Most couples can benefit from some practical information on how to increase their chances of achieving conception on their own (Box 7.2).

## BOX 7.2

### Nursing Care Planning to Empower a Family

**Q.** Cheryl Carl asks you, "Is there anything we can do to help increase our chances of conception?"

**A.** The following are time-honored suggestions to help aid conception:

- Determine the time of ovulation through the use of basal body temperature or analysis of cervical secretions and then plan sexual relations for every other day around the time of ovulation.
- Although frequent intercourse may stimulate sperm production, men need sperm recovery time after ejaculation to maintain an adequate sperm count. This is why coitus every other day, rather than every day, during the fertile period will probably yield faster results.

- The male-superior position is the best position for coitus to achieve conception because it places sperm closest to the cervical opening.
- The male should try for deep penetration so ejaculation places sperm as close as possible to the cervix. Elevating a woman's hips on a small pillow can facilitate sperm being deposited near the opening to the cervix.
- A woman should remain on her back with knees drawn up for at least 20 minutes after ejaculation to help sperm remain near the cervix.
- Don't use douching or lubricants before or after intercourse so vaginal pH is unaltered, which can interfere with sperm mobility.
- Eat a diet high in slowly digested carbohydrates, low in saturated or trans fats, and moderate in protein.
- Maintain a body weight that results in a body mass index between 18.5 and 24.9.
- Exercise about 30 minutes per day to help keep blood glucose and insulin levels stabilized.
- Choose a new activity the two of you can do together, such as learning how to bowl or ballroom dance, so you create an activity separate from planning a baby. This not only helps to pass the time in a positive way but also offers a positive outlook for a month when you don't conceive.

### *What If... 7.1*

**The nurse hears Cheryl Carl repeat she believes her subfertility problem is her fault because she's too rigid. Does a rigid personality affect fertility? How could the nurse help Cheryl feel more comfortable about what has happened in her life?**

## Fertility Assessment

The age of a couple and the degree of apprehension they feel about possible subfertility can make a difference in determining when they should be referred for fertility evaluation. Although some healthcare plans or specific settings set limits on the age range in which fertility testing can be scheduled, such as not before age 18 years and not after age 45 years, other settings do not establish such limits, allowing couples of any age to benefit from assessment.

As a rule:

- If a woman is younger than 35 years of age, it is usually suggested she have an evaluation after 1 year of subfertility.
- If a woman is older than 35 years, she should be seen after 6 months. Referral is recommended sooner because assisted reproductive strategies such as IVF, as well as common alternatives to natural childbearing such as adoption, are also limited by age. It would be doubly unfortunate if a couple delayed fertility testing

so long they not only learned they could not conceive but also were considered to be “too old” to be prospective parents by alternative methods.

- If the couple is extremely apprehensive or knows of a specific problem that could be causing their difficulty in conceiving, studies should never be delayed, regardless of the couple’s age (Fritz & Speroff, 2010).

Because most fertility tests are conducted in ambulatory settings, nurses play key roles on fertility teams to help achieve this goal, such as:

- Educating couples about the variety of tests and procedures that may be performed
- Helping patients identify and express their feelings about their desire to have a child
- Helping patients express how far they are willing to go in testing and procedures to achieve a child or how they might feel if, at the end of testing, it is revealed pregnancy will not be possible
- Assuming responsibility for health assessment, patient education, and counseling
- Helping educate couples about advanced techniques of assisted reproduction, many of which are complex and demand knowledgeable, ongoing involvement from the couple
- Counseling patients about available alternatives when pregnancy cannot be achieved, such as adoption or child-free living

No matter what problem is suspected, basic fertility assessment begins with a health history and physical examination of both sexual partners.

### *QSEN Checkpoint Question 7.1*

#### **PATIENT-CENTERED CARE**

Cheryl is unhappy that she waited until she bought a house to plan on having a child. What fact could the nurse cite to Cheryl?

- a. She should have begun trying to conceive by age 25 years, but her outcome should still be positive.
- b. She asked for testing well before the average woman, who asks at age 30 years.
- c. Waiting for 1 year after being unable to conceive is the average time for seeking help.
- d. We all make decisions in life that later on we wish we had not made.

*Look in Appendix A for the best answer and rationale.*

## **HEALTH HISTORY**

Nurses often assume the responsibility for the initial history taking with a subfertile couple. Because of the wide variety of factors that may be responsible for subfertility, it is critical to include a thorough history. Examples of important questions to include for

a minimum history for both men and women are addressed in [Box 7.3](#).

### BOX 7.3

#### Initial History Taking for the Subfertile Couple

##### **History taking for men should include:**

- His general health
- A typical 24-hr food intake, including alternative therapies such as herbs and whether he ingests alcohol, uses recreational drugs, or smokes or uses tobacco
- If he had a congenital health problem, such as hypospadias or cryptorchidism (defined later) or a past illness such as mumps orchitis, urinary tract infection, or a sexually transmitted disease that could affect fertility
- If he ever had radiation to his testes because of childhood cancer, X-rays, or an industrial accident
- If he had an operation such as surgical repair of a hernia or torsion of the testes, which could have compromised the blood supply to his testes
- If he has any current illness, particularly an endocrine one or a low-grade infection
- If his job or lifestyle involves sitting all day
- What his sexual practices are, such as frequency of coitus, masturbation, coital positions used, or if he ever experiences failure to achieve ejaculation
- What past contraceptive measures, if any, he has used or if he has children from a previous relationship

##### **History taking for women should include:**

- Her general health
- Nutrition, including an adequate source of folic acid and avoidance of trans fats
- Current or past reproductive tract problems, such as infections
- Past history of a childhood cancer treated with radiation that might have reduced ovarian function or any exposure to occupational hazards, such as X-rays or toxic substances
- Abdominal or pelvic operations that could have compromised blood flow to pelvic organs
- Overall health, emphasizing endocrine problems such as galactorrhea (breast nipple secretions) or symptoms of thyroid dysfunction (always tired or hyperactive)
- If she is from a country that allows the practice, ask about female circumcision because this can leave vulvar scars that interfere with penetration and deposition of sperm close to the cervix
- History of contraceptive use
- Past pregnancies, miscarriages, or abortions
- If she can detect ovulation through such symptoms as breast tenderness, midcycle “wetness,” or lower abdominal pain (*mittelschmerz*)
- The use of douches or intravaginal medications or sprays that could interfere with

vaginal pH

- A menstrual history, including age of menarche; length, regularity, and frequency of menstrual periods; amount of flow; and any difficulties the woman experiences, such as dysmenorrhea or premenstrual dysphoric disorder (PDD) (see [Chapter 47](#))

Asking about alternative therapies is also important because a couple who wants to have a child could be simultaneously investigating nontraditional methods that they have heard will aid in conception ([Read, Carrier, Whitley, et al., 2014](#)). Asking about herbs they may be using can reveal use of an herb that could be causing subfertility or one that would interfere with any procedure or medication prescribed for them after their subfertility investigation is complete.

Most couples assume subfertility is the woman's problem. Many women, even after a careful explanation that the problem is their male partner's and not theirs, continue to show low self-esteem, as if the fault did rest with them. While obtaining health histories, be certain to take time with each partner individually and as a couple to encourage questions and to discuss overall attitudes toward sexual relations, pregnancy, and parenting. A frank discussion centered on resolving the couple's fears and clearing up any long-standing confusion or misinformation will help to set a positive tone for future interactions and, hopefully, establish a feeling of trust and increased self-esteem. Talking with both partners can also help them clarify their feelings about subfertility and why they are seeking help in this area of their life ([Box 7.4](#)).

#### BOX 7.4

#### Nursing Care Planning Tips for Effective Communication

Cheryl Carl has been trying to get pregnant for 4 years. She and her husband agreed to in vitro fertilization at a cost of approximately \$10,000 per month, even though her religion does not approve of this technique. Every time you see her at the fertility clinic, she seems sadder than the previous time.

*Tip:* Support patients and help them find ways to continue to feel good about themselves to maintain self-esteem. Be careful not to criticize patients for making choices that were not the same as yours would have been. Patients may not make the same choices about fertility testing or management you might make because such decisions are based on individual circumstances and situations.

**Nurse:** How is everything going, Mrs. Carl?

**Mrs. Carl:** Fine. I'm just tired of no results.

**Nurse:** Considering you have been trying for such a long time, I think you're doing very well.

**Mrs. Carl:** Being patient is hard.

**Nurse:** Think of how well learning to be patient the way you're doing now will help you become a good parent.

---

It is not unusual to see a couple move through steps of denial, anger, bargaining, and depression before they reach a level of acceptance that they are different in this one area of life from others but that they are not limited in their ability to achieve in other areas. Acceptance in this way helps them make adjustments in their wants or plans and feel fulfilled again.

## PHYSICAL ASSESSMENT

After a thorough history, both men and women need a complete physical examination. For men, important aspects of this include whether secondary sexual characteristics, such as pubic hair, are present as well as no genital abnormalities, such as the absence of a vas deferens or the presence of undescended testes or a **varicocele** (enlargement of a testicular vein), are present. A hydrocele (a collection of fluid in the tunica vaginalis of the scrotum) is rarely associated with subfertility but should be documented if present.

For women, a thorough physical assessment, including a breast and thyroid examination, is necessary to rule out current illness. Of particular importance, again, are secondary sex characteristics, which indicate maturity and suggest good pituitary function (see [Chapter 33](#) for a discussion of Tanner stages). A complete pelvic examination, including a Pap test (see [Chapter 11](#)), is needed to rule out anatomic disorders and infection.

## FERTILITY TESTING

Basic fertility testing is geared toward answering three questions:

1. Is there sperm of good quality and number available?
2. Are ova (eggs) available (i.e., woman is ovulating)?
3. Is it possible for the sperm and egg to meet in a receptive environment?

To answer these questions, only three tests are commonly used: semen analysis in men and ovulation monitoring and tubal patency assessment in women. Nurses play key roles in preparing couples for these tests, helping them schedule the studies appropriately, and supporting them while they wait for results ([Allan & Mounce, 2015](#)).

Additional testing for men, if warranted, can include urinalysis; a complete blood count; blood typing, including Rh factor; a serologic test for syphilis; a test for the presence of HIV; erythrocyte sedimentation rate (an increased rate indicates inflammation); protein-bound iodine (a test for thyroid function); cholesterol level (arterial plaques could interfere with pelvic blood flow); and follicle-stimulating hormone (FSH), luteinizing hormone (LH), and testosterone levels ([Niederberger, 2016](#)).

Advanced testing for women may include a rubella titer; a serologic test for syphilis; an HIV evaluation; a thyroid uptake determination; and assays for FSH, estrogen, LH, and serial progesterone levels. If a woman has a history of galactorrhea (breast milk

secretions), a serum prolactin level will be obtained, as increased prolactin levels reduce the secretion of pituitary hormones. A pelvic sonogram may be performed to rule out ovarian, tubal, or uterine structural disorders.

## Factors That Cause Male Subfertility

The factors that most commonly lead to male subfertility include:

- Disturbance in **spermatogenesis** (production of sperm cells)
- Inadequate production of FSH and LH in the pituitary, which stimulates the production of sperm
- Obstruction in the seminiferous tubules, ducts, or vessels, which prevent the movement of spermatozoa
- Qualitative or quantitative changes in the seminal fluid, which prevent **sperm motility** (movement of sperm)
- Development of autoimmunity, which immobilizes sperm
- Problems in ejaculation or deposition, which prevents spermatozoa from being placed close enough to a woman's cervix to allow ready penetration and fertilization
- Chronic or excessive exposure to X-rays or radioactive substances, general ill health, poor diet, and stress, all of which may interfere with sperm production

## LIMITED SPERM COUNT

The **sperm count** is the number of sperm in a single ejaculation or in a milliliter of semen. The minimum sperm count considered normal has:

- Thirty-three to 46 million sperm per milliliter of seminal fluid, or 50 million per ejaculation
- Fifty percent of sperm that are motile
- Thirty percent that are normal in shape and form

Spermatozoa must be produced and maintained at a temperature slightly lower than body temperature to be fully motile. This is why the testes, in which sperm are produced and stored, are suspended in the scrotal sac away from body heat. Any condition that significantly increases body temperature, such as a chronic infection from tuberculosis or recurrent sinusitis, has the potential to raise scrotal heat enough to lower a sperm count. Actions that directly increase scrotal heat, such as working at a desk job or driving a great deal every day (e.g., salesmen, motorcyclists) may have lower sperm counts compared with men whose occupations allow them to be ambulatory at least part of each day. Frequent use of hot tubs or saunas may also lower sperm counts.

Maintaining an ideal body weight (body mass index [BMI] of 18.5 to 24.9) is a general preventative health measure. Excessive weight may alter testosterone production and sperm production (Calderon, Gomez-Martin, Vega-Pinero, et al., 2016).

Congenital abnormalities are yet another reason sperm count may be lowered. Abnormalities may include **cryptorchidism** (undescended testes) if surgical repair was

not completed until after puberty or if the spermatic cord became twisted after the surgery.

A varicocele, or varicosity (enlargement) of the internal spermatic vein, can also increase temperature and congestion within the testes, which may slow and disrupt spermatogenesis. Although more research is needed to determine whether a varicocele does increase temperature, surgical removal of the varicocele (varicocelectomy) may decrease warmth and improve fertility in some men ([Agarwal & Esteves, 2016](#)).

Other conditions that may inhibit sperm production include:

- Past trauma to the testes
- Surgery on or near the testicles that has resulted in impaired testicular circulation
- Endocrine imbalances, particularly of the thyroid, pancreas, or pituitary glands
- Drug use or excessive alcohol use
- Environmental factors, such as exposure to X-rays or radioactive substances

Men who are exposed to radioactive substances in their work environment should be provided with adequate protection of the testes. When you are assisting with pelvic X-rays, be certain men and boys are furnished a protective lead shield to guard against radiation to the testes.

## Testing for Sperm Number and Availability

A number of common tests, such as semen analysis and sperm motility, help to identify whether adequate sperm are present for conception.

### Analysis of Pituitary Hormones

A blood test and analysis can determine whether adequate levels of FSH and LH are present. When a man has typical male features (such as facial hair growth, laryngeal prominence, and a deeper voice), limited sperm count is rarely a problem.

### Semen Analysis

On average, ejaculation for a semen analysis should produce a minimum of 1.4 to 1.7 ml of semen and should contain a minimum of 33 to 46 million spermatozoa per milliliter of fluid ([World Health Organization, 2010](#)). Semen analysis includes the following steps:

1. The patient is instructed to be sexually abstinent 2 to 4 days prior to the analysis.
2. The patient ejaculates by masturbation into a clean, dry specimen jar or a special condom (one without spermicide).
3. The number of sperm in the specimen are counted and then examined under a microscope within 1 hour of ejaculation ([Box 7.5](#)).

#### BOX 7.5

#### Nursing Care Planning Based on Family Teaching

## TIPS FOR ENSURING AN ACCURATE SEMEN ANALYSIS

**Q.** Bob Carl asks you, “What is the right way to do a semen sample?”

**A.** Effective guidelines include:

- Abstain from intercourse or masturbation for about 3 days.
- Use a clean, dry plastic or glass container with a secure lid to collect the sample.
- Collect the specimen as close as possible to your usual time of sexual activity.
- Avoid using any lubricants before you collect the specimen.
- After you’ve collected the specimen in the container, close it securely and write down the time you collected it.
- Take the specimen to the laboratory or healthcare provider’s office immediately so it can be analyzed within 1 hour of collection.
- Keep the specimen at body temperature while transporting it. Carrying it next to your chest is one way to do this.

The analysis may need to be repeated after 2 or 3 months because spermatogenesis is an ongoing process and 30 to 90 days is needed for new sperm to reach maturity. If patients are reluctant to have their sperm counted at a healthcare facility, they have the option to use various self-test kits to test sperm motility at home. These kits are available online. If the man has a vas deferens obstruction, sperm can be obtained by testes biopsy.

### *Concept Mastery Alert*

Semen specimens should be kept at body temperature during transportation. Patients can be advised to carry the specimen next to the body in an inside pocket to accomplish this goal.

## Sperm Penetration Assay and Antisperm Antibody Testing

For impregnation to take place, sperm must be mobile enough to navigate the vagina, uterus, and a fallopian tube to reach the ova. Although sperm penetration studies are rarely necessary, they may be scheduled to determine whether a man’s sperm, once they reach an ovum, can penetrate it effectively. With the use of an assisted reproductive technique such as IVF, poorly mobile sperm or those with poor penetration can be injected directly into a woman’s ovum under laboratory conditions (intracytoplasmic sperm injection), bypassing the need for sperm to be fully mobile.

### *What If . . . 7.2*

**While the Carls are undergoing IVF, Cheryl’s mother asks the nurse, “How can I ever love a child created in a ‘test tube?’” How would the nurse answer her?**

---

## Therapy for Increasing Sperm Count and Motility

If sperm are present but the total count is low, a man may be advised to abstain from coitus for 7 to 10 days at a time to increase the count. Ligation of a varicocele (if present) and changes in lifestyle, such as avoiding recreational marijuana use, wearing looser clothing, avoiding long periods of sitting, and avoiding prolonged hot baths, may also help reduce scrotal heat and increase the sperm count.

## OBSTRUCTION OR IMPAIRED SPERM MOTILITY

In some men, adequate sperm are manufactured, but there is obstruction at some point along the pathway spermatozoa must travel to reach the outside: the seminiferous tubules, the epididymis, the vas deferens, the ejaculatory duct, or the urethra (see [Chapter 5, Fig. 5.1](#)). Diseases such as *mumps orchitis* (testicular inflammation and scarring due to the mumps virus), epididymitis (inflammation of the epididymis), and infections such as gonorrhea or ascending urethral infection can result in this type of obstruction because adhesions form and occlude sperm transport ([Han, Liu, Zhou, et al., 2016](#)). Congenital stricture of a spermatic duct may occasionally be seen. Benign hypertrophy of the prostate gland occurs in most men beginning at about 50 years of age. Pressure from the enlarged gland on the vas deferens can then interfere with sperm transport. Infection of the prostate, through which the sperm and seminal fluid must pass, or infection of the seminal vesicles (spread from a urinary tract infection) can change the composition of the seminal fluid enough to reduce sperm motility.

A few men who have vasectomies develop an autoimmune reaction or form antibodies that immobilize their own sperm after the procedure; they also may experience long-term pain unless the procedure is reversed ([Horovitz, Tjong, Domes, et al., 2012](#)). It is conceivable that men with obstruction in the vas deferens from other causes, such as scarring after an infection, could also develop an autoimmune reaction that immobilizes sperm the same way.

Anomalies of the penis, such as hypospadias (urethral opening on the ventral surface of the penis), epispadias (urethral opening on the dorsal surface), or Peyronie disease (a bent penis) can cause sperm to be deposited too far from the sexual partner's cervix to allow optimal cervical penetration. Extreme obesity in a male may also interfere with effective penetration and deposition ([Campbell, Lane, Owens, et al., 2015](#)).

## Testing for Sperm Transport Disorders

Sperm transport disorders are suspected when FSH and LH hormones, which stimulate the production of sperm, are adequate but the sperm count remains limited.

## Therapy for Sperm Transport Disorders

If sperm are not able to pass through the vas deferens because of obstruction, surgery to relieve the obstruction is extensive, costly, and may not have a positive outcome. A

better solution can be extracting sperm from a point above the blockage and injecting it into the vagina or uterus of the man's partner by intrauterine insemination (IUI) (Bahadur, Ilaibuccus, Al-Habib, et al., 2015). If the problem appears to be that sperm are immobilized by vaginal secretions due to an immunologic factor, the response can be reduced by abstinence or condom use for about 6 months. However, to avoid this prolonged time interval (which is difficult for a couple who want to have a child immediately), washing of the sperm followed by IUI may be preferred. The administration of corticosteroids to a woman may have some effect in decreasing sperm immobilization because it reduces her immune response and antibody production.

## EJACULATION PROBLEMS

**Erectile dysfunction** or the inability to achieve an erection (formerly called impotence), which may occur from psychological problems; diseases such as a cerebrovascular accident, diabetes, or Parkinson disease; use of certain antihypertensive agents; as well as the discontinuation of finasteride, a drug used for male pattern baldness (Glina, Roehrborn, Esen, et al., 2015), may result in erectile dysfunction. This condition is *primary* if the man has never been able to achieve erection and ejaculation and *secondary* if the man was able to achieve ejaculation in the past but now has difficulty. Erectile dysfunction can be a difficult problem to solve if it is associated with stress because this is not easily relieved.

Premature ejaculation (ejaculation before penetration) is another factor that may interfere with the proper deposition of sperm. It is another problem often attributed to psychological causes. Adolescents may experience it until they become more experienced in sexual techniques.

### Testing for Ejaculation Concerns

Ejaculation concerns are identified by a sexual history. It may be difficult for a man to discuss this area of his life, especially if a nurse is female, so skillful patient interviewing technique is required.

### Therapy for Ejaculation Concerns

Solutions for erectile dysfunction include psychological or sexual counseling as well as the use of a phosphodiesterase inhibitor, such as sildenafil (Viagra) or tadalafil (Cialis) (see Chapter 5). Dapoxetine, a short-acting selective serotonin reuptake inhibitor, is a drug that has been developed especially for the treatment of premature ejaculation and shows good results when taken about 1 hour before planned coitus (Yue, Dong, Hu, et al., 2015).

### QSEN Checkpoint Question 7.2

#### SAFETY

The Carls introduce themselves to the nurse as an “infertile” couple. As a safety measure, the nurse would want them to understand which of the following?

- a. Couples are not termed infertile until they have been trying to conceive for 2 years.
- b. Infertility can cause depression, so the couple should report any feeling of sadness.
- c. If their relationship is not monogamous, they still need to use safer sex practices.
- d. Infertility is related to antibiotic-resistant infections, so they need to be tested for these.

---

*Look in [Appendix A](#) for the best answer and rationale.*

---

## Factors That Cause Female Subfertility

The factors that cause subfertility in women are analogous to those causing subfertility in men:

- Limited production of FHS or LH, which interfere with ova growth
- Anovulation (faulty or inadequate expulsion of ova)
- Problems of ova transport through the fallopian tubes to the uterus
- Uterine factors, such as tumors or poor endometrial development
- Cervical and vaginal factors, which immobilize spermatozoa
- Poor nutrition, increased body weight, and lack of exercise, which may compound these problems

### ANOVULATION

The steps of ova formation and ovulation are described in [Chapter 5](#). **Anovulation** (absence of ovulation or release of ova from the ovary), the most common cause of subfertility in women, may occur from a genetic abnormality such as Turner syndrome (hypogonadism), in which there is limited ovarian tissue available to produce ova. More often, it results from a hormonal imbalance caused by a condition such as hypothyroidism, which interferes with hypothalamus-pituitary-ovarian interaction. Ovarian tumors or polycystic ovary syndrome may also produce anovulation due to feedback stimulation on the pituitary. Chronic or excessive exposure to X-rays or radioactive substances, general ill health, poor diet, and stress may all contribute to poor ovarian function ([Fritz & Speroff, 2010](#)).

Nutrition, body weight, and exercise are all important for adequate ova production because they all influence the blood glucose/insulin balance ([Best & Bhattacharya, 2015](#)). When either glucose or insulin levels are too high, they can disrupt the production of FSH and LH, leading to ovulation failure. Vitamin D may also be instrumental in maintaining pituitary hormone levels ([Shahrokhi, Ghaffari, & Kazerouni, 2016](#)).

The ideal body weight to maintain is a BMI of 18.5 to 24.9. Eating slowly digested carbohydrate foods (e.g., brown rice, pasta, dark bread, beans) and fiber-rich vegetables (e.g., asparagus, broccoli) rather than easily digested carbohydrate foods (e.g., white bread, cold breakfast cereals) can not only increase fertility by keeping insulin levels balanced but also may prevent gestational diabetes when a woman becomes pregnant (Sanabria-Martínez, García-Hermoso, Poyatos-León, et al., 2015).

Exercising 30 minutes per day by walking or doing mild aerobics also helps to regulate blood glucose levels and increase fertility, complementing healthy eating habits. Stress may play a role in limiting ovulation as this may lower hypothalamic secretion of the gonadotropin-releasing hormone (GnRH), which then lowers the production of LH and FSH, which leads to anovulation.

Decreased body weight or a body fat ratio of less than 10%, as may occur in female athletes such as competitive runners or in women who are excessively lean or anorexic, can reduce pituitary hormones such as FSH and LH and halt ovulation (termed hypogonadotropic hypogonadism) (Fritz & Speroff, 2010).

The most frequent cause, however, for anovulation is naturally occurring variations in ovulatory patterns or polycystic ovary syndrome, a condition in which the ovaries produce excess testosterone, thus lowering FSH and LH levels, which then causes irregular and unpredictable menstrual cycles (Ecklund & Usadi, 2015).

Polycystic ovary syndrome is associated with metabolic syndrome, which is diagnosed in patients with:

- Waist circumference of 35 in. or more in women
- Fasting blood glucose over 100 mg/dl
- Serum triglycerides over 150 mg/dl
- Blood pressure over 135/85 mmHg
- High-density lipoprotein cholesterol over 50 mg/dl
- Development of hirsutism (unwanted body hair) (Ebrahimi-Mamaghani, Saghafi-Asl, Pirouzpanah, et al., 2015).

Metabolic syndrome is also associated with increased cardiac disease, so efforts to reduce weight and lower triglycerides and cholesterol can improve heart health as well. It is discussed further in [Chapter 11](#).

## Testing for Anovulation

Many tests to detect ovulation can be completed independently by women at home, giving them both a sense of control over what is happening and the ability to learn more about the functioning of their bodies.

### Ovulation Monitoring

The fastest way to investigate if ovulation is occurring is to measure the woman's serum progesterone level during the luteal phase of her menstrual cycle (about day 21 to day 28 of a typical cycle). If this is elevated, it implies a corpus luteum has formed or

ovulation has occurred.

The least costly way to determine a woman's ovulation pattern is to ask her to record her basal body temperature (BBT) for at least 4 months. To determine this, a woman takes her temperature each morning, before getting out of bed or engaging in any activity, eating, or drinking, using a special BBT or tympanic thermometer. She plots this daily temperature on a monthly graph while noting any conditions that might affect her temperature, such as an infection or sleeplessness. At the time of ovulation, the BBT can be seen to dip slightly (about 0.5°F), it then rises to a level about 1 degree higher than her preovulation temperatures and then stays at that level until 3 or 4 days before the next menstrual flow. This increase in BBT marks the time of ovulation because it occurs immediately after ovulation (and at the beginning of the luteal phase of the menstrual cycle, which can occur only if ovulation has occurred). If the temperature rise does not last at least 10 days, it suggests a woman has a luteal phase defect (progesterone is not being produced long enough in a cycle so adequate endometrium for implantation can be laid down). Typical graphs of BBT are shown in [Figure 7.1](#).

**Figure 7.1** Basal body temperature graph. **(A)** A woman’s temperature dips slightly at midpoint in the menstrual cycle and then rises sharply, which is an indication of ovulation. Toward the end of the cycle (the 24th day), her temperature begins to decline, indicating progesterone levels are falling and she did not conceive. **(B)** A woman’s temperature rises at the midpoint in the cycle and remains at that elevated level past the time of her normal menstrual flow, suggesting pregnancy has occurred. **(C)** There is no preovulatory dip, and no rise of temperature anywhere during the cycle. This is the typical pattern of a woman who does not ovulate.

*What If... 7.3*

**Cheryl Carl tells the nurse she works nights as a cocktail waitress, goes to**

**bed at 4 am, and then wakes at 6 am to drive her husband to work. Starting at noon, she sleeps for 4 or 5 hours before getting up to go to work. When during the day should the nurse tell her is the best time to record her BBT?**

### Ovulation Determination by Test Strip

Various brands of commercial kits are available for assessing the upsurge of LH that occurs just before ovulation and can be used in place of BBT monitoring. A woman dips a test strip into a midmorning urine specimen and then compares it with the kit instructions for a color change. Such kits are purchased over the counter, are easy to use, and have the advantage of marking the point just before ovulation occurs rather than just after ovulation, as is the case with BBT. They are not as economical as simple temperature recording, but they are advantageous for women with irregular work or daily activity, which can make BBT measurements inaccurate.

Several test kits can be found online that contain materials to test both FSH on the third day of a woman's menstrual cycle (an abnormally high level is an indicator her ovaries are not responding well to ovulation) as well as sperm motility for the male. The woman's result is available in 30 minutes; the man's result is available in 10 minutes. The kits are expensive but can be helpful to a couple as a first step in self-fertility testing. Be certain the woman realizes this is not a test of her time of ovulation but a test whether she has adequate FSH to stimulate egg growth; therefore, she shouldn't use the test at the midpoint of her menstrual cycle.

Polycystic ovary syndrome can be detected by examining the woman's menstrual history, but even if a woman experiences regular monthly menstruation, it does not necessarily indicate she is also ovulating on a regular basis (Balen, 2012). Fasting-glucose, testosterone, and estrogen levels are analyzed. A pelvic sonogram can be used to confirm cysts are present on the ovaries and may be the cause of subfertility (Hamilton, 2012).

### Therapy for Anovulation

If a disturbance in ovulation is identified as the subfertility concern, administration of GnRH is a possibility (this will stimulate the pituitary to secrete more FSH and LH). Therapy with clomiphene citrate (Clomid) or letrozole (Femara), a newer drug, may also be used to stimulate ovulation (Box 7.6). In other women, ovarian follicular growth can be stimulated by the administration of combinations of FSH and LH in conjunction with administration of human chorionic gonadotropin (hCG) to produce ovulation. If increased prolactin levels are identified, bromocriptine (Parlodel) is added to the medication regimen to reduce prolactin levels and allow for the rise of pituitary gonadotropins (Karch, 2015).

#### BOX 7.6

#### Nursing Care Planning Based on Responsibility for Pharmacology

## CLOMIPHENE CITRATE (CLOMID)

**Action:** Clomiphene citrate (Clomid) is an estrogen agonist commonly used to stimulate the ovary. The drug binds to estrogen receptors, decreasing the number of available estrogen receptors, which falsely signals the hypothalamus to increase follicle-stimulating hormone and luteinizing hormone secretion. This results in ovulation (Karch, 2015).

**Pregnancy Category:** X

**Dosage:** Initially, 50 mg/day orally for 5 days (started anytime if no menstrual flow has occurred recently or about the fifth day of the cycle if menstrual flow is occurring). If ovulation does not occur with this initial therapy, the drug can be followed by a prescription of 100 mg/day for 5 days started as early as 30 days after the initial course of therapy. This second course may be repeated one more time.

**Possible Adverse Effects:** abdominal discomfort, distention, bloating, nausea, vomiting, breast tenderness, vasomotor flushing, ovarian enlargement, ovarian overstimulation, multiple births, and visual disturbances

## NURSING IMPLICATIONS

- Ensure women have had a pelvic examination and baseline hormonal studies before therapy.
- Review medication scheduling. Urge women to use a calendar or some other system to mark their treatment schedule and also to determine and plot ovulation.
- Remind patients that timing intercourse with ovulation is important for achieving pregnancy.
- Advise patients 24-hour urine samples may be periodically necessary.
- Caution patients to report any bloating, stomach pain, blurred vision, unusual bleeding, bruising, or visual changes.
- Inform patients that therapy can be repeated for a total of three courses; if no results are obtained, therapy will be discontinued at that point.

Administration of either clomiphene citrate or gonadotropins may overstimulate an ovary, causing multiple ova to come to maturity, and possibly resulting in multiple births. Counsel women who receive these agents that this is a possibility.

## TUBAL TRANSPORT PROBLEMS

Difficulty with tubal transport usually occurs because scarring has developed in the fallopian tubes, which is typically caused by chronic salpingitis (chronic pelvic inflammatory disease). This could also result from a ruptured appendix or from abdominal surgery, which involved infection that spread to the fallopian tubes and left adhesion formation in the tubes. Complete tubal obstruction is the chief problem if a

woman had a tubal ligation in years past but now wants to become pregnant.

**Pelvic inflammatory disease (PID)** is infection of the pelvic organs: the uterus, fallopian tubes, ovaries, and their supporting structures. The initial source of the infection is usually a sexually transmitted disease such as chlamydia or gonorrhea. PID occurs at a rate of about 25 per 100 women; in other words, one-fourth of all women will experience this type of infection in a lifetime. About 12% of those who acquire PID will be left subfertile because of tubal scarring (Sheth & Keller, 2015).

PID invasion of fallopian tubes is most apt to occur at the end of a menstrual period because menstrual blood provides such an excellent growth medium for bacteria. There also is a loss of the normal cervical mucus barrier at this time, which increases the risk of initial invasion. When PID is left unrecognized and untreated, it enters a chronic phase, which causes the scarring that can lead to stricture of the fallopian tubes and the resulting fertility problem.

There is a higher incidence of PID among women who have multiple sexual partners (Oman & Burke, 2015). Based on this, it is good advice for women to limit the number of their sexual partners or always insist on condom protection to help reduce the incidence of sexually transmitted infections and possibly subfertility.

### Testing for Tubal Patency

Ultrasound or X-ray imaging and direct visualization by a hysteroscope of fallopian tubes are all effective methods used to determine the patency of fallopian tubes.

#### Sonohysterosalpingogram

A sonohysterosalpingogram is a sonographic examination of the fallopian tubes and uterus using an ultrasound contrast agent introduced into the uterus through a narrow catheter inserted into the uterine cervix (Fig. 7.2) followed by intravaginal scanning. If the tubes are patent, they will fill with the contrast medium and be detailed on the ultrasound screen. The procedure is contraindicated if infection of the vagina, cervix, or uterus is present (infectious organisms might be forced through the tubes into the pelvic cavity); it is usually scheduled just following a menstrual flow when a woman could not be pregnant.

**Figure 7.2** Insertion of a contrast medium for a sonohysterosalpingogram. The contrast medium outlines the uterus and fallopian tubes on sonogram to demonstrate patency.

Although only a small amount of contrast medium is used, it does slightly distend the uterus and tubes, possibly causing momentary painful uterine cramping. After the study, the small amount of contrast medium used drains out through the vagina. Although it is possible that the procedure could be therapeutic as well as diagnostic as the pressure of the solution could break up adhesions as it passes through the fallopian tubes, this is unlikely because the amount of contrast medium used is so small. Although extremely rare, the procedure carries a small risk of infection (a chlamydia screen before the procedure is usually advised); although unlikely, an allergic reaction to the contrast medium or embolism from the medium entering a uterine blood vessel could also occur.

### Hysterosalpingogram

A hysterosalpingogram is similar to a sonohysterosalpingogram except a radiopaque contrast medium is used and the fallopian tubes are revealed by X-ray. This procedure uses more contrast medium than with the sonogram technique so the force of the injected solution may actually break up tubal adhesions, and thus may be therapeutic as well as diagnostic. Because an X-ray is used, which might be harmful to a growing pregnancy, the procedure must be scheduled immediately following a menstrual flow when pregnancy could not be present.

### Transvaginal Hydrolaparoscopy

Transvaginal hydrolaparoscopy is begun with the instillation of a paracervical local anesthetic block followed by introduction of a hysteroscope into an incision just behind the cervix through the cul-de-sac of Douglas into the peritoneal cavity. About 200 ml of normal saline is then introduced to move the bowel away from the uterus so the posterior wall of the uterus, the ovaries, and the fallopian tubes can be assessed. Tubal patency can be evaluated if, following the insertion of a small amount of dye into the cervix, it can be viewed exiting the fimbrial end of the tubes. At the end of the procedure, the fluid is drained from the peritoneal cavity; the small incision will heal without stitches (Lo Monte, Capobianco, Piva, et al., 2015).

### Therapy for Lack of Tubal Patency

If the subfertility problem is identified as tubal insufficiency from inflammation, the prescription of diathermy or steroid administration may be helpful to reduce adhesions. Hysterosalpingography (instillation of a contrast dye under X-ray monitoring) can be attempted to see if the force of the dye insertion will break adhesions. Canalization of the fallopian tubes and plastic surgical repair (microsurgery) are other possible treatments. If peritoneal adhesions or nodules of endometriosis are holding the tubes fixed and away from the ovaries, these can be removed by laparoscopy or laser surgery (Magos, 2012).

It is possible for fallopian tubes, which have been ligated as a contraception procedure, to be reopened surgically but the success of the operation is not more than 70% to 80%. Also, the irregular incision line left by surgery can result in an ectopic pregnancy (i.e., a tubal pregnancy) if a fertilized ovum is stopped at the irregular point (Malacova, Kemp-Casey, Bremner, et al., 2015). IVF is more commonly used today and more apt to result in a viable pregnancy.

### QSEN Checkpoint Question 7.3

#### TEAMWORK & COLLABORATION

Cheryl Carl is scheduled to have a sonohysterosalpingography. Which of the following instructions would the nurse want the care team members to know so patient teaching can be consistent?

- She may feel some mild cramping when the contrast medium is inserted.
- The X-ray of the uterus will reveal any fibroid tumors or adhesions present.
- She will not be able to conceive for at least 3 months after the procedure.
- Many women experience mild bleeding for up to 2 hours as an aftereffect.

*Look in Appendix A for the best answer and rationale.*

### UTERINE CONCERNS

Tumors such as fibromas (leiomyomas) may be a rare cause of subfertility if they block the entrance of the fallopian tubes into the uterus or limit the space available on the

uterine wall for effective implantation. A congenitally deformed uterine cavity may also limit implantation sites, but this also is rare.

Endometriosis and poor secretion of estrogen or progesterone are more common uterine reasons for subfertility as these result in inadequate endometrial formation (overproduction or underproduction), which then interferes with implantation and embryo growth.

**Endometriosis** refers to the implantation of uterine endometrium, or nodules, that have spread from the interior of the uterus to locations outside the uterus (Woo & Yates, 2015). The occurrence of endometriosis may indicate the endometrial tissue has different or more friable qualities than usual (perhaps due to a luteal phase defect) and therefore is a type of endometrium that also does not support embryo implantation as well as usual.

Endometriosis symptoms begin in adolescence, with the most common sites of endometrium spread to the fallopian tubes, the cul-de-sac of Douglas, the ovaries, the uterine ligaments, and the outer surface of the uterus and bowel (Fig. 7.3). Some evidence of endometriosis occurs in as many as 50% of women, usually from reflux through the fallopian tubes at the time of menstruation. If viable particles of endometrium, which enter a tube this way, begin to proliferate, they can cause tubal obstruction; growths on the ovaries can displace fallopian tubes away from the ovaries, preventing the entrance of ova into the tubes. Peritoneal macrophages, which are drawn to nodules of endometrium, can destroy sperm.

**Figure 7.3** Common sites of endometriosis formation.

### Testing for Uterine Concerns

Tests to determine if a uterine concern is leading to subfertility include a sonogram or

hysteroscopy to view the structure of the uterus, blood work to analyze for hormones, and perhaps an endometrial biopsy.

## Hysteroscopy

Hysteroscopy is visual inspection of the uterus through the insertion of a hysteroscope (a thin hollow tube) through the vagina, cervix, and into the uterus. This is helpful to further evaluate uterine adhesions, malformations, or other abnormalities such as fibroid tumors or polyps that were discovered on sonogram imaging. Women are screened for chlamydia before the examination to avoid introduction of bacteria into the uterus.

## Uterine Endometrial Biopsy

Uterine endometrial biopsy may be used to reveal an endometrial problem, such as a luteal phase defect. If the endometrium sample removed by biopsy resembles a corkscrew (a typical progesterone-dominated endometrium) seen in the second half of a menstrual cycle, this suggests ovulation has occurred. Although very diagnostic of progesterone-associated concerns, endometrial biopsies are being performed less commonly than they once were, having been replaced with serum progesterone level evaluations that are simpler and also suggest ovulation has occurred.

If an endometrial biopsy is required, it is done 2 or 3 days before an expected menstrual flow (day 25 or 26 of a typical 28-day menstrual cycle). After a paracervical block and a screen for chlamydia, a thin probe and biopsy forceps are introduced through the cervix. A woman may experience mild-to-moderate discomfort from maneuvering the instruments. There may be a moment of sharp pain as the biopsy specimen is taken from the anterior or posterior uterine wall. Possible complications include pain, excessive bleeding, infection, and uterine perforation. This procedure is contraindicated if pregnancy is suspected (although the chance it would interfere with a pregnancy is probably less than 10%) or if an infection such as acute PID or cervicitis is present. Caution the woman that she might notice a small amount of vaginal spotting after the procedure. For follow-up, she needs to telephone her primary care provider if she develops a temperature greater than 101°F, has a large amount of bleeding, or passes clots. She needs to telephone the healthcare agency when she has her next menstrual flow because this helps “date” the endometrium and the accuracy of the analysis.

## Laparoscopy

Laparoscopy is the introduction of a thin, hollow, lighted tube (a fiber optic telescope or laparoscope) through a small incision in the abdomen, just under the umbilicus, to examine the position and state of the fallopian tubes and ovaries. This allows an examiner to view whether the ovaries are close enough to the fallopian tubes to allow an ovum to enter. It is rarely done unless the results of a uterosalpingography are abnormal because it involves general anesthesia, which is necessary because of the pain caused by

extensive maneuvering. It is scheduled during the follicular phase of a menstrual cycle. The woman is positioned in a steep Trendelenburg position (which brings the reproductive organs down out of the pelvis). Carbon dioxide is usually introduced into the abdomen to move the abdominal wall outward and to offer better visualization. Women may feel bloating of the abdomen from the infusion of the carbon dioxide after such a procedure. If some carbon dioxide escapes under the diaphragm, they may feel extremely sharp shoulder pain from the pressure of the gas on the cervical nerves.

During the procedure, a contrast medium can be injected into the uterus through a polyethylene cannula placed in the cervix to assess tubal patency (if tubes are patent, the dye will appear in the abdominal cavity). A scope may be passed directly into a fallopian tube to reveal information about the presence and condition of the fimbria and the tubal lining. If fimbria have been destroyed by PID, the chance for a normal conception is in doubt because ova seem to be unable to enter a tube if fimbrial currents are absent.

### **Therapy for Uterine Concerns**

If the problem of subfertility appears to be a luteal phase defect, this can be corrected by progesterone vaginal suppositories begun on the third day of a woman's temperature rise and continued for the next 6 weeks (if pregnancy occurs) or until a menstrual flow begins.

If a myoma (fibroid tumor) or intrauterine adhesions are found to be interfering with fertility, a myomectomy, or surgical removal of the tumor and adhesions, can be scheduled (Bailey, Jaslow, & Kutteh, 2015). If the growth is small, this can be done by a hysteroscopic ambulatory procedure. During the procedure, an intrauterine device (IUD) may be inserted to prevent the uterine sides from touching and forming new adhesions; the woman may be prescribed estrogen for 3 months as another method to prevent adhesion formation. This treatment can be difficult for a woman to accept because preventing pregnancy (using an IUD) is exactly what she does not want to do. Be certain she has a good explanation of the IUD's purpose and that it can be easily removed in about 1 month's time.

For problems of abnormal uterine formation, such as a septate uterus, surgery is also available. However, these defects are usually related to early pregnancy loss, not initial subfertility. Endometriosis can be treated both medically and surgically; treatment is discussed in [Chapter 47](#) with other causes of dysmenorrhea.

## **VAGINAL AND CERVICAL CONCERNS**

At the time of ovulation, the cervical mucus is thin and watery and can be easily penetrated by spermatozoa for a period of 12 to 72 hours. If coitus is not synchronized with this time, the cervical mucus may be too thick to allow spermatozoa to penetrate the cervix. Infection or inflammation of the cervix (erosion) can also cause cervical mucus to thicken so much that spermatozoa cannot penetrate it easily or survive in it. A

stenotic cervical os or obstruction of the os by a polyp may further compromise sperm penetration. This is rarely enough of a problem to be the sole cause of subfertility, however. A woman who has undergone dilatation and curettage (D&C) procedures several times or cervical conization (cervical surgery) should be evaluated in light of the possibility that scar tissue and tightening of the cervical os has occurred.

Infection of the vagina can cause the pH of vaginal secretions to become acidotic, thus limiting or destroying the motility of spermatozoa. Some women appear to have sperm-immobilizing or sperm-agglutinating antibodies in their blood plasma, which act to destroy sperm cells in the vagina or cervix. Either of these immune-based problems can limit the ability of sperm to survive in the vagina and enter the uterus.

### Testing and Therapy for Vaginal and Cervical Concerns

If sperm do not appear to survive in vaginal secretions because secretions are too scant or tenacious, a woman may be prescribed low-dose estrogen therapy to increase mucus production during days 5 to 10 of her cycle. Conjugated estrogen (Premarin) is a type of estrogen prescribed for this purpose.

If a vaginal infection is present, the infection will be treated according to the causative organism based on culture reports (see [Chapter 47](#)). Vaginal infections such as trichomoniasis and moniliasis tend to recur, requiring close supervision and follow-up. If the woman's sexual partner is the source of infection, and is therefore reinfesting her, the partner needs antibiotic therapy as well. Caution women who are prescribed metronidazole (Flagyl) for a *Trichomonas* infection; although no studies have shown fetal malformations after its use, it may be teratogenic early in pregnancy and therefore should not be continued if the woman suspects she has become pregnant.

## Unexplained Subfertility

In a small percentage of couples, no known cause for subfertility can be discovered. It may be that the problem of one partner alone is not significant, but when combined with a small problem in the other partner, together, these become sufficient to create subfertility. It is obviously discouraging for couples to complete a fertility evaluation and be told their inability to conceive cannot be explained. Offer active support to help the couple find alternative solutions at this point, such as continuing to try to conceive, using an assisted reproductive technique, choosing to adopt, or agreeing to a child-free life.

### QSEN Checkpoint Question 7.4

#### INFORMATICS

Cheryl Carl is diagnosed as having endometriosis as a cause of her subfertility. The nurse would want her electronic health record to reflect the fact that this condition interferes with fertility because of which of the following?

- a. The ovaries stop producing estrogen and progesterone.
- b. The uterine cervix becomes very inflamed and swollen.
- c. Pressure on the pituitary leads to decreased FSH levels.
- d. Endometrial implants obstruct both of the fallopian tubes.

Look in [Appendix A](#) for the best answer and rationale.

## Assisted Reproductive Techniques

If ovulation, sperm production, or sperm mobility problems cannot be corrected, assisted reproductive strategies are the next step for a couple to consider. Before beginning any of these procedures, urge a woman to be in excellent health by discontinuing smoking or recreational drug behaviors, ingesting a diet high in protein, and having a BMI within a normal range of 18.5 to 24.9. She probably also will have, if she has not already had them, tests for HIV and hepatitis C; a hormone profile including levels of FSH, LH, estrogen, and progesterone to test for ovarian reserves (whether ovaries have the capacity to produce multiple oocytes); as well as an intravaginal sonogram to visual usual structures. Whether a woman feels comfortable choosing assisted reproduction is strongly socioculturally related, as people on a limited budget and without health insurance may not be able to afford these therapies, or their religion or cultural beliefs may make these unacceptable procedures. LGBT couples may also feel uncomfortable seeking reproductive advice. In all instances, culturally sensitive care is required by the nurse ([Box 7.7](#)).

### BOX 7.7

#### Nursing Care Planning to Respect Cultural Diversity

Obtaining a sexual history is often difficult because cultural taboos can make couples feel uncomfortable discussing this part of their life. Simple factors, such as how often couples engage in sexual relations, for example, are influenced by culture and religion. For example, according to Orthodox Jewish law, a couple may not engage in sexual relations for 7 days following menstruation (the *nida* period). This practice can result in fertility problems if a woman ovulates within the 7-day period. Some cultures forbid alternative insemination because preserving male lineage is so important. The Roman Catholic Church does not approve of in vitro fertilization or any form of conception outside the body. Being aware of cultural differences can help you understand the different ways couples react to a diagnosis of subfertility and help you appreciate the full meaning of this diagnosis to an individual couple.

## ALTERNATIVE INSEMINATION

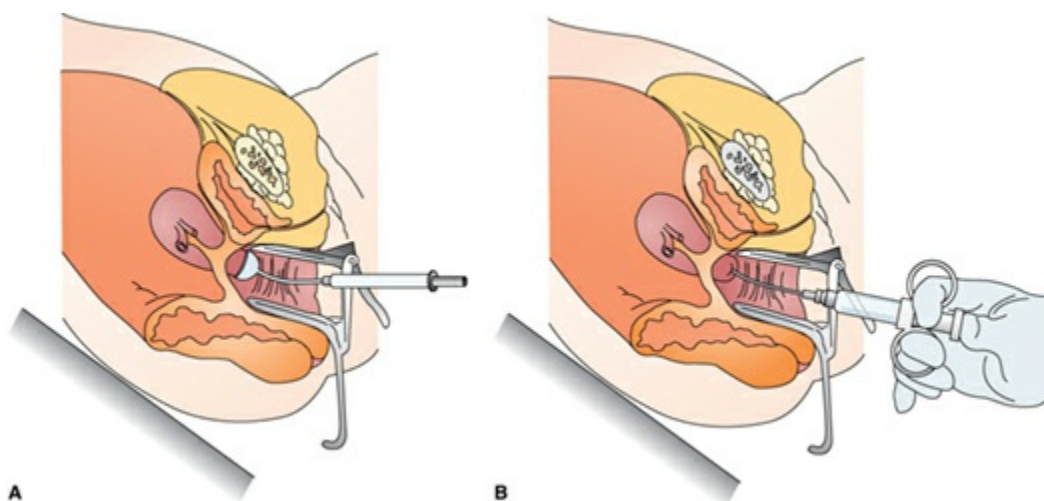

Alternative or IUI is the instillation of sperm from a masturbatory sample into the female reproductive tract by means of a cannula to aid conception at the time of

ovulation (Kop, van Wely, Mol, et al., 2015). The sperm can either be instilled into the cervix (intracervical insemination) or directly into the uterus (IUI) at the time of predicted ovulation. BBT charting, mucus analysis, or urinary test kits for LH can be used to detect the day of ovulation (Hamilton, 2012).

Either the male partner's sperm (alternative insemination by male partner) or donor sperm (alternative insemination by donor) can be used. These procedures are used if the male partner has no sperm or an inadequate sperm count, if a woman has a vaginal or cervical factor that interferes with sperm motility, or a woman has hormonal issues affecting fertility. Donor insemination can be used if the man has a known genetic disorder he does not want to be transmitted to children or if a woman does not have a male partner. It is also a useful procedure for men who underwent a vasectomy but now wish to have children. In the past, men who underwent chemotherapy or radiation for testicular cancer had to accept being child-free afterward because they were no longer able to produce sperm. Today, sperm can be cryopreserved (frozen) in a sperm bank before radiation or chemotherapy and then used for alternative insemination afterward (Araki, Yao, Asayama, et al., 2015).

One disadvantage of using cryopreserved sperm is that it tends to have slower motility than unfrozen specimens. However, although the rate of conception may be lower from this source, there appears to be no increase in the incidence of congenital anomalies in children conceived by this method, and sperm remain viable even after years of storage.

To prepare for alternative insemination, a woman receives an injection of clomiphene (Clomid) or FSH 1 month prior to the insemination so follicle growth of ova is stimulated and a day of ovulation can be predicted. On the selected day of insemination (confirmed by a serum analysis of progesterone), the sperm sample is instilled next to her cervix using a device similar to a cervical cap or diaphragm, or sperm are injected directly into the uterus using a flexible catheter (Fig. 7.4).

**Figure 7.4** Alternative insemination. (A) Sperm are deposited next to the cervix, or (B) injected directly into the uterine cavity.

Donors for alternative insemination are volunteers who have no history of disease and no family history of possible inheritable disorders. The blood type, or at least the Rh factor, can be matched with the woman's to prevent incompatibility. Sperm can be selected according to desired physical or mental characteristics if desired. If FSH was used to stimulate follicle growth, caution women that the chance for a multiple birth (twins or triplets) increases so she can be prepared for this (Trew & Lavery, 2012).

Because conception through alternative insemination takes an average of 6 months to achieve, and some couples may have religious or ethical beliefs that prohibit the use of sperm from either the male partner or a donor, it may not be right for every couple. Also, because it can be a discouraging process for a couple to have to wait 6 months (or longer) to see results, couples may need support to continue the technique.

### ***QSEN Checkpoint Question 7.5***

#### **QUALITY IMPROVEMENT**

Bob Carl asks the nurse several questions about the way in which his wife may be prepared for IUI. The clinical protocol for this procedure should include which of the following?

- a. The patient would undergo genetic testing prior to the procedure.
- b. The patient would wear a transdermal estrogen patch for 2 weeks prior to the procedure.
- c. The patient would receive an injection of clomiphene (Clomid) or FSH 1 month prior to the procedure.
- d. The patient would be prescribed bed rest for 48 to 72 hours following the procedure.

*Look in Appendix A for the best answer and rationale.*

Some states have specific laws regarding inheritance, child support, and responsibility concerning children conceived by donor insemination, which may also limit whether a couple finds the technique desirable.

## **IN VITRO FERTILIZATION**

In vitro fertilization (IVF) is most often used for couples who have not been able to conceive because the woman has obstructed or damaged fallopian tubes. It is also used when the man has oligospermia or a very low sperm count. IVF may also be helpful for couples when an absence of cervical mucus prevents sperm from entering the cervix or antisperm antibodies cause immobilization of sperm. In addition, couples with unexplained subfertility of long duration may be helped by IVF.

For the procedure, one or more mature oocytes are removed from a woman's ovary by laparoscopy and fertilized by exposure to sperm in a laboratory. About 40 hours after fertilization, the laboratory-grown fertilized ova (now zygotes) are inserted into a woman's uterus, where, ideally, one or more of them will implant and grow.

A donor ovum, rather than the woman's own ovum, can be used for a woman who does not ovulate or who carries a sex-linked disease she does not want to pass on to her children. Young women who had extensive ovarian radiation or ovaries removed before surgery for ovarian cancer can have oocytes cryopreserved before surgery and used for IVF (Brezina, Ding, Ke, et al., 2015).

As with alternative insemination, 1 month before the procedure, the woman is given FSH to stimulate oocyte growth. Beginning about the 10th day of the menstrual cycle, the ovaries are examined daily by sonography to assess the number and size of developing ovarian follicles. When a follicle appears to be mature, a woman is given an injection of hCG, which causes ovulation in 38 to 42 hours.

A needle is then introduced intravaginally and guided by ultrasound, and the oocyte is aspirated from its follicle. Because of the drugs given to induce ova maturation, many oocytes may ripen at once, and perhaps as many as 3 to 12 can be removed. The oocytes chosen are incubated for at least 8 hours to ensure viability. In the meantime, the male partner or donor supplies a fresh or frozen semen specimen. The sperm cells and oocytes are mixed and allowed to incubate in a growth medium. Genetic analysis to reveal chromosomal abnormalities or the potential sex can be completed at this point.

In the past, many sperm were necessary even under laboratory conditions to allow sperm to make their way through the resistant zona pellucida surrounding the ovum. A number of techniques, such as creating passages through the resistant cells (i.e., zona drilling), have been discovered to help sperm cross the zona. In some instances, it has been possible to inject sperm directly under the zona pellucida (i.e., intracytoplasmic sperm injection). This is the technique that makes it possible for fertilization to take place with only one sperm. Worry that this technique could lead to an increased number of birth defects is unproven (Thornhill, Fanning, Davis, et al., 2015).

After fertilization of the chosen oocytes occurs, the zygotes formed almost immediately begin to divide and grow. By 40 hours after fertilization, they will have undergone their first cell division. In the past, multiple eggs were chosen and implanted to ensure a pregnancy resulted, but this technique also resulted in many multiple births. Because newborns from multiple births have a much smaller chance of surviving the neonatal period than others, today if a woman is under 35 years of age, only one or two fertilized eggs are chosen and transferred back to her uterine cavity through the cervix by means of a thin catheter. In women age 40 years, up to five embryos may be transferred (Duke & Christianson, 2015) (Fig. 7.5).

**Figure 7.5** Steps involved in in vitro fertilization. **(A)** Ovulation. **(B)** Capture of ova (done here intra-abdominally). **(C)** Fertilization of ova and growth in culture medium. **(D)** Insertion of fertilized ova into uterus.

If the couple desires, any eggs that are not used can be cryopreserved for use at a later time. As with sperm cryopreservation, egg cryopreservation presents a range of ethical and religious dilemmas as to who should “own” them if the couple should divorce or disagree about their disposal at a later date.

A lack of progesterone can occur if the corpus luteum was injured by the aspiration of the follicle. Therefore, progesterone or LH may be prescribed to a woman following IVF if it is believed she will not produce enough on her own to support implantation. Proof the zygote has implanted can be demonstrated by a routine serum pregnancy test as early as 11 days after transfer. A few women develop an ovarian hyperstimulation syndrome with IVF. Their ovaries become swollen and painful and they may have accumulating abdominal and lung fluid. Women need to report these symptoms so ovarian stimulation can be halted until their ovaries return to normal; removing a number of oocytes and cryopreserving them can reduce the need for further stimulation with future procedures (Thomsen & Humaidan, 2015).

In some centers, nurse practitioners are the healthcare providers who complete oocyte removal and transfer. In all centers, nurses have a responsibility to supply support and counseling to help sustain a couple through the process. The recovery rate for harvesting ripened eggs is high (about 90%), as is the ability to fertilize eggs by sperm in vitro. However, the overall live birth rate by IVF is as low as 41% to 43% per treatment cycle for women under 35 years; it is as low as 13% to 18% for woman age 40 years (American Pregnancy Association, 2015).

About 25% of pregnancies end in spontaneous miscarriage (the same rate as for natural pregnancies). Once a pregnancy has been successfully established, a woman’s prenatal care is the same as for any pregnancy, although the pregnancy may be categorized as high risk because women who have IVF procedures tend to be older than average, may be obese, and may have accompanying uterine concerns (Ensing, Abu-Hanna, Roseboom, et al., 2015). Because the couple was committed to the procedure, the typical couple adjusts to pregnancy and parenthood well. Encourage the woman and offer support for breastfeeding so she can be as successful with this as other women (de

Lacey, Peterson, & McMillan, 2015).

If a sonogram reveals that a multiple pregnancy of more than two zygotes has been achieved, selective termination of gestational sacs until only two remain may be recommended to help ensure the pregnancy will come to term. This is done by intra-abdominal injection of potassium chloride into the gestational sacs chosen to be eliminated (Gupta, Fox, Feinberg, et al., 2015). This is obviously a difficult decision for a couple to agree upon, so they may need maximum support at this step.

IVF is expensive (about \$12,000 to \$17,000 per cycle) and is available only at specialized centers. A complication of maternal infection can occur if bacteria are introduced at any point in the transfer. Waiting to be accepted by a center's program and then waiting for the time to obtain the oocyte, allow for laboratory growth, and then pregnancy success is a major psychological strain. Couples report a feeling of social isolation during this time and weariness answering friends' and family's questions about when they will have a baby. Supply empathic support for them through this difficult time. [Box 7.8](#) illustrates interprofessional care map for nursing and team planning for a couple who are having difficulty conceiving a child.

## BOX 7.8

### Nursing Care Planning

#### AN INTERPROFESSIONAL CARE MAP FOR A COUPLE SEEKING A FERTILITY EVALUATION

Cheryl and Bob Carl married when they were both 25 years old. Three years later, they are now undergoing their second cycle of in vitro fertilization and embryo transfer. They have applied for a second mortgage on their house to finance the fertility testing. Today, at a visit, Mrs. Carl stated, "This is my fault because I'm so rigid. Look how I had to buy the house before I could even consider getting pregnant, and now we'll probably lose it. I've made our whole life revolve around trying to get pregnant instead of enjoying life."

**Family Assessment:** Couple live in three-bedroom, middle-income home; husband works as a bank manager; wife works as a receptionist in a medical office. Husband reports finances as "not good." Couple both appear discouraged about their apparent inability to have children.

**Patient Assessment:** Past medical history negative for any major health problems; wife reports a menstrual cycle of 5 days' duration with moderate flow every 30 to 37 days; never any dysmenorrhea. Used a combined estrogen/progestin oral contraceptive for 6 years; discontinued 3 years ago. Baseline laboratory studies and vital signs within normal limits.

**Nursing Diagnosis:** Situational low self-esteem related to seeming inability to conceive

**Outcome Criteria:** Couple verbalizes feelings about subfertility and effect on self-

esteem; participates actively in care and treatment decisions; states they feel some control over situation and required treatment.

<b>Team Member Responsible</b>	<b>Assessment</b>	<b>Intervention</b>	<b>Rationale</b>	<b>Expected Outcome</b>
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Assess couple's lifestyle to identify areas in which they are successful.	Review and reinforce with patient activities they have achieved successfully.	Identifying positive attributes can provide a foundation for rebuilding self-esteem.	Couple names at least three positive achievements, such as graduating from college or planting a garden.
	Assess if there is a common interest they could draw upon.	Ask couple to propose a new activity that would interest both of them.	Beginning a new activity can eliminate total concentration on fertility management.	Couple names and begins to participate in a new activity by 2 weeks' time.
<i>Teamwork and Collaboration</i>				
Nurse/social worker	Assess the couple's community for available community resources.	Ask couple if they would like a referral to a support group, such as Resolve.	A national organization can help provide effective support during a family crisis.	Couple confirms they have contacted an outside support group and have attended at least one meeting or online chat group.
<i>Procedures/Medications for Quality Improvement</i>				
Nurse/primary healthcare provider	Assess whether couple needs a review of IVF procedure and how their	Encourage patients to ask questions about procedure; if prescribed an	Fully informed patients are better able to participate in their own care.	Patients state they understand procedure and are interested in being an active

	participation is important for success.	ovulation stimulant, review dosage, and administration schedule.		part of it by asking questions and demonstrating successful medication adherence.
--	---	--	--	---

*Nutrition*

Nurse/nutritionist	Assess whether couple ingests a healthy diet in light of busy lifestyle.	Remind patient to take prenatal vitamin (because of folic acid content) during fertility studies to be well prepared when pregnancy is achieved.	Folic acid is necessary in early pregnancy to help prevent neural tube anomalies. Overall health may contribute to fertility.	Patient demonstrates she has filled her prenatal vitamin prescription and confirms she takes them daily. Patient lists a healthy diet and states she does not smoke or take recreational drugs.
--------------------	--	--	---	---

*Patient-Centered Care*

Nurse	Assess whether couple is continuing to have a positive relationship in light of the diagnosis of unexplained subfertility.	Help partners review reasons they married, other than to have children.	Helping a couple find common interests can help them remain a couple and better prepare them for a parenting partnership.	Couple states they are taking steps to remain a close couple in light of the stress and possible negative results of assisted reproduction.
-------	--	---	---	---

*Spiritual/Psychosocial/Emotional Needs*

Nurse	Attempt to identify what it means to have	Clarify any misconceptions patients may	Misconceptions can negatively affect self-	Patients accurately describe
-------	---	---	--	------------------------------

unexplained subfertility for each patient, individually and as a couple.	have about unexplained subfertility.	esteem.	situation and manifest adequate self-esteem.
--	--------------------------------------	---------	--

*Informatics for Seamless Healthcare Planning*

Nurse	Assess whether couple has any further questions about assisted reproduction and how they are active partners in the procedure. Assess for intimate partner violence.	It is common for assisted reproduction to be extremely stressful. After pregnancy is achieved, waiting for a much-desired pregnancy to come to term can be just as stressful.	Identifying and describing stressful situations can help the couple prepare for them. Unresolved, stress can lead to intimate partner violence.	Couple states they feel well equipped to manage whatever changes assisted reproduction brings to their life.
	Determine who the couple has to turn to for support outside of healthcare providers.	Discuss possible support persons and groups.	Additional support can assist in reinforcing positive attributes, thus enhancing self-esteem.	Patients list at least two persons or groups to use for support.

**GAMETE INTRAFALLOPIAN AND ZYGOTE INTRAFALLOPIAN TRANSFER**

In gamete intrafallopian transfer (GIFT) procedures, ova are obtained from ovaries exactly as in IVF. Instead of waiting for fertilization to occur in the laboratory, however, both ova and sperm are instilled, within a matter of hours, using a laparoscopic technique, into the open end of a patent fallopian tube. Fertilization then occurs in the tube, and the zygote moves to the uterus for implantation. It requires at least one patent fallopian tube; it may be a preferred procedure by some couples because conception occurs in the fallopian tube and so is not contradictory to their religious beliefs.

Zygote intrafallopian transfer (ZIFT) is similar to IVF in that the egg is fertilized in

the laboratory, but like GIFT, the fertilized egg is transferred by laparoscopic technique into the end of a waiting fallopian tube. Although available, this technique is little used today because of the extensive laparoscopic technique needed.

## SURROGATE EMBRYO TRANSFER

Surrogate embryo transfer is an assisted reproductive technique for a woman who does not produce ova. For the process, the oocyte is donated by a friend, relative, or an anonymous donor (Check, Wilson, Levine, et al., 2015). The menstrual cycles of the donor and recipient are synchronized by administration of gonadotropic hormones. At the time of ovulation, the donor's ovum is removed by a transvaginal, ultrasound-guided procedure. The oocyte is then fertilized in the laboratory by the recipient woman's partner's sperm (or donor sperm) and placed in the recipient woman's uterus by embryonic transfer. Once pregnancy occurs, it progresses the same as an unassisted pregnancy.

### *QSEN Checkpoint Question 7.6*

#### EVIDENCE-BASED PRACTICE

It is generally agreed that breast milk is the natural and best food for babies for the entire first year or at least until 6 months. To see if women who had babies through assisted reproductive techniques such as IVF choose to breastfeed as much as women having babies without an assisted technique, researchers interviewed 183 women who conceived using an assisted technique whether they breastfed their baby or not. Results showed that more women who conceived with the help of an assisted technique began breastfeeding than others (89.3% vs. 83.3%). By 3 months, however, a smaller number of women who had used an assisted technique were exclusively breastfeeding (46% vs. 57%); at 8 months, only 23% were still breastfeeding versus 57% of nonassisted women. Researchers attributed the decline in breastfeeding among women who used an assisted technique to more anxiety late in pregnancy and possibly to receiving suboptimal advice about assisted reproduction and breastfeeding from healthcare providers (Hammarberg, Fisher, Wynter, et al., 2011).

Based on the previous study, assuming Cheryl Carl's IVF is successful and she becomes pregnant, what would the nurse advise her during her pregnancy?

- a. "You may be unable to breastfeed because with IVF, you develop immune factors."
- b. "You should breastfeed as this will increase your fertility for a second pregnancy."
- c. "After your child's birth, you should be able to begin breastfeeding effectively."
- d. "Try not to worry; worry causes hormones necessary for vaginal birth to decrease."

*Look in Appendix A for the best answer and rationale.*

## PREIMPLANTATION GENETIC DIAGNOSIS

The individual retrieval of oocytes and their fertilization under laboratory conditions has led to close inspection and recognition of differences in sperm and oocytes. After the oocytes are fertilized in IVF and ZIFT procedures, the DNA of both sperm and oocytes can be examined for specific genetic abnormalities such as Down syndrome or hemophilia (Dahdouh, Balayla, Audibert, et al., 2015).

Couples participating in intrauterine transfer and alternative insemination can also have the sex of their children predetermined using these methods. Such techniques can be useful because popular methods to influence the sex of a child (such as douching with a baking soda mixture before coitus to have a boy or with a vinegar solution to have a girl) have been proven to be more folklore than scientific fact. Allowing couples to choose the sex of children has ethical concerns because it could result in skewed male/female ratios if used by a majority of couples.

## Alternatives to Childbirth

For some couples, even treatment for subfertility with procedures such as IVF is not successful. These couples need to consider still other options.

## SURROGATE MOTHERS

A surrogate mother is a woman who agrees to carry a pregnancy to term for a subfertile couple or an LGBT couple (Dar, Lazer, Swanson, et al., 2015). The surrogate may provide the ova, which is then impregnated by the man's sperm in the laboratory. In other instances, the ova and sperm both may be donated by the subfertile couple; in a third technique, both donor ova and sperm are used. Surrogate mothers are often friends or family members who assume the role out of friendship or compassion, or they can be referred to the couple through an agency or attorney and receive monetary reimbursement for their expenses. The subfertile couple can enjoy the pregnancy as they watch it progress in the surrogate.

A number of ethical and legal problems arise if the surrogate mother decides at the end of pregnancy that she has formed an attachment to the fetus and wants to keep the baby despite the pre-pregnancy agreement she signed. Court decisions have been split on whether the surrogate or the subfertile couple has the right to the child. Another potential problem occurs if the child is born imperfect and the subfertile couple then no longer wants the child. Who should have responsibility in this instance? For these reasons, the couple and the surrogate mother must be certain they have given adequate thought to the process and to what will be the outcome should these problems occur before they attempt surrogate mothering.

## ADOPTION

Adoption is an alternative for subfertile and LGBT couples, those individuals who have genetic-related health conditions or health conditions that would make pregnancy high risk. There are now fewer children available for adoption in the United States than there were in the past. Couples often consider physically or cognitively challenged children or children born outside the United States for adoption. The process of adoption is discussed in [Chapter 3](#) with different types of families.

## CHILD-FREE LIVING

Child-free living is another option available to both fertile and subfertile couples. For many subfertile couples who have been through the rigors and frustrations of subfertility testing and unsuccessful treatment regimens, child-free living may emerge as the option they finally wish to pursue. A couple in the midst of fertility testing may begin to reexamine their motives for pursuing pregnancy and may decide pregnancy and parenting are not worth the emotional or financial cost of future treatments. They may decide the additional stress of going through an adoption is not for them either, or they may simply decide children are not necessary for them to complete their family unit.

Child-free living can be as fulfilling as having children because it allows a couple more time to help other people and contribute to society through personal accomplishments. It has advantages for a couple in that it also allows time for both members to pursue careers. They can travel more or have more time and money to pursue hobbies or continue their education. If a couple still wishes to include children in their lives in some way, many opportunities are available to do this through family connections (most parents welcome offers from siblings or other family members to share in childrearing), through volunteer organizations (such as Big Brother or Big Sister programs), or through local schools and town recreational programs.

Many couples who believe overpopulation is a major concern choose child-free living even if subfertility is not present. Parents who choose child-free living typically rate their marriage as happier than for those with children probably because of the decreased expense involved and the availability of more free time, which allow them greater freedom in life ([Avison & Furnham, 2015](#)).

### *What If . . . 7.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals with respect to subfertility (see [Box 7.1](#)). What would be a possible research topic to explore pertinent to this goal that would be applicable to the Carl family and that would also advance evidence-based practice?**

## KEY POINTS FOR REVIEW

- Subfertility is said to exist when a pregnancy has not occurred after 1 year of

unprotected coitus. Sterility refers to the inability to conceive due to a known condition.

- About 14% of couples experience subfertility. The incidence increases with the age of the couple.
- Subfertility testing can be an intense psychological stressor for couples. Help couples to not only persist through the experience but also maintain their relationship as a couple.
- Couples who are told a subfertility problem has been discovered are apt to suffer a loss of self-esteem. Offering support to help them recognize that they are still productive, healthy people in other aspects of their lives helps in planning nursing care that not only meets QSEN competencies but best meets the family's total needs.
- Male factors that contribute to subfertility are inadequate sperm count, obstruction or impaired sperm motility, and problems with ejaculation. Female factors that cause subfertility are problems with ovulation, cervical or tubal transport, or impaired implantation.
- Basic subfertility assessment procedures consist of a health history; a physical examination; laboratory tests to document general health; and specific tests for semen, ovulation, tubal patency, and uterine environment.
- Measures to induce fertility are aimed at improving sperm number and transport, decreasing infections, stimulating ovulation, improving nutrition, and regulating hormones.
- Alternative insemination, donor egg transfer, IVF, adoption, surrogate motherhood, and child-free living are all possible solutions for subfertile and LGBT couples.

### CRITICAL THINKING CARE STUDY

Laura, age 40 years, has had three miscarriages in the first trimester, and she and her husband are anxious to have their first child. She is considering a surrogate because she is worried she will have another miscarriage with a subsequent pregnancy.

1. What further information do you want to ask her to assist with her decision making?
2. How would you address her concerns about attempting another pregnancy?
3. Laura's husband prefers they adopt because he is unsure about using a surrogate. How would you address his concerns?

# 8

## The Nursing Role in Genetic Assessment and Counseling

*Amy Alvarez, 26 years old, is a woman you meet at a genetic counseling center. She was adopted as a newborn and never felt a need to locate her birth parents because her adoptive parents provided her with a “close-to-perfect” childhood. After college, she married the most eligible bachelor in her hometown. She is now pregnant with her first child. At 15 weeks into her pregnancy, after serum and sonography testing, she has been advised her child may have translocation Down syndrome. She asks you, “How could this happen? There’s no disease like that in either of our families. Can you imagine how this will change my life?”*

*Previous chapters described common family types and how they are affected by sociocultural and community influences. This chapter discusses information about the necessary assessments, care, and guidelines for counseling of families if it is discovered there is a potential for a genetic disorder in the family. Such information can influence the health of a childbearing or childrearing family for generations to come.*

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Identify 2020 National Health Goals related to genetic disorders that nurses can help the nation achieve.
2. Assess a family for adjustment to the probability of inheriting a genetic disorder.
3. Formulate nursing diagnoses related to genetic disorders.
4. Establish expected outcomes that meet the needs of the family undergoing genetic assessment and counseling as well as manage seamless transitions across differing healthcare settings.
5. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
6. Implement nursing care such as counseling a family with a genetic disorder.
7. Evaluate expected outcomes for achievement and effectiveness of care.
8. Integrate knowledge of genetic disorders with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

As many as 1 in 20 newborns inherits a genetic disorder. As many as 70% of pediatric hospital admissions may be for genetic-influenced disorders (Simpson, Holzgreve, & Driscoll, 2012). The possibility a child could have a genetic disorder crosses the minds of most pregnant women and their partners at some point during pregnancy, whether or not there is any family history of such disorders. This causes pregnant couples to ask healthcare providers about their chances of having a child with a genetic disorder and about genetic testing (Tasker, McClure, & Acerini, 2013).

**Genetics** is the study of the way such disorders occur. Because genetics is a constantly changing field of study, it is important for nurses to keep current with new advances so they can appreciate how a new discovery will affect a family and the child's therapy or if it could cure the child (Minear, Alessi, Allyse, et al., 2015). Twenty years ago, for example, most children with cystic fibrosis (a disorder of lung and pancreatic dysfunction) died in early childhood. Today, with good management, such children live into adulthood because the gene mutation that causes the disorder has been identified, giving hope for an eventual cure for this puzzling illness, including a new view of counseling (Prakash, Moore, & Yáñez-Muñoz, 2016).

Due to the Human Genome Project and the determination of the location of specific genes in the human genome, it has become a national priority to improve screening techniques for genetic disorders, and a number of 2020 National Health Goals speak to this area of maternal and child health (Box 8.1).

A number of 2020 National Health Goals speak directly to genetic diseases and screening, including:

- Increase the number of states (and the District of Columbia) that verify through linkage with vital records all newborns are screened shortly after birth for conditions mandated by their state-sponsored screening program from 21% to 45%.
- Reduce the proportion of children diagnosed with a disorder through newborn blood spot screening who experience developmental delay requiring special education services from 15.1% to 13.6%.
- Increase the proportion of screen-positive children who receive follow-up testing within the recommended time period from 98.1% to 100%.
- Increase the proportion of youth with special healthcare needs whose healthcare provider has discussed transition planning from pediatric to adult health care from 41.2% to 45.3%.
- Reduce the number of children and youth with disabilities (aged 21 years and younger) living in congregate care residences from 28,890 to 26,001 (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these goals by being sensitive to the need for and educating parents about genetic screening in preconception, prenatal, and birth settings.

### *Nursing Process Overview*

#### FOR GENETIC ASSESSMENT AND COUNSELING

##### **ASSESSMENT**

Assessment measures for genetic disorders begin with a detailed family history, preferably of three generations; a physical examination of both the parents and any affected children; and an ever-growing series of laboratory assays of blood, amniotic fluid, and maternal and fetal cells. For example, in the first trimester, women are offered a routine sonogram screening (a nuchal translucency scan) and an analysis of maternal serum levels of  $\alpha$ -fetoprotein (MSAFP), pregnancy-associated plasma protein A (PAPP-A), and free beta hCG to evaluate for chromosomal disorders in the fetus. (**Chromosomes** are threadlike structures of nucleic acids and protein found in the nucleus of most living cells, carrying genetic information in the form of genes.) Additionally, women over the age of 35 years may be offered a more accurate noninvasive blood test, circulating cell-free DNA (cfDNA) testing, to screen for chromosomal disorders. Chorionic villi sampling (CVS) and amniocentesis are both techniques that may be offered to women who are older than 35 years of age, or to those whose genetic testing is abnormal, to diagnose chromosomal genetic disorders.

The CVS and amniocentesis are diagnostic tests that assess the **karyotype** (a graphic representation of the chromosomes present)—when fetal chromosomes are photographed and displayed, which can provide a definite answer about the presence or absence of chromosomal disorders. Couples who already know of the existence of a genetic disorder in their family or those who have had a previous child born with a congenital anomaly can opt for cfDNA testing, CVS, or amniocentesis, independent of their age, for more accurate screening and diagnosis of chromosomal disorders. Nurses serve as members of genetic assessment and counseling teams to help obtain the initial family history, assist with the physical examination, obtain blood serum for analysis, and assist with procedures such as amniocentesis as part of this process.

The decision to undergo either CVS or amniocentesis is a major one for a couple because, as a rule, they are not making a decision simply for CVS or amniocentesis; if the analysis from these reveals their child has a disorder, they then have to make a second decision about the future of the pregnancy.

Deciding to terminate a pregnancy based on a laboratory finding is rarely easy. If a couple decides to terminate the pregnancy, they need support for their decision to end the pregnancy. If they decide not to terminate the pregnancy, they may need support during the remainder of the pregnancy and in the days following birth. If a couple could not believe what the test showed was true, only when they inspect the baby and see the test was accurate—the child does have a genetic disorder—do they grasp the reality of what has happened. This can result in long-lasting depression, guilt, or grief for the perfect child they had hoped for at the beginning of the pregnancy.

## **NURSING DIAGNOSIS**

Typical nursing diagnoses related to the area of genetic disorders include:

- Decisional conflict related to continuation of genetic-affected pregnancy
- Fear related to outcome of genetic screening tests
- Situational low self-esteem related to identified chromosomal disorder
- Deficient knowledge related to inheritance pattern of the family's inherited disorder
- Readiness for enhanced knowledge related to potential for genetic transmission of disease
- Altered sexuality pattern related to fear of conceiving a child with a genetic disorder

## **OUTCOME IDENTIFICATION AND PLANNING**

Outcome identification and planning for families undergoing a genetic assessment differ according to the types of assessments performed and the results obtained. This may include determining what information the couple needs to know before testing can proceed or helping couples arrange for further assessment measures. When counseling such families, it is helpful to guide them to concentrate on short-term goals and actions or to help them look first at the immediate needs of their family, the fetus, and the newborn and later on at what type of continued follow-up will be

necessary. For instance, after the birth, will the baby need to be hospitalized for immediate surgical correction of accompanying congenital anomalies, or will the parents be able to take the baby home? The kind of special schooling the child will need is a decision that can wait until later.

Help identify healthcare personnel with whom the parents will need to maintain contact during the next few months such as a surgeon or an orthopedist. Ensuring the parents have healthcare providers they know they can turn to, especially when they are moving out of the denial stage, helps them move forward to their next step in accepting their child's diagnosis faster.

It is also helpful to identify support people who can assist the parents during their time of disorganization. Support people may include the usual family resources, such as grandparents or other family members. In some families, however, these people are as disturbed by the diagnosis as the parents and therefore cannot offer their usual support. Refer parents to helpful websites and other resources when appropriate.

### **IMPLEMENTATION**

Parental reactions to the knowledge their child has a possible genetic disorder or to the birth of a child with a genetically inherited disorder usually involves a grief reaction, similar to that experienced by parents whose child has died at birth (their "perfect" child is gone). Both parents may pass through stages of shock and denial ("This cannot be true"), anger ("It's not fair this happened to us"), and bargaining ("If only this would go away") before they reach reorganization and acceptance ("It has happened to us and it is all right"). For some couples, a genetic disorder is diagnosed during the pregnancy; for others, it may not be discovered until birth or possibly not even until the child is of school age. For these parents, these reactions will occur at that later point of diagnosis. Support couples in whatever stage they have reached when you care for them and help them work through and adjust to their child's diagnosis.

### **OUTCOME EVALUATION**

Examples of expected outcomes for a family with a known genetic disorder include:

- Couple states they feel capable of coping no matter what the outcome of genetic testing.
- Patient accurately states the chances of a genetic disorder occurring in her next child.
- Couple states they have resolved their feelings of low self-esteem related to birth of a child with a genetic disorder.

A couple's decisions about genetic testing and childbearing do not necessarily remain constant. For example, a decision made at age 25 years not to have children because of a potential genetic disorder may be difficult to maintain at age 30 years because the couple sees many of their friends with growing families. Be certain such couples have the contact information of a genetic counselor. Urge them to call periodically for news of recent advances in genetic screening techniques or disease

therapy so they can remain current and well informed for future planning.

## Genetic Disorders

Inherited or genetic disorders are disorders that can be passed from one generation to the next because they result from some disorder in the gene or chromosome structure. Genetic disorders occur in some ethnic groups more than others because people tend to marry within their own cultural group (Box 8.2). In addition, concern is increasing that some genetic disorders may occur due to occupational hazards, such as toxic substances in the environment of workplaces (Kiku, Voronin, & Golokvhast, 2015).

### BOX 8.2

#### Nursing Care Planning to Respect Cultural Diversity

Different ancestry backgrounds cause different genetic disorders to be more common in some ethnic groups than in others. The blood disorder  $\beta$ -thalassemia, for example, occurs most frequently in families of Greek or Mediterranean heritage, whereas  $\alpha$ -thalassemia occurs most often in persons from the Philippines or Southeast Asia. Sickle-cell anemia occurs most often in people with an African ancestry. Tay-Sachs disease, a deterioration of muscle and mental facilities, occurs most often in people of eastern Jewish ancestry.

It is important that families who are at high risk for particular genetic disorders such as these be informed of the incidence of these disorders among those of their ethnic heritage and offered genetic screening as appropriate during preconception counseling.

Genetic disorders occur at the moment an ovum and sperm fuse or even earlier, in the meiotic division phase of the ovum or sperm when the chromosome count is halved from 46 to 23. Some genetic disorders are so severe that fetal growth cannot continue past that point. This early cell division is so precarious, in fact, that up to 50% of first trimester spontaneous miscarriages may occur as the result of chromosomal disorders (McNair & Altman, 2015). Other genetic disorders do not affect life in utero, so the result of the disorder only becomes apparent at the time of fetal testing or after birth. **Cytogenetics** is the study of chromosomes by light microscopy and the method by which chromosomal aberrations are identified.

Women having in vitro fertilization (IVF) can have both the egg and sperm examined for genetic disorders of single-gene or chromosome concerns before implantation. With ongoing stem cell research, it may be possible not only to identify aberrant genes for disorders this way but also to insert healthy genes in their place using stem cell implantation (Daughtry & Chavez, 2016). Gene replacement therapy is encouraging in the treatment of blood, neural tube, eye, and congenital metabolic

disorders as well as for cancers and immunodeficiency syndromes (Kumar, Dunn, & Carcao, 2016; Wang, Liu, Xiang, et al., 2015).

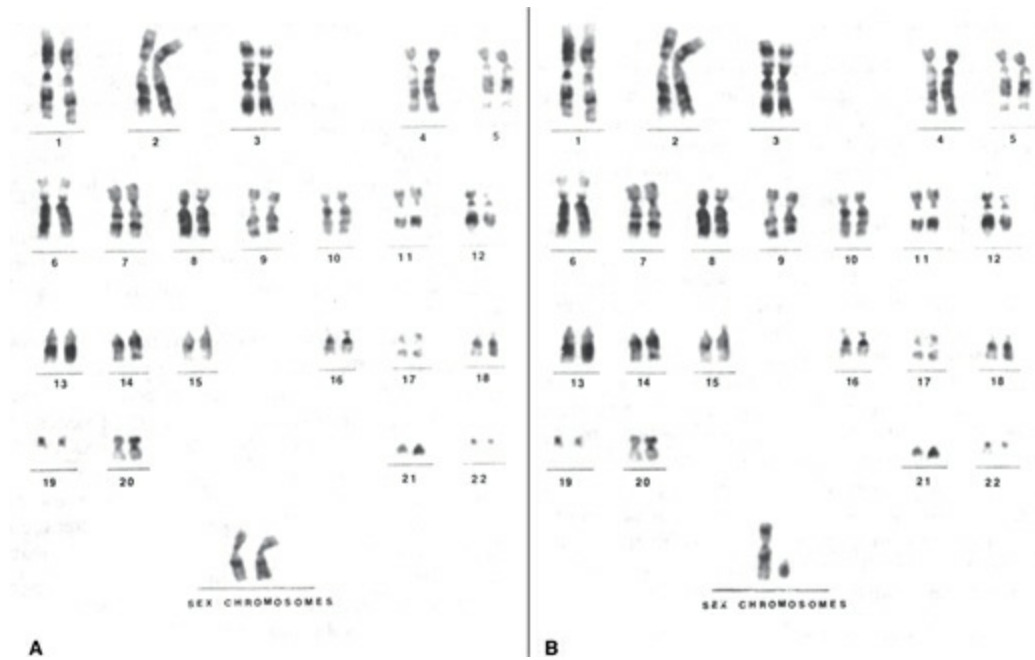

Stem cells can be obtained from bone marrow (adult cells), embryos, or umbilical cord blood (embryonic stem cells). After giving birth, some women today privately bank or donate a sample of cord blood to a public stem cell bank so stem cells can be available for bone marrow or other cell transplantation procedures if someone in their community needs them. A second large source of adult stem cells for replacement therapy is menstrual blood; this also may be a contribution women can make toward stem cell research (Du, Yuan, Qu, et al., 2016).

Neither the American Congress of Obstetricians and Gynecologists (ACOG) nor the American Academy of Pediatrics (AAP) recommends private cord blood banking unless the family has a relative with a disorder known to be treatable by a stem cell transplant because banking is costly and the length of viability of stem cells is unknown, so an infant's own stem cells might not be available if the child should develop a disease in the future (Armitage, 2016).

## NATURE OF INHERITANCE

**Genes** are the basic units of heredity that determine both the physical and cognitive characteristics of people. Composed of segments of DNA, they are woven into strands in the nucleus of all body cells to form chromosomes.

In humans, each cell, with the exception of the sperm and ovum, contains 46 chromosomes (44 autosomes and 2 sex chromosomes). Spermatozoa and ova each carry only half of the chromosome number (23 chromosomes). For each chromosome in a sperm cell, there is a like chromosome of similar size, shape, and function in the ovum. Because genes are always located at fixed positions on chromosomes, there are two like genes (**alleles**) on autosomes for every trait in the ovum and sperm. The one chromosome that does not have a mirror match is the chromosome for determining sex. If in the zygote formed from the union of a sperm and ovum, the sex chromosomes are both type X (large symmetric), the individual is genetically female (Fig. 8.1A). If one sex chromosome is an X and one a Y (a smaller type), the individual is genetically male (Fig. 8.1B).

**Figure 8.1** Photomicrographs of human chromosomes karyotypes. **(A)** A normal female karyotype. **(B)** A normal male karyotype.

A person's **phenotype** refers to his or her outward appearance or the expression of genes. A person's **genotype** refers to his or her actual gene composition. It is impossible to predict a person's genotype from the phenotype, or outward appearance.

A person's **genome** is the complete set of genes present (about 50,000 to 100,000). A normal genome is abbreviated as 46XX or 46XY (the designation of the total number of chromosomes plus a graphic description of the sex chromosomes present). If a chromosomal aberration exists, it is listed after the sex chromosome pattern. In such abbreviations, the letter *p* stands for short arm disorders and *q* stands for long arm disorders. For example, the abbreviation 46XX5p— is the abbreviation for a female with 46 total chromosomes but with the short arm of chromosome 5 missing (cri-du-chat syndrome). In Down syndrome, the person has an extra chromosome 21, so this is abbreviated as 47XX21+ or 47XY21+(Fig. 8.2).

**Figure 8.2** Karyotype of trisomy 21. (Courtesy of Dr. Kathleen Rao, Dept. of Ped., UNC.)

## MENDELIAN INHERITANCE: DOMINANT AND RECESSIVE PATTERNS

The principles of genetic inheritance of disease are the same as those that govern genetic inheritance of other physical characteristics, such as eye or hair color. These principles were discovered and described by Gregor Mendel, an Austrian naturalist, in the 1800s and are known as Mendelian laws.

A person who has two like genes for a trait—two healthy genes, for example (one from the mother and one from the father)—is said to be **homozygous** for that trait. If the genes differ (a healthy gene from the mother and an unhealthy gene from the father, or vice versa), the person is said to be **heterozygous** for that trait. Many genes are dominant in their action over others. When dominant genes are paired with nondominant (recessive) ones, the dominant genes are always expressed in preference to the recessive genes (a gene for brown eyes, for example, is dominant over one for blue eyes; a child born with a gene for brown eyes and a recessive one for blue eyes will have brown eyes). An individual with two homozygous genes for a dominant trait is said to be *homozygous dominant*; an individual with two genes for a recessive trait is said to be *homozygous recessive*.

### QSEN Checkpoint Question 8.1

#### QUALITY IMPROVEMENT

Amy Alvarez, 26 years of age, is pregnant with her first child and is experiencing significant stress following her recent diagnostic findings. The nurse would be providing high-quality care if completing which of the following?

- a. Provided Amy with hope and downplaying the potential for negative outcomes
- b. Referred Amy to websites and journals in the field of genetics
- c. Described the most serious consequences of genetic disorders
- d. Described genetics in a way that directly meets her learning needs

---

*Look in [Appendix A](#) for the best answer and rationale.*

---

## Genetic Counseling and Testing

It is advantageous for an individual concerned with the possibility of transmitting a disease to his or her children to ask for genetic counseling at a preconception health visit for advice on the inheritance of disease because counseling can serve to:

- Provide concrete, accurate information about the process of inheritance and inherited disorders
- Reassure people who are concerned their child may inherit a particular disorder that the disorder will not occur
- Allow people who are affected by inherited disorders to make informed choices about future reproduction
- Allow people to pursue potential interventions that may exist such as fetal surgery
- Allow families to begin preparation for a child with special needs

Genetic counseling can result in making individuals feel “well” or free of guilt for the first time in their lives if they discover a disorder they were worried about is not an inherited one but rather occurred by chance.

In other instances, counseling can result in informing individuals they are carriers of a trait responsible for a child’s condition. Even when people understand they had no control over this, knowledge about passing a genetic disorder to a child can cause guilt and self-blame. Marriages and relationships can end unless both partners receive adequate support.

It is essential that information revealed in genetic screening be kept confidential because such information could be used to damage a person’s reputation or harm a future career or relationship. This necessity to maintain confidentiality prevents healthcare providers from alerting other family members about the inherited characteristic unless the member requesting genetic assessment has given consent for the information to be revealed. In some instances, a genetic history reveals information that a family doesn’t want the other members to know, such as that a child has been adopted, is the result of alternative insemination, or that the current husband is not the child’s father. The member of the family seeking counseling has the right to decide whether this information may be shared with other family members.

Keeping information secure is assured by the Genetic Information Nondiscrimination Act of 2008, which bars employers from using individuals’ genetic

information when making hiring, firing, job placement, or promotion decisions (Soo-Jin Lee & Borgelt, 2014). The act also prohibits group health plans and health insurers from denying coverage to a healthy individual or charging that person higher premiums based solely on a genetic predisposition to developing a disease in the future.

The ideal time for discussing whether the possibility of a genetic disorder exists is before a first pregnancy at a preconception health visit (Fletcher & Russo, 2015). Some couples take this step even before committing themselves to marriage, so they can offer not to involve their partner in a marriage if children of the marriage would be subject to a serious inherited disorder. Other couples first become aware of the need for genetic counseling after the birth of a first child with a disorder or fetal genetics testing (like first trimester screening, cfDNA, CVS, or amniocentesis) reveals that a chromosomal disorder may exist.

If a couple did not receive counseling before a first pregnancy, it is best if they receive it before a second pregnancy. A couple may not be ready for this, however, until the initial shock of their first child's condition and the grief reaction that may accompany it have run their course. Only then are they ready for information and decision making (Box 8.3).

### BOX 8.3

#### Nursing Care Planning Based on Family Teaching

##### GENETIC SCREENING

**Q.** Amy Alvarez is anxious to have her fetus's health confirmed. She asks you, "Why do I have to wait so late in pregnancy for genetic studies by amniocentesis?"

**A.** A genetic analysis is done on skin cells obtained from amniotic fluid. The test cannot be scheduled until enough amniotic fluid is present for analysis, which is about the 15th week of pregnancy. Fortunately, it is possible to do an analysis of fetal red cells circulating in maternal blood very early (at about 10 weeks) in pregnancy.

**Q.** Why do laboratories take so long to return karyotyping results?

**A.** Karyotyping has traditionally (and by necessity) been done on cells at the metaphase (center phase) of division, so the laboratory had to delay testing until the cells had grown to reach this phase. New techniques now allow an analysis to be done immediately so results are available much sooner.

**Q.** If there are no inherited diseases in a couple's family, should the couple have a karyotype done "just to be sure" before they have their first baby?

**A.** A genetic analysis is not routinely recommended unless there is evidence or suspicion of genetic disease in the family. Remember, karyotyping reveals only diseases present on chromosomes. A "perfect" karyotype, therefore, doesn't guarantee a newborn will not be ill in a noninherited way.

Even if a couple decides not to have more children, be certain they know genetic counseling is available for them should their decision change. Also be certain they are aware that as their children reach reproductive age, they too may benefit from genetic counseling. Couples who are most apt to benefit from a referral for genetic testing or counseling include:

- *A couple who has a child with a congenital disorder or an inborn error of metabolism.* Many congenital disorders occur because of teratogenic invasion during pregnancy that has gone unrecognized. Learning the disorder occurred by a chance occurrence rather than inheritance is important because the couple will not have to spend the remainder of their childbearing years concerned another child may be born with the disorder (although a chance circumstance could occur again). If a definite teratogenic agent, such as a drug a woman took during pregnancy, can be identified, the couple can be advised about preventing this occurrence in a future pregnancy.
- *A couple whose close relatives have a child with a genetic disorder such as a chromosomal disorder or an inborn error of metabolism.* It is difficult to predict the expected occurrence of many “familial” or multifactorial disorders because they may involve more than one abnormal gene. In these instances, counseling should include educating the couple about the disorder, treatment available, and the prognosis or outcome of the disorder. Based on this information, the couple can make an informed reproductive choice about children.
- *Any individual who is a known carrier of a chromosomal disorder.* Understanding his or her own chromosome structure and the process by which future children could be affected can help such individuals make an informed choice about reproduction and also alert the person to the importance of fetal karyotyping during any future pregnancy. [Box 8.4](#) shows an interprofessional care map illustrating both nursing and team planning for a woman concerned about genetic disorders.

#### BOX 8.4

#### Nursing Care Planning

### AN INTERPROFESSIONAL CARE MAP FOR A COUPLE CONCERNED ABOUT GENETIC DISORDERS IN FUTURE CHILDREN

Amy Alvarez is a woman you meet at a genetic counseling center. She was adopted as a newborn and never felt a need to locate her birth parents because her adoptive parents provided a “close-to-perfect” childhood for her. After college, she married the most eligible bachelor in her hometown. She is now pregnant with her first child. At 15 weeks into her pregnancy, she has been advised that her child may have translocation Down syndrome. She asks you, “Why is this happening? There’s no disease like this in either of our families.”

**Family Assessment:** Patient’s family history is unknown because she was adopted.

Husband's family has no history of Down syndrome but does have two cousins who are cognitively challenged. Patient is presently attending law school. Husband works as a county public defender. Family lives in condo by lake front. Finances rated as "good."

**Patient Assessment:** Patient's and husband's past medical histories show no evidence of major health problems. Pregnancy is at 15 weeks. Maternal serum  $\alpha$ -fetoprotein showed decreased level.

**Nursing Diagnosis:** Readiness for enhanced knowledge related to possible genetic disorder inheritance.

**Outcome Criteria:** Couple accurately states the cause of this genetic disorder and agrees to further genetic testing to confirm fetal diagnosis and describes range of options open to them so any decision they make regarding the pregnancy is an informed one.

Team Member Responsible	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse/nurse practitioner	Obtain a detailed history of the patient and spouse, including information about family members and other relatives.	Perform a physical examination to document current health.	A thorough history and physical examination provide baseline information to direct need for follow-up.	Couple participates fully in health examination, so family history obtained is as complete as possible.
<i>Teamwork and Collaboration</i>				
Nurse/genetic counselor	Assess whether couple would like to speak to an expert in the field of genetics to clarify their understanding.	Refer patient to genetic counselor so they can be aware of exact inheritance pattern and options available.	Couples cannot make informed choices without being aware of extent of problem.	Couple meets with genetic counselor within 1 week.
<i>Procedures/Medications for Quality Improvement</i>				
Nurse/primary healthcare provider	Perform genetic testing. Develop a family	Be certain couple receives written	A family genogram may provide	Couple receives results of test in a timely and

	genogram for patient and spouse.	documentation of chromosome disorder to take to genetic counselor.	additional information about the patient's and spouse's family histories.	appropriate manner. A family genogram is developed and maintained with electronic health documentation.
--	----------------------------------	--	---	---

---

*Nutrition*

---

Nurse/dietitian	Assess the couple's nutrition patterns.	Analyze whether couple maintains healthy diet during testing and consultation period.	A healthy diet during pregnancy is important if pregnancy will be continued.	Patient confirms she continues to take prenatal vitamins and adequate protein intake.
-----------------	---	---	--	---

---

*Patient-Centered Care*

---

Nurse/nurse practitioner	Ask couple if they have further questions about their particular inheritance pattern.	Review with the couple the mode of transmission and chances for manifesting Down syndrome in children.	Down syndrome may be inherited at a higher incidence in a balanced translocation carrier than in others.	Couple accurately describes the mode of transmission of Down syndrome.
--------------------------	---	--	--	--

---

*Spiritual/Psychosocial/Emotional Needs*

---

Nurse	Assess whether couple would be interested in contacting the hospital's religious counselor for support or learning activities to reduce stress.	If requested, instruct the couple in positive coping mechanisms. Include activities such as information sharing, relaxation and breathing exercises, and physical activity.	Positive coping mechanisms assist in controlling fear and minimizing its intensity, thus promoting effective problem solving.	Couple demonstrates positive coping mechanisms. Couple states the emotional support they received throughout their period of genetic screening and counseling was adequate.
-------	---	---	---	---

## *Informatics for Seamless Healthcare Planning*

Nurse/social worker	Assess community for support organizations available.	If the couple chooses to continue the pregnancy, refer them to national support group (e.g., Down Syndrome Foundation) and local parents support group.	Additional counseling and support may be necessary as pregnancy progresses. Community resources can help reduce feelings of isolation and loneliness.	Couple records the names and telephone numbers of support groups as well as the genetic counseling team and states they will keep numbers available if they should need further information.
---------------------	---	---	---	--

- *Any individual who has an inborn error of metabolism or chromosomal disorder.* Any person with a disease should know the inheritance pattern of the disease and should be aware if prenatal diagnosis is possible for his or her particular disorder.
- *A consanguineous (closely related) couple.* The more closely related two people are, the more genes they have in common, so the more likely it is that a recessively inherited disease will be expressed. A brother and sister, for example, have about 50% of their genes in common; first cousins have about 12% of their genes in common.
- *Any woman older than 35 years of age and any man older than 55 years of age.* This is directly related to the association between advanced parental age and the occurrence of Down syndrome.
- *Couples of ethnic backgrounds in which specific illnesses are known to occur.* Mediterranean people, for example, have a high incidence of thalassemia, a blood disorder; those with a Chinese ancestry have a high incidence of glucose-6-phosphate dehydrogenase (G6PD) deficiency, a blood disorder where destruction of red cells can occur ([Panepinto, Punzalan, & Scott, 2015](#)).

## **NURSING RESPONSIBILITIES**

Nurses play important roles in assessing for signs and symptoms of genetic disorders, in offering support to individuals who seek genetic counseling, and in helping with reproductive genetic testing procedures.

A great deal of time may need to be spent offering support for a grieving couple confronted with the reality of how tragically the laws of inheritance have affected their lives. Direct counseling is a role for nurses only if they are adequately prepared in the

study of genetics, however, because without this background, genetic counseling can be dangerous and destructive (Box 8.5).

## BOX 8.5

### Nursing Care Planning Tips for Effective Communication

Amy Alvarez tells you her mother has advised her not to have any more children rather than risk having another child with Down syndrome.

*Tip:* Reassure the patient while explaining the need for enough time to obtain accurate information. Because we live in an age in which information can be obtained quickly, people tend to believe predictions about the inheritance of disorders can also be supplied quickly. Because Amy is a balanced translocation carrier, more aspects than her age must be considered when predicting her chance for having children with Down syndrome.

**Nurse:** Hello, Amy. What's the reason you've come to the clinic today?

**Amy:** I need to know what is the chance all my children will have Down syndrome.

**Nurse:** That isn't the kind of question I can answer off the top of my head. Let me ask you some questions about your family to get started and then we can talk to a genetic counselor to get your answer.

Whether one is acting as the nurse member of a genetic counseling team or as a genetic counselor, some common principles apply.

- The individual or couple being counseled needs a clear understanding of the information provided. People may listen to the statistics of their situation ("Your child has a 25% chance of having this disease") and construe a "25% chance" to mean if they have one child with the disease, they can then have three other children without any worry. A 25% chance, however, means *with each pregnancy*, there is a 25% chance the child will have the disease (chance has no "memory" of what has already happened). It is as if the couple had four cards, all aces, with the ace of spades representing the disease. When a card is drawn from the set of four, the chance of it being the ace of spades is one in four (25%). When the couple is ready to have a second child, it is as if the card drawn during the first round is returned to the set, so the chance of drawing the ace of spades in the second draw is exactly the same as in the first draw. Similarly, the couple's chance of having a child with the disease remains one in four in each successive pregnancy.
- It is never appropriate for a healthcare provider to impose his or her own values or opinions on others. Individuals with known inherited diseases in their family must face difficult decisions, such as how much genetic testing to undergo or whether to terminate a pregnancy that will result in a child with a specific genetic disease. Be certain couples have been told all the options available to them and

then leave them to think about the options and make their decision by themselves. Help them to understand that no one is judging their decision because they are the ones who must live with the decision in the years to come.

### ***QSEN Checkpoint Question 8.2***

#### **EVIDENCE-BASED PRACTICE**

If it is predicted during a pregnancy that a couple will have a child with Down syndrome, the couple is asked to make a choice whether they want to continue the pregnancy or terminate it at that point. To discover how couples feel about having a child with Down syndrome, researchers surveyed 2,044 parents on the mailing lists of six nonprofit Down syndrome organizations. The majority of parents reported they are happy with their decision to have their child and find their sons and daughters great sources of love and pride. Ninety-nine percent reported they love their affected son or daughter, 97% reported being proud of them, 79% felt their outlook on life was more positive because of them, only 5% felt embarrassed by them, and only 4% regretted having them. In a following study, siblings also reported their relationship with their affected sibling as a positive one. Less than 10% felt embarrassed, and less than 5% expressed a desire to trade their sibling in for another brother or sister (Skotko, Levine, & Goldstein, 2011a, 2011b).

Based on the findings of the previous studies, how would the nurse answer Mrs. Alvarez's question, "Can you imagine how this will change my life?"

- a. "You're right. Having a genetically affected child can potentially be a serious burden."
- b. "Don't worry so much about what others think; just concentrate on your own life."
- c. "Change can create good things in life; I believe as a door closes, a window opens."
- d. "Would it help if you talk to a family who has a child with Down syndrome?"

*Look in Appendix A for the best answer and rationale.*

## **THE ASSESSMENT FOR GENETIC DISORDERS**

A genetic assessment begins with careful study of the pattern of inheritance in a family. A history, physical examination of family members, and laboratory analysis, such as karyotyping or DNA analysis, are performed to define the extent of the problem and the chance of inheritance. Parents can obtain a DNA analysis from a profit-making private laboratory (direct-to-consumer marketing), but this is rarely advised because genetic results usually need to be accompanied by counseling to be certain parents understand the often-complicated result narrative.

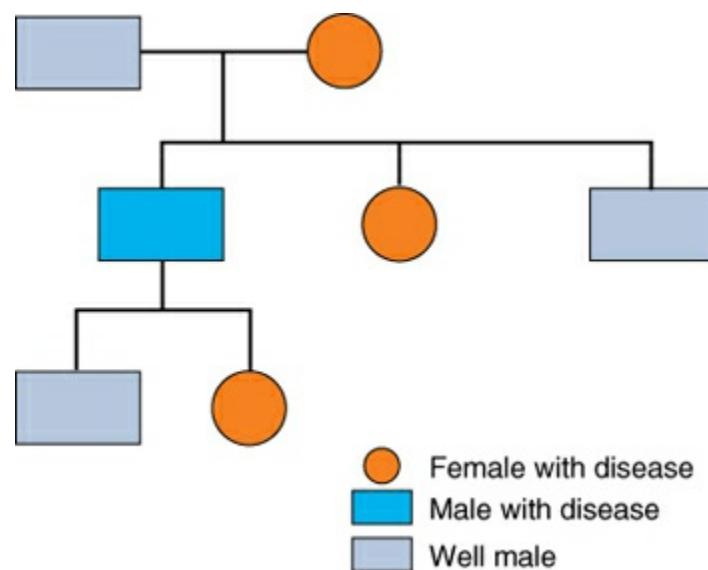

### **History**

Taking a health history for a genetic diagnosis can be difficult because the facts detailed may evoke uncomfortable emotions such as sorrow, guilt, or inadequacy in parents. Try, however, to obtain information and document diseases in family members for a minimum of three generations because a history can be a chief tool in discovering transmitted disorders (Edelman, Lin, Doksum, et al., 2014). Remember to include half brothers and sisters or anyone related in any way as family. Document the mother's age because some disorders increase in incidence with age. Document also whether the parents are consanguineous or related to each other.

Documenting the family's ethnic background can reveal risks for certain disorders that occur more commonly in some ethnic groups than others. If the couple seeking counseling is unfamiliar with their family history, ask them to talk to senior family members about other relatives (grandparents, aunts, uncles) before they come for an interview about such instances as spontaneous miscarriage or children in the family who died at birth. In many instances, these children died of unknown chromosomal disorders or were miscarried because of 1 of the 70 or more known chromosomal disorders inconsistent with life.

Many people have only sketchy information about their families, such as "The baby had some kind of nervous disease" or "Her heart didn't work right." Attempt to obtain as much information as you can by asking the couple to describe the appearance or activities of the affected individual ("She had no left side to her heart") or asking for permission to obtain health records.

An extensive prenatal history of any affected person should be obtained to determine whether environmental conditions could account for the condition. Based on the previous information, draw a family genogram (Fig. 8.3). Such a diagram helps to not only identify the possibility of a chromosomal disorder occurring in a particular couple's children but also identify other family members who might benefit from genetic counseling.

**Figure 8.3** Family genogram: X-linked dominant inheritance.

When a child is born dead, parents are advised to have a chromosomal analysis and autopsy performed on the infant. If, at some future date, they wish genetic counseling, this would allow their genetic counselor to have additional medical information.

### Physical Assessment

Because genetic disorders often occur in varying degrees of expression, a careful physical assessment of any family member with a disorder, that person’s siblings, and the couple seeking counseling is necessary because it is possible that another family member has such a minimal expression of the disorder, it has gone previously undiagnosed. During inspection, pay particular attention to certain body areas, such as the space between the eyes; the height, contour, and shape of ears; the number of fingers and toes; and the presence of webbing because these often suggest structural genetic disorders. **Dermatoglyphics** (the study of surface markings of the skin) is also helpful because unusual fingerprints, abnormal palmar creases, hair whorls, or coloring of hair are also present with some disorders.

Careful inspection of newborns is often the first time a child with a potential chromosomal disorder is identified. Infants with multiple congenital anomalies, those born at less than 35 weeks gestation, and those whose parents have had other children with chromosomal disorders need extremely close assessment. [Table 8.1](#) lists the physical characteristics suggestive of some common inherited syndromes in children.

**TABLE 8.1 COMMON PHYSICAL CHARACTERISTICS OF CHILDREN WITH CHROMOSOMAL SYNDROMES**

Characteristic	Probable Syndrome
Late closure of fontanelles	Down syndrome
Bossing (prominent forehead)	Fragile X syndrome
Microcephaly (small head)	Trisomy 18, trisomy 13
Low-set ears	Trisomy 18, trisomy 13
Slant of eyes	Down syndrome
Epicanthal fold	Down syndrome
Abnormal iris color	Down syndrome
Large tongue	Down syndrome
Prominent jaw	Fragile X syndrome
Low-set hairline	Turner syndrome
Multiple hair whorls	Trisomy 18, trisomy 13
Webbed neck	Turner syndrome
Wide-set nipples	Trisomy 13
Heart disorders	Many syndromes

Large hands	Fragile X syndrome
Clinodactyly (curved little finger)	Down syndrome
Overriding of fingers	Trisomy 18
Rocker-bottom feet	Trisomy 18
Abnormal dermatoglyphics (fingerprints)	Down syndrome
Simian crease on palm	Down syndrome
Absence of secondary sex characteristics	Klinefelter syndrome, Turner syndrome

## Screening and Diagnostic Testing

Many screening and diagnostic tests are available to provide clues or to diagnose disorders. Before pregnancy, DNA analysis or karyotyping of both parents and an already affected child provides a picture of the family’s genetic pattern and can be used for prediction in future children. Once a woman is pregnant, several other tests may be performed to help in the prenatal diagnosis of a genetic disorder. These include first trimester nuchal translucency and hormonal screening, cfDNA testing, quadruple test analysis, CVS, amniocentesis, percutaneous umbilical blood sampling (PUBS), and sonography. All of these tests not only reveal important information but also create ethical and personal concerns for parents because, if an abnormality is discovered, parents are asked to make a decision whether to continue the pregnancy (Hume & Chasen, 2015). Table 8.2 highlights these screening techniques and diagnostic tests.

**TABLE 8.2 GENETIC DISORDER SCREENING AND DIAGNOSTIC TESTS**

Test Type	Timing	Process	Risks	Results
Preimplantation diagnosis	Day 3 or day 5 embryo	Cell sample obtained from day 3 or day 5 embryo prior to implantation in mother during in vitro fertilization process	Invasive to embryo, risk of destruction of embryo	Only 9–11 of chromosomes can be evaluated from sample.
Nuchal translucency	11–14 weeks	Ultrasound to assess thickness at fetus’s neck, maternal blood draw	Noninvasive, ultrasound and maternal blood draw	Screening test for Down syndrome, trisomy 18 and 13
cfDNA	11+ weeks, can be done as	Maternal blood draw, fetal cell fragments in	Noninvasive, maternal blood draw	Screening test for abnormal amounts of

	early as 7 weeks	maternal blood are assessed		chromosomes and microdeletions in fetal DNA
Chorionic villi sampling	10–12 weeks	Biopsy of placenta (Fig. 8.4)	Invasive, risk of miscarriage	Diagnostic test for karyotype (Fig. 8.1)
Maternal quadruple marker screen	15–20 weeks	Maternal blood draw	Noninvasive, maternal blood draw	Screening test for Down syndrome, trisomy 18 and 13
Amniocentesis	15–18 weeks	Collection of amniotic fluid containing fetal skin cells through maternal abdomen	Invasive, risk of miscarriage	Diagnostic for fetal karyotype; Table 8.3 shows common chromosomal disorders that can be diagnosed through amniocentesis.
Percutaneous umbilical blood sampling	>17 weeks	Fetal umbilical blood sampling through maternal abdomen (Fig. 8.5)	Invasive, risk of miscarriage	Diagnostic for fetal karyotype and fetal blood diseases
Fetal anatomy ultrasound	18–22 weeks, ideal timing	Ultrasound of the fetal anatomy	Noninvasive, ultrasound	Screening test for visual fetal anomalies (cleft lip, etc.)
Fetoscopy	Second and third trimesters	Small camera and instruments passed into the amniotic sac to view and treat anomalies	Invasive, risk of miscarriage	Often used to treat disorders like twin-to-twin transfusion
Newborn	Day 2–	A blood sample via	Noninvasive,	Screening for

screening	several weeks after birth	heel prick or blood draw from newborn	blood draw from newborn	genetic disorders via serum DNA or other factors
-----------	---------------------------	---------------------------------------	-------------------------	--

cfDNA, cell-free DNA.

**Figure 8.4** Chorionic villi sampling. Because the villi arise from trophoblast cells, their chromosome structure is the same as in the fetus.

**Figure 8.5** Percutaneous umbilical blood sampling. Blood is withdrawn from the umbilical cord using an amniocentesis technique.

**TABLE 8.3** COMMON GENETIC DISORDERS THAT CAN BE DETECTED BY MATERNAL SERUM, AMNIOCENTESIS, OR CHORIONIC VILLUS SAMPLING

Syndrome	Chromosomal Characteristics	Clinical Signs in Child
Down syndrome	Extra chromosome 21	Cognitively challenged Protruding tongue Epicanthal folds Hypotonia
Translocation Down syndrome	Translocation of a chromosome, perhaps 21/14	Same clinical signs as trisomy 21
Trisomy 18	Extra chromosome 18	Cognitively challenged Congenital malformations
Trisomy 13	Extra chromosome 13	Cognitively challenged Multiple congenital

		malformations Eye agenesis
Cri-du-chat syndrome	Deletion of short arm of chromosome 5	Cognitively challenged Facial structure anomalies Peculiar catlike cry
Fragile X syndrome	Distortion of the X chromosome	Cognitively challenged
Philadelphia chromosome	Deletion of one arm of chromosome 21	Chronic granulocytic leukemia
Turner syndrome	Only one X chromosome present (45XO)	Short stature Streak ovaries Infertility Webbed neck
Klinefelter syndrome	An extra X chromosome present (47XXY)	Small testes Gynecomastia Subfertility

### *What If... 8.1*

**Amy tells the nurse, “My family will be so ashamed if a genetic defect happens in our family.” What does her statement tell the nurse about her family’s knowledge of genetic disorders?**

## REPRODUCTIVE ALTERNATIVES

Some couples are reluctant to seek genetic counseling because they are afraid they will be told it would be unwise to have children. Helping them to realize viable alternatives for having a family exist can allow them to seek the help they need.

Alternative insemination by donor (AID) is an option for couples if the genetic disorder is one inherited by the male partner or is a recessively inherited disorder carried by both partners. AID is available in all major communities and can permit the couple to experience the satisfaction and enjoyment of a usual pregnancy ([Duke & Christianson, 2015](#)).

If the inherited problem is one arising from the female partner, surrogate embryo transfer is an assisted reproductive technique that is a possibility ([Check, Wilson, Levine, et al., 2015](#)). For this, an oocyte is donated by a friend or relative or provided by an anonymous donor, which is then fertilized by the male partner’s sperm in the laboratory and implanted into a woman’s uterus. Like AID, donor embryo transfer offers the couple a chance to experience a usual pregnancy.

Use of a surrogate mother (a woman who agrees to be alternately inseminated, typically by the male partner’s sperm, and bear a child for the couple) is yet another possibility ([Dar, Lazer, Swanson, et al., 2015](#)). All of these procedures are expensive

and, depending on individual circumstances, may have disappointing success rates. Assisted reproductive techniques are discussed in more detail in [Chapter 7](#).

Adoption is an alternative many couples can also find rewarding (see [Chapter 3](#)). Lastly, choosing to remain child free should not be discounted as a viable option. Many couples who have every reason to think they will have healthy children choose this alternative because they believe their existence is full and rewarding without the presence of children.

Diagnosis of a disorder during pregnancy with prompt treatment at birth to minimize the prognosis and outcome of the disorder is another route to explore. Termination of a pregnancy that reveals a chromosomal or metabolic disorder is also an option.

Help couples decide on a solution that is correct for them, not one they sense you or a counselor feels would be best. They need to consider the ethical philosophy or beliefs of other family members when making their decision, although ultimately, they must do what they believe is best for them as a couple. A useful place to start counseling is with values clarification, to be certain a couple understands what is most important to them.

## **FUTURE POSSIBILITIES**

Stem cell research is looking at the possibility immature cells from a healthy embryo (stem cells) could be implanted into an embryo with a known abnormal genetic makeup, replacing the abnormal cells or righting the affected child's genetic composition ([Davidson, Mason, & Pera, 2015](#)). Although presently possible, stem cell research is costly and produces some ethical questions (e.g., Is it ethical to change the life course of a fetus who has no rights? Is it ethical to use embryo cells as a source of stem cells?).

## **LEGAL AND ETHICAL ASPECTS OF GENETIC SCREENING AND COUNSELING**

Nurses can be instrumental in making sure couples who seek genetic counseling receive results in a timely manner and with compassion about what the results may mean to future childbearing. Always keep in mind several legal responsibilities of genetic testing, counseling, and therapy including:

- Participation by couples or individuals in genetic screening must be elective.
- People desiring genetic screening must sign an informed consent for the procedure.
- Results must be interpreted correctly yet provided to the individuals as quickly as possible.
- The results must not be withheld from the individuals and must be given only to those persons directly involved.
- After genetic counseling, persons must not be coerced to undergo procedures such as abortion or sterilization. Any procedure must be a free and individual decision.

Failure to heed these guidelines could result in charges of invasion of privacy, breach of confidentiality, or psychological injury caused by “labeling” someone or imparting unwarranted fear and worry about the significance of a disease or carrier state. If couples are identified as being at risk for having a child with a genetic disorder and are not informed of the risk and offered an appropriate diagnostic procedure such as amniocentesis during a pregnancy, they can bring a “wrongful birth” lawsuit if their child is born with the unrevealed genetic disorder.

### *What If... 8.2*

**Amy Alvarez is pregnant with twins. One twin fetus is diagnosed as having Down syndrome and the other is not. How would the nurse counsel her if she wanted to abort the affected child when the procedure also might endanger the child without the disorder?**

## Unfolding Patient Stories: Amelia Sung • Part 1

**Amelia Sung** is 36 years old and 8 weeks pregnant with her second child. She tells the nurse that she is considering an amniocentesis due to her age. What information would the nurse include when providing education on an amniocentesis? (Amelia Sung’s story continues in [Chapter 20](#).)

Care for Amelia and other patients in a realistic virtual environment: *vSim for Nursing* ([thepoint.lww.com/vSimMaternityPed](http://thepoint.lww.com/vSimMaternityPed)). Practice documenting these patients’ care in DocuCare ([thepoint.lww.com/DocuCareEHR](http://thepoint.lww.com/DocuCareEHR)).

## Common Chromosomal Disorders Resulting in Physical or Cognitive Developmental Disorders

A number of chromosomal disorders are easily detected at birth on physical examination. Many of these disorders leave children cognitively challenged (discussed in [Chapter 54](#)).

### TRISOMY 13 SYNDROME (47XY13+ OR 47XX13+)

In trisomy 13 syndrome (Patau syndrome), the child has an extra chromosome 13 and is severely cognitively challenged. The incidence of the syndrome is low, approximately 0.45 per 1,000 live births. Midline body disorders such as cleft lip and palate, heart disorders (particularly ventricular septal defects), and abnormal genitalia are present. Other common findings include microcephaly with disorders of the forebrain and forehead, eyes that are smaller than usual (microphthalmos) or absent, and low-set ears

(Gezer, Ekin, Gezer, et al., 2015). Most of these children do not survive beyond early childhood (Fig. 8.6).

**Figure 8.6** An infant with trisomy 13 syndrome has **(A)** a cleft lip and palate and **(B)** supernumerary digits (polydactyly). (© NMSB/Custom Medical Stock Photograph.)

### **TRISOMY 18 SYNDROME (47XY18+ OR 47XX18+)**

Children with trisomy 18 syndrome (Edwards syndrome) have three copies of chromosome 18. The incidence is approximately 0.23 per 1,000 live births. These children are severely cognitively challenged and tend to be small for gestational age, have markedly low-set ears, a small jaw, congenital heart defects, and usually misshapen fingers and toes (the index finger deviates or crosses over other fingers). Also, the soles of their feet are often rounded instead of flat (rocker-bottom feet). As in trisomy 13 syndrome, most of these children do not survive beyond infancy (Karaman, Aydin, & Göksu, 2015).

### **CRI-DU-CHAT SYNDROME (46XX5P- OR 46XY5P-)**

Cri-du-chat syndrome is the result of a missing portion of chromosome 5. In addition to an abnormal cry, which sounds much more like the sound of a cat than a human infant's cry, children with cri-du-chat syndrome tend to have a small head, wide-set eyes, a downward slant to the palpebral fissure of the eye, and a recessed mandible. They are severely cognitively challenged (Levy & Marion, 2015).

## TURNER SYNDROME (45X0)

The child with Turner syndrome (gonadal dysgenesis) has only one functional X chromosome. The child is short in stature and has only streak (small and nonfunctional) ovaries. She is sterile and, with the exception of pubic hair, secondary sex characteristics do not develop at puberty. The hairline at the nape of the neck is low set, and the neck may appear to be webbed and short (Fig. 8.7). A newborn may have appreciable edema of the hands and feet and a number of congenital anomalies, most frequently coarctation (stricture) of the aorta as well as kidney disorders. The incidence of the syndrome is approximately 1 per 10,000 live births. The disorder can be identified on a sonogram during pregnancy (a nuchal translucency scan) because of the extra skin at the sides of the neck (Levy & Marion, 2015).

**Figure 8.7** A 3-year-old with Turner syndrome. Note the wide neck folds.

Although children with Turner syndrome may be severely cognitively challenged, difficulty in this area is more commonly limited to learning disabilities. Socioemotional adjustment problems may accompany the syndrome because of the lack of fertility and if the nuchal folds are prominent.

Human growth hormone administration can help children with Turner syndrome achieve additional height (Ranke, 2015). If treatment with estrogen is begun at approximately 13 years of age, secondary sex characteristics will appear, and osteoporosis from a lack of estrogen during growing years may be prevented. If females continue taking estrogen for 3 out of every 4 weeks, this produces withdrawal bleeding which results in a menstrual flow. This flow, however, does not correct the basic problem of sterility; ovarian tissue is scant and inadequate for ovulation because of the basic chromosomal aberration. A woman with Turner syndrome could, however, have IVF with surrogate oocyte transfer in order to become pregnant (Levitsky, Luria, Hayes, et al., 2015).

### **KLINEFELTER SYNDROME (47XXY)**

Children with Klinefelter syndrome are males with an extra X chromosome. Characteristics of the syndrome may not be noticeable at birth. At puberty, secondary sex characteristics do not develop; the child's testes remain small and produce ineffective sperm (Palma Sisto & Heneghan, 2015). Affected individuals tend to develop gynecomastia (increased breast size) and have an increased risk of male breast cancer. The incidence of the syndrome is about 1 per 1,000 live births. Karyotyping can be used to reveal the additional X chromosome.

### **FRAGILE X SYNDROME (46XY23Q-)**

Fragile X syndrome is the most common cause of cognitive challenge in males. It is an X-linked disorder in which one long arm of an X chromosome is defective, which results in inadequate protein synaptic responses (Contractor, Klyachko, & Portera-Cailliau, 2015). The incidence of the syndrome is about 1 in 4,000 males.

Before puberty, boys with fragile X syndrome may typically demonstrate maladaptive behaviors such as hyperactivity, aggression, or autism. They may have reduced intellectual functioning, with marked deficits in speech and arithmetic (Vekeman, Gauthier-Loiselle, Faust, et al., 2015). On physical exam, frequent findings identified are a large head, a long face with a high forehead, a prominent lower jaw, large protruding ears, and obesity. Hyperextensive joints and cardiac disorders may also be present. After puberty, enlarged testicles may become evident. Affected individuals are fertile and can reproduce.

Carrier females may show some evidence of the physical and cognitive characteristics. Although intellectual function from the syndrome cannot be improved, a combination of stimulants,  $\alpha$  agonists, atypical antipsychotics, and serotonin reuptake inhibitors may improve symptoms of poor concentration and impulsivity (Espinell, Charen, Huddleston, et al., 2015).

### **DOWN SYNDROME (TRISOMY 21) (47XY21+ OR 47XX21+)**

Trisomy 21, the most frequently occurring chromosomal disorder, occurs in about 1 in

800 pregnancies. In women who are older than 35 years of age, the incidence is as high as 1 in 100 live births (Levy & Marion, 2015).

The physical features of children with Down syndrome are so marked that fetal diagnosis is possible by sonography in utero. The nose is broad and flat. The eyelids have an extra fold of tissue at the inner canthus (an epicanthal fold), and the palpebral fissure (opening between the eyelids) tends to slant laterally upward. The iris of the eye may have white specks, called Brushfield spots. The tongue is apt to protrude from the mouth because the oral cavity is smaller than usual. The back of the head is flat, the neck is short, and an extra pad of fat at the base of the head causes the skin to be so loose it can be lifted easily and so thin it can be revealed on a fetal sonogram (Fig. 8.8A).

**Figure 8.8** (A) Typical facial features of a child with Down syndrome. (B) A simian line, a horizontal crease seen in children with Down syndrome. (© SPL/Custom Medical Stock Photograph.)

The ears may be low set. Muscle tone is poor, giving the newborn a rag doll appearance. This muscle tone can be so lax that the child's toe can be touched against the nose (not possible in the average mature newborn). The fingers of many children with Down syndrome are short and thick, and the little finger is often curved inward. There may be a wide space between the first and second toes and between the first and second fingers. The palm of the hand shows a peculiar crease (a simian line) or a single horizontal crease rather than the usual three creases in the palm (Fig. 8.8B).

Children with Down syndrome are usually cognitively challenged to some degree. The challenge can range from an IQ of 50 to 70 to a child who is profoundly affected (IQ less than 20). The extent of the cognitive challenge is not evident at birth, but the fact the brain is not developing well is usually evidenced by a head size smaller than the

10th or 20th percentile at well-child healthcare visits.

Internally, congenital heart disease, especially an atrioventricular defect, is common. Stenosis or atresia of the duodenum, strabismus, and cataract disorders may also be present. In addition, the child's immune function may be altered because as these children grow, they are prone to upper respiratory tract infections. Probably due to a second gene aberration, they tend to develop acute lymphocytic leukemia about 20 times more frequently than the general population (Israeli, 2015). Even if children are born without an accompanying disorder such as heart disease or don't develop leukemia, their life span usually is limited to only 50 to 60 years because aging seems to occur faster than usual.

It's important for children with Down syndrome to be enrolled in early educational and play programs so they can develop to their full capacity (see Chapter 54). Because they are prone to infections, sensible precautions such as using a good hand washing technique are important when caring for them. The enlarged tongue may interfere with swallowing and cause choking unless the child is fed slowly. Because their neck may not be fully stable, an X-ray to ensure stability is recommended before they engage in strenuous activities such as competitive sports or Special Olympics. As with all newborns, these infants need a physical examination at birth to enable the detection of the genetic disorder and the initiation of parental counseling, support, and future planning.

### **QSEN Checkpoint Question 8.3**

#### **TEAMWORK & COLLABORATION**

Amy Alvarez's child is born with Down syndrome. What is a common physical feature of newborns with this disorder that the nurse would want all of the team members to recognize?

- a. Spastic neck muscles
- b. An unusual pattern of palm creases
- c. A white lock of forehead hair
- d. Wrinkles on the soles of the feet

*Look in Appendix A for the best answer and rationale.*

## **CHILDHOOD TUMORS**

A number of cancers in children are also associated with chromosomal aberrations. Chief among these are retinoblastoma (chromosome 13), Wilms tumor (chromosome 11), and neuroblastoma (chromosome 1 or 11; Venkatesan, Natarajan, & Hande, 2015). Siblings of children with these cancers need to be tested to reveal if they carry the gene aberration as well and followed closely by a healthcare provider so early diagnosis and therapy can begin.

### *What If . . . 8.3*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals with respect to genetic disorders (see Box 8.1). What would be a possible research topic to explore pertinent to this goal that would be applicable to Amy’s family and that would also advance evidence-based practice?**

## **KEY POINTS FOR REVIEW**

- Genetic disorders are those resulting from a distortion in the structure or number of genes or chromosomes. Genetics, the study of gene variation, includes examining how and why such disorders occur.
- A phenotype is a person’s outward appearance. Genotype refers to the actual gene composition. A person’s genome is the complete set of genes present. A karyotype is a graphic representation of the chromosomes present.
- A person is homozygous for a trait if he or she has two like genes for the trait. A person is heterozygous if he or she has two unlike genes for the trait.
- Mendelian laws predict the likely incidence of recessive or dominant diseases.
- Genetic counseling can be a role for nurses with advanced preparation and education. An assessment of genetic disorders consists of a health history, physical examination, and screening and diagnostic studies such as first trimester screening, cfDNA testing, CVS, and amniocentesis.
- Some karyotyping tests, such as CVS and amniocentesis, introduce a risk of spontaneous or threatened miscarriage. Be certain women undergoing these tests remain in the healthcare facility for at least 30 minutes after these procedures to be certain vaginal bleeding, uterine cramping, or abnormal fetal heart rate is not present. Women with an Rh-negative blood type need Rh immune globulin administration after these procedures.
- An important aspect of genetic counseling is respecting a couple’s right to privacy. Be certain information gained from testing remains confidential and is not given indiscriminately to others, including other family members.
- Common genetic disorders include Down syndrome (trisomy 21), trisomy 13, trisomy 18, Turner syndrome (45XO), and Klinefelter syndrome (47XXY). Most of these syndromes include some degree of cognitive challenge.
- People who are told a genetic disorder does exist in their family may suffer a loss of self-esteem. Offering support to help them deal with the feelings they experience helps in planning nursing care that not only meets QSEN competencies but also best meets the family’s total needs.

## **CRITICAL THINKING CARE STUDY**

Gabby Castro, 24 years of age, works as a police officer; her dream is to become a homicide detective. She learned last week her brother, Alex, 26 years of age, has fragile X syndrome. She always knew he was aggressive (and now is serving a jail term for armed robbery), but she thought his aggression was because they moved a lot when they were little and so she thought he never had a chance to achieve in school. Gabby's fiancé, Stanley, 25 years of age, is a manager in his family's hardware store. He asks if the reason she enjoys being a police officer (he views this as mainly a man's occupation) could be because she's missing her X chromosomes. He wants her to have a DNA analysis before they get married to be certain a son won't have fragile X syndrome.

1. Fragile X syndrome is one of the most frequently seen chromosomal abnormalities in boys. Is it true this is associated with aggression? Could the family's frequent moves have contributed to the syndrome?
2. Is it probable that Gabby carries a gene for fragile X syndrome? Is it fair for Stanley to ask her to have a DNA analysis before he agrees to marry her?
3. Stanley asks if the reason Gabby wants to be a detective could be because her X chromosomes are missing. Is this likely? Would you recommend Gabby rethink her relationship with Stanley before agreeing to marriage?

## UNIT 3

# The Nursing Role in Caring for Families During Normal Pregnancy, Birth, the Postpartum, and Newborn Period

## Nursing Care During Normal Pregnancy and Care of the Developing Fetus

*Liz Calhorn, an 18-year-old, is 20 weeks pregnant. Although she says she knows she should have stopped smoking before pregnancy, she has not been able to do this as yet. Twice during the pregnancy (at the 4th and 10th week), she drank beer at summer picnics. Today, at a clinic visit, she tells you she has felt her fetus move. She states, “Feeling the baby move made me realize there’s someone inside me, you know what I mean? It made me realize it’s time I started being more careful with what I do.” Liz works at a fast-food restaurant. Her boyfriend (the father of fetus) is supportive but has no money to give her. Patient states, “I’m not getting married. Just not ready for that big commitment yet.”*

*Feeling a fetus move is often the trigger that makes having a baby “real” for many women. The more women know about fetal development before and after this event, the easier it is for them to begin to think of the pregnancy not as something interesting happening to them but as an act producing a separate life. A previous chapter described reproductive anatomy. This chapter adds information about fetal growth and development and assessment of fetal health.*

**In light of Liz’s revelation, what additional health teaching does she need?**

### KEY TERMS

age of viability  
 amniotic membrane  
 cephalocaudal  
 chorionic membrane  
 chorionic villi  
 decidua  
 embryo  
 estimated date of birth  
 fertilization  
 fetoscopy  
 fetus

**foramen ovale**  
**hydramnios**  
**implantation**  
**McDonald's rule**  
**meconium**  
**nonstress test**  
**oligohydramnios**  
**organogenesis**  
**surfactant**  
**trophoblast**  
**umbilical cord**  
**zygote**

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe the growth and development of a fetus by gestational age in weeks.
2. Identify 2020 National Health Goals addressing fetal growth and development and address how nurses can help the nation achieve these goals.
3. Assess fetal growth and development through maternal and pregnancy landmarks.
4. Formulate nursing diagnoses related to the needs of a fetus.
5. Establish expected outcomes to meet the perceived needs of a growing fetus as well as manage a seamless transition from fetus to newborn.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care to help ensure both a safe fetal environment and a safe pregnancy outcome.
8. Evaluate expected outcomes for achievement and effectiveness of care.
9. Integrate knowledge of fetal growth and development with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

It is a unique situation to provide care for the patient who cannot be evaluated directly. The healthy development of the unborn child, referred to as the **fetus**, pregnancy can determine the health of the newborn, and health as a newborn is a positive predictor for health throughout the individual's life span

Unit 3 addresses the nursing role and care you might expect to provide to families

during normal pregnancy, birth, and the postpartum and newborn periods. This chapter focuses on the structures of the female reproductive system that must function in harmony to sustain and promote the newborn's growth and development, the various stages of fetal development, and assessment of normal fetal development. Because you cannot have healthy children without healthy intrauterine growth, several 2020 National Health Goals speak to the importance of protecting fetal growth (Box 9.1).

## BOX 9.1

### Nursing Care Planning Based on 2020 National Health Goals

A number of 2020 National Health Goals address fetal growth.

- Reduce the fetal death rate (death between 20 and 40 weeks of gestation) to no more than 5.6 per 1,000 live births from a baseline of 6.2 per 1,000.
- Reduce low birth weight to an incidence of 7.8% of live births and very low birth weight to 1.4% of live births from baselines of 8.2% and 1.5%.
- Increase the proportion of women of childbearing potential with an intake of at least 400 mg of folic acid from fortified foods or dietary supplements from a baseline of 23.8% to 26.2% (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Folic acid deficiency in pregnancy can lead to midline closure defects such as neural tube disorders. Nurses can help the nation achieve these goals by urging women to plan their pregnancies so they can enter the pregnancy in good health and with an optimum folic acid level. Educating women about the importance of attending prenatal care is another important role.

### *Nursing Process Overview*

#### TO HELP ENSURE FETAL HEALTH

##### **ASSESSMENT**

Assessing fetal growth throughout pregnancy, by measuring fundal height and fetal heart rate, is important because these signs of fetal development provide guidelines for determining the well-being of a fetus. For the expectant family, knowledge about fetal growth and development can help a woman understand some of the changes going on in her body as well as allow all family members to begin thinking about and accepting a new member to their family. For this reason, assessing fetal development at prenatal visits and conveying the findings are important, providing the family in as much detail as parents' request.

##### **NURSING DIAGNOSIS**

Common nursing diagnoses related to growth and development of the fetus focus on the pregnant woman and the family as well as the fetus. Examples might include:

- Readiness for enhanced knowledge related to usual fetal development

- Anxiety related to lack of fetal movement
- Deficient knowledge related to the need for good prenatal care for healthy fetal well-being

## **OUTCOME IDENTIFICATION AND PLANNING**

Plans for care should include ways to educate potential parents about teratogens (i.e., any substance harmful to a fetus) that have the potential to interfere with fetal health. Outcome criteria established for teaching about fetal growth should be realistic and based on the parents' previous knowledge and desire for information. When additional assessment measures are necessary, such as an amniocentesis or an ultrasound examination, add this information to the teaching plan, explaining why further assessment is necessary and what the parents can expect from the procedure.

Refer women and their families to online resources for further information when appropriate. Helpful resources addressing pregnancy, birth, and postpartal care are available.

### **IMPLEMENTATION**

Most expectant parents are interested in learning about how mature their fetus is at various points in pregnancy as this helps them visualize their expected newborn. This, in turn, helps them to understand the importance of implementing healthy behaviors, such as eating well and avoiding substances that may be dangerous to a fetus such as recreational drugs. Viewing a sonogram and learning the fetal sex is a big step toward helping initiate bonding between the parents and the infant. Remember each woman's pregnancy is unique to her; be certain implementations are individualized for each woman for the best chance of outcome success.

### **OUTCOME EVALUATION**

An outcome evaluation related to fetal growth and development usually focuses on determining whether a woman or family has made any changes in lifestyle necessary to ensure fetal growth and whether a woman voices confidence that her baby is healthy and growing. Examples of expected outcomes include:

- Parents describe smoke-free living by next prenatal visit.
- Patient records number of movements fetus makes during 1 hour daily.
- Couple attends all scheduled prenatal visits.
- Patient states she is looking forward to the birth of her baby.

## **The Nursing Role and Nursing Care During Normal Pregnancy and Birth**

Thanks to the work of modern research and photographers who have been able to capture the process of fertilization and fetal development by ultrasound and high-tech photography, nurses can better understand and assess fetal growth and development.

Attending to the psychological and physiologic changes of pregnancy assures the health of the mother, and a healthy mother is a positive predictor for a healthy baby. A pregnant woman's body systems undergo specific changes during pregnancy to support the growth of the fetus (see [Chapter 10](#)). Accurate evaluation of these changes through assessment of the pregnant woman and her family will help you identify those changes that require an intervention (see [Chapter 11](#)).

You can foster a healthy outcome by obtaining a complete history and providing a physical examination that focuses on those components that influence fetal development. Vital signs are monitored following a recommended interval during pregnancy. Prenatal visits include standard guidelines, which may be altered if a pregnancy is at risk due to complications. Nursing care for the laboring mother (see [Chapters 15 and 16](#)), postpartum care for the mother and newborn (see [Chapter 17](#)), and newborn care of the term infant (see [Chapter 18](#)) decrease the need for interventions.

## Stages of Fetal Development

In just 38 weeks, a fertilized egg (ovum) matures from a single cell to a fully developed fetus ready to be born. Although different cultures or religions debate the point at which life begins, for ease of discussion, all agree fetal growth and development can be divided into three time periods:

- Pre-embryonic (first 2 weeks, beginning with fertilization)
- Embryonic (weeks 3 through 8)
- Fetal (from week 8 through birth)

[Table 9.1](#) lists common terms used to describe the fetus at various stages in this growth.

**TABLE 9.1 TERMS USED TO DESCRIBE FETAL GROWTH**

Name	Time Period
Ovum	From ovulation to fertilization
Zygote	From fertilization to implantation
Embryo	From implantation to 5–8 weeks
Fetus	From 5–8 weeks until term
Conceptus	Developing embryo and placental structures throughout pregnancy
<b>Age of viability</b>	The earliest age at which fetuses survive if they are born is generally accepted as 24 weeks or at the point a fetus weighs more than 500–600 g

## FERTILIZATION: THE BEGINNING OF PREGNANCY

**Fertilization** (also referred to as conception and impregnation) is the union of an ovum and a spermatozoon. This usually occurs in the outer third of a fallopian tube, termed the *ampullar portion*.

Usually, only one of a woman's ova reaches maturity each month. Once the mature ovum is released (i.e., ovulation), fertilization must occur fairly quickly because an ovum is capable of fertilization for only about 24 hours (48 hours at the most). After that time, it atrophies and becomes nonfunctional. Because the functional life of a spermatozoon is also about 48 hours, possibly as long as 72 hours, the total critical time span during which sexual relations must occur for fertilization to be successful is about 72 hours (48 hours before ovulation plus 24 hours afterward).

As the ovum is extruded from the graafian follicle of an ovary with ovulation, it is surrounded by a ring of mucopolysaccharide fluid (the zona pellucida) and a circle of cells (the corona radiata). The ovum and these surrounding cells (which increase the bulk of the ovum and serve as protective buffers against injury) are propelled into a nearby fallopian tube by currents initiated by the fimbriae—the fine, hairlike structures that line the openings of the tubes. A combination of peristaltic action of the tube and movements of the tube cilia help propel the ovum along the length of the tube.

Normally, an ejaculation of semen averages 2.5 ml of fluid containing 50 to 200 million spermatozoa per milliliter or an average of 400 million sperm per ejaculation (Welliver, Benson, Frederick, et al., 2016). At the time of ovulation, there is a reduction in the viscosity (thickness) of the woman's cervical mucus, which makes it easy for spermatozoa to penetrate it. Sperm transport is so efficient close to ovulation that spermatozoa deposited in the vagina generally reach the cervix within 90 seconds and the outer end of a fallopian tube within 5 minutes after deposition.

The mechanism whereby spermatozoa are drawn toward an ovum is probably a species-specific reaction, similar to an antibody–antigen reaction. Spermatozoa move through the cervix and the body of the uterus and into the fallopian tube, toward a waiting ovum by the combination of movement by their flagella (tails) and uterine contractions.

All of the spermatozoa that reach the ovum cluster around its protective layer of corona cells. Hyaluronidase (a proteolytic enzyme) is released by the spermatozoa and dissolves the layer of cells protecting the ovum. Under ordinary circumstances, only one spermatozoon is able to penetrate the cell membrane of the ovum. Once it penetrates the cell, the cell membrane changes composition to become impervious to other spermatozoa. An exception to this is the formation of gestational trophoblastic disease in which multiple sperm enter an ovum; this leads to abnormal zygote formation (DiGiulio, Wiedaseck, & Monchek, 2012) (see Chapter 21).

Immediately after penetration of the ovum, the chromosomal material of the ovum and spermatozoon fuse to form a **zygote**. Because the spermatozoon and ovum each carried 23 chromosomes (22 autosomes and 1 sex chromosome), the fertilized ovum has 46 chromosomes. If an X-carrying spermatozoon entered the ovum, the resulting child will have two X chromosomes and will be assigned female at birth (XX). If a Y-

carrying spermatozoon fertilized the ovum, the resulting child will have an X and a Y chromosome and will be assigned male at birth (XY).

Fertilization is never a certain occurrence because it depends on at least three separate factors:

- Equal maturation of both sperm and ovum
- Ability of the sperm to reach the ovum
- Ability of the sperm to penetrate the zona pellucida and cell membrane and achieve fertilization

Out of this single-cell fertilized ovum (zygote), the future child and also the accessory structures needed for support during intrauterine life (placenta, fetal membranes, amniotic fluid, and umbilical cord) will form.

## IMPLANTATION

Once fertilization is complete, a zygote migrates over the next 3 to 4 days toward the body of the uterus, aided by the currents initiated by the muscular contractions of the fallopian tubes. During this time, mitotic cell division, or cleavage, begins. The first cleavage occurs at about 24 hours; cleavage divisions continue to occur at a rate of about one every 22 hours so by the time the zygote reaches the body of the uterus; it consists of 16 to 50 cells. Over the next 3 or 4 days, large cells tend to collect at the periphery of the ball, leaving a fluid space surrounding an inner cell mass. At this stage, the structure is termed a *blastocyst*. The cells in the outer ring are **trophoblast** cells. They are the part of the structure that will later form the placenta and membranes. The inner cell mass (embryoblast cells) is the portion of the structure that will form the embryo.

**Implantation**, or contact between the growing structure and the uterine endometrium, occurs approximately 8 to 10 days after fertilization. About 8 days after ovulation, the blastocyst sheds the last residues of the corona and zona pellucida, brushes against the rich uterine endometrium (in the second [secretory] phase of the menstrual cycle), and settles down into its soft folds. The stages to this point are depicted in [Figure 9.1](#).

**Figure 9.1** Ovulation, fertilization, and implantation. The blastocyst is differentiated into three germ layers—the ectoderm, mesoderm, and endoderm. Cells at the periphery are trophoblast cells that mature into the placenta.

Implantation usually occurs high in the uterus on the posterior surface. If the point of implantation is low in the uterus, the growing placenta may occlude the cervix and make birth of the child difficult (placenta previa) because the placenta can block the birth canal. Almost immediately, the blastocyst burrows deeply into the endometrium and establishes an effective communication network with the blood system of the endometrium. Once implanted, the zygote is called an **embryo**.

Implantation is an important step in pregnancy because as many as 50% of zygotes never achieve it (Gardosi, 2012). In these instances, the pregnancy ends as early as 8 to 10 days after conception, often before a woman is even aware she was pregnant. Occasionally, a small amount of vaginal spotting appears on the day of implantation because capillaries are ruptured by the implanting trophoblast cells. A woman who normally has a particularly scant menstrual flow could mistake implantation bleeding for her menstrual period. If this happens, the predicted date of birth of her baby (based on the time of her last menstrual period) will be calculated 4 weeks late.

**QSEN Checkpoint Question 9.1**

**TEAMWORK & COLLABORATION**

Liz Calhorn, 18 years of age, asks how much longer her nurse practitioner will refer to the baby inside her as an embryo. To ensure team members use terms consistently, the nurse would want them to know the conceptus is classified as an embryo at what time?

- a. At the time of fertilization
- b. When the placenta forms
- c. From implantation until 20 weeks
- d. From implantation until 5 to 8 weeks

---

*Look in [Appendix A](#) for the best answer and rationale.*

---

## Embryonic and Fetal Structures

The placenta and membranes, which will serve as the fetal lungs, kidneys, and digestive tract in utero as well as help provide protection for the fetus, begin growth in early pregnancy in coordination with embryo growth.

### THE DECIDUA OR UTERINE LINING

After fertilization, the corpus luteum in the ovary continues to function rather than atrophying under the influence of human chorionic gonadotropin (hCG) secreted by the trophoblast cells. This hormone also causes the uterine endometrium to continue to grow in thickness and vascularity instead of sloughing off as in a usual menstrual cycle. The endometrium is now typically termed the **decidua** (the Latin word for “falling off”) because it will be discarded after birth of the child.

### CHORIONIC VILLI

As early as the 11th or 12th day after fertilization, miniature villi, resembling probing fingers and termed **chorionic villi**, reach out from the trophoblast cells into the uterine endometrium to begin formation of the placenta. Chorionic villi have a central core consisting of connective tissue and fetal capillaries surrounded by a double layer of cells, which produce various placental hormones, such as hCG, somatomammotropin (human placental lactogen [hPL]), estrogen, and progesterone. The middle layer, the *cytotrophoblast* or Langhans’ layer, appears to have a second function to protect the growing embryo and fetus from certain infectious organisms such as the spirochete of syphilis early in pregnancy. Because this layer of cells disappears between the 20th and 24th week of pregnancy, this is why syphilis is not considered to have a high potential for fetal damage early in pregnancy, only after the point at which cytotrophoblast cells are no longer present. The layer appears to offer little protection against viral invasion at any point, increasing the vulnerability of the fetus to viruses (Stohl & Satin, 2011).

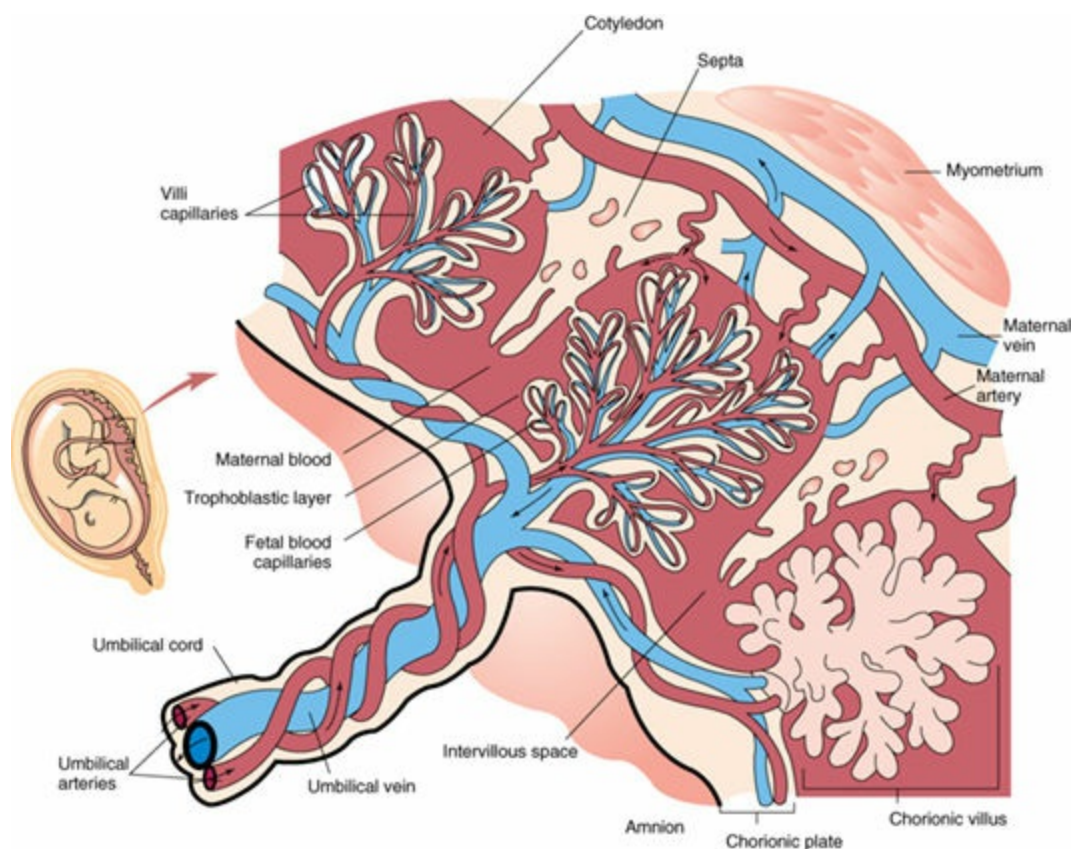

### THE PLACENTA

The placenta (Latin for “pancake,” which is descriptive of its size and appearance at

term) grows from a few identifiable trophoblastic cells at the beginning of pregnancy to an organ 15 to 20 cm in diameter and 2 to 3 cm in depth, covering about half the surface area of the internal uterus at term (Huppertz & Kingdom, 2012).

## Circulation

Placental circulation is shown in Figure 9.2. As early as the 12th day of pregnancy, maternal blood begins to collect in the intervillous spaces of the uterine endometrium surrounding the chorionic villi. By the third week, oxygen and other nutrients such as glucose, amino acids, fatty acids, minerals, vitamins, and water osmose from the maternal blood through the cell layers of the chorionic villi into the villi capillaries. From there, nutrients are transported to the developing embryo.

**Figure 9.2** Placental circulation.

Placental transfer is dynamic, allowing all but a few substances to cross from the mother into the fetus. Because almost all drugs are able to cross into the fetal circulation, it is important that a woman take no nonessential drugs (including alcohol and nicotine) during pregnancy (Ordean, Kahan, Graves, et al., 2015). For example, alcohol perfuses across the placenta and may cause fetal alcohol spectrum disorder (e.g., unusual facial features, low-set ears, and cognitive challenge). Because it's difficult to tell what quantity is "safe," pregnant women are advised to drink no alcohol during pregnancy to avoid these disorders (Rogers & Worley, 2012).

Theoretically, because the exchange process depends on osmosis, there is no direct exchange of blood cells between the embryo and the mother during pregnancy. Occasionally, however, fetal cells do cross into the maternal bloodstream as well as fetal enzymes such as  $\alpha$ -fetoprotein (AFP) produced by the fetal liver (this allows testing of fetal cells for genetic analysis as well as the level of AFP in the maternal blood).

As the number of chorionic villi increases with pregnancy, the villi form an increasingly complex communication network with the maternal bloodstream. Intervillous spaces grow larger and larger, becoming separated by 30 or more partitions or septa. These compartments, known as cotyledons, are what make the maternal side of the placenta look rough and uneven.

To provide enough blood for exchange, the rate of uteroplacental blood flow in pregnancy increases from about 50 ml/min at 10 weeks to 500 to 600 ml/min at term. No additional maternal arteries appear after the first 3 months of pregnancy; instead, to accommodate the increased blood flow, the arteries increase in size. The woman's heart rate, total cardiac output, and blood volume all increase to supply blood to the placenta (Pipkin, 2012). Braxton Hicks contractions, the barely noticeable uterine contractions present from about the 12th week of pregnancy on, aid in maintaining pressure in the intervillous spaces by closing off the uterine veins momentarily with each contraction.

Uterine perfusion and placental circulation are most efficient when the mother lies on her left side, as this position lifts the uterus away from the inferior vena cava, preventing blood from becoming trapped in the woman's lower extremities. If the woman lies on her back and the weight of the uterus compresses on the vena cava, known as vena cava syndrome, placental circulation can be so sharply reduced that supine hypotension (i.e., very low maternal blood pressure and poor uterine circulation) can occur (Coad & Dunstall, 2011a).

At term, the placental circulatory network has grown so extensively that a placenta weighs 400 to 600 g (1 lb), one-sixth the weight of the newborn. If a placenta is smaller than this, it suggests circulation to the fetus may have been compromised and/or inadequate. A placenta bigger than this also may indicate circulation to the fetus was threatened because it suggests the placenta was forced to spread out in an unusual manner to maintain a sufficient blood supply. The fetus of a woman with diabetes may also develop a larger than usual placenta from excess fluid collected between cells.

## Endocrine Function

Besides serving as the source of oxygen and nutrients for the fetus, the syncytial (outer) layer of the chorionic villi develops into a separate and important hormone-producing system.

### Human Chorionic Gonadotropin

The first placental hormone produced, hCG, can be found in maternal blood and urine

as early as the first missed menstrual period (shortly after implantation has occurred). Levels vary throughout pregnancy. The pregnant woman's blood serum will be completely negative for hCG within 1 to 2 weeks after birth. Finding no serum hCG after birth can be used as proof that placental tissue is no longer present.

hCG's purpose is to act as a fail-safe measure to ensure the corpus luteum of the ovary continues to produce progesterone and estrogen so the endometrium of the uterus is maintained. hCG also may play a role in suppressing the maternal immunologic response so placental tissue is not detected and rejected as a foreign substance. Because the structure of hCG is similar to that of luteinizing hormone of the pituitary gland, if the fetus is male, it exerts an effect on the fetal testes to begin testosterone production and maturation of the male reproductive tract (Huppertz & Kingdom, 2012).

At about the eighth week of pregnancy, the outer layer of cells of the developing placenta begins to produce progesterone, making the corpus luteum, which was producing progesterone, no longer necessary. In coordination with this, the production of hCG, which sustained the corpus luteum, begins to decrease at this point.

## Progesterone

Estrogen is often referred to as the “hormone of women,” and progesterone as the “hormone that maintains pregnancy.” This is because, although estrogen influences a female appearance, progesterone is necessary to maintain the endometrial lining of the uterus during pregnancy. It is present in maternal serum as early as the fourth week of pregnancy as a result of the continuation of the corpus luteum. After placental production begins (at about the 12th week), the level of progesterone rises progressively during the remainder of the pregnancy. This hormone also appears to reduce the contractility of the uterus during pregnancy, thus preventing premature labor.

## Estrogen

Estrogen (primarily estriol) is produced as a second product of the syncytial cells of the placenta. Estrogen contributes to the woman's mammary gland development in preparation for lactation and stimulates uterine growth to accommodate the developing fetus.

## Human Placental Lactogen (Human Chorionic Somatomammotropin)

hPL is a hormone with both growth-promoting and lactogenic (i.e., milk-producing) properties. It is produced by the placenta beginning as early as the sixth week of pregnancy, increasing to a peak level at term. It promotes mammary gland (breast) growth in preparation for lactation in the mother. It also serves the important role of regulating maternal glucose, protein, and fat levels so adequate amounts of these nutrients are always available to the fetus.

## Placental Proteins

In addition to hormones, the placenta also produces a number of plasma proteins. The function of these has not been well documented, but they may contribute to decreasing the immunologic impact of the growing placenta and help prevent hypertension of pregnancy (discussed in [Chapter 21](#)) ([Song, Li, & An, 2015](#)).

## THE AMNIOTIC MEMBRANES

The chorionic villi on the medial surface of the trophoblast (i.e., those that are not involved in implantation because they do not touch the endometrium) gradually thin until they become the **chorionic membrane**, the outermost fetal membrane. The amniotic membrane, or amnion, forms beneath the chorion ([Fig. 9.3](#)). The **amniotic membrane** is a dual-walled sac with the chorion as the outmost part and the amnion as the innermost part. The two fuse together as the pregnancy progresses, and by term, they appear to be a single sac. They have no nerve supply, so when they spontaneously rupture at term (a pregnant woman's "water breaks") or are artificially ruptured via a procedure, neither the pregnant woman nor fetus experiences any pain ([Coad & Dunstall, 2011b](#)).

**Figure 9.3** Membranes, with embryo lying within amniotic sac.

In contrast to the chorionic membrane, the second membrane (the amniotic membrane) not only offers support to amniotic fluid but also actually produces the fluid. In addition, it produces a phospholipid that initiates the formation of prostaglandins, which may be the trigger that initiates labor.

## THE AMNIOTIC FLUID

Amniotic fluid never becomes stagnant because it is constantly being newly formed and absorbed by direct contact with the fetal surface of the placenta. The major method of absorption, however, happens within the fetus. Because the fetus continually swallows the fluid, it is absorbed from the fetal intestine into the fetal bloodstream. From there, it goes to the umbilical arteries and to the placenta and is exchanged across the placenta to the mother's bloodstream.

At term, the amount of amniotic fluid has grown so much it ranges from 800 to 1,200 ml. If for any reason the fetus is unable to swallow (esophageal atresia or anencephaly are the two most common reasons), excessive amniotic fluid or **hydramnios** (more than 2,000 ml in total or pockets of fluid larger than 8 cm on ultrasound) will result ([Ghionzoli, James, David, et al., 2012](#)). Hydramnios may also occur in women with diabetes because hyperglycemia causes excessive fluid shifts into the amniotic space ([Perović, Garalejić, Gojnić, et al., 2012](#)).

Early in fetal life, as soon as the fetal kidneys become active, fetal urine adds to the quantity of the amniotic fluid. A disturbance of kidney function, therefore, may cause **oligohydramnios** or a reduction in the amount of amniotic fluid. Oligohydramnios can be detected by ultrasound. The amniotic fluid index is measured, and it should be at least 5 cm. The vertical pocket of amniotic fluid should be greater than 2 cm ([American Congress of Obstetricians and Gynecologists \[ACOG\], 2014](#)). The appropriate amount of amniotic fluid ensures adequate kidney function.

The most important purpose of amniotic fluid is to shield the fetus against pressure or a blow to the mother's abdomen. Because liquid changes temperature more slowly than air, it also protects the fetus from changes in temperature. Another function is that it aids in muscular development, as amniotic fluid allows the fetus freedom to move. Finally, it protects the umbilical cord from pressure, thus protecting the fetal oxygen supply.

Even if the amniotic membranes rupture before birth and the bulk of amniotic fluid is lost, some will always surround the fetus in utero because new fluid is constantly being formed. Amniotic fluid is slightly alkaline, with a pH of about 7.2. Checking the pH of the fluid at the time membranes rupture and amniotic fluid is released helps to differentiate amniotic fluid from urine because urine is acidic (pH 5.0 to 5.5).

## THE UMBILICAL CORD

The **umbilical cord** is formed from the fetal membranes, the amnion and chorion, and

provides a circulatory pathway that connects the embryo to the chorionic villi of the placenta. Its function is to transport oxygen and nutrients to the fetus from the placenta and to return waste products from the fetus to the placenta. It is about 53 cm (21 in.) in length at term and about 2 cm (0.75 in.) thick. The bulk of the cord is a gelatinous mucopolysaccharide called Wharton jelly, which gives the cord body and prevents pressure on the vein and arteries that pass through it.

An umbilical cord contains only one vein (carrying blood from the placental villi to the fetus) and two arteries (carrying blood from the fetus back to the placental villi). The number of veins and arteries in the cord is always assessed and recorded at birth because about 1% to 5% of infants are born with a cord that contains only a single vein and artery. Of these infants, 15% to 20% are found to have accompanying chromosomal disorders or congenital anomalies, particularly of the kidney and heart (Schneider, 2011).

The rate of blood flow through an umbilical cord is rapid (350 ml/min at term). The adequacy of blood flow (blood velocity) through the cord, as well as both systolic and diastolic cord pressure, can be determined by ultrasound examination. Counting the number of coils in the cord may be used as a prediction of healthy fetal growth, as hypocoiling is associated with maternal hypertension and hypercoiling is associated with respiratory distress in the newborn (Chitra, Sushanth, & Raghavan, 2012).

Because the rate of blood flow through the cord is so rapid, it is unlikely a knot or twist in the cord will interfere with the fetal oxygen supply. In about 20% of all births, a loose loop of cord is found around the fetal neck (nuchal cord) at birth (Hoh, Sung, & Park, 2012). If this loop of cord is removed before the newborn's shoulders are born (not usually hard to do) so there is no traction on it, the oxygen supply to the fetus remains unimpaired.

The walls of the umbilical cord arteries are lined with smooth muscle. When these muscles contract after birth, the cord arteries and vein are compressed to prevent hemorrhage of the newborn through the cord. Because the umbilical cord contains no nerve supply, it can be clamped and cut at birth without discomfort to either the child or mother.

### *QSEN Checkpoint Question 9.2*

#### **SAFETY**

Liz Calhorn tells the nurse she is worried her baby will be born with a congenital heart disease. What assessment of the umbilical cord at birth would be most important to help detect congenital heart defects?

- a. Assessing whether the pH of the Wharton jelly is higher than 7.2
- b. Assessing whether the umbilical cord has two arteries and one vein
- c. Measuring the length of the cord to be certain it is longer than 3 ft
- d. Determining that the umbilical cord is neither green nor yellow stained

*Look in Appendix A for the best answer and rationale.*

## Origin and Development of Organ Systems

Following the moment of fertilization, the zygote, which later becomes an embryo and then a fetus, begins to grow at an active pace.

### STEM CELLS

During the first 4 days of life, zygote cells are termed *totipotent stem cells*, or cells so undifferentiated they have the potential to grow into any cell in the human body. In another 4 days, as the structure implants and becomes an embryo, cells begin to show differentiation or lose their ability to become any body cell. Instead, they are slated to become specific body cells, such as nerve, brain, or skin cells, and are termed *pluripotent stem cells*. In yet another few days, the cells grow so specific they are termed *multipotent*, or are so specific they cannot be deterred from growing into a particular body organ such as spleen or liver or brain (Chen, Sun, Li, et al., 2016).

### ZYGOTE GROWTH

As soon as conception has taken place, development proceeds in a **cephalocaudal** (head-to-tail) direction; that is, head development occurs first and is followed by development of the middle and, finally, the lower body parts. This pattern of development continues after birth as shown by the way infants are able to lift up their heads approximately 1 year before they are able to walk.

### PRIMARY GERM LAYERS

As a fetus grows, body organ systems develop from specific tissue layers called germ layers. At the time of implantation, the blastocyst already has differentiated to a point at which three separate layers of these cells are present: the *ectoderm*, the *endoderm*, and the *mesoderm* (see Fig. 9.1). Each of these germ layers develops into specific body systems (Table 9.2). Knowing which structures arise from each germ layer is helpful to know because coexisting congenital disorders found in newborns usually arise from the same germ layer. For example, a fistula between the trachea and the esophagus (both of which arise from the endoderm layer) is a common birth anomaly. In contrast, it is rare to see a newborn with a malformation of the heart (which arises from the mesoderm) and also a malformation of the lower urinary tract (which arises from the endoderm). One reason rubella infection is so serious in pregnancy is because this virus is capable of infecting all three germ layers so can cause congenital anomalies in a myriad of body systems (White, Boldt, Holditch, et al., 2012).

**TABLE 9.2 ORIGIN OF BODY TISSUE**

Germ Layer	Body Portions Formed
Ectoderm	Central nervous system (brain and spinal cord) Peripheral nervous system

	<p>Skin, hair, nails, and tooth enamel</p> <p>Sense organs</p> <p>Mucous membranes of the anus, mouth, and nose</p> <p>Mammary glands</p>
Mesoderm	<p>Supporting structures of the body (connective tissue, bones, cartilage, muscle, ligaments, and tendons)</p> <p>Upper portion of the urinary system (kidneys and ureters)</p> <p>Reproductive system</p> <p>Heart, lymph, and circulatory systems and blood cells</p>
Endoderm	<p>Lining of pericardial, pleura, and peritoneal cavities</p> <p>Lining of the gastrointestinal tract, respiratory tract, tonsils, parathyroid, thyroid, and thymus glands</p> <p>Lower urinary system (bladder and urethra)</p>

All organ systems are complete, at least in a rudimentary form, at 8 weeks gestation (the end of the embryonic period). During this early time of **organogenesis** (organ formation), the growing structure is most vulnerable to invasion by teratogens (i.e., any factor that affects the fertilized ovum, embryo, or fetus adversely, such as a teratogenic medicine; an infection such as toxoplasmosis; cigarette smoking; or alcohol ingestion) (Box 9.2). Figure 9.4 illustrates critical periods of fetal growth when it is most important for women to minimize their exposure to teratogens. The effect of individual teratogens and how to avoid them is discussed in Chapter 12.

### BOX 9.2

#### Nursing Care Planning Based on Family Teaching

**Q.** Liz Calhorn tells you, “I have to work. How can I guard against fetal teratogens at work?”

**A.** Here are a number of helpful tips:

- Ask your employer for a statement on hazardous substances at your work site; discuss your need to avoid these substances during pregnancy.
- Ask your employer to maintain a smoke-free site if that is not already a rule.
- Avoid any room, such as a coffee room, where smokers gather.
- Refrain from drinking alcohol, a frequent accompaniment to work lunches or social functions; ask for nonalcoholic drinks to be available at such events.
- Locate a fellow coworker who will “buddy” with you to help you avoid alcohol or tobacco at work activities.
- If quitting smoking is difficult, try a supportive telephone or Internet quitline. Ask your primary healthcare provider before using a nicotine patch, nicotine gum, or bupropion (Zyban), a drug to assist smokers to quit. Both nicotine and Zyban are category C drugs; Zyban is particularly contraindicated in women with symptoms

**Figure 9.5** Fetal circulation.

Blood arriving at the fetus from the placenta is highly oxygenated. This blood enters the fetus through the umbilical vein (which is still called a vein even though it carries oxygenated blood because the direction of the blood is toward the fetal heart). Specialized structures present in the fetus then shunt blood flow to first supply the most important organs of the body: the liver, heart, kidneys, and brain. Blood flows from the umbilical vein to the ductus venosus, an accessory vessel that discharges oxygenated blood into the fetal liver, and then connects to the fetal inferior vena cava so oxygenated blood is directed to the right side of the heart. Because there is no need for the bulk of blood to pass through the lungs, the bulk of this blood is shunted as it enters the right atrium into the left atrium through an opening in the atrial septum called the **foramen ovale**. From the left atrium, it follows the course of adult circulation into the left ventricle, then into the aorta, and out to body parts.

A small amount of blood that returns to the heart via the vena cava does leave the right atrium by the adult circulatory route; that is, through the tricuspid valve into the right ventricle and then into the pulmonary artery and lungs to service the lung tissue. However, the larger portion of even this blood is shunted away from the lungs through an additional structure, the *ductus arteriosus*, directly into the descending aorta.

As the majority of blood cells in the aorta become deoxygenated, blood is transported from the descending aorta through the umbilical arteries (which are called arteries because they carry blood away from the fetal heart) back through the umbilical cord to the placental villi, where new oxygen exchange takes place.

At birth, an infant's oxygen saturation level is 95% to 100% and pulse rate is 80 to 140 beats/min. Because there is a great deal of mixing of blood in the fetus, the oxygen saturation level of fetal blood reaches only about 80%. A normal fetal heart rate is 110 to 160 beats/min, supplying needed oxygen to cells. Even with this low blood oxygen saturation level, however, carbon dioxide does not accumulate in the fetal system because it rapidly diffuses into maternal blood across a favorable placental pressure gradient.

### **Fetal Hemoglobin**

Fetal hemoglobin differs from adult hemoglobin in several ways. It has a different composition (two  $\alpha$  and two  $\gamma$  chains compared with two  $\alpha$  and two  $\beta$  chains of adult hemoglobin). It is also more concentrated and has greater oxygen affinity, two features that increase its efficiency. Because hemoglobin is more concentrated, a newborn's hemoglobin level is about 17.1 g/100 ml compared with a normal adult level of 11 g/100 ml; a newborn's hematocrit is about 53% compared with a normal adult level of 45%.

The change from fetal to adult hemoglobin levels begins before birth ( $\gamma$  cells are exchanged for  $\beta$  cells), but the process is still not complete at birth. Major blood dyscrasias, such as sickle cell anemia, tend to be defects of the  $\beta$ -hemoglobin chain, which is why clinical symptoms of these disorders do not become apparent until the bulk of fetal hemoglobin has matured to adult hemoglobin, at about 6 months of age (Panepinto & Scott, 2011).

## **RESPIRATORY SYSTEM**

At the third week of intrauterine life, the respiratory and digestive tracts exist as a single tube. Like all body tubes, initially, this forms as a solid structure, which then canalizes (i.e., hollows out). By the end of the fourth week, a septum begins to divide the esophagus from the trachea. At the same time, lung buds appear on the trachea.

Until the seventh week of life, the diaphragm does not completely divide the thoracic cavity from the abdomen. This causes lung buds to extend down into the abdomen, reentering the chest only as the chest's longitudinal dimension increases and the diaphragm becomes complete (at the end of the seventh week). If the diaphragm

fails to close completely, the stomach, spleen, liver, or intestines may be pulled up into the thoracic cavity. This causes the child to be born with intestine present in the chest (i.e., diaphragmatic hernia), compromising the lungs and perhaps displacing the heart (Gowen, 2011).

Other important respiratory developmental milestones include:

- Spontaneous respiratory practice movements begin as early as 3 months gestation and continue throughout pregnancy.
- Specific lung fluid with a low surface tension and low viscosity forms in alveoli to aid in expansion of the alveoli at birth; it is rapidly absorbed shortly after birth.
- **Surfactant**, a phospholipid substance, is formed and excreted by the alveolar cells of the lungs beginning at approximately the 24th week of pregnancy. This decreases alveolar surface tension on expiration, preventing alveolar collapse and improving the infant's ability to maintain respirations in the outside environment at birth (Rojas-Reyes, Morley, & Soll, 2012).

Surfactant has two components: lecithin and sphingomyelin. Early in the formation of surfactant, sphingomyelin is the chief component. At approximately 35 weeks, there is a surge in the production of lecithin, which then becomes the chief component by a ratio of 2:1. As a fetus practices breathing movements, surfactant mixes with amniotic fluid. Using an amniocentesis technique, an analysis of the lecithin/sphingomyelin (L/S) ratio in surfactant (whether lecithin or sphingomyelin is the dominant component) is a primary test of fetal maturity. Respiratory distress syndrome, a severe breathing disorder, can develop if there is a lack of surfactant or it has not changed to its mature form at birth (see Chapter 26).

Any interference with the blood supply to the fetus, such as placental insufficiency or maternal hypertension, may raise steroid levels in the fetus and enhance surfactant development. Synthetically increasing steroid levels in the fetus (e.g., the administration of betamethasone to the mother late in pregnancy) can also hurry alveolar maturation and surfactant production without interfering with permanent lung function prior to a preterm birth (Smith, 2016).

### *QSEN Checkpoint Question 9.3*

#### **INFORMATICS**

Liz Calhorn asks the nurse why her nurse midwife is concerned whether her fetus's lungs are producing surfactant. The nurse's best answer would be:

- a. "Surfactant keeps lungs from collapsing at birth, so it aids newborn breathing."
- b. "Surfactant is produced by the fetal liver, so its presence reveals liver maturity."
- c. "Surfactant is necessary for antibody production, so it helps prevent infection."
- d. "Surfactant reveals mature kidney function, as it is important for fetal

growth.”

*Look in Appendix A for the best answer and rationale.*

## NERVOUS SYSTEM

Like the circulatory system, the nervous system begins to develop extremely early in pregnancy.

- A neural plate (a thickened portion of the ectoderm) is apparent by the third week of gestation. The top portion differentiates into the neural tube, which will form the central nervous system (brain and spinal cord), and the neural crest, which will develop into the peripheral nervous system.
- All parts of the brain (cerebrum, cerebellum, pons, and medulla oblongata) form in utero, although none are completely mature at birth. Brain growth continues at high levels until 5 or 6 years of age.
- Brain waves can be detected on an electroencephalogram (EEG) by the eighth week.
- The eye and inner ear develop as projections of the original neural tube.
- By 24 weeks, the ear is capable of responding to sound, and the eyes exhibit a pupillary reaction, indicating sight is present.

The neurologic system seems particularly prone to insult during the early weeks of the embryonic period and can result in neural tube disorders, such as a meningocele (i.e., herniation of the meninges), especially if there is lack of folic acid (which is contained in green leafy vegetables and pregnancy vitamins) (Cohen & Uddin, 2011). All during pregnancy and at birth, the system is vulnerable to damage if anoxia should occur.

## ENDOCRINE SYSTEM

The function of endocrine organs begins along with neurosystem development.

- The fetal pancreas produces insulin needed by the fetus (insulin is one of the few substances that does not cross the placenta from the mother to the fetus).
- The thyroid and parathyroid glands play vital roles in fetal metabolic function and calcium balance.
- The fetal adrenal glands supply a precursor necessary for estrogen synthesis by the placenta.

## DIGESTIVE SYSTEM

The digestive tract separates from the respiratory tract at about the fourth week of intrauterine life and, after that, begins to grow extremely rapidly. Initially solid, the tract canalizes (hollows out) to become patent. Later in the pregnancy, the endothelial cells of the gastrointestinal tract proliferate extensively, occluding the lumen once more, and the tract must canalize again. Atresia (blockage) or stenosis (narrowing) of the track are common fetal anomalies and develop if either the first or second canalization does not

occur (Lin, Munsie, Herdt-Losavio, et al., 2012). The proliferation of cells shed in the second recanalization forms the basis for meconium (see following discussion).

Because of this rapid intestinal growth, by the sixth week of intrauterine life, the intestine becomes too large to be contained by the abdomen. A portion of the intestine, therefore, is pushed into the base of the umbilical cord, where it remains until about the 10th week of intrauterine life or until the abdominal cavity has grown large enough to accommodate the bulky intestines. As intestine returns to the abdominal cavity at this point, it must rotate 180 degrees. Failure to do so can result in inadequate mesentery attachments, possibly leading to volvulus of the intestine in the newborn.

If any intestine remains outside the abdomen in the base of the cord, a congenital anomaly, termed *omphalocele*, will be present at birth. A similar defect, *gastroschisis*, occurs when the original midline fusion that occurred at the early cell stage is incomplete (Hay, Levin, Deterding, et al., 2016).

**Meconium**, a collection of cellular wastes, bile, fats, mucoproteins, mucopolysaccharides, and portions of the vernix caseosa (i.e., the lubricating substance that forms on the fetal skin), accumulates in the intestines as early as the 16th week. Meconium is sticky in consistency and appears black or dark green (obtaining its color from bile pigment). An important neonatal nursing responsibility is recording that a newborn has passed meconium as this rules out a stricture (noncanalization) of the anus (Marcelis, de Blaauw, & Brunner, 2011).

The gastrointestinal tract is sterile before birth. Because vitamin K, necessary for blood clotting, is synthesized by the action of bacteria in the intestines, vitamin K levels are almost nonexistent in a fetus and are still low in a newborn (vitamin K is routinely administered intramuscularly at birth). Sucking and swallowing reflexes are not mature until the fetus is approximately 32 weeks gestation, or weighs 1,500 g. However, strong suck and swallowing reflexes may not be present until the fetus is full term.

The ability of the gastrointestinal tract to secrete enzymes essential for carbohydrate and protein digestion is mature at 36 weeks. However, amylase, an enzyme found in saliva and necessary for digestion of complex starches, does not mature until 3 months after birth. Many newborns have also not yet developed lipase, an enzyme needed for fat digestion (a reason breast milk is the best food for newborns because its digestion does not depend on these enzymes).

The liver is active throughout intrauterine life, functioning as a filter between the incoming blood and the fetal circulation and as a deposit site for fetal stores such as iron and glycogen. Unfortunately, during intrauterine life, the fetal liver is unable to prevent recreational drugs or alcohol ingested by the mother from entering the fetal circulation and possibly causing birth anomalies (Singer, Moore, Fulton, et al., 2012). Newborns need careful assessment at birth for hypoglycemia (low blood sugar) and hyperbilirubinemia (excessive breakdown products from destroyed red blood cells), two serious problems that can occur in the first 24 hours after birth because, although active, liver function is still immature.

## MUSCULOSKELETAL SYSTEM

During the first 2 weeks of fetal life, cartilage prototypes provide position and support to the fetus. Ossification of this cartilage into bone begins at about the 12th week and continues all through fetal life and into adulthood. Carpals, tarsals, and sternal bones generally do not ossify until birth is imminent. A fetus can be seen to move on ultrasonography as early as the 11th week, although the mother usually does not feel this movement (*quicken*) until 16 to 20 weeks of gestation. It is usually felt earlier in multigravida women.

### *What If . . . 9.1*

**Liz Calhorn repeats that not only have her feelings toward her baby changed since she felt the baby move but she's also more interested in how to keep him safe now. How would the nurse modify the health teaching with her because of this?**

## REPRODUCTIVE SYSTEM

A child's sex is determined at the moment of conception by a spermatozoon carrying an X or a Y chromosome and can be ascertained as early as 8 weeks by chromosomal analysis or analysis of fetal cells in the mother's bloodstream. At about the sixth week after implantation, the gonads (i.e., ovaries or testes) form. If testes form, testosterone is secreted, apparently influencing the sexually neutral genital duct to form other male organs (i.e., maturation of the wolffian, or mesonephric, duct). In the absence of testosterone secretion, female organs will form (i.e., maturation of the müllerian, or paramesonephric, duct). This is an important phenomenon because if a woman should unintentionally take an androgen or an androgen-like substance during this stage of pregnancy, a child who is chromosomally female could appear more male than female at birth. If deficient testosterone is secreted by the testes, both the müllerian (female) duct and the wolffian (male) duct could develop (i.e., pseudohermaphroditism, or intersex) (Kutney, Konczal, Kaminski, et al., 2016).

The testes first form in the abdominal cavity and do not descend into the scrotal sac until the 34th to 38th week of intrauterine life. Because of this, many male preterm infants are born with undescended testes. These boys need a follow-up to be certain their testes do descend when they reach what would have been the 34th to 38th week of gestational age because testicular descent does not always occur as readily in extrauterine life as it would have in utero. Testes that do not descend (cryptorchidism) require surgery as they are associated with poor sperm production and possibly testicular cancer later in life (Kelsey, Barker, Bartz, et al., 2016).

## URINARY SYSTEM

Although rudimentary kidneys are present as early as the end of the fourth week of intrauterine life, the presence of kidneys does not appear to be essential for life before birth because the placenta clears the fetus of waste products. Urine, however, is formed by the 12th week and is excreted into the amniotic fluid by the 16th week of gestation. At term, fetal urine is being excreted at a rate of up to 500 ml/day. An amount of amniotic fluid less than usual (oligohydramnios) suggests fetal kidneys are not secreting adequate urine and that there is a kidney, ureter, or bladder disorder (Kumar, 2012).

The complex structure of the kidneys gradually develops during intrauterine life and continues to mature for months afterward. The loop of Henle, for example, is not fully differentiated until the fetus is born. Glomerular filtration and concentration of urine in the newborn are still not efficient because the ability to concentrate urine is still not mature at birth. Early in the embryonic stage of urinary system development, the bladder extends as high as the umbilical region, and there is an open lumen between the urinary bladder and the umbilicus. If this fails to close, (termed a *patent urachus*), this is revealed at birth by the persistent drainage of a clear, acid-pH fluid (urine) from the umbilicus (Samra, McGrath, & Wehbe, 2011).

## **INTEGUMENTARY SYSTEM**

The skin of a fetus appears thin and almost translucent until subcutaneous fat begins to be deposited underneath it at about 36 weeks. Skin is covered by soft downy hairs (lanugo) that serve as insulation to preserve warmth in utero as well as a cream cheese-like substance, vernix caseosa, which is important for lubrication and for keeping the skin from macerating in utero. Both lanugo and vernix are still present at birth.

## **IMMUNE SYSTEM**

Immunoglobulin (Ig) G maternal antibodies cross the placenta into the fetus as early as the 20th week and certainly by the 24th week of intrauterine life to give a fetus temporary passive immunity against diseases for which the mother has antibodies. These often include poliomyelitis, rubella (German measles), rubeola (regular measles), diphtheria, tetanus, infectious parotitis (mumps), hepatitis B, and pertussis (whooping cough). Infants born before this antibody transfer has taken place have no natural immunity and so need more than the usual protection against infectious disease in the newborn period.

A fetus only becomes capable of active antibody production late in pregnancy. Generally, it is not necessary for a fetus to produce antibodies because they need to be manufactured only to counteract an invading antigen, and antigens rarely invade the intrauterine space. Because IgA and IgM antibodies (the types which develop to actively counteract infection) cannot cross the placenta, their presence in a newborn is proof that the fetus has been exposed to an infection.

## **MILESTONES OF FETAL GROWTH AND DEVELOPMENT**

When fetal milestones occur can be confusing because the life of the fetus is typically measured from the time of ovulation or fertilization (ovulation age), but the length of a pregnancy is more commonly measured from the first day of the last menstrual period (gestational age). Because ovulation and fertilization take place about 2 weeks after the last menstrual period, the ovulation age of the fetus is always 2 weeks less than the length of the pregnancy or the gestational age.

Both ovulation and gestational age are typically reported in lunar months (4-week periods) or in trimesters (3-month periods) rather than in weeks. In lunar months, a total pregnancy is 10 months (40 weeks or 280 days) long; a fetus grows in utero for 9.5 lunar months or three full trimesters (38 weeks or 266 days).

The following discussion of fetal developmental milestones is based on gestational weeks because it is helpful when talking to expectant parents to correlate fetal development with the way they measure pregnancy—from the first day of the last menstrual period. [Figure 9.6](#) illustrates the comparative size and appearance of human embryos and fetuses at different stages of development.

**Figure 9.6** Human embryos at different stages of life. **(A)** Implantation in uterus 7 to 8 days after conception. **(B)** The embryo at 32 days. **(C)** At 37 days. **(D)** At 41 days. **(E)** Between 12 and 15 weeks. (Petit Format/Nestle/Science Source/Photo Researchers.)

### End of Fourth Gestational Week

- The length of the embryo is about 0.75 cm; weight is about 400 mg.
- The spinal cord is formed and fused at the midpoint.
- The head is large in proportion and represents about one third of the entire structure.
- The rudimentary heart appears as a prominent bulge on the anterior surface.

- Arms and legs are bud-like structures; rudimentary eyes, ears, and nose are discernible.

### End of Eighth Gestational Week

- The length of the fetus is about 2.5 cm (1 in.); weight is about 20 g.
- Organogenesis is complete.
- The heart, with a septum and valves, beats rhythmically.
- Facial features are definitely discernible; arms and legs have developed.
- External genitalia are forming, but sex is not yet distinguishable by simple observation.
- The abdomen bulges forward because the fetal intestine is growing so rapidly.
- A sonogram shows a gestational sac, which is diagnostic of pregnancy (Fig. 9.7).

**Figure 9.7** Sonogram showing the characteristic circle diagnostic of pregnancy (the gestational sac). (From Stephenson, S. R. [2012]. *Diagnostic medical sonography: Obstetrics and gynecology* [3rd ed.]. Baltimore, MD: Lippincott Williams & Wilkins.)

### End of 12th Gestational Week (First Trimester)

- The length of the fetus is 7 to 8 cm; weight is about 45 g.
- Nail beds are forming on fingers and toes.
- Spontaneous movements are possible, although they are usually too faint to be felt by the mother.
- Some reflexes, such as the Babinski reflex, are present.

- Bone ossification centers begin to form.
- Tooth buds are present.
- Sex is distinguishable on outward appearance.
- Urine secretion begins but may not yet be evident in amniotic fluid.
- The heartbeat is audible through Doppler technology.

### **End of 16th Gestational Week**

- The length of the fetus is 10 to 17 cm; weight is 55 to 120 g.
- Fetal heart sounds are audible by an ordinary stethoscope.
- Lanugo is well formed.
- Both the liver and pancreas are functioning.
- The fetus actively swallows amniotic fluid, demonstrating an intact but uncoordinated swallowing reflex; urine is present in amniotic fluid.
- Sex can be determined by ultrasonography.

### **End of 20th Gestational Week**

- The length of the fetus is 25 cm; weight is 223 g.
- Spontaneous fetal movements can be sensed by the mother.
- Antibody production is possible.
- Hair, including eyebrows, forms on the head; vernix caseosa begins to cover the skin.
- Meconium is present in the upper intestine.
- Brown fat, a special fat that aids in temperature regulation, begins to form behind the kidneys, sternum, and posterior neck.
- Passive antibody transfer from mother to fetus begins.
- Definite sleeping and activity patterns are distinguishable as the fetus develops biorhythms that will guide sleep/wake patterns throughout life.

### **End of 24th Gestational Week (Second Trimester)**

- The length of the fetus is 28 to 36 cm; weight is 550 g.
- Meconium is present as far as the rectum.
- Active production of lung surfactant begins.
- Eyelids, previously fused since the 12th week, now open; pupils react to light.
- Hearing can be demonstrated by response to sudden sound.
- When fetuses reach 24 weeks, or 500 to 600 g, they have achieved a practical low-end age of viability if they are cared for after birth in a modern intensive care nursery.

### **End of 28th Gestational Week**

- The length of the fetus is 35 to 38 cm; weight is 1,200 g.
- Lung alveoli are almost mature; surfactant can be demonstrated in amniotic fluid.

- Testes begin to descend into the scrotal sac from the lower abdominal cavity.
- The blood vessels of the retina are formed but thin and extremely susceptible to damage from high oxygen concentrations (an important consideration when caring for preterm infants who need oxygen).

### End of 32nd Gestational Week

- The length of the fetus is 38 to 43 cm; weight is 1,600 g.
- Subcutaneous fat begins to be deposited (the former stringy, “little old man” appearance is lost).
- Fetus responds by movement to sounds outside the mother’s body.
- An active Moro reflex is present.
- Iron stores, which provide iron for the time during which the neonate will ingest only breast milk after birth, are beginning to be built.
- Fingernails reach the end of fingertips.

### End of 36th Gestational Week

- The length of the fetus is 42 to 48 cm; weight is 1,800 to 2,700 g (5 to 6 lb).
- Body stores of glycogen, iron, carbohydrate, and calcium are deposited.
- Additional amounts of subcutaneous fat are deposited.
- Sole of the foot has only one or two crisscross creases compared with a full crisscross pattern evident at term.
- Amount of lanugo begins to diminish.
- Most fetuses turn into a vertex (head down) presentation during this month.

### End of 40th Gestational Week (Third Trimester)

- The length of the fetus is 48 to 52 cm (crown to rump, 35 to 37 cm); weight is 3,000 g (7 to 7.5 lb).
- Fetus kicks actively, sometimes hard enough to cause the mother considerable discomfort.
- Fetal hemoglobin begins its conversion to adult hemoglobin.
- Vernix caseosa starts to decrease after the infant reaches 37 weeks gestation and may be more apparent in the creases than the covering of the body as the infant approaches 40 weeks or more gestational age.
- Fingernails extend over the fingertips.
- Creases on the soles of the feet cover at least two thirds of the surface.

In primiparas (i.e., women having their first baby), the fetus often sinks into the birth canal during the last 2 weeks of pregnancy, giving the mother a feeling the load she is carrying is less. This event, termed *lightening*, is a fetal announcement that the fetus is in a ready position and birth is nearing.

## DETERMINATION OF ESTIMATED BIRTH DATE

It is impossible to predict with a high degree of accuracy the exact day an infant will be born because fewer than 5% of pregnancies end exactly 280 days from the last menstrual period; fewer than half end within 1 week of the 280th day.

Traditionally, this date was referred to as the estimated date of confinement (EDC). Because women are no longer “confined” after childbirth, the acronym EDB (**estimated date of birth**) is more commonly used today.

If fertilization occurred early in a menstrual cycle, the pregnancy will probably end “early”; if ovulation and fertilization occurred later than the midpoint of the cycle, the pregnancy will end “late.” Because of these normal variations, a pregnancy ending 2 weeks before or 2 weeks after the calculated EDB is considered well within the normal limit (38 to 42 weeks). Gestational age wheels and birth date calculators, which can be used to predict a birth date are available, but calculation by Naegele’s rule is the standard method used to predict the length of a pregnancy ([Box 9.3](#)).

### BOX 9.3

#### Naegele’s Rule

To calculate the date of birth by this rule, count backward 3 calendar months from the first day of a woman’s last menstrual period and add 7 days. For example, if the last menstrual period began May 15, you would count back 3 months (April 15, March 15, February 15) and add 7 days, to arrive at the predicted date of birth as February 22.

#### *What If . . . 9.2*

**Liz Calhorn first came to the prenatal clinic on August 5 and told the nurse she had her last menstrual period from March 13 to March 18. What would be her child’s EDB?**

## Assessment of Fetal Growth and Development

Tests for fetal growth and development are commonly done for a variety of reasons, including to:

- Predict the outcome of the pregnancy
- Manage the remaining weeks of the pregnancy
- Plan for possible complications at birth
- Plan for problems that may occur in the newborn infant
- Decide whether to continue the pregnancy
- Find conditions that may affect future pregnancies

Both fetal growth and development can be compromised if a fetus has a metabolic or chromosomal disorder that interferes with normal growth, if the supporting structures

such as the placenta or cord do not form normally, or if environmental influences such as the nicotine in cigarettes causes fetal growth restriction (including testes growth in a male fetus) (Virtanen, Sadov, & Toppari, 2012).

Nursing responsibilities for these assessment procedures include verifying that a signed consent form has been obtained as needed (which is necessary if the procedure poses any risk to the mother or fetus that would not otherwise be present), being certain the woman and her support person are aware of what the procedure will entail and any potential risks, preparing the woman physically and psychologically, providing support during the procedure, assessing both fetal and maternal responses during and after the procedure, providing any necessary follow-up care, and managing equipment and specimens. Box 9.4 shows an interprofessional care map illustrating both nursing and team planning for fetal care, including assessment procedures.

#### BOX 9.4

### Nursing Care Planning

#### AN INTERPROFESSIONAL CARE MAP FOR A WOMAN UNDERGOING FETAL STUDIES

Liz Calhorn, an 18-year-old, is about 20 weeks pregnant (can't remember date of last menstrual period). Although she says she knows she should have stopped smoking before pregnancy, she has not been able to do this as yet. Twice during the pregnancy (at the 4th and 10th week), she drank beer at summer picnics. Today, at a clinic visit, she tells you she has felt her fetus move. She states, "Feeling the baby move made me realize there's someone inside me, you know what I mean? It made me realize it's time I started being more careful with what I do." Liz works at a fast food restaurant. Boyfriend (father of fetus) is supportive but has no money to offer her for support. Patient states, "I'm not getting married. Just not ready for that level of commitment yet."

**Family Assessment:** Patient lives in one-bedroom apartment; supports self by working at a fast food restaurant. States, "My parents would help out if I begged them, but I'm not going to do that."

**Patient Assessment:** Patient smokes a pack of cigarettes a day. Takes aspirin, 10 g, for almost daily sinus headaches. No recreational drug use.

**Nutrition:** Breakfast: None, to help control her weight.

Lunch: A hotdog and salad. One diet cola.

Dinner: Macaroni and cheese; applesauce. One cup coffee.

Snack: Half bag of potato chips and cream-cheese dip.

**Physical examination:** Fundal height is 16 cm. Fetal heart tones by Doppler at 160 beats/min. Has been advised to have an ultrasound done to assess for fetal growth and to date pregnancy.

**Nursing Diagnosis:** Risk for altered fetal growth related to inadequate nutrition and

alcohol and nicotine consumption

**Outcome Criteria:** Patient consents to sonogram for fetal growth assessment; reports lessened alcohol and cigarette use at the next visit.

<b>Team Member Responsible</b>	<b>Assessment</b>	<b>Intervention</b>	<b>Rationale</b>	<b>Expected Outcome</b>
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Ask patient to describe a “typical day” to reveal any actions possibly detrimental to fetal growth.	Discuss common actions unsafe during pregnancy, such as smoking and drinking alcohol.	Knowing what constitutes unsafe practices during pregnancy is a woman’s best safeguard against fetal harm.	Patient states she will stop drinking alcohol; is using a supportive Internet quitline to help reduce smoking.
<i>Teamwork and Collaboration</i>				
Primary healthcare provider/nurse	Determine whether sonogram department has appointments free in coming week.	Schedule sonogram 1 week in advance with sonogram department.	Patient believes she might be 20 weeks pregnant. Fundal height, recent fetal movements correspond more closely to 16 weeks.	Patient reports for scheduled ultrasound in 1 week.
<i>Procedures/Medications for Quality Improvement</i>				
Nurse	Assess what prescription or over-the-counter or alternative therapies patient is using.	Discuss with patient inadvisability of taking aspirin during pregnancy; suggest she take acetaminophen (Tylenol) instead.	Acetylsalicylic acid (aspirin) can lead to bleeding or prolonged pregnancy.	Patient reports at next prenatal visit she takes acetaminophen for any pain.
<i>Nutrition</i>				
Nurse/nutritionist	Ask patient for a 24-hour recall	Discuss the advisability of	Knowing what constitutes a	Patient reports at prenatal visits

	nutrition history.	eating breakfast while pregnant to help avoid hypoglycemia in fetus.	healthy diet helps ensure a fetus will receive adequate nutrients.	she eats breakfast before leaving for work in the morning; includes more protein in intake.
--	--------------------	--	--	---

*Patient-Centered Care*

Nurse	Determine whether patient understands ultrasound is not an X-ray, so it is not harmful to the fetus.	Instruct patient about preparation for sonogram (drink fluid; avoid emptying bladder).	A well-prepared patient is more apt to result in an effective procedure and a satisfied patient.	Patient will describe accurate preparations for procedure; receives printed instructions for ambulatory ultrasound.
-------	--	--	--	---

*Spiritual/Psychosocial/Emotional Needs*

Primary healthcare provider/nurse	Assess the extent of factors, such as alcohol and cigarette use, that could have led to intrauterine growth restriction.	Review the possibility with patient that her pregnancy dating may be wrong because fundal height is below usual. Alternate cause could be fetal growth restriction.	Understanding contributors to fetal health is necessary for women to make informed choices during pregnancy.	Patient states she understands the discrepancy in fundal height and weeks gestation following explanation.
-----------------------------------	--	---	--	--

*Informatics for Seamless Healthcare Planning*

Nurse/primary healthcare provider	Perform complete assessment to help ensure continuity of care with other services.	Mark chart as high-risk patient for intrauterine growth restriction (fundal height below average for weeks gestation).	Documenting risk factors helps to safeguard the fetus.	The patient chart documents high-risk status.
-----------------------------------	--	--	--	---

Providing follow-up care may include being certain a couple understands the results of a test and how to interpret it. When a result is positive, parents feel assured their infant is growing well. When results are not encouraging, a couple may experience a mixture of emotions. They may express being committed to the pregnancy but express concerns regarding a desire to protect their child, themselves, and their family from the burden of having a child with a severe disability. In some instances, they will be asked to make a life and death decision depending on the results. Quiet listening so a couple has time to thoroughly think through what option will be right for them may be difficult to do but is usually the soundest action for healthcare providers (Reed & Berrier, 2016).

## HEALTH HISTORY

Like all assessments, a fetal assessment begins with a health history. Ask the mother specifically about any prepregnancy illnesses such as gestational diabetes or heart disease because these both can interfere with fetal growth. Ask about any drugs a woman takes; for instance, common drugs taken for recurrent seizures can be teratogenic and therefore pose a risk in pregnancy (Mawhinney, Campbell, Craig, et al., 2012). Inquire about nutritional intake because if a woman is not eating a well-balanced diet, she may not be taking in enough nutrients for fetal growth (Whitney & Rolfes, 2012). Be certain to also ask about personal habits such as cigarette smoking, both prescription and recreational drug use, alcohol consumption, and exercise because all of these may influence glucose/insulin balance and fetal growth. Most women are aware alcohol ingestion can harm a fetus (e.g., fetal alcohol spectrum disorder) but many are not yet aware of fetal tobacco syndrome (Wong, Ordean, & Kahan, 2011). This syndrome applies to the fetus of a woman who smokes more than five cigarettes a day and who is born growth restricted (i.e., birth weight under 2,500 g at term). Smoking may also be a cause of ectopic (tubal) pregnancy as fallopian tubes may become irritated (Shao, Zou, Wang, et al., 2012).

Most women instinctively protect a fetus growing inside them so pregnancy may be the push they need to improve their lifestyle (Box 9.5). Asking if a woman has had any exposure to teratogens can reveal exposure to such substances as chemicals, paint fumes, cleaning products, poor air quality, or a loud noise level (Krueger, Horesh, & Crossland, 2012). Asking about unintentional injuries or intimate partner violence can help reveal whether the pregnant woman and fetus could have suffered any trauma from these sources (e.g., intimate partner violence tends to increase during pregnancy because of the stress a pregnancy can create) (Dalton, 2012).

### BOX 9.5

#### Nursing Care Planning to Respect Cultural Diversity

Different cultures have different ideas as to what foods to eat, how much exercise is good during pregnancy, and whether fetal tests for well-being are ethical. Cultural beliefs also affect everyday things, such as believing it is wrong to have a photograph

taken during pregnancy because that will alert unknown spirits that the woman is pregnant (the origin of lullabies were songs to keep away Lilith, an avenging creature in Jewish folklore who was thought to bring harm to babies). Believing photographs are harmful may make a woman reluctant to have a sonogram taken during pregnancy; unlike most women, she may not like a photograph of the ultrasound for a baby keepsake.

Some religions also do not support a full range of contraception options; in these instances, the nurse can assist by recommending other natural family planning options that align with the woman's preferences.

## PHYSICAL EXAMINATION

A physical examination of the mother is the second step in evaluating fetal health. Assess maternal weight and general appearance because both obesity and underweight are clues that the mother's nutrition may not be adequate for sound fetal growth (Warren, Rance, & Hunter, 2012). Bruises may indicate intimate partner violence that could have bruised the fetus as well. An elevated blood pressure may be the beginning of hypertension of pregnancy, which can restrict fetal growth (Vest & Cho, 2012).

### QSEN Checkpoint Question 9.4

#### EVIDENCE-BASED PRACTICE

To investigate whether there are any psychosocial predictors of women who smoke during pregnancy, a cross-sectional analysis of a birth cohort was reviewed. In this prospective study, the answers to questionnaires completed by 514 mothers shortly after the birth of their full-term infants found that 14.8% of the participants smoked. Of those women responded that they smoked during pregnancy, they were also more likely to have the following characteristics: lower education, maternal age less than 20 years, unmarried, history of elective abortion, history of unplanned pregnancy, lack of emotional acceptance of the pregnancy by the mother and father, emotional distress, and alcohol consumption (Širvinskienė, Žemaitienė, Jusienė, et al., 2016).

Based on the previous study, which statement by Liz Calhorn would make the nurse most worried she might have difficulty quitting smoking during the remainder of her pregnancy?

- "I sometimes do have a few beers on the weekend with my boyfriend."
- "When I feel tense, I like to shop. It really takes away that bad feeling."
- "I'm trying to stop smoking so I won't have to smoke around my baby."
- "My mother had five children with no trouble; why am I so different?"

Look in [Appendix A](#) for the best answer and rationale.

## ESTIMATING FETAL HEALTH

A number of procedures, both noninvasive and invasive, are used to evaluate fetal

health. Because there are many procedures, helping a woman with a high-risk pregnancy maintain a sense of control or empowerment as she is scheduled for them is an important nursing responsibility (Box 9.6).

### BOX 9.6

#### Nursing Care Planning to Empower a Family

Women may find the names of tests like maternal serum  $\alpha$ -fetoprotein (MSAFP) and substances being tested for (acetylcholinesterase) so confusing that they feel as if their life is being taken over by scheduled tests or exams. To help a woman maintain control:

- Encourage her to ask questions until her primary healthcare provider simplifies instructions or test results enough that she thoroughly understands them.
- Encourage her to set the time and date of appointments if possible so she can fit fetal testing in with her schedule rather than be expected to appear “on command.”
- Encourage her to bring her significant other with her for fetal testing so he or she hears the same explanation she does and so that person can also ask questions rather than hearing the information second hand.
- Don’t refer to a fetus as “it” during testing because that is such an impersonal term. If the woman has chosen a name, use that while referring to her fetus; otherwise, use “he or she.”
- Respect modesty during exams where the woman’s abdomen will be exposed. Movie stars are often pictured today with their pregnant abdomen on view, but not every woman wants her body exposed unnecessarily that way.
- Remember that late in pregnancy, women’s movements can be painful and may feel awkward, so respect that asking a woman to step up and lie on an examining table is not asking her to complete an easy task. Offer help as necessary but also remember feeling independent is an empowering feeling.

### Fetal Growth

As a fetus grows, the uterus expands to accommodate its size. Although not evidence grounded, typical fundal (top of the uterus) measurements are:

- Over the symphysis pubis at 12 weeks
- At the umbilicus at 20 weeks
- At the xiphoid process at 36 weeks

**McDonald’s rule**, another symphysis–fundal height measurement (although, again, not documented to be thoroughly reliable), is an easy method of determining midpregnancy growth. Typically, tape measurement from the notch of the symphysis pubis to over the top of the uterine fundus as a woman lies supine is equal to the week of gestation in centimeters between the 20th and 31st weeks of pregnancy (e.g., in a pregnancy of 24 weeks, the fundal height should be 24 cm) (Fig. 9.8).

**Figure 9.8** Measuring fundal height from the superior aspect of the pubis to the fundal crest. The tape is pressed flat against the abdomen for the measurement.

A fundal height much greater than this standard suggests a multiple pregnancy, a miscalculated due date, a large-for-gestational-age (LGA) infant, hydramnios (increased amniotic fluid volume), or possibly even gestational trophoblastic disease (see [Chapter 21](#)). A fundal measurement much less than this suggests the fetus is failing to thrive (e.g., intrauterine growth restriction), the pregnancy length was miscalculated, or an anomaly interfering with growth has developed. McDonald's rule becomes inaccurate during the third trimester of pregnancy because the fetus is growing more in weight than in height during this time.

## ASSESSING FETAL WELL-BEING

A number of actions or procedures are helpful in detecting and documenting the fetus is not only growing but also apparently healthy.

### Fetal Heart Rate

Fetal heart sounds can be heard and counted as early as the 10th to 11th week of pregnancy by the use of an ultrasound Doppler technique ([Fig. 9.9](#)). This is done routinely at every prenatal visit past 10 weeks.

**Figure 9.9** Measuring fetal heart rate with a Doppler transducer, which detects and broadcasts the fetal heart rate to the parents-to-be as well as you.

### **Daily Fetal Movement Count (Kick Counts)**

Fetal movement that can be felt by the mother (quickening) occurs at approximately 18 to 20 weeks of pregnancy and peaks in intensity at 28 to 38 weeks. After that time, a healthy fetus moves with a degree of consistency at about 10 times per hour. In contrast, a fetus who is not receiving enough nutrients because of poor maternal nutrition or placental insufficiency has greatly decreased movements. The technique for “kick counts” varies from institution to institution, but a typical method used is to ask women with high-risk pregnancies to:

- Lie in a left recumbent position after a meal.
- Observe and record the number of fetal movements (kicks) their fetus makes until they have counted 10 movements.
- Record the time (typically, this is under an hour).
- If an hour passes without 10 movements, they should walk around a little and try a count again.
- If 10 movements (kicks) cannot be felt in a second 1-hour period, they should telephone their primary healthcare provider. The fetus could be healthy but sleeping during this time, so lack of typical movements may not be serious, but it is an indication for further assessment.

Kick counts are particularly useful in growth-restricted or postterm pregnancies to reveal if a fetus is still receiving adequate nutrition (Caughey, 2012). Make certain the woman knows fetal movements do vary, especially in relation to sleep cycles, her activity, and the time since she last ate. Otherwise, she can become unduly worried her

fetus is in jeopardy when the fetus is asleep or just having an inactive time.

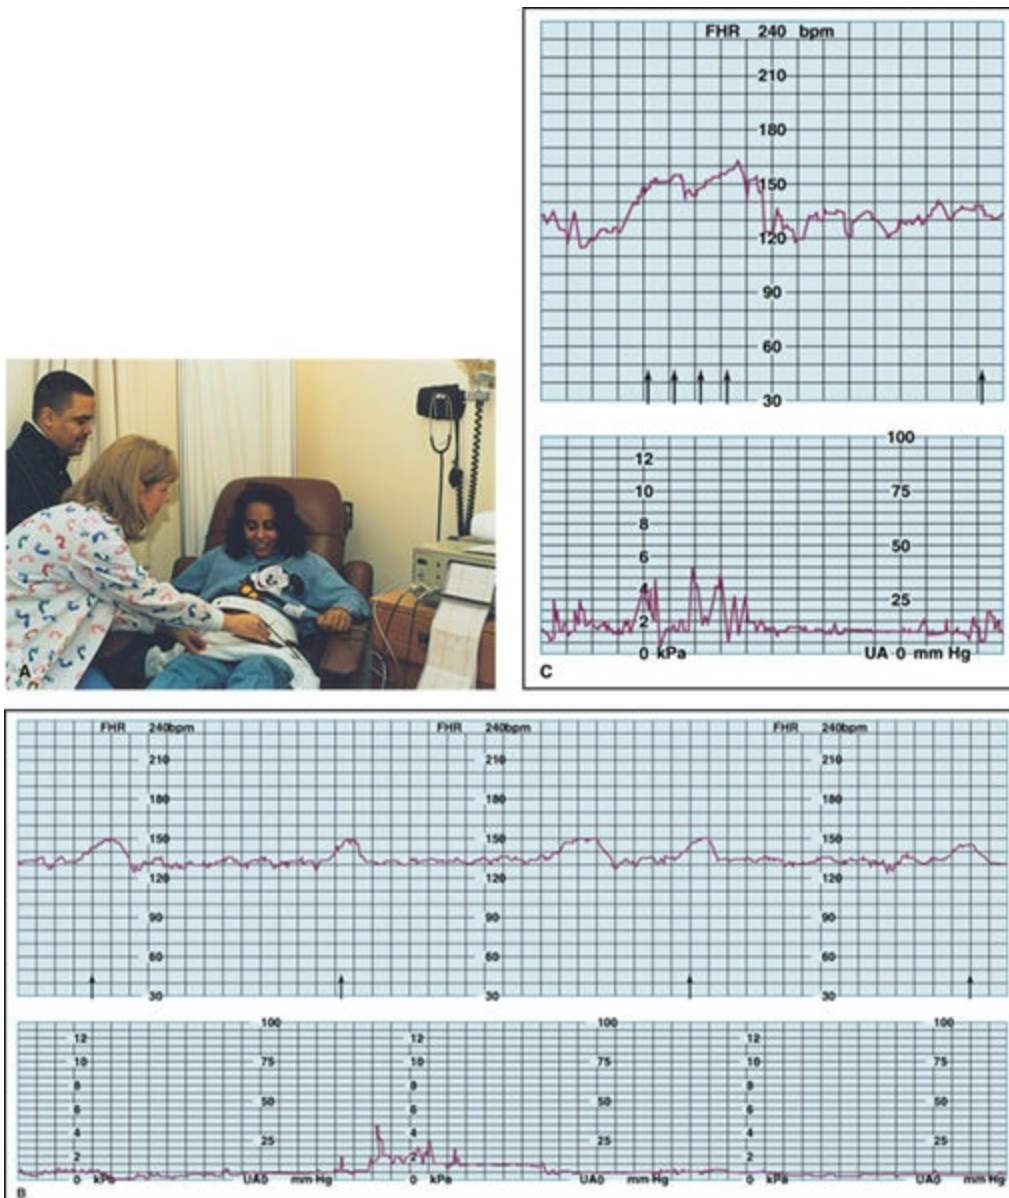

### *What If... 9.3*

**The nurse gives instructions to Liz Calhorn to count fetal movements (count kicks) daily after lunch, and she tells the nurse she can't do that because she snacks all day long rather than eats at regular times. Which would be more important: that she should count kicks after meals or that she do it every day?**

### Rhythm Strip Testing

The term “rhythm strip testing” refers to an assessment of fetal well-being and assesses the fetal heart rate for a normal baseline rate. For this, help the woman into a semi-Fowler’s position (either in a comfortable lounge chair or on an examining table or bed with an elevated backrest) to prevent her uterus from compressing the vena cava and causing supine hypotension syndrome during the test. Attach an external fetal heart rate monitor abdominally ([Fig. 9.10A](#)). Record the fetal heart rate for 20 minutes.

**Figure 9.10** Rhythm strip and nonstress testing of fetal heart rate. **(A)** The woman sits in a comfortable chair to avoid supine hypotension. Both a uterine contraction monitor and fetal heart rate monitor are in place on her abdomen. (Photograph by Melissa Olson, with permission of Chestnut Hill Hospital, Philadelphia, PA.) **(B)** A rhythm strip. The upper strip signifies heart rate; the lower strip indicates uterine activity. *Arrows* signal fetal movement. **(C)** Baseline fetal heart rate on this strip is 130 to 132 beats/min. This strip shows fetal heart rate acceleration in response to fetal movement, shown by arrows. (Photograph by Melissa Olson, with permission of Chestnut Hill Hospital, Philadelphia, PA.)

The baseline reading refers to the average rate of the fetal heartbeat. Variability denotes the small changes in rate that occur from second to second if the fetal

parasympathetic nervous system is receiving adequate oxygen and nutrients. In the rhythm strip in [Figure 9.10B](#), for example, the baseline (average) of the fetal heartbeat is 130 beats/min. Variability is present.

Long-term variability reflects the state of the fetal sympathetic nervous system. On a rhythm strip, it is the differences in heart rate that occur over the 20-minute time period. Note in [Figure 9.10B](#) how the heart rate varies from 150 to 130 beats/min. Because the average fetus moves about twice every 10 minutes, and movement causes the heart rate to increase, there will typically be two or more instances of fetal heart rate acceleration in a 20-minute rhythm strip.

Variability is rated as:

- Absent: No peak-to-trough range is detectable.
- Minimal: An amplitude range is detectable but the rate is 5 beats/min or fewer.
- Moderate or normal: An amplitude range is detectable; rate is 6 to 25 beats/min.
- Marked: An amplitude range is detectable; rate is greater than 25 beats/min ([ACOG, 2009](#)).

Rhythm strip testing requires a woman to remain in a fairly fixed position for 20 minutes. Keep her well informed of the importance and purpose of the test and be certain she understand the meaning of the results after the test. Electronic fetal heart rate recording is further discussed in [Chapter 15](#) as it can also be used to assess fetal well-being at the beginning of labor.

## Nonstress Testing

A **nonstress test** measures the response of the fetal heart rate to fetal movement. Position the woman and attach both a fetal heart rate and a uterine contraction monitor. Instruct the woman to push the button attached to the monitor (similar to a call bell) whenever she feels the fetus move. This will create a dark mark on the paper tracing at these times.

When the fetus moves, the fetal heart rate should increase approximately 15 beats/min and remain elevated for 15 seconds. It should decrease to its average rate again as the fetus quiets ([Fig. 9.10C](#)). If no increase in beats per minute is noticeable on fetal movement, further testing may be necessary to rule out poor oxygen perfusion of the fetus.

A nonstress test usually is done for 20 minutes. The test is said to be reactive (healthy) if two accelerations of fetal heart rate (by 15 beats or more) lasting for 15 seconds occur after movement within the time period. The test is nonreactive (fetal health may be affected) if no accelerations occur with the fetal movements. The results also can be interpreted as nonreactive if no fetal movement occurs or if there is low short-term fetal heart rate variability (less than 6 beats/min) throughout the testing period ([Bienstock, Fox, Wallach, et al., 2015](#)).

If a 20-minute period passes without any fetal movement, it may only mean that the fetus is sleeping, although other reasons for lessened variability are maternal smoking, drug use, or hypoglycemia. Although not evidence based, if you give the woman an oral

carbohydrate snack, such as orange juice, it can cause her blood glucose level to increase enough to cause fetal movement. The fetus also may be stimulated by a loud sound (discussed later) to cause movement.

Because both rhythm strip and nonstress testing are noninvasive procedures and cause no risk to either the pregnant woman or fetus, they can be used as screening procedures in all pregnancies. They can be conducted at home daily as part of a home monitoring program for the woman who is having a complication of pregnancy. If a nonstress test is nonreactive, an additional fetal assessment, such as a biophysical profile test, will be scheduled.

### Vibroacoustic Stimulation

For acoustic (sound) stimulation, a specially designed acoustic stimulator is applied to the mother's abdomen to produce a sharp sound of approximately 80 dB at a frequency of 80 Hz, thus startling and waking the fetus (Bienstock et al., 2015).

During a standard nonstress test, if a spontaneous acceleration has not occurred within 5 minutes, apply a single 1- to 2-second sound stimulation to the lower abdomen. This can be repeated again at the end of 10 minutes if no further spontaneous movement occurs, so two movements within the 20-minute window can be evaluated.

### Ultrasonography

Ultrasonography, which measures the response of sound waves against solid objects, is a much-used tool for fetal health assessments. It can be used to:

- Diagnose pregnancy as early as 6 weeks gestation.
- Confirm the presence, size, and location of the placenta and amniotic fluid.
- Establish a fetus is growing and has no gross anomalies such as hydrocephalus; anencephaly; or spinal cord, heart, kidney, and bladder concerns.
- Establish the sex if a penis is revealed.
- Establish the presentation and position of the fetus.
- Predict gestational age by measurement of the biparietal diameter of the head or crown-to-rump measurement.
- Discover complications of pregnancy, such as the presence of an intrauterine device, hydramnios (excessive amniotic fluid) or oligohydramnios (lessened amniotic fluid), ectopic pregnancy, missed miscarriage, abdominal pregnancy, placenta previa (a low-implanted placenta), premature separation of the placenta, coexisting uterine tumors, or multiple pregnancy. Genetic disorders such as Down syndrome and fetal anomalies such as neural tube disorders, diaphragmatic hernia, or urethral stenosis also can be diagnosed. Fetal death can be revealed by a lack of heartbeat and respiratory movement.
- After birth, a sonogram may be used to detect a retained placenta or poor uterine involution in the new mother.

For an ultrasound, intermittent sound waves of high frequency (above the audible

range) are projected toward the uterus by a transducer placed on the abdomen or in the vagina. The sound frequencies that bounce back from the fetus can be displayed on an oscilloscope screen as a visual image. The frequencies returning from tissues of various thicknesses and properties present distinct appearances. A permanent record can be made of the scan for the woman's electronic health record; a copy of the scan can be offered to her as a baby book souvenir.

Images are so clear that the fetal heart as well as movement of the extremities, such as bringing a hand to the mouth to suck a thumb, can be seen. A parent who is in doubt her fetus is well or whole can be greatly reassured by viewing such a sonogram image.

Before an ultrasound examination, be certain a woman has received a good explanation of what the procedure will be like and reassurance that the process does not involve X-rays and so will be safe for the fetus (Box 9.7). This means it is also safe for the father of the child to remain in the room during the test and see the images as well.

### BOX 9.7

#### Nursing Care Planning Tips for Effective Communication

Liz Calhorn is scheduled for an ultrasound. She is 20 weeks pregnant with her first child. She has been coming to her prenatal visits by herself. She has not missed any scheduled appointments. Liz is healthy and has had no complications thus far with her pregnancy.

*Tip:* Avoid becoming so engrossed in sharing personal feelings that you forget to listen to what the patient is actually saying. Consider what the patient wants and carefully listen for any underlying fears.

**Nurse:** Do you have any questions about what will happen, Liz?

**Liz:** I guess. I can't decide if I want to know my baby's sex or not.

**Nurse:** That's an individual decision. What things are you thinking about?

**Liz:** I think I'd rather be surprised. I know I don't want a boy.

**Nurse:** You don't want a boy?

**Liz:** A guy got me into this trouble. The last thing I need is another one around the house.

**Nurse:** Let's talk about what it will mean if you should have a boy.

The sound waves reflect best if the uterus can be held stable so it is helpful if the woman has a full bladder at the time of the procedure. To ensure this, ask her to drink a full glass of water every 15 minutes beginning 90 minutes before the procedure and to not void until after the procedure.

Help the woman up to an examining table and drape her for modesty, but with her abdomen exposed. To prevent supine hypotension syndrome, place a towel under her right buttock to tip her body slightly so the uterus will roll away from the vena cava. A gel is then applied to her abdomen to improve the contact of the transducer. Be certain

the gel is at room temperature or even slightly warmer or it may cause uncomfortable uterine cramping. The transducer is then applied to her abdomen and moved both horizontally and vertically until the uterus and its contents are fully scanned (Fig. 9.11). Ultrasonography also may be performed using an intravaginal technique, although this is not necessary for routine testing.

**Figure 9.11** A sonogram being recorded. Notice the mother's interest in being able to see her baby's first photograph.

Although the long-term effects of ultrasound are not yet known, the technique appears to be safe for both mother and fetus and causes no discomfort to the fetus. Usually, the only discomfort for the woman is the messiness of the contact lubrication and a strong desire to void before the scan is completed. Taking home a photograph of the sonographic image can enhance bonding because it is proof the pregnancy exists and the fetus appears well. As desirable as it is, however, caution women against having ultrasound images done just for the purpose of having "keepsake" photographs. Commercial firms offering these services are not well regulated, and their equipment may be outdated and unsafe.

In medical practice, a number of specific features are studied by sonogram.

### Biparietal Diameter

Ultrasonography may be used to predict fetal maturity by measuring the biparietal diameter (side-to-side measurement) of the fetal head. In 80% of pregnancies in which the biparietal diameter of the fetal head is 8.5 cm or greater, it can be predicted the infant will weigh more than 2,500 g (5.5 lb) at birth or is at a fetal age of 40 weeks.

**Figure 9.12** is a sonogram showing the biparietal diameter of a fetus at 26 weeks. **Figure 9.13** shows a fetus close to term.

**Figure 9.12** A sonogram at 26 weeks gestation showing measurement of the biparietal diameter. (From Cosby, K. S., & Kendall, J. L. [2014]. *Practical guide to emergency ultrasound* [2nd ed.]. Philadelphia, PA: Wolters Kluwer.)

**Figure 9.13** A sonogram showing a fetus close to term.

## Doppler Umbilical Velocimetry

Doppler ultrasonography measures the velocity at which red blood cells in the uterine and fetal vessels travel. Assessment of the blood flow through uterine blood vessels is helpful to determine the vascular resistance present in women with gestational diabetes or hypertension and whether resultant placental insufficiency is occurring. Decreased velocity is an important predictor that uterine growth restriction will occur because it reveals that only a limited number of nutrients are able to reach the fetus (Kaponis, Harada, Makrydimas, et al., 2011).

### Placental Grading for Maturity

Placentas can be graded by ultrasound based on the particular amount of calcium deposits present in the base. Placentas are graded as:

- 0: between 12 and 24 weeks
- 1: 30 to 32 weeks
- 2: 36 weeks
- 3: 38 weeks (Because fetal lungs are apt to be mature by 38 weeks, a grade 3 placenta suggests the fetus is mature.)

### Amniotic Fluid Volume

The amount of amniotic fluid present is yet another way to estimate fetal health because a portion of the fluid is formed by fetal kidney output. If a fetus is becoming so stressed in utero that circulatory and kidney function is failing, urine output and, consequently, the volume of amniotic fluid will decrease. A decrease in amniotic fluid volume puts the fetus at risk for compression of the umbilical cord with interference of nutrition as well as lack of room to exercise and maintain muscle tone. Between 28 and 40 weeks, the total pockets of amniotic fluid revealed by sonogram average 12 to 15 cm. An amount greater than 20 to 24 cm indicates hydramnios (i.e., excessive fluid, perhaps caused by inability of the fetus to swallow). An amount less than 5 to 6 cm indicates oligohydramnios (i.e., decreased amniotic fluid, perhaps caused by poor perfusion and kidney failure).

### Nuchal Translucency

Children with a number of chromosome anomalies have unusual pockets of fat or fluid present in their posterior neck, which show on sonograms as nuchal translucency. Chromosomal anomalies associated with this are discussed in [Chapter 7](#).

### *QSEN Checkpoint Question 9.5*

#### **Patient-Centered Care**

Liz Calhorn is scheduled to have an ultrasound examination and the nurse wants to ensure that she understands and is prepared for this procedure to mitigate her anxiety. What instruction would the nurse give her before her examination?

- a. “Use the restroom immediately before the procedure to reduce your bladder size.”
- b. “The intravenous fluid used to dilate your uterus does not hurt the fetus.”
- c. “You will need to drink at least three glasses of water before the procedure.”
- d. “You can have medicine for the pain of any contractions caused by the test.”

*Look in Appendix A for the best answer and rationale.*

## Biophysical Profile

A biophysical profile combines five parameters (i.e., fetal reactivity, fetal breathing movements, fetal body movement, fetal tone, and amniotic fluid volume) into one assessment. The fetal heart and breathing record measures short-term central nervous system function; the amniotic fluid volume helps measure long-term adequacy of placental function. The scoring for a complete profile is shown in Table 9.3. By this system, each item has the potential for scoring a 2, so 10 would be the highest score possible. A biophysical profile is more accurate in predicting fetal well-being than any single assessment (Oyelese & Vintzileos, 2011). Because the scoring system is similar to an Apgar score determined at birth on infants, it is often referred to as a fetal Apgar score.

**TABLE 9.3 BIOPHYSICAL PROFILE SCORING**

Assessment	Instrument	Criteria for a Score of 2
Fetal breathing	Sonogram	At least one episode of 30 s of sustained fetal breathing movements within 30 min of observation
Fetal movement	Sonogram	At least three separate episodes of fetal limb or trunk movement within a 30-min observation
Fetal tone	Sonogram	The fetus must extend and then flex the extremities or spine at least once in 30 min.
Amniotic fluid volume	Sonogram	A pocket of amniotic fluid measuring more than 2 cm in vertical diameter must be present
Fetal heart reactivity	Nonstress test	Two or more accelerations of fetal heart rate of 15 beats/min lasting 15 s or more following fetal movements in a 20-min period

Biophysical profiles may be done as often as daily during a high-risk pregnancy. The fetal scores are as follows:

- A score of 8 to 10 means the fetus is considered to be doing well.
- A score of 6 is considered suspicious.
- A score of 4 denotes a fetus potentially in jeopardy.

For simplicity, some centers use only two assessments (amniotic fluid index [AFI]

and a nonstress test) for the analysis. Referred to as a modified biophysical profile, this predicts short-term viability by the nonstress test and long-term viability by the AFI. A healthy fetus should show a reactive nonstress test and an AFI range between 5 and 25 cm (Bienstock et al., 2015). Nurses play a large role in obtaining the information for both a modified and a full biophysical profile by obtaining either the nonstress test or the sonogram reading.

### **Magnetic Resonance Imaging**

Magnetic resonance imaging (MRI) is yet another way to assess a growing fetus. Because the technique apparently causes no harmful effects to the fetus or woman, MRI has the potential to replace or complement ultrasonography as a fetal assessment technique because it can identify structural anomalies or soft tissue disorders (O'Connor, Rooks, & Smith, 2012). An MRI may be most helpful in diagnosing complications such as ectopic pregnancy or trophoblastic disease (see Chapter 21) because later in a pregnancy, fetal movement (unless the fetus is sedated) can obscure the findings.

### **Maternal Serum**

Because a number of trophoblast cells pass into the maternal bloodstream beginning at about the seventh week of pregnancy, maternal serum analysis can reveal information about the pregnant woman as well as the fetus.

#### **Maternal Serum $\alpha$ -Fetoprotein**

AFP is a substance produced by the fetal liver that can be found in both amniotic fluid and maternal serum (maternal serum  $\alpha$ -fetoprotein [MSAFP]). The level is abnormally high if the fetus has an open spinal or abdominal wall defect because the open defect allows more AFP to enter the mother's circulation than usual. Although the reason is unclear, the level is low if the fetus has a chromosomal defect such as Down syndrome. MSAFP levels begin to rise at 11 weeks gestation and then steadily increase until term. Traditionally assessed at the 15th week of pregnancy, between 85% and 90% of neural tube anomalies and 80% of babies with Down syndrome can be detected by this method (Rogers & Worley, 2012).

#### **Maternal Serum for Pregnancy-Associated Plasma Protein A**

Pregnancy-associated plasma protein A (PAPP-A) is a protein secreted by the placenta; low levels in maternal blood are associated with fetal chromosomal anomalies, including trisomies 13, 18, and 21 or small-for-gestational-age (SGA) babies. A high PAPP-A level may predict an LGA baby.

#### **Quadruple Screening**

Quadruple screening analyzes four indicators of fetal health: AFP, unconjugated estriol (UE; an enzyme produced by the placenta that estimates general well-being), hCG (also produced by the placenta), and inhibin A (a protein produced by the placenta and corpus luteum associated with Down syndrome).

As with the measurement of MSAFP, quadruple testing requires only a simple venipuncture of the mother. Because it measures four separate values, it is the most common of the maternal serum tests used today ([Manipalviratn, Trivax, & Huang, 2013](#)).

## Fetal Gender

Although fetal gender is usually determined by an ultrasound screen at about 4 months, it can be determined as early as 7 weeks by analysis of maternal serum. This early diagnosis could be helpful to a woman who has an X-carrying genetic disorder so she could discover if she has a male fetus who could inherit the disease or a female fetus who will be disease-free ([Mortarino, Garagiola, Lotta, et al., 2011](#)). Screening of this type has some ethical connotations because if the fetus is determined to be the “wrong” gender, there could be serious consequences for the now unwanted child.

## Invasive Fetal Testing

If a genetic or growth concern is identified by noninvasive measures, a number of invasive measures allow for more refined investigation. Examples include chorionic villi sampling and amniocentesis (see [Chapter 8](#)).

If the woman has Rh-negative blood, Rho(D) immune globulin (RhIG; RhoGAM) is administered after the procedure to prevent fetal isoimmunization or help ensure maternal antibodies will not form against any placental red blood cells that might have accidentally been released into the maternal bloodstream during the procedure.

Amniotic fluid (obtained through amniocentesis, [Fig. 9.14](#)) can be analyzed for:

- AFP
- Acetylcholinesterase, another compound that rises to high levels if a neural tube anomaly is present
- Bilirubin determination. The presence of bilirubin may be analyzed if a blood incompatibility is suspected. If bilirubin is going to be analyzed, the specimen must be free of blood or a false-positive reading will occur.
- Chromosome analysis. A few fetal skin cells are always present in amniotic fluid so these cells may be cultured and stained for karyotyping for genetic analysis. Examples of genetic diseases that can be detected by prenatal amniocentesis and their significance to health are discussed in [Chapter 7](#).
- Color. Normal amniotic fluid is the color of water; late in pregnancy, it may have a slightly yellow tinge. A strong yellow color suggests a blood incompatibility (the yellow results from the presence of bilirubin released from the breakdown of red blood cells). A green color suggests meconium staining, a phenomenon

associated with fetal distress.

- **Fibronectin.** Fibronectin is a glycoprotein that plays a part in helping the placenta attach to the uterine decidua. Early in pregnancy, it can be assessed in the woman's cervical mucus, but the amount then fades until, after 20 weeks of pregnancy, it is no longer present in cervical mucus. As labor approaches and cervical dilation begins, it can be found again in cervical or vaginal fluid. Damage to fetal membranes from cervical dilatation releases a great deal of the substance, so detection of fibronectin in either the amniotic fluid or in the mother's vagina late in pregnancy can serve as an announcement that preterm labor may be beginning.
- **Inborn errors of metabolism.** A number of inherited diseases that are caused by inborn errors of metabolism can be detected by amniocentesis. For a condition to be identified, an errant enzyme must be present in the amniotic fluid as early as the time of the procedure. Examples of illnesses that can be detected in this way are sickle cell disease, cystic fibrosis, muscular dystrophy, Tay-Sachs disease, and maple syrup urine disease (an amino acid disorder).
- **L/S ratio.** Lecithin and sphingomyelin are the protein components of the lung enzyme surfactant that the alveoli begin to form at the 22nd to 24th weeks of pregnancy. Following an amniocentesis, the L/S ratio may be determined quickly by a shake test (if bubbles appear in the amniotic fluid after shaking, the ratio is mature), but the specimen is then sent for laboratory analysis for a definite analysis. An L/S ratio of 2:1 is traditionally accepted as lung maturity. Infants of mothers with severe diabetes may have false-mature readings of lecithin because stress to the infant in utero tends to mature lecithin pathways early. This means fetal values must be considered in light of the presence of maternal diabetes or the infants may be born with mature lung function but be immature overall (a fragile giant), causing them to not do well in postnatal life ([Hay et al., 2016](#)). Some laboratories interpret a ratio of 2.5:1 or 3:1 as a mature indicator in infants of women with diabetes.
- **Phosphatidylglycerol and desaturated phosphatidylcholine.** These are additional compounds, in addition to lecithin and sphingomyelin, found in surfactant. Pathways for these compounds mature at 35 to 36 weeks. Because they are present only with mature lung function, if they are present in the sample of amniotic fluid, it can be predicted with even greater confidence that respiratory distress syndrome is not likely to occur.

**Figure 9.14** Amniocentesis. A pocket of amniotic fluid is located by sonogram. A small amount of fluid is removed by needle aspiration.

**QSEN Checkpoint Question 9.6**

**QUALITY IMPROVEMENT**

Liz Calhorn is scheduled to have an amniocentesis to test for fetal maturity. To help make sure the procedure is successful, what instruction would be best to give her before this procedure?

- “Void (pee) immediately before the procedure to reduce the size of your bladder.”
- “The X-ray used to reveal your fetus’s position will have no long-term fetal effects.”
- “The IV fluid used to dilate your uterus is isotonic saline so will not hurt the fetus.”

- d. “Your fetus will have less amniotic fluid for the rest of pregnancy, but that’s all right.”

*Look in [Appendix A](#) for the best answer and rationale.*

## Percutaneous Umbilical Blood Sampling

Percutaneous umbilical blood sampling (PUBS; also called cordocentesis or funicentesis) is the aspiration of blood from the umbilical vein for analysis. After the umbilical cord is located by sonography, a thin needle is inserted by amniocentesis technique into the uterus and is then guided by ultrasound until it pierces the umbilical vein. A sample of blood is then removed for blood studies, such as a complete blood count, direct Coombs test, blood gases, and karyotyping. To ensure the blood obtained is fetal blood, it is submitted to a Kleihauer–Betke test, which measures the difference between adult and fetal hemoglobin. If a PUBS test reveals that the fetus is anemic, blood may be transfused into the cord using this same technique. Because the umbilical vein continues to ooze for a moment after the procedure, there is a high chance fetal blood could enter the maternal circulation after the procedure, so RhIG is given to Rh-negative women to prevent sensitization. Fetal heart rate and uterine contractions need to be monitored before and after the procedure to be certain uterine contractions are not beginning and also by ultrasound to be certain no bleeding is evident. This procedure carries little additional risk to the fetus or woman over amniocentesis and can yield information not available by any other means, especially about blood dyscrasias.

## Fetoscopy

The use of a **fetoscopy**, in which the fetus is visualized by inspection through a fetoscope (an extremely narrow, hollow tube inserted by amniocentesis technique), can be yet another way to assess fetal well-being. This method allows direct visualization of both the amniotic fluid and the fetus ([Richter, Wergeland, DeKoninck, et al., 2012](#)). If a photograph is taken through the fetoscope, it can document a problem or reassure parents that their infant is perfectly formed. The main reasons the procedure is used are to:

- Confirm the intactness of the spinal column.
- Obtain biopsy samples of fetal tissue and fetal blood samples.
- Determine meconium staining is not present.
- Perform elemental surgery, such as inserting a polyethylene shunt into the fetal ventricles to relieve hydrocephalus or anteriorly into the fetal bladder to relieve a stenosed urethra. It may be possible to repair a neural tube defect such as meningocele or improve the outcome of myelomeningocele by fetoscopy ([Danzer, Johnson, & Adzick, 2012](#)).

The earliest time in pregnancy a fetoscopy can be performed is approximately the 16th or 17th week. For the procedure, the mother is draped as for amniocentesis. A local anesthetic is injected into the abdominal skin. The fetoscope is then inserted through a

minor abdominal incision. If the fetus is very active, meperidine (Demerol) may be administered to the woman to help sedate the fetus to avoid fetal injury by the scope and allow for better observation.

A fetoscopy carries a small risk of premature labor or amnionitis (infection of the amniotic fluid). To avoid infection, the woman may be prescribed antibiotic therapy after the procedure. The number of procedures performed by a fetoscopy is limited because of the manipulation involved and the ethical quandary of the mother's autonomy being compromised by fetal needs if further procedures are necessary such as asking the pregnant woman to undergo general anesthesia so the fetus can have surgery.

## Women With Unique Needs or Concerns

Fetal assessment can be more difficult in some women than others. For example, it is more difficult to hear fetal heart sounds in a morbidly obese woman. If the straps for fetal heart rate monitors are not long enough to circle a woman's abdomen, they may need to be held in place manually. If a woman is not easily mobile, she can have difficulty obtaining a clean catch urine for protein and glucose testing. Be ready to assist in these circumstances as needed.

Women who are wheelchair challenged can remain in their wheelchair for fetal heart rate monitoring. All individuals who use wheelchairs need to periodically press on the armrests with their hands and raise their buttocks off the seat of the wheelchair to help prevent pressure ulcers as the danger of ulcers increases with pregnancy because of the added weight. During a lengthy test, a woman may need to take a break to stretch; mark the break on a rhythm strip so a sudden corresponding fetal movement on the strip is not misinterpreted.

Remember that women who are hearing challenged will not be able to hear their baby's heartbeat by Doppler assessment. Observing a rhythm strip is a better method to prove to them their fetus appears healthy. In contrast, a woman who is visually impaired would be most assured by listening to the beeping of a Doppler rather than the blurry outlines (for her) of a rhythm strip. Women with special needs are further discussed in [Chapter 22](#). Assess each woman individually to be certain each has obtained and understands the results of fetal assessments accurately and doesn't have continuing questions about her baby's health.

### *What If . . . 9.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals in respect to fetal health (see [Box 9.1](#)). What would be a possible research topic to explore pertinent to this goal that would be applicable to Liz and her family and also advance evidence-based practice?**

## Unfolding Patient Stories: Brenda Patton • Part 1

**Brenda Patton** is 18 years old at 24 weeks gestation with her first child. During the prenatal visit, what questions would the nurse ask to evaluate fetal well-being? What factors can interfere with normal growth and development of the fetus? Describe the assessments the nurse performs to monitor fetal growth and development. (Brenda Patton's story continues in [Chapter 22](#).)

Care for Brenda and other patients in a realistic virtual environment: *vSim for Nursing* ([thepoint.lww.com/vSimMaternityPed](http://thepoint.lww.com/vSimMaternityPed)). Practice documenting these patients' care in DocuCare ([thepoint.lww.com/DocuCareEHR](http://thepoint.lww.com/DocuCareEHR)).

### KEY POINTS FOR REVIEW

- Being aware of healthy fetal growth helps in planning nursing care that not only meets Quality & Safety Education for Nurses (QSEN) competencies but also best meets a family's need for health teaching.
- The union of a single sperm and egg (fertilization) signals the beginning of pregnancy.
- The fertilized ovum (zygote) travels by way of a fallopian tube to the uterus, where implantation takes place in about 8 days.
- From implantation to 5 to 8 weeks, the growing structure is called an embryo. The period after 8 weeks until birth is the fetal period.
- Growth of the umbilical cord, amniotic fluid, and amniotic membranes proceeds in concert with fetal growth. The placenta produces a number of important hormones: estrogen, progesterone, hPL, and hCG.
- Various methods to assess fetal growth and development include fundal height, fetal movement, fetal heart tones, ultrasonography, MRI, MSAFP, amniocentesis, PUBS, quadruple screening, and fetoscopy.
- A biophysical profile is a combination of fetal assessments that predicts fetal well-being better than measuring single parameters.

### CRITICAL THINKING CARE STUDY

Maeve is a 35-year-old woman who is about 3 months pregnant. She recently broke her fibula in a touch football game and so has her leg encased in a midcalf level cast. It's not a walking cast, so she will be using a wheelchair for the next 6 weeks. She's worried she'll gain too much weight because she's no longer active. Because she's not sure of the date of her last menstrual period, she'd like a sonogram done to date her pregnancy. She asks if that can be done with her in a wheelchair.

1. How would you answer Maeve's question about using her wheelchair for a sonogram?

2. What other special considerations does Maeve need with regard to fetal health because she uses a wheelchair?
3. Maeve asks you if her baby has hair yet. That's important to her because if her baby is a boy she doesn't want him to be as bald as her husband, who at 36, has already lost most of his hair.

## Nursing Care Related to Psychological and Physiologic Changes of Pregnancy

*Lauren Maxwell is a part-time model who has come to your clinic for her first prenatal visit. She has a 3-year-old at home. She tells you she missed her period 4 weeks ago and immediately took a home pregnancy test. She's happy it was positive but also sad because she had to turn down a modeling assignment in Paris for the summer. "I want to have a second child," she explains, "Just not so soon." You suspect she's also anxious because she says, "I know there's no turning back but what will a second child do to my career?" She adds her husband, John, doesn't seem a bit worried. "Is that a good thing or not?" she asks. She also seems concerned about being a good parent as she says, "I'd die if I turn into the same kind of parent as my mother."*

*In addition to the positive home pregnancy test, Lauren presents with amenorrhea, breast tenderness, fatigue, and morning sickness. She's interested in learning when she will begin to look pregnant and what she can do for the morning sickness.*

*Previous chapters discussed reproductive anatomy and physiology. This chapter adds information about the physiologic and psychological changes that occur in both a woman and her partner during pregnancy. Knowing such information can help you protect the health of a family and a fetus for the next 9 months.*

**What psychological development tasks of pregnancy does Lauren need to complete? Should you assure her that her worry about being a good parent is unfounded?**

### KEY TERMS

**ballottement**

**Braxton Hicks contractions**

**Chadwick's sign**

**couvade syndrome**

**diastasis**

**Goodell's sign**

**Hegar's sign**  
**lightening**  
**linea nigra**  
**melasma**  
**Montgomery's tubercles**  
**multipara**  
**operculum**  
**polyuria**  
**primigravida**  
**quickenning**  
**striae gravidarum**

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe common psychological and physiologic changes that occur with pregnancy and the relationship of the changes to pregnancy diagnosis.
2. Identify 2020 National Health Goals related to preconception counseling and prenatal care that nurses can help the nation achieve.
3. Assess a woman and her support team for psychological adjustment to the physiologic changes that occur with pregnancy.
4. Formulate nursing diagnoses related to adjustments necessary because of psychological and physiologic changes of pregnancy.
5. Identify expected outcomes in relation to a family's psychological and physical adaptation to pregnancy to help them manage seamless transitions across differing healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care, such as health teaching related to the expected changes of pregnancy.
8. Evaluate outcomes for achievement and effectiveness of goals to be certain expected outcomes have been achieved.
9. Integrate knowledge of psychological and physiologic changes of pregnancy with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

Patients are often interested in learning more about the physical or psychological changes that pregnancy brings because these changes both verify the reality and mark

the progress of pregnancy.

Physiologic changes of pregnancy occur gradually but eventually affect all of a woman's organ systems. They are necessary changes because they allow a woman's body to be able to provide oxygen and nutrients for her growing fetus as well as extra nutrients for her own increased metabolism. They also ready her body for labor and birth and for lactation (breastfeeding) once her baby is born (Bernstein & VanBuren, 2013). Despite the magnitude of these changes, such as a woman's blood volume doubling in amount, they are all extensions of normal physiology. At the end of pregnancy, her body will virtually return to its prepregnant state.

Psychological changes of pregnancy occur in response not only to the physiologic alterations happening but also to the increased responsibility associated with welcoming a new and completely dependent person to a family.

Because pregnancy changes are extensions of normal psychological and physiologic baselines, pregnancy represents a time of wellness, not of illness. A major responsibility for nurses caring for pregnant women and their families is to help the family maintain a feeling of wellness throughout the pregnancy and into early parenthood (Rogers & Worley, 2016). Box 10.1 shows 2020 National Health Goals relevant to these changes that come with pregnancy.

#### BOX 10.1

#### Nursing Care Planning Based on 2020 National Health Goals

A number of 2020 National Health Goals speak to the care necessary because of physiologic and psychological changes of pregnancy:

- Increase abstinence from alcohol, cigarettes, and illicit drugs among pregnant women from baselines of 89.4%, 89.6%, and 94.9% to target levels of 98.4%, 98.6%, and 100%.
- Reduce maternal deaths from a baseline of 12.7/100,000 live births to a target of 11.4/100,000.
- Increase the proportion of pregnant women who receive early and adequate prenatal care from a baseline of 70.5% to a target level of 77.6% (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these objectives by being certain women receive counseling in nutrition, safer sex practices, and low uses of alcohol and tobacco before pregnancy so they can enter intended pregnancies in the best health possible.

### *Nursing Process Overview*

#### FOR HEALTHY ADAPTATION TO PREGNANCY

##### **ASSESSMENT**

Ideally, assessment for pregnancy begins before the pregnancy with preconception counseling. During a preconception assessment, evaluate a woman's overall health

status, nutritional intake (ask specifically about sufficient intake of folic acid and protein), and lifestyle (especially drinking, smoking, and recreational drug habits); identify any potential problems (such as a risk for ectopic pregnancy because of tubal scarring); and identify a woman's understanding and expectations of conception, pregnancy, and parenthood.

In early pregnancy, be certain you establish a trusting relationship with a woman so she will see you as a person who is capable of counseling her and helping her solve problems and in whom she will be able to confide about any worries she has. Continue to assess a woman's health and nutritional status as well as the well-being of her fetus at all prenatal visits. Physical changes can be learned through health history, physical assessment, and laboratory tests. An assessment in psychological areas is obtained primarily through interviewing and should include societal, cultural, family, and personal influences as a woman adapts to pregnancy.

### **NURSING DIAGNOSIS**

Examples of nursing diagnoses involving the changes that occur with pregnancy include:

- Altered breathing patterns related to respiratory system changes of pregnancy
- Disturbed body image related to weight gain from pregnancy
- Deficient knowledge related to normal changes of pregnancy
- Imbalanced nutrition, less than body requirements, related to early morning nausea
- Powerlessness related to unintended pregnancy
- Possible impaired health and prenatal care behaviors associated with cultural beliefs

### **OUTCOME IDENTIFICATION AND PLANNING**

Planning nursing care in connection with the physiologic and psychological changes of pregnancy should involve a plan to review the common concerns women have about being pregnant before changes occur, so there are no surprises. Refer patients to helpful websites and other resources when appropriate (see [Chapter 9](#)).

### **IMPLEMENTATION**

Most women of childbearing age have a mental picture of themselves or a good idea of how they will look in a dress before they try it on. They participate in sports or other activities that conform to that self-image. Then, in a span of 9 months, they gain 25 to 30 lb and their figure changes so drastically that their prepregnancy clothes may no longer fit. At the beginning of a pregnancy, a woman may feel constantly nauseated; toward the end, the extra weight and the strain of waiting may make her feel tired and short of breath. Endocrine changes can make her feel moody and quick to cry.

Help women at prenatal visits to voice their concerns about the changes happening to them so any worry brought on by these changes does not lead to a stressful 9 months for them or prevent solid bonding with their baby.

## OUTCOME EVALUATION

Evaluation should determine whether a woman has really “heard” your teaching. Remember that people under stress do not always comprehend well, so it is not unusual for a woman who is worried about her pregnancy to pocket away information, thinking, “I’ll concentrate on that when it happens to me, not now.” Then, when a particular change does happen, she realizes she has forgotten what you said. Examples of outcome criteria you might strive for include:

- Patient states she is able to continue her usual lifestyle throughout pregnancy.
- Family members describe ways they have adjusted their lifestyles to accommodate the mother’s fatigue.
- Couple states they appreciate the physiologic changes of pregnancy and even though they are causing discomfort, they know these are healthy changes.

## Psychological Changes of Pregnancy

Pregnancy is such a huge change in a woman’s life; it brings about more psychological changes than any other life event besides puberty (Fletcher & Russo, 2015). How a woman adjusts to a pregnancy depends a great deal on psychological aspects, such as the environment in which she was raised, the messages about pregnancy her family communicated to her as a child, the society and culture in which she lives as an adult, and whether the pregnancy has come at a good time in her life (Silveira, Ertel, Dole, et al., 2015).

For many women, a prenatal visit is the first time they have seen a healthcare provider since childhood. Guidance given during this time can be instrumental in not only guiding a woman safely through a pregnancy but also connecting her back with ongoing health care.

## SOCIAL INFLUENCES

From the first part of the 20th century until about the 1960s, there was such heavy emphasis on medical management for women during pregnancy that it conveyed the idea that pregnancy was a 9-month-long illness. The pregnant woman went alone to a physician’s office for care; at the time of birth, she was separated from her family, hospitalized in seclusion from visitors, and even from the new baby for 1 week afterward so the newborn could be fed by nurses.

Today, pregnancy is viewed as a healthy span of time best shared with a supportive partner and/or family. Women bring their families for prenatal care visits as well as to watch the birth. Women choose what level of pain management they want to use for labor and birth; many women choose to breastfeed their newborn.

How well a pregnant woman and her partner feel during pregnancy and are prepared to meet the challenges this new responsibility brings is related to their cultural background, their personal beliefs, the experiences reported by friends and relatives, as

well as by the current plethora of information available on the Internet. Nurses play an important role in teaching women about their healthcare options as well as continuing to work with other healthcare providers to “demedicalize” or humanize childbirth (Heatley, Watson, Gallois, et al., 2015).

## CULTURAL INFLUENCES

A woman’s cultural background may strongly influence how active a role she wants to take in her pregnancy because certain beliefs and taboos can place restrictions on her behavior and activities (Guelfi, Wang, Dimmock, et al., 2015). To learn about the beliefs of a particular woman and her partner, ask at prenatal visits if there is anything the couple believes should or should not be done to make the pregnancy successful and keep the fetus healthy. Supporting these beliefs shows respect for the individuality of a woman and her knowledge of good health (Box 10.2).

### BOX 10.2

#### Nursing Care Planning to Respect Cultural Diversity

Women react differently on realizing they are pregnant based on their individual circumstances and their cultural expectations.

Women eat different foods during pregnancy based on what they perceive will be “good” or “bad” for their infant. Assess women’s intake carefully to be certain a particular woman is not eating nonfood substances such as ice cubes or raw flour, for instance (called pica), during pregnancy. These habits result from a woman entering pregnancy with low iron stores so iron-deficient anemia results. Cravings such as ice cubes are harmless to a fetus, but asking about pica can reveal women eating substances such as paint chips or sniffing gasoline, which could be harmful to fetal growth.

Before evidence-based practice was available to scientifically support why pregnancy brought about changes in a woman’s body, different societies devised differing explanations about why changes occurred. These myths became so well engrained in cultures that some persist to the present. For example, a belief that lifting your arms over your head during pregnancy will cause the cord to twist or that watching a lunar eclipse will cause a birth deformity are still believed by women in some cultures (Lauderdale, 2016). Find a compromise that will assure a woman that these are not really harmful to a fetus but that still respects these beliefs.

## FAMILY INFLUENCES

The family in which a woman was raised can be influential to her beliefs about pregnancy because it is part of her cultural environment. If she and her siblings were loved and their births were seen as a pleasant outcome of their family, she is more likely

to have a positive attitude toward learning she is pregnant than if she and her siblings were blamed for the breakup of a marriage or a relationship, for example. A woman who views mothering as a positive activity is more likely to be pleased when she becomes pregnant than one who does not value mothering.

## INDIVIDUAL DIFFERENCES

A woman's ability to cope with or adapt to stress plays a major role in how she can resolve any conflict she feels at becoming a mother. This ability to adapt (e.g., to being a mother without needing mothering, to loving a child as well as a partner, to becoming a mother for each new child) depends, in part, on her basic temperament, on whether she adapts to new situations quickly or slowly, on whether she faces them with intensity or maintains a low-key approach, and on whether she has had experience coping with change and stress (Guedes & Canavarro, 2014).

The extent to which a woman feels secure in her relationship with the people around her, especially the father of her child or her chief support person, is usually also important to her acceptance of a pregnancy. Anxiety as to whether her partner may soon disappear, leaving her alone to raise a child, may make her reexamine whether her pregnancy is a wise life step.

Yet another influence on how women perceive pregnancy as a positive or negative experience is past experiences (Muzik, McGinnis, Bocknek, et al., 2016). A woman who thinks of brides as young but mothers as old may believe pregnancy will rob her of her youth. If she's concerned about her appearance, she may worry pregnancy will permanently stretch her abdomen and breasts. She may also worry pregnancy will rob her financially and ruin her chances of job promotion (referred to as a "mommy track") (Misri & Swift, 2015).

These are real feelings and must be taken seriously when assessing or counseling pregnant women. Women who do not have a supportive partner may look to healthcare providers during pregnancy to fill the role of an attentive listener (Adeniran, Aboyeji, Fawole, et al., 2015).

### Partner's Adaptation

The more emotionally attached a partner is to a pregnant woman, the closer the partner's attachment is apt to be to the child (Fuentes, Faria, Beeghly, et al., 2016). Whether partners are able to form a close relationship with each other, as well as accept a pregnancy and a coming child, depends on the same factors that affect the pregnant woman's decision making: cultural background, past experience, and relationships with family members (Fortinash & Holoday Worret, 2012).

Although partners may be inarticulate about such emotional factors, they may be able to convey such feelings by a touch or a caress, which is one reason a partner's presence is always desirable at a prenatal visit and certainly in a birthing room.

## The Psychological Tasks of Pregnancy

During the 9 months of pregnancy, a woman and her partner run a gamut of emotions, ranging from surprise at finding out about the pregnancy (or wishing she were not), to pleasure and acceptance as they begin to identify with the coming child at the middle of pregnancy, to worry for themselves and the child, to acute impatience near the end of pregnancy (Table 10.1). Once the child is born, a woman and her partner may feel surprised again that the pregnancy is over and they really do have a child.

**TABLE 10.1 COMMON PSYCHOLOGICAL CHANGES THAT OCCUR WITH PREGNANCY**

Psychological Change	Description
First trimester task: Accepting the pregnancy	The woman and her partner both spend time recovering from the surprise of learning they are pregnant and concentrate on what it feels like to be pregnant. A common reaction is ambivalence, or feeling both pleased and not pleased about the pregnancy.
Second trimester task: Accepting the fetus	The woman and her partner move through emotions such as narcissism and introversion as they concentrate on what it will feel like to be a parent. Role-playing and increased dreaming are common.
Third trimester task: Preparing for the baby and end of pregnancy	The woman and her partner prepare clothing and sleeping arrangements for the baby but also grow impatient as they ready themselves for birth.

From a physiologic standpoint, it is fortunate that a pregnancy is 9 months long because this gives the fetus time to mature and be prepared for life outside the protective uterine environment. From a psychological standpoint, the 9-month period is also fortunate because it gives a family time to prepare emotionally as well. These psychological changes are frequently termed “guaranteeing safe passage” for the fetus (Box 10.3).

### BOX 10.3

#### Nursing Care Planning Tips for Effective Communication

You have seen Lauren Maxwell in your prenatal clinic every month for the last 3 months. At visits, she answers questions but rarely volunteers any information. You’d like her to talk more about how she feels about her pregnancy and her plans for the

new baby.

*Tip:* Focus on the patient's concerns, allowing her to express them fully. Avoid cutting off the conversation by talking too much about your own needs and expectations. Some people are naturally shy and are not interested in casual conversations at healthcare visits. Others are not talkative because they are not aware healthcare providers are interested in them as individuals.

**Nurse:** Good morning. Lauren. How are you today?

**Lauren:** Tired.

**Nurse:** Tell me about that.

**Lauren:** I am so tired by noon every day I can't get any work done. I should never have gotten pregnant.

**Nurse:** You're so tired you can barely get your work done?

**Lauren:** No one in our financial situation should be having a baby.

Although the average woman is happy to be pregnant, don't underestimate the effect the emotional and physical upheavals brought about by the hormonal changes of pregnancy can cause. These can be so tremendous that they can influence whether a pregnancy is carried to term, which may not only lead to poor acceptance of the child but also to postpartum depression or, in rare instances, psychosis (Biaggi, Conroy, Pawlby, et al., 2016; Lilliecreutz, Larén, Sydsjö, et al., 2016).

## FIRST TRIMESTER: ACCEPTING THE PREGNANCY

### The Woman

The task of women during the first trimester of pregnancy is to accept the reality of the pregnancy; later will come the task of accepting the baby. Most cultures structure celebrations around important life events such as coming of age, marriages, birthdays, and deaths, all of which have rituals to help individuals face and accept the coming change in their lives. A diagnosis of pregnancy is a similar rite of passage, but an unusual one among passages, because the suspicion of pregnancy is made initially not on something happening but the absence of something: a missed menstrual flow.

With the availability and common use of reproductive planning measures today, it would seem few pregnancies would still be a surprise. In reality, as many as 49% of pregnancies are still unintended, unwanted, or mistimed (Centers for Disease Control and Prevention [CDC], 2015). Because no woman can be absolutely confident in advance that she will be able to conceive until it happens, even planned pregnancies are a surprise to some extent because a woman can be amazed it either happened so quickly or took so long.

### *QSEN Checkpoint Question 10.1*

## EVIDENCE-BASED PRACTICE

How women feel about being pregnant has a great deal to do with how anxious they are about becoming pregnant. To investigate whether women look forward to a second birth or whether anxiety about their first birth makes them reluctant to have a second child, researchers interviewed 908 women who had given birth to at least one child, asking them to “please describe your feelings when you think about giving birth in the future.”

Results showed that two thirds of women who responded had mostly positive feelings; one third of women stated they were frightened of future childbirth. The qualitative analysis resulted in an overall theme of women feeling a mixture of both dread and delight at the thought of a second pregnancy (Rilby, Jansson, Lindblom, et al., 2012).

Based on the previous study, which statement by Lauren would make the nurse believe she’s having a typical reaction to her second pregnancy?

- a. “I’m feeling good about having a second baby, but a bit worried at the same time.”
- b. “I think having a second child is going to be totally wonderful. I’m sure it will be so much easier.”
- c. “I’m really looking forward to watching my two children play together in the future.”
- d. “I’d rather my husband had this one; knowing what it all involves makes it even harder.”

---

Look in [Appendix A](#) for the best answer and rationale.

Following their initial surprise, women often experience feelings less than pleasure and closer to anxiety or a feeling of *ambivalence*. Ambivalence doesn’t mean positive feelings counteract negative feelings and a woman is left feeling nothing. Instead, it refers to the interwoven feelings of wanting and not wanting, feelings which can be confusing to an ordinarily organized woman.

Fortunately, most women who were not happy about being pregnant at the beginning are able to change their attitude toward their pregnancy by the time they feel the child move inside them. Some healthcare plans provide for a routine sonogram at about this time in pregnancy, between 18 and 22 weeks, to date the pregnancy and to assess for growth anomalies. This can be a major step in promoting acceptance because women can see a beating heart or a fetal outline or can learn the sex of their fetus (Lindberg, Maddow-Zimet, Kost, et al., 2015).

Although most women self-diagnose their pregnancy by using a urine pregnancy test strip, hearing their pregnancy officially diagnosed at a first prenatal visit is another step toward accepting a pregnancy. Because this happens, woman often comment after such a visit they feel “more pregnant” or it makes a first visit more than an ordinary one. Early diagnosis is important because the earlier a woman realizes she is pregnant or comes for a first prenatal visit, the sooner she can begin to safeguard fetal health by measures such as discontinuing all drugs not specifically prescribed or approved by her

primary healthcare provider (Chakraborty, Anstice, Jacobs, et al., 2015).

## The Partner

In the past, partners were forgotten persons in the childbearing process. Unwed fathers were dismissed as not interested in either the pregnancy or the woman's health. A female partner was completely ignored. In actuality, all partners are important and should be encouraged to play a continuing emotional and supportive role in a pregnancy.

Accepting the pregnancy for a partner means not only accepting the certainty of the pregnancy and the reality of the child to come but also accepting the woman in her changed state. Like women, partners may also experience a feeling of ambivalence. A partner may feel proud and happy at the beginning of pregnancy, for example. Soon, however, it's easy to begin to feel both overwhelmed with what the loss of a salary will mean to the family if the woman has to quit work, and a feeling close to jealousy of the growing baby who, although not yet physically apparent, seems to be taking up a great deal of the woman's time and thought (Da Costa, Zelkowitz, Dasgupta, et al., 2015). Remember, once partners feel an attachment to a coming child, they can then feel as deep a sense of loss as the woman if the pregnancy should end before term or the baby is born with a unique concern. In addition, they may not have anyone to turn to for support because no one recognizes how involved they were in the pregnancy. To help both male and female partners resolve these feelings, be certain to make partners feel welcome at prenatal visits or during fetal testing, provide an outlet for them to discuss concerns, and offer parenting information as necessary.

### *QSEN Checkpoint Question 10.2*

#### **QUALITY IMPROVEMENT**

Lauren wasn't totally happy about learning that she was pregnant. What psychological task is important for the woman to complete during the first trimester of her pregnancy?

- a. Accepting morning sickness nausea
- b. Accepting the fact that she is pregnant
- c. Appreciating the responsibility of having a baby
- d. Choosing a name for her baby

*Look in Appendix A for the best answer and rationale.*

## **SECOND TRIMESTER: ACCEPTING THE BABY**

As soon as fetal movements can be felt, psychological responses of both partners usually begin to change.

## The Woman

During the second trimester, the psychological task of a woman is to accept she is having a baby, a step up from accepting the pregnancy. This change usually happens at **quickening**, or the first moment a woman feels fetal movement. Until a woman experiences for herself this proof of the child's existence and although she ate to meet nutritional needs and took special vitamins to help the fetus grow, it seemed more like just another part of her body. With quickening, the fetus becomes a separate identity. She then may imagine herself as a mother, teaching her child the alphabet or how to ride a bicycle. This anticipatory role-playing is an important activity for midpregnancy as it leads her to a greater concept of her condition and helps her realize she is more than just pregnant—there is a separate human being inside her.

Women often use the term “it” to refer to their fetus before quickening but begin to use *he* or *she* afterward. Some women continue to use *it*, however, so doing so is not a sign of poor attachment but an individual preference as some women believe referring to the child as “she” or “he” will bring bad luck or disappointment if the sonogram report was wrong.

Most women can pinpoint a moment during each pregnancy when they knew definitely they wanted their child. The firmer this attachment, the less postpartum depression they are apt to experience ([Brummelte & Galea, 2015](#)).

For a woman who carefully planned the pregnancy, this moment of awareness may occur as soon as she recovers from the surprise of learning she has actually conceived. For others, it may come when she announces the news to her parents and hears them express their excitement or when she sees a look of pride on her partner's face. For example, shopping for baby clothes for the first time, setting up the crib, or seeing a blurry outline on a sonogram screen may suddenly make the coming baby seem real and desired ([Fig. 10.1](#)).

**Figure 10.1** A growing abdomen and fluttering fetal movements help to make a pregnancy a reality.

Accepting the baby as a welcome addition to the family might not come, however, until labor has begun or a woman first hears her baby's cry or feeds her newborn. If a woman has a complication of pregnancy, it could take several weeks after the baby is born for her to accept that the birth was real and to come to terms with motherhood.

A good way to measure the level of a woman's acceptance of her coming baby is to measure how well she follows prenatal instructions. Until a woman views the growing life inside her as something desired, it may be difficult for her to substitute a high-protein food for her favorite high-calorie coffee drink, for instance. After all, until her abdomen begins to enlarge, watching herself gain weight may be the most certain proof she has that she is pregnant.

### **The Partner**

As a woman begins to actively prepare for the coming baby, a partner increasingly may feel as if he or she is left standing in the wings, waiting to be asked to take part in the event. To compensate for this feeling, a partner may become overly absorbed in work, striving to produce something concrete on the job as if to show the woman is not the

only one capable of creating something. This preoccupation with work may limit the amount of time a partner spends with family or is available for prenatal visits, just when the pregnant woman most needs emotional support.

Some men may have difficulty enjoying the pregnancy because they have been misinformed about sexuality, pregnancy, and women's health. A man might believe, for example, that breastfeeding will make his wife's breasts no longer attractive or that after birth, sexual relations will no longer be enjoyable. Such a man needs education to correct misinformation. Read the pamphlets supplied by your prenatal healthcare setting and ask: Do they contain mainly information about childbirth and pregnancy from a woman's perspective? Would they be relevant to a supportive partner?

### *What If... 10.1*

**Lauren repeats to the nurse she “would die” if she thought she might become the same type of parent as her mother. Her husband is not worried about his ability to be a father. How would it change the nurse’s assessment and any patient education the nurse might provide if he felt the same way as her?**

## **THIRD TRIMESTER: PREPARING FOR PARENTHOOD**

During the third trimester, couples usually begin “nest-building” activities, such as planning the infant's sleeping arrangements, choosing a name for the infant, and “ensuring safe passage” by learning about birth. These preparations are evidence the couple is completing the third trimester task of pregnancy or preparing for parenthood.

Couples at this point are usually interested in attending prenatal classes and/or classes on preparing for childbirth. It's helpful to ask a couple what specifically they are doing to get ready for birth to see if they are interested in taking such a class and to document how well prepared they will be for the baby's arrival. Attending a childbirth education class or one on preparing for parenthood can not only help a couple accept the fact they are about to become parents but also expose them to other parents as role models who can provide practical information about pregnancy and child care (Jones, Feinberg, & Hostetler, 2014). Chapter 14 discusses the usual curriculum of childbirth and parenthood education classes.

Although pregnancy is a happy time for most women, certain external life contingencies such as an unwanted pregnancy, financial difficulties, lack of emotional support, or high levels of stress can slow the psychological work of pregnancy or attachment to the child (Biaggi et al., 2016) (Box 10.4). During prenatal visits, ask such questions as “Is pregnancy what you thought it would be?” or “Has anything changed in your home life since you last came to clinic?” to reveal if any situation that could potentially interfere with bonding has occurred. It is unrealistic to believe any one healthcare professional has all the solutions to the problems couples reveal when asked

these questions. An interprofessional approach (referral to a nutritionist, a primary healthcare provider, or social services) is often necessary to help solve some of these multifaceted problems.

#### BOX 10.4

### Assessing Events That Could Contribute to Difficulty Accepting a Pregnancy

- Pregnancy is unintended.
- Learning the pregnancy is a multiple, not a single one.
- Learning the fetus has a developmental abnormality.
- Pregnancy is less than 1 year after a previous one.
- Family has to relocate during pregnancy (involves a need to find new support people).
- The woman has a role reversal (a previously supporting person becomes dependent or vice versa).
- The main family support person suffers a job loss.
- The woman's relationship ends because of partner infidelity.
- There is a major illness in self, partner, or a relative.
- There is loss of a significant other.
- Complications of pregnancy occur, such as severe hypertension.
- The woman has a series of devaluing experiences such as failure in school or work.

## ADDITIONAL PREPARATION WORK TO COMPLETE IN PREGNANCY

In addition to the three main tasks of pregnancy, more subtle emotions also surface or need to be worked through.

### Reworking Developmental Tasks

An important task to complete during pregnancy is working through previous life experiences or Erikson's developmental tasks of autonomy, industry, and identity (Erikson, 1993). Needs and wishes that have been repressed for years may surface to be studied and reworked, often to an extreme extent along these lines.

Fear of being separated from family or fear of dying are common preschool fears that can be revived during pregnancy. A clue that might signal a woman's distress over this could be "Am I ever going to make it through this?" Such an expression might simply mean she is tired of her backache, but it also might be a plea for reassurance she will survive this event in her life.

Part of gaining a sense of identity is establishing a working relationship with parents, which may still be an awkward one since adolescence. For the first time in her

life, a woman during pregnancy can begin to empathize with the way her mother used to worry because she's already begun to worry about her child when she feels no movement for a few hours. This can make her own mother become more important to her and a new, more equal relationship may develop.

Teenagers who are pregnant need to resolve the double conflict of still establishing a sense of identity (teenagers are still children developmentally) at the same time they are planning to be a mother. Unless these feelings are examined and resolved, teenagers can have a difficult time thinking about enjoying their pregnancy or becoming a mother.

A partner needs to do the same reworking of old values and forgotten developmental tasks. A man has to rethink his relationship with his father, for example, to understand better what kind of father he will be. Some men may have had emotionally distant fathers and wish to be more emotionally available to their own children. Support from healthcare providers and exposure to caring role models can be instrumental in helping a man achieve this goal.

### **Role-Playing and Fantasizing**

Another step in preparing for parenthood is role-playing, or fantasizing about what it will be like to be a parent. Just as a child learns what to do by following a mother as she sets a table or balances her checkbook, a pregnant woman may begin to spend time with other pregnant women or mothers of young children to learn how to be a mother. As a part of this role-playing process, women's dreams tend to focus on the pregnancy and concerns about keeping themselves and their coming child safe.

There is concern that a young adolescent will have inadequate role models for motherhood; they are either other teens her age, who typically are not interested in a commitment to mothering, or possibly her own mother, who may have struggled with poverty or her own lack of support. Try to locate good role models (e.g., in classes for mothers, at the healthcare agency, or in a social agency) for adolescents so they can find a good maternal role model to copy and modify their own behavior.

A woman's partner also has the same role-playing to do during pregnancy, to imagine himself or herself as the parent of a boy or a girl. A partner who is becoming a parent for the first time may have to change a view of being a carefree individual to being a significant member of a family unit. If the partner already is a parent from a former relationship, he or she has to cast aside the parent-of-one identity to accept a parent-of-two image, and so forth.

Other support persons who will have an active role in raising the child, such as grandparents, close friends, or an ex-spouse, also have to work out their roles with regard to the pregnancy and impending parenthood. This may be particularly difficult because the roles for these support persons may not be clearly defined, and no role model may be apparent (Hayslip, Blumenthal, & Garner, 2015).

## **EMOTIONAL RESPONSES THAT CAN CAUSE CONCERN IN**

## **PREGNANCY**

Because of all the tasks that need to be worked through during a pregnancy, emotional responses can vary greatly, but common reactions include grief, narcissism, introversion or extroversion, body image and boundary concerns, couvade syndrome, stress, mood swings, and changes in sexual desire. These are all normal, so it is helpful to caution a pregnant woman and her partner that these common changes may occur so they're not alarmed if they appear. Otherwise, a partner can misinterpret the woman's mood swings, decreased sexual interest, introversion, or narcissism not as changes from pregnancy but as a loss of interest in their relationship.

### **Grief**

The thought that grief can be associated with such a positive process as having a child seems at first incongruent. But before a woman can take on a mothering role, she has to give up or alter her present role as she will never be the woman she has been in exactly the same way again. She will never be able to be as irresponsible and carefree again, or perhaps sleep soundly for the next few years. All of this takes mental preparation, which may manifest as a form of grief, as she incorporates her new role as a mother into her other roles as daughter, wife, business professional, or friend. Partners must also incorporate a new role as a parent into their other roles in life.

### **Narcissism**

Self-centeredness (narcissism) may be an early reaction to pregnancy. A woman who previously perhaps was barely conscious of her body, who dressed in the morning with little thought about what to wear, suddenly begins to concentrate on these aspects of her life. She dresses so her pregnancy will or will not show. She may lose interest in her job or community events because the work seems alien to the more important event taking place inside her.

Narcissism may also be revealed by changes in activity. A woman may stop playing tennis, for example, even though her primary healthcare provider has assured her it will do no harm in moderation. She may criticize her partner's driving, although it never bothered her before. She does these things to unconsciously protect her body and her baby. Her partner may demonstrate the same behavior by reducing risky activities, such as mountain biking, trying to ensure he or she will be present to raise their child.

This need of a woman to protect her body has implications for nursing care. It means a woman may regard unnecessary nudity as a threat to her body (e.g., be sure to drape properly for pelvic and abdominal examinations). She may resent casual remarks such as "Oh my, you've gained weight" (i.e., a threat to her appearance) or "You don't like milk?" (i.e., a threat to her judgment).

There is a tendency to organize health instructions during pregnancy around the baby: "Be sure to keep this appointment. You want to have a healthy baby." "You really ought to eat more protein for the baby's sake." This approach may be particularly

inappropriate early in pregnancy, before the fetus stirs and before a woman is convinced not only that she is pregnant but also that there is a baby inside her. At early stages, a woman may be much more interested in doing things for herself because it is her body, her tiredness, and her well-being that will be directly affected (e.g., “Eat protein because it keeps your fingernails from breaking” or “Protein will give you long-term energy”).

### **Introversion Versus Extroversion**

Introversion, or turning inward to concentrate on oneself and one’s body, is a common finding during pregnancy. Some women, however, react in an entirely opposite fashion and become more extroverted. They are more active, appear healthier than ever before, and are more outgoing. This tends to occur in women who are finding unexpected fulfillment in pregnancy, perhaps who had seriously doubted they would be lucky enough or fertile enough to conceive. Such a woman regards her expanding abdomen as public proof of her ability to fulfill the maternal role. Although these changes may make a woman become more varied in her interests during pregnancy, she may be puzzling to those around her who liked her for her quiet and self-contained manner.

### **Body Image and Boundary**

Body image (i.e., the way your body appears to yourself) and body boundary (i.e., a zone of separation you perceive between yourself and objects or other people) both change during pregnancy as a woman begins to envision herself as a mother or becoming “bigger” in many different ways. Changes in concept of body boundaries are so startling that a pregnant woman may walk far away from an object such as a table to avoid bumping against it. At the same time, she may perceive herself as needing body boundaries as if her body were delicate and easily harmed.

### **Stress**

Because pregnancy brings with it such a major role change, it can cause extreme stress in a woman who was not planning to be pregnant or if she finds her lifestyle changing dramatically after she becomes pregnant. Stress in pregnancy, like stress at any time, can make it difficult for a woman to make decisions, be as aware of her surroundings as usual, or maintain time management with her usual degree of skill. This may cause people who were dependent on her before pregnancy to feel neglected because now that she is pregnant, she seems to have strength only for herself. If a woman was in a violent relationship before the pregnancy, the increased stress of pregnancy is apt to cause even more violence. Privately asking whether intimate partner violence has ever occurred in the past to help predict if it could occur during pregnancy is an important part of prenatal interviewing (Van Parys, Deschepper, Michielsen, et al., 2015).

To help families keep their perspective for the full length of a pregnancy, remind them that any decrease in the ability to function that happens to a pregnant woman is a reaction to the stress of pregnancy. A woman may need to remind an employer that any

lack of decision-making ability is no different than in people who are feeling stress because of marital discord or a loved one's illness. Pregnancy may actually be less stressful and less of a concern than those situations because of its predictable 9-month duration.

## Depression

Depression—a feeling of sadness marked by loss of interest in usual things, feelings of guilt or low self-worth, disturbed sleep, low energy, and poor concentration—is a common finding in late adolescents. Depression causes as many as 15% of women to enter pregnancy feeling depressed; others grow depressed during pregnancy, especially if they lack a meaningful support person (Chojenta, Lucke, Forder, et al., 2016). Screening for women who have a history of depression is important at a preconception visit as common drugs prescribed for depression can be teratogenic to a fetus as well as cause hypertension in the woman (Zoega, Kieler, Nørgaard, et al., 2015). It is also important to investigate if the woman has a meaningful support person or the stress and anxiety that can come with pregnancy can increase depression substantially and lead to postpartum depression (see Chapter 25).

A woman with few support people around her almost automatically has more difficulty adjusting to and accepting a pregnancy and a new child than women with more support. A woman who begins a pregnancy with a strong support person and then loses that person through trauma, illness, separation, or divorce needs special attention with regard to loneliness and depression. Evaluate her carefully as to how she is managing and give her extra support as needed because her feeling of loss is likely to be extremely acute. Knowing she has supportive healthcare providers she can call on when needed is the one thing that may make her pregnancy acceptable to her.

### QSEN Checkpoint Question 10.3

#### TEAMWORK & COLLABORATION

Lauren Maxwell is aware she's been showing some narcissism since becoming pregnant. How would the nurse describe this phenomenon to an unlicensed care provider?

- She feels pulled in multiple directions.
- She feels a need to sleep more than usual.
- Her thoughts tend to be mainly about herself.
- She often feels emotionally “numb.”

Look in *Appendix A* for the best answer and rationale.

## Couvade Syndrome

Many partners experience physical symptoms such as nausea, vomiting, and backache to the same degree or even more intensely than their partners during a pregnancy; some

begin to gain weight along with their partner. As a woman’s abdomen begins to grow, partners may perceive themselves as growing larger too, as if they were the ones who were experiencing changing boundaries the same as the pregnant woman. These symptoms apparently result from stress, anxiety, and empathy for the pregnant woman. The phenomenon is common enough that it has been given a name: **couvade syndrome** (from the French word “to hatch”). The more a partner is involved in or attuned to the changes of the pregnancy, the more symptoms a partner may experience. A close marital relationship, which this reflects, can increase the strength of the partner–infant attachment (Fuertes et al., 2016). Such symptoms are only worrisome and require psychological attention if they become so extreme that they create intolerable emotional stress.

### *What If . . . 10.2*

**John finds himself calling in sick at least 3 days a week because of “nausea.” Because his wife, Lauren, is 5 months pregnant, would the nurse assume his symptoms are because of couvade syndrome?**

## **Emotional Lability**

Mood changes occur frequently in a pregnant woman, partly as a symptom of narcissism (i.e., her feelings are easily hurt by remarks that would have been laughed off before) and partly because of hormonal changes, particularly the sustained increase in estrogen and progesterone. Mood swings may be so common that they can make a woman’s reaction to her family and to healthcare routines unpredictable. She may cry over her children’s bad table manners at one meal, for example, and find the situation amusing or even charming at the next. Caution families that such mood swings occur beginning with early pregnancy so they can accept them as part of a normal pregnancy (Box 10.5).

### **BOX 10.5**

#### **Nursing Care Planning Based on Family Teaching**

**Q.** Lauren Maxwell tells you she has noticed extreme mood swings since she’s been pregnant. She asks you how she can reduce them.

**A.** Everyone is different, but good measures to try include:

- Avoid fatigue because when you’re tired, your normal defenses are most likely to be down.
- Reduce your level of stress by setting priorities. Ask yourself if everything you’re doing really needs to be done.
- Don’t let little problems grow into big ones; attack them when they first occur.
- Try to view situations from other people’s perspective. They’re not as involved in

your pregnancy as you are so things that don't seem important to you may be important to them.

- Let others know you're aware you're having trouble with emotions since you became pregnant. Your family and friends will be more than willing to help you through this time if they realize your shifting emotions are a concern to you.

## Changes in Sexual Desire

Most women report their sexual desire changes, at least to some degree, during pregnancy. Women who formerly were worried about becoming pregnant might truly enjoy sexual relations for the first time during pregnancy. Others might feel a loss of desire because of their increase in estrogen, or they might unconsciously view sexual relations as a threat to the fetus they must protect. Some may worry coitus could bring on early labor.

During the first trimester, most women report a decrease in libido because of the nausea, fatigue, and breast tenderness that accompany early pregnancy. During the second trimester, as blood flow to the pelvic area increases to supply the placenta, libido and sexual enjoyment can rise markedly. During the third trimester, sexual desire may remain high, or it may decrease because of difficulty finding a comfortable position and increasing abdominal size. When a couple knows early in pregnancy such changes may occur, it's easier for them to interpret these in the correct light or as a normal change, not as loss of interest in a sexual partner or as a diminishment of the strength of the total relationship (Yıldız, 2015). Suggestions for helping women and their partners adjust to these circumstances are discussed in [Chapter 12](#).

## Changes in the Expectant Family

Most parents are aware that their older children need preparation when a new baby is on the way; however, knowing preparation is needed and being prepared to explain where babies come from are two different things. For this reason, many couples appreciate suggestions from healthcare providers as to how this task can be accomplished.

Both preschool and school-age children may need to be assured periodically during pregnancy a new baby will be an addition to the family and will not replace them or change their parents' affection for them. Preparing a child for the birth of a sibling is discussed in [Chapters 14](#) and [31](#) with other growth and development concerns.

## The Confirmation of Pregnancy

A medical diagnosis of pregnancy serves to date when the birth will occur and also helps predict the existence of a high-risk status. Most women who come to a healthcare facility for a diagnosis of pregnancy have already guessed they are pregnant based on a multitude of subjective symptoms as well as having completed a home pregnancy test, so a healthcare visit is more a confirmation of pregnancy than a diagnosis. If a

pregnancy was planned, this official confirmation of pregnancy produces a feeling of intense fulfillment and achievement. If the pregnancy was not planned (remember almost half of pregnancies are unintended), it can result in an equally extreme crisis state.

From the day a pregnancy is officially confirmed, most women try to eat a more nutritious diet, give up cigarette smoking and alcohol ingestion, and stop taking nonessential medications. Because a woman may not take these measures before confirmation of her pregnancy, this makes early confirmation of pregnancy important. If a woman does not wish to continue the pregnancy, early confirmation is also imperative; therapeutic termination of pregnancy should be carried out at the earliest stage possible for the safest outcome (Gerdts, Dobkin, Foster, et al., 2016).

Before there were sonograms and maternal serum pregnancy tests, pregnancy was diagnosed on symptoms reported by the woman and the signs elicited by a healthcare provider. These signs and symptoms, still important today, are traditionally divided into three classifications: presumptive (subjective symptoms), probable (objective signs), and positive (documented signs) (Table 10.2).

**TABLE 10.2 PRESUMPTIVE, PROBABLE, AND POSITIVE INDICATIONS OF PREGNANCY**

<b>Time From Implantation (Weeks)</b>	<b>Presumptive Finding</b>	<b>Probable Finding</b>	<b>Positive Finding</b>	<b>Description</b>
1		Maternal serum test		A venipuncture of blood serum reveals the presence of human chorionic gonadotropin hormone
2	Breast changes			Feelings of tenderness, fullness, tingling; enlargement and darkening of areola
2	Nausea, vomiting			Nausea or vomiting on arising or when fatigued
2	Amenorrhea			Absence of menstruation
3	Frequent urination			Sense of having to void more often than usual
6		Chadwick's		Color change of the

		sign	vagina from pink to violet
6		Goodell's sign	Softening of the cervix
6		Hegar's sign	Softening of the lower uterine segment
6		Sonographic evidence of gestational sac	Characteristic ring is evident
8			Sonographic evidence of fetal outline
			Fetal outline can be seen and measured by sonogram
10–12			Fetal heart audible
			Doppler ultrasound reveals heartbeat
12	Fatigue		General feeling of tiredness
12	Uterine enlargement		Uterus can be palpated over symphysis pubis
16		Ballottement	When lower uterine segment is tapped on a bimanual examination, the fetus can be felt to rise against the abdominal wall
18	Quickening		Fetal movement felt by woman
20			Fetal movement felt by examiner
			Fetal movement can be palpated through abdomen
20		Braxton Hicks contractions	Periodic uterine tightening occurs
20		Fetal outline felt by examiner	Fetal outline can be palpated through abdomen
24	Linea nigra		Line of dark pigment forms on the

24	Melasma	abdomen Dark pigment forms on face
24	Striae gravidarum	Stretch marks form on abdomen

## PRESUMPTIVE (SUBJECTIVE) SYMPTOMS

Presumptive symptoms are those which, when taken as single entities, could easily indicate other conditions (Fletcher & Russo, 2015). These findings, discussed in connection with the body system in which they occur, are experienced by the woman but cannot be documented by an examiner (Box 10.6).

BOX 10.6

### Nursing Care Planning Using Assessment

#### ASSESSING A WOMAN FOR PRESUMPTIVE SYMPTOMS OF PREGNANCY

## PROBABLE SIGNS

In contrast to presumptive symptoms, probable signs of pregnancy are objective and so can be verified by an examiner. Although they are more reliable than presumptive symptoms, they still do not positively diagnosis a pregnancy (Box 10.7).

BOX 10.7

### Nursing Care Planning Using Assessment

#### ASSESSING A WOMAN FOR PROBABLE SIGNS OF PREGNANCY

## Laboratory Tests

The commonly used laboratory tests for pregnancy are based on the use of a venipuncture or a urine specimen to detect the presence of human chorionic gonadotropin (hCG), a hormone created by the chorionic villi of the placenta, in the urine or blood serum of the pregnant woman. Because these tests are only accurate 95% to 98% of the time, positive results from these tests are considered probable rather than positive signs.

In the nonpregnant woman, no units of hCG will be detectable because there are no trophoblast cells producing hCG. In the pregnant woman, trace amounts of hCG appear in her serum as early as 24 to 48 hours after implantation and reach a measurable level (about 50 milli-International Unit/ml 7 to 9 days after conception. Levels peak at about 100 milli-International Unit/ml between the 60th and 80th day of gestation. After that point, the concentration of hCG declines again so, at term, it is again barely detectable in serum or urine.

## Home Pregnancy Tests

A number of brands for pregnancy testing are available over the counter, take only 2 to 3 minutes to complete, and have a high degree of accuracy (97% to 99%) if the instructions are followed exactly because they can detect as little as 35 milli-International Unit/ml of hCG. For the test, a woman dips a reagent strip into her stream of urine. A color change or the appearance of two bars on the strip denotes pregnancy.

Tips to give the woman for successful testing include:

- Check the expiration date on the package to be certain the kit has not expired; an outdated kit can give false-positive results.
- Read the instruction pamphlet provided with the test, noting especially the time period you should wait before reading the result, and follow this instruction carefully.
- A concentrated urine sample such as a first urine in the morning tests best. Don't drink a large quantity of water beforehand because this can dilute a urine sample.
- Read the test results at the exact time the instructions dictate. Reading the strip after the designated time can cause inaccurate results (e.g., denoting that you are pregnant when you are not).
- Some prescription medicines, like methadone or chlorthalidone, may cause false-positive results. Contact your healthcare provider if you get an unexpected positive result and ask if any medication you are taking could cause that result.
- Early prenatal care is the best safeguard to ensure a successful pregnancy. If your test result is positive, your next step should be to make a healthcare appointment as early as possible to begin care.

Most manufacturers suggest a woman wait until at least the day of the missed menstrual period to test. If a woman thinks she is pregnant but gets a negative result, she could repeat the test 1 week later if she still has not had a menstrual flow. If symptoms of pregnancy persist after two tests, she needs to see her healthcare provider as she might have another condition causing the amenorrhea; she would need appropriate diagnosis and therapy for this.

A worry about the common use of home test kits is that because women do not have to come to a healthcare setting for confirmation of pregnancy, they may not seek prenatal care until something seems to be going wrong with their pregnancy or until they feel they need to arrange added healthcare provider coverage for the birth. After a positive pregnancy test, the first step should therefore be to arrange for prenatal care (Attilakos & Overton, 2012).

## POSITIVE SIGNS OF PREGNANCY

There are only three documented or positive signs of pregnancy:

1. Demonstration of a fetal heart separate from the mother's
2. Fetal movements felt by an examiner
3. Visualization of the fetus by ultrasound

## Demonstration of a Fetal Heart Separate From the Mother's

Although a fetal heart beat cannot be heard through an ordinary stethoscope until 18 to 20 weeks of pregnancy, an echocardiography can demonstrate a heartbeat as early as 5 weeks. An ultrasound can reveal a beating fetal heart as early as the sixth to seventh week of pregnancy. Doppler instrumentation that converts ultrasonic frequencies to audible frequencies is able to detect fetal heart sounds as early as the 10th to 12th week of gestation.

The fetal heart rate ranges between 120 and 160 beats/min. Sounds are more difficult to hear if a woman's abdomen has a great deal of subcutaneous fat or if there is a larger-than-normal amount of amniotic fluid present (polyhydramnios). They are heard best when the position of the fetus is determined by palpation and the stethoscope is placed over the area of the fetal back.

## Fetal Movements Felt by an Examiner

Fetal movements may be felt by a woman as early as 16 to 20 weeks of pregnancy. An objective examiner can discern fetal movements at about the 20th to 24th week of pregnancy unless the woman is extremely obese. This outside evaluation is considered the more reliable assessment because a woman could mistake the movement of gas through her intestines for fetal movement.

## Visualization of the Fetus by Ultrasound

Ultrasound is the most common method for confirmation of pregnancy today. If a woman is pregnant, a characteristic ring, indicating the gestational sac, will be revealed on an oscilloscope screen as early as the fourth to sixth week of pregnancy. This method also gives information about the site of implantation and whether a multiple pregnancy exists. By the eighth week, a fetal outline can be seen so clearly that the crown-to-rump length can be measured to establish the gestational age of the pregnancy. Seeing the fetal outline on a sonogram is also clear proof for a couple that they are pregnant if they had any doubt up to that point (Zheng, 2012b).

### Concept Mastery Alert

Although *probable signs* of pregnancy (such as laboratory tests, ballottement, and softening of the cervix) are objective and can be verified by an examiner, they are not reliable enough to positively diagnosis a pregnancy. The only three *positive signs* of pregnancy are demonstration of a fetal heartbeat separate from the mother's, fetal movement felt by an examiner, and visualization of the fetus by ultrasound.

## QSEN Checkpoint Question 10.4

### INFORMATICS

Lauren Maxwell did a urine pregnancy test but was surprised to learn a positive result is not a sure sign of pregnancy. As the nurse is recording her result in the electronic health record, she asks what a positive sign would be. The nurse should cite what finding?

- a. She has noticed consistent abdominal and uterine growth.
- b. She can feel her fetus move more than once per hour.
- c. A serum tests reveals hCG.
- d. A fetal heartbeat can be seen during an ultrasound exam.

*Look in [Appendix A](#) for the best answer and rationale.*

## Physiologic Changes of Pregnancy

Physiologic changes that occur during pregnancy are the basis for the signs and symptoms used to confirm a pregnancy. They can be categorized as local (i.e., confined to the reproductive organs) or systemic (i.e., affecting the entire body). For easy reference, [Table 10.3](#) summarizes the changes that occur during a typical 40-week pregnancy.

**TABLE 10.3 TIMETABLE FOR PHYSIOLOGIC CHANGES OF PREGNANCY**

Location of Change	First Trimester	Second Trimester	Third Trimester
Cardiovascular	Blood volume increasing Pseudoanemia may occur Clotting factors increasing	Blood pressure slightly decreased	Blood pressure returns to prepregnancy levels
Ovarian	Corpus luteum active	Corpus luteum fading	
Uterine	Steady increased growth	Placenta producing estrogen and progesterone, steady increased growth	Steady increased growth
Cervix	Softening begins	Softening increases	“Ripe”
Vaginal	White discharge present		Increasing in amount
Musculoskeletal		Progressive cartilage softening Lordosis increasing	Possible back or pelvic girdle pain
Pigmentation		Progressively increasing	

Kidney	Maternal glomerular filtration rate increasing Glycosuria begins and increases Aldosterone increased, aiding retention of sodium and fluid	
Gastrointestinal		Slowed peristalsis
Thyroid	Increased metabolic rate	

## REPRODUCTIVE SYSTEM CHANGES

Reproductive tract changes are those involving the uterus, ovaries, vagina, and breasts.

### Uterine Changes

The most obvious alteration in a woman's body during pregnancy is the increase in size of the uterus to accommodate the growing fetus. Over the 10 lunar months of pregnancy, the uterus increases in length, depth, width, weight, wall thickness, and volume.

- Length grows from approximately 6.5 cm to 32 cm.
- Depth increases from 2.5 cm to 22 cm.
- Width expands from 4 cm to 24 cm.
- Weight increases from 50 g to 1,000 g.
- Early in pregnancy, the uterine wall thickens from about 1 cm to about 2 cm; toward the end of pregnancy, the wall thins to become supple and only about 0.5-cm thick.
- The volume of the uterus increases from about 2 ml to more than 1,000 ml. This makes it possible for a uterus to hold a 7-lb (3,175-g) fetus plus 1,000 ml of amniotic fluid for a total of about 4,000 g.

This great uterine growth is due partly to formation of a few new muscle fibers in the uterine myometrium but principally to the stretching of existing muscle fibers (by the end of pregnancy, muscle fibers in the uterus because of fibroblastic tissue that forms between them, are two to seven times longer than they were before pregnancy). Because uterine fibers simply stretch during pregnancy and are not newly built, the uterus is able to return to its prepregnant state at the end of the pregnancy with little difficulty and almost no destruction of tissue (Edmonds, 2012).

By the end of the 12th week of pregnancy, the uterus is large enough that it can be palpated as a firm globe under the abdominal wall, just above the symphysis pubis. An important factor to assess regarding uterine growth at healthcare visits is its constant,

steady, and predictable increase in size (Fig. 10.2).

- By the 20th or 22nd week of pregnancy, it typically reaches the level of the umbilicus.
- By the 36th week, it usually touches the xiphoid process and can make breathing difficult.
- About 2 weeks before term (the 38th week) for a **primigravida**, a woman in her first pregnancy, the fetal head settles into the pelvis and the uterus returns to the height it was at 36 weeks.

**Figure 10.2** Fundus height at various weeks of pregnancy.

This settling of the fetus into the midpelvis is termed **lightening** because a woman's breathing is so much easier that she feels as if her load is lightened. The point at which lightening will occur is not predictable in a **multipara** (a woman who has had one or more children). In such women, it may not occur until labor begins.

Uterine height is measured from the top of the symphysis pubis to over the top of the uterine fundus (Zheng, 2012a). Although growth of a uterus implies a pregnancy is causing the increase in size because a uterine tumor could also cause uterine growth, uterine growth is only a presumptive symptom of pregnancy.

The exact shape of the expanding uterus can be influenced by the position of the fetus. As the uterus grows larger, it pushes the intestines to the sides of the abdomen, elevates the diaphragm and liver, compresses the stomach, and puts pressure on the bladder. It usually remains in the midline during pregnancy, although it may be pushed

slightly to the right side because of the larger bulk of the sigmoid colon on the left. A woman may worry there will not be enough room inside her abdomen for this much increase in size. You can assure her the abdominal contents will readily shift to accommodate uterine enlargement (Fig. 10.3).

**Figure 10.3** Crowding of abdominal contents late in pregnancy.

Uterine blood flow increases during pregnancy as the placenta requires more and more blood for perfusion. Doppler ultrasonography has shown that, before pregnancy, uterine blood flow is 15 to 20 ml/min. By the end of pregnancy, it expands to as much as 500 to 750 ml/min, with 75% of that volume going to the placenta. Measuring an increase in placenta blood volume and velocity is an important gauge of fetal health (Khong, Kane, Brennecke, et al., 2015).

Circulation to the uterus increases so much that toward the end of pregnancy, one sixth of a woman's blood supply is circulating through the uterus at any given time; this means uterine bleeding in pregnancy has to always be regarded as serious because it could result in sudden and major blood loss. Caution women to contact their healthcare provider if any vaginal bleeding occurs during pregnancy.

A bimanual examination (two fingers of an examiner are placed in the vagina, the other hand on the abdomen) can demonstrate, during a pregnancy, that the uterus feels more anteflexed, larger, and softer to the touch than usual. At about the sixth week of pregnancy (at the time of the second missed menstrual flow), the lower uterine segment

just above the cervix becomes so soft when it is compressed between examining fingers on bimanual examination that the wall feels as thin as tissue paper (Fletcher & Russo, 2015). This extreme softening of the lower uterine segment is known as **Hegar's sign** (Fig. 10.4).

**Figure 10.4** Examining for Hegar's sign. If the sign is present, the wall of the uterus is softer than usual.

During the 16th to 20th week of pregnancy, when the fetus is still small in relation to the amount of amniotic fluid present, if the lower uterine segment is tapped sharply during a pelvic exam, the fetus can be felt to bounce or rise in the amniotic fluid up against a hand placed on the abdomen. This phenomenon, termed **ballottement** (from the French word *ballotter*, meaning “to quake”), may, however, also be simulated by a loosely attached uterine tumor and, therefore, is no more than a probable sign of pregnancy.

Between the 20th and 24th week of pregnancy, the uterine wall becomes thinned to such a degree a fetal outline within the uterus may be palpated by a skilled examiner. Because a tumor with calcium deposits could simulate a fetal outline, palpation of what seems to be a fetus, like other uterine assessments, does not constitute a sure confirmation of pregnancy.

Uterine contractions begin early in pregnancy, at least by the 12th week, and are present throughout the rest of pregnancy, becoming stronger and harder as the pregnancy advances. A woman experiences them as waves of hardness or tightening across her abdomen. If a hand is placed on her abdomen, an examiner may be able to feel these contractions as well; an electronic monitor can easily measure both the frequency and length of such contractions.

These “practice” contractions, termed **Braxton Hicks contractions**, serve as warm-up exercises for labor and also play a role in ensuring the placenta receives adequate blood. They may become so strong in the last month of pregnancy that a woman mistakes them for labor contractions (i.e., false labor). One way they can be differentiated from true contractions is that true contractions cause cervical dilation, and Braxton Hicks contractions do not ([Attilakos & Overton, 2012](#)). Although these contractions are always present with pregnancy, they also could accompany any growing uterine mass; so, like ballottement, they are no more than a probable sign of pregnancy.

### **Amenorrhea**

Amenorrhea (i.e., an absence of a menstrual flow) occurs with pregnancy because of the suppression of follicle-stimulating hormone (FSH) by rising estrogen levels. In a healthy woman who has menstruated previously, the absence of a menstrual flow strongly suggests impregnation has occurred. Amenorrhea, however, also heralds the onset of menopause or could result from unrelated reasons such as uterine infection, anxiety (perhaps over becoming pregnant), a chronic illness such as severe anemia, hormonal imbalance, or undue stress. It also is seen in athletes who train strenuously, especially in long-distance runners and ballet dancers if their body fat percentage drops below a critical point ([Mountjoy, Sundgot-Borgen, Burke, et al., 2014](#)). Amenorrhea is, therefore, only a presumptive symptom of pregnancy.

### **Cervical Changes**

In response to the increased level of circulating estrogen produced by the placenta during pregnancy, the cervix of the uterus becomes more vascular and edematous than usual. A mucus plug, called the **operculum**, forms to seal out bacteria and help prevent infection in the fetus and membranes. Increased fluid between cells causes it to soften in consistency, and increased vascularity causes it to darken from a pale pink to a violet hue (**Goodell’s sign**).

The consistency of a nonpregnant cervix can be compared with that of the nose; the consistency of a pregnant cervix more closely resembles an earlobe. Just before labor, the cervix becomes so soft it takes on the consistency of butter or is said to be “ripe” for birth ([Wu & Chou, 2015](#)).

### **Vaginal Changes**

Under the influence of estrogen, the vaginal epithelium and underlying tissues increase in size as they become enriched with glycogen. Muscle fibers loosen from their connective tissue base in preparation for great distention at birth. This increase in the activity of the epithelial cells results in a slight white vaginal discharge throughout pregnancy (but this is only a presumptive symptom as vaginal infections also produce discharges).

An increase in the vascularity of the vagina parallels the vascular changes in the uterus. The resulting increase in circulation changes the color of the vaginal walls from their normal light pink to a deep violet (**Chadwick's sign**).

Vaginal secretions before pregnancy have a pH value greater than 7 (an alkaline pH). During pregnancy, the pH level falls to 4 or 5 (an acid pH), which helps make the vagina resistant to bacterial invasion for the length of the pregnancy. This occurs because of the action of *Lactobacillus acidophilus*, a bacteria that grows freely in the increased glycogen environment, which increases the lactic acid content of secretions.

## Ovarian Changes

Ovulation stops with pregnancy because of the active feedback mechanism of estrogen and progesterone produced early in pregnancy by the corpus luteum and late in pregnancy by the placenta. This feedback causes the pituitary gland to halt production of FSH and luteinizing hormone (LH); without stimulation from FSH and LH, ovulation does not occur.

The corpus luteum that was created after ovulation continues to increase in size on the surface of the ovary until about the 16th week of pregnancy, by which time the placenta takes over as the chief provider of progesterone and estrogen. The corpus luteum, no longer essential for the continuation of the pregnancy, regresses in size and appears white and fibrous on the surface of the ovary (a corpus albicans).

### *QSEN Checkpoint Question 10.5*

#### **PATIENT-CENTERED CARE**

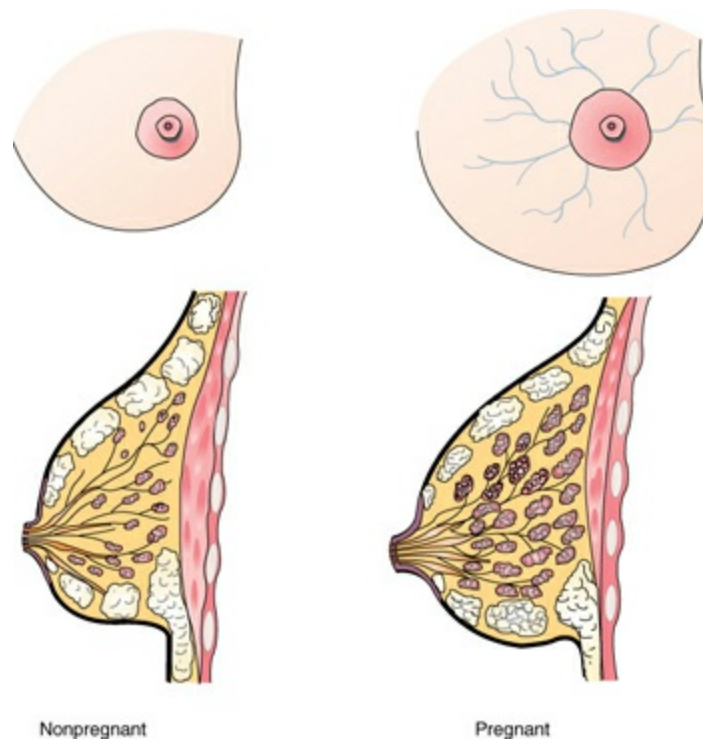

Lauren Maxwell's doctor told her she had a positive Chadwick's sign. When she asks the nurse what this means, the best answer would be which of the following?

- "Your abdomen feels soft and tender, a normal finding."
- "Your uterus has tipped forward, a potential complication."
- "Your cervical mucus feels sticky, just as it should feel."
- "Your vagina looks dark in color, a typical pregnancy sign."

*Look in Appendix A for the best answer and rationale.*

## CHANGES IN THE BREASTS

Subtle changes in the breasts may be one of the first physiologic changes of pregnancy a woman notices (at about 6 weeks) (Fig. 10.5). Typical changes are a feeling of fullness, tingling, or tenderness that occurs because of the increased stimulation of breast tissue by the high estrogen level in her body. As the pregnancy progresses, breast size increases because of growth in the mammary alveoli and in fat deposits. The areola of the nipple darkens, and its diameter increases from about 3.5 cm (1.5 in.) to 5 cm or 7.5 cm (2 or 3 in.). There is additional darkening of the skin surrounding the areola in some women, forming a secondary areola.

**Figure 10.5** Comparison of nonpregnant and pregnant breasts.

Early in pregnancy, the breasts begin readying themselves for the secretion of milk. By the 16th week, colostrum—the thin, watery, high-protein fluid that is the precursor of breast milk—can be expelled from the nipples. As vascularity of the breasts increases, blue veins may become prominent over the surface of the breasts. The sebaceous glands of the areola (**Montgomery’s tubercles**), which keep the nipple supple and help to prevent nipples from cracking and drying during lactation, enlarge and become protuberant.

Talking to women during pregnancy about breast changes and how these changes are devised to aid breastfeeding can be the trigger that alerts women to the importance of breastfeeding for their baby (Pratts & Lawson, 2015).

## SYSTEMIC CHANGES

Although the physiologic changes first noticed by a woman are apt to be those of the reproductive system, changes also occur in almost all body systems.

### Endocrine System

Almost all aspects of the endocrine system increase during pregnancy in order to support fetal growth (Table 10.4) (Burton & Jauniaux, 2015).

**TABLE 10.4** ENDOCRINE SYSTEM CHANGES IN PREGNANCY

Placenta*	Produces estrogen and progesterone (which help maintain the pregnancy), hCG (which allows detection of early pregnancy), and other hormones during pregnancy that impact growth of the baby and uterus and timing
-----------	---

	and onset of labor
Pituitary gland*	Late in pregnancy produces increased levels of prolactin (milk production); produces oxytocin which is necessary for labor contractions
Thyroid†	Increases levels of hormones that increase the basal metabolic rate by 20% and can lead to increased emotional lability, perspiration, tachycardia, and palpitations†
Adrenal glands*	Increases levels of corticosteroids and aldosterone inhibit immune response, thereby preventing rejection of fetus
Pancreas*	Increases insulin production but insulin is less effective due to estrogen, progesterone, and other hormones that are antagonists to insulin. This allows for more glucose to be circulating in the maternal blood stream to be available to the fetus.

hCG, human chorionic gonadotropin.

### QSEN Checkpoint Question 10.6

#### SAFETY

Lauren Maxwell overheard her doctor say insulin is not as effective during pregnancy as usual. How would the nurse explain how decreased insulin effectiveness safeguards the health of her fetus?

- Decreased effectiveness of insulin prevents the fetus from having low blood sugar.
- Because insulin is ineffective, it cannot cross the placenta and harm the fetus.
- The lessened action of insulin prevents the fetus from gaining too much weight.
- It is the mother, not the fetus, who is guarded by this decreased insulin action.

Look in [Appendix A](#) for the best answer and rationale.

### Immune System

Immunologic competency during pregnancy decreases, probably to prevent a woman's body from rejecting the fetus as if it were a transplanted organ. Immunoglobulin G (IgG) production is particularly decreased, which can make a woman more prone to infection during pregnancy. A simultaneous increase in the white blood cell count may help to counteract this decrease in the IgG response.

### Integumentary System

As the uterus increases in size, the abdominal wall must stretch to accommodate it. This

stretching (plus possibly increased adrenal cortex activity) can cause rupture and atrophy of small segments of the connective layer of the skin, leading to streaks (**striae gravidarum**) on the sides of the abdominal wall and sometimes on the thighs (Fig. 10.6). During the months after birth, striae gravidarum lighten to a silvery color (striae albicantes or atrophicae), and, although permanent, they become barely noticeable.

**Figure 10.6** Skin changes in pregnancy: striae gravidarum and linea nigra. (sokolenok/Shutterstock.com)

Often, the abdominal wall has difficulty stretching enough to accommodate the growing fetus, causing the rectus muscles underneath the skin to actually separate, a condition known as **diastasis**. If this happens, after pregnancy, the separation can be assessed through physical exam, and physical therapy can be offered for persistent diastasis.

The umbilicus is stretched by pregnancy to such an extent that by the 28th week, its depression becomes obliterated and it is pushed so far outward in some women, it appears as if it has turned inside out, protruding as a round bump at the center of the abdominal wall.

Extra pigmentation generally appears on the abdominal wall because of melanocyte-stimulating hormone from the pituitary. A narrow, brown line (**linea nigra**) may form, running from the umbilicus to the symphysis pubis and separating the abdomen into right and left halves (see Fig. 10.6). Darkened or reddened areas may appear on the face as well, particularly on the cheeks and across the nose. This is known as **melasma** (chloasma) or the “mask of pregnancy.” With the decrease in the level of melanocyte-stimulating hormone after pregnancy, these areas lighten but do not always disappear.

Vascular spiders or telangiectasias (small, fiery-red branching spots) sometimes develop on the skin, particularly on the thighs. Palmar erythema, as mentioned earlier, may occur on the hands. Both of these symptoms result from the increased level of estrogen in the body; telangiectasias may fade but not completely disappear after pregnancy. The activity of sweat glands increases throughout the body beginning early

in pregnancy, leading to increased perspiration. Fewer hairs on the head enter a resting phase because of overall increased metabolism, so scalp hair growth is increased.

## Respiratory System

A local change that often occurs in the respiratory system is marked congestion, or “stuffiness,” of the nasopharynx, a response, again, to increased estrogen levels. Women may worry this stuffiness indicates an allergy or a cold. Not realizing it is a symptom of pregnancy, some women take over-the-counter cold medications or antihistamines in an effort to relieve the congestion. Ask women at prenatal visits if they are taking any kind of medicine for this to detect this possibility and to be certain the medication they are taking is safe during pregnancy.

Because the uterus enlarges so much during pregnancy, the diaphragm, and ultimately, the lungs, receive an increasing amount of pressure. Toward the end of pregnancy, this can actually displace the diaphragm by as much as 4 cm upward. Even with all this crowding, however, a woman’s vital capacity (the maximum volume exhaled after a maximum inspiration) does not decrease during pregnancy because, although the lungs are crowded in the vertical dimension, they can still expand horizontally. Two major changes do occur with pregnancy: a more rapid than usual breathing rate (18 to 20 breaths/min) and a chronic feeling of shortness of breath (Pipkin, 2012).

The physiologic reasons for those changes include:

- Residual volume (the amount of air remaining in the lungs after expiration) is decreased up to 20% because of the pressure of the diaphragm.
- Tidal volume (the volume of air inspired) is increased up to 40% as a woman draws in deeper breaths trying to increase the effectiveness of her air exchange.
- Total oxygen consumption increases by as much as 20%.
- The increased level of progesterone appears to set a new level in the hypothalamus for acceptable serum carbon dioxide levels ( $PCO_2$ ) because, during pregnancy, a woman’s body tends to maintain a  $PCO_2$  at closer to 32 mmHg than the usual 40 mmHg. This low  $PCO_2$  level is helpful as it causes a favorable  $CO_2$  gradient at the placenta (i.e., because the fetal  $CO_2$  level is higher than that in the mother,  $CO_2$  crosses readily from the fetus to the mother).
- To keep the mother’s pH level from becoming acidic because of the load of  $CO_2$  being shifted to her from the fetus, increased expiration (mild hyperventilation) to blow off excess  $CO_2$  begins early in pregnancy.
- At full term, a woman’s total ventilation capacity may have risen by as much as 40%. This increased ventilation may become so extreme toward the end of pregnancy that a woman develops a respiratory alkalosis or exhales more than the usual amount of  $CO_2$ . To compensate, kidneys excrete plasma bicarbonate in urine to lower this pH. This results in increased urination or **polyuria**, a sign of pregnancy.

- The slight increase in pH in serum because of the changed expiratory effort is advantageous because it slightly increases the binding capacity of maternal hemoglobin and thereby raises the oxygen content of maternal blood (PO<sub>2</sub>), from a usual level of about 92 mmHg to about 106 mmHg. This can be advantageous to fetal growth because it helps ensure good oxygenation of the fetus.
- The total respiratory changes and the compensating mechanisms that occur in the respiratory system can be described as a chronic respiratory alkalosis fully compensated by a chronic metabolic acidosis (Cunningham, Leveno, Bloom, et al., 2014).

Changes in respiratory function during pregnancy are summarized in [Table 10.5](#).

**TABLE 10.5 RESPIRATORY CHANGES DURING PREGNANCY**

Variable	Change
Vital capacity	No change
Tidal volume	Increased by 30%–40%
Respiratory rate	Increased by 1 or 2 breaths/min
Residual volume	Decreased by 20%
Plasma PCO <sub>2</sub>	Decreased to about 27–32 mmHg
Plasma pH	Increased to 7.40–7.45
Plasma PO <sub>2</sub>	Increased to 104–108 mmHg
Respiratory minute volume	Increased by 40%
Expiratory reserve	Decreased by 20%

## Temperature

Early in pregnancy, body temperature increases slightly because of the secretion of progesterone from the corpus luteum (the temperature, which increased at ovulation, remains elevated). As the placenta takes over the function of the corpus luteum at about 16 weeks, the temperature usually decreases to normal.

## Cardiovascular System

Changes in the circulatory system are extremely significant to the health of a fetus because they determine whether there will be adequate placental and fetal circulation for oxygenation and nutrition. [Table 10.6](#) summarizes these changes.

**TABLE 10.6 CHANGES IN THE CARDIOVASCULAR SYSTEM AND CARDIOVASCULAR NEEDS DURING PREGNANCY**

Assessment		
Factor	Prepregnancy	Pregnancy
		Reason

Cardiac output		25%–50% increase	Increased blood volume
Heart rate (beats/min)	70–80	80–90	Increased blood volume
Blood volume (ml)	4,000	5250	Compensate for blood loss at birth, ensure transport of nutrients to fetus*
Red blood cell mass (mm <sup>3</sup> )	4.2 million	4.65 million	Increased blood volume requires increased RBCs
Leukocytes (mm <sup>3</sup> )	7,000	25,000–30,000	To accommodate increased blood volume
Fibrinogen (mg/dl)	300	450	To accommodate increased blood volume
Blood pressure (BP)		Decreases in second trimester, rises to prepregnancy level in third trimester (Fig. 10.7)	Increased heart rate and cardiac output usually cause no change in BP.
Iron		Need 800 µg more daily	Fetal growth, increase in maternal red blood cells†
Folic acid		Need 400 µg daily	Low folic acid leads to large nonfunctioning red blood cells and increase risk for fetal neural tube and abdominal wall defects
Peripheral blood flow		Impaired blood return from lower extremities through the pelvis (due to weight of the baby)	Leads to edema and varicosities in vulva, rectum, and legs‡
Supine hypotension syndrome		Lying supine compresses the vena cava, blood	Decreased cardiac output and hypotension leading to faintness and palpitations and possibly fetal hypoxia**

	return to the heart decreases (Fig. 10.8)	
Blood constitution	Increased clotting factors, platelets, white blood cells, lipids. Decreased protein level	Increased clotting factors and platelets help with bleeding during delivery, white blood cells increase to protect against infection and as a result of blood volume increases, blood lipids increase to provide energy to the fetus. Protein decreases as a result of the proteins being used by the fetus and can lead to edema.††

RBCs, red blood cells.

**Figure 10.7** Blood pressure determination is an important assessment during pregnancy. Normally, this does not elevate during pregnancy.

(iofoto/Shutterstock.com)

**Figure 10.8** Supine hypotension can occur if a pregnant woman lies on her back. (A) The weight of the uterus compresses the vena cava, trapping blood in the lower extremities. (B) If a woman turns on her side, pressure is lifted off of the vena cava.

### *What If... 10.3*

**Lauren’s husband is worried because his wife sometimes has heart palpitations and often seems short of breath. He tells the nurse, “She eats almost nothing to stay ‘model-slim.’ Should she even have tried to have another child?” How would the nurse answer him?**

## **Gastrointestinal System**

At least 50% of women experience some nausea and vomiting early on in pregnancy. For many women, this is the first sensation a woman experiences with pregnancy (it can be noticed even before the first missed menstrual period). It is most apparent early in the morning, on rising, or if a woman becomes fatigued during the day.

Known as morning sickness, nausea and vomiting begins to be noticed at the same time levels of hCG and progesterone begin to rise, so these may contribute to its cause. Another reason may be a systemic reaction to increased estrogen levels or decreased glucose levels because glucose is being used in such great quantities by the growing fetus. Nausea usually subsides after the first 3 months, after which time a woman may have a voracious appetite (Festin, 2015). Many alternate or complementary methods to help reduce nausea are available, such as acupuncture or wrist bands (discussed in Chapter 13). Box 10.8 is an interprofessional care map illustrating both nursing and team planning for a woman with nausea of pregnancy.

### **BOX 10.8**

### **Nursing Care Planning**

## AN INTERPROFESSIONAL CARE MAP FOR A WOMAN EXPERIENCING HER SECOND PREGNANCY

Lauren Maxwell is a part-time model who explains to you, “I was planning on getting pregnant. Just not so soon.” You suspect she’s anxious about the pregnancy because she also says, “I know there’s no turning back, but what will this do to my career?”

**Family Assessment:** The Maxwells have been married for 3.5 years and live in a two-bedroom apartment. Husband, John, works as a chef in a nearby Italian restaurant. Patient, Lauren, works part-time as a model while she attends cooking school. Finances are listed as “tight” but “okay.”

**Patient Assessment:** Lauren presents with amenorrhea, breast tenderness, fatigue, and morning sickness. She is interested in when she will begin to look pregnant and what she can do for the morning sickness (she has eaten almost nothing for 2 days).

**Nursing Diagnoses:** Altered nutrition pattern related to nausea of early pregnancy.  
Anxiety related to pregnancy and becoming a parent.

**Outcome Criteria:** Patient states she is able to eat at least one full meal a day despite nausea; names two complementary therapies she is using to decrease nausea; states she is managing anxiety through self-help measures with support from significant others.

Team Member Responsible	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Determine whether patient is able to carry out usual activities (attending work and/or school, keeping house) by obtaining a health history.	Work with patient to see if modifications (going to work later, giving more home responsibility to husband) could help alleviate symptoms.	Documenting whether patient can complete normal activities helps to verify extent of concerns.	Patient reports she is able to attend school and work part-time as long into pregnancy as she desires.
<i>Teamwork and Collaboration</i>				
Nurse/nutritionist	Assess if patient would like additional suggestions for dealing with nausea from	Consult with nutritionist if nausea interferes with eating in 1 week.	Nausea can become extreme if not recognized as potentially serious in early	Patient meets with nutritionist if she still describes incapacitating nausea at 1-

	team expert.		pregnancy.	week telephone follow-up.
<i>Procedures/Medications for Quality Improvement</i>				
Nurse/primary healthcare provider	Assess whether patient would like to try a complementary therapy, such as a motion sickness band or eating dry crackers before meals.	Review pros and cons of any alternative therapy chosen with patient.	Many alternative therapies are effective at reducing symptoms of nausea during pregnancy.	Patient states she has tried at least one alternative therapy by 1-week follow-up telephone call.
<i>Nutrition</i>				
Nurse/nutritionist	Ask patient to list 24-hour recall nutrition history. Ask if pregnancy weight gain causes her anxiety because of her modeling career.	Examine 24-hour recall history and analyze for nutrition deficits. Make suggestions for better intake.	Documenting the problem best identifies its extent. Anxiety can compound nausea.	Patient gives 24-hour recall history and helps determine any nutritional deficits and possible solutions.
<i>Patient-Centered Care</i>				
Nurse	Determine whether patient had the same degree of nausea with her first pregnancy and, if so, how she managed symptoms.	Provide clinic pamphlet to patient; discuss with patient how nausea, although uncomfortable, is a usual symptom of early pregnancy.	Recognizing that a symptom is normal can help a patient accept discomfort. Nausea of pregnancy responds to many self-help measures.	Patient reports at 1-week follow-up phone call she recognizes nausea as a normal part of early pregnancy and is taking active steps to relieve it.
<i>Psychosocial/Spiritual/Emotional Needs</i>				
Nurse	Assess if patient	Urge patient to	Differences in	Patient says she

is concerned about the differences in her feelings and her husband's feelings toward pregnancy will interfere with their relationship.	discuss pregnancy fears with husband.	reactions to pregnancy can potentially interfere with degree of support from significant other.	has discussed her fears with her husband and will continue to do so as pregnancy progresses.
--	---------------------------------------	---	--

*Informatics for Seamless Healthcare Planning*

Nurse	Assess if patient has any further questions before she leaves the clinic.	“Brainstorm” with patient as needed to help her determine a solution to any concerns identified.	Unanswered questions can lead to increased anxiety over coming weeks.	Patient confirms her questions have been answered; has telephone number for clinic if further concerns arise.
-------	---	--	---	---

In addition to nausea, other gastrointestinal tract changes occur:

- Although the acidity of stomach secretions decreases during pregnancy, heartburn can readily result from reflux of stomach contents into the esophagus, caused by both the upward displacement of the stomach by the uterus, and a relaxed cardioesophageal sphincter, caused by the action of relaxin produced by the ovary. Interventions for heartburn are discussed in [Chapter 13](#).
- As the uterus increases in size, it pushes the stomach and intestines toward the back and sides of the abdomen. At about the midpoint of pregnancy, this pressure may be sufficient to slow intestinal peristalsis and the emptying time of the stomach, leading to renewed heartburn, constipation, and flatulence.
- Pressure from the uterus on veins returning from the lower extremities can lead to hemorrhoids.
- The entire gastrointestinal tract may become less active from the combined actions of relaxin and progesterone. This natural slowing of the stomach and intestine can be helpful because the blood supply is reduced in the gastrointestinal tract as more blood is drawn to the uterus.
- Women with chronic gastric reflux usually find their condition either improved because the acidity of the stomach is decreased or worsened because of upward uterine pressure.
- Because of the gradual slowing of the gastrointestinal tract, decreased emptying of bile from the gallbladder may result. This can lead to reabsorption of bilirubin

into the maternal bloodstream, giving rise to a symptom of generalized itching (subclinical jaundice). A woman who has had gallstones may have an increased tendency for stone formation during pregnancy as a result of the increased plasma cholesterol level and additional cholesterol incorporated in bile.

- Some pregnant women notice hypertrophy at their gum lines and bleeding of gingival tissue when they brush their teeth. There also may be increased saliva formation (hyperptyalism), probably as a local response to increased levels of estrogen. This is an annoying but not a serious problem.
- A lower-than-normal pH of saliva may lead to increased tooth decay if tooth brushing is not done conscientiously. This can be a problem for homeless women or any women who do not have frequent access to a place to brush their teeth.

## Urinary System

Like other systems, the urinary system undergoes specific physiologic changes during pregnancy, including alterations in fluid retention and renal, ureter, and bladder function. These changes, summarized in [Table 10.7](#), result from:

- Effects of high estrogen and progesterone levels
- Compression of the bladder and ureters by the growing uterus
- Increased blood volume that increases kidney production of more urine
- Postural influences

**TABLE 10.7 URINARY TRACT CHANGES DURING PREGNANCY**

Variable	Change
Renal function	Changes to excrete waste from maternal and fetal blood supplies
Glomerular filtration rate	Increased by 50%
Blood urea nitrogen	Decreased by 25%, BUN of 15 mg/100 ml or higher is abnormal
Creatinine	Decreased in pregnancy, creatinine clearance should be 90–180 ml/min in 24-hour urine sample, serum creatinine greater than 1 mg/100 ml is abnormal
Renal threshold for sugar	Decreased to allow slight spillage
Ureter and bladder function	Increase in urinary output but also physiologic increase in urinary stasis (bladder infections and pyelonephritis are more likely)
Bladder	Increased by 1,000 ml

capacity	
Diameter of ureters	Increased by 25%
Frequency of urination	Increased slightly in first trimester, last 2 weeks of pregnancy increases to 10–12 times per day
Fluid retention	Increased aldosterone production causes increased sodium reabsorption and fluid retention

Solomon, J. S., & Altaus, J. E. (2015). Preterm labor & premature rupture of membranes. In J. L. Bienstock, H., Fox, E. E. Wallach, et al. (Eds.), *The Johns Hopkins manual of gynecology and obstetrics* (5th ed., pp. 128–138). Philadelphia, PA: Wolters Kluwer.

## Musculoskeletal System

Calcium and phosphorus needs are increased during pregnancy because an entire fetal skeleton must be built. As pregnancy advances, a gradual softening of a woman’s pelvic ligaments and joints occurs to create pliability and to facilitate passage of the baby through the pelvis at birth. This softening is probably caused by the influence of both the ovarian hormone relaxin and placental progesterone. This excessive mobility of joints can cause discomfort late in pregnancy, especially if there is a separation of the symphysis pubis. Separation this way causes acute pain and makes walking difficult and painful.

To change her center of gravity and make ambulation easier, a pregnant woman tends to stand straighter and taller than usual. This stance is sometimes referred to as the “pride of pregnancy.” Standing this way, with the shoulders back and the abdomen forward, however, creates a lordosis (forward curve of the lumbar spine), which may lead to chronic backache, particularly in older women (Cakmak, Ribeiro, & Inanir, 2016) (Box 10.9).

### BOX 10.9

#### Nursing Care Planning to Empower a Family

**Q.** You notice Lauren Maxwell rubbing her back at a prenatal visit. She asks how she can keep her backache from becoming worse.

**A.** Backache is a common symptom of pregnancy because of the strain the extra uterine weight puts on lower vertebrae. Common measures to relieve backache in pregnancy include:

- Limit the use of high heels because they add to the natural lordosis of pregnancy.
- Try to rest daily with feet elevated.
- Walk with head high and pelvis straight.
- Pelvic rocking (see [Chapter 14](#)) at the end of the day may relieve pain for the night.

Backache should be reported if:

- It is experienced as waves of pain (i.e., could be preterm labor).
- There are accompanying urinary symptoms, such as frequency and pain on urination (i.e., could be a urinary tract infection).
- The back is tender at the point of backache (i.e., could be pyelonephritis or a kidney infection or a ruptured vertebrae).
- Rest doesn't relieve it (i.e., could be a muscle strain).

## Patients With Unique Concerns in Pregnancy

### TRANSGENDER PATIENTS

Transgender men (men whose sex assigned at birth was female) may seek pregnancy. Discontinuation of testosterone hormone therapy and the physiologic changes of pregnancy will often bring up self-identity issues. Being a transgender or gender variant individual can feel isolating, and this isolation can deepen during pregnancy. Many transgender male patients will need extra support during the preconception time period as well as during the pregnancy itself (Ellis, Wojnar, & Pettinato, 2014).

Transgender women (women whose sex assigned at birth was male) may really want to carry a pregnancy and, with new medical research on uterus transplants, may be able to do so. Uterus transplants are still in the early stages and have not yet been attempted for transgender women (Murphy, 2015).

### PATIENTS WITH DISABILITIES

Women with disabilities may also have specific concerns about how to care for themselves during pregnancy and for their child when he or she is born, and they need a careful assessment of their feelings about having a baby and any special adjustments they may need to make during pregnancy (Horner-Johnson, Darney, Kulkarni-Rajasekhara, et al., 2016). Assess if they are concerned their child may be born with their disability. Research or ask a knowledgeable team member to be certain your advice will be accurate before assuring them this is not apt to happen.

### RESTLESS LEG SYNDROME AND CARPAL TUNNEL SYNDROME

Two other concerns that arise more frequently in pregnant women than others are restless leg syndrome and carpal tunnel syndrome.

*Carpal tunnel syndrome* is named for the Greek word *karpos* meaning “wrist” and the narrow space where the median nerve passes between the bones of the wrist. Repetitive movements, such as typing or swinging a tennis racket, can irritate the nerve resulting in sensations of pain, tingling, and numbness. Probably because of the effect of the hormone relaxin secreted by the placenta, pregnant women seem to be more susceptible to this condition than others (Meems, Truijens, Spek, et al., 2015). Actions women can take to avoid the syndrome and usual therapy is discussed in Chapter 49.

*Restless leg syndrome* is the uncontrollable urge to move the legs, often

accompanied by itching, tingling, or aching to such an extent a person has difficulty falling or staying asleep (Oyieng'o, Kirwa, Tong, et al., 2016). It tends to occur more often in pregnant women and people with iron deficiency than others. Therapy for the condition is discussed in [Chapter 51](#).

#### *What If . . . 10.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals with regard to psychological or physiologic changes in pregnancy (see [Box 10.1](#))? What would be a possible research topic to explore pertinent to this goal that would be applicable to Lauren or her family and that would also advance evidence-based practice?**

### **KEY POINTS FOR REVIEW**

- The ability of a woman to accept and enjoy a pregnancy depends on social, cultural, family, and individual influences.
- The psychological tasks of pregnancy are centered on ensuring safe passage for the fetus. They consist of, in the first trimester, accepting the pregnancy; in the second trimester, accepting the baby; and in the third trimester, preparing for parenthood.
- Common emotional responses that occur with pregnancy can include grief, narcissism, introversion or extroversion, stress, couvade syndrome, body image and boundary confusion, emotional lability, and changes in sexual desire.
- Physiologic changes that occur with pregnancy are both local, such as uterine, ovarian, and vaginal changes as well as systemic changes such as those that occur in the endocrine, respiratory, cardiovascular, urinary, and immune systems.
- Women may have read about the expected psychological and physiologic changes of pregnancy but once they are experiencing them may find them more intense than anticipated.
- The confirmation of pregnancy may be assisted by three levels of findings: presumptive (subjective), probable (objective), and positive (documented).
- The positive signs of pregnancy are demonstration of a fetal heartbeat separate from the mother's, fetal movement felt by an examiner, and visualization of a fetus by ultrasound.
- Although a woman may be in a prenatal healthcare setting for only an hour, if her pregnancy is confirmed at that visit, she invariably feels “more pregnant” when she leaves. Early diagnosis or confirmation is important so a woman can begin to change unhealthy habits or have adequate time to carry out a therapeutic termination of pregnancy.
- Teaching women common psychological and physiologic changes that occur with pregnancy helps to plan nursing care that not only meets QSEN competencies but also best meets a family's total needs.

## CRITICAL THINKING CARE STUDY

Joella Sanchez is a 22-year-old woman who just realized she is pregnant. She is delighted with the news, and so she was surprised to hear her 4-year-old daughter, Michelle, scream that she didn't want a brother or sister. Joella and Michelle both live with Joella's mother in a two-bedroom house. Her mother's reaction to learning about the pregnancy was to ask, "How will I fit another crib in here?" Joella works nights as a nurse's assistant at a local nursing home. Her supervisor's reaction was to frown and say, "Don't ask me to change your work schedule because you're tired all the time."

1. Is Michelle's reaction to learning a new sibling is on the way unusual? What could Joella do to win her over about the new baby?
2. Both Joella's mother and her work supervisor don't sound happy about the new baby either. What could Joella do to win them over?
3. Joella is happy about her pregnancy but surrounded by a circle of negative reactions. Could this affect her acceptance of the pregnancy? What patient education can you provide to assist her in responding to these reactions?

# 11

## Nursing Care Related to Assessment of a Pregnant Family

*Sandra Czerinski is a 29-year-old woman, 12 weeks pregnant, who comes for a first prenatal visit. She is concerned because she did not realize she was pregnant until a week ago. As a result, she has been actively dieting (two diet drinks plus one meal of mainly vegetables daily) and lifting weights at a health club. She has not had a pelvic examination since she was in high school, when she had a vaginal infection. She remembers that examination as being very painful. She is worried she has a urinary tract infection now because she has to “go all the time.” She does not want any blood work done because she does not have health insurance.*

*Previous chapters described normal reproductive anatomy and physiology and the psychological and physiologic changes that occur during pregnancy. This chapter adds information about care needed during pregnancy to help ensure a healthy outcome for both the woman and her child.*

**What type of health teaching does Sandra need? Is Sandra a high-risk or a low-risk patient?**

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe the areas of health assessment commonly included in prenatal visits.
2. Identify 2020 National Health Goals related to prenatal care that nurses can help the nation achieve.
3. Assess the readiness for parenthood and the health status of a pregnant woman and her family.
4. Formulate nursing diagnoses related to a woman's health status during pregnancy.
5. Identify expected outcomes to help ensure a safe pregnancy as well as manage seamless transitions across healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care such as establishing a risk score for a patient during pregnancy.
8. Evaluate expected outcomes for the childbearing family to establish achievement and effectiveness of goals.
9. Integrate knowledge of pregnancy health assessment with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

Prenatal care, essential for ensuring the overall health of newborns and their mothers, is a major strategy for helping to reduce complications of pregnancy such as the number of preterm or low-birth-weight babies born each year (Mehta & Sokol, 2013). Prenatal care is so important that several 2020 National Health Goals directly address it (Box 11.1).

### BOX 11.1

#### Nursing Care Planning Based on 2020 National Health Goals

A number of 2020 National Health Goals speak directly to the importance of prenatal care:

- Increase the proportion of pregnant women who receive early and adequate prenatal care from a baseline of 70.5% to a target of 77.6%.
- Increase the proportion of pregnant women who attend a series of prepared childbirth classes (developmental).
- Increase the proportion of women delivering a live birth who received preconception care services and practiced key recommended preconception health

behaviors (developmental).

- Increase the proportion of women of childbearing potential who have an intake of at least 400 mg of folic acid from fortified foods or dietary supplements before pregnancy from a baseline of 23.8% to a target level of 26.2%.
- Increase the proportion of mothers who achieve a recommended weight gain during their pregnancies (developmental) (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these goals by educating women and their families about the importance of both preconception and prenatal care as well as making sites for prenatal care “family friendly” or maximally receptive to women and families.

Ideally, preparation for a healthy pregnancy begins during a woman’s childhood as good preparation includes a lifetime of an adequate intake of calcium and vitamin D to prevent rickets (which can distort pelvic size), adequate immunizations against contagious diseases so a woman has protection against viral diseases such as rubella and varicella during pregnancy, and maintenance of an overall healthy lifestyle to ensure the best state of health possible for a woman and her partner when entering pregnancy. Preconception care and risk assessment should be provided at every healthcare visit throughout the childbearing years for both men and women.

Other phases of an overall healthy lifestyle are a positive attitude about sexuality, womanhood, and childbearing. Once a woman becomes sexually active, preparation for a successful pregnancy includes practicing safer sex, regular pelvic examinations, and prompt treatment of any sexually transmitted infection to prevent complications that could lead to subfertility (Price, Ades, Soldan, et al., 2016). It also includes not smoking, drinking alcohol, or using recreational drugs. Acquisition and use of reproductive life planning information can help ensure each pregnancy is intended and wanted.

The initial prenatal visit is the first time many women have been to a healthcare facility since their routine health maintenance visits of childhood and adolescence. It also may be the first time they have had an appointment that focuses more on health promotion than on the diagnosis of disease. A woman usually comes with a specific goal in mind for the visit, such as confirming her pregnancy. However, a prenatal visit is much more than this; it is also a time for health promotion, pregnancy education, and encouraging a pattern of healthy behaviors for the family to use in the future. Individualized teaching varies depending on the lifestyle, age, and parity of a woman and her degree of family support (Hussein, Kai, & Qureshi, 2016).

Urging her to continue prenatal care is important because lack of prenatal care is associated with pregnancy complications such as preterm birth (Demont-Heinrich, Hawkes, Ghosh, et al., 2014).

### *Nursing Process Overview*

## FOR PRENATAL CARE

### ASSESSMENT

The first prenatal visit is a time to establish baseline data relevant to a woman's health and identify health-promotion strategies that will be important at every prenatal visit. This begins by obtaining a detailed health and sexual history including screening for the risk of teratogen (any factor that may adversely affect the fetus) exposure as well as any concerns a woman has about her pregnancy. Explaining why specific assessment data are important has the potential to lead to health teaching. For instance, while you are weighing a woman, discuss the importance of a healthy body mass index (BMI) and how her expected weight gain over the coming months will be calculated based on her prepregnancy value. Relating assessment information and health-promotion activities this way helps keep a woman and her family both well informed and eager to comply with further healthcare recommendations.

### NURSING DIAGNOSIS

Although most women probably have used a home pregnancy kit to find out if they are pregnant, the first prenatal visit officially confirms this, so nursing diagnoses usually focus on the response of a woman and her family to that information.

Examples include:

- Decisional conflict related to desire to be pregnant
- Risk for ineffective coping related to confirmation of unintended pregnancy

Nursing diagnoses appropriate to prenatal care include:

- Health-seeking behaviors related to guidelines for nutrition and activity during pregnancy
- Deficient knowledge regarding exposure to teratogens during pregnancy
- Health-seeking behaviors related to strong cultural desire to have a healthy child
- Risk for injury to fetus related to lifestyle choices

### OUTCOME IDENTIFICATION AND PLANNING

Be certain to reserve sufficient time at prenatal visits so care can be thorough and there is enough time to set realistic goals and expected outcomes with both a birthing parent and her partner, if needed. Establishing a pattern of regular appointments is crucial to the provision of effective, individualized prenatal care, so be certain a patient schedules an appointment for a following visit. Ask if she has transportation to the healthcare facility because lack of transportation can be a major reason women don't consistently attend prenatal care.

It will be important to emphasize the need to visit reliable websites as not all websites about pregnancy are evidence based or monitored by a healthcare provider of any type. Refer patients and their families to helpful websites and other resources when appropriate (see [Chapter 9](#)).

### IMPLEMENTATION

An important nursing intervention at prenatal visits is teaching women and their

families about a safe pregnancy lifestyle. Women often discount prepared lists, believing their pregnancy is too personal to be a condition for which there are routine lists of advice. Advice, therefore, needs to be individualized for each woman. For visual learners, it can be helpful to offer a woman and her partner pamphlets that cover the same topics discussed verbally. Be certain all printed materials you give to families are consistent with what you say and with the views of the patient's obstetric healthcare provider. In addition, reinforce to the woman that she should feel free to call or e-mail the healthcare setting between visits with any problems or questions. Some women may feel reluctant to "bother" a healthcare provider outside of scheduled visits unless you give them this permission.

### **OUTCOME EVALUATION**

Evaluation during prenatal visits should concentrate on a woman's initial understanding of the goals for care during pregnancy and assessing outcomes established for specific concerns. Examples of expected outcomes include:

- Couple state they have reached a mutual decision to both stop smoking.
- Patient states she feels well informed about the common body changes of pregnancy and actions to take to relieve any discomfort these cause.
- Patient lists ways to avoid exposure to teratogens at her work site during pregnancy.

## **Health Promotion and Assessment Before and During Pregnancy**

The overall purposes of prenatal care are to:

- Establish a baseline of present health
- Determine the gestational age of the fetus
- Monitor fetal development and maternal well-being
- Identify women at risk for complications
- Minimize the risk of possible complications by anticipating and preventing problems before they occur
- Provide education about pregnancy, lactation, and newborn care

### **THE PRECONCEPTION VISIT**

Preconception care is best if it is not provided at a single visit but included at every healthcare visit for all women of childbearing age. Before planning a pregnancy, a woman should schedule a specific appointment with her primary care provider to obtain accurate reproductive life planning information, receive reassurance about fertility (based on a thorough health history and physical examination), and identify any problems that may need correction to help ensure fertility (Bienstock, Fox, & Wallach, 2015). At this visit, her hemoglobin level and blood type (including Rh factor) may be

determined and, if appropriate, a Papanicolaou (Pap) smear taken (a cervical swab obtained to rule out cervical cancer) ([American Congress of Obstetricians and Gynecologists \[ACOG\], 2015](#)). If a vaginal infection such as chlamydia is found to be present, this can be treated to help ensure fertility. Yeast infections do not tend to interfere with fertility, although, if present, they should be treated as well. Be certain to counsel women on the importance of a diet with adequate protein, folic acid, iron, and vitamins. A prenatal vitamin may be prescribed to ensure folic acid intake will be adequate for pregnancy. Stress the importance of early prenatal care for when pregnancy occurs. If vaccinations are not current, women can be immunized against influenza at a preconception visit ([Marshall, McMillan, Andrews, et al., 2016](#)).

## CHOOSING A HEALTHCARE PROVIDER FOR PREGNANCY AND CHILDBIRTH

Once a woman becomes pregnant, her next step is to choose a primary healthcare provider to care for her throughout the pregnancy and birth. Nurses contribute to the success of prenatal care through individualized assessment, counseling, and educating. Many clinics and group practices provide an initial educational seminar for women in the early stages of their pregnancy, often led by a nurse, nurse-midwife or nurse practitioner. Some practices form cohorts of women to meet monthly (cluster prenatal care) and discuss their concerns to be certain they will have support from others during pregnancy ([Barger, Faucher, & Murphy, 2015](#); [Ickovics, Earnshaw, Lewis, et al., 2016](#); [Trotman, Chhatre, Darolia, et al., 2015](#)). [Box 11.2](#) summarizes ways prenatal care can be individualized so all women feel comfortable in prenatal settings and return for continuing care.

### BOX 11.2

#### Suggestions to Individualize Prenatal Care

- Schedule appointments for women within 1 week after they first call the healthcare setting so they see the healthcare site as one interested in meeting their particular needs.
- Try to schedule further appointments at times convenient for a birthing parent and her support person and with the obstetric care provider of choice depending on the type of practice. Some patients choose to see one provider exclusively, whereas some choose to meet as many people in a group practice as possible during the course of their pregnancy.
- Ask whether there are outside pressures, such as having to report for work or older children coming home from school, that make a certain time of day for appointments best.
- Try to schedule appointments so there won't be a long wait time because later in pregnancy, a woman may feel uncomfortable sitting for a long stretch of time. Almost every woman is too busy to spend unnecessary time waiting at healthcare

facilities.

- Make waiting time at the site educational by providing materials such as pamphlets or videos on pregnancy in the waiting room.
- Provide privacy for assessments such as blood pressure and weight.
- Be certain that pregnant women meet healthcare providers while fully clothed and upright, not naked and in a lithotomy position on an examining table.
- Encourage women to feel responsible for their health record. If a woman's first language is not English, contact an interpreter if necessary to be certain she understands prenatal instructions and will feel free to ask questions.
- Educate pregnant women about care options and encourage them to participate in making decisions about their care.
- Encourage family members and friends to accompany the patient for prenatal care. Allow them to enter the examination room and participate in all aspects of care to the extent they and the woman desire.
- Be certain women have a specific person's name and that person's phone number or e-mail contact in case they have any pregnancy-related questions before their next visit.

### *QSEN Checkpoint Question 11.1*

#### **EVIDENCE-BASED PRACTICE**

One of the first things a woman who suspects she is pregnant must do is choose a primary healthcare provider to guide her through her pregnancy. Many women ask, “What type of care provider should I choose?”

To investigate whether pregnancy care and outcomes differed when women chose a nurse-midwife rather than a physician as their primary care provider, researchers examined 15 different trials involving 17,674 women. Researchers interviewed a sample of 6,421 Canadian women, all 15 years of age or older, all who had given birth to a singleton baby, and all who were living with their infant. Results of the study showed women whose primary prenatal care provider was a nurse-midwife were more likely to be satisfied with their maternity care experience and information provided on pregnancy and birth topics and have improved outcomes for both the birthing parent and the infant. They were prescribed fewer ultrasounds and were more likely to attend prenatal classes. They were almost half as likely to have labor induced and 7.33 times more likely to experience a medication-free birth, experienced fewer inductions, forceps or vacuum deliveries, amniotomies, episiotomies, preterm births, and fewer overall fetal or neonatal deaths before 24 weeks gestation. Women who chose midwifery led continuity care had higher rates of unmedicated childbirth ([Sandall, Soltanni, Gates, et al., 2016](#)). Postpartally, they were more likely to initiate and maintain breastfeeding at 3 and 6 months ([O'Brien, Chalmers, Fell, et al., 2011](#)).

Based on the previous study, if Sandra asks the nurse if she should choose a nurse-

midwife as her primary care provider, how would the nurse best answer her question?

- a. “Of course. Nurses are always more ‘patient friendly’ than physicians.”
- b. “Who you choose is such a personal choice; I shouldn’t give you any advice.”
- c. “Nurse-midwives tend to use less medication with birth. Is that important to you?”
- d. “Nurse-midwives don’t talk to women as much as doctors. Would you like that?”

---

*Look in [Appendix A](#) for the best answer and rationale.*

---

## HEALTH ASSESSMENT DURING THE FIRST PRENATAL VISIT

Women should schedule a first prenatal visit as soon as they suspect they are pregnant. Although evidence-based practice is investigating whether the number of prenatal visits traditionally scheduled is still needed during a usual pregnancy, after the first prenatal visit, return appointments are usually scheduled every 4 weeks through the 28th week of pregnancy, every 2 weeks through the 36th week, and then every week until birth. Women categorized as high risk are followed more frequently.

An important focus of all prenatal visits, in addition to education about pregnancy and helping a woman achieve a healthy pregnancy lifestyle, is to assure women that their pregnancy is progressing well. Another important action is to screen for danger signs that might reveal a complication is beginning. The major causes of serious illness or death during pregnancy for women today are hypertension, hemorrhage, embolism, infection, morbid obesity, and anesthesia-related complications such as intrapartum cardiac arrest ([Centers for Disease Control and Prevention \[CDC\], 2016d](#)).

Screening at a first prenatal visit to detect subtle signs of any of these conditions includes an extensive health history, a complete physical examination (including a pelvic examination), and obtaining blood and urine specimens for laboratory analysis. Ultrasonography has decreased the need to manually measure pelvic diameters for this purpose.

### *QSEN Checkpoint Question 11.2*

#### **PATIENT-CENTERED CARE**

Sandra Czerinski feels healthy, so she asks the nurse why she needs to bother coming for prenatal care. What benefit should the nurse cite when responding to Sandra’s statement?

- a. Discovering any allergies can reduce the risk of preterm labor.
- b. It allows for the collection of accurate epidemiologic and demographic data.
- c. It provides time for education about pregnancy and birth.
- d. It provides important time to interact with a prenatal group.

---

*Look in [Appendix A](#) for the best answer and rationale.*

---

## The Initial Interview

Because obtaining an initial health history can be time-consuming, a woman may be asked to complete some necessary forms before arrival. Appropriate interviewing techniques, however, are important to obtain a thorough and meaningful health history and the rapport established by face-to-face interviewing with healthcare personnel may be as much a reason a woman returns for follow-up care as her desire to be assured her pregnancy is progressing normally (Box 11.3). Some women are extremely frightened at the thought of birth and thus need education and assurance about this as well (Rouhe, Salmela-Aro, Toivanen, et al., 2015).

### BOX 11.3

#### Nursing Care Planning Tips for Effective Communication

Sandra has come to her obstetrician's office for a first prenatal visit.

*Tip:* Ask additional questions to prompt patients to elaborate. Such questions often reveal poor nutrition, poor exercise, or risky pregnancy patterns such as alcohol intake. Most people are not aware how much information can be revealed by a typical day history, so they give only a scant description of their day.

**Nurse:** The first thing I'd like you to do is describe what a typical day is like for you.

**Ms. Czerinski:** I don't have typical ones. Or very interesting ones.

**Nurse:** What about yesterday? Could you describe that to me?

**Ms. Czerinski:** Up at 7:00, at work by 9:00. A friend picked me up after work and we celebrated his birthday. Back home and in bed by 10:00. That's it.

**Nurse:** What did you have for breakfast?

**Ms. Czerinski:** Nothing. I was far too rushed to eat.

**Nurse:** Dinner?

**Ms. Czerinski:** We went to a bar. Cheese blintzes, I think. And beer. A lot of beer.

Remember that pregnancy symptoms are subtle, so a woman may not regard certain information as important, causing her to provide vague answers instead of specific information in these areas. She may be unaware, for example, that she is the only person who knows the answer to a question such as "How do you feel about being pregnant?" or "Have you been taking anything for your nausea in the morning?" For best success, remember the following:

- Interviewing is best accomplished in a private, quiet setting. Pregnancy is too private an affair to be discussed in a crowded hallway or a full waiting room.
- Caution a woman that a first visit may be lengthy because of all the things that need to be accomplished. This prevents a woman from trying to fit the visit in between other errands or from having to terminate the interview because of another appointment.

- Be certain to ask how a patient wants you to address her taking into account gender identification. Make certain she also knows your name and understands your role. If she views you as someone only gathering preliminary data, she may be willing to discuss superficial facts (name, address, phone number, and the like) but will resist discussing more intimate things (her feelings toward this pregnancy, the difficulty she has reworking old fears, or how scared she is about birth).

## SUPPORT PERSON'S ROLE

Both partners and young children accompany women for prenatal care (Fig. 11.1). Some women bring a female friend or a relative as their best support person. If family members are present, should they be included in an initial interview? As a whole, interviewing is most effective if it is a one-to-one interaction because a woman may be unwilling to mention certain concerns when her family is present for fear of worrying them.

**Figure 11.1** Including a support person in the labor room who also was involved in the prenatal preparation is helpful to the mother. (Monkey Business Images/Shutterstock.com)

If childbearing is to be a family affair, however, it is important to determine a partner's degree of acceptance of the pregnancy and how well prepared he or she is of assuming a new parenting role. Including the fetus's siblings in a prenatal visit also provides them an opportunity to be involved.

Interviewing a woman alone and then inviting the support person and family to join her while you talk about pregnancy symptoms with them as a family can be an effective

compromise. In addition, providing some private interview time with a partner allows the partner to express any of his or her concerns or worries.

If a woman wishes, a partner can accompany her during the physical examination. After confirmation of pregnancy, include the partner in healthcare information or suggestions.

## COMPONENTS OF THE HEALTH HISTORY

An initial interview includes both present and past history. General principles of interviewing are discussed in [Chapter 34](#). Included in [Table 11.1](#) is a review of elements pertinent to a pregnancy history.

**TABLE 11.1 PATIENT PROFILE: TYPICAL DAY AND SOCIAL HISTORY FOR A PREGNANT PATIENT**

	<b>Recommended Questions</b>	<b>Findings That Require Further Action</b>	<b>Patient Education</b>
Nutrition	<p>Can you provide a 24-hour recall of food you've eaten today?</p> <p>Do you ever vomit excess food you've eaten after meals? (see <a href="#">Chapter 54</a> for discussion of eating disorders)</p> <p>Are you happy with your weight?</p> <p>Are you on a diet now?</p>	<p>An affirmative answer may indicate an eating disorder (see <a href="#">Chapter 54</a>)</p> <p>Dieting is not advised during pregnancy to be certain a fetus receives adequate nutrients for growth</p>	<p>Women need to take a prenatal vitamin that contains folic acid (minimum 400 mg/day) all during pregnancy. Although the vitamin is found in vegetable and fruit sources, women are unable to eat enough of these natural sources to achieve an adequate amount. Prenatal vitamins also supply higher amounts of iron (30 mg on average).</p>
Exercise	<p>What type of exercise do you enjoy each week?</p> <p>How much and how frequently do you exercise each week?</p>	<p>Although good for her, if a woman hikes or camps, it can put her at risk for exposure to Lyme disease, an infection</p>	<p>Asking about the type, amount, and frequency of exercise helps determine her routine pattern and whether that will be consistent with a recommended level for pregnancy (<a href="#">ACOG, 2016b</a>; <a href="#">Haakstad, Torset, &amp; Bø,</a></p>

		carried by deer ticks. Ask if she knows about precautions to prevent this disease (see <a href="#">Chapter 43</a> ).	<a href="#">2016</a> ). Daily exercise is healthy for women all through life and has been demonstrated to reduce common pregnancy discomforts. Suggestions for exercise that should be safe during pregnancy are provided in <a href="#">Chapter 12</a> .
Hobbies	What hobbies do you enjoy?	Working with lead-based glazes and ceramics can cause exposure to lead, a known teratogen ( <a href="#">Ford, 2015</a> ).	Most hobbies are harmless, but certain ones need to be discontinued or carefully managed during pregnancy.
Tobacco, alcohol, and drug consumption	Do you smoke cigarettes? If so, how often? Do you drink alcohol? If so, how often? Do you use any drugs, such as marijuana or cocaine, recreationally? Do you use any drugs intravenously? (Although this type of information under usual circumstances may not be readily revealed, most	If a woman answers vaguely about how much she smokes or drinks (“I drink socially” or “I only smoke occasionally”), ask her to clarify exactly what she means by “socially” or “occasionally” so you can more accurately evaluate the frequency of these events.	Drugs and alcohol are associated with preterm or low-birth-weight infants ( <a href="#">Roozen, Peters, Kok, et al., 2016</a> ). Intravenous drugs increase the risk of exposure to HIV and hepatitis B through the use of contaminated needles.

women will answer these questions honestly during pregnancy because they are concerned about protecting the health of their fetus.)

Medication and herbal therapy

Do you take any medications, prescribed or over-the-counter?  
Do you take any herbal preparations?

Tetracycline, an antibiotic commonly prescribed for facial acne, causes long bone defects in the fetus and will need to be discontinued during pregnancy (Karch, 2013).  
Many women take herbal supplements to relieve the nausea of early pregnancy. Even seemingly innocent alternative therapies could be detrimental if they stimulate uterine contractions or in any other way interfere with fetal health.

The effect on a growing fetus by all medications, both prescribed and over-the-counter, will have to be evaluated.

Intimate partner violence	<p>Beginning with a normalizing statement can open the door to communication:</p> <p>All couples argue, but have you ever been in a situation where you were fighting and felt unsafe?”</p> <p>Other types of question you could ask include:</p> <p>Have you ever been hurt by anyone?</p> <p>Are you afraid of anyone?</p> <p>Have you ever been forced to have sex when you didn't want to?</p>	<p>Women and adolescents who are trapped in a violent intimate partner relationship need to be identified because both the amount and severity of violence are apt to increase with pregnancy (L. James, Brody, &amp; Hamilton, 2013).</p>
---------------------------	--	--

**Demographic Data**

Demographic data usually obtained include name, age (additional testing such as genetic screening may be necessary if she is over age 35 years), address, telephone number, e-mail address, religion, ethnicity, type and place of employment, and health insurance information.

**Chief Concern**

The chief concern is the reason the woman has come to the healthcare setting—in this

instance, the fact that she is or thinks she is pregnant.

- Document the date of her last menstrual period, whether it was normal for her and whether she has used a home test pregnancy kit.
- Elicit information about the usual signs that occur with early pregnancy, such as nausea, vomiting, breast changes, or fatigue.
- Ask if she is feeling any discomfort with her pregnancy, such as constipation, backache, or frequent urination.
- Ask also about any danger signs of pregnancy, such as bleeding, abdominal pain, continuous headache, visual disturbances, or swelling of the hands and face.
- Document whether the pregnancy was intended. If you feel uncomfortable asking about this directly, use a statement such as “All pregnancies are a bit of a surprise. Is that how it was with this one?” Another way to word such a question might be “Some couples plan on having children right away; some plan on waiting. How was it with you?” If a woman says the pregnancy was not intended, explore with her if she has reached a decision about whether to continue with the pregnancy. A question such as “Some women change their mind about wanting a baby once they realize they are pregnant; some don’t. How has it been for you?” is an effective way to obtain this type of information because it indicates that either answer is possible and acceptable. You just want her to tell you which is happening.

## Family Profile

Obtaining information about the woman’s family structure and function early in an interview helps you get to know her, identify her important support persons, shape the nature and kind of questions you want to ask, and evaluate the possible impact of the woman’s culture on care. It also lays a foundation for health teaching. Areas important to ask about include:

- Marital status and support people available, and if a partner will be accompanying her for visits. As a rule, both married and unmarried women want you to know their married status because they want to alert you if they do not have a firm support person available. [Box 11.4](#) offers suggestions to help make a partner feel like an important part of prenatal visits.
- Educational level of her and her partner (helps you estimate the level of teaching you will need to plan).
- If she works outside the home, exactly what her job consists of; for example, does it involve heavy lifting, long hours of standing in one position, or handling a toxic substance (all actions that may need to be modified during pregnancy)?
- Size and structure of the apartment or house. You’ll need this information so you can talk with her in the coming months about space for a baby. If she is restricted from climbing stairs more than once or twice a day during the last part of pregnancy or after birth, knowing whether essential rooms are located on the ground floor is helpful.

- Family composition. It is important to assess not only the structure of the home but also who the patient lives with and what the relationships are. This is helpful for identifying support persons in addition to identifying any potential issues that may exist in the living situation.
- Lifestyle. Are finances a problem? Does the woman take usual safety precautions such as use of a seat belt when in her car? Does she smoke, drink alcohol, or use recreational drugs? Does she have smoke and carbon monoxide monitors in her home?
- Document whether a woman has recently experienced any lifestyle changes such as a change in status from independence to dependence, a chronic illness, the death or loss of a significant person, a geographic move, financial hardship, or lack of support people. These are all examples of stressful situations that could hinder a woman's ability to accept her pregnancy and child.

#### BOX 11.4

### Nursing Care Planning Based on Family Teaching

**Q.** Sandra asks you, “What can I do to make sure my boyfriend feels involved with my prenatal care?”

**A.** Have you tried these ideas?

- Ask for appointments to be scheduled at a time that is convenient for both of you.
- A prenatal visit can be lengthy. Be certain your partner reserves enough time so the visit doesn't become more of an inconvenience than an enjoyable event.
- Ask your partner to accompany you into the examining room at visits so you both can share your pregnancy progress or decisions.
- Be certain your partner listens to the fetal heart at visits as soon as it can be heard.
- If a sonogram is scheduled, ask your partner to view it with you (it's an exciting moment for both of you to see your fetus moving).

### History of Past Illnesses

Questions about a woman's past medical history are important because a past condition can become active during or immediately following pregnancy. Representative diseases that pose potential difficulty during pregnancy include kidney disease, heart disease (coarctation of the aorta and heart valve problems cause concern most often), hypertension, sexually transmitted infections (including hepatitis B and C, herpes, and HIV), diabetes, thyroid disease, recurrent seizures, gallbladder disease, urinary tract infections, varicosities, phenylketonuria, tuberculosis, and asthma.

It is also important to ask whether a woman had childhood diseases such as chickenpox (varicella), mumps (epidemic parotitis), measles (rubeola), German measles (rubella), and poliomyelitis or if she has had immunizations against these illnesses. Confirm whether a woman has had a human papillomavirus (HPV) vaccine; many

women are not yet aware that the vaccine has the potential not only to prevent HPV infections but also to prevent cervical cancer. It is now routinely prescribed for both male and female adolescents (CDC, 2016b).

From the information obtained about common infectious diseases and immunizations, you can estimate the degree of antibody protection a woman has against these diseases if she is exposed to them during her pregnancy. Pregnant women appear to develop more complications from influenza (the flu), for example, than others, so a woman who will be pregnant during the flu season (October through May) should receive an influenza vaccine (Marshall et al., 2016).

She cannot be immunized with the oral Sabin poliomyelitis vaccine or with the vaccine against measles, mumps, or rubella because the vaccines for these contain live viruses that could be harmful to the fetus if the virus crossed the placenta (McLean, Fiebelkorn, Temte, et al., 2013). Because many women don't know if they have ever had rubella, almost all women have blood drawn for an antibody titer against rubella at a first prenatal visit. After birth, a woman who shows a high titer could then be immunized against the disease to provide fetal protection for a following pregnancy.

Be certain to ask also about any allergies, including any drug sensitivities. This information will not only be important for prenatal treatment of any potential infections or conditions that may occur during pregnancy but also will alert the birth team if someone has an allergy and is unable to communicate that for any reason.

Any past surgical procedures are also important to document because adhesions resulting from past abdominal surgery such as a ruptured appendix could interfere with uterine growth. If a birthing parent has had a prior cesarean birth, the details will be important to know for planning route of delivery and to evaluate placental location.

### History of Family Illnesses

Identifying any illnesses that occur frequently in a woman's relatives can help identify potential problems a woman or her infant could experience during pregnancy or after birth. Ask specifically about cardiovascular and renal disease, diabetes, cognitive impairment, blood disorders, and any known genetically inherited diseases or congenital anomalies.

### Day History/Social Profile

Information about a woman's current nutrition, elimination, sleep, recreation, and interpersonal interactions can be elicited best by asking a woman to describe what her typical day is like. If any of this information is not reported spontaneously as she describes her day, ask for additional details. An overview is provided in Table 11.2.

**TABLE 11.2 TYPICAL ASSESSMENTS FOR A FIRST PREGNANCY VISIT**

Health History	
Demographic	Name, address, age, ethnicity, telephone number, health insurance

data	
Chief concern (her reason for coming for prenatal care)	Was this pregnancy intended? When was the woman's last normal menstrual period (LNMP)? Any exposure to infectious diseases or ingestion of drugs other than those prescribed since a woman thinks she has been pregnant?
Family and social profile	What is the birthing parent's family composition? Do they have a support person? What is their occupation? Source of income? Level of exercise? Hobbies? Substance use? Living conditions? Nutrition? Sleep pattern? Tobacco and alcohol use?
Past medical history	Any past history of abdominal surgery, kidney disease, heart disease, hypertension, sexually transmitted infections, diabetes, or allergies? Are all immunizations up to date?
Gynecologic history	When was menarche? What is length of menstrual cycle? Duration of menstrual flow? History of dysmenorrhea? Any gynecologic surgeries?
Obstetric history	Any previous pregnancies? When? Type and outcome of birth? Any history of previous miscarriages or therapeutic abortions?
Review of systems	Brief review of all body systems
<b>Physical Examination</b>	
Baseline data	Height, weight, prepregnancy body mass index, vital signs, fundal height measurement (after 12 weeks), fetal heart sounds
System assessment	Full physical examination to confirm general health
Pelvic examination	General assessment; Pap smear (if age appropriate) and human papillomavirus (HPV) culture; additional cultures for chlamydia, gonorrhea; pelvic measurements may be taken
<b>Laboratory Assessment</b>	
Blood	Complete blood count, serologic test for syphilis, blood type and Rh, maternal serum $\alpha$ -fetoprotein (MSAFP), pregnancy-associated plasma protein A (PAPP-A), antibody titer against Rh, hepatitis B and possibly C, rubella, varicella and HIV

Urinalysis	Clean catch for glucose, protein, and culture
Tuberculosis	Purified protein derivative (PPD; Mantoux) test or serum test
Ultrasound	To date pregnancy or confirm fetal health (if date of last menstrual period is unknown)

## GYNECOLOGIC HISTORY

In the past, most women had children early in their childbearing years, so they experienced few reproductive tract or women's health disorders, such as breast disease, before pregnancy. Today, with women delaying conception of their first child past 30 years of age, it is not unusual to discover a woman who has had a reproductive tract or breast disorder. [Table 11.3](#) lists common gynecologic illnesses that occur and their possible significance in pregnancy.

**TABLE 11.3 COMMON GYNECOLOGIC DISORDERS SEEN IN PREGNANCY**

Disorder	Possible Symptoms	Significance and Suggested Therapy
<i>Disorders of the Vulva</i>		
Cysts or infection of Skene or Bartholin glands	Cysts appear as asymptomatic swelling at the sides of the urinary meatus or vestibule; if infected, glands appear swollen and reddened and can be painful	Such cysts are surgically incised to prevent blockage of the gland duct. Infections are treated with antibiotics.
Condylomata acuminata	Painless cauliflower-like lesion on vulva	Tends to occur in women with chronic vaginitis. Caused by the same virus that causes common warts. Removed by cryocautery or knife excision, or treated with medication.
Lichen sclerosis	Whitish papules on the vulva; asymptomatic	No need for removal; the area is biopsied, however, because leukoplakia, a potentially cancerous condition, has an almost identical appearance.
Leukoplakia	Thick, gray, patchy epithelium that cracks;	Therapy involves hydrocortisone and frequent return visits to

	possibly a premalignant state that infects easily, accompanied by itching and pain	healthcare personnel (every 6 months) for observation to detect any changes suggestive of carcinoma.
Carcinoma of the vulva	A shallow vulvar ulcer that does not heal	Vulvar cancer occurs most often in postmenopausal women; represents only 3%–4% of all reproductive tract cancers in women. Therapy is vulvectomy—vagina is left intact, and sexual relations and pregnancy, with cesarean birth to prevent tearing of fibrotic vulvar tissue, may be possible afterward.
Female genital cutting	Surgical removal of the clitoris; possibly vagina is sewed closed	Illegal in United States; done as a cultural ritual in young girls from African and Middle Eastern countries. Vaginal stricture may need to be excised to allow for menstrual flow and childbirth.

#### *Disorders of the Vagina and Cervix*

Cervical polyp	Red, vascular, protruding pedunculated tissue that bleeds readily with trauma	May be discovered because of vaginal spotting on coitus, tampon insertion, or vaginal examination. Removed vaginally by excision. Often associated with chronic cervical inflammation.
Cervicitis (erosion)	Reddened cervical tissue with a whitish exudate	Douching with a vinegar solution aids healing. May be treated with cryosurgery if extensive.
Nabothian cyst	Clear shining circles on cervix from blocked gland ducts	No therapy necessary.
Cervical carcinoma	Postcoital spotting, unexplained vaginal discharge, or spotting between menstrual	The most frequent type of reproductive tract malignancy seen; risk factors include coitus with multiple partners or

	periods	uncircumcised males, herpes type 2 or human papillomavirus (HPV) infections. Diagnosed by Pap test or colposcopy. Therapy is conization, radiation, or surgical excision. Pregnancy is possible following cervical carcinoma; cesarean birth may be necessary because of fibrotic cervical tissue. HPV vaccine can reduce the incidence.
--	---------	--

*Disorders of the Ovaries*

Endometrial cyst	Chocolate-brown cyst on tender enlarged ovary; may cause acute pain if rupture occurs	Endometriosis is the cause; occurs in women age 20–40 years. Therapy is surgical excision; ovary may or may not be removed depending on extent of cyst.
Follicular cyst	Amenorrhea and possibly dyspareunia; ovary tender and enlarged	Cysts typically regress after 1 or 2 months; low-dose oral contraceptive may be prescribed for 6–12 weeks to suppress ovarian activity; estrogen may be continued for 6 months.
Polycystic ovary syndrome	A syndrome of chronic follicular cysts, anovulation, insulin resistance, and excess testosterone production leading to perimenopausal onset of hirsutism, obesity, subfertility, and elevated triglycerides	Excess testosterone secretion by ovaries leads to inhibition of follicle-stimulating hormone and anovulation, causing subfertility. Weight loss, reduction in triglycerides and cholesterol levels, clomiphene citrate therapy to induce ovulation, and a combination of spironolactone (Aldactone) with estrogen-progestin oral contraceptives to reduce hirsutism are all used as therapy.
Corpus luteum cyst	Delayed menstrual flow	A corpus luteum persists rather

	followed by prolonged bleeding; ovary enlarged and tender	than atrophies. Most regress in about 2 months; a low-dose oral contraceptive may be prescribed for 6 weeks to suppress ovarian activity.
Dermoid cyst	Asymptomatic; ovary enlarged on examination	Cyst originates from embryonic tissue; may contain hair, cartilage, and fat. Most common ovarian tumor of childhood; also occurs at age 30–50 years. Therapy is surgical resection.
Serous cystadenoma	Bilateral; asymptomatic except for signs of pelvic pressure	The most common type of ovarian cyst; high malignancy rate of 20%–30%. Therapy is surgical resection.
Carcinoma	Asymptomatic; intermenstrual bleeding	Ovarian cancer originates in epithelial tissue most often in women over 50 years of age. Tendency may be inherited; environmental contamination such as use of talcum powder may play a role in development. Therapy is hysterectomy and salpingo-oophorectomy.

### *Disorders of the Uterus*

Endometrial polyp	Intermenstrual bleeding	Polyp is removed by dilatation and curettage.
Leiomyomas (fibroids)	Asymptomatic or with increased menstrual flow; uterus may be enlarged	Muscle and fibrous connective tissue form in response to estrogen stimulation. May increase in size during pregnancy; may cause interference with cervical dilatation and result in postpartal hemorrhage. Stress to the myometrium by uterine contractions may be the original cause of formation. Therapy is embolization (blocking the

		blood supply), oral contraceptives or gonadotropin-releasing hormone agonists to lower estrogen level, surgical resection (myomectomy), or hysterectomy if childbearing is complete.
Endometrial carcinoma	Vaginal bleeding between menstrual periods	Diagnosis is by endometrial washing, not Pap test. Initial therapy is hysterectomy.
Uterine prolapse	Vaginal pressure and low back pain	The uterus has descended into the vagina due to overstretching of uterine supports and trauma to the levator ani muscle. Occurs most often in women who had insufficient prenatal care, birth of a large infant, a prolonged second stage of labor, bearing-down efforts or extraction of a baby before full dilatation, instrument birth, and poor healing of perineal tissue postpartally. Therapy is surgery to repair uterine supports or placement of a pessary, a plastic uterine support. Women with pessaries in place need to return for a pelvic examination every 3 months to have the pessary removed, cleaned, and replaced and the vagina inspected; otherwise, vaginal infection or erosion of the vaginal walls can result. Surgical replacement is also possible.

### Menstrual History

A woman's past experience with her reproductive system may have some influence on how well she accepts a pregnancy as well as whether she'll develop a complication. Information to obtain includes her age of menarche (first menstrual period) and how

well she was prepared for it. Ask about her usual cycle, including the interval, duration, amount of menstrual flow, and any discomfort she feels. If she has discomfort with periods, document when the discomfort occurs, how long it lasts, and what she does to relieve it.

This is important because some women with severe dysmenorrhea can be looking forward to pregnancy because it will mean 9 months without discomfort. However, if she describes menstrual cramps as “horrible” and wonders “how I live through them some months,” you can anticipate that she might need additional counseling to help her prepare for the pain of labor. Anticipate the need for counseling in the postpartum period about active ways to relieve menstrual discomfort when menstrual periods resume (see [Chapter 47](#)).

### Perineal and Breast Self-Examination

Perineal self-examination is inspecting the external genitalia monthly for signs of infection or lesions (see [Chapter 34](#) for the technique). Immigrants from other countries may have had female genital cutting (clitoris removed) in childhood; this needs to be documented because scarring and strictures may limit the size of the vaginal opening ([Box 11.5](#)).

#### BOX 11.5

#### Nursing Care Planning to Respect Cultural Diversity

Female genital cutting is the removal of a portion or all of the female genitalia done in early adolescence as a way of attempting to controlling sexual activity in girls before marriage. The practice arises from religious or cultural customs.

Both the clitoris and the labia minora may be removed; the labia majora may be stitched closed. If keloid formation or scarring occur, the vaginal opening may be so obstructed that neither menstrual flow nor childbirth may be possible; coitus can be difficult and painful. Female genital cutting is seen most in women from African and Middle Eastern nations. The practice is illegal in the United States and opposed by the World Health Organization because it violates a woman’s right to well health and physical integrity. It is an important assessment to make when obtaining a health history at preconception or first prenatal visits because it influences not just sexual health but the ability to conceive and whether vaginal childbirth will be possible.

Breast self-examination is no longer thought to yield enough reliable information to be continued as a monthly self-care routine, but women should be alerted to normal breast changes during pregnancy and about the responsibility to begin having mammograms when they reach 40 to 45 years of age depending on risk status ([American Cancer Society \[ACS\], 2015](#)). Clinical breast examination in women of average risk has not been shown to be effective in average risk women at any age.

However, it may be helpful in identifying any anatomical issues with breastfeeding that may occur (King, Brucker, Kriebs, et al., 2015).

## Past Surgery

Any type of past surgery on the reproductive tract is important to document because it can influence a woman's ability to conceive and give birth. For example, if a woman had tubal surgery following an ectopic pregnancy, her statistical risk of another tubal pregnancy is greater than usual because of possible tubal scarring. If she had uterine surgery, a cesarean birth may be necessary because her uterus may not be able to contract as efficiently as usual because of a surgical scar or she may be at risk for uterine rupture. If she has undergone frequent dilatation and curettage of the uterus or cervical biopsies, her cervix may be weakened or unable to remain closed for 9 months, leading to preterm birth unless she has a surgical procedure (cerclage) to prevent premature dilation (see Chapter 21).

### *Concept Mastery Alert*

Tubal surgery following an ectopic pregnancy may cause tubal scarring, which increases the patient's risk of a subsequent ectopic pregnancy.

## Reproductive Planning

Ask also about what reproductive planning method, if any, a woman has been using. Occasionally, a woman may become pregnant with an intrauterine device (IUD) in place. If this occurs, its location needs to be evaluated prior to making the decision to proceed with removal. Another woman, not certain she is pregnant, may be continuing to take an oral contraceptive. If a pregnancy is confirmed, you can assure her taking the pill while pregnant will not cause fetal harm but she should discontinue taking it for the remainder of pregnancy (Charlton, Mølgaard-Nielsen, Svanström, et al., 2016).

## Sexual History

Be certain to obtain a sexual history, including the number of sexual partners and the use of safer sex practices, to establish a woman's risk for contracting a sexually transmitted infection such as herpes (a viral infection spread by direct contact) or hepatitis C (a viral infection spread by contact with blood or by intercourse with a partner who is infected). Include history taking regarding patients' sexual orientation and gender identity as there are increasing numbers of patients who grow more comfortable discussing their lesbian, gay, bisexual, and transgender healthcare requirements with their providers. It is the responsibility of the healthcare team to be aware of recent evidence-based practices to best serve these patients (Makadon & Goldhammer, 2015).

## Stress Incontinence

As part of any woman's gynecologic history, assess for the possibility of stress incontinence (incontinence of urine on laughing, coughing, deep inspiration, jogging, or running). Urinary incontinence occurs with these actions because they cause the diaphragm to descend, which then increases overall abdominal pressure and bladder tension; increased tension leads to sudden emptying if the woman lacks strength in her perineal muscles or bladder supports. Commonly, this weakness occurs from past difficult births, the birth of large infants, grand multiparity, or instrument births. During pregnancy, stress incontinence can become intensified from the increasing abdominal pressure of the growing uterus. Some women, however, accept this incontinence as a normal consequence of childbearing and may not report it unless asked.

Women can relieve stress incontinence to some degree by strengthening perineal muscles with the use of Kegel exercises (periodic tightening of the perineal muscles; see [Chapter 12](#)). Surgical correction to increase support to the bladder neck could be performed following the pregnancy.

### *QSEN Checkpoint Question 11.3*

#### **INFORMATICS**

The nurse is reviewing Sandra's electronic health record. While doing so, the nurse asks Sandra to clarify and confirm her surgical history. Why is it important to ask Sandra about past surgery during a pregnancy health history?

- a. Previous use of general anesthetics is a risk factor for preterm labor.
- b. Adhesions from surgery could potentially limit uterine growth.
- c. Previous experience with surgery means that she will likely be comfortable in a hospital setting.
- d. Abdominal incisions are associated with potential uterine rupture.

*Look in [Appendix A](#) for the best answer and rationale.*

## **OBSTETRIC HISTORY**

Do not assume the current pregnancy is a woman's first pregnancy simply because she is very young or says she has only recently been married. She may have had an adolescent pregnancy or this could be a second marriage. For each previous pregnancy, document the newborn's sex and the place and date of birth. Review the pregnancy briefly by asking:

- Was the pregnancy intended?
- How did the pregnancy go, overall? Did she have any complications, such as vaginal spotting, swelling of her hands or feet, falls, or surgery?
- Did she take any medication? If so, what and why?
- Did she receive prenatal care? If so, when did she start?
- What was the duration of the pregnancy?

- What was the duration of labor? Was it what she expected? Worse? Better?
- What was the type of birth? Vaginal or cesarean? Vertex or breech? In a healthcare facility or at home? What type of anesthesia, if any, was used?
- Did she have stitches following birth?
- Did she have any complications following birth, such as excessive bleeding or infection?
- What was the infant's birth weight and sex? Did the infant cry right away? What was the infant's Apgar score?
- Was any special care needed for the baby, such as suctioning, oxygen, or an incubator?
- Was the baby discharged from the healthcare setting with her?
- What is the child's present state of health?

Ask also about any previous miscarriages or therapeutic abortions and whether she had any complications during or following those. If a woman's blood type is Rh negative, ask if she received Rh immune globulin (RhIG [RhoGAM]) after miscarriages, abortions, or previous births, so you will know whether Rh sensitization could have occurred. In conjunction, ask if she has ever had a blood transfusion to establish possible risk of hepatitis B or HIV exposure or Rh sensitization from a blood transfusion.

After this history of previous pregnancies is obtained, rate the woman's status with respect to the number of times she has been pregnant, including the present pregnancy (her gravida status) and the number of children over the age of viability (20 weeks gestation) she has previously delivered (her para status). [Table 11.4](#) explains these terms. For example, a woman who had two previous pregnancies that ended in miscarriages at 12 weeks (under the age of viability) and is now pregnant is a gravida 3, para 0. If she had given birth from the two previous pregnancies and is now pregnant, she would be gravida 3, para 2.

**TABLE 11.4 TERMS RELATED TO PREGNANCY STATUS**

Key Terms	Definition
<b>Para</b>	The number of pregnancies that have reached viability, regardless of whether the infants were born alive
<b>Gravida</b>	A woman who is or has been pregnant
<b>Primigravida</b>	A woman who is pregnant for the first time
<b>Primipara</b>	A woman who has given birth to one child past age of viability
<b>Multigravida</b>	A woman who has been pregnant previously
<b>Grand multipara</b>	A woman who has carried five or more pregnancies to viability
<b>Multipara</b>	A woman who has carried two or more pregnancies to viability
<b>Nulligravida</b>	A woman who has never been and is not currently pregnant

---

A more comprehensive system for classifying pregnancy status (GTPAL or GTPALM) provides greater detail on a woman's pregnancy history. By this system, the gravida classification remains the same, but para is broken down as follows:

T: the number of full-term infants born (infants born at 37 weeks or after)

P: the number of preterm infants born (infants born before 37 weeks)

A: the number of spontaneous miscarriages or therapeutic abortions

L: the number of living children

Using this system, a woman in the first example who is pregnant and has two children at home would be gravida 3, para 2002 (GTPAL) or gravida 3, para 2002 (GTPAL). A multigestation pregnancy is considered as one para. For example, a woman who had term twins, then one preterm infant, and is now pregnant again would be a gravida 3, para 2103 (GTPAL).

### *What If... 11.1*

**A pregnant woman has the following past history: a boy born at 39 weeks gestation, alive and well; a girl born at 40 weeks gestation, alive and well; and a girl born at 33 weeks gestation, alive and well. How would the nurse summarize her gravida and para status?**

## REVIEW OF SYSTEMS

A review of systems completes the subjective information of a health history. Use a systematic approach, such as head to toe, and explain what you will be doing by an explanation such as "I'm going to start at the top of your head and go through to your toes, asking about body parts or systems and any diseases you may have had." A review of systems helps women recall concerns they forgot to mention earlier, such as a urinary tract infection, a condition that can influence the outcome of pregnancy and thus would be important to your history taking.

The following body systems and questions about conditions constitute the minimum information to be addressed in a review of systems for a first prenatal visit:

- *Head:* Headache? Head injury? Seizures? Dizziness? Fainting?
- *Eyes:* Vision? Glasses or contacts needed? Diplopia or double vision? Infection? Glaucoma? Cataract? Pain? Recent changes? Last vision examination and outcome?
- *Ears:* Infection? Discharge? Earache? Hearing loss? Tinnitus? Vertigo?
- *Nose:* Epistaxis (nose bleeds)? Discharge? How many colds a year? Allergies? Postnasal drainage? Sinus pain?
- *Mouth and pharynx:* Dentures? Condition of teeth? Toothaches? Any bleeding of gums? Hoarseness? Difficulty in swallowing? Tonsillectomy? Last dental examination and outcome?

- *Neck*: Stiffness? Masses?
- *Breasts*: Lumps? Secretion? Pain? Tenderness?
- *Respiratory system*: Cough? Wheezing? Asthma? Shortness of breath? Pain? Serious chest illness, such as tuberculosis or pneumonia?
- *Cardiovascular system*: History of heart murmur? History of heart disease such as rheumatic fever or Kawasaki disease? Hypertension? Any pain? Palpitations? Anemia? Does she know her blood pressure? Has she ever had a blood transfusion?
- *Gastrointestinal system*: What was her prepregnancy weight? Vomiting? Diarrhea? Constipation? Change in bowel habits? Rectal pruritus? Hemorrhoids? Pain? Ulcer? Gallbladder disease? Hepatitis? Appendicitis?
- *Genitourinary system*: Urinary tract infection? Hematuria? Frequent urination? Sexually transmitted infection? Pelvic inflammatory disease? Hepatitis B? HIV? Did she have a problem getting pregnant? Is subfertility a concern?
- *Extremities*: Varicose veins? Pain or stiffness of joints? Any fractures or dislocations? Carpal tunnel syndrome? Restless leg syndrome?
- *Skin*: Any rashes? Acne? Psoriasis?

## INTERVIEW CONCLUSION

End an interview by asking if there is anything you have not covered that the woman wants to discuss; this gives her one more chance to ask any questions she has about this new life experience. Explore any further concerns she mentions because these can be equally as important as her first concern mentioned.

## Physical Examination

The next step in health assessment is physical examination. Ask a woman to void for a clean-catch urine specimen before the examination because this will provide a urine specimen for either immediate dipstick or laboratory testing of bacteria, protein, glucose, and ketone determinations. In addition, an empty bladder makes the pelvic examination more comfortable and, by reducing bladder size, allows for easier identification of pelvic organs. If you are not already familiar with obtaining a clean-catch urine specimen, [Box 11.6](#) provides instructions.

### BOX 11.6

#### Nursing Care Planning Using Procedures

### OBTAINING A CLEAN-CATCH URINE SPECIMEN

**Purpose:** Helping a woman obtain a clean-catch urine specimen

Procedure	Principle
1. Ask the woman to wash her hands.	1. Handwashing helps prevent spread of

2. She then needs to open the commercial clean-catch urine specimen kit and moisten the cotton balls with the antiseptic solution or open the prepared antiseptic wipes.

3. a. Ask the woman to sit on the commode and separate her labia with her nondominant hand.

- b. She should then cleanse her perineum, washing from front to back, using a cotton ball or wipe for only one stroke and then discarding it.

4. Caution her to avoid touching the

microorganisms.

2. Preparation enhances efficiency and decreases the possibility of contamination during the procedure.

3. Cleansing helps prevent microorganisms from entering the urine specimen.

Cleansing from front to back prevents bringing rectal contamination forward.

4. Careful handling of equipment

inside of the container or cap.

5. The woman should begin urinating, allowing the first urine to flow into the toilet. Next, she should hold the container under the urine stream until approximately 10–20 ml has been obtained. Once the specimen is obtained, she can remove the container, release her hand from her labia, and finish voiding into the toilet.

6. To finish, she should cap the specimen container, wash her hands, and bring the specimen to you. Encourage her to report whether she felt any pain on urination.

prevents contamination.

5. The first flow of urine washes microorganisms and debris from the urinary meatus and thus shouldn't be collected. Collecting the specimen midstream helps ensure that a sterile specimen is obtained.

6. Capping the container prevents inadvertent spilling and possible contamination of the specimen. Pain on urination is a symptom of urinary tract infection.

A physical examination at a first prenatal visit typically includes inspection of major body systems, with emphasis on the changes that occur with pregnancy or that could signal a developing complication. General techniques of physical examination are discussed in [Chapter 34](#).

## **BASELINE HEIGHT/WEIGHT AND VITAL SIGN MEASUREMENT**

A woman's weight and height are measured at a first prenatal visit to establish a pregnancy BMI to serve as a baseline for future comparison. Record this assessment with her prepregnancy BMI, if available, to determine how much weight she has already gained or lost ([Fig. 11.2](#)). When obtaining women's weight, be certain to convey an air of "weight gain is healthy" so a woman feels comfortable gaining 30 to 40 lb during pregnancy (many patients, especially younger ones, with a lower BMI need to gain 40 lb to help ensure a healthy fetus).

**Figure 11.2** A woman weighs in at a prenatal visit. Pregnant women may need reassurance that gaining weight aids fetal growth. (© Barbara Proud.)

Measure vital signs, including blood pressure, respiratory rate, and pulse rate, again, for baseline levels. A sudden increase in blood pressure and a sudden weight gain are both danger signs that gestational hypertension may be occurring. A sudden increase in pulse or respirations could suggest undetected bleeding. If close monitoring of blood pressure will be necessary during pregnancy, teach a support person or the woman herself how to do this so the woman can continue assessing blood pressure at home.

## **ASSESSMENT OF BODY SYSTEMS**

Physical examination always begins with an inspection of general appearance to form an overall impression of a woman's health and well-being. General appearance is important because the manner in which people dress, the way they speak, and the body posture they assume all suggest how they feel about themselves. Remember that not all

women are thoroughly happy about being pregnant. After the general assessment, examine the patient head-to-toe by beginning with the head and scalp and ending with the extremities and the skin (Table 11.5).

**TABLE 11.5 HEAD-TO-TOE ASSESSMENT FOR PREGNANT PATIENT**

<b>System</b>	<b>Signs and Symptoms That Require Further Action</b>	<b>Considerations and Actions</b>
General appearance and mental status	Poor hygiene Soiled or inappropriate clothing Inappropriate affect Multiple bruises or lacerations	Assess for IPV. Consider social and mental health components.
Head and scalp	Dry or sparse hair Lack of hygiene Headache	Provide nutritional counseling. Consider social and mental health components. Assess BP.
Eyes	Eyelid edema Swollen optic disk Visual changes	Asses BP: concern for hypertensive disorder. Assess diabetic status.
Nose and sinuses	Nasal congestion Tender sinuses	Patient education about this normal discomfort of pregnancy; avoid the use of any medicated nasal spray as it can lead to or exacerbate hypertension. Consider infection.
Ears	Feeling of fullness Pain or discharge	Patient education about normal discomfort of pregnancy Concern for infection
Mouth, teeth, throat	Poor dentition/oral hygiene Gingival hypertrophy	Refer to dentist. Provide documentation of pregnancy. Patient education about normal discomfort of pregnancy
Neck	Enlarged thyroid or nodule on thyroid	Consider thyroid disorder or nutritional deficiency.
Lymph nodes	Palpable	Assess for symptoms and signs of infection or illness.
Breasts	Normal changes: • Darker areola	Patient education about these normal discomforts and changes in pregnancy

	<ul style="list-style-type: none"> <li>• Prominent Montgomery's tubercles</li> <li>• Increase in size</li> <li>• Breast tenderness</li> <li>• Prominent vascularization</li> <li>• Colostrum from nipples</li> <li>• Enlarged supernumerary nipples</li> </ul> <p>Abnormal changes:</p> <ul style="list-style-type: none"> <li>• Masses, lesions, peau d'orange, nipple retraction</li> </ul>	Concern for breast cancer
Heart	Murmur Supine hypotension and/or heart palpitations	May be a normal change in pregnancy but requires evaluation Patient education about normal changes and proper positioning in pregnancy
Lungs	Dyspnea in third trimester Increased respiratory rate	Patient education about normal discomforts and changes in pregnancy
Back	Backache Scoliosis	Discuss posture and normal discomforts of pregnancy. Consider anesthesia consult for planned epidural.
Rectum	Hemorrhoids	Patient education about normal discomforts and changes in pregnancy Recommend over the counter hemorrhoid remedies.
Extremities and skin	Relaxed or loose joints Itching palms and soles of feet Edema	Patient education about normal discomforts and changes in pregnancy Requires medical evaluation for liver condition Assess for temporal relationship. This could be dependent edema and normal, or it may be a symptom of a serious condition related to hypertension. Obtain BP.

IPV, intimate partner violence; BP, blood pressure.

### *What If... 11.2*

**Sandra’s job at a commercial laundry ironing sheets keeps her on her feet for long periods. Is she likely to be exposed to toxic substances doing this work? Is there a greater opportunity than usual for her to develop upper respiratory infections? What effect might her job have on her hips and posture?**

## MEASUREMENT OF FUNDAL HEIGHT AND FETAL HEART SOUNDS

At about 12 to 14 weeks of pregnancy, the uterus becomes palpable as a firm globular sphere showing over the symphysis pubis. It grows to reach the umbilicus at 20 to 22 weeks and the xiphoid process of the sternum at 36 weeks. In primiparas, it then often returns to about 4 cm below the xiphoid process because of “lightening” for the rest of pregnancy. If a woman is past 12 weeks of a pregnancy, assess whether the fundus of the uterus is palpable, measure the fundal height (from the top notch of the symphysis pubis to the superior aspect of the fundus), and plot the height on a graph such as the one shown in [Figure 11.3](#); plotting uterine growth at each visit this way can help detect any unusual variation in uterine or fetal growth. If an abnormality is detected, further investigation with ultrasound can be scheduled to determine the cause of the unusual increase or lack of growth.

**Figure 11.3** Plotting uterine height on a uterine height graph at prenatal visits (recorded typically after 12 weeks gestation) helps to monitor whether fundal height is increasing.

Auscultate for fetal heart sounds (a rate of 110 to 160 beats/min is normal) by

Doppler if the pregnancy is past 10 weeks (the lower limit at which they can usually be heard). Palpate for fetal outline and position after the 28th week as a further estimation of fetal size and growth.

### *QSEN Checkpoint Question 11.4*

#### QUALITY IMPROVEMENT

Sandra reports that the palms of her hands are always itchy, and the nurse notices scratches on them when you perform a physical examination. The nurse's plan of care should specify that this problem is most likely due to what factor in women who are pregnant?

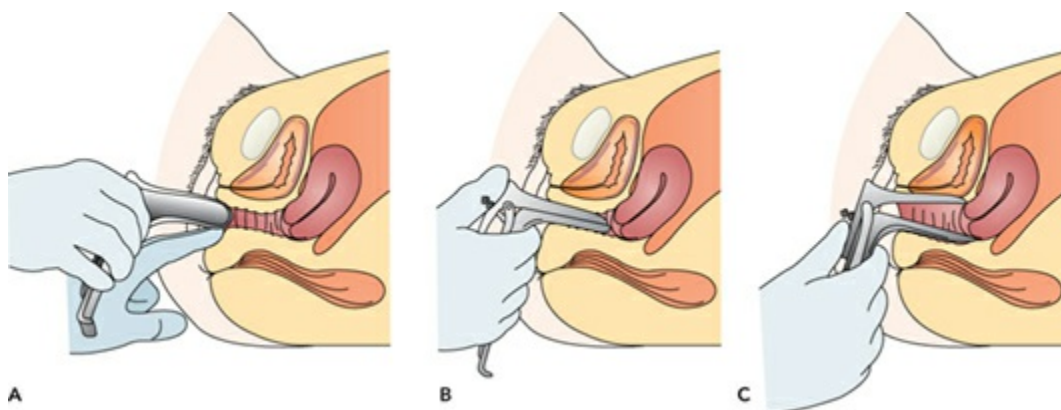

- Anxiety or fear about the pregnancy
- A potential Rh incompatibility
- Peripheral edema related to changes in fluid and electrolyte levels
- A common reaction to increasing estrogen levels

*Look in Appendix A for the best answer and rationale.*

#### PELVIC EXAMINATION

A pelvic examination reveals information on the health of both a woman's internal and external reproductive organs. The following equipment is required:

- A **speculum** (a metal or plastic instrument with movable flat blades; Fig. 11.4)
- A spatula and/or broom for cervical sampling
- Clean examining gloves
- Lubricant
- A glass slide or liquid collection device for a Pap smear
- A culture tube
- Two or three sterile cotton-tipped applicators or cytobrushes for obtaining cervical cultures
- A good examining light
- A movable stool at correct sitting height

**Figure 11.4** Insertion of a vaginal speculum. (A) Blades held

obliquely on entering the vagina. **(B)** Blades rotated to horizontal position as they pass the introitus. **(C)** Blades separated by depressing thumbpiece and elevating handle. The position of the blades is maintained by adjusting a thumbscrew.

Pelvic examinations have the reputation of being painful and causing a loss of modesty. If this is a first pregnancy and the patient is under the age of 21 years, it may be the first time a woman has ever had this type of examination. Having heard stories about how painful these examinations can be may cause a woman to tense just thinking about it. When pelvic muscles are tense, however, not only can the examination become painful but also an examiner has difficulty assessing the status of pelvic organs. This examination may be particularly difficult if a patient has a history of sexual abuse or assault.

Allow a woman the opportunity to talk with the person performing the examination while sitting up, before being placed in a lithotomy position, because this can enhance her sense of self-esteem and control. Many women want their support person to remain with them at the head of the table during the examination. In addition, it is customary, especially on an initial visit, for a nurse or nursing assistant to be in the room with a woman for a pelvic examination to offer additional support. This is true whether the examiner is male or female.

After the woman empties her bladder, have her lie in a **lithotomy position** (on her back with her thighs flexed and her feet resting in the examining table stirrups; [Fig. 11.5](#)). If a woman is uncomfortable in a lithotomy position, the exam can be done with her lying flat on a bed or table with her knees raised. Make sure her buttocks extend slightly beyond the end of the examining table if possible. Place a pillow under her head or slightly elevate the head of the examination table to help her relax her abdominal muscles. Properly drape her with a draw sheet over her abdomen that extends over her legs for modesty.

**Figure 11.5** A lithotomy position used for a pelvic examination. Help position a woman with her buttocks just over the edge of the table.

Drape appropriately for modesty.

When serving as a support person, remember to remain at the head of the table so you can hold a woman's hand or put a hand on her shoulder if she needs the support of physical contact. Give explanations of what is happening, what she might be feeling (such as pressure), and what the examiner is doing as needed. Conversation with the examiner over her head is not helpful. Suggesting a woman breathe in and out (not hold her breath as she is likely to do) is a good technique to help her relax (holding her breath pushes the diaphragm down and makes the pelvic organs tense and unyielding).

## External Genitalia

A pelvic examination begins with inspection of the external genitalia. Any signs of inflammation, infection, ulcerations, lesions, vaginal discharge, or circumcision are noted.

A herpes simplex 2 viral infection appears as clustered, pinpoint vesicles on an erythematous (reddened) base on the vulva that feel painful when touched or irritated. It is important that these are detected during pregnancy because the presence of herpes lesions on the vulva or vagina at the time of birth may necessitate cesarean birth to prevent exposing the fetus to the virus during passage through the birth canal. Note the presence of a herpes infection in the woman's record so she can receive prophylactic treatment at the end of her pregnancy to prevent neonatal transmission during birth which could result in a life-threatening neonatal infection (S. H. James & Kimberlin, 2015).

Next, the Skene glands that empty into the urethra and Bartholin glands that enter into the posterior vagina are checked for size and consistency. If they are swollen or emit a discharge, the discharge is cultured because an infection here could be caused by something as simple as streptococci; it may also be a more serious infection such as gonorrhea or chlamydia that could cause subfertility in the woman and conjunctivitis in her newborn.

Problems with vaginal muscle wall support, such as a rectocele (a forward pouching of the rectum into the posterior vaginal wall) or a cystocele (a pouching of the bladder into the anterior vaginal wall), are usually evaluated next. To reveal these, while the labia are gently separated to allow a view of the vaginal walls, a woman is asked to bear down as if she were moving her bowels, an action that will reveal irregular pouching on the vaginal walls.

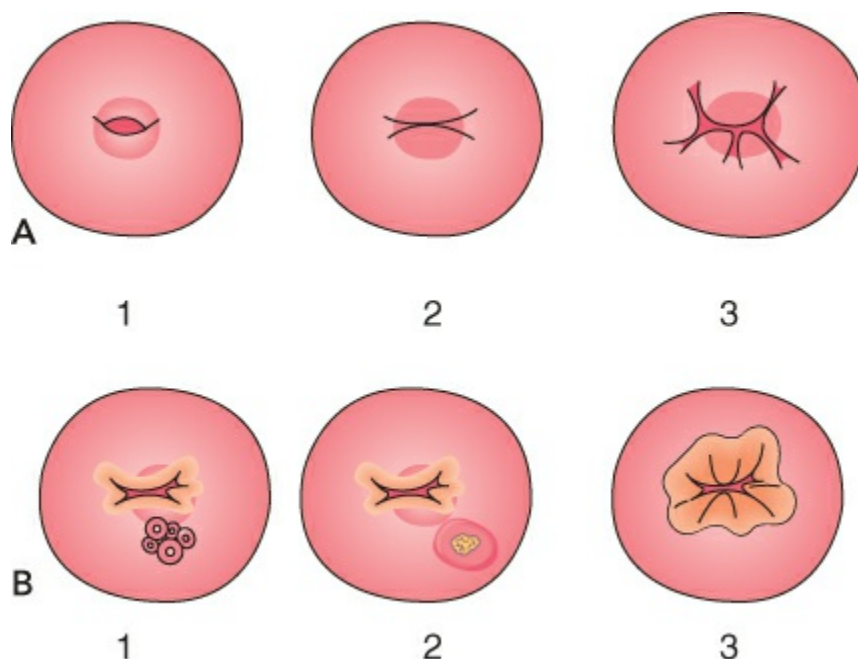

## Internal Genitalia

To view the cervix, the vagina must be opened and held open with a speculum. When fully inserted and rotated to this horizontal position, the blades are opened and the cervix becomes visible. They are secured in the open position by a thumb screw (metal speculum) or sliding latch (plastic speculum) at the side (see Fig. 11.4C).

With the speculum in place, the cervix is inspected for position. Normally, the

uterine cervix is centered in the vagina; the cervix of a retroverted uterus will be positioned anteriorly, and the cervix of an anteverted uterus is positioned posteriorly. The cervix color (a nonpregnant cervix is light pink; in pregnancy, it changes to almost purple) and any lesions, ulcerations, discharge, or otherwise abnormal appearance are documented.

In a nulligravida (a woman who is not now or never has been pregnant), the cervical os appears round and small (Fig. 11.6A1). In a woman who has had a previous vaginal birth, the cervical os has much more of a slitlike appearance (see Fig. 11.6A2). If a woman had a cervical tear during a previous birth, the cervical os may appear as a transverse crease the width of the cervix or a typical star-like (stellate) formation (see Fig. 11.6A3).

**Figure 11.6** (A) Appearances of the cervix. (1) Nulligravida cervix. (2) Cervix after childbirth. (3) “Stellate” cervix seen after mild cervical tearing. (B) Possible cervical lesions. (1) Herpes simplex 2. (2) Chancre of syphilis. (3) Erosion or infection.

If a cervical infection is present, cervical lesions (herpes simplex 2; see Fig. 11.6B1), chancre (syphilis; see Fig. 11.6B2), or a mucus discharge may be present. With infection, the epithelium of the cervical canal often enlarges and spreads onto the area surrounding the os, giving the cervix a reddened appearance that bleeds easily (**erosion**; see Fig. 11.6B3).

Typical infections that might be found are trichomoniasis, candidal (yeast) infection, gonorrhea, and chlamydia. Trichomoniasis, a protozoal infection, if present, causes petechial spots on the vaginal walls, cervical redness, and a profuse, whitish, bubbly discharge. It is important that trichomoniasis and bacterial vaginosis be treated in pregnancy as there is a link between these infections and preterm birth (Meites, Gaydos,

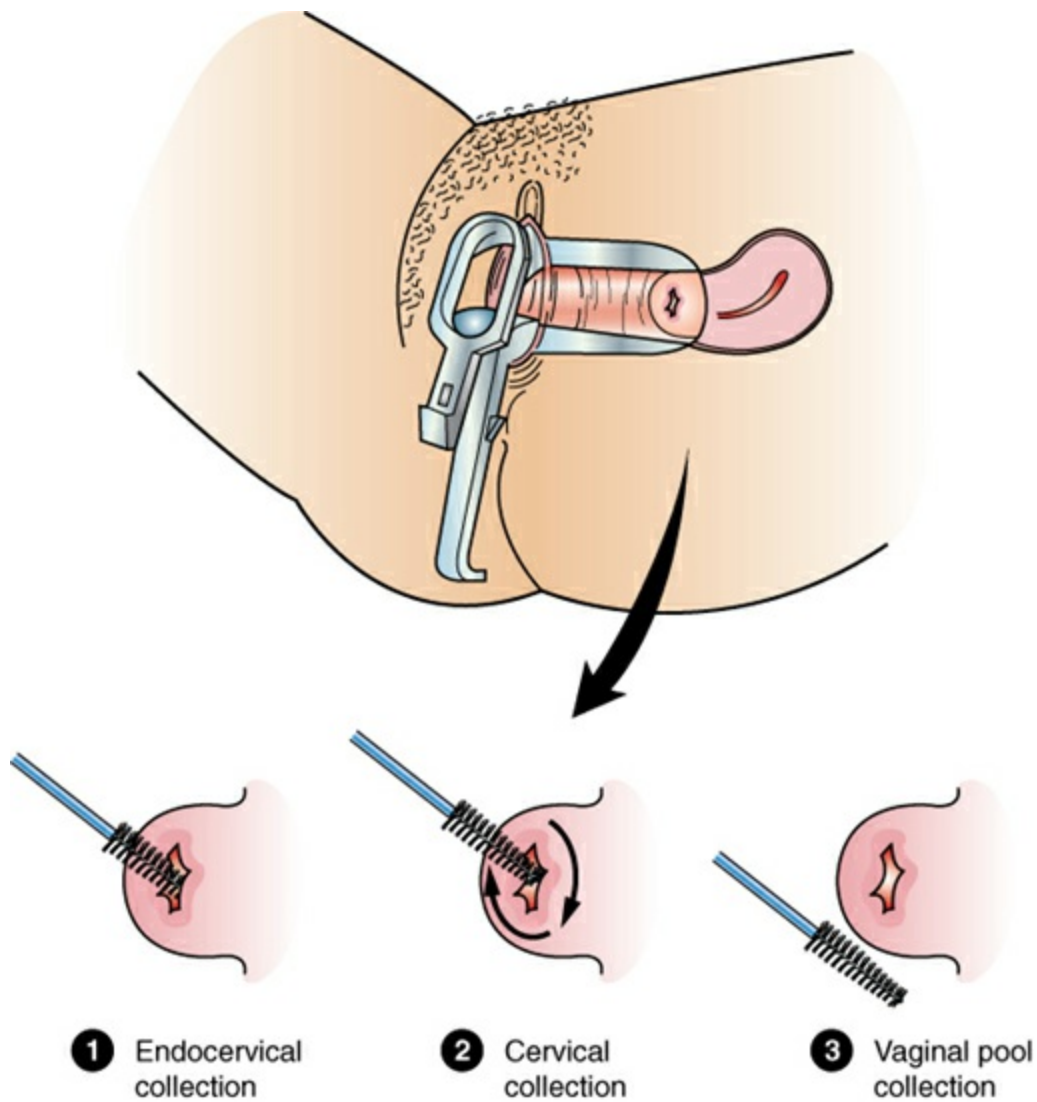

Hobbs, et al., 2015). A candidal infection causes an itching and burning sensation in addition to producing a clumpy cheese-like discharge that may cause bleeding if scraped away from the vaginal walls. A gonorrhea infection presents with a thick, greenish-yellow discharge and extreme inflammation. Chlamydia is called a “silent” or “invisible” infection because it shows almost no external symptoms but internally may cause a mucopurulent cervical discharge and slight cervical redness (Price et al., 2016). Cultures for gonorrhea and chlamydia should be collected during the initial pelvic exam and between 35 and 37 weeks for patients aged 25 years and under.

A nonpregnant woman needs medication to relieve discomfort from these infections. A pregnant woman needs medication to not only relieve discomfort but also prevent preterm birth or transmission of the infection to the newborn as the newborn passes through the birth canal at term (S. H. James & Kimberlin, 2015; Meites et al., 2015). A candidal infection in the newborn, for example, causes thrush or *oral candidiasis*. A chlamydia infection can cause pneumonia or conjunctivitis in a newborn. Gonorrhea causes such a severe conjunctivitis that it can lead to blindness (Workowski & Bolan, 2015). Specific therapies for these infections are discussed in Chapter 47.

Carcinoma of the cervix appears as an irregular, granular growth. Cervical polyps (red, soft, pedunculated benign protrusions) are also occasionally seen at the os to the cervix. Women should have a first Pap smear to detect cervical cancer when they reach 21 years of age and then every 3 years thereafter (ACOG, 2016a).

### **Papanicolaou Smear**

A Pap smear is taken from the endocervix at a first prenatal visit to be certain a precancerous or cancerous condition of the uterine cervix, vulva, or vagina is not present (Fig. 11.7). In addition, a photograph of the cervix may be taken to document the appearance of a suspicious lesion on the cervix or confirm that a previous lesion from an infection has healed.

**Figure 11.7** Obtaining a Papanicolaou smear from the cervix.

The most commonly used classification system used to interpret Pap smears is the Bethesda system shown in [Table 11.6](#). Be certain when discussing results of Pap exams with woman that they are not overinterpreting results ([Nayar & Wilbur, 2015](#)). As shown in [Table 11.6](#), the first three levels describing squamous cells reveal some abnormal cells are present, but only the last category indicates that cancer is present.

**TABLE 11.6 INTERPRETATION OF PAP SMEARS BY THE BETHESDA SYSTEM**

Finding	Interpretation
Negative	No precancerous or cancerous cells are found.
<i>Squamous Cells</i>	
Atypical squamous cells (ASC)	Some cells appear different than normal but cannot be classified as precancerous.

Low-grade squamous intraepithelial lesion (LSIL)	Mild precancerous changes may have been found in some cells.
High-grade squamous intraepithelial lesion (HSIL)	Moderate to severe precancerous changes may have been found in some cells.
Squamous cell carcinoma	Cancerous cells are present.
<i>Glandular Cells</i>	
Atypical glandular cells	There is an increased risk of precancer or cancerous cells.
Adenocarcinoma	Cancerous cells are present.

From Mackay, H. T. (2012). Gynecologic disorders. In S. J. McPhee, M. Papadakis, & M. W. Radow (Eds.), *Current medical diagnosis and treatment*, (pp. 727–759). Columbus, OH: McGraw-Hill.

Women who engage in anal intercourse may have an anal swab taken as well as vaginal swabs to detect anal squamous neoplasms. The technique for obtaining an anal Pap smear is the same as that for vaginal specimens (a cytobrush is used). Caution the patient that she may have slight rectal bleeding following this procedure so she isn't unnecessarily concerned.

### *What If . . . 11.3*

**The foot of an examining table in a clinic faces the room door, leaving women to feel exposed if someone should walk in unexpectedly. This saves an examiner steps, but is this the best position for the table?**

## Vaginal Inspection

Before the vaginal speculum is removed, a culture for trichomoniasis (microscope slide wet mount sample) or group B *Streptococcus* (done at 35 to 37 weeks gestation) may be taken. Some Pap test specimen can be analyzed for gonorrhea, chlamydia, and HPV, so a separate swab for these infections is not required. Treatment to eliminate all of these infections during early pregnancy helps guard maternal, fetal, and newborn health (Meites et al., 2015).

In a nonpregnant woman, vaginal walls are light pink; pregnancy may turn them dark blue to purple. Any areas of inflammation, ulceration, lesions, or discharge should be noted.

## Examination of Pelvic Organs

Following the speculum examination, a bimanual (two-handed) examination is performed to assess the position, contour, consistency, and tenderness of pelvic organs (Fig. 11.8).

**Figure 11.8** A bimanual examination to determine uterine size.

Abnormalities that can be noted by bimanual examination include ovarian cysts, enlarged fallopian tubes (perhaps from pelvic inflammatory disease), and an enlarged uterus. An early sign of pregnancy (Hegar's sign) is elicited on bimanual examination as well (see [Chapter 10](#), [Fig. 10.4](#)).

### **Rectovaginal Examination**

After a bimanual pelvic examination, the hand is withdrawn from the vagina. The index finger is reinserted into the vagina and the middle finger into the rectum. By palpating the tissue between the examining fingers in this way, it is possible to assess the strength and irregularity of the posterior vaginal wall. This maneuver may be slightly uncomfortable for a woman because of rectal pressure.

After completing the examination, any excess lubricant is wiped away from the vaginal and rectal openings. Be certain to wipe front to back to prevent bringing rectal contamination forward from the rectum to the vagina. [Box 11.7](#) shows an

interprofessional care map illustrating both nursing and team planning for a first prenatal visit including support during a pelvic examination.

BOX 11.7

**Nursing Care Planning**

**AN INTERPROFESSIONAL CARE MAP FOR A WOMAN’S FIRST PRENATAL VISIT**

Sandra Czerinski is a 29-year-old woman, 12 weeks pregnant, who comes for a first prenatal visit. She’s concerned because she didn’t realize she was pregnant until a week ago. As a result, she has been actively dieting plus lifting weights at a health club. She hasn’t had a pelvic examination since she was in high school, when she had a vaginal infection. She remembers that exam as being very painful. She is worried she has a urinary tract infection now because she has to “go all the time.” She does not want any blood work done because she is not sure if her health insurance will cover the entire fee.

**Family Assessment:** Single woman; lives by herself in one-bedroom apartment. Works at a laundry. Boyfriend is a roofing salesman; out of town 4 days a week

**Patient Assessment:** Gravida 1, para 0. Last menstrual period 3 months ago. Had nausea last month but thought it was the “flu.”

Menarche at age 11 years; menstrual cycle every 29 days, 6 days duration with moderate flow and mild cramps. Past history positive for sinusitis; appendectomy at age 12 years. Smokes about 1/2 pack per day, “more when I’m stressed at work”; denies alcohol use. “I drink club soda with lime or mineral water.”

ROS: Height, 5 ft 5 in.; prepregnancy weight, 160 lb (BMI: 27.5 or overweight). Slight gingival hyperplasia; breasts full and slightly tender

Pelvic examination by nurse-midwife: cervical os round, clean, and slightly soft; uterus enlarged and soft; + Chadwick’s sign, + Hegar’s sign, + Goodell’s sign. Uterine height palpable at one finger over symphysis pubis. Fetal heart rate via Doppler at 152 beats/min.

Remainder of physical examination within normal limits. Weight today: 177 lb.

**Nursing Diagnosis:** Health-seeking behaviors related to guidelines for healthy pregnancy

**Outcome Criteria:** Patient states importance of stopping smoking, identifies measures she will take to reduce number of cigarettes smoked per day, and states she will no longer try to lose weight. Makes appointment for follow-up visits.

Team Member Responsible	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse/nurse-	Assess patient’s	Discuss the	Assessing	Patient

midwife	expectations about the pregnancy, including if she expects to continue to work and continue present lifestyle.	effect of pregnancy on her partner and any religious or cultural beliefs that would interfere with her ability to adapt to pregnancy changes.	expectations is important to assist a woman in identifying areas of need and adaptation necessary for pregnancy.	describes the likely effect of the pregnancy on herself and partner; identifies areas where she anticipates life changes.

---

*Procedures/Medications for Quality Improvement*

---

Nurse/nurse-midwife	Establish baseline findings of present health.	Obtain initial health history and physical exam.	Initial assessment provides a baseline for future comparison and identification of factors that may place a patient at risk.	Patient receives a thorough initial assessment, to lay a psychological and physiologic foundation of healthcare information for prenatal care.
Nurse	Obtain additional measures of wellness during pregnancy.	Obtain weight, vital signs, and urine and blood specimens.	A baseline weight and vital signs are necessary for future comparison.	Patient's weight and vital signs are monitored and compared with previous values at each

				prenatal visit.
<i>Nutrition</i>				
Nurse/nutritionist	Obtain a 24-hour nutrition recall.	Discuss with patient her increased nutritional needs during pregnancy. Provide information about a high-protein diet with prenatal vitamin supplementation.	A well-balanced diet with adequate fluid intake and use of prenatal vitamins helps to ensure an optimal environment for fetal growth and development.	Patient voices an understanding of the increased food she needs during pregnancy. Patient voices she will discontinue dieting.
<i>Patient-Centered Care</i>				
Nurse	Assess if patient is interested in decreasing smoking during pregnancy.	Instruct patient in the effects of smoking on the fetus. Assist patient with methods to reduce and stop smoking, if possible.	Nicotine in cigarettes has been shown to be teratogenic to a fetus.	Based on the fetal effects of nicotine, patient describes a plan to stop smoking at least until after the birth and, ideally, long term.
Nurse	Assess if patient is aware of the danger signs of pregnancy she will need to report immediately should they occur.	Instruct patient about possible danger signs. Emphasize that although these signs are important, they do not necessarily mean something is wrong.	Knowledge of possible danger signs allows for early detection and prompt intervention should it be necessary.	Patient and partner list danger signs of pregnancy to report immediately.
<i>Psychosocial/Spiritual/Emotional Needs</i>				
Nurse	Assess if patient has questions or concerns about	Assure patient that concern during pregnancy is a	Anxiety can interfere with ability to adjust to pregnancy.	Patient describes any concerns about pregnancy and

success of pregnancy.	normal response. Include information about physiologic and psychological changes of pregnancy.	Reviewing information reinforces understanding.	receives appropriate information or assurance.
-----------------------	--	---	--

*Informatics for Seamless Healthcare Planning*

Nurse	Assess whether patient will have any difficulty continuing with prenatal care.	Assist patient with setting up appointments for future visits keeping in mind that she is concerned about her health insurance coverage.	Assisting with setting appointments helps to ensure adherence.	Patient states plan for expected antepartal care visits and affirms her willingness to adhere to the plan.

**QSEN Checkpoint Question 11.5**

**TEAMWORK & COLLABORATION**

Sandra has not had a pelvic examination since she was in high school. Consequently, the nurse-midwife has asked the nurse to help make her more at ease during her first prenatal pelvic examination. What action should the nurse take?

- a. Have her take a deep breath and hold it as long as she can during the examination.
- b. Tell her to bear down slightly as the speculum is inserted.
- c. Encourage her to moan in a low-pitched tone because this will push down the diaphragm.
- d. Teach her to breathe slowly and evenly while being examined.

*Look in Appendix A for the best answer and rationale.*

**The Pelvis: Establishing Adequacy for Childbirth**

The pelvis is a bony ring formed by four united bones: the two innominate (flaring hip) bones, which form the anterior and lateral portion of the ring, and the coccyx and sacrum, which form the posterior aspect (Fig. 11.9). The pelvis serves both to support and protect pelvic organs.

- Each innominate bone is divided into three parts: *ilium*, *ischium*, and *pubis*.
- The ilium forms the upper and lateral portion. The flaring superior border forms

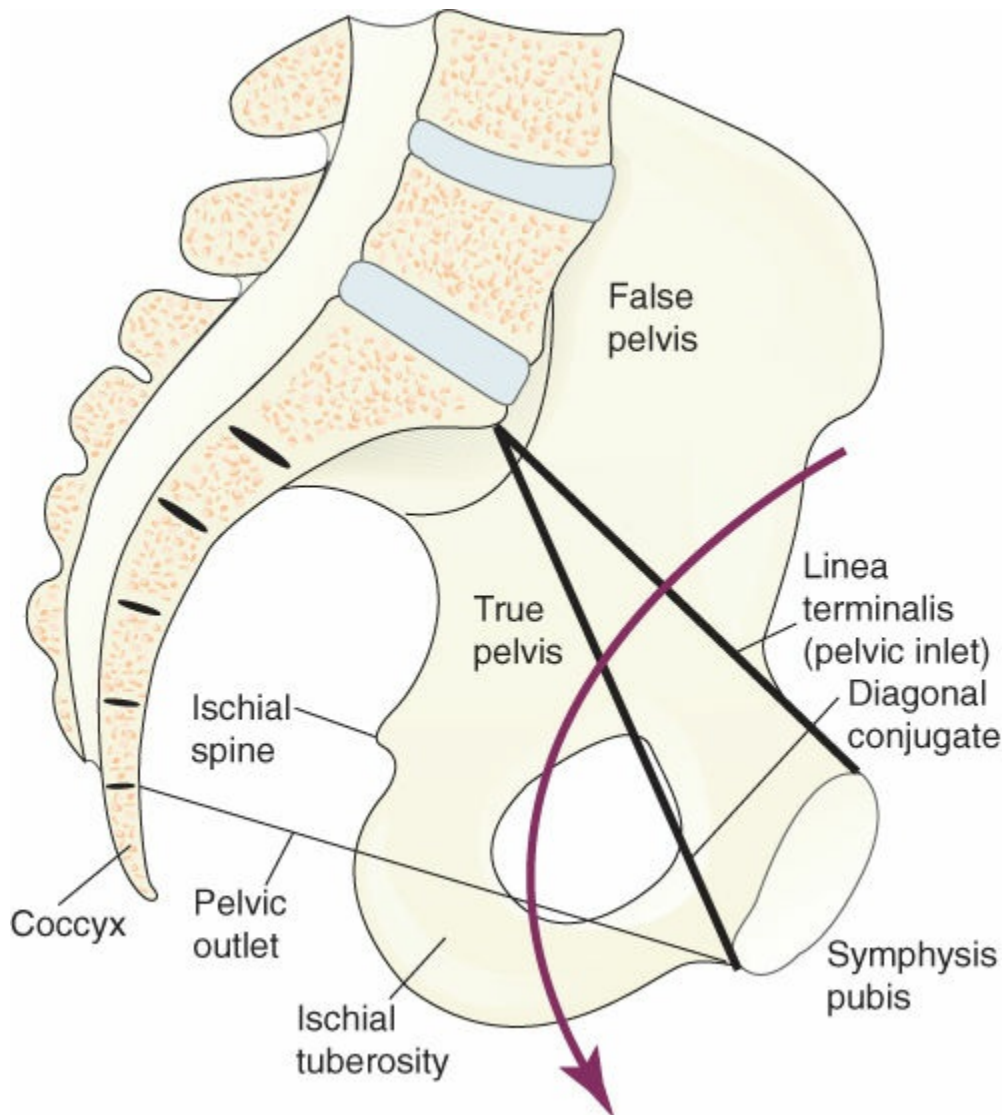

the prominence of the hip (the crest of the ilium).

- The ischium is the inferior portion.
- At the lowest portion of the ischium are two projections: the ischial tuberosities, or the part of the bone on which a person sits. These projections are important markers used to determine lower pelvic width.
- The ischial spines are small projections that extend from the lateral aspects of the pelvis into the pelvic cavity. They mark the midpoint of the pelvis. Their location is used to assess the level to which a fetus has descended into the birth canal just before or during labor.
- Where the two anterior portions of the innominate bone meet is the symphysis pubis.
- The sacrum is the upper posterior portion of the pelvic ring. There is a marked anterior projection of this bone at the point where it touches the lower lumbar vertebrae (the sacral prominence), which is used as a landmark when securing pelvic measurements.
- The coccyx, just below the sacrum, is composed of five very small bones fused together. Although the bone itself is stiff, there is a degree of movement possible in the joint between the sacrum and the coccyx (the sacrococcygeal joint). This movement is important during labor because it permits the coccyx to be pressed backward, allowing more room for the fetal head to pass through the bony pelvic ring at birth.

**Figure 11.9** Structure of the pelvis.

For obstetric purposes, the pelvis is further divided into the false pelvis (the superior half) and the true pelvis (the inferior half) (Fig. 11.10). The false pelvis supports the uterus during the late months of pregnancy and aids in directing the fetus into the true pelvis for birth. The false pelvis is divided from the true pelvis only by an imaginary line, the linea terminalis. This imaginary line is drawn from the sacral prominence at the back of the pelvis to the superior aspect of the symphysis pubis at the front.

**Figure 11.10** True and false pelvis. Portion above linea terminalis is false pelvis; portion below is true pelvis. *Arrow* shows “stovepipe” curve the fetus must follow to be born.

Other important terms in relation to the pelvis are the inlet, the outlet, and the pelvic cavity.

- The *inlet* is the entrance to the true pelvis, or the upper ring of bone through which the fetus must pass to be born vaginally. It is at the level of the linea terminalis or is marked by the sacral prominence in the back, the ilium on the sides, and the superior aspect of the symphysis pubis in the front. If you looked

down at the pelvic inlet, the passageway would appear heart-shaped because of the jutting sacral prominence. It is wider transversely (sideways) than in the anteroposterior dimension.

- The *outlet* is the inferior portion of the pelvis, or that portion bounded in the back by the coccyx, on the sides by the ischial tuberosities, and in the front by the inferior aspect of the symphysis pubis. In contrast to the inlet of the pelvis, the greatest diameter of the outlet is its anteroposterior diameter.
- The *pelvic cavity* is the space between the inlet and the outlet. This space is not a straight but a curved passage; the purpose of its curve is to slow and control the speed of birth. The snugness of the cavity also serves to compress the chest of the fetus as he or she passes through. This helps to expel lung fluid and mucus and thereby better prepare lungs for good aeration at birth.

For a baby to be born vaginally, he or she must be able to pass through the inlet, the cavity, and the outlet of the pelvic bone. This is not a problem for the average fetus; it may, however, be a problem if the mother is a young adolescent who has not yet achieved full pelvic growth (girls younger than age 14 years are most prone to this difficulty) or a woman who has had a pelvic injury from something such as an automobile accident.

### Estimating Pelvic Size

It is impossible to predict from the outward appearance of a woman whether her pelvic ring will be adequate for a fetus to pass through its center without difficulty.

Differences in pelvic contour occur mainly because of hereditary factors, but disease such as rickets, now rarely seen in the United States but still a concern in undeveloped countries, may cause contraction of the pelvis and severely narrow the pelvic outlet (Okeke, Enwereji, Onwuka, et al., 2015).

Once a woman has given birth vaginally, her pelvis has been proven adequate for vaginal birth, so it is unnecessary for pelvic measurements to be repeated unless she had an intervening history or trauma to the pelvis between pregnancies.

Types of pelvises found in women can be categorized into four groups (Fig. 11.11): android, anthropoid, gynecoid, and platypelloid.

- A *gynecoid*, or “female,” pelvis has an inlet that is well rounded forward and backward and has a wide pubic arch. This pelvic type is ideal for childbirth.
- In an *android*, or “male,” pelvis, the pubic arch forms an acute angle, making the lower dimensions of the pelvis extremely narrow. A fetus may have difficulty exiting from this type of pelvis.
- In an *anthropoid*, or “ape-like,” pelvis, the transverse diameter is narrow; the anteroposterior diameter of the inlet is larger than usual. Even though the inlet is large, the shape of the pelvis does not accommodate a fetal head as well as a gynecoid pelvis.
- A *platypelloid*, or “flattened,” pelvis has a smoothly curved oval inlet, but the anteroposterior diameter is shallow. A fetal head might not be able to rotate to

match the curves of the pelvic cavity.

**Figure 11.11** Types of pelvises. **(A)** *Android*, or “male,” pelvis. **(B)** *Anthropoid*, or “ape-like,” pelvis. **(C)** *Gynecoid*, or “female,” pelvis. **(D)** *Platypelloid*, or “flattened,” pelvis.

Internal pelvic measurements reveal the diameters of the inlet and outlet and can be obtained by pelvimetry at the time of a routine sonogram examination done to date a pregnancy. The following measurements are most commonly determined:

- The **diagonal conjugate** is the measurement between the anterior surface of the sacral prominence and the posterior surface of the symphysis pubis. The average measurement is 10.5 to 11 cm.
- The **ischial tuberosity** diameter is the distance between the ischial tuberosities, or the transverse diameter of the outlet (the narrowest diameter at that level, or the one most apt to cause a misfit). It is made at the medial and lowermost aspect of the ischial tuberosities at the level of the anus. A diameter of 11 cm is considered adequate because it will allow the widest diameter of the fetal head, or 9 cm, to pass freely through the outlet.

## Laboratory Assessment

A number of laboratory studies are included as part of assessment at a first prenatal visit to confirm general health and rule out sexually transmitted infection that could injure a growing fetus. Normal levels for these studies are available at

<http://thePoint.lww.com/Flagg8e>.

## URINALYSIS

Urine is tested for proteinuria (protein in urine), glycosuria (glucose in urine), nitrites (bacteria in urine), and pyuria (white blood cells in urine suggesting an infection). All four of these can be assessed by point of care tests, or the urine can be sent for microscopic examination in a laboratory.

## BLOOD SERUM STUDIES

The following serum studies are usually obtained at a first prenatal visit:

1. A complete blood count, including hemoglobin or hematocrit and red cell index to determine the presence of anemia, a white blood cell count to determine infection, and a platelet count to estimate clotting ability.
2. A genetic screen for common ethnically inherited diseases. African American women, for example, may have a blood sample taken to screen for sickle-cell trait or disease and glucose-6-phosphate dehydrogenase (G6PD). Asian and Mediterranean women may have this done for  $\beta$ -thalassemia, those with Jewish ancestry may have this done for Tay-Sachs disease, and Caucasian women may be tested to see if they are a carrier for cystic fibrosis.
3. A serologic test for syphilis (venereal disease research laboratory [VDRL] or rapid plasma reagin test). If syphilis is present, it must be treated early in pregnancy before fetal damage occurs.
4. Blood typing (including Rh factor). Blood type is documented because blood may have to be made available if a woman has bleeding during pregnancy and to detect the possibility of ABO and Rh isoimmunization.
5. Cultures for chlamydia and gonorrhea should be collected for each patient at the initial pelvic examination. By identifying these often asymptomatic infections, the patient can be appropriately treated with antibiotics and the risk of neonatal morbidity reduced. A test of cure should be done for these conditions as well as a repeat culture between 35 and 37 weeks. All patients aged 25 years and under should have a repeat gonorrhea and chlamydia test at 35 to 37 weeks regardless of prior infection status.
6. Maternal serum  $\alpha$ -fetoprotein (MSAFP) and pregnancy-associated plasma protein A. Both of these levels will be elevated if a neural tube or abdominal defect is present in the fetus; they may be decreased if a chromosomal anomaly is present. These tests are not routinely done at a first prenatal visit because they are most accurate if scheduled between 16 and 18 weeks of pregnancy. If levels are elevated or decreased, a sonogram or amniocentesis will be prescribed to clarify fetal health (Choi, Van Riper, & Thoyre, 2012).
7. An indirect Coombs test (determination of whether Rh antibodies are present in an Rh-negative woman). This test is generally repeated at 28 weeks of pregnancy. If an Rh-negative woman's titer is not elevated, she will be offered RhIG (RhoGAM) at 28 weeks of pregnancy, after any procedure that might

cause placental bleeding (amniocentesis or external version), and within 72 hours after delivery.

8. Serum antibody titers for rubella, hepatitis B (HBsAg), hepatitis C, varicella (chickenpox) may be assessed. These tests determine whether a woman is protected against these diseases if exposure should occur during pregnancy. Vaccines against these diseases can then be offered in the postpartum period. HBsAg testing may be repeated at about 36 weeks.
9. HIV screening. The CDC recommends that all women be tested in early pregnancy for HIV, and those at high risk should be retested in the third trimester (CDC, 2016a). High-risk criteria include women who have used or are using intravenous drugs; have engaged in sex with multiple partners; have had sexual partners who are infected or are at risk because they are bisexual, intravenous drug users, or hemophiliac; or received a blood transfusion between 1977 and 1985. Screening for HIV is done by an enzyme-linked immunosorbent assay (ELISA) on a blood sample. If this is positive, the finding is confirmed by a second test (a Western blot). Testing for HIV early in pregnancy allows a woman who is found to be HIV antibody positive the opportunity to begin therapy with a combination of anti-retrovirals which can decrease the risk of her infant acquiring the virus. It also allows a woman the option of choosing to terminate a pregnancy if she chooses. Because there is still no cure for HIV infection, some women may choose not to have a blood titer taken because they would rather not know they have the illness. Screening is increased in states who use the opt out method for HIV testing. This means that the patient will have HIV testing done along with their other serum testing unless they specifically ask not to be tested for this virus. Because HIV testing is controversial, be certain the information given about test results is relayed accurately and with tact and compassion (a high blood antibody titer means the woman has been exposed to the virus, not that she is necessarily infected). The result of HIV testing, like all patient information, is confidential; be certain not to report this information to anyone other than the woman.
10. If a woman has a history of previously unexplained fetal loss, has a family history of diabetes, has had babies who were large for gestational age (9 lb or more at term), has a BMI over 30, or has glycosuria, she will need to be scheduled for a 50-g oral 1-hour glucose loading or tolerance test (sometimes called a glucose challenge test) toward the end of the first trimester (12 weeks) to rule out gestational diabetes. The addition of a serum (HbA1C) has the best predictive value for identifying diabetes (Hughes, Moore, Gullam, et al., 2015).

If she is not high risk, she will have this test prescribed routinely at the 24th to 28th week of pregnancy. A glucose challenge test analyzes how well a woman's body is able to process sugar or whether the insulin-antagonistic effects of placental hormones are counteracting pancreatic insulin and causing an elevated blood glucose (a sign of gestational diabetes, which as many as 2% to 5% of women develop during pregnancy).

Normally, a woman's plasma glucose level should not exceed 130 to 140 mg/dl at 1 hour after glucose ingestion (see [Chapter 20](#) for a discussion of further testing and nursing responsibilities for women with diabetes in pregnancy).

## **TUBERCULOSIS SCREENING (MANTOUX TEST)**

The incidence of tuberculosis is on the rise as more people with lowered immune system function, such as a woman with HIV infection, contract tuberculosis and then spread it to others through coughing. Consequently, a woman's primary care provider may prescribe a purified protein derivative (PPD) tuberculin test for a woman as a test for tuberculosis.

For this test, a small amount (0.1 ml) of tuberculin units are injected by a needle and syringe intradermally (just under the top layer of skin). In 48 to 72 hours, the area is inspected. If the woman has tuberculosis, has been exposed to tuberculosis, or has received the bacille Calmette–Guérin (BCG) vaccine for tuberculosis, a reddened, raised, hardened area (called induration) will appear at the injection site. If the induration area is at least 10 cm in diameter, the test is considered positive (a person has been either exposed to tuberculosis or has tuberculosis); in a person with a lowered immune response, 5 cm can be considered a positive result.

If a woman has a positive result, a chest X-ray will be prescribed to assess her current disease status. Women are often reluctant to have X-rays done during pregnancy because they know radiation is harmful to a growing fetus. You can assure her that her fetus will be protected as long as she is given a lead apron to cover her abdomen.

Tuberculosis screening may also be done by a blood serum test called an interferon-gamma release assay (IGRA). IGRA testing is the preferred method because:

- In a woman who has a history of tuberculosis or who has received the BCG vaccine, a PPD test can cause an extreme reaction. BCG vaccine is not administered to people in the United States, but women from other countries may have received it.
- It can offer results for a woman who states it will be difficult for her to return for a follow-up appointment for a PPD test to be read and interpreted.

Screening for tuberculosis early in pregnancy is important because it is a chronic and debilitating disease that increases the risk of miscarriage. Further, the change in the shape of the maternal lung tissue as the growing uterus presses on the lungs may reactivate already healed lesions, thus worsening the disease ([LaCourse, Greene, Dawson-Hahn, et al., 2016](#)).

## **ULTRASONOGRAPHY**

If the date of the last menstrual period is unknown, a woman will be scheduled for a sonogram to confirm the pregnancy length and document healthy fetal growth at 7 to 11 weeks of pregnancy. An ultrasound may also be done, ideally between 11 and 13 weeks of pregnancy, as a part of a first trimester screening to assess for increased risk of Down

syndrome. A sonogram can be scheduled between 16 and 20 weeks gestation to verify healthy fetal structures and gender. Be certain women know that a sonogram done under 8 weeks will show only the presence of a gestation sac, not a moving, kicking fetus, so their expectations of what they will see are not disappointing (Gonçalves, 2016).

## Risk Assessment

Following information gathering at a first prenatal visit, findings are analyzed to determine whether a pregnancy is apt to continue with a good outcome or there is likely to be some risk that it will end before term or with an unfavorable fetal or maternal outcome (a high-risk pregnancy).

Table 11.7 lists a minimum of factors that would identify a pregnancy as high risk. A woman identified as high risk will need close observation during prenatal visits to be certain the pregnancy is progressing well; the infant born of a woman identified this way needs close observation in the neonatal period until it is confirmed the newborn is responding well to postuterine life.

**TABLE 11.7 ASSESSMENTS THAT MIGHT CATEGORIZE A PREGNANCY AS AT RISK**

Assessment	Risk Factors
Obstetric history	<ul style="list-style-type: none"> <li>Existing uterine or cervical anomaly</li> <li>History of subfertility, recurrent miscarriages, or grand multiparity</li> <li>Last pregnancy less than 1 year previous</li> <li>History of abnormal Pap smear</li> <li>Previous premature cervical dilatation, preterm labor, preterm birth, low–birth-weight infant, or cesarean birth</li> <li>Previous macrosomic infant or multiple gestation</li> <li>Previous abnormal gestational trophoblastic disease</li> <li>Previous ectopic pregnancy or stillborn/neonatal death</li> <li>Previous infant with neurologic deficit, birth injury, or congenital anomaly</li> </ul>
Past illness history	<ul style="list-style-type: none"> <li>A chronic disease such as diabetes mellitus, heart disease, renal disease, or chronic hypertension</li> <li>Emotional disorder or cognitive challenge</li> <li>Family history of severe inherited disorders</li> <li>Fibroid tumors or previous surgeries on reproductive organs</li> <li>Maternal reproductive tract anomalies or malignancy</li> <li>Seizure disorders</li> <li>Sexually transmitted infections</li> <li>Surgery required during pregnancy</li> </ul>

Current obstetric status	<ul style="list-style-type: none"> <li>Abnormal fetal surveillance tests</li> <li>Abnormal presentation; fetal version necessary</li> <li>Premature separation of the placenta or placenta previa</li> <li>Cervical cerclage</li> <li>Limited prenatal care</li> <li>Maternal weight loss or weight gain less than 10 lb by midpregnancy</li> <li>Multiple gestation or hydramnios (excessive amniotic fluid)</li> <li>Gestational hypertension or preeclampsia</li> <li>Premature rupture of membranes or preterm labor</li> <li>Rh sensitization</li> <li>Sexually transmitted infection</li> </ul>
Psychosocial factors	<ul style="list-style-type: none"> <li>Attempt or ideation of self-injury</li> <li>Dangerous occupation</li> <li>Lack of support people</li> <li>Inadequate finances; inadequate nutrition or poor housing</li> <li>Lack of acceptance of pregnancy</li> </ul>
Demographic factors	<ul style="list-style-type: none"> <li>Maternal age under 16 years or over 40 years</li> </ul>
Lifestyle	<ul style="list-style-type: none"> <li>Alcohol use during pregnancy</li> <li>Smoking greater than 10 cigarettes a day or living with a person who smokes this much</li> <li>Heavy lifting or long periods of standing</li> <li>Recreational drug use</li> <li>Unusual stress</li> </ul>

Risk assessment should be updated at each prenatal visit because events can cause a pregnancy first rated as low risk to change to high risk. [Chapters 20](#) through [22](#) discuss specific conditions that cause high-risk pregnancy and nursing for these responsibilities.

## Signs Indicating Possible Complications of Pregnancy

Although most signs that suggest a complication may be occurring appear toward the end of pregnancy, women need to be aware of what these are from the beginning. To introduce the topic of danger signs, assure a woman you have every reason to believe she is going to have a normal, uncomplicated pregnancy (assuming that is true) but, if any danger signs do occur, you want her to be informed as to what they are so she can inform her healthcare provider by telephone or e-mail immediately. Be certain you give her an alternate contact number to call if the healthcare facility is closed. Assure her as well that if one of these danger signs should occur, it serves merely as a signal of the possibility that something may be happening, not that something serious has already happened. It is important for her to report a danger sign immediately, though, so it can

be dealt with before something harmful does occur. A pregnant woman should report the following signs or symptoms immediately:

- Vaginal bleeding. A woman should report vaginal bleeding, no matter how slight, because some of the serious bleeding complications of pregnancy begin with only slight spotting. If a woman reports bleeding, ask her how she discovered the blood. If she found it on toilet paper following a bowel movement, she's probably reporting spotting from hemorrhoids. Until the bleeding is found to be innocent this way, however, all women with spotting need further evaluation.
- Persistent vomiting. Once- or twice-daily vomiting is not uncommon during the first trimester of pregnancy. Persistent, frequent vomiting is not normal nor is vomiting that continues past the 12th week of pregnancy. Persistent or extended vomiting depletes the nutritional supply available to a fetus and thus is a danger to the pregnancy. (See [Chapter 13](#) for an in-depth discussion of persistent vomiting [hyperemesis gravidarum].)
- Chills and fever or pain on urination. Chills and fever may be symptoms of a relatively benign gastroenteritis, but they also may indicate an intrauterine infection, a potentially serious complication for both a woman and a fetus. Pain on urination is a symptom of a urinary infection, which is potentially serious because these infections are associated with preterm birth. Because a woman cannot make a definite determination about the cause of a fever herself, further evaluation by a healthcare provider is necessary.
- Sudden escape of clear fluid from the vagina. When a gush of clear fluid is discharged suddenly from the vagina, it means the membranes have ruptured and mother and fetus are now both threatened because the uterine cavity is no longer sealed against infection. If a fetus is small so the head does not fit snugly into the cervix, the umbilical cord may prolapse. If the fetal head then presses on the misplaced cord, oxygenation can be compromised and the fetus will be in immediate and grave danger. Alerting a healthcare provider to any sudden escape of fluid is crucial so a safe and controlled birth can be planned.

Occasionally, a woman confuses stress incontinence (involuntary loss of urine on coughing or sneezing or lifting a heavy object) for membranes breaking. In this situation, vaginal examination typically reveals that the membranes are still intact and the pregnancy is not in danger. Urine can be identified by Nitrazine paper as urine is acidotic (the test strip turns yellow), whereas amniotic fluid is alkaline (the strip turns blue).

- Abdominal or chest pain. Abdominal or chest pain at any time is a signal something is abnormal, so a woman should also report these immediately. Some women may think abdominal pain is normal because the growing uterus is deflecting other organs from their usual alignment, but a pregnant uterus normally expands painlessly. Abdominal pain is therefore a sign of some other problem, such as a tubal (ectopic) pregnancy, separation of the placenta, preterm labor, or something unrelated to the pregnancy but perhaps equally serious, such

as appendicitis, ulcer, or pancreatitis. Chest pain and shortness of breath may indicate a pulmonary embolus, a complication that can follow thrombophlebitis.

- Gestational hypertension. Gestational hypertension refers to a potentially severe and even fatal elevation of blood pressure that occurs during pregnancy usually after 20 weeks of pregnancy. A number of symptoms signal that gestational hypertension is developing:
  - Rapid weight gain (over 2 lb/week in the second trimester, over 1 lb/week in the third trimester)
  - Swelling of the face or fingers
  - Flashes of light or dots before the eyes
  - Dimness or blurring of vision
  - Severe, continuous headache
  - Decreased urine output
  - Right upper quadrant pain unrelated to fetal position
  - Blood pressure increased above 140/90 mmHg

One by one, these are vague symptoms, so a woman may need some help appreciating they are important enough to report during pregnancy. Some edema of the ankles during pregnancy is normal, for example, particularly if it occurs after a woman has been on her feet all day. Swelling of the hands (ask if she has noticed if her rings are tight) or face (difficulty opening eyes in the morning because of edema of the eyelids), however, indicates edema that is more extensive than usual. Visual disturbances or a continuous headache may signal cerebral edema or acute hypertension.

Be certain a woman is not reporting symptoms such as visual difficulties and headaches she had before she became pregnant. If she had the same symptoms before pregnancy as she is reporting now, she may need to see an ophthalmologist rather than her obstetrician for help with the problem. (See [Chapter 21](#) for an in-depth discussion of gestational hypertension.)

- Increase or decrease in fetal movement. Because a fetus normally moves more or less the same amount every day, an unusual increase or decrease in movement suggests a fetus responding to a need for more oxygen. Be certain to ask a woman about typical fetal movements and whether she has noticed any increase or decrease in this rate. If there has been a change, she is a candidate for further testing such as a fetal “kick count” or a nonstress test. Common tests of fetal movement and health of this type are discussed in [Chapter 9](#).
- Uterine contractions before 37 weeks of pregnancy. Women do have faint and irregular Braxton Hicks contractions prior to this point, but regular rhythmic contractions before 37 weeks suggest preterm birth is beginning. A woman needs to lie down, drink a glass of water to ensure she is well hydrated, and telephone her obstetric care provider. Such contractions may be innocent, but it is better to report them than to ignore them and allow a preterm birth to continue.

### *QSEN Checkpoint Question 11.6*

## SAFETY

The nurse is reviewing danger signs of pregnancy with Sandra. In the interests of safety, which of the following would the nurse tell her to report if it should occur?

- a. Her uterus becomes palpable over the symphysis pubis before 12 weeks.
- b. Blue veins appear and can be readily observed on both of her breasts.
- c. She gains more than 3 lb a week beginning at 20 weeks.
- d. She tends to lose her balance when she wears high-heeled shoes.

Look in [Appendix A](#) for the best answer and rationale.

Be certain that after a first prenatal visit, a woman understands she needs to continue with spaced prenatal care. No one likes surprises, so reviewing with a woman what she can expect at future visits can help her understand the importance of keeping them. [Box 11.8](#) lists components of assessments and care important for these continuing prenatal visits.

### BOX 11.8

#### Nursing Care Planning to Empower a Family

## ASSESSMENTS AND INTERVENTIONS A WOMAN CAN EXPECT AT CONTINUING PRENATAL VISITS

### Health Interview

Interim history or new personal or family developments since last visit (every visit)

Review of danger signs of pregnancy (every visit)

Review of symptoms of beginning labor (every visit)

Any new concerns with pregnancy or family since last visit (every visit)

### Physical Examination

Blood pressure (every visit)

Clean-catch urine for glucose, protein, and leukocytes (every visit)

Blood serum level for maternal serum  $\alpha$ -fetoprotein (MSAFP) and pregnancy-associated plasma protein A (PAPP-A) (at 16 weeks)

VDRL test for syphilis if possibility of new exposure

Glucose screen (24–28 weeks)

Glucose challenge (24–28 weeks), if warranted

Anti-Rh titer (28 weeks)

Group B *Streptococcus* (GBS) screen (35–37 weeks)

### Fetal Health

Fetal heart rate counted (every visit)

Fundal height measured (every visit)

Questions about quickening (first fetal movement, which occurs at 16–20 weeks) or

continuing fetal movement (every visit)  
Ultrasound dating of pregnancy (if necessary)  
Ultrasound evaluation for fetal health (about 20 weeks)

### *What If... 11.4*

**The nurse is interested in exploring one of the 2020 National Health Goals related to prenatal care (see [Box 11.1](#)). Most government-sponsored money for nursing research is allotted based on these goals. What would be a possible research topic to explore pertinent to these goals that would be applicable to Sandra or her family and also advance evidence-based practice?**

## **KEY POINTS FOR REVIEW**

- The purpose of prenatal care is to establish a baseline of present health, determine the gestational age of the fetus, monitor fetal development, identify women at risk for complications, and minimize the risk of possible complications of pregnancy by anticipating and preventing problems before they occur as well as providing time for education about pregnancy and possible dangers. Planning nursing care that includes these things and not only meets QSEN competencies but also best meets the family's total needs.
- Prenatal care has the potential to reduce the incidence of preterm birth and the infant mortality rate.
- A first prenatal visit confirms a pregnancy, but it is also a time for important assessments such as a health history, physical examination, and laboratory tests. The physical examination includes measurement of fundal height and assessment of fetal heart sounds if the pregnancy is beyond 12 weeks, a pelvic examination (including a Pap smear and HPV test), and possibly an estimation of pelvic size.
- A first prenatal visit sets the tone for visits to follow. Maintaining a supportive manner is helpful to establish rapport and allow a woman to feel comfortable returning for future care.
- Common pelvic types include gynecoid (well-rounded with a wide pubic arch), anthropoid (narrow), platypelloid (flattened), and android (male or with a sharp pubic arch). A gynecoid pelvis is ideal for childbearing; however, vaginal birth is often achieved with other pelvis shapes.
- For a pelvic examination, pregnant women should remain in a lithotomy or supine position for as short a time as possible to help prevent thromboembolism and supine hypotension syndrome.
- Danger signs for women to report during pregnancy are vaginal bleeding, persistent vomiting, chills and fever, escape of fluid from the vagina, abdominal or chest pain, swelling of the face and fingers, shortness of breath not related to activity, vision changes or continuous headache, rhythmic cramping, burning with urination, and a

pronounced decrease in fetal movement.

- Remember that a family, not a woman alone, is having a baby, and include family members in procedures and health teaching as desired.

### CRITICAL THINKING CARE STUDY

Macie is a 40-year-old, G5 T3 P0 A1 L2 woman pregnant with her fifth child. She had a miscarriage with her second pregnancy, and her last child died at 3 months from sudden infant death syndrome (SIDS). Her other two children are healthy, ages 5 and 3 years. She has heard that using pacifiers and putting babies to sleep on their backs decreases the chance of SIDS and is worried she caused her baby girl's death.

1. Pregnancy creates a vulnerable period for Macie because she may be dealing with both losses from her previous pregnancies. What actions can you take to ensure that Macie will discuss openly her fears and concerns about this pregnancy?
2. Macie works as a cheerleading coach. Her husband works at adding insulation to homes. What special questions would you want to ask her about her job to see if it poses some concerns during pregnancy? About her husband's job?
3. How could grieving for the loss of her children affect Macie's adaptation to this pregnancy?

## 12

# Nursing Care to Promote Fetal and Maternal Health

*Julberry Adams, a single, 30-year-old woman, is 4 months pregnant when you first see her in a prenatal clinic. She works as a curator for an art gallery but has missed work this past week because of nausea. She is worried she will not be able to work past 6 months of her pregnancy because her job involves a great deal of walking. She has already stopped her volunteer work teaching children's swimming at the YMCA. She wants to travel to see her sister in St. Louis because her sister is very ill but has heard pregnant women should not drive more than 100 miles at a time. She asks you if marijuana would help reduce her early pregnancy nausea.*

*Previous chapters discussed normal reproductive anatomy and physiology and the changes that occur with pregnancy. This chapter adds information about the usual health teaching women need during pregnancy to ensure a healthy outcome for themselves and their child.*

**What additional health teaching does Ms. Adams need?**

## KEY TERMS

**cytomegalovirus**

**fetal alcohol spectrum**

**herpes simplex virus (HSV)**

**leukorrhea**

**Sims position**

**teratogen**

**toxoplasmosis**

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe common lifestyle behaviors important for a healthy pregnancy outcome.
2. Identify 2020 National Health Goals related to a healthy pregnancy lifestyle that nurses can help the nation achieve.

3. Assess a woman for minor discomforts of pregnancy and corresponding measures to counteract such discomforts as well as healthy lifestyle practices and concerns during pregnancy.
4. Formulate nursing diagnoses concerned with a healthy pregnancy.
5. Identify expected outcomes to promote a healthy pregnancy, such as limiting exposure to teratogens, as well as manage seamless transitions across differing healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care to promote healthy practices during pregnancy.
8. Evaluate outcomes for achievement and effectiveness of care.
9. Incorporate knowledge of a healthy lifestyle with the interplay of the nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

The health of a fetus and the health of a mother are inextricably linked. Generally, a woman who eats well and takes care of her own health during pregnancy provides a healthy environment for fetal growth and development. However, a woman may need instructions on exactly what constitutes a healthy lifestyle during pregnancy. Most women have questions regarding how much extra rest they need, what type of exercise they can continue, and whether all the changes going on in their bodies, some of which bring them at least slight daily discomfort, are normal. Because of this, a major role in promoting maternal and fetal health is education about these subjects. Providing empathetic advice about ways to prevent or alleviate minor discomforts of pregnancy and keeping abreast of the latest evidence-based practice studies on maternal exposure to **teratogens** (factors detrimental to fetal health) are all part of this role. Because the health of women is so important to a nation, the United Nations (UN) lists “improve maternal health” and “reduce child mortality” as Millennium Global Health Goals (UN, 2015). Because effective prenatal care is such an important means to improve women’s health, the 2020 National Health Goals speak to the importance of all pregnant women receiving counseling and prenatal care (Box 12.1).

#### BOX 12.1

#### Nursing Care Planning Based on 2020 National Health Goals

A number of 2020 National Health goals speak to the importance of women maintaining a healthy lifestyle during pregnancy:

- Increase the proportion of pregnant women who receive early and adequate

prenatal care from a baseline of 70.5% to a target of 77.6%.

- Increase to 100% from a baseline of 94.9% the proportion of pregnant women who abstain from illicit drugs during pregnancy.
- Increase to 98.5% from a baseline of 89.6% the proportion of pregnant women who abstain from cigarette smoking during pregnancy.
- Increase to 95% from a baseline of 90% the proportion of pregnant women who abstain from alcohol during pregnancy.
- Increase to 100% from a baseline of 95% the proportion of pregnant women who abstain from binge drinking (i.e., drinking a large amount of alcohol over a short time with the primary intention of becoming intoxicated) during pregnancy (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Because nurses are important members of prenatal healthcare teams, they play an important role in ensuring women are aware that preconception and early pregnancy care are important. Evidence-based practice and nursing research to answer such questions as to which aspects of preconception care are most important in reducing pregnancy complications and which are effective incentives to make women come in early for prenatal care would be important to help the nation meet these goals.

### *Nursing Process Overview*

#### FOR HEALTH PROMOTION OF A FETUS AND MOTHER

##### **ASSESSMENT**

A thorough health history, physical evaluation, and initial laboratory data are obtained at a first prenatal visit. A continuing assessment concentrates on screening for any abnormalities in physical or emotional health that might be occurring and for the possibility of teratogens in the pregnant woman's environment. Encourage the woman to discuss whatever concerns she is having during all visits. Although some of these concerns may represent minor common body changes associated with a normal pregnancy, others may be early indicators of potential problems such as gestational hypertension or gestational diabetes. Knowing what is happening as soon as possible allows you to provide information and guidance on ways to alleviate any discomforts of pregnancy and also allows you to alert a woman's obstetric provider (nurse-midwife or obstetrician) of your findings as soon as they appear.

##### **NURSING DIAGNOSIS**

Examples of nursing diagnoses related to health promotion of the pregnant woman and fetus include:

- Health-seeking behaviors related to interest in maintaining optimal health during pregnancy
- Anxiety related to body changes of pregnancy
- Risk of deficient fluid volume related to gestational nausea and vomiting
- Disturbed body image related to changes in appearance with pregnancy

- Risk of altered sexual patterns related to fear of harming fetus during pregnancy
- Disturbed sleep pattern related to frequent need to empty bladder during night
- Risk for fetal injury related to intimate partner violence

## **OUTCOME IDENTIFICATION AND PLANNING**

When establishing goals and outcomes, be certain that plans are individualized and realistic for a woman's situation and lifestyle. Try to turn long-term goals into more manageable, short-term ones if possible. For example, a goal of reducing smoking during pregnancy may be more realistic than a goal of stopping smoking forever. Eliminating the pressure of making a major permanent lifestyle change this way can help a woman concentrate her efforts on herself and her fetus over the next several months. Continued reinforcement of her progress could then help her to continue reducing the number of cigarettes smoked or to quit smoking altogether after the baby is born so she can provide a smoke-free environment for her child. Similarly, you cannot set a goal for a woman to be free of the nausea of early pregnancy. The best you can expect to accomplish is to be certain she maintains good nutrition and adequate weight gain in the face of it.

Often, helping a woman plan to avoid teratogens is difficult because a total change in lifestyle and environment, such as not smoking, not drinking alcohol, or changing a work environment, may be impossible. Fortunately, most women are highly motivated to complete a pregnancy satisfactorily. With this level of motivation, planning becomes the task of determining the best route to achieve a goal rather than educating about the need for goal achievement.

Be certain women do not consult online pregnancy forums where lay people are the main contributors as these may contain anecdotal information that is often misleading or incorrect. Refer women to helpful websites and other resources when appropriate (see [Chapter 9](#)).

## **IMPLEMENTATION**

The major intervention associated with health promotion during pregnancy is education. Although the average woman is aware minor body changes will occur with pregnancy, these changes may seem extreme when they are happening to *her*. Often, adolescent girls are uninformed about common minor body changes during pregnancy because they lack a set of peers with pregnancy experience and so are surprised by them. Even an adolescent who knows it is normal for breast tenderness to occur during pregnancy may not be sure the amount she is feeling is normal. A woman who had a mental image of herself as someone who would not gain much weight during pregnancy may be very concerned because she is, in fact, gaining a great deal of weight. Education about minor body changes can switch this type of worry situation into a pleasant reminder that the pregnancy is progressing as expected.

## **OUTCOME EVALUATION**

An evaluation is an ongoing process at prenatal healthcare visits. Expected outcomes

developed with a woman at one prenatal visit need to be assessed at the next.

Examples of expected outcomes include:

- Patient states measures she will use to manage increased discomfort from hemorrhoids formed during pregnancy.
- Patient reports she is resting for half an hour twice a day.
- Patient verbalizes positive statements about her appearance.
- Patient and her partner both state they have stopped smoking.
- Patient expresses positive feelings about the manner in which her prenatal care providers accommodated her cultural needs.
- Patient documents by use of a pedometer that she walks the length of a city block daily.

## Health Promotion During Pregnancy

Women in prenatal care settings create an ideal teaching audience because the average woman is eager to learn more about her pregnancy and the steps she can take to maintain health during pregnancy. In addition to general health teaching, good role modeling, such as not smoking in prenatal settings and exhibiting a healthy lifestyle including sound nutrition and exercise, is important (Power, Wilson, Hogan, et al., 2013).

When planning teaching strategies, a woman's receptiveness to instruction is key. Regardless of how excited and pleased a woman is about being pregnant, she can assimilate only so much information at one time. It is important, therefore, to be selective about the health information you provide and include those points most relevant to the individual woman. For example, you would want to discuss varicosity prevention more for a woman with a history of varicosities in a former pregnancy than for one who is pregnant for the first time and is athletic. Keep in mind that health measures taught must be maintained for an extended time—40 weeks. To help a woman follow changes for this long, choose individualized priorities, so health advice is specific and meaningful (Box 12.2).

### BOX 12.2

#### Nursing Care Planning to Respect Cultural Diversity

What people do to keep well is culturally influenced. Some women, for example, may rely on herbs and folk remedies for minor discomforts of pregnancy; others feel a need to rely on only medical management.

Implementing prenatal care to meet the needs of all of the different cultures represented in the United States includes careful assessment to identify individual needs. It then may include providing special classes in prenatal health, exploring how health-promotion regimens fit with women's cultural belief systems, and maintaining

an attitude of advocacy to help women adjust to a more formal healthcare system than they are used to.

Also remember the basic tenet of teaching and learning: Learning is enhanced when the information has direct and immediate application to that person. This principle means devising a plan that spaces out health-promotion and health-maintenance information into two sections. The first should include teaching those measures that are immediately applicable; the second should come later and include those measures that have relevance only toward the end of pregnancy.

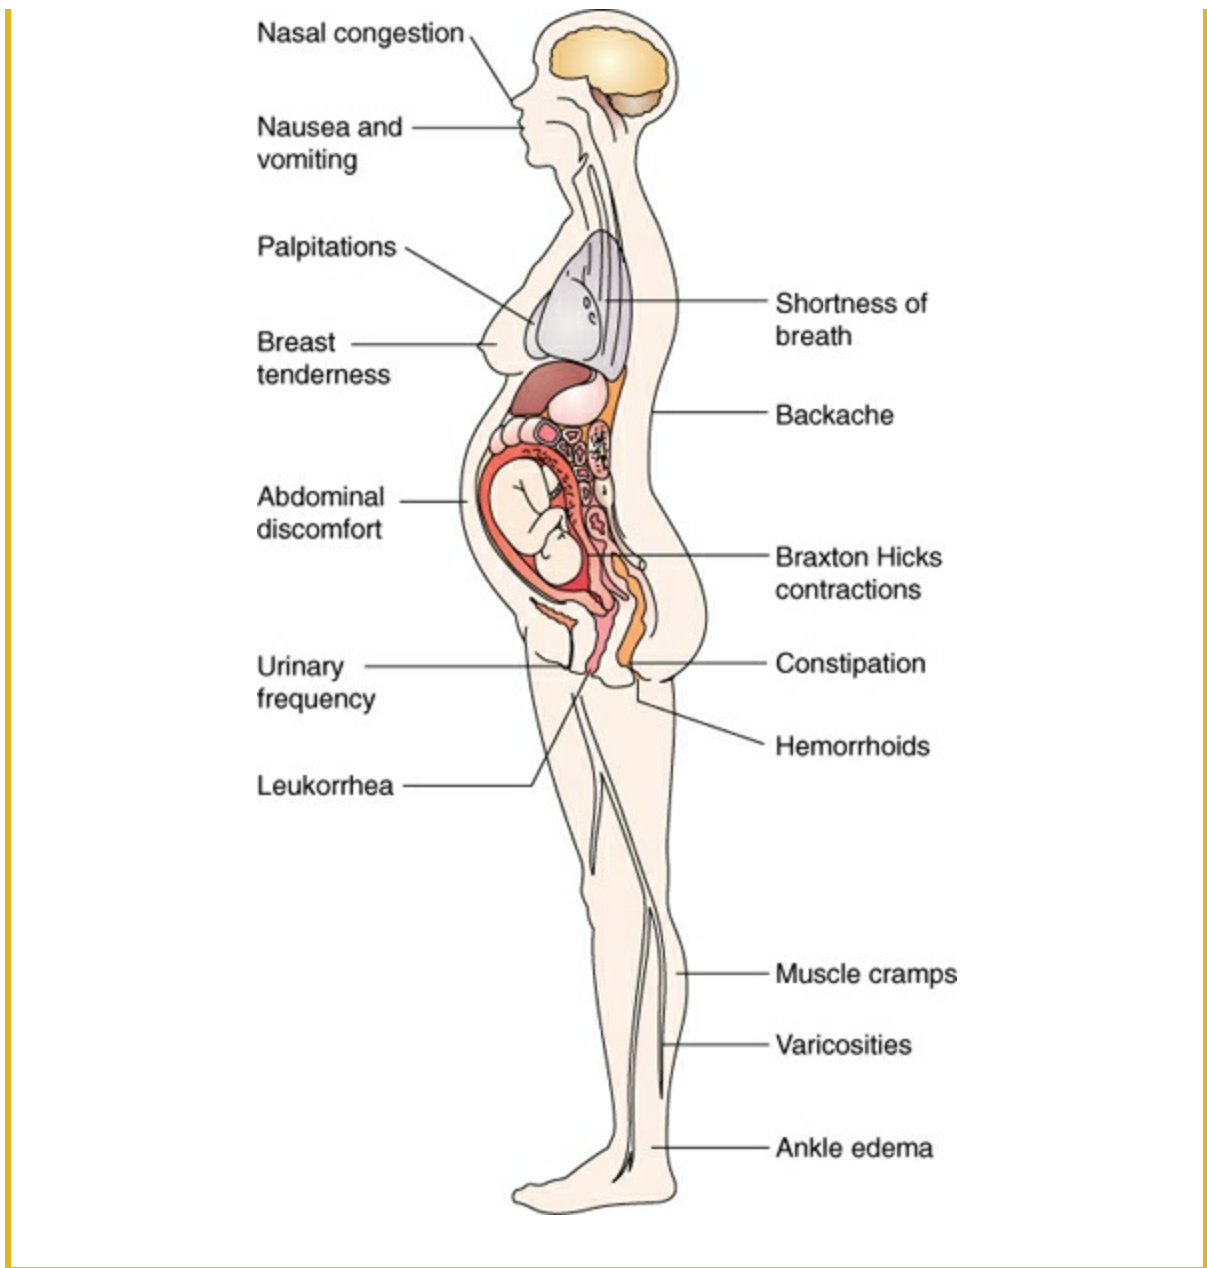

Remind the woman at every visit to bring problems to her healthcare provider's attention as soon as she becomes worried; otherwise, a provider has no opportunity to take the necessary measures to prevent long-term discomfort or symptoms. For example, common minor body changes associated with early pregnancy are shown in [Box 12.3](#). Many women, however, do not mention these discomforts or body changes unless specifically asked because they may not be aware of their significance to a pregnancy or because they are reluctant to take up a busy healthcare provider's time for little things. To illustrate, a woman experiencing constipation may not mention it early enough to take preventive measures against the occurrence of hemorrhoids, which can become a long-term problem not only throughout the pregnancy but afterward as well.

### BOX 12.3

#### Nursing Care Planning Using Assessment

##### ASSESSING A WOMAN FOR MINOR BODY CHANGES OF PREGNANCY

*Concept Mastery Alert*

The technique of *anticipatory guidance* (i.e., psychologically preparing a person for an unfamiliar event) can be helpful in promoting fetal and maternal health. Knowing what to expect can help a patient prepare for what is ahead and lead to more effective coping and better health.

**SELF-CARE NEEDS**

Because pregnancy is a state of wellness, few special care measures or advice other than common sense measures about self-care are needed. Many women, however, have heard different warnings about what they should or should not do during pregnancy, which may mean that they need some help separating fact from fiction. Doing so may enable

the woman to enjoy her pregnancy unhampered by unnecessary restrictions. In no other area of nursing, except possibly infant feeding, does there seem to be as many misconceptions or inappropriate information available to women.

## Bathing

During pregnancy, sweating tends to increase because a woman excretes waste products for both herself and the fetus. She also has an increase in vaginal discharge. For these reasons, daily tub baths or showers are recommended. Women should not soak for long periods in extremely hot water or in hot tubs, however, as heat exposure for a lengthy time could lead to hyperthermia in the fetus and birth defects, specifically esophageal atresia, omphalocele, and gastroschisis (Wilde, Petersen, & Niswander, 2014).

As pregnancy advances, a woman may have difficulty maintaining her balance when getting in and out of a bathtub. If so, she should change to showering or sponge bathing for her own safety. If membranes rupture or vaginal bleeding is present, tub baths become contraindicated because there might be a danger of developing a uterine infection.

## Breast Care

Women need to make few changes related to breast care during pregnancy. A general rule is: as her breast size increases, a woman should be certain to wear a firm, supportive bra with wide straps to spread breast weight across the shoulders. Interestingly, evidence shows that a woman's breasts enlarge more if the fetus she carries is male than if the fetus is female (Żelaźniewicz & Pawłowski, 2015). Regardless of fetal sex, women may need to buy a larger bra size halfway through pregnancy to accommodate breast changes. Assuming a woman plans on breastfeeding, recommend she choose bras suitable for this (open in the front), so she can continue to use them after the baby's birth.

At about the 16th week of pregnancy, colostrum secretion begins in the breasts. The sensation of a fluid discharge from the breasts can be frightening unless a woman has been cautioned of this possibility. Teach her to wash her breasts with clear tap water (no soap, because that could be drying and cause her nipples to crack) daily to remove the colostrum and reduce the risk of infection. After washing, she should dry her nipples well by patting them with a soft towel.

If colostrum secretion is profuse, a woman may need to place gauze squares or breast pads inside her bra, changing them frequently to maintain dryness. Otherwise, constant moisture next to the breast nipples can cause nipple excoriation, pain, and fissuring. Asking about colostrum at prenatal visits provides a good time to also discuss the benefits of breastfeeding for both a woman and her child (see [Chapter 19](#)).

## Dental Care

There is a strong correlation between poor oral health and preterm birth, so maintaining

good oral health during pregnancy is important (Gupta, Jain, Mohan, et al., 2015). Without adequate brushing, gingival tissue tends to hypertrophy and, unless a pregnant woman brushes her teeth well, pockets of plaque form readily between the swollen gum line and teeth, possibly leading to periodontal diseases (Papapanou, 2015).

When bacteria in the mouth interact with sugar, this lowers the pH of the mouth, creating an acid medium that can lead to etching or destruction of the enamel of teeth (i.e., tooth decay). Because 9 months is a fairly long time to be without preventive dental care, in addition to stressing brushing on arising, after meals, and at bedtime, encourage pregnant women to see their dentists regularly for routine examination and cleaning. Encourage women to snack on nutritious foods, such as fresh fruits and vegetables rather than sugar-rich snacks to reduce the amount of sugar in contact with their teeth. If a woman has trouble avoiding sweet snacks such as candy, suggest eating snacks that dissolve easily (like a chocolate bar) rather than one that remains in the mouth a long time (like chewy caramel). This helps to minimize the level of sugar in the mouth and its long-term contact with teeth.

Women should question the need for X-rays during pregnancy; however, if these are necessary for dental health, they can be done safely as long as a woman's abdomen is shielded with a lead apron.

### **Perineal Hygiene**

Women have increased vaginal discharge during pregnancy and so need to maintain good perineal hygiene. Caution them to always wipe front to back after voiding to prevent bringing contamination forward from the rectum. Even if the vaginal discharge seems excessive, douching is contraindicated because the force of the irrigating fluid could cause the solution to enter the cervix, leading to a uterine infection. In addition, douching alters the pH of the vagina, leading to an increased risk of vaginal bacterial growth (Sheth & Keller, 2015).

### **Clothing**

Maternity clothing should be comfortable. Women should be cautioned to avoid garters, extremely firm girdles with panty legs, and knee-high stockings during pregnancy because these may impede lower extremity circulation. Suggest wearing shoes with a moderate-to-low heel to minimize pelvic tilt and possible backache as well as to reduce the risk of falling.

## **SEXUAL ACTIVITY**

Sexual changes occur during pregnancy. Many of these changes were reviewed in Chapter 5.

Asking a woman at a prenatal visit if she has any questions about sexual activity allows her to voice concerns about coitus (Box 12.4). This conversation allows a woman to feel more comfortable and secure that coitus is not harming her fetus. You

may need to replace myths with facts, such as:

- Coitus on the expected due date does not initiate labor.
- Orgasm does not initiate preterm labor.
- Coitus does not cause rupture of the membranes.

#### BOX 12.4

### Nursing Care Planning Tips for Effective Communication

Julberry Adams is 4 months pregnant and no longer lives with the father of her baby.

*Tip:* Health teaching is an art separate from teaching morality. Avoid cutting off communication by making a judgment about the information a patient might need. Actively listen to your patient, focus on the patient's needs and concerns, and supply the information the patient has requested.

**Nurse:** Do you have any questions, Ms. Adams?

**Julberry:** How long into pregnancy can I have sex?

**Nurse:** Basically, as long as you're comfortable and you don't have any complications.

**Julberry:** Good. My new boyfriend made me promise to ask today.

**Nurse:** Since you mentioned a new partner, let's review STI testing and condom use during pregnancy. Do you have any other questions about sex during pregnancy that you or your partner were wondering about?

It is true that semen contains abundant prostaglandins, which can act to help soften a cervix and ready it for labor, but whether the amount in a single ejaculation combined with the slight amount of oxytocin released with female orgasm is enough to begin cervical softening is unproven (Kafaei Atrian, Sadat, Rasolzadeh Bidgoly, et al., 2014). Women who have a history of previous preterm birth should consult their obstetric provider for specific advice as to whether they should be concerned about this.

Women whose membranes have ruptured or who have vaginal spotting should be advised against coitus until examined by their primary care provider to prevent possible infection or complications related to a malpositioned placenta (placenta previa). Also caution about partner oral–female genital contact because accidental air embolism has been reported from this act during pregnancy as well as in the postpartal period from air entering open or fragile uterine arteries. Anal sex may be uncomfortable because of pregnancy-related hemorrhoids. In addition, the act may allow bacteria to spread from the rectum to the vagina.

Changes in sexual position may be needed to increase comfort. Otherwise, there are no sexual restrictions during pregnancy (March of Dimes, 2015). Caution women with a nonmonogamous male sexual partner that the partner needs to use a condom to prevent transmission of a sexually transmitted infection during pregnancy (Hotchin, 2015).

### **TEAMWORK & COLLABORATION**

A member of the care team is relating some statements made by Julberry Adams. Which statement would alert the nurse and the care team that there is a need to review self-care practices during pregnancy with the patient?

- a. “I take either a shower or tub bath because I know both are safe.”
- b. “I wash my breasts with clear water, not with soap, every day.”
- c. “I know if my partner uses a condom it can tear fetal membranes.”
- d. “I’m wearing low-heeled shoes to try to avoid backache.”

*Look in [Appendix A](#) for the best answer and rationale.*

### **EXERCISE**

Extreme exercise in women has been associated with difficulty conceiving but after pregnancy occurs, moderate exercise is healthy (Wahlqvist, Krawetz, Rizzo, et al., 2015). During pregnancy, exercise can offer a general sense of well-being. It also helps prevent circulatory stasis in the lower extremities. For some women, teaching about exercise focuses on both helping them realize the need for exercise and urging them to get enough. Others may need to be cautioned to restrict exercise, such as for those who participate in contact sports like touch football or unrefereed soccer.

As a rule, average, well-nourished women should exercise during pregnancy about three times weekly for 30 consecutive minutes (Fletcher & Russo, 2015). Their exercise program should consist of 5 minutes of warm-up exercises, an active “stimulus” phase of 20 minutes, and then 5 minutes of cool-down exercises. Movements that exercise large muscle groups rhythmically, such as walking, are best but the type of activity chosen should depend on their interests. Advise women to eat a protein and a complex carbohydrate such as peanut butter and whole wheat bread at least 15 minutes before exercise to keep blood sugar from falling during exercise and to drink water before and after to prevent dehydration.

As a rule, a woman can continue any sport she participated in before pregnancy unless it was one that involved body contact, such as soccer. If a woman is a competent horsewoman, for example, there is little reason for her to discontinue riding until it becomes uncomfortable. Pregnancy is not the time to learn to ride, however, because a beginning rider is at greater risk for being thrown than an experienced one. The same principle applies to skiing and bicycling. An accomplished skier or bicyclist may continue the activity in moderation until balance becomes a problem. Pregnancy is not the time to learn to ski or ride a bicycle, however, because the lack of skill could result in many falls.

The intensity of the exercise program depends on cardiopulmonary fitness. Both pregnant and nonpregnant women should exercise at 70% to 85% of their maximum heart rate. The easiest way to calculate this is for women to subtract their age from 220

and then calculate 70% or 85% of that number. For example, after exercise, a 23-year-old woman should have a pulse range of 137 to 167 beats/min ( $220 - 23 [= 197] \times 70\% [= 137.90]$  or  $85\% [= 167.4]$ ). For a woman of 35 years, this target range would be 129 to 157 beats/min. An additional way for women to assess if they are exercising too strenuously is to evaluate their ability to continue talking while exercising. If a woman is too short of breath to do this, she is exercising beyond her target heart rate.

Because walking is the best exercise during pregnancy, women should be encouraged to take a walk daily unless inclement weather, many levels of stairs, or an unsafe neighborhood are contraindications. Yoga is also a good exercise as long as positions are limited to those in which pregnant women are able to maintain balance (Polis, Gussman, & Kuo, 2015). Jogging, in contrast, is questioned because of the strain the extra weight of pregnancy places on the knees. Late in pregnancy, jogging can also cause pelvic pain from relaxed symphysis pubis movement.

Swimming is a good activity for pregnant women and, like bathing, is not contraindicated as long as membranes are intact. It not only increases muscle tone but may help relieve backache. Diving, long-distance swimming, or any other activity carried out to a point of extreme fatigue should be avoided. A moderate-impact aerobics program such as dancing is well tolerated during pregnancy, but a high-impact aerobics program is usually contraindicated because it can be strenuous on both pelvic and knee joints (Erdener & Budgett, 2016).

An epidemiologic study suggests an elevation of maternal body temperature by  $2^{\circ}\text{C}$  for at least 24 hours can cause a range of fetal defects, but there is little information on thresholds for shorter exposures such as occur with exercise. Use of hot tubs and saunas after workouts, similar to a hot bath, should be limited to no longer than 15 minutes, again on the chance these can lead to hyperthermia in the fetus and birth defects, specifically esophageal atresia, omphalocele, and gastroschisis (Agopian, Tinker, Lupo, et al., 2014).

General guidelines for exercise during pregnancy are highlighted in [Box 12.5](#). Beginning an exercise program during pregnancy not only offers the advantage of being healthy during pregnancy but also provides long-term benefits such as:

- Lowering cholesterol levels
- Reducing the risk of osteoporosis
- Increasing energy levels
- Maintaining a healthy body weight
- Decreasing the risk of heart disease
- Increasing self-esteem and well-being

## BOX 12.5

### Nursing Care Planning Based on Family Teaching

#### **GUIDELINES FOR EXERCISE IN PREGNANCY**

**Q.** Julberry Adams asks you, “How much should I be exercising now that I’m

pregnant?”

A. New and intense exercise should never be started for the first time during pregnancy. Use the following recommendations as guidelines for safe exercise:

1. Perform scheduled exercise periods (about three times per week for 30 minutes) rather than engaging in intermittent activity.
2. Do not perform vigorous exercise in hot, humid weather or if you have a fever to avoid overexerting yourself or developing hyperthermia.
3. Avoid activities that require jumping, jarring motions, or rapid changes in direction such as jogging because your joints may be unstable late in pregnancy.
4. Exercise on a wooden floor or a tightly carpeted surface to reduce shock to the abdomen or knees and to provide a sure footing.
5. To avoid muscle cramping, avoid exercises and motions that involve deep flexion or joint extension, such as stretching with the toes extended.
6. Always start your exercise program by warming up for approximately 5 minutes with activities such as slow walking or stationary cycling with low resistance.
7. End your exercise program with a period of gradually declining activity that includes gentle, stationary stretching. Because of the increased risk of joint injury, do not stretch to the point of maximum resistance.
8. Measure your heart rate at times of peak activity. Talk with your obstetric provider about target heart rate and limits and don't exceed them.
9. When getting up from lying on the floor, do so gradually to prevent dramatic blood pressure changes or stretching of the round ligament, which can lead to sharp abdominal pain.
10. Drink liquids liberally before and after exercise to prevent dehydration. If necessary, interrupt your activity to replenish fluids.
11. Eat a protein and complex carbohydrate snack before exercise to help maintain serum glucose levels.
12. If you were sedentary before pregnancy, begin your exercise program with physical activity of very low intensity and advance your activity level gradually.
13. Stop any activity and contact your obstetric provider if any unusual symptoms appear such as dizziness or vaginal bleeding.
14. Perform strenuous activities for no longer than 20 minutes.
15. To prevent supine hypotension syndrome do not exercise in the supine position (lying flat on your back) after the fourth month of pregnancy.
16. Avoid exercises that employ a Valsalva maneuver (holding your breath while bearing down) because this action increases blood pressure and decreases blood supply to the fetus.
17. Make sure your caloric intake is adequate to meet not only the extra energy needs of pregnancy but also those of the exercise performed.

Women who know they have an incompetent cervix or have had cerclage to correct

this and women who develop any complication of pregnancy such as bleeding, gestational hypertension, preterm rupture of membranes, preterm labor, or whose fetus is growth restricted should consult with their obstetric provider before beginning or continuing an exercise program.

## SLEEP

The optimal condition for body growth occurs when growth hormone secretion is at its highest level—that is, during sleep. This, plus the overall increased metabolic demand of pregnancy, appears to be the physiologic reason pregnant women require an increased amount of sleep or at least need rest to build new body cells during pregnancy.

Pregnant women rarely have difficulty falling asleep at night because of this increased physiologic need for sleep. If a woman does have trouble falling asleep, drinking a glass of warm milk may help. Relaxation exercises (e.g., lying quietly, systematically relaxing neck muscles, shoulder muscles, arm muscles) also may be effective.

A good resting or sleeping position is a left-sided **Sims position**, with the top leg forward (Fig. 12.1). This position puts the weight of the fetus on the bed, not on the woman, and allows good circulation in lower extremities.

**Figure 12.1** A modified Sims position is a good rest position during pregnancy. Notice the weight of the fetus rests on the bed.

Be certain a woman knows to avoid resting flat on her back because supine hypotension syndrome (i.e., faintness, diaphoresis, and hypotension from the pressure of the expanding uterus on the inferior vena cava) can develop in this position. If needed, placing a rolled pillow behind her can act as a reminder not to turn onto her back. Also, be certain women know not to rest with their knees sharply bent either when sitting or lying down because of the increased risk of venous stasis that this causes below the knee.

Sleep deprivation during pregnancy is associated not only with fatigue in the woman but also with the possibility of growth restriction in her fetus (Tsai, Lin, Wu, et al., 2016). To obtain enough sleep and rest during pregnancy, pregnant women may need to begin sleep earlier in the evening as well as schedule a rest period during the afternoon (Maness & Khan, 2015).

Late in pregnancy, a woman often finds herself awakened from sleep at short, frequent intervals by the activity of her fetus. Pregnant women also have a higher incidence of “restless leg syndrome” (waking at night because of spontaneous leg

movement) than nonpregnant women. Pramipexole dihydrochloride (Mirapex), a class C drug frequently recommended for restless leg syndrome, should not be taken during pregnancy ([Schneider, Krafft, Manconi, et al., 2015](#)).

Frequent waking such as this can lead to loss of rapid eye movement (REM) sleep. Loss of REM sleep causes a woman to feel anxious and not well rested, even though she has slept her usual number of hours. Pyrosis (heartburn), dyspnea (shortness of breath), snoring, or sleep apnea (particularly in obese women) also can cause a woman to wake up, especially if she has been lying flat. Recommend sleeping with two or three pillows or on a couch with an armrest in these instances.

## EMPLOYMENT

Changes in public assistance laws that encourage women to seek employment have led to more women working during pregnancy than ever before. Unless a woman's job involves exposure to toxic substances, lifting heavy objects, other kinds of excessive physical strain, long periods of standing or sitting, or having to maintain body balance, there are few reasons a woman cannot continue to work throughout pregnancy. Women may, however, experience some discrimination from fellow workers ([Lee, Symanski, Lupo, et al., 2016](#)).

Women who are unable to continue working are protected from loss of employment benefits during pregnancy by federal law (Public Law 95-555) unless they work for a company with fewer than 15 employees.

According to federal law, an employer cannot:

- Deprive women of seniority rights, in pay or promotion, because they take a maternity leave
- Treat women returning from maternity leave as new hires, starting over on the eligibility period for pension and other benefits
- Force pregnant women to leave their job if they are able to and want to continue working
- Refuse to hire women just because they are pregnant or fire them for the same reason
- Refuse to cover employees' normal pregnancy and birth expenses in the company health plan or pay less for pregnancy than for other medical conditions
- Refuse to pay sick leave or disability benefits to women whose difficult pregnancies keep them off the job

Passed in 1993, the Family and Medical Leave Act is another federal law that guarantees women the right to 12 weeks of unpaid, job-protected leave on the birth of a child; the adoption or foster placement of a child; when a woman is needed to care for a parent, spouse, or child with a serious health condition; or because of a serious health condition from which she suffers (29 C.F.R. 825.11). Specifically mentioned in this law is any period of incapacity because of pregnancy or for prenatal care. Families need to be educated about this important law because many women are still not aware they can take time off from work during pregnancy or spend time with a new baby. In addition,

women may be able to qualify for provisions under the Americans with Disabilities Act (ADA) if their reason for quitting work is because of a physical or mental impairment that substantially limits one or more major life activities ([ADA Amendments Act, 2008](#)).

Some occupations are hazardous during pregnancy and should be discontinued because they bring women into contact with harmful substances. For example, nurses working with anesthetic gases in operating rooms or dental offices are reported to have a higher incidence of spontaneous miscarriage and, possibly, congenital anomalies in children than nurses working in other locales, probably because of exposure to nitrous oxide ([National Institute for Occupational Safety and Health \[NIOSH\], 2010](#)). Nurses working with chemotherapy agents may also be at risk and so should wear gloves to protect themselves from exposure to these drugs. Ribavirin (Virazole), an antiviral formerly used to treat respiratory syncytial virus (RSV) infections, is also apparently teratogenic. It is administered by inhalation to individuals with RSV in hematopoietic cell or heart and lung transplant recipients or orally to chronic hepatitis C patients. Both male and females trying to conceive and women who are pregnant should avoid inhaling the drug ([Karch, 2015](#)).

Other problems that can occur with employment include interference with adequate rest and nutrition. Urge a woman who works outside her home to put her feet up and rest when performing tasks that can be done in that position. Review what she eats at fast-food restaurants or packs for herself to be certain she plans ways to make lunch as nutritious as if she were eating at home.

Most women work to augment or supply family income, not for fun. Even those who could afford to leave their jobs may not be willing to sacrifice the collegial relationships and sense of fulfillment derived from work, or the lifestyle their income allows them to enjoy. Counseling them to reserve periods during the day for rest and to eat a healthy diet is more effective than suggesting they resign from their jobs during pregnancy to get more rest ([Box 12.6](#)).

## BOX 12.6

### Nursing Care Planning to Empower a Family

#### GUIDELINES FOR PREGNANT WOMEN WORKING OUTSIDE THEIR HOME

**Q.** Julberry Adams asks you, “Now that I’m pregnant, can I continue to work at the art gallery?”

**A.** Use the following suggestions as guidelines for safe work practices during pregnancy:

- Plan rest periods during your break periods rather than running errands, etc.
- Try to use at least part of your lunch hour to rest. Lie on your left side in a break room if possible. If this is not possible, then rest sitting with your legs elevated.
- If your job involves long periods of standing, think of times you could sit and

- elevate your legs (working in a low file drawer, reading time in a classroom, etc.).
- Walk around periodically to avoid prolonged standing or sitting in one position if possible; stretch your back periodically to avoid backache.
  - Wear support hose to improve venous return to your lower extremities.
  - Avoid excessive overtime or working longer than 8-hour shifts.
  - Empty your bladder every 2 hours to help prevent urinary tract infection.
  - Get extra rest on weekends or days off.
  - Take great caution when working around equipment that requires good balance. Avoid ladders late in pregnancy, when balance can be a problem.
  - Learn your target heart rate for exercise. If your job involves strenuous exercise, stop and rest at the point your target heart rate is exceeded.
  - Be certain you are not relying on fast foods for lunch. Take time to pack or purchase nutritious foods.

### *QSEN Checkpoint Question 12.2*

#### **QUALITY IMPROVEMENT**

The nurse is reviewing an educational pamphlet that has been frequently provided to pregnant women. What statement from the pamphlet suggests that revision is necessary?

- a. “You may want to jog rather than walk to get an increased amount of exercise.”
- b. “Be certain to rest or sleep on your side, not flat on your back.”
- c. “Plan to pack a lunch every day so that you won’t eat junk food.”
- d. “Try to walk around your desk every hour to help leg circulation.”

*Look in [Appendix A](#) for the best answer and rationale.*

#### **TRAVEL**

Because we live in such a mobile society, many women have questions about travel during pregnancy. Early in a normal pregnancy, there are no restrictions unless the woman needs to travel to a malaria-prone, Zika virus, or other at-risk region (where she would need vaccine protection). If a woman is susceptible to motion sickness, advise her not to take any medication for this unless it is specifically prescribed or approved by her primary care provider. Suggest she use a “sea-sick” wrist or acupuncture band for this instead. Late in pregnancy, travel plans should take into consideration the possibility of early labor, requiring birth at a strange setting where a woman’s obstetric history will be unknown.

Regardless of the month of her pregnancy, if a woman plans to spend time at a remote location, such as could happen to a migrant worker, or a woman taking a family vacation at a campsite, be certain she has investigated the location of a nearby healthcare facility should an unexpected complication occur ([van den Akker & van](#)

[Roosmalen, 2016](#)). Caution her not to eat unwashed fruits or vegetables or raw meats and not to drink unpurified water. If she is going to be away from home for an extended time, she should make arrangements to visit a healthcare provider in that area so she can keep the schedule of her regular prenatal visits. Encourage her to make these plans far enough in advance so her records can be copied and carried by her or, with her consent, an electronic record can be forwarded to the interim healthcare provider. Also, make certain she has enough of her prescribed vitamin supplement plus adequate prescriptions for refills as necessary.

Advise a woman who is taking a long trip by automobile to plan for frequent rest or stretch periods. Preferably every hour, but at least every 2 hours, she should get out of the car and walk a short distance. This break relieves stiffness and muscle aches and improves lower extremity circulation, helping prevent varicosities, hemorrhoids, and thrombophlebitis.

Pregnant women may drive automobiles as long as they fit comfortably behind the steering wheel. They should use seat belts like everyone else. Occasionally, uterine rupture has been reported from seat belt use, but overall evidence confirms seat belts reduce mortality among pregnant women in car accidents, as they do for everyone ([Fletcher & Russo, 2015](#)). Both shoulder harnesses and lap belts should be used. The lap belt should be worn as snugly as comfortable so that it fits under the abdominal bulge and across the pelvic bones. The shoulder harness should be snug but comfortable, worn across the shoulder, chest, and upper abdomen. A pad may be placed under the shoulder harness at the neck to avoid chafing ([Fig. 12.2](#)).

**Figure 12.2** Encourage women to wear seat belts during pregnancy. The bottom strap should cross beneath the abdomen.

Pregnancy is also a time for the family to think about transportation safety for the newborn. Purchasing a car seat is an investment that not only is legally required for transporting infants but also helps guarantee their safety. Families who cannot afford to purchase an infant car seat may want to ask friends or relatives about the possibility of borrowing one they may no longer need. Many hospitals and local Red Cross chapters provide infant seats on a rental or loan basis for families who may find it difficult to obtain one in other ways. An easy way to determine if a used car seat is up-to-date is to check the website <http://www.safercar.gov/parents/CarSeats/Car-Seat-Safety.htm>.

Traveling by plane for women is not contraindicated during pregnancy as long as the plane has a well-pressurized cabin (which is true of commercial airlines but not of all small private planes), the woman is offered an extension seat belt as needed, and the woman is not required to sit in one position for a long time (Tucker, 2014).

Some airlines do not permit women who are more than 7 months pregnant to board; others require written permission from her provider. Advise a woman to investigate

these restrictions by calling the airline or a travel agency before making such travel plans.

With businesses becoming global, more women than ever before are asked to travel internationally. Women who travel abroad may need additional safety measures such as a vaccine for protection against cholera or antibiotic prophylaxis for malaria before they can safely enter certain countries (Tucker, 2014). The influenza vaccine is recommended if it is flu season (October through May) for all pregnant women (Sukumaran, McCarthy, Kharbanda, et al., 2015).

Before accepting or allowing any immunization, however, a woman should ask her provider to verify it will be safe. All live virus vaccines (e.g., measles, mumps, rubella, and yellow fever) are contraindicated during pregnancy and should not be administered unless the risk of the disease outweighs the risk to the pregnancy because live virus vaccines can cross the placenta and infect the fetus. Pregnancy does not alter indications for rabies vaccine because without the vaccine, a fatal disease could occur. Tetanus is also treated the same in pregnant women as in others.

### *What If . . . 12.1*

**Julberry Adams tells the nurse she usually drives to her parents' home for vacation but can't this year because she no longer fits behind the wheel of her compact car. She asks the nurse if it would be better for her to take the train or fly. How would the nurse best respond?**

## **MINOR BODY CHANGES OF PREGNANCY: THE FIRST TRIMESTER**

Although most women are pleased to discover they are pregnant, for some women, the symptoms of early pregnancy cause much discomfort. Providing empathetic and sound advice about ways to relieve discomfort helps promote overall health and well-being. Although these early symptoms are classified as minor, they may not seem minor to a woman who wakes each morning feeling so nauseated she wonders if she will ever feel like herself again. Each of these symptoms has the potential to lead to secondary problems that could be serious, so signs and symptoms need to be identified as they occur.

### **Nursing Diagnoses and Related Interventions**

**Nursing Diagnosis:** Health-seeking behaviors related to learning more about minor body changes of early pregnancy, such as morning nausea

**Outcome Evaluation:** Patient states she is familiar with early body changes of

pregnancy and will take measures to relieve them.

Because each woman's experience is unique, nursing diagnoses and care must be developed according to each woman's individual needs. Additional nursing diagnoses that might be developed for women experiencing the minor body changes of early pregnancy include:

- Health-seeking behaviors related to interest in using herbal remedies to relieve discomfort early in pregnancy
- Constipation related to reduced peristalsis in pregnancy
- Fatigue related to increased physiologic need for sleep and rest during pregnancy
- Acute pain related to frequent muscle cramps secondary to physiologic changes of pregnancy
- Disturbed sleep pattern related to frequent movement of fetus during night

### **Breast Tenderness**

Breast tenderness is often one of the first symptoms noticed in early pregnancy and may be most noticeable on exposure to cold air. For most women, the tenderness is minimal and transient, something they are aware of but not something that overly concerns them. If the tenderness is enough to cause discomfort, encourage a woman to wear a bra with a wide shoulder strap for support and to dress warmly to avoid cold drafts if cold increases symptoms. If actual pain exists, the presence of conditions such as nipple fissures or other explanations for the pain, such as breast abscess, need to be ruled out.

### **Palmar Erythema**

Palmar erythema, or palmar pruritus, occurs in early pregnancy and is probably caused by increased estrogen levels. Constant redness or itching of the palms can make a woman believe she has developed an allergy. Explain that this type of itching in early pregnancy is normal to prevent a woman from spending time and effort trying different soaps or detergents or attempting to implicate certain foods she has eaten as the cause of her discomfort. She may find calamine lotion to be soothing. As soon as a woman's body adjusts to the increased level of estrogen, the erythema and pruritus disappear (Coad & Dunstall, 2011).

### **Nausea, Vomiting, Constipation, and Pyrosis**

At least half of pregnant women experience gastrointestinal symptoms such as nausea, vomiting, constipation, and pyrosis. Because these symptoms are related to nutrition, they are discussed in [Chapter 13](#).

### **Fatigue**

Fatigue is extremely common in early pregnancy, probably because of increased metabolic requirements (Haakstad, Torset, & Bø, 2016). Much of it can be relieved by

increasing the amount of rest and sleep. Some women, however, are reluctant to take time out of their day to do this. They know pregnancy is not an illness and so they proceed as if nothing is happening to them. Rarely is there justification during a normal pregnancy for women to take extra days off from work because of their condition, but it is also unrealistic to proceed as if nothing is happening. Fatigue can increase the amount of morning nausea a woman experiences. If she becomes too tired, she may not eat properly and nutrition can suffer. If she remains on her feet without at least one break during a day, the risk for varicosities and the danger of thromboembolic complications increase.

For all these reasons, ask women at prenatal visits whether they manage to have at least one short rest period every day. A woman who works outside her home at a job that requires her to be on her feet most of the day might use part of her lunch hour to sit with her feet elevated (Fig. 12.3). After she returns home from work in the evening, she may need to modify her customary routine from typical activities such as cooking dinner or watching a child's soccer game to resting, then cooking dinner or going to the soccer game, or resting while her partner cooks dinner.

**Figure 12.3** A “feet-up” break during a workday helps prevent ankle edema. ([Photographee.eu/Shutterstock.com](http://Photographee.eu/Shutterstock.com))

### *QSEN Checkpoint Question 12.3*

#### **EVIDENCE-BASED PRACTICE**

Almost all women experience a number of minor discomforts during pregnancy. To investigate whether these symptoms are serious enough to lead to depression, researchers scored 1,507 Australian women during their first pregnancy on a depression inventory questionnaire. The women were also asked what minor body changes they were experiencing. The most frequent body changes reported were exhaustion (86.9%), morning nausea (64.3%), back pain (45.6%), constipation (43.5%), and severe headache or migraine (29.5%). Women who reported five or more physical health problems were 3 times more likely to also report depressive

symptoms (Perlen, Woolhouse, Gartland, et al., 2013).

Based on the previous study, which statement by Julberry would give the nurse the most concern that she should be assessed at her next prenatal visit as to whether she could be depressed?

- a. “I wake up every morning with backache. Do I need a new mattress?”
- b. “I like the job I do, although I come home exhausted almost every day.”
- c. “Between the headache, the backache, and the nausea, pregnancy isn’t fun.”
- d. “The amount of constipation I have is a surprise; I don’t usually get that.”

*Look in Appendix A for the best answer and rationale.*

## Muscle Cramps

Decreased serum calcium levels, increased serum phosphorus levels, and, possibly, interference with circulation commonly cause muscle cramps of the lower extremities during pregnancy. This problem is best relieved if a woman lies on her back momentarily and extends the involved leg while keeping her knee straight and dorsiflexing the foot until the pain disappears (Fig. 12.4).

**Figure 12.4** Relieving a leg cramp in pregnancy. Pressing down on the knee and pressing the toes backward (dorsiflexion) relieves most cramps. Here, a woman’s partner helps.

Taking a calcium supplement, which would lower the phosphorus level, may be helpful. If a woman is experiencing frequent leg cramps, she may be advised to take magnesium lactate or citrate once in the morning and again in the evening as these bind phosphorus in the intestinal tract and thereby lower its circulating level; however, there is a lack of strong evidence that this decreases the frequency or intensity of leg cramps (Zhou, West, Zhang, et al., 2015). Elevating lower extremities frequently during the day to improve circulation and avoiding full leg extension, such as stretching with the toes pointed, may also be helpful. Typically, muscle cramps are a minor symptom of pregnancy, but the pain is extreme and the intensity of the contraction can be frightening. Always ask at prenatal visits if this is a problem. Otherwise, women may

not realize cramping is pregnancy related and so fail to report it.

## Hypotension

Supine hypotension is a symptom that occurs when a woman lies on her back and the uterus presses on the inferior vena cava, impairing blood return to her heart (Wang, Xu, Zhou, et al., 2015). A woman experiences an irregular heart rate and a feeling of apprehension. Relieving the problem is simple: If a woman turns or is turned onto her side, pressure is removed from the inferior vena cava, blood flow is restored, and the symptoms quickly fade. To prevent the syndrome, advise pregnant women to always rest or sleep on their side, not their back. If they can only fall asleep on their back, they should insert a small firm pillow under their right hip to cause the weight of their uterus to shift off their inferior vena cava.

If a woman rises suddenly from a lying or sitting position or stands for an extended time in a warm or crowded area, she may faint from the same phenomenon (blood pooling in the pelvic area or lower extremities). Rising slowly and avoiding extended periods of standing prevents this problem. If a woman should feel faint, sitting with her head lowered—the same action as for any person who feels faint—alleviates the problem.

## Varicosities

Varicosities, or the development of tortuous leg veins, commonly form in pregnancy because the weight of the distended uterus puts pressure on the veins returning blood from the lower extremities (Attilakos & Overton, 2012). This causes blood pooling and vessel distention. The veins become enlarged, inflamed, and painful. Although usually confined to the lower extremities, varicosities can extend up to and including the vulva. They occur most frequently in women with a family history of varicose veins, those who are obese, and those who have a large fetus or a multiple pregnancy. Urge such women to take active measures to prevent varicosities beginning in early pregnancy; if left until late in pregnancy, the best they will be able to accomplish is relief of pain from already formed varicosities.

Resting in a Sims position or on the back with the legs raised against the wall (with a small firm pillow under their right hip) or elevated on a footstool for 15 to 20 minutes twice a day is a good precaution (Fig. 12.5). Caution women not to sit with their legs crossed or their knees bent and to avoid constrictive knee-high hose or garters.

**Figure 12.5** Position to relieve varicosities. The mother keeps a pad under her right hip to prevent supine hypotensive syndrome.

Some women who developed varicosities during a previous pregnancy may need elastic support stockings for relief of varicosities in a second pregnancy. If a woman needs to wear these, urge her to put them on before she arises in the morning because once she is on her feet, blood pooling begins, and the stockings will be less effective. When applied properly, the stockings should reach an area above the point of distention.

Be certain a woman understands the stockings she buys should be labeled “medical support hose.” Otherwise, as many pantyhose manufacturers advertise their stockings as giving “firm support,” she may assume erroneously this is sufficient for her.

Because it stimulates venous return, exercise is as effective as rest periods for alleviating varicosities. Most women assume they do not need set exercise periods during pregnancy because they work hard at other activities. If they analyze the type of work they do, however, they may realize a great deal of their work leads to venous stasis of their lower extremities. Women stand in one position to wash dishes, run a copying machine, defend a patient in court, process a part on an assembly line, or teach a class. Sitting at a desk for prolonged periods of time with legs bent at the knee also encourages venous stasis.

To increase circulation, advise women to break up these long periods of sitting or standing with a “walk break” at least twice a day. As a rule, their families or fellow workers will benefit by accompanying them on such walks as partners may discover that when they analyze their day, they, too, sit more than walk during their workday.

Vitamins C, A, and B complex are all important for circulatory health. Vitamin C appears to be most important as it is necessary for the formation of blood vessel collagen and endothelium. Ask at prenatal visits if women are taking a daily prenatal vitamin as well as including fresh fruit or juice in their diet every day as yet another measure to help prevent varicosities.

### *What If . . . 12.2*

**Julberry knows taking a prenatal vitamin every day is important but is having trouble remembering to take one. What are some suggestions the nurse could make to help her remember to take this daily?**

## **Hemorrhoids**

Hemorrhoids (i.e., varicosities of the rectal veins) occur commonly in pregnancy because of pressure on these veins from the bulk of the growing uterus (Zielinski, Searing, & Deibel, 2015). Daily bowel evacuation to prevent constipation, drinking adequate fluid, eating adequate fiber, and resting in a modified Sims position are all helpful measures to both prevent these and relieve pain. At day's end, assuming a knee–chest position (Fig. 12.6) for 10 to 15 minutes is an excellent way to reduce the pressure on rectal veins. A knee–chest position may initially make a woman feel light-headed. If this happens, advise her to remain in this position for only a few minutes at first and then gradually increase the time until she can maintain the position comfortably for about 15 minutes.

**Figure 12.6** Knee–chest position. Because the weight of the uterus is shifted forward, this position promotes free flow of urine from the kidneys (preventing urinary tract stasis and infection) and better circulation in the rectal area (preventing hemorrhoids).

In addition to the previous measures, a stool softener such as docusate sodium (Colace) may be recommended if a woman already has hemorrhoids when she enters pregnancy. Replacing external hemorrhoids with gentle finger pressure and applying witch hazel, a cold compress, or over-the-counter hemorrhoid cream are other helpful measures to relieve pain. Hydrocortisone-pramoxine (Proctofoam-HC) is a prescription medication that is also helpful and is safe for the fetus (Lohsiriwat, 2015). As with varicosities, think prevention, not just providing help for already established hemorrhoids.

### QSEN Checkpoint Question 12.4

#### PATIENT-CENTERED CARE

Julberry Adams tells the nurse she has developed painful hemorrhoids. She admits that she is embarrassed to discuss this problem but acknowledges that it needs to be addressed. The best advice to give her would be which of the following?

- “Take a tablespoon of mineral oil with each of your meals.”
- “Omit most of the fiber from your diet. This will prevent constipation.”
- “Lie on your stomach daily to drain blood from rectal veins.”
- “Witch hazel pads feel cool against swollen hemorrhoids.”

Look in [Appendix A](#) for the best answer and rationale.

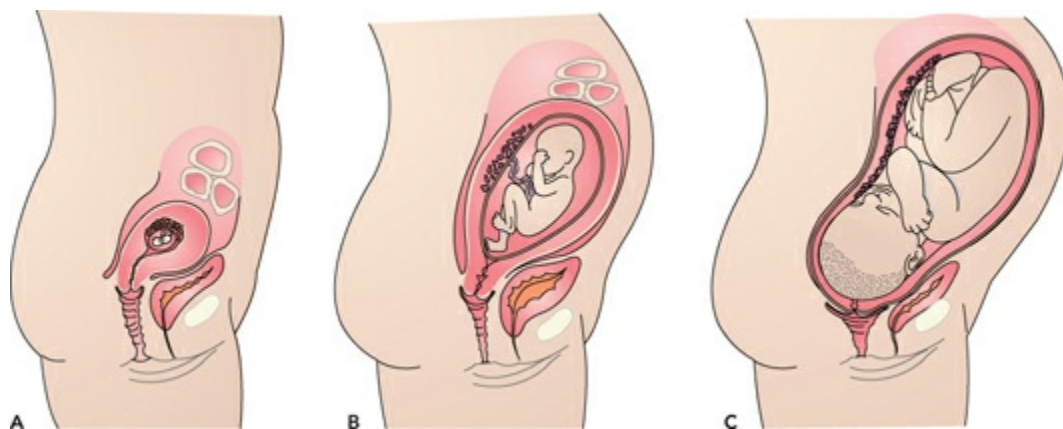

### Heart Palpitations

On sudden movement, such as turning over in bed, a pregnant woman may experience a bounding palpitation of the heart (Nelson-Piercy, 2012). This is probably because of circulatory adjustments necessary to accommodate her increased blood supply.

Although only momentary, the sensation can be frightening because the heart seems to stop for an instant or skip a beat. It is reassuring for women to learn heart palpitations are normal and are to be expected on occasion. Only if they occur very frequently or continuously or are accompanied by pain should they be a concern. Gradual, slow movements will help prevent this from happening.

### Frequent Urination

Frequent urination occurs in early pregnancy because the growing uterus presses on the anterior bladder. This sensation lasts about 3 months, beginning as early as the first or second missed menstrual period, disappears in midpregnancy as the uterus rises above the bladder, and then returns again in late pregnancy as the fetal head presses against the bladder (Fig. 12.7).

**Figure 12.7** Bladder changes during pregnancy. (A) Early pregnancy: The uterus presses against the bladder, causing frequent urination. (B)

Middle pregnancy: Urinary frequency is relieved. (C) Late pregnancy: The uterus is again pressing on the bladder, leading to the recurrence of urinary frequency.

Caution women not to wait but to void as often as necessary, as urine stasis can lead to infection. When a woman reports frequency of urination, be certain this is the only urinary symptom she is experiencing. Ask her about any burning or pain on urination or whether she has noticed any blood in her urine, which are signs of a urinary tract infection.

Women should not restrict their fluid intake to diminish frequency of urination, as fluids are necessary to allow their blood volume to double. Decreasing daily caffeine intake due to the risks caffeine poses for low birth weight may have the added benefit of reducing urinary frequency. Most importantly, a woman needs to understand voiding more frequently is a normal pregnancy finding. The sensation of frequency will probably return after lightening (the settling of the fetal head into the inlet of the pelvis at pregnancy's end). Unless she is cautioned, she may worry at that time that she has a urinary tract infection. Again, unless other symptoms are present, she can be assured this is a normal finding.

Occasionally, a woman notices stress incontinence (involuntary loss of urine on coughing or sneezing) during pregnancy. Although this is largely unpreventable, doing Kegel exercises (alternately contracting and relaxing perineal muscles; [Box 12.7](#)) not only helps strengthen urinary control but also directly strengthens perineal muscles for birth ([Sangsawang & Sangsawang, 2015](#)).

#### BOX 12.7

#### Kegel Exercises

Kegel exercises are exercises designed to strengthen the pubococcygeal muscles. Each is a separate exercise and should be done about three times per day.

1. Squeeze the muscles surrounding the vagina as if stopping the flow of urine. Hold for 3 seconds. Relax. Repeat this sequence 10 times.
2. Contract and relax the muscles surrounding the vagina as rapidly as possible 10 to 25 times.
3. Imagine you are sitting in a bathtub of water and squeeze muscles as if sucking water into the vagina. Hold for 3 seconds. Relax. Repeat this action 10 times.
4. Caution: Don't regularly start and stop the flow of urine during urination to try and strengthen muscles as this can lead to incomplete emptying of the bladder.

It may take as long as 6 weeks of exercise before pubococcygeal muscles are strengthened. In addition to strengthening urinary control and preventing stress incontinence, Kegel exercises can lead to increased sexual enjoyment because of tightened vaginal muscles and can help avoid tearing of the perineum with childbirth.

## Abdominal Discomfort

Some women experience uncomfortable feelings of abdominal pressure early in pregnancy. Women with a multiple pregnancy may notice this throughout pregnancy. Many pregnant women typically stand with their arms crossed in front of them because the weight of their arms resting on their abdomen relieves this discomfort.

When a woman stands up quickly, she may experience a pulling pain, sometimes sharp and frightening, in her right or left lower abdomen from tension on a round ligament. She can prevent this from happening by always rising slowly from a lying to a sitting or from a sitting to a standing position. Because round ligament pain may simulate the abrupt pain that occurs with ruptured ectopic pregnancy, a woman's description of the pain needs to be evaluated carefully. If ectopic pregnancy is suggested, she should be referred to her obstetric provider (Fletcher & Russo, 2015).

## Leukorrhea

**Leukorrhea**, a whitish, viscous vaginal discharge or an increase in the amount of normal vaginal secretions, occurs in response to the high estrogen level and the increased blood supply to the vaginal epithelium and cervix in pregnancy. A daily bath or shower to wash away accumulated secretions and prevent vulvar excoriation usually controls this problem. Wearing cotton underpants and sleeping at night without underwear can be helpful to reduce moisture and possible vulvar excoriation. Some women may need to wear a perineal pad to absorb the discharge. Caution women not to use tampons because this could lead to stasis of secretions and subsequent infection. Advise women to contact their obstetric provider if there is a change in the color, odor, or character of this discharge as these suggest infection. Caution women not to douche; douching is contraindicated generally and especially throughout pregnancy because fluid could be forced into the uterine cervix (Sheth & Keller, 2015).

A woman with vulvar itching (pruritus) accompanying a vaginal discharge needs additional evaluation because this strongly indicates infection. Be certain that when describing pruritus, the woman is not describing burning on urination, which is a sign of an early bladder infection (which also needs therapy, but of a different type). Therapy for common vaginal infections, such as candidiasis, that present with pruritus are discussed in Chapter 47.

Avoiding tight underpants and pantyhose may help prevent vulvar and vaginal infections, particularly yeast infections. Although over-the-counter medications for yeast infections are available, caution women to contact their healthcare provider rather than self-treat vaginal infections during pregnancy so their healthcare provider knows that infections are occurring.

A woman who is uncomfortable about discussing this part of her body or who associates vaginal infections with poor hygiene or sexually transmitted infections may be reluctant to mention an irritating vaginal discharge at a healthcare visit. At each prenatal visit, therefore, be sure to ask women specifically whether they are

experiencing this problem.

### *What If . . . 12.3*

**Julberry Adams tells the nurse she has urinary frequency. She also reports a white vaginal discharge. What questions would the nurse need to ask to evaluate whether she is experiencing a normal finding of pregnancy or a possible urinary tract infection?**

## **MINOR BODY CHANGES OF PREGNANCY: SECOND AND THIRD TRIMESTERS**

At about the midpoint of pregnancy (the 20th to 24th weeks), a woman is usually ready for further health teaching that relates to the new symptoms that occur in the latter half of pregnancy. As she starts to view the child within her as a separate person, she becomes interested in discussing and making plans for the signs and symptoms of beginning labor, birth, and the infant's care. The midpoint of a pregnancy is also a good time to review precautionary measures to prevent constipation, varicosities, and hemorrhoids, as these increase in intensity as the pregnancy progresses.

### **Nursing Diagnoses and Related Interventions**

**Nursing Diagnosis:** Health-seeking behaviors related to learning more about the minor body changes of late pregnancy such as Braxton Hicks contractions

**Outcome Evaluation:** Patient states she feels confident in self-managing the minor body changes of late pregnancy.

Examples of other possible nursing diagnoses associated with the minor body changes of middle-to-late pregnancy are:

- Pain related to almost constant backache
- Acute abdominal pain related to sudden postural change in pregnancy
- Anxiety related to shortness of breath, resulting from expanding uterine pressure on the diaphragm
- Deficient knowledge related to beginning signs of labor

### **Muscular/Skeletal Discomfort**

As pregnancy advances, a lumbar lordosis develops and postural changes necessary to maintain balance lead to backache (see [Box 12.3](#)). Wearing shoes with low-to-moderate heels reduces the amount of spinal curvature necessary to maintain an upright posture.

Encouraging a woman to walk with her pelvis tilted forward (i.e., putting pelvic support under the weight of the fetus) is also helpful. In addition, applying local heat from a heating pad may aid in relieving backache (Liddle & Pennick, 2015).

To avoid back strain and worsen the condition, advise women to squat rather than bend over to pick up objects. Also encourage women to always lift objects by holding them close to the body. For some women, a firmer mattress during this time may be required. Sliding a board under the mattress is a cost-effective alternative for achieving a firmer sleeping surface rather than buying a new mattress. Pelvic rocking or tilting, an exercise described in Chapter 14, also helps to prevent and relieve backache.

Obtaining a detailed account of a woman's back symptoms is crucial because back pain can be an initial sign of a bladder or kidney infection. Too often, women are observed at a prenatal visit only lying in a lithotomy position on an examining table. Always assess the manner in which a woman walks and what type of shoes she wears as she moves from a waiting room to an examining room to evaluate whether her posture or shoes could be a cause of backache.

Generally, acetaminophen (Tylenol) is considered to be safe and effective for relieving this type of pain during pregnancy. Acupuncture can also be effective (Carr, 2015). Caution women not to take herbal remedies, muscle relaxants, or other analgesics (or any other medication) for back pain without first consulting their obstetric provider.

A second skeletal problem that occurs at a greater incidence during pregnancy than at any other time is carpal tunnel syndrome or pain at the wrist from compression of the median nerve. Therapy for this is discussed in Chapter 49.

## Headache

Many women experience headaches during pregnancy, apparently from their expanding blood volume, which puts pressure on cerebral arteries. Trying to reduce any possible causative situations, such as eye strain or tension, may lessen the number of headaches they experience. Resting with an ice pack on the forehead and taking a usual adult dose of acetaminophen usually furnishes adequate relief (Spierings & Sabin, 2016).

Compounds with ibuprofen (Motrin, Advil) (class C drugs) are not usually recommended because they cause premature closure of the ductus arteriosus in the fetus. Additionally, they have been found to contribute to fetal renal damage, low amniotic fluid, and fetal intracranial hemorrhage. Although a few women who have migraine headaches find these worsen during pregnancy, most women notice considerable improvement with this type of headache because of increased estrogen levels (see Chapter 49). Caution women that if a headache seems unusually intense or continuous, they should report it to their primary care provider as a continuous sharp headache may be a sign of high blood pressure, a danger sign of pregnancy.

## Dyspnea

As the expanding uterus places pressure on the diaphragm, lung compression and shortness of breath result. A woman will notice this primarily at night if she lies flat. She will definitely notice it on exertion. To relieve nighttime dyspnea, advise her to sleep with her head and chest elevated so the weight of the uterus falls away from her diaphragm. As pregnancy progresses, she may require two or more pillows to sleep at night and she may need to limit her activities during the day to prevent exertional dyspnea. Always question women about this important symptom at prenatal visits to be certain the sensation is not continuous, which could describe a respiratory disorder (Goland, Perelman, Asalih, et al., 2015).

### **Ankle Edema**

Most women experience some swelling of their ankles and feet during late pregnancy, most noticeably at the end of the day. Women are often first conscious of this when they kick off their shoes to rest and then cannot put them on again comfortably.

As long as proteinuria and hypertension are absent, ankle edema of this nature is a normal occurrence of pregnancy. It is probably caused by general fluid retention and reduced blood circulation in the lower extremities because of uterine pressure. This simple edema can be relieved best by resting in a left side-lying position because this increases the kidney's glomerular filtration rate and also allows for good venous return. Sitting for half an hour in the afternoon and again in the evening with the legs elevated is also helpful. Caution women to avoid wearing constricting clothing such as panty girdles or knee-high stockings because these impede lower extremity circulation and venous return.

Although ankle edema is common, it is important not to dismiss a report of lower extremity edema as insignificant until you are certain a woman does not exhibit any signs such as proteinuria, edema of other, nondependent body parts, or has had a sudden increase in weight as these, in conjunction with ankle edema, are beginning signs of gestational hypertension (Ohno, Terauchi, Tamakoshi, et al., 2016).

### **Braxton Hicks Contractions**

Beginning as early as the 8th to 12th week of pregnancy, the uterus periodically contracts and then relaxes again (Coad & Dunstall, 2011). Early in pregnancy, these sensations, termed Braxton Hicks contractions, are not apt to be noticeable. By middle or late pregnancy, the contractions become so strong a woman who tenses at the sensation may experience pain, similar to a forceful menstrual cramp. Although these contractions are not a sign of beginning labor, women should telephone or e-mail their primary care provider to report them so they can be evaluated. A rhythmic pattern of even very light but persistent contractions could be a beginning sign of preterm labor.

#### ***QSEN Checkpoint Question 12.5***

**INFORMATICS**

Julberry Adams has done some online research about the ankle edema that she typically experiences by the end of each day. Which statement by her would reveal that she has read accurate information about the cause of this?

- a. “I know this is a beginning complication; I’ll call my doctor tonight.”
- b. “I understand this is from eating too much salt; I’ll restrict that more.”
- c. “I’ll rest with my feet up to take pressure off my leg veins.”
- d. “I know this is from gaining too much weight; I’ll start to diet tomorrow.”

*Look in [Appendix A](#) for the best answer and rationale.*

## Preventing Fetal Exposure to Teratogens

A teratogen is any factor, chemical or physical, that adversely affects the fertilized ovum, embryo, or fetus. A fetus is extremely vulnerable to environmental injury, specifically at the beginning or early weeks of pregnancy. Although the causes of many anomalies occurring in utero are still unknown, many specific teratogenic factors have been isolated.

### EFFECTS OF TERATOGENS ON A FETUS

Several factors influence the amount of damage a teratogen can cause. The strength of the teratogen is the first one. For example, radiation is a known teratogen. In small amounts (everyone is exposed to some radiation every day, such as from the rays of the sun), it causes no damage. However, in large doses (e.g., a woman received radiation to treat cancer of the cervix during pregnancy), serious fetal defects or death could occur ([Basta, Bak, & Roszkowski, 2015](#)).

The timing of the teratogenic insult is a second factor that makes a significant difference. If a teratogen is introduced before implantation, for example, either the zygote is destroyed or it appears unaffected. If the insult occurs when the main body systems are being formed (in the second to eighth weeks of embryonic life), a fetus is very vulnerable to injury. During the last trimester, the potential for harm again decreases because all the organs of a fetus are formed and are merely maturing. The times when different anatomic areas of a fetus are most likely to be affected by teratogens are shown in [Chapter 9, Figure 9.4](#).

Two exceptions to the rule that deformities usually occur in early embryonic life are the effects caused by the organisms of syphilis and **toxoplasmosis**. These two infections can cause abnormalities in organs that were originally formed normally. Intimate partner violence is another teratogen that can be responsible for injury to a fetus at any stage of pregnancy ([Demelash, Nigatu, & Gashaw, 2015](#)).

A third factor determining the effects of a teratogen is the teratogen’s affinity for specific body tissues. Lead and mercury, for example, attack and disable nervous tissue ([Dórea, 2015](#)). Thalidomide (Immunoprin), originally used to treat nausea in pregnancy, is now prescribed for cancer therapy, and it may cause limb defects ([Coombes, 2016](#)).

Tetracycline (Apo-Tetra), a common antibiotic, causes tooth enamel deficiencies, and possibly, long bone deformities. The rubella virus affects many organs, with the eyes, ears, heart, and brain the four most commonly attacked (Karch, 2015).

## Nursing Diagnoses and Related Interventions

**Nursing Diagnosis:** Health-seeking behaviors related to learning more about avoiding teratogens that can affect fetal growth

**Outcome Evaluation:** Patient states she feels confident in monitoring her environment for the presence of possible teratogens.

Much of the health history information obtained at prenatal visits is taken to help determine if there is a possibility a woman is unknowingly being exposed to teratogens during her pregnancy. Examples of nursing diagnoses associated with maternal exposure to teratogens include:

- Health-seeking behavior related to mother's interest in avoiding exposure to harmful substances she could contact at work
- Risk for fetal injury related to lack of knowledge about teratogenicity of alcohol, drugs, and tobacco
- Risk for fetal infection related to transmission from mother to fetus of genital herpes

## TERATOGENIC MATERNAL INFECTIONS

Teratogenic maternal infections involve viral, bacterial, or protozoan organisms, which cross the placenta from mother to fetus. Most infections that may detract from a healthy pregnancy outcome cause relatively mild, flu-like symptoms in the woman but can have much more serious effects on a fetus or newborn. Preventing and predicting fetal injury from an infection is complicated because when a disease is subclinical (without any symptoms in the mother), it is difficult to analyze any effect on the fetus.

When newborns are tested to see if antibodies against the common infectious teratogenic diseases are present, the test is described collectively under the umbrella term TORCH, an acronym for toxoplasmosis, rubella, cytomegalovirus, and herpes simplex virus (Neu, Duchon, & Zachariah, 2015.). Some laboratories spell the test as TORSCH to show they also screen for syphilis. Still, other laboratories identify the O with "other infections," which could include hepatitis B virus (HBV) or chlamydia (discussed in Chapter 47). In addition to TORCH screening, ask women if it is all right to screen them for human immunodeficiency virus (HIV); you must obtain separate permission for this test (Camacho-Gonzalez, Kingbo, Boylan, et al., 2015).

## Malaria

**Malaria** in humans is caused by intraerythrocytic protozoa of the genus *Plasmodium* transmitted to humans by the bite of an infected female *Anopheles* mosquito. Healthcare providers can contract it from infected blood products. During pregnancy, women can transmit malaria to a fetus. Most malaria infections in the United States occur among people who have traveled to areas where malaria is epidemic, such as Africa or South America.

A number of drugs, such as chloroquine (Aralen) in the first trimester and mefloquine (Lariam) in the second or third trimesters, are helpful. Women who will be visiting an area known to be epidemic for malaria can begin treatment as prophylaxis up to 2 weeks before travel (Tinto, Sevene, Dellicour, et al., 2015).

## Toxoplasmosis

Toxoplasmosis, a protozoan infection, is spread most commonly through contact with uncooked meat, although it may also be contracted through handling cat stool in soil or cat litter (Hampton, 2015).

As many as 1 in 900 pregnancies may be affected by toxoplasmosis. Prepregnancy serum analysis can be done to identify women who have never had the disease and so are susceptible (about 50% of women). Removing a cat from the home during pregnancy as a means of prevention is not necessary as long as the cat is healthy. However, taking in a new cat, which could be infected, is unwise. Instruct pregnant women to avoid undercooked meat and also not to change a cat litter box or garden in soil in an area where cats may defecate to avoid exposure to the disease. Also, reinforce proper hand washing after handling uncooked meat.

## Rubella (German Measles)

The rubella virus usually causes only a mild rash and mild systemic illness in a woman, but the teratogenic effects on a fetus can be devastating, such as hearing impairment, cognitive and motor challenges, cataracts, cardiac defects (most commonly patent ductus arteriosus and pulmonary stenosis), restricted intrauterine growth (i.e., small for gestational age), thrombocytopenic purpura, and dental and facial clefts, such as cleft lip and palate (Grant, Reef, Dabbagh, et al., 2015).

Typically, a rubella titer from a pregnant woman to estimate whether a woman is susceptible to rubella is obtained on the first prenatal visit. A titer greater than 1:8 suggests immunity to the disease. A titer of less than 1:8 suggests a woman is susceptible to viral invasion. A titer that is greatly increased over a previous reading or is initially extremely high suggests a recent infection has occurred.

A woman who is not immunized before pregnancy cannot be immunized during pregnancy because the vaccine contains a live virus that would have effects similar to those occurring with a subclinical case of rubella. After rubella immunization, a woman is advised not to become pregnant for about 3 months, until the rubella virus is no

longer active. Immediately after a pregnancy, assess whether a woman who has a low rubella titer would like to be immunized to provide protection against rubella in future pregnancies.

An increasing concern is women who demonstrate antibodies against rubella yet still become reinfected during pregnancy. Because of this, all pregnant women should avoid contact with children with rashes. Infants who are born to mothers who had rubella during pregnancy may be capable of transmitting the disease for a time after birth. Because of this, such an infant is isolated from other newborns during the newborn period. Be certain a woman is aware her infant might infect others, including pregnant women. Nurses who care for pregnant women or newborns should receive immunization against rubella to ensure they neither spread nor contract the disease (CDC, 2016).

### **Herpes Simplex Virus (Genital Herpes Infection)**

Genital **herpes simplex virus (HSV)** is a sexually transmitted infection spread by intimate contact. The first time a woman contracts an HSV infection, systemic involvement occurs. The virus spreads into the bloodstream (viremia) and, if a woman is pregnant, can cross the placenta to a fetus, thus posing substantial fetal risk (Lopez-Medina, Cantey, & Sánchez, 2015). Typically, HSV-2 is the cause of genital outbreaks and is caused by genital-to-genital contact. Increasingly, HSV-1 can cause genital outbreaks and is often transmitted during oral sex. The management of genital herpes is the same whether HSV-1 or HSV-2 is the cause.

If the infection takes place in the first trimester, severe congenital anomalies or spontaneous miscarriage can occur. If the infection invades during the second or third trimester, there is a high incidence of premature birth, intrauterine growth restriction, neurologic disease, and continuing infection of the newborn at birth. Mortality may be as high as 60% (Martin & Satin, 2015).

If a woman has had oral HSV, typically HSV-1, infections (popularly called cold sores) before contracting genital herpes, or if the genital outbreak is a recurrence, antibodies to the virus in her system help reduce the severity of the outbreak and help prevent spread of the virus to the fetus across the placenta.

If genital lesions are present at the time of birth, however, a fetus may contract the virus from direct exposure during birth. For this reason, if a woman has existing genital lesions at the time of birth, cesarean birth is usually advised to reduce the risk of this route of infection. This awareness of the placental spread of HSV has increased the importance of obtaining information about exposure to HSV or any painful perineal or vaginal lesions that might indicate this infection at prenatal visits through conscientious history taking.

Acyclovir (Zovirax) or valacyclovir (Valtrex) can both be safely administered to women who develop lesions during pregnancy as well as to their newborns at birth (Groves, 2016). Either drug is recommended daily as prophylaxis at 36 weeks of pregnancy to prevent a lesion at the time of birth. The primary mechanism for

protecting a fetus, however, is disease prevention. Urging women to practice safer sex is important to lessen their exposure to this and other sexually transmitted infections.

## Cytomegalovirus

**Cytomegalovirus** (CMV), a member of the HSV family, is another teratogen that can cause extensive damage to a fetus while causing few symptoms in a woman (Martin & Satin, 2015). It is not sexually transmitted but spreads from person to person by droplet infection such as occurs with sneezing. If a woman acquires a primary CMV infection during pregnancy and the virus crosses the placenta, the infant may be born with severe neurologic challenges (e.g., hydrocephalus, microcephaly, or spasticity) or with eye damage (e.g., optic atrophy or chorioretinitis), hearing impairment, or chronic liver disease. The newborn's skin may be covered with large petechiae (i.e., "blueberry-muffin" lesions). Because a woman has almost no symptoms, she may not even be aware she contracted an infection. Diagnosis in the mother or infant can be established by the isolation of CMV antibodies in blood serum. Unfortunately, there is no treatment for the infection even if it presents in the mother with enough symptoms to allow detection. Because there is no treatment or vaccine for the disease, routine screening for CMV during pregnancy is not recommended. Advise women to wash hands thoroughly before eating and to avoid crowds of young children at daycare or nursery school settings to help prevent exposure (Drew, Stapleton, Abu, et al., 2015).

Like HSV, a primary CMV infection may become latent, reactivating periodically. These recurrences are not thought to have a teratogenic effect on a fetus, but they can cause infection of a newborn during birth from genital secretions or postpartum from exposure to CMV-infected breast milk. CMV infection contracted at or shortly after birth is not associated with serious adverse effects except in babies of very low birth weight.

## Syphilis

Syphilis, a sexually transmitted infection, is of great concern for the maternal–fetal population. Despite the availability of accurate screening tests and proven medical treatment, it is growing in incidence; it places a fetus at risk for intrauterine or congenital syphilis (Su, Brooks, Davis, et al., 2016). Early in pregnancy, when the cytotrophoblast layer of the chorionic villi is still intact, the causative spirochete of syphilis, *Treponema pallidum*, apparently cannot cross the placenta and damage the fetus. When this layer atrophies at about the 16th to 18th week of pregnancy, however, the spirochete can cross and cause extensive fetal damage. If syphilis is detected in the mother and treated with an antibiotic such as intramuscular benzathine penicillin (Bicillin L-A) in the first trimester, a fetus is rarely affected. If left untreated beyond the 18th week of gestation, hearing impairment, cognitive challenge, osteochondritis, and fetal death are possible.

For these reasons, serologic screening (either by a venereal disease research

laboratory [VDRL] or a rapid plasma reagin [RPR] test) is done at a first prenatal visit; the test may then be repeated again close to term (the eighth month) if recent exposure is a concern. Even when a woman has been treated with antibiotics, the serum titer remains high up to 200 days; an increasing titer, however, suggests reinfection has occurred. In an infant born to a woman with syphilis, the serologic test for syphilis may remain positive for up to 3 months even though the disease was treated during pregnancy.

The newborn with congenital syphilis may have congenital anomalies, extreme rhinitis (sniffles), and a characteristic syphilitic rash, all of which identify the baby as high risk at birth ([Akahira-Azuma, Kubota, Hosokawa, et al., 2015](#)). When the baby's primary teeth come in, they are often oddly shaped (i.e., Hutchinson teeth). As the infant requires long-term follow-up, medical and nursing care of the newborn with congenital syphilis is discussed in [Chapter 47](#). As with all sexually transmitted infections, prevention through safer sex practices is key.

### Other Viral Diseases

It is difficult to detect other viral teratogens, but rubeola (measles), coxsackievirus, infectious parotitis (mumps), varicella (chickenpox), poliomyelitis, influenza, and viral hepatitis all may be teratogenic. Women are advised to be vaccinated against influenza before pregnancy. If contracted during pregnancy, parvovirus B19, the causative agent of erythema infectiosum (also called fifth disease) and a common viral disease in school-age children, can cross the placenta and attack the red blood cells of the fetus. Infection with the virus during early pregnancy is associated with fetal death. If the infection occurs late in pregnancy, the infant may be born with severe anemia and congenital heart disease ([American College of Obstetricians and Gynecologists, 2015](#)).

## TERATOGENIC MATERNAL EXPOSURES

### Potentially Teratogenic Vaccines

Live virus vaccines, such as measles, human papillomavirus (HPV), mumps, rubella, and poliomyelitis (Sabin type), are contraindicated during pregnancy because they may transmit a viral infection to a fetus ([Fletcher & Russo, 2015](#)). Care must be taken in routine immunization programs at high schools to be certain adolescents about to be vaccinated are not pregnant. Women who work in biologic laboratories where vaccines are manufactured are well advised to use protective gear or not to work with live virus products during pregnancy.

### Teratogenic Drugs

Many women assume the rule of being cautious with drugs during pregnancy applies only to prescription drugs and continue to take over-the-counter drugs or herbal supplements freely during pregnancy. Although not all drugs cross the placenta (heparin, for example, does not because of its large molecular size), most do ([Fig. 12.8](#)).

**Figure 12.8** A woman needs to think twice before taking an over-the-counter medicine during pregnancy to be certain it will be safe for both herself and her fetus.

To help ensure the safety of drugs during pregnancy, the [U.S. Food and Drug Administration \(FDA, n.d.\)](#) rates drugs according to five categories in relation to pregnancy ([Table 12.1](#)). Always look for a drug’s listed category before administering it to a pregnant woman to be certain it will be safe to administer. In addition, two principles always govern drug intake during pregnancy:

- Any drug or herbal supplement, under certain circumstances, may be detrimental to fetal welfare. Therefore, during pregnancy, women should not take any drug or supplement not specifically prescribed or approved by their obstetric provider.
- A woman of childbearing age should not take any drug other than one prescribed by a obstetric provider to avoid exposure to a drug should she become pregnant.

**TABLE 12.1 FDA PREGNANCY RISK CATEGORIES OF DRUGS**

Category	Description	Example
A	No risk to fetus. Studies have not shown risk of fetal harm.	Thyroid hormone (Synthroid)
B	No risk in animal studies. Well-controlled studies in pregnant women are not available. It is assumed there is little to no risk in pregnant women.	Insulin aspart (NovoLog)
C	Animal studies indicate risk to the fetus. Controlled studies on pregnant women are not available. Risk versus benefit of the drug must be determined.	Docusate sodium (Colace)
D	Risk to the human fetus has been proven. Risk versus benefit of the drug must be determined. Could be used in lifesaving situations.	Lithium citrate (Lithobid)
X	Risk to the human fetus has been proven. Risk outweighs	Thalidomide

the benefit so the drug should be avoided during pregnancy. (Immunoprin)

From U.S. Food and Drug Administration. (n.d.). *FDA pregnancy categories*. Washington, DC: Author.

The classic example of a drug that can cause harm in pregnancy is thalidomide (Immunoprin), which was once liberally prescribed for morning nausea in Europe. Never approved for use in the United States, thalidomide caused amelia or phocomelia (i.e., total or partial absence of extremities) in 100% of instances when taken between the 34th and 45th day of pregnancy. Thalidomide is again available as it is effective as an anticancer drug, specifically for patients with multiple myeloma or hepatic cancer, so women still need to be cautioned about its detrimental fetal effects (Sherbet, 2015).

Finasteride (Propecia), a drug taken by both men and women to restore hair growth, is an example of a drug that may be readily available in a modern home but which is documented to cause fetal deformities (Varothai & Bergfeld, 2014). Other examples of drugs capable of being teratogenic are shown in Box 12.8.

### BOX 12.8

#### Nursing Care Planning Based on Responsibility for Pharmacology

##### SOME POTENTIALLY OR POSITIVELY TERATOGENIC DRUGS

Category	Example	Drug Use	Teratogenic Effect
Alcohol (ethanol)	Wine, beer, whiskey	Social use	Fetal alcohol spectrum disorder
Analgesics	Acetylsalicylic acid (aspirin) Nonsteroidal anti-inflammatory drugs (NSAIDs)	Minor pain relief	Prolonged pregnancy; maternal bleeding Patent ductus arteriosus
Antineoplastics	Methotrexate (Trexall) Cyclophosphamide (Cytoxan)	Chemotherapy Chemotherapy	Multiple anomalies Multiple anomalies
Androgens	Danazol (Cyclomen)	Endometriosis	Masculinization of female fetus
Anticonvulsants	Phenytoin (Dilantin) Valproic acid (Depakote) Carbamazepine (Tegretol)	Seizures	Fetal hydantoin syndrome Neural tube defects Neural tube defects Possibly fetal anomalies

	Lamotrigine (Lamictal)		
Anticoagulants	Warfarin (Coumadin)	Anticoagulation	Fetal bleeding or anomalies
Antidepressants	Imipramine (Tofranil)	Elevate mood	Cardiovascular anomalies
Antidiabetic agents	Chlorpropamide (Apo-Chlorpropamide)	Lower blood glucose	Neonatal hypoglycemia
Antischizophrenic	Lithium (Lithobid)	Schizophrenia	Polyhydramnios
Antithyroid	Methimazole (Tapazole)	Hypothyroidism	Hypothyroidism in fetus
Antibiotics	Sulfonamides Tetracycline (Apo-Tetra)	Infection Infection	Hyperbilirubinemia in newborn Teeth and bone deformities
Anthelmintics	Lindane (Gammallin)	Eradication of lice	Manufacturer recommends limiting exposure to two dosages
Antivirals	Ribavirin (Rebetol)	Respiratory infection, chronic hepatitis C	Multiple anomalies
Angiotensin-converting enzyme inhibitors	Enalapril (Vasotec); captopril (Capoten)	Reduce hypertension	Oligohydramnios (reduced amount of amniotic fluid)
Caffeine	Coffee, soft drinks, chocolate	Social use	Low birth weight
Hypoglycemics	Tolbutamide (Orinase)	Type 2 diabetes	Profound hypoglycemia in newborn
Nicotine	Tobacco	Relaxation	Growth restriction
Radiopharmaceuticals	Iodide-131 (Hicon)	Diagnostic studies	May destroy thyroid of fetus
Narcotics	Cocaine Heroin	Social pleasure	Dysmorphic and central nervous system (CNS) anomalies Growth restriction;

			narcotic abstinence in newborn
Tranquilizers	Diazepam (Valium)	Reduce anxiety	Growth restriction; CNS dysfunction, hypotonia, respiratory depression
Vaccines (live)	Rubella (ProQuad)	Provide immunity	Possible infection in fetus
Vitamin A derivatives	Acitretin (Soriatane)	Psoriasis	Craniofacial, cardiac, CNS anomalies

Source: Briggs, G. G., Freeman, R. K., Towers, C. V., et al. (2017). *Drugs in pregnancy and lactation* (11th ed.). Philadelphia, PA: Wolters Kluwer.

Almost all recreational drugs put a fetus at risk in two ways: The drug may have a direct teratogenic effect and, if taken intravenously, the drug increases the mother's risk of exposure to diseases such as HIV and hepatitis B and C ([Kamarulzaman & Altice, 2015](#)).

Narcotics such as meperidine (Demerol) and heroin have long been implicated as having serious impacts on intrauterine growth. The use of marijuana alone apparently does not, although the accompanying lifestyle may lead to fetal growth restriction and preterm birth ([Roth, Satran, & Smith, 2015](#)).

Cocaine, particularly in crack form, is potentially harmful to a fetus because it causes severe vasoconstriction in the mother, thus compromising placental blood flow and perhaps dislodging the placenta. Its use is associated with spontaneous miscarriage, preterm labor, meconium staining, and intrauterine growth restriction ([Fletcher & Russo, 2015](#)). Whether cocaine causes long-term effects in the infant remains controversial ([Forray & Foster, 2015](#)). See [Chapter 22](#) for more information on the potential hazards of cocaine or heroin use during pregnancy.

An area of recreational drug use rising in incidence is that of inhalant abuse ("huffing"). Substances frequently used as inhalants include gasoline, butane lighter fluid, Freon, glue, and nitrous oxide ([NIOSH, 2010](#)). Although the teratogenic properties of these inhalants are not well studied, they all carry the possibility of a respiratory distress effect on the mother, which could limit the oxygen supply to a fetus. They are used most often by adolescents as they are easy to obtain on a limited budget.

## Herbs

Herbs are not regulated by the FDA in the same way as medications; therefore, they are not rated with regard to their safety in pregnancy. Even though most are safe, American ginseng, used to improve general well-being, has been associated with birth defects; and St. John's wort, an herb taken as a mood enhancer, can interfere with the action of seizure-control drugs, such as phenytoin (Dilantin) and phenobarbital (Phenobarb), and so should be avoided by women prescribed such drugs ([National Center for](#)

[Complementary and Alternative Medicine \[NCCAM\], 2010](#)).

Green tea, a common breakfast drink, was thought to interfere with the absorption of folic acid, but this has not been confirmed in further studies. As folic acid is needed in pregnancy to help prevent birth defects, women could avoid it in pregnancy or when hoping to soon become pregnant ([Gormack, Peek, Derraik, 2015](#)). As with medicine, women should not take herbs in pregnancy until they discuss the herbs' safety with their obstetric provider.

### **Teratogenicity of Alcohol**

Evidence confirms that when women consume a large quantity of alcohol during pregnancy, their babies demonstrate a high incidence of characteristic congenital craniofacial deformities including short palpebral fissures, a thin upper lip, an upturned nose, as well as cognitive impairment **fetal alcohol spectrum** ([Charness, Riley, & Sowell, 2016](#)). Fetuses cannot remove the breakdown products of alcohol from their body. The large buildup of these leads to vitamin B deficiency and accompanying neurologic damage.

Because of individual variations in metabolism, it is impossible to define a safe level of alcohol consumption. Women, therefore, should be screened for alcohol use at a first prenatal visit and are best advised to abstain from alcohol completely for the remainder of their pregnancy. Be certain to ask about binge drinking (e.g., consuming more than four alcoholic drinks in an evening with the intention of becoming intoxicated) because women may refer to this as only "occasional drinking." If necessary, refer women with alcohol addiction to an alcohol treatment program as early in pregnancy as possible to help them reduce their alcohol intake.

### **Teratogenicity of Tobacco**

Cigarette smoking is associated with infertility in women. If used by a pregnant woman, it has been shown to cause fetal growth restriction. In addition, a fetus may be at greater risk for being stillborn and, after birth, may be at a greater risk than others for sudden infant death syndrome ([Mohlman & Levy, 2016](#)).

Low birth weights in infants of smoking mothers result from vasoconstriction of the uterine vessels, an effect of nicotine. This limits the blood supply to a fetus. Another contributory effect may be related to inhaled carbon monoxide. Secondary smoke, or inhaling the smoke of another person's cigarettes, may be as harmful as actually smoking because of inhaled carbon monoxide. All prenatal healthcare settings should be smoke-free environments for this reason.

If a woman cannot stop smoking during pregnancy (and, realistically, many women cannot), reducing the number of cigarettes smoked per day should help diminish adverse effects on a fetus as well as also protect a woman's own health from long-term illnesses, such as chronic respiratory diseases, in the future.

The best way to urge women to discontinue smoking is to educate them about the

risks to themselves and their fetus at the first prenatal visit and then offer a support program to help them throughout the pregnancy. It may be effective to encourage women to sign a contract with their healthcare provider to try to stop or to join a smoking-cessation program. Be certain pregnant women know it would be best if they didn't enter a stop-smoking program that uses drug therapy such as nicotine patches until it is clear if such patches are not harmful to a fetus (Coleman, Chamberlain, Davey, et al., 2015). Box 12.9 shows an interprofessional care map illustrating both nursing and team planning to address decreasing alcohol and tobacco use during pregnancy.

## BOX 12.9

### Nursing Care Planning

#### AN INTERPROFESSIONAL CARE MAP FOR A PREGNANT WOMAN WITH THREATS TO FETAL HEALTH

Julberry Adams, a single, 30-year-old woman, is 4 months pregnant when you first see her in a prenatal clinic. She works as a curator for an art gallery but has missed work this past week because of nausea. She's worried she will not be able to work past 6 months of her pregnancy because her job involves a great deal of walking. She has already stopped her volunteer work teaching children's swimming at the YMCA. She wants to travel to see her sister in St. Louis because her sister is very ill but has heard pregnant women should not drive more than 100 miles. She asks you if marijuana would help reduce her early pregnancy nausea.

**Family Assessment:** Patient lives by herself in one-bedroom apartment. Rates finances as "Good, unless I have to quit work because of pregnancy." She asks you, "Will I have to have an ultrasound? I'm worried about that."

**Patient Assessment:** Gravida 1, para 0. Unsure of date of last menstrual period, but it was about 11 weeks ago. Uterine height barely above symphysis. Fetal heart rate at 148 beats/min by Doppler. History of frequent sinus headaches. "I use Sudafed (pseudoephedrine) at least three to four times a week; sometimes other things." Smokes one-half pack of cigarettes "some days." Drinks two to three glasses of wine per week at art gallery functions. Denies history of marijuana or other recreational drug use.

**Nursing Diagnosis:** Risk for fetal injury related to knowledge deficit concerning possible fetal exposure to teratogens

**Outcome Criteria:** Patient reports a decrease in smoking to less than 10 cigarettes per day and no alcohol consumption by next prenatal visit; verbalizes no use of recreational drugs, including marijuana.

Patient states she has contacted healthcare provider about whether she should continue to use sinus medications.

Team Member Responsible	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Assess what activities patient wants to participate in during pregnancy.	Discuss with the patient her desired activities and any modification necessary for pregnancy.	Finding a match between desired activities and necessary modifications will help with adherence.	Patient discusses what activities she intends to continue during pregnancy and ways to modify them as necessary.
Nurse/obstetric provider	Assess patient's work and travel plans.	Assure patient she can continue to work and can travel to visit her sister.	Reassurance helps patient maintain usual lifestyle.	Patient states she will continue work and maintain contact with sister.
<i>Teamwork and Collaboration</i>				
Nurse/obstetric provider	Assess what medications patient is currently taking.	Consult with healthcare provider about safety of over-the-counter (OTC) sinus medications.	Not all OTC medications are safe during pregnancy.	Patient states she will follow recommendations of obstetric provider regarding medications.
<i>Procedures/Medications for Quality Improvement</i>				
Nurse/obstetric provider	Anticipate the need for follow-up ultrasound examination to date pregnancy.	Explain the need for ultrasound exam to assess dating and possible fetal growth restriction because of alcohol and cigarette smoking habits.	Teratogen exposure may have slowed fetal growth, which will be revealed by ultrasound exam. Date of last menstrual period is unknown.	Patient states she understands the purpose of the ultrasound exam and will allow exam to be scheduled.
<i>Nutrition</i>				
Nurse/nutritionist	Assess patient's	Suggest patient replace alcohol	Alcohol consumption	Patient voices intent to replace

lifestyle to identify beverages she could substitute for alcohol, measures she could use for nausea.	consumption with caffeine-free beverages. Suggest measures to combat nausea and vomiting, such as dry crackers or acupuncture band.	during pregnancy is associated with fetal alcohol spectrum disorder. Decreasing nausea to increase food intake aids fetal growth and development.	alcohol consumption with caffeine-free beverages. Patient suggests measures that appeal to her to reduce nausea and vomiting.
--	---	---	---

---

*Patient-Centered Care*

Nurse/obstetric provider	Assess whether patient has tried any nonmedicinal measures to relieve sinus headaches.	Discuss with patient possible nonmedicinal measures to assist with sinus headache relief, such as saline nasal sprays, humidification, and warm compresses to nasal area.	Complementary comfort measures may provide symptomatic relief without danger to the fetus.	Patient describes two complementary therapies she will try to relieve sinus congestion.
--------------------------	--	---	--	---

---

*Psychosocial/Spiritual/Emotional Needs*

Nurse/social worker	Discuss with patient whether her current support system is adequate.	Help patient locate at least one person she can depend on if a pregnancy emergency should arise.	Pregnancy can be a very stressful time for a woman who lacks a secure support system.	Patient telephones or e-mails the healthcare facility with questions rather than relying on nonexperienced friends for information; names one reliable support person.
---------------------	--	--	---	--

---

*Informatics for Seamless Healthcare Planning*

---

Nurse	Assess extent of cigarette smoking.	Encourage the patient to decrease smoking and quit if possible. Offer suggestions to accomplish this goal, including use of sugar-free gums or candies, distraction, and activity. Refer to a smoking-cessation group if appropriate.	Cigarette use during pregnancy can lead to fetal growth restriction. Support and suggestions provide concrete measures to assist patient with cutting down and quitting.	Patient voices intention to decrease smoking and, if possible, quit smoking during pregnancy.
-------	-------------------------------------	---	--	---

## Environmental Teratogens

Teratogens such as impure air or water can be as damaging to a fetus as those that are directly or deliberately ingested. Women are exposed to these through contact at home or at work sites. Breathing air filled with pollutants, for example, has been shown to lead to fetal growth restriction (Forde, Dewailly, Robertson, et al., 2014).

## Metal and Chemical Hazards

Pesticides and carbon monoxide, such as from automobile exhaust, should be avoided as these are examples of chemical teratogens. Arsenic, a byproduct of copper and lead smelting, used in pesticides, paints, and leather processing; formaldehyde, used in paper manufacturing; and mercury, used in the manufacture of electrical apparatuses and found in high proportions in swordfish and tuna, are all teratogens that can be found at work sites.

Lead poisoning generally is considered a problem of young children who eat lead-based paint chips, but it can be a fetal hazard as well. Women may ingest lead by drinking water that travels through old pipes that are leaking lead, by “sniffing” lead-based gasoline, or eating paint chips (paint tastes sweet and may be eaten as a symptom of pica). Lead ingestion during pregnancy may lead to a newborn who is both cognitively and neurologically challenged (Dórea, 2015).

## Radiation

Rapidly growing cells are extremely vulnerable to destruction by radiation. This makes radiation a potent teratogen to unborn children because they have such a high proportion of rapidly growing cells. Radiation produces a range of malformations depending on the stage of development of the embryo or fetus and the strength and length of exposure. If

the exposure occurs before implantation, for example, the growing zygote apparently is killed. If the zygote is not killed, it survives apparently unharmed. The most damaging time for exposure and subsequent damage is from implantation to 6 weeks after conception (a time when many women are not yet aware they are pregnant). The nervous system, brain, and the retinal innervation are growing rapidly at this time and so are most affected (CDC, 2014).

Even with this danger of radiation, X-rays to maternal parts other than the pelvis, including computerized tomography (CT) can be performed safely during pregnancy as long as a lead pelvic shield is provided (Nelson-Piercy, 2012). If a woman of childbearing age requires a pelvic X-ray for any reason, this should be scheduled during the first 10 days of a menstrual cycle (when pregnancy is unlikely because ovulation has not yet occurred); during pregnancy, X-rays of the pelvis should be avoided except in emergency situations. Even fluoroscopy, which uses lower radiation doses than regular X-ray photography, should also be avoided during pregnancy—again, except in an emergency. A serum pregnancy test to rule out pregnancy can be completed on women who have reason to believe they might be pregnant before diagnostic tests involving X-rays are scheduled.

X-rays should be taken at term only if the data obtained are vitally important for birth and cannot be obtained by any other means. Sonography and magnetic resonance imaging can be used for confirmation of situations such as a multiple pregnancy because these do not appear to be teratogenic (Siauve, Chalouhi, Deloison, et al., 2015). Although still being investigated, long-term use of slight radiation sources, such as a computer, microwave oven, or cellular phone, also do not appear to be teratogenic (Shah & Farrow, 2014).

In addition to immediate fetal damage, evidence demonstrates that radiation can have long-lasting effects on the health of a child. There appears to be an increased risk of cancer in children who are exposed to radiation in utero. Exposure of the fetal gonads could lead to a genetic mutation that will not be evident until the next generation (Brent, 2015).

### **Hyperthermia and Hypothermia**

Hyperthermia to a fetus can be detrimental to growth because it interferes with cell metabolism. This can occur from the use of saunas, hot tubs, or tanning beds; from a work environment next to a furnace, such as in welding or steel making; or from a high maternal fever early in pregnancy (4 to 6 weeks). For this reason, advise pregnant women not to use hot tubs, saunas, or tanning beds during pregnancy.

The effect of hypothermia on pregnancy is not well known. Because the uterus is an internal organ, a woman's body temperature would have to be lowered significantly before a great deal of fetal temperature change would result.

### **Teratogenic Maternal Stress**

There is some evidence that a pregnancy filled with anxiety and worry beyond the usual amount could produce physiologic changes through their effects on the sympathetic division of the autonomic nervous system. The primary change this would cause includes constriction of the peripheral blood vessels (i.e., a fight-or-flight syndrome). If the anxiety is prolonged, the constriction of uterine vessels (the uterus is a peripheral organ) could substantially interfere with the blood and nutrient supply to a fetus (Latendresse, Wong, Dyer, et al., 2015).

It is important to remember these phenomena are characteristic only of long-term, extreme stress, not the normal anxiety of pregnancy. Personal tragedies such as a house fire, illness or death of one's partner, difficulty with relatives, marital discord, living in a war zone, and illness or death of another child are examples of stressful situations that might provoke this excessive level of anxiety.

It's not easy to help a woman resolve complex problems of this type during pregnancy because they are complicated. To prevent maternal stress from becoming severe, advise counseling for women with low stress levels at prenatal care visits before the levels become extreme.

### Infections That Cause Illness at Birth

A number of infections are not teratogenic to a fetus during pregnancy but are harmful if they are present at the time of birth. Gonorrhea, candidiasis, chlamydia, streptococcus B, and hepatitis B infections are examples of these. Chapters 45 and 47 discuss the effects of these infections on maternal, fetal, and neonatal health.

#### QSEN Checkpoint Question 12.6

##### SAFETY

Julberry Adams makes the following statements. Which one would the nurse rate as the safest practice?

- “My brother takes medicine for heartburn; if I think of it, I’ll borrow his.”
- “I’m going to get a measles shot; I don’t want measles while I’m pregnant.”
- “There are so many medicines for headache; I’ll ask my doctor what to take.”
- “I know all over-the-counter medicine is safe; that’s why it’s over the counter.”

Look in [Appendix A](#) for the best answer and rationale.

### Preparation for Labor

At about the midpoint of pregnancy, along with cautioning women about new minor body changes and possible teratogenic threats, it is a good time to review the signs or symptoms that signal the beginning of labor so women will not be surprised by these happenings or dismiss them as something other than the important events that they are. These are discussed in the following sections and summarized in [Table 12.2](#).

**TABLE 12.2 BEGINNING SIGNS AND SYMPTOMS OF LABOR**

Sign or Symptom	Cause
Lightening	Sinking of the fetal head into the true pelvis
Slight loss of weight	As progesterone level falls, more fluid is excreted, slightly lowering body weight
Excess energy	Burst of adrenaline to provide energy for labor
Backache	Beginning but unrecognized uterine contractions
Ripening of the cervix	Prostaglandins soften the cervix to allow for shortening and dilatation
Rupture of membranes	Membranes have ruptured with release of amniotic fluid
Show	Internal cervical mucus plug has been released
Uterine contractions	True beginning of labor

## PRELIMINARY SIGNS OF LABOR

In the days or hours before labor begins, a woman often experiences subtle signs or symptoms that signal labor is imminent. Because these signs and symptoms are subtle, they are easily missed if a woman is not informed of them in advance.

### Lightening

In primiparas, *lightening*, or descent of the fetal presenting part (usually the fetal head) into the pelvis, occurs approximately 10 to 14 days before labor begins. This fetal descent changes a woman's abdominal contour because it positions the uterus lower and more anterior in the abdomen. Lightening gives a woman relief from the diaphragmatic pressure and shortness of breath she has been experiencing and in this way "lightens" her load. Lightening probably occurs early in primiparas this way because of tight abdominal muscles. In multiparas, it is not as dramatic and usually occurs on the day of labor or even after labor has begun. As the fetus sinks lower into the pelvis, a woman may experience shooting leg pains from the increased pressure on a sciatic nerve, increased amounts of vaginal discharge, and urinary frequency from pressure on her bladder.

### Increase in Energy

A woman may awaken on the morning of labor full of energy, in contrast to the feeling of chronic fatigue that she has been feeling for the previous month. This increase in activity is related to a boost in epinephrine release, which is initiated by a decrease in progesterone production by the placenta. This additional epinephrine prepares a

woman's body for the work of labor ahead. It's important that the woman recognizes this sensation for what it is or she may use this burst of energy to clean her house or finish paperwork at the office and exhaust herself before labor begins. If she can recognize this symptom as an initial sign of labor, she can conserve her energy in preparation for labor.

### **Slight Loss of Weight**

As progesterone level falls, body fluid is more easily excreted from the body. This increase in urine production can lead to a weight loss between 1 and 3 lb.

### **Backache**

Because labor contractions begin in the back, an intermittent backache stronger than usual may be the first symptom a woman notices.

### **Braxton Hicks Contractions**

In the last week or days before labor begins, a woman usually notices extremely strong Braxton Hicks contractions. A woman having her first child may have such difficulty distinguishing between these and true contractions that she may come to the labor unit of a hospital or birthing center believing she is in labor. It is discouraging for a woman when this happens (strong Braxton Hicks contractions cause true discomfort) to be told she is not in true labor and should return home. When this happens, you can assure the woman that misinterpreting labor signals is common. Remind her that if contractions have become strong enough to be mistaken for true labor, true labor is not far away.

### **Ripening of the Cervix**

Ripening of the cervix is an internal sign seen only on pelvic examination. Throughout pregnancy, the cervix feels softer than usual to palpation, similar to the consistency of an earlobe (Goodell's sign). At term, the cervix becomes still softer (described as "butter soft"), and it tips forward. Cervical ripening this way is an internal announcement that labor is very close at hand.

## **SIGNS OF TRUE LABOR**

Signs of true labor involve both uterine and cervical changes. The contrast between true and false labor is summarized in [Chapter 15, Table 15.3](#).

### **Uterine Contractions**

True labor contractions usually begin in the back and sweep forward across the abdomen similar to the tightening of a rubber band. They gradually increase in frequency and intensity over a period of hours. Because contractions are involuntary and come without warning, their intensity can be frightening in early labor. Helping a

woman appreciate that she can predict when her next one will occur and therefore can control the degree of discomfort she feels by using breathing exercises offers her a sense of control.

Advise a woman to telephone her primary care provider when contractions begin to alert healthcare personnel that she is in labor. Her healthcare provider will advise her as to what point in labor she should come to the healthcare facility she has chosen or when to begin preparations for home birth if that is her choice. The typical time for this is when contractions are 5 minutes apart, but this will vary depending on a woman's past and present pregnancy history. In all instances, if a woman should become exceptionally anxious, be home alone, or have a long drive, she should be given options as to when it would be best for her to leave home.

### Show

As the cervix softens and ripens, the mucus plug that filled the cervical canal during pregnancy is expelled. The exposed cervical capillaries seep blood as a result of pressure exerted by the fetus. This blood, mixed with mucus, takes on a pink tinge and is referred to as "show" or "bloody show." Women need to be aware of this event so they do not think they are bleeding abnormally.

### Rupture of the Membranes

Labor may begin with rupture of the membranes, experienced either as a sudden gush or as a scanty, slow seeping of clear fluid from the vagina. Some women may worry if their labor begins with a rupture of the membranes because they have heard labor will then be "dry," and this will cause it to be difficult and long. Actually, amniotic fluid continues to be produced until delivery of the membranes after the birth of their child, so no labor is ever "dry." Early rupture of the membranes can actually be advantageous as it can cause the fetal head to settle snugly into the pelvis, aiding cervical dilation and shortening labor.

A woman should telephone her obstetric provider immediately when her membranes rupture as two risks are associated with ruptured membranes: intrauterine infection and prolapse of the umbilical cord (which could cut off the oxygen supply to the fetus) (Maher & Heavey, 2015). In most instances, the fetal head is already snugly fitting the cervix, so prolapse is not a concern. If labor does not spontaneously begin by 24 hours after membrane rupture and the pregnancy is at term, labor will likely be induced to help reduce the risk of infection.

#### *What If... 12.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals with respect to fetal and maternal health (see Box 12.1). What would be a possible research topic to explore pertinent to this goal that would**

**be applicable to Julberry or her family and that would also advance evidence-based practice?**

## **KEY POINTS FOR REVIEW**

- Prenatal education is an important part of prenatal care. The more women know about measures they should take during pregnancy to safeguard their health, the more likely they will be to avoid substances or activities harmful to fetal growth.
- Urge women to find the best way for them to modify their individual lifestyle for pregnancy as this helps in planning nursing care that not only meets QSEN competencies but also best meets the family's total needs. Remember, pregnancy is 9 months long, so modifications must be agreeable to the woman or she will not maintain them over such a long time.
- Women need to make provisions for rest periods during their day and to be aware of any potential teratogens at a work site, such as exposure to radiation or heavy metals.
- Women who travel should plan for break periods to avoid congestion in their lower extremities. Seat belts should be used when traveling by car. On an airplane, a woman may need to ask for an extension seat belt.
- Common minor body changes of early pregnancy include breast tenderness, constipation, palmar erythema, nausea and vomiting, fatigue, muscle cramps, pain from varicosities or hemorrhoids, heart palpitations, frequency of urination, and leukorrhea. If women know these symptoms may occur, they will not interpret them as complications but usual events.
- Minor body changes of middle or late pregnancy include backache, dyspnea, ankle edema, Braxton Hicks contractions, sleep disturbance, restless leg syndrome, and carpal tunnel syndrome. Caution women that contractions could be a sign of labor.
- Women should take active measures to avoid exposure to infectious diseases such as rubella, HIV, hepatitis B and C, cytomegalovirus, HSV, syphilis, and toxoplasmosis during pregnancy.
- Counsel pregnant women about the necessity to avoid the use of any drug or herbal supplement not specifically approved by their obstetric provider as well as alcohol and tobacco.
- It is almost impossible for a woman to modify a behavior, such as smoking, if her support person does not agree to change also. Including a woman's family in care is an important way to help support persons understand the need for the modification and increasing cooperation.
- Beginning signs of labor for which a pregnant woman should be alert include lightening, show, excess energy, rupture of membranes, and uterine contractions.

## **CRITICAL THINKING CARE STUDY**

Emma Hennigan is a 34-year-old woman who is 3 months pregnant with her second

pregnancy. She has a 2-year-old son at home. She tells you this pregnancy has not “been fun” because it is so different from her first pregnancy. She has had nausea, fatigue, and frequent urination 24/7 for the last 3 months. She wants to quit her job as a short-order cook so she can feel better, but her boyfriend won’t let her “even consider this” as they need the money. The only thing she does all week to feel “like her old self” or to make the pregnancy “bearable” is to jog around a neighborhood park two times a day.

1. Emma wants to quit work so she feels better. Would you recommend she do this?
2. Emma needs to use a restroom often at work because she has the symptom of frequent urination. This is difficult, however, because this involves a long walk and time away from cooking. She asks if drinking less fluid will help relieve this symptom. How would you advise her?
3. Emma has two breaks during the day during which she jogs—the only activity that is making her pregnancy “bearable.” Would you encourage her to continue doing this for the remainder of her pregnancy?

## The Nursing Role in Promoting Nutritional Health During Pregnancy

*Tori Alarino, 19 years old, is 4 months pregnant. She works at a fast-food restaurant and eats breakfast and lunch at the restaurant. Her partner, Alessa, works four evenings a week, so Tori cooks for herself on those evenings. She dislikes milk, so she drinks milkshakes as a source of calcium. She is concerned because she has already gained 23 lb. She craves oranges, eating six to eight of them a day. She tells you, “I thought pregnant women always craved pickles and ice cream. What’s wrong with me?”*

*Previous chapters described reproductive normal anatomy and physiology, the changes associated with pregnancy, and common discomforts and danger signs of pregnancy. This chapter adds information about prenatal nutrition, an important aspect to help ensure a healthy outcome for both a woman and her child.*

**What nutritional counseling does Tori need?**

### KEY TERMS

**bariatric surgery**

**body mass index**

**complete protein**

**Hawthorne effect**

**hypercholesterolemia**

**hyperplasia**

**hypertrophy**

**incomplete protein**

**lactase**

**obese**

**overweight**

**pica**

**pyrosis**

**underweight**

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Discuss recommendations for healthy nutrition during pregnancy.
2. Identify 2020 National Health Goals related to pregnancy nutrition that nurses can help the nation achieve.
3. Assess a woman for nutritional adequacy during pregnancy.
4. Formulate nursing diagnoses related to nutritional concerns during pregnancy.
5. Develop expected outcomes to assist a pregnant woman to achieve optimal nutrition during pregnancy as well as manage seamless transitions across differing healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care that encourages healthy nutritional practices during pregnancy.
8. Evaluate outcomes for achievement and effectiveness of nursing care to be certain expected outcomes have been achieved.
9. Integrate knowledge of nutrition and pregnancy with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

Although adequate nutrition during pregnancy cannot guarantee a good pregnancy outcome, it does make an important contribution because both the nutritional state a woman brings into pregnancy and her nutrition during pregnancy have a direct bearing on her health and on fetal growth and development. A poor diet, such as one deficient in folic acid before and during pregnancy, for example, is associated with fetal growth restriction or birth anomalies such as neural tube defects ([Atta, Fiest, Frolkis, et al., 2016](#)).

Good nutrition during pregnancy is recognized as so important that the subject is addressed in 2020 National Health Goals ([Box 13.1](#)).

### BOX 13.1

#### Nursing Care Planning Based on 2020 National Health Goals

A number of 2020 National Health Goals speak to nutrition in pregnancy. These include:

- Reduce iron deficiency among pregnant women from a baseline of 16.1% to 14.5%.

- Increase the proportion of women of childbearing potential with intake of at least 400 µg of folic acid from fortified foods or dietary supplements from a baseline of 23.8% to a target of 26.2%.
- Increase the proportion of women who achieve a recommended weight gain during their pregnancies (developmental) (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these goals by stressing the importance of balanced nutrition for all people so women enter pregnancy with adequate nutritional stores, especially of folic acid. They can help pregnant women plan ways to ingest adequate iron daily and to remember to take their prenatal vitamin (which contains an iron and folic acid supplement) daily.

### *Nursing Process Overview*

## FOR PROMOTING NUTRITIONAL HEALTH DURING PREGNANCY

### ASSESSMENT

An assessment begins with a woman's preconception nutrition patterns. From this assessment, determine whether a patient is eating healthy food sources and healthy proportions of food (Fig. 13.1). Also, evaluate any cultural, environmental, or social lifestyles that could affect eating habits. A 24-hour recall history followed by a physical examination to document weight and vitality are the best ways to secure necessary information, confirm well-balanced nutrition, and identify areas for teaching and learning.

**Figure 13.1** Note that the word protein is substituted for meat; vegetables occupy the largest portion on the plate. (From U.S.

Department of Agriculture. [2012]. *Choose my plate: A guide to daily food choices*. Washington, DC: Author.)

## **NURSING DIAGNOSIS**

Nursing diagnoses related to the nutritional status of a pregnant woman consider the desired health and growth of both the fetus and the woman. A woman who is eating large amounts of nutritionally inferior food and a woman who has difficulty eating because of fatigue or nausea may both be at risk for the same problem: fetal growth restriction. Being sensitive to a woman's concern about maintaining her own appearance can help her keep a healthy perspective about "eating for two" and the need to gain sufficient weight. Examples of nursing diagnoses include:

- Imbalanced nutrition, less than body requirements, related to increased physiologic needs
- Imbalanced nutrition, less than body requirements, related to nausea every morning
- Health-seeking behaviors related to determining best food choices in pregnancy
- Imbalanced nutrition, more than body requirements, related to overeating or poor food choices
- Deficient knowledge related to need for increased intake of nutrients and calories during pregnancy

## **OUTCOME IDENTIFICATION AND PLANNING**

In large health centers, nutritionists are available to meet with women prenatally and help them plan nutrition during pregnancy. In other settings, a nutritionist may be available only for women with special needs, so the responsibility for nutrition advice falls directly on nurses. When helping a woman set expected outcomes for improving her nutrition, be certain to consider all the cultural and lifestyle factors that give different meanings to food. Because food is an expensive commodity, consider financial resources as well. Teaching about long-term outcomes such as building iron stores or bone mass is as important as short-term goals, such as to eat better for a week. Eating more nutritious foods for a week will probably not lead to a radical change. However, continuing a healthy eating pattern throughout the pregnancy (and maintaining it throughout life) will bring about important changes and help prepare a woman for feeding her family nutritionally for the years to come. Refer to helpful websites and other resources when appropriate (see [Chapter 9](#)).

## **IMPLEMENTATION**

As anyone who has ever tried to change a nutritional pattern knows, this can be a lonely and seemingly unrewarding endeavor as results occur slowly. Begin by emphasizing the physiologic basis for nutritional needs in pregnancy (a woman is building a whole new person). Based on this, explain what nutritional deficits you have identified and then show the woman how to change her nutritional pattern to improve this situation.

Pregnant women are usually highly motivated to adopt healthy behaviors for the sake of their baby's health; although they still need support and encouragement because this can involve a major life change, such as eating a different lunch than everyone around them is eating, getting up 15 minutes earlier to prepare breakfast rather than just dashing to work with only coffee, or resisting having a soft drink with dinner and drinking a calcium-fortified drink, like almond milk, instead.

Asking women to list what foods they eat daily and to bring in a chart to show you at a prenatal visit is an effective motivating technique. In research studies, this is called a **Hawthorne effect**, or a positive change in behavior that occurs because of the attention received. Because of this effect, the average woman will eat better than she usually does so her list of food looks better when she presents it. As soon as she realizes these better eating patterns are making her feel better, she will hopefully continue them indefinitely.

### **OUTCOME EVALUATION**

When evaluating whether a woman's nutritional pattern has been improved, rely on the most important assessments: weight, energy level, general appearance, bowel function, hydration status, and, when available, hemoglobin and urinalysis findings. Urge women to be honest about whether they are actually following a nutrition plan. If they are not, it probably means the plan did not fit their lifestyle or degree of motivation. Examples of outcomes that would demonstrate improved nutrition include:

- Patient demonstrates weekly menus that include three main meals and two snacks per day.
- By next prenatal visit, patient demonstrates knowledge of meat and nonmeat sources of protein by providing menus of meals eaten in the last week that include fish, eggs, beans, or peanut butter.
- Patient verbalizes correct information about calcium needs during pregnancy.
- Patient states she is able to make up later in the day meals missed because of nausea.
- Patient's food lists for 1 week include three sources of calcium per day.
- Patient describes pattern she is using to drink at least eight glasses of fluid daily.

## **Relationship of Maternal Nutrition and Fetal Health**

During pregnancy, a woman must eat adequately to not only support her own nutrition but also to supply enough nutrients so the fetus can grow. Adequate protein and calcium intake is vital because so much of these are needed by the fetus to build a strong body framework. Adequate protein may also help prevent complications of pregnancy such as gestational hypertension or preterm birth. Either deficiencies or overuse of vitamins may contribute to poor intrauterine growth (Johnston, Sharma, & Abe, 2016).

Therefore, a pregnant woman should be counseled to consult her primary care provider

prior to taking any new vitamin or herbal supplement aside from her prescribed prenatal vitamin.

Early in pregnancy, fetal growth occurs largely by an increase in the number of cells formed (**hyperplasia**); late in pregnancy, it occurs mainly by enlargement of existing cells (**hypertrophy**). This means a fetus deprived of adequate nutrition early in pregnancy could be small for gestational age because of an inadequate number of cells formed in the body. Later on, although the number of cells may be normal, restricted growth can occur because cells cannot grow to their full potential. To ensure early pregnancy deficiencies do not occur, encourage women of childbearing age to follow a healthy nutrition plan before pregnancy (preconception care) that specifically supplies adequate folic acid (400 µg/day) (Fletcher & Russo, 2015). Otherwise, in the time before a woman recognizes she is pregnant (about 6 weeks), her poor diet and lack of important nutrient stores could already have seriously impaired fetal growth (Atta et al., 2016).

Pregnancy provides opportune nutrition “teaching moments” as a woman finds herself suddenly more interested in her weight and well-being than usual (C. L. Martin, Siega-Riz, Sotres-Alvarez, et al., 2016). Always comment on the things a woman is doing correctly rather than what she is doing wrong. Positive reinforcement, a basic rule of teaching, enhances learning, self-esteem, and compliance more than criticism. Remember, women will have some degree of nutritional “backsliding” on holidays and special events. To help prevent this, a woman needs to make definite, concrete plans for what foods to avoid as well as how to substitute healthy foods for them.

Be careful when nutrition counseling not to make general statements such as “Eat high-protein foods.” Food in the supermarket, after all, is not labeled “high protein”; it’s labeled meat, cheese, and so forth. Based on this, provide advice whenever possible in more specific terms such as “Eat three servings of some type of protein, like meat, eggs, fish, beans or nuts, every day.” An effective counseling session should also include teaching the patient how to read a food label and adequately measure serving size.

The word “diet” has come to mean a form of unpleasant food denial for most women. Rather than talk about a “pregnancy diet,” therefore, talk about “foods that are best for you during pregnancy” or “pregnancy nutrition.” These terms not only sound more positive but also refer more closely to what you are encouraging a woman to do: Eat healthy meals.

Giving a woman a clearly written list of suggested foods may be a help to some women. Be certain a list of that type is short, clear, and specific. Complicated lists of foods or a list of don’ts tend to be overwhelming and, therefore, ignored.

## **RECOMMENDED WEIGHT GAIN DURING PREGNANCY**

One of the things women begin to wonder about when they first realize they are pregnant is how much weight they will gain during pregnancy. As a rule, the average woman should gain 11.3 to 15.8 kg (25 to 35 lb) during pregnancy. To predict individual weight gain, first calculate a woman’s **body mass index** (BMI) or the ratio of

body fat to weight and height. This can be done most easily by visiting a websites such as the one run by the National Heart, Lung and Blood Institute ([www.nhlbi.nih.gov/health/educational/lose\\_wt/BMI/bmicalc.htm](http://www.nhlbi.nih.gov/health/educational/lose_wt/BMI/bmicalc.htm)). A BMI calculator for children and teenagers can be found at [www.apps.nccd.cdc.gov/dnpabmi/calculator.aspx](http://www.apps.nccd.cdc.gov/dnpabmi/calculator.aspx).

Women whose weight falls into the normal BMI category (18.5 to 24.9) should aim to gain 25 to 35 lb; **underweight** women or those whose BMI is less than 18.5 should gain 28 to 40 lb; **overweight** women (a BMI over 25 to 29.9) should gain 15 to 25 lb; and **obese** women (a BMI over 30) should gain 11 to 20 lb ([Institute of Medicine \[IOM\] & National Research Council, 2009](#)).

Weight gain in pregnancy occurs from both fetal growth and an accumulation of maternal stores ([Box 13.2](#)) and increases by approximately 0.8 kg (1.5 lb) per month during the first trimester and then 0.4 kg (1 lb) per week during the last two trimesters (a trimester minimum weight gain of 4.5 lb, 12 lb, and 12 lb, respectively). Although this may seem to be a lot of weight gain, women can be assured most of the weight gained with pregnancy is easily lost afterward.

- To ensure adequate fetal nutrition, advise women not to diet to lose weight during pregnancy.
- A woman who reaches the midpoint of pregnancy and has gained less than 10 lb needs to have her daily nutrition intake reevaluated as low weight gain is associated with fetal growth restriction.
- Even obese women need to gain a minimum of 0.5 lb per week or 11 to 15 lb total to help ensure adequate fetal growth.
- Weight gain will be higher for a multiple pregnancy than for a single pregnancy ([Table 13.1](#)). You can encourage women who are pregnant with multiple fetuses to gain at least 1 lb per week for a total of 37 to 54 lb.
- Sudden increases in weight suggest fluid retention or polyhydramnios (excessive amniotic fluid); a loss of weight suggests illness and should also be carefully evaluated at prenatal visits.

**TABLE 13.1 TOTAL WEIGHT GAIN DURING PREGNANCY, BY PREPREGNANCY BODY MASS INDEX (BMI)**

Prepregnancy BMI	BMI+ (kg/m <sup>2</sup> ) (WHO)	Total Weight Gain Range (lb) Single Fetus	Total Weight Gain Range (lb) Multiple Fetuses <sup>a</sup>
Underweight	<18.5	28–40	
Normal weight	18.5–24.9	25–35	37–54
Overweight	25.0–29.9	15–25	31–50
Obese (includes all classes)	≥30.0	11–20	25–42

WHO, World Health Organization.

<sup>a</sup>Weight gain recommendations for multiple fetuses are provisional.

Institute of Medicine & National Research Council. (2009). *Weight gain during pregnancy: Reexamining the guidelines*. Washington, DC: The National Academies Press.

## BOX 13.2

### Nursing Care Planning Using Assessment

#### ASSESSING MATERNAL WEIGHT GAIN

### The Woman Who Is Underweight

A woman who enters a pregnancy underweight needs nutritional counseling just as much as an overweight woman. Underweight is defined as a state in which a woman's weight is 10% to 15% less than the ideal weight for her height, or a BMI of less than 18.5. Most women who are underweight tire easily because they have an accompanying

iron-deficiency anemia. Even when underweight women gain more weight than usual during a pregnancy, they still tend to have a higher than usual incidence of low-birth-weight infants and preterm birth (Akahoshi, Arima, Miura, et al., 2016). This is one reason why preconception healthcare visits and assessments are so important.

Women may be underweight for a variety of reasons, including:

- Dieting for weight loss
- Inability to buy adequate food while impoverished (however, many low-income women are obese rather than underweight because starchy foods are less expensive than those with a higher protein content, such as meat and eggs)
- Excessive worry or stress, which can lead to a loss of appetite
- Depression, which can cause a chronic loss of appetite
- An eating disorder, such as anorexia nervosa or bulimia, in which a woman has developed an unhealthy relationship with food (Kimmel, Ferguson, Zerwas, et al., 2016) (see Chapter 54)

The primary reason women are underweight, however, is insufficient intake of food because of chronic, poor nutritional habits.

Convincing women who are underweight to eat more may be difficult because you are asking women to change lifelong eating habits. Counseling also can be challenging because you are asking her to take in additional food during the first trimester of pregnancy when fetal need is greatest and a woman has nausea and vomiting.

Begin counseling by asking a woman for a 24-hour nutrition recall. Total daily caloric intake for the underweight woman may need to be as high as 3,200 calories (500 to 1,000 calories more than the usual specified daily amount). Work with women to develop menus based on well-planned meals rather than on quick take-out foods. Suggest additional calories in the form of a concentrated formula such as an instant liquid breakfast drink. Be certain a woman understands that this should not be a high-protein drink used for high-protein dieting regimens. High-protein diets of this nature are not recommended for long-term use by anyone, but they should be completely avoided by women during pregnancy.

A 500-calorie increase over normal requirements should result in a weight gain of an additional pound per week. Be certain to plan for this additional gain when the total weight gain during pregnancy is calculated at each office visit. Otherwise, the total weight gain of a woman may seem excessive when it is actually healthy.

If a lack of nutritional stores makes a woman feel tired, urge her to schedule adequate rest periods daily so she can feel sufficiently energetic to prepare nutritious meals. Be certain she is taking her prescribed vitamin and iron supplements. Additional nutritional counseling during the postpartum period may be necessary so she can maintain better nutrition throughout her life and enter a subsequent pregnancy (if she desires one) in a state of nutritional health.

## **The Woman Who Is Overweight**

A woman is considered overweight if she is 20% above ideal weight or has a BMI over

25. She is considered obese if she is 50% above ideal body weight for height, or her BMI is above 30. As many as 60% of women in the United States are overweight; 35% are obese ([Centers for Disease Control and Prevention \[CDC\], 2016](#)). Less-educated women and those living in poverty tend to be more overweight than others. Obesity during pregnancy is serious because it is associated with an increased incidence of gestational diabetes and gestational hypertension ([Simhan, 2016](#)).

Although obesity may occur from hypothyroidism, it most often occurs as a result of excessive caloric intake and decreased energy expenditure. It becomes a problem during pregnancy because:

- Pregnancy causes circulatory volume to increase by 20% to 50% and metabolism to increase to meet the demands of the pregnancy, placing additional stress on a possibly already overworked body.
- It is often difficult to hear fetal heart tones in an obese woman; palpating for position and size of a fetus at birth is also difficult.
- Obese women are at increased risk for giving birth to infants with macrosomia (excessive fetal growth); this increases the incidence of cesarean births in this population ([Declercq, MacDorman, Osterman, et al., 2015](#)).
- Performing a cesarean birth, if necessary, may be difficult because of the excessive adipose tissue that must be incised to reach the uterus.
- The pregnancies of obese women are more apt to be prolonged, leading to postmature infants.
- Ambulating during pregnancy and immediately afterward is more difficult because of the increased energy expenditure necessary, increasing the risk of complications such as thrombophlebitis and pneumonia.
- Many overweight women are hypertensive when they enter pregnancy and develop severe gestational hypertension ([Stang & Huffman, 2016](#)).

Most obesity is caused by overeating, but the habit of overeating has many causes. For some women, overeating is a habit learned in childhood when they were told “clean their plate”; for others, it is a coping mechanism for stress. Because pregnancy can be stressful, it may be a particularly difficult time for a woman to change her food intake pattern. If a woman has been serving her family, as well as herself, an excessive amount of calories, then the entire family may have to change their eating pattern to bring about a change in a woman’s intake. The children of obese women also tend to be obese probably because of excessive food served to them combined with the lack of physical exercise ([Saltzman, Pineros-Leano, Liechty, et al., 2016](#)).

Dieting to reduce weight is not recommended during pregnancy. If carbohydrates are reduced too much, the body will use protein and fat for energy, thus depriving the fetus of protein for growth ([Bodnar, Siminerio, Himes, 2016](#)), which can also lead to ketoacidosis. Although the long-term effects of mild ketoacidosis on a fetus are not well studied, it can be avoided if the daily caloric intake, even in the most obese woman, does not go below 1,500 to 1,800 per day.

Overweight women tend to exercise less than women of normal weight. Try to

encourage all pregnant women, including overweight or obese women, to engage in an exercise program, such as walking, in conjunction with dietary changes.

Helping a woman look at her nutrition in terms of empty calorie versus nutritious foods may help her to eat less fatty and more protein-rich foods. Early in pregnancy, when she is eager to appear pregnant, may be the most difficult time to limit intake. Stress that a fetus grows best on nutritious foods, not necessarily those with the most calories. Provide additional nutritional counseling in the postpartum period so she can prepare more nutritious meals in the future for herself and her growing family. If successful, she will not enter another pregnancy severely overweight.

### **The Woman Who Is Morbidly Obese**

When a woman weighs over 300 lb or has a BMI over 40, she is classified as morbidly obese. During a pregnancy, she presents with a series of special care problems because she is even more prone to complications of pregnancy, such as:

- Gestational or type 2 diabetes
- Hypertension
- Back pain
- Thrombophlebitis or thromboembolism (she may be prescribed support hose to aid lower leg circulation)
- Difficulty sleeping or sleep apnea (which may make her feel tired over and above normal pregnancy fatigue)
- Difficulty hearing fetal heart sounds and palpating for fetal position
- Difficulty exercising
- Prolonged pregnancy with a high rate of cesarean birth ([Renes, Barka, Gyurkovits, et al., 2017](#))

Children born of an obese mother may develop obesity, diabetes, and cardiovascular diseases later in life at a higher proportion than average weight women ([Barbour, 2014](#)).

At a prenatal visit, morbidly obese women may need special care equipment furnished for them such as a wider examining table, a larger examining gown, a wider wheelchair, and longer straps for fetal monitoring equipment than usual. Be discreet when arranging for this type of equipment for a woman as she may be sensitive to her appearance and weight.

Although women with morbid obesity generally eat larger amounts of food, take a nutrition history to be assured their larger intake includes protein-rich, not empty-calorie, foods.

## **COMPONENTS OF HEALTHY NUTRITION FOR THE PREGNANT WOMAN**

The old saying that a pregnant woman must “eat for two” is not as much a myth as it is a truism. It does not mean, however, a woman should eat enough for two adults, just enough to provide nutrients for herself and a growing fetus. To do this, many women

will not have to increase by much the quantity of food they eat, but they will have to increase the quality.

A good way to feel assured a woman is eating the right kinds of foods during pregnancy is to compare the foods she eats to the U.S. Department of Agriculture (USDA, 2012) food guidelines (see Fig. 13.1).

Common suggestions for a healthy intake are shown in Box 13.3. When discussing nutrition and portion size using a representative plate, remember to refer to servings of food rather than milligrams or percentages because this is how a woman will measure the amount she plans to eat.

### BOX 13.3

#### Nursing Care Planning to Empower a Family

##### Healthy Eating Begins With Building a Healthy Plate of Food

- Fill half of your plate with fruits and vegetables.
- Switch to skim or 1% milk.
- Make at least half of your grains whole grains.
- Vary your protein food choices so you include lean sources.

##### Cut Back on Foods High in Solid Fats, Added Sugars, and Salt

- Read food labels and eliminate foods high in sodium.
- Try to eliminate foods high in solid (saturated) fat.

##### Eat the Right Amount of Calories for You

- Enjoy your food but eat less.
- Cook more often at home, where you are in control of what's in your food.
- When eating out, choose lower calorie menu options.

##### Model Good Nutrition

- Provide healthy snacks as well as healthy meals.
- Remember that you are your children's most important role model.
- Don't just tell children to eat their vegetables—show them that you eat and enjoy vegetables every day.

## Energy (Calorie) Needs

The average recommended daily allowance (RDA) of calories for women of childbearing age is 2,200. An additional 300 calories, or a total caloric intake of 2,500 calories, is recommended to meet the increased needs of pregnancy (Whitney & Rolfes, 2016). In addition to supplying energy for a fetus, this increase provides calories to sustain an elevated metabolic rate in the mother because of increased thyroid function and her increased workload from the extra weight she carries. If a woman should begin restricting her carbohydrate intake so her calorie intake is below this in order to avoid gaining weight, her body will begin to break down protein to supply energy, depriving a fetus of essential protein, and possibly resulting in ketoacidosis, a possible cause of fetal growth restriction and newborn neurologic disorders.

Advise women to obtain their carbohydrate calories from complex carbohydrates (cereals and grains) rather than simple carbohydrates (sugar and sweets) because complex carbohydrates are more slowly digested. Doing so will help regulate glucose and insulin levels more consistently. Do not recommend sugar substitutes for women during pregnancy because a pregnant woman needs sugar to maintain glucose levels. Even obese women should never consume fewer than 1,500 calories per day (Whitney & Rolfes, 2016).

When helping a woman plan an increased caloric intake, consider her lifestyle. For example, many women commonly skip meals, have erratic eating patterns, or rely on fast and convenience foods. During pregnancy, in addition to carbohydrate calories, a woman needs protein calories furnished by eating foods rich not only in protein but also in fat, iron, and other essential nutrients. Suggest preparing snacks such as carrot sticks or cheese and crackers early in the day, when fatigue is usually less, and keeping them readily available in the refrigerator. Otherwise, later in the day when she is tired, a woman may snack on empty-calorie foods such as pretzels and doughnuts simply because they require no preparation.

Measuring fundal height at prenatal visits is an indirect way to assess if a woman's nutrition intake is adequate. The easiest method for determining if a woman's caloric intake is adequate is assessing if she is gaining weight. Keep in mind a woman's weight gain pattern is as important as the total weight gain. Even if a woman has surpassed her target weight before the end of the third trimester, encourage her not to restrict her caloric intake. She should continue to gain weight because a fetus grows rapidly during these final weeks.

## Protein Needs

The RDA for protein in women is 34 to 46 g. During pregnancy, the need for protein increases to 71 g daily. If protein needs are met, overall nutritional needs are likely to be met as well (with the possible exceptions of vitamins A, C, and D) because of the high incorporation of other nutrients with protein foods. If protein intake is inadequate, iron, B vitamins, calcium, and phosphorus also will probably be inadequate. Vitamin B<sub>12</sub> is found almost exclusively in animal protein, so if animal protein is excluded from the diet, vitamin B<sub>12</sub> deficiency can occur unless this is supplemented. This is why it is important to ascertain whether your patient follows a vegetarian or vegan diet during your initial assessment. Such a diet may lead to serious vitamin deficiencies that can affect both the mother and fetus unless supplements are added.

Meat, poultry, fish, yogurt, eggs, and milk best supply extra protein because the protein in these forms contains all nine essential amino acids required (**complete proteins**). The protein in nonanimal sources does not contain all essential amino acids (and so is an **incomplete protein** source). It is possible to provide all amino acids by combining nonanimal or incomplete proteins. Proteins that when cooked together provide all essential amino acids are termed *complementary proteins*. Examples are

beans and rice, legumes and rice, or beans and wheat.

A woman with a family history of high cholesterol levels (**hypercholesterolemia**) probably should not eat more than two or three eggs per week. She also should monitor her intake of red meat because of the high cholesterol content. Encourage such women to eat lean meat, to cook with olive oil instead of lard or butter, and to remove the skin from poultry to reduce its fat content. She also should not eat lunch meats such as bologna or salami as food staples because their protein content may not be high, their fat content is invariably exceptionally high, and they may be a source of *Listeria*, a bacteria harmful to fetal growth (Pfaff & Tillett, 2016).

Milk is another rich source of protein. Unfortunately, some women resist drinking it because it can be high in calories and fat. Others cannot drink it because of lactose intolerance. Women who are lactose intolerant can add a lactase supplement to milk (which predigests milk and makes it possible for them to drink it without discomfort) or substitute soy milk (Sethi, Tyagi, & Anurag, 2016). Nonfat milk supplies the same amount of protein as regular milk with half the calories of regular milk and so can be recommended. Buttermilk, although it contains a large amount of sodium, can also be substituted for milk; chocolate or another flavoring can be added to make milk palatable. Yogurt, cheese, cream soup, custards, and egnogs are yet other good substitutes for milk.

### ***QSEN Checkpoint Question 13.1***

#### **TEAMWORK & COLLABORATION**

Tori Alarino has a BMI of 25 and is considered to be slightly overweight. The interprofessional team should recommend what range of weight gain during her pregnancy?

- a. 10 to 12 lb
- b. 15 to 25 lb
- c. 30 to 35 lb
- d. 40 to 60 lb

*Look in Appendix A for the best answer and rationale.*

### **Fat Needs**

Omega-3 fatty acids, particularly linoleic acid, are fats that are essential for new cell growth but that cannot be manufactured by the body. Vegetable oils such as safflower, corn, olive, peanut, and cottonseed; fatty fish; omega-3–infused eggs; and omega-3–infused spreads are all good sources (Lauritzen, Brambilla, Mazzocchi, et al., 2016). Pregnant women should ingest 200 and 300 mg of omega-3 fatty acids daily. An added advantage of using vegetable oils rather than animal-based oils (butter) is that they have low cholesterol contents. For this reason, they are recommended for all adults as a means of preventing hypercholesterolemia and coronary heart disease. Because some

fish may be contaminated by mercury, alert women that the American Pregnancy Association (APA) recommends that marlin, orange roughy, tilefish, swordfish, shark, king mackerel, and bigeye and yellowfin tuna should be avoided during pregnancy. For information regarding other types of fish, the Natural Resources Defense Council has a list of fish and their mercury levels all women can assess to be informed on what they are consuming (APA, 2016).

## Vitamin Needs

The intake of vitamins as a daily dietary supplement has become common place. Many women will already be taking a woman’s multivitamin, or, if they were intending pregnancy, a prenatal vitamin (Box 13.4). Although the requirements for both fat- and water-soluble vitamins increase during pregnancy to support the growth of new fetal cells, there is new evidence that supplementation with a multivitamin does not improve maternal or fetal outcomes. The best way for a woman to help ensure she and her baby have necessary nutrients is by consuming a well-balanced diet. Folic acid is the only vitamin recommended for daily supplementation as the evidence is clear that adequate folic acid helps prevent neural tube defects (World Health Organization [WHO], 2016). Vitamin requirements are discussed in greater detail in Table 13.2.

**TABLE 13.2 VITAMIN NEEDS FOR THE PREGNANT WOMAN**

Vitamin	Essential Functions	Signs of Deficiency	Relevant Foods and Supplementation	Recommended Amounts	Evidence
Vitamin D	Aids calcium absorption, formation of bones/teeth, and immune function	Low birth weight, increased rates of preeclampsia	Fortified milk, eggs, salmon	No standard, suggested 600 IU daily	Not recommended to increase maternal perinatal outcomes. WHO recommends for a beneficial effect on soluble
Vitamin A	New cell growth, healthy skin, oral health, vision	Tender gums or tongues, cracks in skin around mouth, poor night vision	Dark green and yellow vegetables and fruits, liver, milk, butter, cheese, eggs	In areas where vitamin A deficiency is a severe public health problem: 10,000 IU daily or 25,000 IU	Not recommended to increase maternal perinatal outcomes. WHO recommends impr

				weekly	conc over solul
Vitamin C	Antioxidant, collagen formation	Scurvy, easy bruising, swollen and bleeding gums	Fresh vegetables and fruit	Suggested 85 mg daily	No ber with supp with not reco to in mate perin outc WHI
Folic acid	Red blood cell formation, prevents neural tube defects	Megaloblastic anemia, fetal neural tube defects	Fresh vegetables and fruit	400 µg daily	Clear e bene reco daily supp

## BOX 13.4

### Nursing Care Planning Based on Responsibility for Pharmacology

#### PRENATAL VITAMINS (MATERNA)

**Action:** A vitamin and mineral combination used to treat or prevent a lack of vitamins or minerals before, during, and after pregnancy and during breastfeeding. The folic acid content helps prevent megaloblastic anemia in the mother and neural tube defects in the fetus.

**Ingredients:** Selected ingredients are vitamin A (1,000 International Units), vitamin D (400 Units), vitamin E (30 International Units), vitamin C (85 mg), vitamin B<sub>1</sub> (1.4 mg), vitamin B<sub>2</sub> (1.4 mg), vitamin B<sub>6</sub> (1.9 mg), vitamin B<sub>12</sub> (2.6 mcg), niacin (18 mg), folic acid (1 mg), pantothenic acid (6 mg), calcium (250 mg), iron (27 mg), copper (1 mg), zinc (7.5 mg), and magnesium (50 mg) ([Wyeth Ayerst](#)

Pharmaceuticals, 2012).

**Dosage:** One tablet daily prior to conception, during pregnancy, and when breastfeeding

**Possible Side Effects:** Nausea, bloating

**Possible Adverse Effects:** Folic acid may mask the signs of pernicious anemia.

### Nursing Implications

- A woman should start taking a prenatal multivitamin at least 10 weeks prior to conception (when she is trying to conceive or planning a pregnancy). She should continue to take this until she stops breastfeeding.
- Tablets are best taken with a meal to help the tablet disintegrate and to maximize nutrient absorption as well as to minimize the potential for gastrointestinal upset among women sensitive to iron.
- If a woman has difficulty swallowing a tablet, she can crush it and mix the crushed tablet in a liquid such as milk or fruit juice.
- Materna can be purchased without a prescription so women can begin taking the medication preconception or before they have made a prenatal healthcare visit.
- Encourage women to take the medication exactly as prescribed; caution women not to exceed the recommended dosage.
- Assist with ways to remind women to take the medication, such as a note on the refrigerator.
- Advise women to keep prenatal vitamins, like all medications, out of the reach of small children to prevent accidental poisoning from the high folate level.

## Mineral Needs

Minerals are necessary for building new cells in a fetus. Because they are found in so many foods and because mineral absorption appears to improve during pregnancy, mineral deficiency, with the exception of iron, is rare. Mineral requirements are discussed in [Table 13.3](#).

**TABLE 13.3 MINERAL NEEDS FOR THE PREGNANT WOMAN**

Essential Mineral	Essential Functions	Relevant Foods and Supplementation	Recommended Amounts	Evidence-Based Evaluation
Calcium	Calcification of fetal bones (as early as 8 weeks)	Milk, cheese, yogurt, leafy greens, almonds	Adolescents—1,300 mg, Adults—1,000 mg	In populations with low dietary intake, supplementation is recommended; reduces risk of preeclampsia

Iodine	Thyroid gland function	Iodized salt, seafood, cranberries	Suggested 250 µg daily where iodized salt use is less than 20%	Strong evidence that populations without iodized salt need supplementation
Iron	Fetal cell development, physiologic anemia of pregnancy	Organ meats, eggs, leafy greens, whole grains, enriched breads, dried fruit	30–60 mg elemental iron daily	Strong evidence supplementation reduces maternal anemia, puerperal sepsis, low birth weight, and preterm birth
Fluoride	Tooth development	Fluoridated water	Supplements only warranted in areas without fluorinated water	Lack of evidence suggesting routine supplementation
Zinc	Immune health	Oysters, red meat, poultry, beans, nuts, whole grains, dairy products	Supplementation only in context of research	Not standard recommended by WHO given lack of evidence

Micronutrient deficiencies in pregnancy worldwide: Health effects and prevention. *Nature Reviews Endocrinology*, 12, 274–289; World Health Organization. (2016). *WHO recommendations on antenatal care for a positive pregnancy experience*. Geneva, Switzerland: Author.

### What If... 13.1

**Tori Alarino insists drinking milkshakes is a good source of calcium. How would the nurse advise her?**

## Fiber Needs

Constipation can occur during pregnancy because bowel peristalsis slows due to the effect of progesterone and pressure of the uterus on the intestine. Eating fiber-rich foods (i.e., foods consisting of parts of the plant cell wall resistant to normal digestive enzymes such as fruit, broccoli, and asparagus) is a natural way to prevent constipation because the bulk of the fiber left in the intestine aids evacuation. Fiber also has the advantage of lowering cholesterol levels and may remove carcinogenic contaminants from the intestine. Eating fiber-rich foods this way is a better choice for preventing

constipation than taking a fiber laxative as it allows a woman to receive nutrients from the food as well as prevents constipation (Kee, Hayes, & McCuistion, 2015).

## Fluid Needs

Extra amounts of water are needed during pregnancy to promote kidney function because a woman must excrete waste products for two. Eight glasses of fluid daily (e.g., two glasses of fluid over and above a daily quart of milk) is a common recommendation.

### *QSEN Checkpoint Question 13.2*

#### **INFORMATICS**

The nurse helps Tori evaluate some claims on a website aimed at pregnant women. The nurse identifies which statement from the website as most accurate?

- “It’s best to take your iron pills with milk.”
- “If you prefer, you can crush your iron pills to disguise the taste.”
- “Iron pills are most effective if taken with a carbonated beverage.”
- “Orange juice is an acceptable beverage to take with your iron pills.”

*Look in Appendix A for the best answer and rationale.*

## **FOODS TO AVOID OR LIMIT IN PREGNANCY**

Foods to avoid during pregnancy include those that are known to be teratogenic and, because a woman’s immunologic resistance is lowered, those that may spread bacteria, such as:

- Raw eggs and undercooked chicken (danger of salmonella)
- Soft unpasteurized cheese (can harbor *Listeria* bacteria)
- Raw milk
- Raw seafood and sushi (can harbor hepatitis A virus)
- Cold cuts (deli meats should be heated until steaming to kill any bacteria)
- Alcoholic beverages (known to cause fetal alcohol spectrum disorder)
- Saccharin (has a long half-life and so can reach toxic levels in a fetus)
- Fish with high mercury content such as mackerel and swordfish
- Weight loss diets or supplements (women need additional nutrients, not less in pregnancy)
- Caffeine (excessive amounts may be a cause of miscarriage, although research is still ongoing)

## **Foods With Caffeine**

Caffeine is thought of by many women as an incidental ingredient in beverages. However, it is a central nervous system stimulant capable of increasing heart rate, urine production in the kidneys, and secretion of acid in the stomach.

A daily intake of over three cups of coffee per day may interfere with fertility (Sharma, Biedenharn, Fedor, et al., 2013). Caffeine has also been associated with an increased risk of miscarriage (Sharma et al., 2013).

Women who want to limit their caffeine intake need to limit not only the amount of coffee they drink but also other sources of caffeine such as chocolate, soft drinks, energy drinks, and tea. If a woman has difficulty omitting these common foods from her diet, she can still reduce the amount of caffeine she ingests by modifying food preparation. For example, instant coffee has less caffeine than brewed coffee. Decaffeinated coffee, as the name implies, contains almost no caffeine.

Tea, like coffee, varies in caffeine content depending on the type and time of brewing, as the longer tea brews, the greater the caffeine content. Both herbal teas that do not contain caffeine and decaffeinated teas are readily available.

Soft drinks do not naturally contain caffeine, an addictive substance; it is added to soft drinks by their manufacturer to increase product sales. To limit the amount of caffeine consumed, encourage pregnant women to choose from the many caffeine-free types available or, better, to drink water, which will help them stay hydrated without extra empty calories or caffeine.

### *What If . . . 13.2*

**Tori Alarino states, “I love coffee. There’s always a pot brewing where I work, and everyone drinks it on morning breaks.” What suggestions could the nurse make to help Tori reduce her caffeine intake?**

## **Artificial Sweeteners**

Artificial sweeteners are used to improve the taste and to limit the caloric content of foods. It is probably safest for pregnant women to reduce their intake of these because they need the glucose of regular sugar to help supply daily energy. Many nonnutritive sweeteners are approved by the U.S. Food and Drug Administration (FDA) as safe for pregnancy, including sucralose (Splenda), aspartame (NutraSweet), acesulfame-K (Ace K), neotame, stevia, and advantame, but large amounts of these sweeteners should probably be avoided until safety in pregnancy is thoroughly confirmed. The use of saccharin is not recommended during pregnancy because it is eliminated so slowly from the fetal bloodstream that it could rise to toxic amounts (Araújo, Martel, & Keating, 2014).

## **Weight Loss Diets**

As a rule, measures to protect against excessive weight gain during pregnancy are wise because excessive weight gain is difficult for women to lose after pregnancy and is part of the reason for the present obesity epidemic (Luke, Kirby, & Wright, 2016). In contrast, weight reduction is not wise. Liquid diets and/or diets that are combined with

weight-reducing drugs are particularly contraindicated because they may lead to fetal ketoacidosis and poor growth. If women have been following such diets before becoming pregnant, they may enter pregnancy with so few nutritional stores that additional vitamin and mineral supplementation may be necessary.

### **QSEN Checkpoint Question 13.3**

#### **EVIDENCE-BASED PRACTICE**

Gaining too much weight in pregnancy can lead to complications in the mother such as gestational diabetes; in addition, the fetus can gain excess weight with possible long-term weight problems. To see how much weight gain women perceived they needed in pregnancy, nurse researchers surveyed 54 women who were less than 20 weeks pregnant. Results of the questionnaire showed 39% of the women were overweight or obese before pregnancy. Daily caloric intake ranged from 599 to 5,856 calories. Women in all racial/ethnic groups were taking in less than recommended amounts of protein, carbohydrates, calcium, iron, folate, and fiber. Central American Hispanic women were the group who perceived they needed to gain the most weight for a healthy pregnancy; Caribbean black women, as a group, perceived they needed to gain the least weight (Brooten, Youngblut, Golembeski, et al., 2012).

This study demonstrated the average woman was taking in less nutrients than required during pregnancy. How should the nurse best advise Tori about what foods she should eat during pregnancy?

- a. “Protein makes you gain weight too rapidly so keep all your meat portions small.”
- b. “Eat as much as you like all during pregnancy; you can always diet close to term.”
- c. “Make sure that you work plenty of leafy green vegetables into your diet.”
- d. “Iron causes constipation so limit your intake of iron-rich foods any way you can.”

*Look in Appendix A for the best answer and rationale.*

## **Assessing Nutritional Health**

Women who follow good nutrition practices before pregnancy come into pregnancy in better health and are best prepared to avoid pregnancy complications (Cheikh Ismail, Bishop, Pang, et al., 2016). The best method for assessing a woman’s nutritional intake before pregnancy or during pregnancy is to ask a woman to describe a “typical day,” or a 24-hour nutrition recall, to isolate usual patterns and possible nutritional risk factors (Table 13.4). First, ask if yesterday was a typical day. If it was, ask a woman to list all the food she ate within the past 24 hours, starting with when she awakened until she went to sleep. Be certain she includes all snack foods as well as sit-down meals. This method of history taking yields much more accurate information than asking a woman

how often she eats specific foods.

**TABLE 13.4 COMMON NUTRITIONAL RISK FACTORS DURING PREGNANCY**

<b>Risk</b>	<b>Rationale</b>
Adolescent (less than 18 years old)	Adolescents require nutrition for both their own growth and fetal growth.
Short intervals between pregnancies	A woman's body has not had time to replace nutritional stores depleted during a previous pregnancy.
Low income	Family may not have resources to purchase iron-rich foods to meet pregnancy nutritional needs.
Food fads or dieting	Foods eaten may not be those adequate for pregnancy.
Drug use (including cigarettes and alcohol)	Drugs may be ingested in preference to healthy foods as well as cause teratogenic effects.
Existence of a chronic illness requiring a special diet	Intake may be low in an essential substance such as carbohydrates or protein.
Underweight or overweight	Underweight and overweight status may indicate chronic inadequate nutrition.
Multiple pregnancy	A woman must supply enough nutrition for multiple fetal development.
Anemic at conception	A woman has no iron stores for fetal growth.
Lactose intolerance	A woman may not be ingesting adequate calcium for fetal skeletal growth.
Post-bariatric surgery	A woman may not be able to eat large enough portions to meet pregnancy nutritional needs.

In addition to actual food intake, ask if a woman thinks she has any problem with nutrition (such as cravings). Also, assess the circumstances of eating, such as cultural preferences, who prepares food in the family, and how many meals are eaten outside the home weekly, as these are important to form a total nutrition picture (Table 13.5). To strengthen history findings, assess a woman's prepregnancy weight and calculate her BMI. People with poor nutrition are typically overweight or underweight and show typical physical signs. Table 13.6 lists important physical examination assessments that suggest a good nutritional intake or evidence of poor nutrition. After obtaining a full nutritional pattern, compare the types and amounts of food the woman eats with those shown in Figure 13.1 to see if all food groups and adequate amounts are included. Comparing foods from the person's 24-hour recall with a food guide is helpful because it shows patients that what they thought was a "perfect" intake is imperfect, or what they thought was a "little" problem actually involves the loss of an entire food group.

Once a woman sees such a deficit exists, she may be more motivated to improve her nutrition. Such a picture also offers an instant reward for a woman who is including all food groups every day.

**TABLE 13.5 AREAS TO ASSESS FOR A TOTAL NUTRITION HISTORY**

<b>Area of Assessment</b>	<b>Pertinent Questions</b>
Food preparation	Who does the cooking at your house? Do you cook for people besides yourself? How do you usually prepare food (fried or baked)? What spices or condiments do you commonly use? What type of oil do you use for frying (saturated or unsaturated)?
Food pattern	How many meals do you eat on a typical day? Which is your biggest meal? How many snacks do you eat a day? What are they? How many meals do you eat outside your home? Where do you eat them? Cafeteria? Fast-food store? Restaurant? Bagged lunch? Are there any foods you cannot or will not eat? Why?
Financial concerns	Does your family have enough money for food? Who does the food shopping? Would you eat differently if more money were available? Do you use any supplementary financial programs such as the SNAP or WIC programs?
Activity level	Are you normally active or sedentary? (An active lifestyle increases calorie need.)
Lifestyle	Were you dieting before you became pregnant? Were you taking oral contraceptives before pregnancy? Do you take supplemental vitamins? What type? How many? Do you drink alcohol? What type? How much? Do you smoke cigarettes? How many?
Health	Do you have any allergies to food? Do you have any trouble with chewing or digestion? What is your bowel movement frequency? What is your stress level? Does stress affect your appetite? Are you ill in any way, such as with heart disease or inflammatory bowel disease? If you have a secondary illness? Are there foods you cannot eat?
Personal food preferences	Are you always hungry for a particular food? Do you ever eat things that are not food such as ice chips or

	<p>laundry starch?</p> <p>Are there any foods you particularly enjoy or dislike?</p> <p>Are there any foods you feel are harmful or particularly beneficial during pregnancy?</p> <p>Do you have any cultural or religious preferences that influence what you eat?</p>
Family dietary patterns	<p>Is anyone in your family on a special diet?</p> <p>Is anyone obviously overweight or underweight?</p> <p>Does your family eat meals together?</p> <p>Is mealtime a social time?</p>

**TABLE 13.6 PHYSICAL SIGNS AND SYMPTOMS OF ADEQUATE PREGNANCY NUTRITION**

<b>Assessment</b>		
<b>Area</b>	<b>Signs of Good Nutrition</b>	<b>Signs of Poor Nutrition</b>
Hair	Shiny; strong, with good body	Hair dull and lifeless (possible protein deficit)
Eyes	Good eyesight, particularly at night; conjunctiva moist and not pale	Pale and dry conjunctiva (iron and fluid deficit); difficulty with night vision (vitamin A deficit)
Mouth	No cavities in teeth; no swollen or inflamed gum line; no cracks or fissures at corners of mouth; mucous membrane moist and pink; tongue smooth and nontender	Fissures at corners of mouth; tongue rough and tender (vitamin A deficit); mucous membrane pale (iron deficit)
Neck	Normal contour of thyroid gland	Thyroid gland enlarged (iodine deficit)
Skin	Smooth, with normal color and turgor; no ecchymotic or petechial areas present	Rough texture; poor turgor (fluid deficit) Vitamin K deficiency leads to petechia
Extremities	Normal muscle mass and circumference; normal strength and mobility; edema limited to slight ankle involvement; normal reflexes	Poor muscle tone; diminished reflexes (protein deficit)
Fingernails and toenails	Smooth; pink; normal contour	Pale; break easily; little growth (protein deficit)

Weight	Within normal limits of ideal weight before pregnancy; following normal pattern of pregnancy weight gain	Overweight or underweight; unusually slow or rapid weight gain (inadequate or excessive carbohydrate)
Blood pressure	Within normal limits for length of pregnancy	Decreased from anemia (iron deficit); increased from hypertension

## Promoting Nutritional Health During Pregnancy

Be certain plans made for improving nutritional patterns take into account a woman's lifestyle, family preferences, financial resources, customs, and cultural desires because she and her family must follow them for 9 months for them to be successful (Fig. 13.2).

**Figure 13.2** Encourage pregnant women and their partners to eat a varied diet with a high iron and protein content. This may be difficult for a woman early in pregnancy because of nausea and late in pregnancy because of fatigue. (© Barbara Proud.)

### FAMILY CONSIDERATIONS

Meal planning is best if it involves the entire family because even if a woman is receptive to changing her eating habits, she may have difficulty carrying out recommendations if her family resists the change. In families where a member has a special nutritional need, such as restricted sodium, change may be even more difficult. You may need to speak with the person who prepares meals for a pregnant adolescent as

well as the adolescent to be certain recommended changes will be carried out.

## FINANCIAL CONSIDERATIONS

Food is costly, so to provide the extra servings required during pregnancy, a woman must spend more on food for herself per week than she was spending previously. Women generally view this increased expense as an investment in their child's health and do not regard it as a burden. A woman on a marginal income, however, although she understands the importance of this, may have difficulty actually doing it. If this occurs, review what foods the woman is eating to be certain she is not filling her plate with less expensive starchy foods, such as pasta, in preference to higher protein foods such as meat. Help her secure available financial assistance such as from the Supplemental Nutrition Assistance Program (SNAP) or the Women, Infants and Children (WIC) Special Supplemental Food Program if needed.

Since 1939, under the SNAP program, a family with a low income can be issued an Electronic Benefit Transfer (EBT) or debit card that can be used to buy food items. SNAP cards cannot be used to buy hot and prepared food, cigarettes, alcohol, personal care items, paper commodities, pet food, household supplies, or medication. The amount of the debit card varies depending on the needs of the family. In general, a family of four whose monthly income is under \$2,000 can increase their monthly food buying power by as much as \$650 per month (USDA, 2016).

The advantage of this type of supplemental program is to help provide money for food but that places almost no restrictions on what foods, except for those mentioned previously. For a low-income family, it can make the difference between a healthy intake and a low-nutrient one.

WIC is a federal program that provides nutritional support for low-income women and children not only to reduce the risk of low birth weight but also to aid with the cost of newborn nutrition. Established in 1972, WIC is funded by the Food and Nutrition Service of the USDA. The program supplies supplemental foods and nutrition education for:

- Pregnant women
- Postpartum women up to 6 months
- Nursing mothers up to 1 year
- Children from birth to age 5 years

Each state defines the income eligibility level for its citizens, but the eligibility for all programs is based on three criteria: income level, geographic area, and nutritional risk. To receive food, patients must live in an area that has been designated as a funding area. The nurse or nutritionist in the healthcare facility determines possible risk and nutritional need and helps enroll a family in the program. Factors considered that put pregnant women at nutritional risk include age (an adolescent or woman over age 40 years), poor obstetric history such as previous spontaneous miscarriage, a short period between pregnancies, having given birth to a previous low-birth-weight infant, gestational diabetes, anemia, poor weight gain, or inadequate consumption of food by

nutrition history.

For the pregnant woman, foods typically offered by the program include those with high-quality protein, iron, calcium, and vitamins A and C, such as fresh fruits and vegetables, eggs, milk, legumes, whole grain cereals and breads, and canned fish. Vegetarian families or those with allergies can receive tofu and soy-based beverages or foods. At predetermined intervals, WIC patients are reevaluated to see if the program supplements are helpful or still necessary. WIC has been successful at improving nutrition during pregnancy because it not only supplies additional food to recipients but also provides periodic evaluations for nutritional counseling ([Andreyeva & Leudicke, 2015](#)).

The school lunch program is yet another federal program that can furnish some pregnant adolescents with nutritional help. Millions of schoolchildren qualify for free or reduced-price school breakfasts or lunches designed to provide one third of requirements for protein, vitamin A, vitamin C, iron, calcium, and calories. Communities are working hard to replace burgers, fries, and burritos with salads, fresh fruits, simply prepared meats, and whole grain breads in schools. Soft drinks are being replaced with fat-free milk or water.

For many adolescents, this improved menu may represent the most nutritious meal they eat all day. Because there is a selection of food choices that can be made, a pregnant adolescent or one with other special needs may need some individual counseling to allow her to choose foods best for her, not those her friends are eating ([Adams, Bruening, Ohri-Vachaspati, et al., 2016](#)).

## CULTURAL CONSIDERATIONS

When helping plan nutrition during pregnancy, try to suggest foods that are individually or culturally favored, as these are the foods women tend to enjoy most and so will eat most consistently. Common cultural differences to be aware of during nutritional counseling are shown in [Box 13.5](#). Remember when counseling using such a table, not to stereotype women into cultural boxes. “Americanized” women may prepare few foods from their ethnic background because their spouse or significant other is of a contrasting culture with differing preferences.

### BOX 13.5

#### Nursing Care Planning to Respect Cultural Diversity

##### CHARACTERISTICS OF CERTAIN ETHNIC DIETS

Group and Place of Origin	Staple Foods	Common Customs
Hispanic Americans from Puerto Rico	Steamed white rice; many varieties of beans; starchy vegetables, such as cassavas or	Milk is rarely consumed as a beverage. Most foods are cooked for long periods of time or

	yams; salted fish or pork; sugared fruit juices; café con leche (coffee and hot milk)	fried. Malt beer is believed to be nutritious and may be given to children and breastfeeding mothers.
Hispanic Americans from Mexico, Central America	Many varieties of beans; steamed rice; corn products such as tortillas; chili peppers, fresh fruit, potatoes; meat; fish; poultry; eggs; milk cheeses; milk custards and bread puddings	Most vegetables are cooked for a long time so they lose most of their nutritional value. Diet is high in fiber and starch. Animal fat is frequently added during food preparation. Diet may be inadequate in calcium, iron, vitamin A, and vitamin C.
Hispanic Americans from Cuba	Stews and casseroles; soup is served daily; fried foods, especially fish, poultry, and eggs; rice; many varieties of beans	Fruits and vegetables are not eaten on a regular basis. Main meal is usually served at lunch.
Southern African Americans from West Africa	Hominy grits; biscuits; corn bread; rice; legumes; sweet potatoes; okra; green leafy vegetables cooked in salt pork; pork, poultry, and fish; thick stews; bread puddings; pies and sweets	African American food patterns are similar to Caucasians in same region. Northern African Americans may be unfamiliar with “soul food.” Frying is common; diet tends to be high in fat and salt, low in calcium.
Chinese Americans (diets vary sometimes with region)	Rice; wheat noodles; many seasonal cooked vegetables and fruits; various shoots; soybean products such as tofu, soy sauces, and soy milk; small portions of meat, fish, poultry, and seafood	Yin (feminine)–yang (masculine) concept of balancing intake; moderation is valued. Diet is high in fiber and many nutrients, is low in fat, and may be low in protein.

Japanese Americans	Rice; vegetables; tofu, bean paste, and soy sauce; fruits; salads; fish, green tea; milk is rarely used by adults	Foods are broiled, steamed, boiled, and stir fried. Meat portions are small. Diet is low in fat, rich in nutrients, high in sodium.
Vietnamese Americans	Rice, rice noodles; curries of asparagus and potatoes; salads; tropical fruits and vegetables; small portions of poultry; eggs; fish; nuoc mam (a strong, fermented fish sauce)	Rice may be eaten at every meal. Lactose intolerance is common. Little fat is used in preparation. Diet may be low in iron and calcium.
Native Americans	Southeast: corn; cornmeal; coontie (flour from a palmlike plant); fried breads; vegetables; alligator, snake, wild hog, duck, fish, and shellfish; Northeast: many berries, beans; corn; pumpkins; fish, lobster, and wild game; Midwest: bison; beans; corn; fruits and vegetables; Southwest: corn, beans, squash, pumpkins, chili peppers, melons, cactus; Northwest: salmon, other fish, bear, elk, wild fruits, nuts, wild greens.	Food has great religious and social significance. Corn is a status food for most tribes. Milk is seldom used; calcium intake may be low.

### **QSEN Checkpoint Question 13.4**

#### **QUALITY IMPROVEMENT**

A health history document is modified by an interprofessional group. To obtain the most accurate nutrition history from a pregnant patient such as Tori, what should the assessment document specify?

- a. Ask the patient to tell how much protein she eats daily.
- b. Assess whether the patient feels satisfied with her nutrition.
- c. Ask the patient to describe what she ate in the last 24 hours.
- d. Prompt the patient to describe her concept of ideal nutrition.

*Look in Appendix A for the best answer and rationale.*

## MANAGING COMMON PROBLEMS AFFECTING NUTRITIONAL HEALTH

Specific nutrition problems may result from a number of factors or circumstances during pregnancy.

### Nausea and Vomiting

As many as three fourths of pregnant women report nausea and vomiting in early pregnancy (Rogers & Worley, 2016). No definite cause has been established for this symptom of early pregnancy, but it may be related to:

- Sensitivity to the high level of chorionic gonadotropin hormone produced by the trophoblast cells
- High estrogen or progesterone levels
- Lowered maternal blood sugar caused by the needs of the developing embryo
- Lack of pyridoxine (vitamin B<sub>6</sub>)
- Diminished gastric motility

Nausea is aggravated by fatigue and possibly by emotional disturbances. Most women notice the sensation as early as the first missed menstrual period and experience it through the first 3 months of pregnancy. The sensation is usually most intense on rising but may occur from smelling certain foods or while a woman is preparing meals. Vomiting at least once daily is common. Women who work nights and sleep days often experience “evening sickness” because that is the time when they arise.

The traditional solution for preventing nausea is for women to keep dry crackers, such as saltines, by their bedside and eat a few before rising because increasing carbohydrate intake seems to relieve nausea better than any other nutrition remedy. Sucking on sour candies may serve the same purpose. A woman may then eat a light breakfast or delay breakfast until 10 am or 11 am, or past the time her nausea seems to persist. To be certain she maintains good food intake during pregnancy even in the face of nausea, urge her to be certain to compensate for any missed meals later in the day. If preparing food for others makes her feel queasy, she might try to give this responsibility to another family member, at least through the worst phase of this symptom. Preparing and freezing meals ahead of time, perhaps at night when the nausea is less bothersome, may also help.

Other therapy such as acupressure, anti-motion sickness wrist bands, and avoiding fluid with meals are other measures effective for many women. It is a good rule for women not to go longer than 3 to 4 hours between meals during pregnancy to prevent

hypoglycemia. To prevent this from happening, women may need to eat a snack before bedtime to compensate for a late breakfast. Some women are able to tolerate fruit and raw vegetables during the morning before other food. Urge a woman to experiment with soups or vegetable drinks she may not usually think of as breakfast foods but that can give her early-morning calories.

Common measures to take to relieve nausea are summarized in [Box 13.6](#). Caution women against self-medicating for nausea by using a scopolamine patch, a drug used for motion sickness. Although it has not been proven unsafe for pregnancy, it is not intended for long-term use. Also caution against taking excessive amounts of antacids containing sodium bicarbonate as their sodium content could cause fluid retention.

## BOX 13.6

### Nursing Care Planning Based on Family Teaching

#### MEASURES TO REDUCE AND EVALUATE NAUSEA DURING PREGNANCY

**Q.** Tori Alarino tells you, “I’ve been nauseated ever since I became pregnant. What can I do to make this better?”

**A.** Common nonpharmacologic measures you can take to *prevent* nausea include:

- Be aware between 50% and 90% of women experience nausea during pregnancy, so what you are experiencing is absolutely normal.
- Eat a few dry crackers, toast, or a sour ball before you get out of bed in the morning to increase your carbohydrate intake.
- Eat small but frequent meals rather than large infrequent ones.
- Avoid greasy or highly seasoned food.
- Delay breakfast until nausea passes (or dinner if it is evening nausea).
- Make up missed meals at some other time of the day to maintain nutrition.
- Avoid sudden movements and fatigue because these may increase or cause nausea.
- Eat a snack before bedtime so delaying breakfast won’t cause you to go a long time between meals.
- Purchase a wrist acupressure band (purchased in travel stores for motion sickness) or schedule an acupuncture visit.

*If nausea is present:*

- Try sipping a carbonated beverage.
- Try a walk outside in the fresh air or take deep breaths through an open window.

*Notify your healthcare provider if:*

- You vomit more than once daily.
- You are losing weight rather than gaining it.
- You have not gained the projected amount of weight for your week of pregnancy.
- You are unable to make up for lost meals some other time of the day.
- You have signs of dehydration such as little urine output.

- Nausea has lasted past 12 weeks of pregnancy.
- The amount of nausea you are feeling is interfering with what you want to do in a day's time.

About 10% of women have nausea and vomiting that are so acute they need additional measures to feel comfortable and to prevent fluid and nutrient shortages. Pyridoxine HCl (vitamin B<sub>6</sub>) or a combination of pyridoxine HCl plus doxylamine succinate (Unisom) can be prescribed. Dimenhydrinate (Dramamine) is an H<sub>1</sub> receptor antagonist that also can be helpful (O'Donnell, McParlin, Robson, et al., 2016). Fortunately, nausea usually disappears spontaneously as women enter their fourth month of pregnancy. If it persists beyond this month or is so extreme in early pregnancy that it interferes with nutrition, it may indicate the development of hyperemesis gravidarum, a serious complication of pregnancy and a complication for which the woman needs additional therapy (O'Donnell et al., 2016).

## Cravings

Cravings for food or aversions to certain foods during pregnancy are so common they are considered a normal part of adaptation to pregnancy.

When taking a nutrition history, ask if a woman notices any particular cravings. As long as this is a healthy type of food, help her plan an intake that includes the food, at least in moderation, to help her enjoy her pregnancy without feeling guilty.

Some women report a craving for foods such as oranges or chocolate. Others, however, crave a nonfood substance (termed **pica**, from the Latin for magpie, a bird that is an indiscriminate eater). The most common form of pica in the past was a craving for laundry starch. Today, women are more apt to report cravings for clay, dirt, cornstarch, or ice cubes (Miao, Young, & Golden, 2015).

Although some of these items do no harm in themselves, the ingestion of large quantities of nonfood substances can leave a woman deficient in nutrients essential for a healthy pregnancy outcome (Box 13.7).

### BOX 13.7

#### Nursing Care Planning Tips for Effective Communication

Tori comes to your prenatal clinic, and you want to obtain her nutrition history.

*Tip:* Ask specific questions about the patient's individual nutrition intake. Most people believe they eat well and so respond that their nutrition is adequate if asked only general questions. Only when they are asked to describe what they ate during one day is the truth revealed. For example, eating ice cubes may reflect iron-deficiency anemia.

**Nurse:** Hi, Tori. Are you eating a nutritious diet?

**Tori:** I eat everything in sight. No problem.

**Nurse:** Tell me what you ate yesterday.

**Tori:** A muffin and coffee for breakfast, a milkshake for lunch, a hamburger and fries for supper. A soft drink before bed. And ice cubes. I suck on them all day like candy.

**Nurse:** Let's talk about ways you might get some fruit and vegetables into your day.

Always ask women at prenatal visits if they crave any nonfood items, as most women do not supply this information unless asked directly. They worry you will find their behavior odd, or they may not realize their habit is pregnancy related as much as being a nervous habit.

Stopping the woman from eating the nonfood substance may be difficult because the habit may be deeply ingrained. Because pica is a symptom that often accompanies iron-deficiency anemia, suggest that her primary care provider assess her serum iron levels as correcting this underlying problem with an iron supplement may correct the pica. At subsequent visits, be certain to assess if a woman's hemoglobin is increasing and ask if she has noticed any difference in her cravings.

### Diminished Gastric Mobility

As peristalsis slows from the effect of progesterone and the weight of a growing uterus presses against her bowel, constipation occurs in nearly 50% of pregnant women (Rungsiprakam, Laopaiboon, Sangkomkamhang, et al., 2015). Discuss preventive measures with women early in pregnancy to help them avoid this problem. Encourage them to evacuate their bowels regularly (many women neglect this first simple rule); increase the amount of roughage in their diet by eating raw fruits, bran, and vegetables; and drink at least eight 8-oz glasses of water daily.

Some women find that prescribed oral iron supplements contribute to constipation. Because this supplement is necessary to build fetal iron stores, help a woman find a method to relieve or prevent constipation other than omitting taking the supplement.

Women should not use mineral oil to relieve constipation as it can prevent absorption of fat-soluble vitamins A, D, E, and K, vitamins necessary for both good fetal and maternal health. Enemas also should be avoided because their action might initiate labor. Over-the-counter laxatives are also contraindicated, as are all nonessential drugs during pregnancy, unless specifically prescribed or sanctioned by a woman's primary healthcare provider. If dietary measures and attempts at regular bowel evacuation fail, a stool softener such as docusate sodium (Colace) or evacuation suppositories such as glycerin may be helpful.

Some women have extensive flatulence accompanying constipation. Recommend avoiding gas-forming foods, such as cabbage or beans, to help control this problem.

### Pyrosis

**Pyrosis** (heartburn) is a burning sensation along the esophagus caused by regurgitation

of gastric contents into the lower esophagus (Phupong & Hanprasertpong, 2015). In pregnancy, it may accompany early nausea; it may also persist beyond the resolution of nausea and even increase in severity as pregnancy advances.

Pyrosis is probably caused by decreased gastric motility (an effect of progesterone, which slows gastric emptying) as well as the effect of pressure from the expanding uterus pushing up against the stomach. Common suggestions to help prevent reflux into the esophagus and relieve pain are:

- Eat small meals frequently rather than large meals.
- Sleep on the left side with two pillows to elevate the upper torso.
- Do not lie down immediately after eating; try to wait at least 2 hours.
- Avoid fatty and fried foods, coffee, carbonated beverages, tomato products, and citrus juices.

Aluminum hydroxide (Amphojel, pregnancy class N or not classified) or a combination of aluminum and magnesium hydroxide (Maalox, class B) may be prescribed for relief. If these do not relieve the discomfort, an H<sub>2</sub> receptor antagonist such as cimetidine (Tagamet, class B) or ranitidine (Zantac, class B) may be prescribed (Attilakos & Overton, 2012). Be certain a woman understands this “chest” pain is from her gastrointestinal tract and, although it is called heartburn, it has nothing to do with her heart.

## Hypercholesterolemia

Women with a family history of hypercholesterolemia may enter pregnancy with already elevated cholesterol levels. During pregnancy, increasing progesterone levels cause a further elevation. Combined with intrahepatic cholestasis, this can lead to an increased risk for gallstone formation (cholelithiasis) and cardiovascular disease during pregnancy. Preventing cholelithiasis is important because gallstones can cause extremely sharp pain. Fortunately, surgery to remove gallstones during pregnancy is possible with new ambulatory laparotomy techniques.

A woman who has had difficulty with hypercholesterolemia before pregnancy may need to continue to eat only moderate amounts of fat during pregnancy to prevent any increase in cholesterol. Helpful ways to reduce cholesterol include:

- Exercising daily
- Eating oat cereal
- Broiling, grilling, or baking meat rather than frying it
- Using a minimum of salad oils
- Substituting new omega-3 products in place of butter
- Eating fish high in omega-3 oil, such as salmon or trout

Although tuna is also high in omega-3 oil, current recommendations are for pregnant women to limit their intake of tuna, swordfish, and mackerel because of their potentially high mercury content (APA, 2016). Eating raw fish is also not advised because of the danger of parasitic contamination.

Urge women to check with their healthcare provider about the wisdom of continuing

to take cholesterol-lowering drugs (statins such as Lipitor, class X) during pregnancy because these drugs are proven to be teratogenic (Bateman, Hernandez-Diaz, Fischer, et al., 2015). A low-cholesterol diet will automatically be lower in calories than the average diet because oils and fats add many calories. Therefore, be certain women watching their fat intake are taking in enough calories for adequate weight gain during pregnancy. Also make certain a woman includes some oil daily (perhaps as olive oil on a salad) so she has included a source of omega-3 oil in her daily intake.

### **QSEN Checkpoint Question 13.5**

#### **PATIENT-CENTERED CARE**

The nurse identifies which statement by Tori as suggesting she has developed pica?

- a. “I eat the erasers off pencils. It helps relieve my heartburn.”
- b. “I can’t eat a thing before 11 o’clock every morning.”
- c. “I notice I’ve been hungry for lemon cookies lately.”
- d. “I crave oranges; can’t get enough of them every day.”

*Look in Appendix A for the best answer and rationale.*

## **Women With Unique Needs**

A number of lifestyles make it difficult for women to enter pregnancy with sound nutrition stores or to make the healthiest nutrition choices during pregnancy. Such women need careful assessments and counseling during pregnancy to help them modify their lifestyle enough so they can meet nutritional needs.

### **THE ADOLESCENT**

A pregnant adolescent needs a higher caloric intake (2,400 calories per day) than a mature woman to supply energy because of the dual demand of consuming enough food to provide for fetal growth and for her own continuing growth. The nutrients most often lacking from a typical adolescent diet tend to be calcium, iron, folic acid, and total calories. Look for sources of these when analyzing a teenager’s pregnancy intake.

An adolescent who is trying to hide an unintended pregnancy may eat very little to keep her abdomen from growing or eat a lot hoping the overall weight she gains will hide the size of her abdomen. She may have been on a diet before pregnancy and want to continue this to “not get fat.” Because she’s not meeting nutritional needs with any of these eating patterns, she runs a high risk of developing anemia, which can lead to fetal growth restriction and possibly preterm birth (Menon, Ferguson, Thomson, et al., 2016).

In their search for identity, adolescents may avoid foods their parents see as important, such as milk, warm cereal, vegetables, or fruit, and indulge instead in foods such as soft drinks, potato chips, and French fries. If they eat lunch or breakfast at a school cafeteria, finding healthy food choices may be difficult.

To help an adolescent plan nutritional intake for pregnancy, respect her right to

reject traditional foods as long as what she does eat includes sufficient nutrients. A cheese and sausage pizza, a glass of milk, and an apple compose a lunch that provides all basic food groups (meat: sausage; bread: pizza crust; vegetable: tomato sauce; dairy: cheese and milk; fruit: apple). A fish or hamburger taco (fish or hamburger, salsa, sour cream, and taco shell) plus a mango or tangerine provides the same.

Most adolescents snack frequently during the day. Toward the end of pregnancy, when preparing nutritious snacks becomes more difficult because of fatigue, you may notice they list more and more “junk food” when detailing what they eat. Advising them to prepare nutritious snacks such as carrot sticks or cheese bites early each day when they have more energy might be helpful. This way, if they are tired later in the day, eating a nutritious snack will not involve so much effort.

Because adolescents often do not prepare the foods they eat, you may need to speak to a parent or a support person (with permission) who does prepare foods to alter the adolescent’s nutrition pattern. Encourage the food preparer to suggest a number of foods that would fill a deficit and let the adolescent choose from them to provide a sense of control.

Adolescents with eating disorders (bulimia or anorexia nervosa) enter pregnancy with major nutrient deficiencies. It is important to identify these teens at the first pregnancy visit so they can receive close supervision and supplementation of specific nutrients as needed (Kimmel et al., 2016).

## **THE WOMAN OLDER THAN 40 YEARS OF AGE**

Today, many women are older than 40 years by the time they have their first child, and many more are older than 40 years when they have their second or third child (J. A. Martin, Hamilton, Osterman, et al., 2015). The nutritional needs of women in this age group are not well studied, but it is obvious women in this age group should maintain the same careful pregnancy nutrition as younger women. Because women in this age group may have slightly decreased kidney function, they should be certain to maintain a high fluid intake to remove waste products for themselves and for their fetus. They need adequate calcium to prevent bone density loss. Many women at this point in life may also be caring for elderly parents and/or have delayed childbearing to establish a career; this means they may eat whatever they are preparing for elderly parents or depend on packed or fast-food lunches for at least part of their nutrition. Focus your nutrition counseling on maintaining adequate nutrition during pregnancy, based on these changing lifestyles.

## **THE WOMAN WITH A STRESSFUL LIFESTYLE**

A stressful lifestyle can interfere with pregnancy nutrition as such women may simply have too many other stresses in their lives to concentrate on eating healthy meals. Examples of women who have this problem might be a busy executive trying to meet project time lines; one taking care of an ill child, partner, or aging parents; or one who is

homeless or lacking enough money to purchase adequate food. Women who live in a situation with intimate partner violence may not have enough freedom to select what foods they prepare or serve to include all food groups every day. A conscientious assessment of women at first prenatal visits (hopefully at preconception visits) can help identify women in this group and provide the additional support they need to achieve adequate nutrition and a safe pregnancy outcome.

## **THE WOMAN WITH NUTRITIONAL DEFICIENCIES**

### **The Woman With Decreased Nutritional Stores**

A woman with high parity or a short interval between pregnancies or one who has been dieting rigorously to lose weight before pregnancy may enter pregnancy with such depleted nutritional reserves she has little to draw on during the first part of pregnancy. If her folic acid intake has been inadequate, her fetus is susceptible to neural tube defects ([Temel, Erdem, Voorham, et al., 2015](#)). This shortage of nutrients may become critical during the time she is unable to eat well because of the usual nausea and vomiting of pregnancy. Be alert for:

- Women from low-income families, who may enter pregnancy with anemia because they haven't been able to purchase iron-rich foods
- Women who used diuretics for a dieting program, who may be deficient in potassium as this can be removed in urine by some diuretics
- Women who have been taking oral contraceptives, who may have decreased folate stores
- Women who were using intrauterine devices or who have menorrhagia (heavy menstrual flow), who may be deficient in iron from excessive blood loss with menstrual flows
- Women who drink alcohol excessively, who may be deficient in thiamine

Women with these decreased nutritional stores need to be identified early in pregnancy through history taking so they can be referred to a nutritionist for specific nutritional counseling. They may need additional supplements during pregnancy to help restore a particular nutrient.

### **The Woman Who Has Been Dieting or Following a Food Fad**

Women who have been dieting and those who have been following a food fad such as eating nothing but cabbage soup are another group who may enter pregnancy with nutrient deficiencies. Be certain to ask if a woman has been dieting at a first prenatal visit.

### **The Woman Who Eats Many Fast-Food Meals**

As many as 70% of women with children work at least part-time outside their homes ([Bureau of Labor Statistics, 2013](#)). This means nutritional counseling for pregnancy must include helping women who rely on packed lunches or fast-food meals to ingest

adequate pregnancy nutrition. One big difficulty with fast-food restaurants is the limited choice of food available. This can cause a woman to grow tired of the same thing and either eat little or have little choice but to eat foods with more empty calories than nutritionally effective ones. Unless there is a salad bar, the menu is apt to be particularly limited in fruits and vegetables. It is helpful to advise her to carry an apple or other fruit to eat along with what she selects from the menu to achieve a better food balance.

Caution women that fast-food restaurants have been associated with outbreaks of infection due to undercooked hamburger (*Escherichia coli*) or contaminated salad bars (*Salmonella*). Caution women to inspect a salad bar for cleanliness and order hamburgers well done to prevent gastrointestinal upsets of severe vomiting and diarrhea, which could lead to a serious fluid and electrolyte imbalance (Torso, Voorhees, Forest, et al., 2015).

A packed lunch poses few problems in pregnancy as long as a woman uses creativity in preparation so she does not grow so tired of packed lunches that she reduces her noontime intake or substitutes fast food in their place. Packing her lunch at bedtime rather than in the morning, when she may feel nauseated (and therefore packs little because nothing looks good), is a good recommendation early in pregnancy. Late in pregnancy, a woman may feel too tired at bedtime to do this and so could change back to preparing it in the morning when she may have more energy.

Including a thermos with a cream soup is a good way to add milk and calcium to her diet. Packing sliced oranges or cucumbers, tomatoes, or apples helps to make a lunch nutritious and also makes food available for a midmorning or midafternoon snack. Having these snacks available prevents her from having long stretches of time without eating or eating empty-calorie foods from vending machines. Box 13.8 is an interprofessional care map illustrating both nursing and team planning for sound nutrition for a woman who works outside her home during pregnancy.

## BOX 13.8

### Nursing Care Planning

#### AN INTERPROFESSIONAL CARE MAP FOR A PREGNANT WOMAN WITH AN INADEQUATE NUTRITIONAL PATTERN

Tori Alarino, 19 years of age, is 4 months pregnant. She works at a fast-food restaurant and eats breakfast and lunch at the restaurant. Her partner, Alessa, works four evenings a week, so Tori cooks for herself on those evenings. She dislikes milk, so she drinks milkshakes as a source of calcium. She is concerned because she has already gained 23 lb. She craves oranges, eating six to eight of them a day. She tells you, “I thought pregnant women always craved pickles and ice cream. What’s wrong with me?”

**Family Assessment:** Patient lives with her partner in a four-bedroom home; partner works as an electrician. Patient’s father (aged 58 years) lives with them since recent divorce.

**Patient Assessment:** Primigravida; last menstrual period (LMP) 16 weeks ago. Height: 5 ft 6 in. Prepregnancy weight: 110 lb (10 lb under desirable weight for height); BMI 17.8 (underweight). Weight today: 116 lb (minimum weight gain for first trimester). History of weight problem during adolescence; usually controls weight by eating only one main meal per day. Reports feeling tired and “rundown.” 24-hour dietary recall: Breakfast: 1 cup coffee with muffin; lunch: 1 milkshake; dinner: 1 hamburger with French fries and 1 milkshake; snacks: 8-oz soft drink.

**Nursing Diagnosis:** Imbalanced nutrition: less than body requirements related to desire to control weight

**Outcome Criteria:** Patient reports increased intake of foods adequate in calories, high in iron, calcium, and protein by next prenatal visit.

Demonstrates weight gain appropriate for stage of pregnancy and prepregnancy weight.

Team Member Responsible	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Assess if the patient’s fatigue is interfering with adequate food preparation.	If fatigue is a problem, recommend preparing food early in day when less fatigued.	Fatigue can increase nausea/vomiting in early pregnancy and can interfere with food preparation throughout pregnancy.	Patient states she is willing to cook and realizes eating fast food at all meals may not meet her nutrition needs during pregnancy.
<i>Teamwork and Collaboration</i>				
Nurse/primary healthcare provider/nutritionist	Assess nutrition requirements based on patient’s BMI and individual preferences.	Consult with nutritionist about recommended caloric and mineral requirements.	Caloric recommendations may need to be increased in light of patient’s BMI and prepregnancy and current weight.	An ideal nutrition plan is created with patient’s input.
<i>Procedures/Medications for Quality Improvement</i>				
Nurse	Assess if patient has	Ask if patient will record all	Keeping a journal provides	Patient brings log to next

	experience with keeping a journal.	food and fluid intake for 1 week; review with patient at next visit.	concrete evidence of patient's adherence to nutritional plan.	prenatal visit and reviews it with prenatal staff.
--	------------------------------------	--	---	--

*Nutrition*

Nurse/nutritionist	Assess if patient could eat more food prepared at home.	Suggest foods that patient's father or partner could prepare. Provide written information as needed.	Involving other family members could improve nutrition for entire family. Printed information enhances learning.	Patient and nutritionist prepare a schedule in which all family members participate in food preparation.
--------------------	---	--	--	--

*Patient-Centered Care*

Nurse/nutritionist	Assess if there are nutritious food choices for the patient at the fast-food restaurant.	Discuss other possible food choices with patient.	Knowledgeable patients can best follow a nutritious meal plan.	Patient lists foods she will include for healthy pregnancy nutrition; if none available, pack own lunch.
--------------------	--	---	--	--

*Psychosocial/Spiritual/Emotional Needs*

Nurse	Question patient about food likes and dislikes. Investigate any cultural influences on food choices.	Ask patient to list foods in each food group that she enjoys cooking or eating.	Ascertaining food preferences and cultural influences provides a baseline for future food selections and suggestions.	Patient lists foods she prefers and knows she can eat consistently.
-------	--	---	---	---

patient to return for prenatal appointments based on work/family obligations.	nurse appointment in 1 week if possible.	and behaviors can be difficult. Scheduling close follow-up provides an opportunity for evaluation and instruction.	for follow-up nutritional counseling.
---	--	--	---------------------------------------

**The Woman Who Cannot Obtain Culturally Preferred Foods**

Because the United States is such a blend of different cultures and people move rapidly from place to place for various reasons, a pregnant woman may find herself living in a community where grocery stores do not stock the foods she is most comfortable eating. If she lives in an apartment, she also has no opportunity to grow any favorites. This situation presents a good opportunity to discuss what she can find as substitutes. Fortunately, most major stores carry a wide range of ethnic foods. Support a woman’s efforts to speak to her grocery store manager to stock an item she prefers as practice for motherhood when she will need to learn to serve as a strong supporter or advocate for her child.

**THE WOMAN WHO HAS HAD BARIATRIC SURGERY**

**Bariatric surgery** is a weight-control method to reduce overeating by surgically reducing stomach size from about 30 to 40 oz to 3 to 4 oz. For gastric bypass surgery, the smaller, upper part of the stomach is stapled to separate it from the rest of the stomach, thereby reducing the amount of food a woman can eat. Next, the small intestine is rerouted and connected to the smaller stomach pouch, lessening the amount of nutrient absorption possible. In Lap-Band surgery, a silicone rubber band is placed around the top of the stomach, creating a small stomach pouch and reducing the amount of food a woman can eat at any one time. A sleeve gastrectomy is a laparoscopic procedure where the greater curve of the stomach is removed, again, reducing the size of the stomach and the amount that can be eaten at any one meal. A sleeve gastrectomy has the advantage of being a laparoscopy procedure and so requires only a small incision, and like Lab-Band surgery, the pyloric valve to the small intestine is left intact.

Gastric bypass surgery results in an average of 60% to 80% loss in presurgery weight; banding and sleeve gastrectomy result in a 45% to 50% weight loss (Monson & Jackson, 2016). Although once limited to mature women, the number of adolescents who are having these types of surgeries is increasing, so ask about bariatric surgery in teenagers as well as mature women (Inge, Courcoulas, Jenkins, et al., 2016).

Both women and adolescents are advised not to become pregnant for about 18 months after a gastric bypass and for 6 months after banding or sleeve gastrectomy. This is the period of greatest weight loss, during which it would be difficult to supply

enough nutrients for sound fetal growth.

After surgery, all women are required to maintain a conscientious diet of small but healthy portions as well as to take daily a chewable or liquid multivitamin supplement that includes iron, folate, vitamin B<sub>12</sub>, vitamin A, vitamin B<sub>1</sub> (thiamine), and zinc. Ask if women have been taking their supplement to establish whether they are entering pregnancy with vitamin deficits. Urge them to eat their protein source first in a meal, so they are certain to ingest enough protein.

If a woman does neglect eating a small meal and eats a large one or one extremely rich in calories (e.g., birthday cake with butter cream frosting, ham with buttered sweet potatoes), this can cause a “dumping syndrome” or sudden symptoms of nausea, bloating, and diarrhea. Be certain to mark the chart of a woman who has had bariatric surgery, so her primary healthcare provider can decide if a 50-g glucose tolerance test will be safe or stimulate acute dumping symptoms. Because a woman who has undergone bariatric surgery will have an overall small intake during pregnancy, her weight gain will be less than others; she is prone to develop iron, protein, folic acid, and vitamin B<sub>12</sub> deficiencies. Women who have had a gastric bypass are also prone to fat-soluble vitamin (vitamins A, D, E, and K) deficiencies because fat is no longer well absorbed.

Women may ask if bariatric surgery was a wise choice for them. You can assure them that following their surgery and subsequent weight loss, they are better candidates for pregnancy than they were when they were morbidly obese. They also have a lesser chance of developing gestational hypertension and gestational diabetes, both serious complications of pregnancy ([Monson & Jackson, 2016](#)).

## THE WOMAN WHO IS VEGETARIAN

Some women are vegetarians because of religious guidelines or moral conviction. Others turn to vegetarianism to both maintain healthy nutrition and avoid excess fat and food contaminants. Vegetarian diets have been shown to be protective in pregnancy ([Pistollato, Sumalla Cano, Elio, et al., 2015](#)).

Most women vegetarians are closer to their ideal weight and have lower serum cholesterol and blood pressure levels than women who eat a more typical American diet. Nurses may find many pregnant women, therefore, who want to exclude meat from their intake ([Pistollato et al., 2015](#)). Vegetarians vary as to what they can eat:

- Lacto-ovo vegetarians eat no animal flesh or fish, but dairy products and eggs are allowed.
- Lacto-vegetarians eat no meat, fish, or eggs, but dairy products are allowed.
- Vegans eat nothing derived from an animal, including butter and eggs.
- Semi-vegetarians usually restrict meat, fish, and poultry.
- Macrobiotics eat whole grains such as brown rice and vegetables; they avoid meat, eggs, milk, and cheese.

To replace meat, fish, and poultry at meals, women need to eat three or more

servings a day of both fruits and vegetables, six or more servings per day of grains, and two or more servings per day of legumes such as kidney, black, or lima beans. Most vegetarians are knowledgeable about nutrients needed and can discuss what foods are high in various nutrients and how they incorporate such foods into their daily intake.

Special concerns during pregnancy are that vegetarians may lack vitamin B<sub>12</sub> (meat is the chief source of this), an adequate intake of calcium because milk is a prime source of this (recommend dark green vegetables or soy milk to supplement this), and vitamin D (fortified soy milk and sunlight are good sources of this). Urge women who are vegetarians to remember to take their daily prenatal supplement, like all women, to ensure adequate iron and folic acid. Vegetarian nutrition for their new infant is discussed in [Chapter 29](#).

## THE WOMAN WITH A MULTIPLE PREGNANCY

Twinning occurs naturally at about 4 in every 1,000 births, but the increased use of intrauterine fertilization has caused the number of multiple births to increase to as high as 15 per 1,000 births ([Kilby & Oepkes, 2012](#)). A woman with a multiple pregnancy tends to gain more weight overall and at a faster pace than a woman carrying a single child because of the increased fetal weight.

- A woman with a normal BMI should gain 37 to 54 lb.
- A woman with an overweight BMI, 31 to 50 lb.
- A woman with an obese BMI, 25 to 42 lb ([IOM & National Research Council, 2009](#)).

To sustain her own nutrition stores, a woman with a multiple pregnancy must ingest high levels of protein and carbohydrate as well as iron and folic acid. For this reason, a multiple pregnancy needs to be recognized early so nutritional supplements as well as overall close supervision can be added as needed ([Kilby & Oepkes, 2012](#)) (see [Chapter 21](#)).

### *What If... 13.3*

**Tori Alarino is pregnant with a multiple pregnancy and tells the nurse she is “eating for three.” The nurse notices on her list of foods that she lists three desserts every day for lunch. Will this hurt her or just add a few extra pounds?**

## THE WOMAN WHO SMOKES OR USES DRUGS OR ALCOHOL

The specific effects of alcohol, cigarette smoking, and substance use on fetal growth are discussed in [Chapter 22](#). In addition to specific teratogenic fetal effects, these substances can lead to general nutrition problems because a woman is ingesting these substances rather than eating nutritious foods.

## THE WOMAN WITH A CONCURRENT HEALTH PROBLEM

Any health concern that requires rigid salt, protein, or carbohydrate restriction poses a potential threat to fetal nutrition. That means women who have medical problems such as kidney disease, diabetes, tuberculosis, bulimia, inflammatory bowel disease, celiac disease, or anorexia nervosa should consult their primary care provider before pregnancy because of the specific metabolic disorders involved with these illnesses. Women who develop gestational diabetes need the same type of nutrition counseling. Nursing interventions and nutrition concerns for women with major health problems such as these are discussed in [Chapter 20](#).

### The Woman With Lactose Intolerance

The sugar in milk is called lactose. In the intestines, lactose is broken down into glucose and galactose by the enzyme **lactase**. Most of the world's population has sufficient lactase as an infant to make this conversion, but the amount of lactase available fades by school age. After this point, people can have difficulty digesting lactose or become lactose intolerant. African Americans, Native Americans, and Asians tend to have the highest percentage of lactose intolerance (approximately 70% of African American adults cannot drink milk). Those most able to tolerate milk are Northern Europeans and their descendants ([Silanikove, Leitner, & Merin, 2015](#)).

When people who are lactose intolerant drink milk, they experience nausea, diarrhea, cramps, gas, and a general feeling of bloating. For these women, fortified soy milk is a good substitute; it is rich in protein, calcium, and vitamin D and is easily digestible. Women who don't like the taste of soy milk may be able to eat cheese because the processing of cheese changes its lactose content; yogurt may also be tolerated. Lactase tablets to be chewed before ingesting milk products can be prescribed to supplement absent lactase, although the woman needs to consult with her primary healthcare provider before taking these as they are a class N drug (not assigned a pregnancy category of safety). Even if a woman does take lactase tablets, a calcium supplement (1,200 mg daily) and a vitamin D supplement (400 International Units) may also be prescribed. This is because the amount of cheese or yogurt needed to replace the calcium of milk is too large to be practical. Because milk is also a good source of protein, be sure to assess whether, without milk, a woman's intake of protein is adequate.

Because many baby magazines, television advertisements, and government pamphlets on pregnancy repeatedly mention that it is important to drink milk during pregnancy, you may need to explain to a woman with lactose intolerance as long as she ingests the same nutrients from other foods, the actual drinking of milk is not important.

#### *QSEN Checkpoint Question 13.6*

#### **SAFETY**

Tori describes the foods she eats daily. Which nutritional risk does the nurse identify as most likely if Tori is a vegetarian?

- a. Lack of iron
- b. Lack of vitamin C
- c. Lack of folic acid
- d. Lack of vitamin B<sub>12</sub>

*Look in [Appendix A](#) for the best answer and rationale.*

### **The Woman With Phenylketonuria**

Phenylketonuria (PKU) is an inherited disorder in which a person cannot convert phenylalanine, an essential amino acid, into tyrosine. Without conversion, phenylalanine accumulates in the person's blood serum, eventually leaving the bloodstream to invade body cells. When brain cells are invaded, severe cognitive impairment and accompanying neurologic damage, such as recurrent seizures, develop (see [Chapter 48](#)). A fetus of a woman with uncontrolled PKU can develop a cognitive impairment, microcephaly, intrauterine growth restriction, and neurologic damage from exposure to excessive phenylalanine levels ([Marcdante & Kliegman, 2015](#)).

Women with the disorder need to avoid foods high in phenylalanine, which are those high in protein such as meat and legumes; examples of foods low in phenylalanine are fruits and vegetables such as orange juice, bananas, squash, spinach, and peas. Children with PKU follow a diet with restricted phenylalanine intake until at least past adolescence. A woman with PKU should consult her healthcare provider when she is planning to become pregnant and, if she is not following a restricted intake, should return to a low-phenylalanine diet for at least 3 months before she becomes pregnant. She then follows this low-phenylalanine diet during the pregnancy and as long as she is breastfeeding. A woman needs to discuss with her primary healthcare provider if she should continue to take sapropterin dihydrochloride (Kuvan), a drug to lower phenylalanine serum levels, during pregnancy as it is a class C category drug (its safety during pregnancy is unproven) ([Karch, 2015](#)).

Because a PKU diet is restrictive, a woman needs support during pregnancy to adhere to such restricted intake. It is particularly disappointing to have to follow the diet if a woman does not become pregnant immediately because each month she is "prepregnant" extends the period she has to follow the restrictions. Women with PKU are usually well informed about their particular nutritional needs. Although they may wish they could eat more liberally, they are aware phenylalanine is destructive to developing brain cells. Not following a restricted plan could leave their future child severely cognitively challenged ([Murphy, 2015](#)).

### **The Woman With Hyperemesis Gravidarum**

Hyperemesis gravidarum (sometimes called pernicious or persistent vomiting) is nausea and vomiting of pregnancy prolonged past week 16 of pregnancy or that is so severe that dehydration, ketonuria, and significant weight loss occur within the first 12 weeks of pregnancy ([O'Donnell et al., 2016](#)). It occurs at an incidence of 2% in pregnant

women. The cause is unknown, but women with the disorder may have increased thyroid function because of the thyroid-stimulating properties of human chorionic gonadotropin. Some studies reveal it is associated with *Helicobacter pylori*, the same bacteria that cause peptic ulcers (Cardaropoli, Rolfo, & Todros, 2014).

With hyperemesis gravidarum, weight loss can be severe because, with so much nausea and vomiting, a woman cannot maintain her usual nutrition. Urine may test positive for ketones, evidence the woman's body is breaking down stored fat and protein for cell growth. An elevated hematocrit concentration may be detected at a monthly prenatal visit because the inability to retain fluid has resulted in hemoconcentration (which is dangerous because it can lead to thromboembolism). In contrast, concentrations of sodium, potassium, and chloride may be reduced because of a woman's low intake; hypokalemic alkalosis may develop from loss of hydrochloric acid from the stomach. In some women, ataxia and confusion, caused by deficiency of vitamin B<sub>1</sub> (thiamine), develops. If left untreated, a woman with hyperemesis may become so dehydrated she can no longer provide a fetus with essential nutrients for growth, and intrauterine growth restriction or preterm birth can result (McCarthy, 2012).

## Assessment

Always try to determine exactly how much nausea and vomiting women are having during pregnancy. Ask the patient to describe the events of the day before:

- How late into the day did the nausea last?
- How many times did she vomit and how much?
- What was the total amount of food she was able to eat?

## Therapeutic Management

Women with hyperemesis gravidarum may need to be hospitalized for about 24 hours to document and monitor their intake, output, and blood chemistries and to restore hydration.

All oral food and fluids are usually withheld for the first 24 hours. Intravenous fluid (e.g., 3,000 ml Ringer's lactate with added vitamin B<sub>1</sub>) may be administered to increase hydration. An antiemetic, such as metoclopramide (Reglan, pregnancy class B), may be prescribed to control vomiting. Throughout this period, carefully measure intake and output, including the amount of vomitus, so the degree of hydration can best be evaluated.

If there is no vomiting after the first 24 hours of oral restriction, small amounts of clear fluid can be started and the woman discharged home, usually with a referral for home care. If she can continue to take clear fluid without vomiting, small quantities of dry toast, crackers, or cereal can be added every 2 or 3 hours, after which the woman may be gradually advanced to a soft diet and then to a regular diet. If vomiting returns at any point, enteral or total parenteral nutrition may be prescribed to ensure she receives adequate nutrition (O'Donnell et al., 2016).

## Nursing Diagnoses and Related Interventions

The main challenge in the beginning of excessive vomiting is fluid deficiency. As hyperemesis of pregnancy continues, lack of total nutrition becomes a concern. A woman with hyperemesis gravidarum needs the opportunity to express how she feels about this strange phenomenon that is happening to her and how it feels to live with ever present nausea. Some women are under such psychosocial stress from this they appreciate counseling to help them decide whether to terminate a pregnancy or allow it to go to completion.

**Nursing Diagnosis:** Imbalanced nutrition, less than body requirements, related to prolonged vomiting

**Outcome Evaluation:** Patient ingests 2,200 calories daily or receives supplemental nutrition intravenously or enterally.

Like the typical nausea and vomiting of pregnancy, the vomiting of hyperemesis gravidarum may be precipitated by fatigue and the smell of cooking. Encourage a woman to serve herself small portions so the amount on her plate does not appear overwhelming. If she is hospitalized, try to limit her exposure to food odors. Be certain hot foods are served hot, and cold foods are served cold. Check to be certain food carts smelling of food such as fish, bacon, or coffee are not parked outside her room door.

An emesis basin is an important piece of equipment for a woman who is vomiting. Put it out of sight, though, and not on a bedside table, so a woman is not constantly reminded of vomiting. Do not urge a woman who is already struggling to eat to “Eat just a little more. You don’t want to hurt your baby.” Urging women to eat in this way may cause them to feel guilty on top of feeling so nauseated.

If a woman is receiving total parenteral nutrition, she needs her blood tested for glucose about twice daily. If her blood glucose is elevated, it suggests the infusion solution contains more glucose than her body’s metabolism can process. In contrast, if ketones are present in her urine, it means her body is not receiving enough nutrients and is breaking down protein. If either of these findings is positive, she needs a nutrition reassessment to see if she needs a change in her prescription for the enteral or total parenteral therapy.

Fortunately, despite its extreme symptoms, if hyperemesis is identified early in pregnancy and managed, it will not lead to pregnancy loss or low birth weight but rather to a healthy pregnancy.

### KEY POINTS FOR REVIEW

- Assessment of nutritional health should include a health history (24-hour recall) and physical examination.
- Aiding women to include about 300 additional calories daily to provide energy, spare protein, and provide for fetal growth requirements not only helps meet QSEN competencies but also best meets a woman's pregnancy needs.
- Important minerals necessary for pregnancy include iron, iodine, calcium, fluoride, sodium, and zinc. Most women need to take an iron supplement to prevent iron-deficiency anemia and may need additional calcium and vitamin D supplementation as well.
- Women should monitor their intake of caffeine and artificial sweeteners during pregnancy and should restrict alcohol and tobacco to the lowest amounts possible.
- Remind women to use prescribed prenatal vitamins rather than over-the-counter ones during pregnancy because prescribed vitamins contain additional folic acid, calcium, and iron supplements. Be certain women regard pregnancy vitamins as medication and follow the medication rule: Take nothing other than medications specifically recommended by their primary care providers, or else toxicity could result.
- Advise pregnant women not to go longer than 3 to 4 hours between meals to avoid hypoglycemia.
- Common nutrition concerns associated with pregnancy include nausea and vomiting, constipation, cravings (including pica), and pyrosis.
- Women who are at high risk for inadequate nutrition include those who are adolescent or over age 40 years; those who have decreased nutrition stores; and women with a multiple pregnancy or who are lactose intolerant, underweight, or overweight. Others at high risk are those with a secondary health concern; who are on a special diet; who use recreational drugs, including alcohol or cigarettes; and those who experience hyperemesis gravidarum (extreme nausea and vomiting).
- Hyperemesis gravidarum is nausea and vomiting of pregnancy that extends past 16 weeks of pregnancy or that is too extreme to allow for adequate nutrition. Women with this condition may need antiemetic medication or nutrition supplemented by total parenteral nutrition or enteral feedings.

### CRITICAL THINKING CARE STUDY

Annette Milano is 26 years old and is 5 months pregnant. She has a PhD in psychology and lives alone in an apartment near the university where she teaches. She tells you she “didn’t mean” to get pregnant and also that she is afraid to go outside at night because gangs “own” her neighborhood. She began feeling nauseated early in pregnancy and has continued to feel this way into her fifth month. She vomits three or four times a day.

24-hour nutrition recall:

Breakfast: none

Lunch: 1 cup of tea, a few dry crackers

Dinner: 1 slice pizza, 1 glass chocolate milk

Snack: 1 apple

Annette knows she is eating very little but tells you, “I have a PhD, so I’m not stupid. You can trust me when I say this is the amount I’ve always eaten, so it is all right for me.”

1. Is Annette’s food intake adequate for pregnancy? How would you respond to her admonition she is not stupid?
2. Suppose Annette is hospitalized so she can receive total parental nutrition. What common steps would you want to take to try to decrease her feeling of nausea?
3. You want to assess Annette daily for dehydration. What would be important factors to assess to see if she is well hydrated?

## Unfolding Patient Stories: Olivia Jones • Part 2

Think back to [Chapter 4](#), where you met **Olivia Jones**, a 23-year-old, gravida 1, para 0 at 30 weeks gestation, who presents with signs and symptoms of preeclampsia requiring bedrest at home. She is obese and informs the nurse that she is eating less due to nausea and unemployment. What are important nursing assessments for nutrition evaluation and nutritional requirements during pregnancy? Outline a nursing plan of care that promotes nutritional health for Olivia, addressing her identified problems and educational needs.

Care for Olivia and other patients in a realistic virtual environment: *vSim for Nursing* ([thepoint.lww.com/vSimMaternityPed](http://thepoint.lww.com/vSimMaternityPed)). Practice documenting these patients’ care in DocuCare ([thepoint.lww.com/DocuCareEHR](http://thepoint.lww.com/DocuCareEHR)).

## Preparing a Family for Childbirth and Parenting

*Elena Garza is a 30-year-old woman who is pregnant with her second child. During her first pregnancy, she did not attend any childbirth classes and received an epidural for the birth. During a prenatal visit for her current pregnancy, Elena tells you she would now like to have a more natural birth in a birthing center. She asks you for information on childbirth education classes. Her partner, Joe, a Navy Seal, wants Elena to go to the hospital and have an epidural like the last time. He says, “The doctors know what they’re doing. Just let them do their job.” After further speaking with Joe, you discover he doesn’t want Elena to go through the pain of natural childbirth because he fears he may be out of town when she’s in labor.*

*Previous chapters discussed normal reproductive anatomy and physiology and nursing care necessary during pregnancy. This chapter adds information about ways couples can make labor and birth a more satisfying experience. The information helps protect the mental as well as the physical health of both women and children throughout the continuum of pregnancy, birth, and childrearing.*

**How can you help alleviate some of Joe’s concerns and best advise the Garzas on preparations for childbirth?**

### KEY TERMS

**alternative birthing centers (ABCs)**

**birthing bed**

**birthing chair**

**birthing room**

**cleansing breath**

**conditioned reflexes**

**conscious relaxation**

**consciously controlled breathing**

**distraction**

**doula**

**effleurage**

gating control theory of pain perception  
labor-birth-recovery-postpartum room (LBRP)  
Leboyer method  
psychoprophylactic  
vaginal birth after cesarean (VBAC)

## OBJECTIVES

After mastering the contents of this chapter, you should be able to:

1. Describe common preparations for childbirth and parenting, including common settings for birth.
2. Identify 2020 National Health Goals related to preparation for parenthood and how nurses can help the nation achieve these goals.
3. Assess the readiness of a couple for childbirth with regard to choice of birth attendant, preparation for labor, and birth setting.
4. Formulate nursing diagnoses related to preparation for childbirth and parenting.
5. Identify expected outcomes for a couple preparing for childbirth and parenting while helping them manage seamless transitions across differing healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care to assist a couple in selecting and preparing for an alternative birth setting such as a freestanding clinic or their home as well as support a woman during labor by controlled breathing.
8. Evaluate outcome criteria for achievement and effectiveness of care.
9. Integrate knowledge of prepared childbirth with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

As active consumers of health care, expectant families can find themselves faced with a wide array of choices for a childbirth experience and preparation for parenting. Three important decisions families need to make before labor include:

- Choice of birth attendant
- Choice of setting
- How much and what type of analgesic they want to use in labor

For example, a woman may elect to have her family doctor, an obstetrician, or a nurse-midwife as her birth attendant. She may choose to be supported by her intimate partner, other family members, friends, or a **doula** (a woman experienced in childbirth

who provides continuous emotional and physical support). She may choose to give birth in a birthing center or a hospital with specially equipped birthing rooms (MacDorman, Mathews, & Declercq, 2014).

No matter what setting the woman or couple choose, expectant parents are well advised to be as prepared as possible for the physical and emotional aspects of childbirth (Black, Entwistle, Bhattacharya, et al., 2016). Box 14.1 shows 2020 National Health Goals related to preparation for childbirth and parenting.

## BOX 14.1

### Nursing Care Planning Based on 2020 National Health Goals

Preparation-for-childbirth classes supply information not only on how to prepare for childbirth but also on how to parent. A number of 2020 National Health Goals that speak directly to such classes or counseling include:

- Increase the proportion of pregnant women who attend a series of prepared childbirth classes (Developmental).
- Increase the proportion of pregnant women who receive early and adequate prenatal care from a baseline of 70.5% to a target of 77.6%.
- Increase the proportion of women delivering a live birth who received preconception care services and practiced key recommended preconception health behaviors (Developmental) (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses have a direct role in helping the nation achieve these objectives by participating as instructors in preparation for childbirth and parenting classes as well as teaching and supervising prenatal care.

## *Nursing Process Overview*

### FOR CHILDBIRTH AND PARENTING EDUCATION

#### **ASSESSMENT**

Assessing each woman's or couple's readiness for decision making about childbirth as well as providing foundation information early in the process can help a woman or couple make plans for childbirth. Some couples have a clear idea of where and how they wish their child's birth to occur from the moment they realize they are pregnant. Others cannot even consider the actual birth until they have adjusted to the idea of pregnancy.

Childbirth education is not just for primiparas because if a woman expecting her second or third child has waited several years between children, she usually appreciates refresher information as much as a primipara hungers for new information. Whether a woman is a primipara or multipara, ask whether either she or her support person wants to attend childbirth or parenting courses. Provide appropriate information on what classes are available and how and when they should

enroll.

## **NURSING DIAGNOSIS**

Nursing diagnoses tend to cluster around whether the woman or couple is sure of their decision about the birth setting and childbirth preparation. Examples include:

- Health-seeking behaviors related to learning more about childbirth and newborn care
- If there is a lack of a support person, the following diagnoses might apply:
  - Ineffective coping related to lack of a support person
  - Anxiety related to absence of significant other
- For a couple unable to make a decision about a childbirth setting, an appropriate diagnosis might be decisional conflict related to lack of information about advantages and disadvantages of various childbirth settings.
- If there are older children in the family, a nursing diagnosis might be anxiety related to sibling role in pending birth event and sibling ability to welcome a new family member.

## **OUTCOME IDENTIFICATION AND PLANNING**

When planning with couples for labor and birth, goals that are set should seem both realistic and flexible. For example, the goal of preparation is to help couples make informed choices rather than to follow a rigid plan.

Not all women want to go through labor without analgesia, so setting a goal to do so would be unrealistic for such a woman. The majority of women, however, want to participate as fully as possible in their labor and birth experience, so setting a goal for them to do that would be very realistic. Some women may be reluctant to attend a childbirth preparation course because of fear attending will mean they are committing themselves to a medication-free birth. You can assure them that learning about medications or other methods to reduce the pain of childbirth does not mean they have to use one or the other of these methods. In the same way, women who are certain they want medication before having taken a class will not be held to this afterward.

Refer couples to helpful websites and other resources when appropriate (see [Chapter 9](#)).

## **IMPLEMENTATION**

Be certain to provide a woman and her partner with information on the benefits and drawbacks of birthing options without influencing them in a particular direction. To remain objective, examine your own attitudes, cultural influences, and values related to childbirth and explore how these beliefs might differ from those of your patients ([Box 14.2](#)). Referring couples to a childbirth preparation course can provide many answers for them in a sympathetic group setting, where feelings and anxieties can be shared. Be familiar with the content of courses available in your community so you can be certain the courses you suggest are appropriate for individual couples and present adequate and accurate information.

Review the arrangements a woman needs to make for labor and birth at the midpoint of pregnancy. No matter how calm a woman seems when discussing these details, many women experience some fear at the last minute and will forget what they need to do when labor begins. Be certain a woman has thought through arrangements for transportation to the hospital or birthing center and for child care if she has other children at home. Be certain a woman who anticipates a home birth has organized her home and purchased supplies for birth well in advance of her expected due date.

### **OUTCOME EVALUATION**

Evaluate whether expected outcomes for childbirth education have been achieved during the last few prenatal visits. By this time, a woman or couple should know where the baby will be born and should have worked out transportation and child care details. Encourage women who will be coached through childbirth by their partners or another support person to continue practicing breathing and relaxation techniques together up to the time of birth so they do not lose these skills. A final evaluation as to whether the couple was satisfied with their birth setting or preparation choices takes place after the birth. Examples of expected outcomes that would demonstrate the success of interventions include:

- The couple states they feel prepared for childbirth.
- The patient states she feels confident she can use breathing exercises for contractions as long as 70 seconds.
- The patient has made preparations for a doula to support her during labor.
- The sibling states she is ready to welcome a new brother or sister into the family.
- The couple states they were well prepared for birth and that it was both a satisfying and a growth experience for them.

#### **BOX 14.2**

### **Nursing Care Planning to Respect Cultural Diversity**

Whether women want or are able to take a childbirth and parenting preparation course depends a great deal on cultural and socioeconomic factors and individual choices. In some cultures, for example, the advice of a friend or family member carries more weight than the advice of a professional healthcare practitioner. A very old cross-cultural belief is a knife placed under the mattress will “cut the pain” better than a Lamaze program, so you may need to advocate to allow this type of pain relief. Asking each woman separately whether she is interested in a course and being certain women are fully informed about the options available are two ways to be certain all women receive as much advice and knowledge as they wish about childbirth.

Who women choose as a support person or coach in labor also differs depending on one’s cultural background. Some women would not think of choosing anyone but

their male partner; whereas others' first choice would be a female relative or friend. Assess each couple individually to be certain cultural preferences such as these are respected.

## Childbirth Education

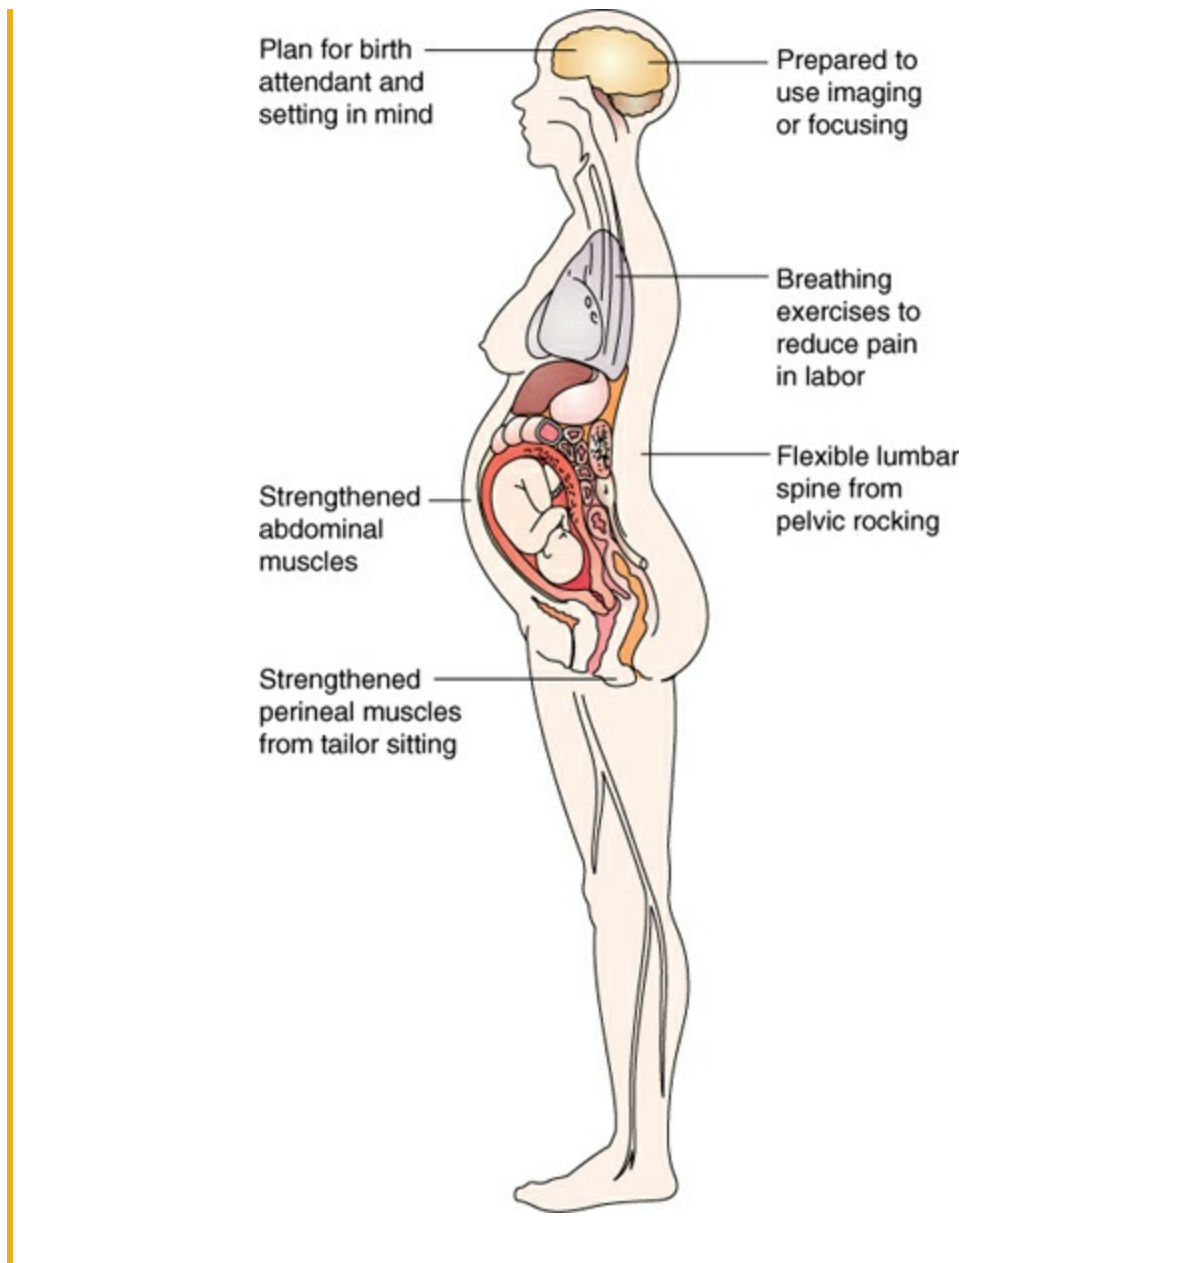

Although parenting is unarguably an important occupation, it is one of the few occupations that requires no formal education, no examination to test a person's ability to take on such a role, and no refresher course to ensure a parent is following healthy standards of childrearing. Assessing whether couples need preparation for childbirth or parenting classes or encouraging them to take one can therefore be extremely important to make childbirth a satisfying experience, to help a family bond with its new member, and to help couples become effective parents (Box 14.3).

BOX 14.3

### Nursing Care Planning Using Assessment

#### ASSESSING A WOMAN'S PREPARATION FOR LABOR

Preparation for childbirth courses that teach this material should be individualized to meet the parents' needs. Classes should be personalized and structured for women with special needs such as adolescents, career women, women who are physically challenged, or those experiencing a high-risk pregnancy. There also are classes available to help prepare siblings or grandparents learn more about their role. Women having a **vaginal birth after cesarean (VBAC)** or women who are having a scheduled cesarean birth can attend classes specially designed for them (Horey, Kealy, Davey, et al., 2013).

Preparation for childbirth courses initially began in the early 1900s to encourage women to come for prenatal care (Godin, Alton, Gangodawilage, et al., 2015). Classes continue today because, with all the birth choices available, they fulfill an important need for education about labor and childbirth. As many as 15% of women express fear

or anxiety about what will happen in labor, so counseling can be very important to alleviate this fear (Ternström, Hildingsson, Haines, et al., 2016).

The overall goals of childbirth education are to prepare expectant parents emotionally and physically for childbirth while promoting wellness behaviors that can be used by parents and families for life. Women usually enjoy such classes because they offer them a sense of “family” if their intimate partner also attends as well as create a sense of empowerment or confidence that they will be knowledgeable enough to participate fully in their birth experience.

## CHILDBIRTH EDUCATORS AND METHODS OF TEACHING

Childbirth educators are usually healthcare providers who have a professional degree in the helping professions as well as a certificate from a course on childbirth education. They teach expectant parents about the physical and emotional aspects of pregnancy, childbirth, and early parenthood as well as present coping skills and labor support techniques. Although childbirth education is an interdisciplinary field, it has historically been associated with nursing, and nurses play major roles in designing and teaching such courses. Most classes are taught in a group format, incorporating a variety of teaching techniques such as DVD or PowerPoint presentations, lectures, and demonstrations (especially for content on relaxation and breathing techniques). One of the most important aspects of these courses, however, is group interaction. Women and their partners enjoy the opportunity to share their fears and hopes about their pregnancy and upcoming birth with others as they learn together (Box 14.4).

### BOX 14.4

#### Nursing Care Planning Tips for Effective Communication

You care for Elena at a prenatal clinic visit. She is in the 24th week of an uncomplicated pregnancy.

*Tip:* Be an active listener as conversation often reveal that time or money concerns are the real reason a couple has decided not to attend a course. Because women should have input into how much preparation they want to do for childbirth, it is easy to take a woman’s answer at face value for not wanting to attend a class. Helping to investigate the many options is the beginning of problem solving.

**Nurse:** Have you signed up for a childbirth preparation class yet, Elena?

**Elena:** No.

**Nurse:** Don’t wait too much longer. You’re already in your sixth month.

**Elena:** I don’t really need to go to one.

**Nurse:** Why is that?

**Elena:** Classes are at the wrong time. And cost too much.

**Nurse:** Let’s work together to find a course that’s right for you. We can use the

Internet to find out what options are available.

## The Childbirth Plan

Most classes for expectant parents urge couples to make a written childbirth plan to include information such as their choice of setting, birth attendant, special needs such as the extent of family participation they wish during labor, birthing positions, medication options, plans for the immediate postpartum period, baby care, and family visitation—all measures to give them a better sense of control (Hidalgo-Lopezosa, Rodríguez-Borrego, & Muñoz-Villanueva, 2013).

Urge couples to make these decisions at least 1 month before the expected day of birth. This way, if an expectant couple has a strong desire in a certain area, this gives them time to communicate their wish so it can be accommodated if possible. If plans are left to the last minute, the couple may find decisions determined by agency policy or the circumstances at the moment rather than by their input.

When talking to couples about their birth plan, be certain it includes flexibility as well as is centered on the ultimate goal of childbirth: a healthy baby and healthy parents rather than concentration on a limited goal, such as not having fetal monitoring or using a particular birthing position. This is because in the event of a complication that requires an emergency cesarean birth, their preference to have the baby without anesthesia will need to be modified. Making a birth plan in a group setting has the advantage of allowing a couple to sort out their questions and feelings about what they want to consider in their plan as they share information with others. [Box 14.5](#) is a sample birth plan.

### BOX 14.5

#### Birth Plan: Elena Garza

##### BIRTH ATTENDANTS

Alexander Coppin, MD, and nurse-midwife Kaitlin Brandywine, or whoever is on call for the big day.

##### BIRTH SETTING

Room Number 1 at Huntington Alternative Birth Center

##### SUPPORT PERSONS

My boyfriend Joe and my sister Adrienne. Adrienne will serve as my doula.

##### ACTIVITIES DURING LABOR

I want to walk around or rock in the rocking chair or play Monopoly.

I want to use breathing exercises with contractions.

I want to wear my own nightgown and listen to Lady Antebellum's CD *Own the Night*

I want to wear my glasses, not my contact lenses.

I want to eat "anything chocolate" during labor.

I want to drink raspberry-flavored water to stay hydrated (partner will supply).

I want a walking epidural for pain as soon as I'm far enough dilated to have it.

#### BIRTH

Position for birth: on my side (no stirrups, please).

No episiotomy please.

Joe wants to cut the cord.

I want my older son to watch if he wants to (my mother will babysit).

I want to cord bank a sample of my baby's blood.

I'm okay with circumcision.

I want the first voice my baby hears to be my voice so no talking please while he's born.

#### POSTPARTUM

I want to breastfeed immediately and exclusively (will probably need some help).

I want to use skin-to-skin care to keep the baby warm.

I want to room-in constantly.

Joe wants to sleep over on bedside cot.

## Preconception Visits

Preconception visits are specific visits for couples who plan to get pregnant within a short time and want to know more about what they can expect pregnancy to be like and what birth setting and procedure choices exist. These visits include recommended preconception nutrition modifications such as a good intake of folic acid (e.g., green leafy vegetables) and protein (e.g., meat, tofu, beans) and perhaps a prenatal vitamin during the time waiting to get pregnant to ensure a healthy fetus (Shannon, Alberg, Nacul, et al., 2014). Box 14.6 lists questions a couple might want to discuss about birth.

### BOX 14.6

#### Nursing Care Planning Based on Family Teaching

#### CHOOSING A BIRTH SETTING

**Q.** Elena and her partner Joe ask you, “There are so many options available for a birth setting. How do we decide which one to choose?”

**A.** Choosing a birth setting is a personal decision. Some questions you might want to ask to help with the decision include:

- What type of healthcare provider do I want to supervise my prenatal care and labor and birth? Nurse-midwife? Family doctor? Obstetrician?
- What settings does a particular childbirth provider let me choose from? A birthing room? An alternative birthing center? My home?
- Will the same person be present at prenatal visits as for the birth? Does the setting offer preparation for childbirth or childrearing classes?

- Will I be allowed to choose a birth position? Will I have input into the amount of anesthesia used? Can a doula be with me in labor? Can administration of ophthalmic ointment for the baby’s eyes be delayed so it doesn’t interrupt bonding? Can I begin breastfeeding immediately? Will nurses who are supportive and informed about breastfeeding be available if I have a problem?
- Will the setting allow my support person to participate? Will he or she be allowed to stay with me throughout labor and birth? Could he or she cut the cord or help with the birth? Can older children participate? Can I record the birth on video or by photographs?
- Is early discharge available? Will a follow-up home visit be included in care?
- If I should have a complication during labor or birth, is there adequate equipment and personnel available for emergency care? If our baby should have a complication, is there provision for immediate emergency care or transport to a high-risk facility? Will my partner be able to go with the baby?

**QSEN Checkpoint Question 14.1**

**PATIENT-CENTERED CARE**

Elena, 30 years of age, shows the nurse the birth plan that she has drafted. Which statement by her would help assure the nurse that she has a workable plan?

- “I’ve written down everything I have to have to make labor a success.”
- “I didn’t include anything my boyfriend wanted; I’m the one having the baby.”
- “My mother strongly suggested I ask for morphine like she did, so I’m going to add that.”
- “I’ve tried to keep it flexible because I know circumstances can change.”

*Look in Appendix A for the best answer and rationale.*

## Expectant Parenting Classes

Expectant parenting classes are designed for couples to attend early in pregnancy. They focus on the woman’s health during a pregnancy by covering such topics as the psychological and physical changes of pregnancy, pregnancy nutrition, routine health care such as dental checkups, and newborn care. A typical course plan for 8 weeks is shown in [Box 14.7](#).

**BOX 14.7**

**Sample Outline for Weekly Expectant Parents Classes**

Lesson 1: Review of Physiologic Changes of Pregnancy and Fetal Growth

Lesson 2: Personal Care During Pregnancy

Nutrition, hygiene such as bathing, dental care, exercise, and rest

Lesson 3: Emotional Changes During Pregnancy

Lesson 4: Labor and Birth

The process of birth, exercises, and breathing techniques, and medication in labor

Lesson 5: Plans for Birth

Birth settings available, supplies to take to birth settings, tour or film of a typical birth

Lesson 6: The Postpartum Period

Lesson 7: Infant Care

Nutrition and hygiene

Lesson 8: Reproductive Life Planning

Both the woman and her support person are invited to classes; the curriculum is individualized for the group members and their needs such as women in the military, sibling preparation, refresher classes for grandparents, classes for expectant adoptive parents, pregnant adolescents, or women with physical disabilities. If all the women in the group already have children, for example, they may not need a tour of a maternity unit as part of the program; instead, they may want to learn what is new in baby food or child care. If all the women in the class work at least part-time, discussion of “brown bag nutrition” and how to include rest periods during work hours might be most useful. If all the women are teenagers, they may be most interested in what is going to happen to their bodies during pregnancy, or what sports are safe to continue. They may also need extended information on how to care for a newborn. They probably will also want a tour of the maternity unit (Fig. 14.1).

**Figure 14.1** An enjoyable part of a preparation-for-parenthood class is touring a maternity service. Here, parents plan for their visit to the hospital through a hospital tour.

## BREASTFEEDING CLASSES

Breastfeeding classes are designed to help women learn more about breastfeeding so

they not only choose breastfeeding over bottle feeding but also continue with breastfeeding for at least 6 months following their child's birth. Such classes cover the physiology of breastfeeding as well as the psychological aspects. Classes are often taught by a certified La Leche League instructor who is an expert on what problems new mothers are apt to encounter (see [Chapter 19](#) for breastfeeding techniques) ([Minert, 2014](#)).

### *What If... 14.1*

**Elena tells the nurse her partner won't be coming to childbirth classes with her because, as a Navy Seal, he may be out of town when she's in labor. She asks the nurse if it is really important to have someone with her. How would the nurse best advise her?**

## PREPARATION FOR CHILDBIRTH CLASSES

Preparation for childbirth classes focus mainly on explaining the psychological and physiologic changes that occur with childbirth and ways to prevent or reduce the pain of childbirth.

Common areas taught include:

- Preparing the expectant woman and her support person for the childbirth experience
- Helping women become more informed about the options available for childbirth
- Explaining the role of both pharmacologic and nonpharmacologic methods of pain control that are useful for labor
- Helping increase the couple's overall enjoyment of and satisfaction with the childbirth experience

In addition to teaching about normal labor and pain relief, classes also include a number of exercises to ready the body for labor.

## EXERCISE DURING PREGNANCY

Encourage women to maintain an active exercise program during pregnancy overall because such a program will both increase blood circulation to the fetus and help prevent excessive weight gain in the mother ([Wahlqvist, Krawetz, Rizzo, et al., 2015](#)).

Women should not, however, enroll or participate in a formal exercise program without their obstetric provider's approval. They should also not attempt to exercise if any of the danger signs of pregnancy are present and should never exercise to a point of fatigue ([Box 14.8](#)).

### BOX 14.8

#### Nursing Care Planning to Empower a Family

##### EXERCISE GUIDELINES FOR LABOR PREPARATION

**Q.** Elena asks you, “How can I be sure the exercises I’m doing to be ready for birth won’t hurt me or my baby?”

**A.** Good rules to follow include:

- Always rise from the floor slowly to prevent feeling dizzy from orthostatic hypotension.
- To rise from the floor, roll over to the side first and then push up to avoid strain on the abdominal muscles or round ligaments because this can cause intense pain.
- To prevent leg cramps when doing leg exercises, never point the toes (extend the heel instead).
- To prevent back pain, do not attempt exercises that hyperextend the lower back.
- Do not hold your breath while exercising, because this increases intra-abdominal and intrauterine pressure.
- Do not continue with exercises if any danger signal of pregnancy occurs.
- Never exercise to a point of fatigue.
- Never practice second-stage pushing. Pushing increases intrauterine pressure and could rupture membranes.

## **Prenatal Yoga**

Prenatal yoga classes are aimed at helping a woman relax and manage stress better for all times in her life, not just pregnancy. Yoga exercises help a woman stay overall fit by their focus on gentle stretching and deep breathing. They can also help a woman experience high self-esteem as she masters difficult levels or positions. Yoga breathing techniques are also useful in labor to help both relaxation and pain management (Polis, Gussman, & Kuo, 2015).

Caution women that as pregnancy progresses, it will become difficult to maintain yoga positions that involve balancing. Urge women to use a chair or a wall for stabilization and to avoid twisting exercises late in pregnancy because when joints soften in preparation for labor, muscle or joint strain could occur.

## **Perineal and Abdominal Exercises**

Women can practice specific exercises to strengthen pelvic and abdominal muscles to make these muscles stronger and more supple for labor. If perineal muscles are supple, this allows for stretching during birth, reduces discomfort, and helps perineal muscles function more efficiently after childbirth, which helps reduce the possibility of urinary incontinence (Mørkved & Bø, 2014).

A woman may begin exercises as early in pregnancy as she likes. Many exercises can be incorporated into daily activities so they take little time from a busy day. It is best, however, for a woman to set aside a specific time each day for practicing exercises; otherwise, her participation may be sporadic. Initially, women should do each exercise only a few times and gradually increase the number with each session.

## Tailor Sitting

Although many women may be familiar with tailor sitting, they may have to be retaught the position, so it is done in a way that stretches perineal muscles without occluding blood supply to the lower legs. A woman should put one leg in front of the other, not put one ankle on top of the other to avoid interfering with leg circulation (Fig. 14.2). As she sits in this position, she should then gently push on her knees toward the floor until she feels her perineum stretch. This is a good position to use to watch television, read, talk to friends on the phone, or file papers in a lower cabinet at work. If a woman sits in this position for at least 15 minutes every day, by the end of pregnancy, her perineum should be so supple when she tailor sits, her knees will almost touch the floor if pushed.

**Figure 14.2** Tailor sitting stretches perineal muscles to make them more supple. Notice that the legs are parallel so one does not compress the other. A woman could use this position for television watching, telephone conversations, or playing with an older child.

## Squatting

Squatting (Fig. 14.3) also stretches the perineal muscles and can be a useful position for second-stage labor as well and, like tailor sitting, should be practiced for about 15 minutes a day. For pelvic muscles to stretch, a woman should keep her feet flat on the

floor and not raise on her tiptoes. Incorporating squatting into daily activities such as picking up toys from the floor reduces the amount of time a woman must devote to daily exercises.

**Figure 14.3** Squatting helps to stretch the muscles of the pelvic floor. Notice the feet are flat on the floor for optimal perineal stretching.

### **Pelvic Floor Contractions (Kegel Exercises)**

Pelvic floor contractions can be done easily during daily activities. While sitting at her desk or working around the house, a woman can tighten the muscles of her perineum by doing Kegel exercises (see [Chapter 12, Box 12.7](#)). Such perineal muscle-strengthening exercises are helpful in the postpartum period to reduce pain and promote perineal healing. They also have long-term effects of increasing sexual responsiveness and helping prevent stress incontinence ([Mørkved & Bø, 2014](#)).

### **Abdominal Muscle Contractions**

Abdominal muscle contractions may help strengthen abdominal muscles during pregnancy, help prevent constipation, and help restore abdominal tone after pregnancy. Strong abdominal muscles can also contribute to effective second-stage pushing during labor. Abdominal contractions can be done in a standing or lying position. A woman merely tightens her abdominal muscles and then relaxes them. She can repeat the exercise as often as she wishes during the day.

### **Pelvic Rocking**

Pelvic rocking ([Fig. 14.4](#)) helps relieve backache during pregnancy and early labor by making the lumbar spine more flexible. It can be done in a variety of positions: on hands and knees, lying down, sitting, or standing. A woman arches her back, trying to

lengthen or stretch her spine. She holds the position for 1 minute and then hollows her back. If a woman does this at the end of the day about five times, it not only increases her flexibility but also helps relieve back pain and make her more comfortable during the night.

**Figure 14.4** Pelvic rocking is helpful for relieving backache during pregnancy and labor. To do this, the woman first hollows her back and then arches it.

### *QSEN Checkpoint Question 14.2*

#### **SAFETY**

Elena asks the nurse which type of exercise is best to strengthen her perineal muscles in anticipation of birth. Which of the following recommendations is safest and most effective?

- Walk or jog 20 minutes daily at a fairly rapid pace.
- Squat or tailor sit for 15 minutes out of every day.
- Periodically bear down as hard as possible while holding her breath.
- Lift both of her legs into the air while she lies on her back.

*Look in [Appendix A](#) for the best answer and rationale.*

### **Birthing Aids**

During early labor, a woman needs to discover what activities she could use for **distraction** that would be unique for her such as playing cards or listening to specific music; further into labor, she should plan what she could use as a greater distraction for even stronger contractions such as singing out loud, having her partner massage her back, or center intently on breathing exercises. Caution her partner that by mid-labor, women become so intent on the process of birthing that they no longer want to talk or joke.

In order to help fetal descent and help relieve pain, women can use an exercise ball, a Jacuzzi tub, or change of position such as squatting, swaying with a partner, or rocking in a chair. These alternative pain and descent methods are discussed in [Chapter 16](#) with other measures that are useful in labor but don't involve practice during

pregnancy.

## Methods to Manage Pain in Childbirth

Beginning in the late 1950s, many specific methods for nonpharmacologic pain reduction during labor were developed. These included the Lamaze, Dick-Read, Kitzinger, and Bradley methods, all named after the professionals who developed them. More recently, childbirth education has moved away from a strict method approach like these to more eclectic ones. Many educators teach a variety of approaches, including the use of complementary or herbal therapies.

Most approaches to reducing discomfort in labor are based on the following three principles:

1. A woman needs to come into labor informed about what causes labor pain and prepared with breathing exercises to use to minimize pain during contractions.
2. A woman experiences less pain if her abdomen is relaxed and the uterus is allowed to rise freely against the abdominal wall with contractions.
3. Using the **gating control theory of pain perception**, distraction techniques can be employed to alter how pain is received ([Box 14.9](#)).

### BOX 14.9

#### Gating Control Mechanisms to Reduce Pain

##### PAIN FLOWS THROUGH PATHWAYS BECAUSE:

1. The endings of small peripheral nerve fibers detect a stimulus.
2. Small nerve fibers transmit the sensation of pain to cells in the dorsal horn of the spinal cord.
3. Impulses pass through a dense, interfacing network of cells in the spinal cord (the substantia gelatinosa).
4. Immediately, a synapse occurs in a motor nerve that initiates a response at the peripheral site. For example, a woman touches a hot stove, the impulse travels to the spinal cord, immediately returns to her fingers, and the woman jerks her hand away from the stove burner.
5. After this short-circuit synapse, the impulse then continues in the spinal cord to reach the hypothalamus and cortex of the brain.
6. The impulse is interpreted (e.g., the burner is hot) and is perceived as pain.

##### GATING THEORY OF PAIN CONTROL

The gating theory of pain perception refers to gate control mechanisms in the substantia gelatinosa that are capable of halting an impulse at the level of the spinal cord so the impulse is never perceived at the brain level as pain—a process similar to closing a gate. Techniques that can assist gating mechanisms include:

- *Cutaneous stimulation*. If large peripheral nerves next to an injury site are stimulated, the ability of the small nerve fibers at the injury site to transmit pain

impulses appears to decrease. Therefore, rubbing an injured part or applying transcutaneous electrical nerve stimulation (TENS) or heat or cold to the site (cutaneous stimulation) are effective maneuvers to suppress pain. Effleurage, or light massage used in the Lamaze method, also accomplishes this.

- *Distraction.* If the cells in the brain cortex that will register an impulse as pain are preoccupied with other stimuli, a pain impulse cannot register. Different childbirth classes use different breathing, vocalization, or focusing techniques such as imaging to accomplish this. Breathing techniques not only furnish distraction but can increase oxygenation to the mother and fetus.
- *Reduction of anxiety.* Pain impulses are perceived more quickly if a woman is anxious. The third technique of gating, therefore, is to reduce patient anxiety as much as possible. Teaching a woman what to expect during labor is a means of achieving this.

### *What If . . . 14.2*

**Elena tells the nurse she does not intend to take a preparation for labor class because she wants to have epidural anesthesia as soon as she is admitted to the hospital in labor. Would the nurse advise her to attend a class?**

## **BRADLEY (PARTNER-COACHED) METHOD**

The Bradley method of childbirth, originated by Robert Bradley, is based on the premise that pregnancy and childbirth are joyful, natural processes and that a woman's partner should play an active role during pregnancy, labor, and the early newborn period. During pregnancy, a woman performs muscle-toning exercises and limits or omits foods that contain preservatives, animal fat, or a high salt content. She reduces pain in labor by abdominal breathing. In addition, she is encouraged to walk during labor and to use an internal focal point as a disassociation technique. The method is used at specific centers in the United States and is used widely in Europe, so it may be a favorite method of an immigrant woman. It is taught by certified Bradley instructors (Bradley, Hathaway, Hathaway, et al., 2008).

## **THE PSYCHOSEXUAL METHOD**

The psychosexual method of childbirth was developed by Sheila Kitzinger in England during the 1950s. The method stresses pregnancy, labor and birth, and the early newborn period are some of the most important points in a woman's life. It includes a program of conscious relaxation and levels of progressive breathing that encourage a woman to "flow with" rather than struggle against contractions (Kitzinger, 2011).

## **THE DICK-READ METHOD**

The Dick-Read method is based on an approach proposed by Grantly Dick-Read, an English physician. The premise is that fear leads to tension, which leads to pain. If a woman can prevent fear from occurring or can break the chain between fear and tension or tension and pain, then she can reduce the pain of labor contractions. A woman achieves lack of fear through education about childbirth, and she achieves reduced pain by focusing on abdominal breathing during contractions (Dick-Read & Gaskin, 2013).

## THE LAMAZE PHILOSOPHY

The Lamaze method of prepared childbirth, a philosophy based on the gating control theory of pain relief, is the one most often taught in the United States today (Amis, 2010). The method is based on the theory that through stimulus-response conditioning, women can learn to use controlled breathing to reduce pain during labor. It was originally termed the **psychoprophylactic** method because it focuses on preventing pain in labor (prophylaxis) by use of the mind (psyche). The method was developed in Russia based on Pavlov's conditioning studies but was popularized by a French physician, Ferdinand Lamaze. Formal classes are organized by Lamaze International and the International Childbirth Education Association.

Lamaze preparation is not so much a method to help a woman cope with labor as it is a total philosophy of how to enjoy a safe and satisfying childbirth experience. Information to guide a woman and her coach through pregnancy such as prenatal nutrition, exercises, and common discomforts of pregnancy are discussed in classes along with information to prepare couples for unexpected circumstances of birth, such as malpresentation, cesarean birth, or the need for analgesia or anesthesia.

Throughout the program, the following six major concepts are stressed:

1. Labor should begin on its own, not be induced.
2. Women should walk, move around, and change positions throughout labor.
3. Women should bring a loved one, friend, or doula for continuous support.
4. Interventions that are not medically necessary should be avoided.
5. Women should be allowed to give birth in other positions than on their back and should follow their body's urges to push.
6. Mother and baby should be kept together after birth; it is best for the mother, for the baby, and for breastfeeding (Amis, 2010).

In addition, the following three main principles are taught in the prenatal period related to the gating control method of pain relief:

1. If a couple understands the process of labor and birth, they can enter labor with decreased tension.
2. Concentrating on breathing patterns or imagery or focusing can block incoming pain sensations.
3. **Conditioned reflexes**, or reflexes that automatically occur in response to a stimulus, can also be used to displace pain during labor. For example, a woman is conditioned to relax automatically on hearing a command ("contraction beginning") or at the feel of a contraction beginning. The responses to

contractions must be recently conditioned to be effective (because conditioned responses fade if not reinforced). This is the reason it is generally recommended that women attend Lamaze classes in the last trimester of pregnancy. A disadvantage of enrolling so late is that it limits the total amount of time directed to perineal exercises. If labor begins early, a woman may have had little or no practice with this type of exercise.

Lamaze classes are kept small, so there is time for individual instruction and attention to each couple (Fig. 14.5). Advise a woman to bring the support person who will serve as her coach in labor to class with her to practice breathing exercises. Exercises taught vary from teacher to teacher, especially in terms of complexity, but have common features, which are discussed as follows.

**Figure 14.5** Every woman needs to be well prepared for birth. Here, a partner practices a position for pushing. Caution women not to actually push to avoid rupturing membranes.

### **Conscious Relaxation**

This is learning to relax body parts so, unknowingly, a woman does not remain tense

and cause unnecessary muscle strain and fatigue during labor. She practices **conscious relaxation** by deliberately relaxing one set of muscles, then another, and another until her body is completely relaxed. Her support person concentrates on noticing symptoms of tension such as a wrinkled brow, clenched fists, or a stiffly held arm. By either placing a comforting hand on the tense body area or telling a woman to relax that area, the support person can help her to achieve complete relaxation.

### The Cleansing Breath

To begin all breathing exercises, a woman breathes in deeply and then exhales deeply (**cleansing breath**). To end each exercise, she repeats this step. It is an important step to take because it limits the possibility of either hyperventilation (blowing off too much carbon dioxide) or hypoventilation (not exhaling enough carbon dioxide), both of which could happen with rapid breathing patterns and can interfere with an adequate fetal oxygen supply. If women do become light-headed during labor from hyperventilation (i.e., develop respiratory alkalosis), breathing into a paper bag can help because it causes rebreathing of exhaled carbon dioxide. The cleansing breath also signals to the woman's partner a contraction is about to begin or has ended.

### QSEN Checkpoint Question 14.3

#### EVIDENCE-BASED PRACTICE

One of the most controversial aspects of childbirth addresses the question of the best birth position for women to use. To evaluate the impact of birth position on maternal risk for obstetric anal sphincter injuries (OASIs), a study was conducted on data from the Stockholm-Gotland Obstetric Database, which included 113,279 singleton spontaneous vaginal births.

The results showed that the lowest risk for OASIS was in the standing position. The highest rates of OASIS were in the lithotomy position. Squatting and birth seat position did increase the risk for OASIS in women who had previously given birth (Elvander, Ahlberg, Thies-Langergren, et al., 2015).

Based on the previous study, what would the nurse like to see included in Elena's birth plan?

- "I don't want any medical interventions in labor, like an IV."
- "I want to labor the same way that you see women do it on TV and in movies."
- "I'm willing to try anything safe that will decrease my risk for tearing."
- "I'm afraid I'll get dizzy if I try to sit up or stand during labor."

*Look in Appendix A for the best answer and rationale.*

### Consciously Controlled Breathing

Using **consciously controlled breathing**, or set breathing patterns at specific rates,

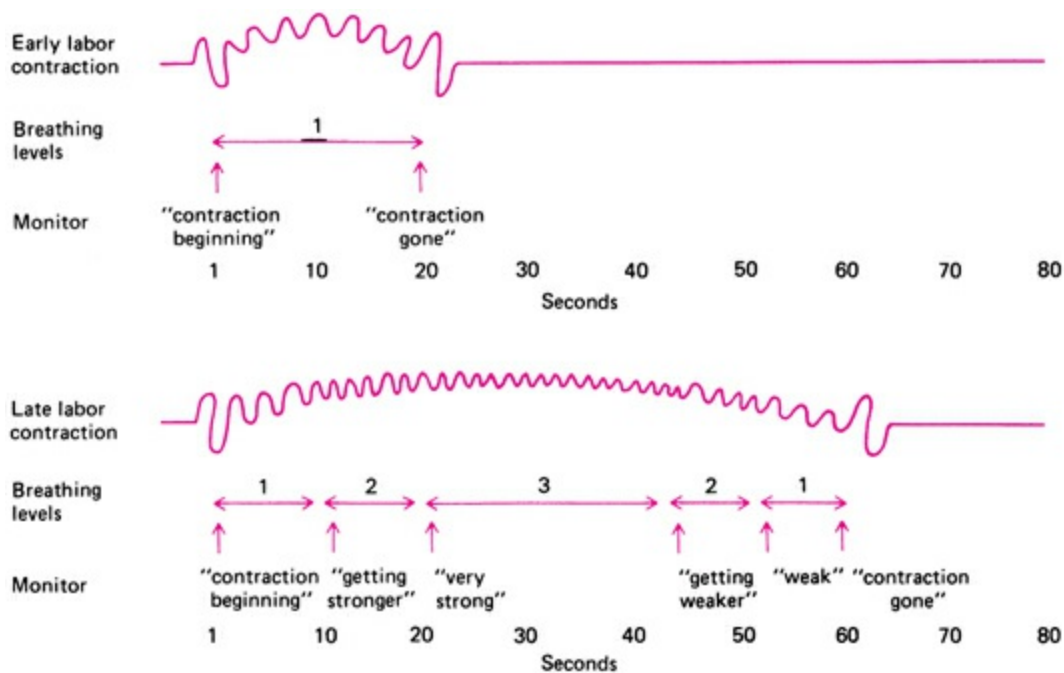

provides distraction as well as prevents the diaphragm from descending fully and putting pressure on the expanding uterus. To practice, after a cleansing breath, a woman inhales comfortably but fully, and then exhales, with her exhalation a little stronger than her inhalation (to help prevent hypoventilation). She practices breathing in this manner at a controlled pace, depending on the intensity of contractions through the following various levels of breathing:

- *Level 1.* Slow deep chest breathing of comfortable but full respirations at a rate of 6 to 12 breaths/min. This level is used for early contractions in labor when the cervical dilation is between 0 and 3 cm.
- *Level 2.* Lighter and more rapid breathing than level 1. The rib cage should expand but be so light that the diaphragm barely moves. The rate of respirations is up to 40 breaths/min. This is a good level of breathing for contractions when cervical dilation is between 4 and 6 cm.
- *Level 3.* Even more shallow and more rapid breathing. The rate is 50 to 70 breaths/min. As the respirations become faster, the exhalation must be a little stronger than the inhalation to allow good air exchange and to prevent hypoventilation. If a woman practices saying “out” with each exhalation, she almost inevitably will make exhalation stronger than inhalation. A woman uses this level for transition contractions when cervical dilation is between 7 and 10 cm. Keeping the tip of her tongue against the roof of her mouth helps prevent her oral mucosa from drying out during such rapid breathing.
- *Level 4.* Another pattern effective for transition contractions is a “pant-blow” pattern, or taking three or four quick breaths (in and out), then a forceful exhalation. Because this type of breathing sounds like a train (breath-breath-breath-huff), it is sometimes referred to as “choo-choo” or “hee-hee-hee-hoo” breathing.
- *Level 5.* Quiet, continuous, very shallow panting at about 60 breaths/min. This can be used during strong contractions or during the second stage of labor to prevent a woman from pushing before full dilatation.

Some courses stop teaching at the point a woman has mastered these levels of breathing; others have her learn to shift from one level to the other on command or at the point she feels a need for more pain relief.

Figure 14.6 illustrates the use of levels of breathing. At the beginning of a mild, early labor contraction, a woman’s coach says, “contraction beginning.” A woman takes a cleansing breath and then breathes at level 1; she feels no bite from the contraction and so does not need to change to a more involved breathing pattern. Later in labor, contractions are stronger and longer. Now, at the sound of “contraction beginning,” a woman takes a cleansing breath and then begins level 1 breathing (three breaths), shifts to level 2 (four to six breaths), and then shifts to level 3 (10 breaths). The contraction is lessening. She shifts down to level 2 (four to six breaths), then to level 1 (three or four breaths). The contraction is gone. She takes a final cleansing breath.

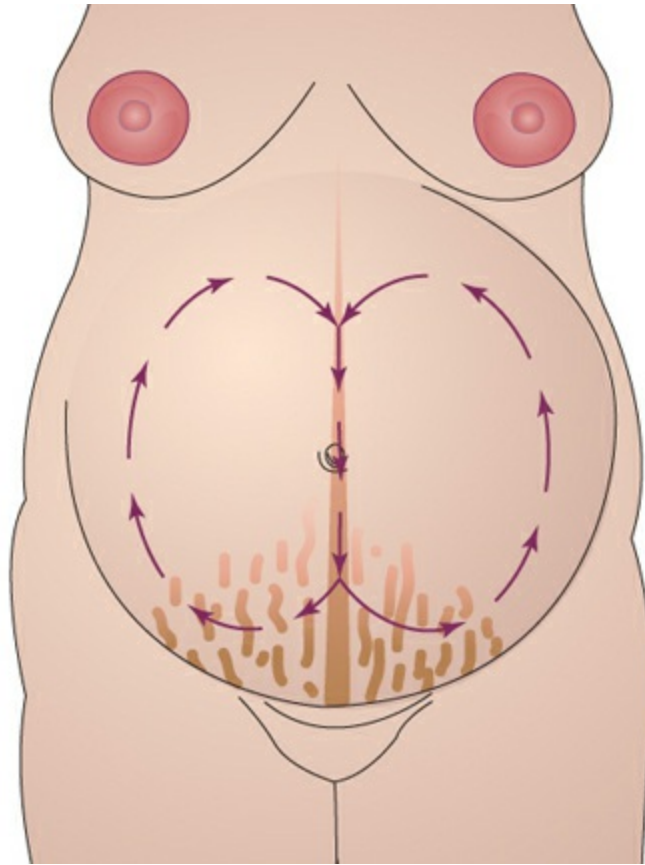

**Figure 14.6** An example of differing breathing patterns during a single contraction. 1, 2, and 3 are levels of breathing. A cleansing breath is taken at the beginning and end of the contraction.

During actual labor, her coach can tell the strength of contractions by resting a hand on her abdomen or observing a uterine contraction monitor. A coach can tell a woman when to shift breathing levels depending on the coach’s estimation of the strength of the contraction with words such as “contraction beginning, getting stronger, now getting weaker, gone.” In the time before transition to the second stage of labor, when contractions are longest and strongest, a woman may need to use her level 4 breathing or continuous light panting as well. A woman who can perform all five levels of breathing and maintain relaxation can be assured she is prepared to handle all labor contractions up to the second stage of labor (Lothian, 2014).

## **Effleurage**

One additional technique to encourage relaxation and displace pain in the Lamaze method is **effleurage**, which is French for “light abdominal massage”; it is done with just enough pressure to avoid tickling. To do this, a woman traces a pattern on her abdomen with her fingertips (Fig. 14.7). The rate of effleurage should remain constant even though breathing rates change. Effleurage serves as a distraction technique and decreases sensory stimuli transmission from the abdominal wall, helping limit local discomfort. If an external electronic monitor is in place on the abdomen, effleurage can be done superior or inferior to it or even on the thighs. Effleurage can also be done by the support person.

**Figure 14.7** Effleurage patterns. During uterine contractions, a woman traces a pattern on her bare abdomen with her fingers.

### **Focusing or Imagery**

Focusing intently on an object (sometimes called “sensate focus”) is another method of keeping sensory input from reaching the cortex of the brain (Chuang, Liu, Chen, et al., 2015). For example, a woman brings into labor a photograph of her partner or children, a graphic design, or just something that appeals to her like an ocean scene she can concentrate on during contractions. Other women use imagery by imagining they are in a calm place such as on a beach watching waves rolling in to them or relaxing on a porch swing (Fig. 14.8). Be careful not to step into a woman’s line of vision during a contraction to break her concentration on an object; also, don’t ask questions or try to talk to women while they are focused and breathing or you will break their concentration.

**Figure 14.8** A woman chooses what she wishes to focus on during labor. Here, a woman creates a playlist with music that she will focus on during contractions.

### Second-Stage Breathing

During the second stage of labor, when the baby is pushed down the birth canal, the type of breathing that is best to use is controversial. In the past, women were told to hold their breath while they pushed. Now, it is believed holding the breath for a prolonged time impairs blood return from the vena cava (a Valsalva maneuver), so this practice is now discouraged. Based on this, suggest women breathe any way that is natural for them, except holding their breath during this stage of labor.

*Women should not practice pushing during pregnancy or if in labor before the end of the first stage* because the possibility they could rupture membranes by doing this is too great. They can practice assuming a good position for pushing (e.g., squatting, sitting upright, leaning on partner) but should always be cautioned not to actually bear down and push.

#### **QSEN Checkpoint Question 14.4**

#### **INFORMATICS**

Elena's sister-in-law has referred her to a website that outlines the Lamaze method for labor and birth. What is the guiding principle of Lamaze childbirth?

- Pain can be interrupted before it registers in the brain as pain.
- Labor contractions are rooted in psychology, not physiology.
- "Brown pain" like labor contractions is unlike other forms of pain.

d. Labor contractions can be eliminated by learned mind control techniques.

*Look in Appendix A for the best answer and rationale.*

## PREPARATION FOR CESAREAN BIRTH

Some women choose to have a cesarean birth to help prevent uterine prolapse or urinary incontinence in later years (Black et al., 2016). To ensure a safe birth, a cesarean birth may become necessary during labor. The specific preparations needed for a cesarean birth as well as a VBAC is discussed in Chapter 24.

## The Birth Setting

Besides how to best prepare for labor, choosing a birth setting is another important decision that a couple needs to make during pregnancy (Alliman & Phillippi, 2016). This decision depends on a woman's health and that of her fetus, the couple's preferences, and how much and what kind of supervision they want for the birth. Although hospitals are the usual site for birth today in the United States, that has not always been true. Up until the late 1800s, childbirth was conducted in the home setting with little pain relief. Analgesia or anesthesia for childbirth first became popular when Queen Victoria birthed Prince Leopold under chloroform in 1853. Although chloroform relieved pain, it also complicated birth because not only were women asleep for one of the most memorable moments of their life but it also caused them to not be able to push effectively during the second stage of labor, thus making it necessary to use a lithotomy position, an episiotomy, and forceps for birth.

Part of the reason for giving so much anesthesia during birth can be attributed to healthcare providers misinterpreting the moment of birth as the time that produces the greatest degree of discomfort. As a result, women were allowed to labor without pain medication and then were given anesthesia or analgesia right before the baby was born. Although the pain felt at birth is intense, it is over quickly, unlike the hours of labor that precede it, making women not as uncomfortable during the actual birth as they are during labor. Birth is also such an exhilarating time that the excitement of the moment and natural perineal anesthesia can mask pain.

Fortunately, based on women's descriptions of the pain of childbirth, birthing practices have changed to better meet women's needs (Keirns, 2015). Nurses are in a strong position to advocate for making childbirth as "natural" a process as possible and conducted in the least restrictive setting possible. At the same time, nurses have a strong responsibility to encourage parents to respect any restriction that will allow the birth to remain safe.

## CHOOSING A BIRTH ATTENDANT AND SUPPORT PERSON

In the United States, most births are supervised by an obstetrician, a physician specializing in labor and birth; a family practitioner; or a nurse-midwife (Hamilton,

[Martin, Osterman, et al., 2015](#)). In addition to selecting who will medically supervise her baby's birth, many women choose a doula, or a person specially prepared to assist with birth. Doulas can be especially helpful as support people because having such a person present frees the father to enjoy the birth rather than feel occupied with coaching instructions. Although research in the subject is not extensive, there are suggestions that rates of oxytocin augmentation, epidural anesthesia, and cesarean birth can all be reduced by doula support ([Kozhimannil, Hardeman, Alarid-Escudero, et al., 2016](#)). With specific education, many nurses are participating as either a doula or special support nurse to women in labor.

## CHOOSING A BIRTH SETTING

Women who are low risk for complications may choose hospitals, birthing centers, or their homes as settings for birth. Women who might have a complication are advised to give birth at birthing centers or hospitals. Women with high-risk pregnancies are advised to give birth in hospitals where more immediate emergency care is available.

### The Hospital Birth

The maternity services of hospitals have changed a great deal in recent years, having been influenced by the Coalition for Improving Maternity Services (CIMS). This organization rates hospitals as to whether they are mother-friendly or not based on if a woman has the opportunity for any of the following:

- Experience a healthy and joyous birth experience, regardless of her age or circumstances
- Give birth as she wishes in an environment in which she feels nurtured and secure
- Have access to the full range of options for pregnancy, birth, and nurturing her baby
- Receive accurate and up-to-date information about the benefits and risks of all procedures, drugs, and tests suggested for use during pregnancy, birth, and the postpartum period, with the right to informed consent and informed refusal
- Receive support for making informed choices about what is best for her and her baby based on her individual values and beliefs ([CIMS, 2015](#)).

To qualify as a mother-friendly hospital, a hospital should not have routine policies that include practices for such things as perineal shaving, admission enemas, withholding food or fluid during labor, rupturing membranes to hurry labor, or the use of continuous intravenous lines or constant fetal monitoring. It also should have low rates of episiotomies, induction for labor, and cesarean births. In contrast, it should also have a high VBAC rate (60% or more [[CIMS, 2015](#)]). Urge women to ask their primary care provider if the hospital they recommend is rated as mother-friendly because this should influence both a couple's choice of a hospital and their birth attendant.

The major advantage of a hospital birth is that equipment and expert personnel are

readily available if the mother, fetus, or newborn should have a complication. When hospital birth is compared to births at alternative settings as to how many complications occur, women who give birth in hospitals invariably have more complications. Remember, though, that women at high risk for complications choose to give birth at hospitals so, of course, more complications will occur there.

A woman usually comes to the hospital when her contractions are approximately 5 minutes apart and regular in pattern. If she has preregistered at the hospital, she is admitted to a **birthing room** without any separation time from her support person. Birthing rooms are also called labor-birth-recovery rooms (LBRs) or **labor-birth-recovery-postpartum rooms (LBRPs)**. Such rooms are decorated in a homelike way, and couples can bring favorite music or reading materials with them to use during labor (Fig. 14.9).

**Figure 14.9** A birthing (labor-birth-recovery) room designed to maintain a homelike atmosphere in a hospital setting.

Women are expected to use a prepared method of childbirth with a minimum of analgesia and anesthesia (although an advantage of a hospital birth is that anesthesia such as an epidural is readily available if needed). The woman's partner or other family members can stay with her throughout labor and birth, allowing a couple and their families to feel they have control over and can share in the birth experience. The bed is

used as a labor bed until birth, when it is then converted into a **birthing bed**. Women can choose a birthing position: squatting, supine with head raised, or side-lying. Woman can choose to use a supine recumbent position (on her back with knees flexed) rather than a lithotomy position (legs elevated into stirrups) because such a position reduces tension on the perineum and is not only more comfortable but also may result in fewer perineal tears than with a lithotomy position.

Following birth, additional cabinets in the room are opened and converted into a space for baby care. A support person can cut the umbilical cord if desired. The mother is encouraged to breastfeed immediately. Some hospitals screen women in early labor with an external monitor to evaluate both fetal heart rate and uterine contractions. If the fetal heart rate is good, monitors are then removed and a simple Doppler monitor is used if any periodic screening is needed as labor progresses.

A **birthing chair**, a comfortable reclining chair with a slide-away seat that allows a woman to assume a comfortable position during labor and also furnishes perineal exposure so a birth attendant can assist with the birth, could also be used (Fig. 14.10). The chair has the advantage of maintaining a woman in a semi-Fowler's position, a position that acts with gravity and so may speed the second stage of labor.

**Figure 14.10** (A) A birthing chair allows a woman to maintain a semi-Fowler's position. (B) A birthing chair used during labor. (© Caroline Brown, RNC, MS, DEd.)

## Postpartum Care

Women giving birth in LBRPs remain in the room with their families for the rest of their hospital stay. Women giving birth in birthing rooms may be transferred to a postpartum unit after birth where they remain for the length of their hospital stay. Both LBRPs and postpartum units serve as “rooming-in” units in which the infant remains in the mother's room either constantly or for most of the day, whichever is her choice. Urge a couple to keep their newborn with them as much as possible so they have ample time to become acquainted and learn their baby's cues for hunger. Mothers can then breastfeed when the infant is hungry, not according to any schedule. There should be no restrictions on visiting for the primary support person; in many institutions, a rollaway bed can be provided so that the partner can remain constantly. Siblings and friends of

the newborn should be allowed to visit as much as the mother chooses. Mother and infant remain in the hospital up to 48 hours and are then discharged home.

### *QSEN Checkpoint Question 14.5*

#### **TEAMWORK & COLLABORATION**

Elena wants to use controlled breathing for early labor and the nurse is reviewing with her doula the actions that Elena will take. What should the nurse review with Elena's doula about controlled breathing early in labor?

- She should try to breathe exclusively through her nose.
- She should breathe as rapidly as possible to distract from early contractions.
- If hypoventilation occurs, she should begin to sip on ice water.
- She should breathe at a rate of 6 to 12 breaths/min for mild contractions.

*Look in [Appendix A](#) for the best answer and rationale.*

### **Alternative Birthing Centers**

**Alternative birthing centers (ABCs)** are wellness-oriented childbirth facilities designed to remove childbirth from the acute care hospital setting while still providing medical resources for emergency care should a complication of labor or birth arise. These settings are established inside, next door, or at least within an easy distance to a hospital. The primary birth attendants tend to be nurse-midwives. Because the facility is located outside an acute care setting, where infections abound, the risk of hospital-acquired infection to a woman is thought to be reduced. Women who deliver in ABCs are screened for potential complications before being rated as eligible for admittance. Because of this, the mortality rate of mothers and infants is no higher and may be lower in these out-of-hospital settings than in hospital settings.

Like hospitals, ABCs have LBRPs where a woman and her support person can invite friends and siblings to participate in the birth. In some centers, a central play area for siblings and cooking facilities are also available. ABCs encourage a woman to express her own needs and wishes during the labor process. A minimum of analgesia and anesthesia is provided, and she can choose a birth position. She can bring her own music or distraction objects, and the partner can perform such tasks as cutting the umbilical cord if he or she chooses.

Women remain in an ABC from 4 to 24 hours after birth. Because minimum analgesia or anesthesia is used, a woman recovers quickly after birth and is ready to be discharged early. [Box 14.10](#) shows an interprofessional care map illustrating both nursing and team planning for a birthing center experience.

## BIRTH AT AN ALTERNATIVE BIRTH CENTER

Elena Garza is pregnant with her second child. During her first pregnancy, she did not attend any childbirth classes and received an epidural for the birth. During a prenatal visit for this pregnancy, Elena tells you she would now like to have a more natural birth in a birthing center. She asks you for information on childbirth education classes. Her partner, Joe, a Navy Seal, wants Elena to go to the hospital and have an epidural like she did with her last pregnancy. After further speaking with Joe, you discover he doesn't want Elena to go through the pain of natural childbirth because he fears he may be out of town when she is in labor.

**Family Assessment:** Elena and Joe live with 4-year-old Josh in an apartment in central downtown. Elena is a stay-at-home mom. Depends on Joe for financial help.

**Patient Assessment:** Pregnancy progressing without evidence of problems or complications. Gravida 2, para 1, 24 weeks gestation. Patient states she wants to use alternative birth center (ABC) but has not contacted one yet; reports concern over previous hospital birth of son. Wants son Josh, now 4 years old, to be a part of new baby's birth. Her sister has volunteered to serve as a doula. Wants to walk during labor and have a ready supply of "anything chocolate" to eat. No childbirth education classes attended with previous pregnancy; not presently enrolled in any with this pregnancy.

**Nursing Diagnosis:** Decisional conflict related to choice of birth setting and birth process

**Outcome Criteria:** Patient and partner state advantages and disadvantages of birth setting options and make final plans for birth and birth setting by 3 weeks' time.

Patient and partner verbalize goal of healthy mother and baby as motivation for choice of birth setting.

Team Member	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Investigate the type of birth facilities available in local area.	Review the requirements, advantages, and disadvantages for birth setting choices available.	Reviewing options allows the couple to make an informed decision appropriate for their needs.	Patient and partner state they have reviewed and understand options available to them.
Nurse	Ask couple if they have plans for child care of	Suggest that couple ask a family member	A caretaker can enhance the experience for	Couple states Elena's mother will serve as

	Josh during labor.	to be caretaker for son during the birth.	the older child by promoting a positive, family-centered event.	caretaker for Josh.
<i>Teamwork and Collaboration</i>				
Nurse/nurse-midwife	Assess what family expects of a doula for labor.	Review responsibilities of a doula with Elena's sister.	Doulas can offer strong support in labor; prearrangements help assure everyone has the same labor and birth goals.	Couple confirms they are pleased with sister serving as a doula.
<i>Procedures/Medications for Quality Improvement</i>				
Nurse/obstetric care provider	Determine if there are any contraindications to active positioning such as walking or swaying during labor.	Educate patient about the few situations, such as placenta previa, that would contradict walking in labor.	Using active positions during labor such as walking has the potential to decrease the time of labor unless contraindicated.	Patient states she will be flexible with regard to wishes in labor based on her own and fetal safety but wants a site that welcomes active movement.
<i>Nutrition</i>				
Nurse	Assess whether patient's chosen food option during labor is approved by ABC chosen.	Help patient modify her goals for nutrition during labor as appropriate based on facility requirements.	Because many choices for food exist, coordinating plans with the facility should result in less stress during labor.	Patient confirms eating chocolate is agreeable with chosen agency.
<i>Family-Centered Care</i>				
Nurse	Obtain information about local	Assist couple as necessary with selecting class	Education can enhance the chances of a	Patient attends the chosen childbirth

	childbirth education classes available.	that fits their resources.	positive childbirth experience.	preparation class before the 38th week of pregnancy.
Nurse	Assess if any classes for sibling preparation for birth are available in community.	Help couple plan for mother and son to attend class on sibling preparation for birth or meet with nurse for instruction.	Adequate preparation for all involved improves the chances of a positive experience.	Couple states they will either attend a class for sibling preparation or meet with nurse for information.

### *Psychosocial/Spiritual/Emotional Needs*

Nurse/nurse-midwife	Explore with patient and partner past experiences with childbirth and current expectations and beliefs.	“Debriefing” or encouraging couple to verbalize feelings about unsatisfactory experience helps to alleviate distress.	Verbalization of feelings permits a safe outlet for emotions.	Couple states their overall goal for childbirth is a safe one for mother and new child and so will be flexible if a complication arises.
---------------------	---	---	---	--

### *Informatics for Seamless Healthcare Planning*

Nurse	Assess if couple has any further questions about birth centers.	Ascertain couple has phone number for and directions to chosen birthing center.	Advance planning can help avoid increased stress at time of birth.	Couple states they are happy with birth setting decision and prepared to follow through on plans.
-------	---	---	--	---

### ***QSEN Checkpoint Question 14.6***

#### **QUALITY IMPROVEMENT**

Suppose Elena follows her boyfriend’s wishes and decides on a hospital birth. What would be an advantage of hospital birth that can be cited to women considering this birth setting?

- a. She can give birth in a sterile environment.
- b. Both labor and childbirth can generally be pain-free.

- c. Extended high-risk newborn care is available.
- d. Hospital care costs are lower than other settings.

*Look in Appendix A for the best answer and rationale.*

## Home Birth

Home birth is the usual mode of birth in developing countries and is also a popular choice for birth in Europe; however, only about 1% of women in the United States choose this method (MacDorman et al., 2014). Home birth may be supervised by a physician, but nurse-midwives are the more likely choice as a birth attendant in this setting. The Frontier Nursing Service of Kentucky is an example of an organization in the United States that maintains an active and well-accepted program of home birth.

Most women who choose home birth are well educated and from middle-income families. They choose home birth so they are not separated from their family for even a short time; they can have their baby close by after birth to help integrate the child into the family; they can have more control over their childbirth experience; and they can give birth in familiar, low-cost surroundings.

Home birth can have a disadvantage in that it puts responsibility on a woman to prepare her home for the birth and to give full care to the infant after birth. Some women, however willing, may be unable to take on these roles because, passing through their first postpartum or “taking-in” phase, they may feel more comfortable maintaining a dependent-passive role than immediately taking responsibility for the infant’s care. They also may feel exhausted from their last weeks of pregnancy or they don’t know the best recourse in a crisis situation.

To be a candidate for a home birth, a woman:

- Should be in good overall health
- Must be able to adjust to changing circumstances
- Must have adequate support people to sustain her during labor and to assist her for the first few days after birth

Women with any complication of pregnancy are not good candidates for home birth. Be certain women planning home birth know the following:

- Adequate equipment other than first-line emergency equipment will not be available.
- An abrupt change of goals may be necessary if a complication occurs.
- Both she and her support person may become exhausted because of the responsibility placed on them during labor or the postpartum period.
- She must be prepared to independently monitor her postpartal status.
- Interference with the “taking-in phase” may occur postpartally because she must “take hold” rather than allow herself a rest phase.

### Concept Mastery Alert

The best candidates for home birth are healthy women who can adjust to changing

circumstances and who have adequate support systems. A woman who chooses home birth should be interested in learning all she can to prepare for the birth.

## CHILDREN ATTENDING BIRTH

Most birthing centers and some hospitals allow children to view the birth of a sibling. It is good advice to suggest that parents and siblings attend a class designed to prepare children to witness a birth beforehand to keep the event from becoming overwhelming. If children will be present, a person separate from the main support person needs to be designated to provide entertainment, explanations, food, and a place for them to nap. This prevents the likelihood that a child who is without supervision during this time will remember the experience as one of rejection rather than an exciting, happy experience. The mother should not be expected to provide such supervision during labor because she will want to concentrate on distraction or breathing techniques.

Help couples to consider whether the birth experience will be a positive and enjoyable one for the family based on the sibling's developmental level and stage. Allowing a child to witness the birth of kittens or puppies might be an alternative way to expose the child to birth.

## Alternative Methods of Birth

In addition to varied settings, several methods of childbirth are popular. These include alternative birth methods such as the Leboyer method of birth, birth under water, and unassisted birthing.

### THE LEBOYER METHOD

Frederick Leboyer was a French obstetrician who postulated moving from a warm, fluid-filled intrauterine environment to a noisy, air-filled, brightly lit birth room creates a major shock for a newborn (Leboyer, 2009). With the **Leboyer method**, the birthing room is darkened so there is no sudden contrast in light; the environment is kept pleasantly warm, not chilled; soft music is played, or at least harsh noises are kept to a minimum; the infant is handled gently; the cord is cut late; and the infant is placed immediately after birth into warm bath water.

Some neonatologists question the wisdom of a warm bath because it could reduce spontaneous respirations and allow a high level of acidosis to occur. Late cutting of the cord supplies extra white blood cells to a baby so the newborn can increase resistance to disease but it also could lead to excess blood viscosity. Certainly, soft music, gentle handling, and a welcoming atmosphere are important ingredients for all birth attendants to incorporate into birth. Providing dim lights (or at least not bright, glaring ones) and providing a warm temperature could be given more consideration in most institutions.

### *What If . . . 14.3*

**Elena wants to have a Leboyer birth. How would the nurse prepare her birthing room?**

---

## **HYDROTHERAPY AND THE WATER BIRTH**

Reclining or sitting in warm water during labor can be soothing; the feeling of weightlessness that occurs under water as well as the relaxation from the warm water both can contribute to reducing discomfort in labor. Using this principle, many birthing settings encourage women to not only labor in warm showers or tubs but also to give birth in spa tubs of warm water (Davies, Davis, Pearce, et al., 2015). Women need to ask if this will be an option at their birth setting if they are interested. One disadvantage is that because most women expel feces from pushing in the second stage of labor, the water bath may become contaminated. Most women who choose underwater birth, however, enjoy the experience and are pleased that they chose this method (Koyyalamudi, Sidhu, Cornett, et al., 2016).

## **UNASSISTED BIRTHING**

Unassisted birthing, freebirthing, or couples birth refers to women giving birth without healthcare provider supervision (Snowden, Tilden, Snyder, et al., 2015). It differs from home birth because, using this technique, a woman learns pregnancy care from reading books or articles found on the Internet and then arranges to have her child birth at home, perhaps accompanied by her family or friends, but without healthcare supervision.

Some women choose this method of birth because they believe birth is such a natural process that no medical supervision is necessary. Others choose it because they have no health insurance and so can't afford either a hospital or alternative birth setting (Snowden et al., 2015). Unassisted birthing is potentially dangerous because, if a complication should occur, the woman may not recognize that what is happening is serious until damage to her child or herself results. Even if she recognizes that a problem is occurring, there is a gap of time before emergency help can arrive to assist her, which puts her at risk for harm. Unassisted birthing is particularly dangerous if a woman avoids prenatal care or depends solely on online information because she may be at high risk for a complication but not know it. Educating women that not all online information is reliable and that supervised birth does not mean they have no choice in their care decisions, such as whether they want pain relief or to use a special position for birth, is an effective way to help women make safer choices about birth.

## **Women With Unique Needs**

There are a number of women who have special needs related to preparations for childbirth.

### **THE WOMAN WITH A DISABILITY**

Care of women with disabilities during pregnancy is discussed in [Chapter 22](#). Women with these special circumstances may need additional help to prepare for labor and birth based on their unique concern. It may not be realistic, for example, for a woman who has chronic back pain to practice pelvic rocking; a woman with poor balance may not be able to practice squatting safely. A woman who is immobile or in a wheelchair may have difficulty attending a preparation class if the classroom is not located in a handicapped-accessible building. Women with vision or hearing disabilities can have difficulty following classroom content. A highly stressed woman may not have the patience to concentrate on learning controlled breathing.

Encourage women with special needs to think through any circumstance that will require special adaptation and be certain they include this requirement in their birth plan.

### **THE WOMAN WITH CULTURAL CONCERNS**

Because the United States has such a diverse mixture of cultures, a preparation for labor and birth class can include women from a diverse mix of cultures. Urging women to share cultural traditions enriches discussions at such classes. Be certain to encourage women who are worried that their cultural preferences will not be respected when they are in labor to discuss their concerns with their primary care provider at their next visit. A woman who believes in circumcision as a religious necessity, for example, does not want to listen to a discussion on the pros and cons of circumcision. A woman who wants to be fully clothed during labor may need to plan on bringing her own nonrevealing gown to a birthing center, and she may not want to be offered showering or tub bathing as pain management because these will not respect modesty. Be certain women include these special needs in their written birth plan so they are not overlooked by busy labor service personnel.

### **THE WOMAN WHO IS OBESE**

Women with a body mass index over 30 may have difficulty practicing exercises such as squatting or tailor sitting because not only do these positions require balance but they also may tire easily. Overweight women should, however, have no difficulty preparing for labor by practicing controlled breathing or doing abdominal and perineal strengthening by doing exercises such as Kegel or abdominal contractions. Urge women to think through what pain management measures they think may cause a problem for them in labor such as leaning forward against a birthing bar or a birthing ball or bathing in warm water (the bar or ball or a plastic tub might not support their weight). For modesty, they may also need to bring their own gown to their birthing center.

Encourage women to add what will be important for them to do or not to do on their birthing plan so they remain active participants in the experience.

#### *What If... 14.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals with respect to preparation for labor (see Box 14.1). What would be a possible research topic to explore pertinent to this goal that would be applicable to Joe and Elena and that would also advance evidence-based practice?**

### **KEY POINTS FOR REVIEW**

- Couples should be encouraged to make a flexible childbirth plan early in pregnancy, which includes a birth attendant, setting, desired method of pain management, and any special wishes.
- Common exercises taught in pregnancy to strengthen perineal muscles are tailor sitting, squatting, and Kegel exercises. Abdominal muscle contraction and pelvic rocking exercises both strengthen the abdominal muscles and help relieve backache.
- Types of childbirth preparations include the Bradley (partner coached), Kitzinger (psychosexual), Dick-Read, and Lamaze methods. Lamaze is the most common method used in the United States.
- Commonly used nonpharmacologic techniques for pain relief in labor are conscious relaxation, consciously controlled breathing, effleurage, focusing, imagery, and hydrotherapy.
- Classes for expectant parents provide information on pregnancy, birth, and child care.
- Common sites for childbirth include hospitals, ABCs, and home settings.
- Couples should determine if their preferred birth setting is rated as mother-friendly before choosing a birth site.
- Considering childbirth as one of the biggest events in a woman's life should help in planning nursing care that not only meets QSEN competencies but also best meets the family's total needs.

### **CRITICAL THINKING CARE STUDY**

Brooke is a 28-year-old woman having her first baby. She has worked as a nurse on a labor and delivery service for the past 3 years. She didn't take a preparation for childbirth class because she felt no material would be presented she didn't already know. She doesn't feel she needs a doula because she has had so much experience with women in labor. Her husband will be with her during labor.

1. Brooke's husband asks you at a prenatal visit if he should time contractions in labor with his watch or by the wall clock. Also, he asks if it will be all right if

Brooke drinks coffee during labor. Why do you think he's asking so many basic questions?

2. Brooke's mother tells you she knows she can't be with Brooke in labor but she wants special permission to hold her new grandson before he's taken away to a nursery. She also wants to make it clear she needs to do that before her ex-husband or his "fluffy" girlfriend have a chance to hold the baby. Does Brooke's mother understand the options available to her in a mother-friendly hospital?
3. Brooke doesn't seem to have shared much information about labor with her family. Can you assume this is because she's so independent she wants to manage her labor by herself, or would you worry she doesn't have a strong support system?

# 15

## Nursing Care of a Family During Labor and Birth

*Celeste Bailey is a 26-year-old woman having her first baby whom you admit to a birthing room. She has been having labor contractions for 6 hours; her contractions are now 45 seconds long and 3 minutes apart. She tells you she wants to have her baby “naturally” without any analgesia or anesthesia. Her husband, a long distance truck driver, is on his way home but has not arrived yet. Her teenage sister who is with her states she has no idea how to coach her, except to pray. As you finish assessing contractions, Celeste grips her abdomen, screams, and shouts, “I’m breathing just like I’m supposed to do! Why does this hurt so bad?”*

*Previous chapters discussed the anatomic and physiologic changes that occur in pregnancy as well as effective steps women can take to prepare for labor. This chapter adds information about the process of labor and how to offer effective support and education to a woman in labor. Without this type of support, labor can be a frightening rather than an enjoyable event.*

**What additional teaching and support does Celeste need so her labor and birth are memorable experiences for her?**

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe common theories explaining the onset of labor and the role of passenger, passage, powers, and psyche in labor.
2. Identify 2020 National Health Goals related to safe labor and birth that nurses can help the nation achieve.
3. Assess a family in labor and birth and identify the woman's readiness, stage, and progression.
4. Formulate nursing diagnoses related to the physiologic and psychological aspects of labor and birth.
5. Develop expected outcomes to meet the needs of a family throughout the labor process as well as manage seamless transitions across differing healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care for a family during labor such as teaching about the stages of labor.
8. Evaluate expected outcomes for achievement and effectiveness of care.
9. Integrate knowledge of labor and birth with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

Labor is the series of events by which uterine contractions and abdominal pressure expel a fetus and placenta from the uterus. Regular contractions cause progressive dilatation of the cervix and create sufficient muscular uterine force to allow a baby to be pushed out into the extrauterine world. Labor represents a time of change as it is both an ending and a beginning for the woman, her fetus, and her family ([Archie & Roman, 2013](#)).

Labor and birth are unique events, requiring a woman to employ all the psychological and physical coping methods she has available. Regardless of the amount of childbirth preparation or the number of times a woman has been through the birth experience, family-centered nursing care is the approach that best supports the woman

as she focuses on the beginning of her new family. This goal for nursing is further emphasized by 2020 National Health Goals ([Box 15.1](#)).

## BOX 15.1

### Nursing Care Planning Based on 2020 National Health Goals

Because labor and birth are potentially high-risk times for both a fetus and a mother, a number of 2020 National Health Goals speak directly to these:

- Reduce the rate of maternal deaths to no more than 11.4 out of 100,000 live births from a baseline of 12.7 out of 100,000 live births.
- Reduce maternal illness due to pregnancy complications developed during hospitalized labor and delivery from a baseline of 31.1% to a target level of 28.0%.
- Reduce cesarean births among low-risk (full-term, singleton, vertex presentation) women from a baseline of 26.5% to a target of 23.9%.
- Reduce the rate of fetal deaths at 20 or more weeks gestation to no more than 5.6 out of 1,000 live births from a baseline of 6.2 out of 1,000.
- Reduce the rate of fetal and infant deaths during the perinatal period (28 weeks gestation to 7 days after birth) to no more than 5.9 out of 1,000 live births from a baseline of 6.6 out of 1,000 live births ([U.S. Department of Health and Human Services, 2010](#); see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these goals by closely monitoring women during labor and birth and by teaching women as much as possible about labor so they are able to use as little analgesia and anesthesia as possible. The less anesthesia and analgesia used, the fewer complications that occur, resulting in reduced fetal or maternal death.

### *Nursing Process Overview*

#### FOR THE WOMAN IN LABOR

##### **ASSESSMENT**

A woman in labor is keenly aware of both nonverbal and verbal expressions around her (i.e., not only words spoken but gestures such as eye rolling or sighing). Because of this sensitivity, an assessment must be done quickly yet thoroughly and gently because she may have difficulty being patient, for example, while admission information is obtained or relaxing for a vaginal examination.

Remember that pain is a subjective symptom. Only the woman can evaluate how much she is experiencing or how much she wants to endure. Assess how much discomfort she is experiencing and how she feels about her labor not only by what she scores on a pain scale but also by subtle signs of pain such as facial tenseness, flushing or paleness of the face, hands clenched in a fist, rapid breathing, or rapid

pulse rate. Appreciate that the fetus as well as the mother is under stress from the process of labor, so both need vital sign assessments.

### **NURSING DIAGNOSIS**

Nursing diagnoses in labor generally relate to a woman's reaction to labor. Common nursing diagnoses include:

- Pain related to labor contractions
- Anxiety related to process of labor and birth
- Health-seeking behaviors related to management of discomfort of labor
- Situational low self-esteem related to inability to use planned childbirth method

Although the discomfort of labor contractions is commonly referred to as “contractions” rather than “pain,” do not omit the word “pain” from a nursing diagnosis because the term strengthens an understanding of the problem as well as alerts a woman she should feel free to ask for something for pain at the point she feels she needs additional help.

### **OUTCOME IDENTIFICATION AND PLANNING**

When establishing expected outcomes for a woman in labor and her partner, be certain they are realistic and that they can be met. Although labor usually takes place over a relatively short time frame (average, 12 hours), it is important not to project a definite time limit for labor to be completed because the length of labor can vary greatly from woman to woman and still be within normal limits. It is necessary also to appreciate the magnitude of labor. It is unlikely all the fear or anxiety experienced during a woman's labor can be completely alleviated. Often, because it is such an unusual and significant experience, the average couple may need guidance in order to be able to employ additional coping measures.

Be certain to incorporate a support person as well as the woman in planning so the experience is a shared one. Although a couple may have learned about the stages of labor and what to expect at each stage during pregnancy, the reality of labor may seem very different from what they imagined. Be certain also that planning is flexible and individualized, allowing the woman to experience the full significance of the event.

### **IMPLEMENTATION**

As much as possible, interventions during labor should always be carried out between contractions so the woman can use a prepared childbirth technique to limit the discomfort of contractions. This calls for good coordination of care among healthcare providers and the woman and her support person. The person a woman chooses to stay with her during childbirth is often culturally determined and varies from being a husband, a significant other or partner, the father of the child, a sister, a parent, or a close friend.

### **OUTCOME EVALUATION**

An evaluation during labor should be ongoing to preserve the safety of the woman

and her newborn. After birth, an evaluation helps to determine the woman's opinion of her experience with labor and birth. Ideally, the experience should not only be one she was able to endure but also one that allowed her self-esteem to grow and the family bond to intensify through a shared experience. It is advantageous to talk to women following birth about their labor experience because doing so serves as a means of evaluating nursing care during labor. It also provides a woman the chance to "work through" the experience and incorporate it into her self-image. Possible outcome criteria include:

- Patient states pain during labor was tolerable because of her advance preparation.
- Patient verbalizes that her need for nonpharmacologic comfort measures was met.
- Patient and family members state the labor and birth experience was a positive growth experience for them, both individually and as a family.

## Theories of Why Labor Begins

Labor normally begins between 37 and 42 weeks of pregnancy, when a fetus is sufficiently mature to adapt to extrauterine life, yet not too large to cause mechanical difficulty with birth. In some instances, labor begins before a fetus is mature (preterm birth). In others, labor is delayed until the fetus and the placenta have both passed beyond the optimal point for birth (postterm birth).

A number of factors are known to be responsible for the initiation of spontaneous labor, although much is still unknown. Factors such as withdrawal of progesterone, an increase of prostaglandins, and other complex biochemical markers have shown to be at work ([Irani & Foster, 2015](#)).

A number of theories, including a combination of factors originating from both the woman and fetus, have been proposed to explain why progesterone withdrawal begins. Some of the theories include:

- The uterine muscle stretches from the increasing size of the fetus, which results in release of prostaglandins.
- The fetus presses on the cervix, which stimulates the release of oxytocin from the posterior pituitary.
- Oxytocin stimulation works together with prostaglandins to initiate contractions.
- Changes in the ratio of estrogen to progesterone occurs, increasing estrogen in relation to progesterone, which is interpreted as progesterone withdrawal.
- The placenta reaches a set age, which triggers contractions.
- Rising fetal cortisol levels reduce progesterone formation and increase prostaglandin formation.
- The fetal membrane begins to produce prostaglandins, which stimulate contractions ([Bienstock, Fox, & Wallach, 2015](#)).

The role of prostaglandins answers the often asked question: Does coitus help

induce labor? Semen does contain prostaglandins, which can be helpful in softening, also known as “**ripening**,” of the cervix; if a cervix is ready to ripen, semen prostaglandins could possibly stimulate the beginning of contractions. Rhythmical contractions brought on by a woman’s orgasm can conceivably help as well, although, again, not until a uterus is prepared and ready for labor.

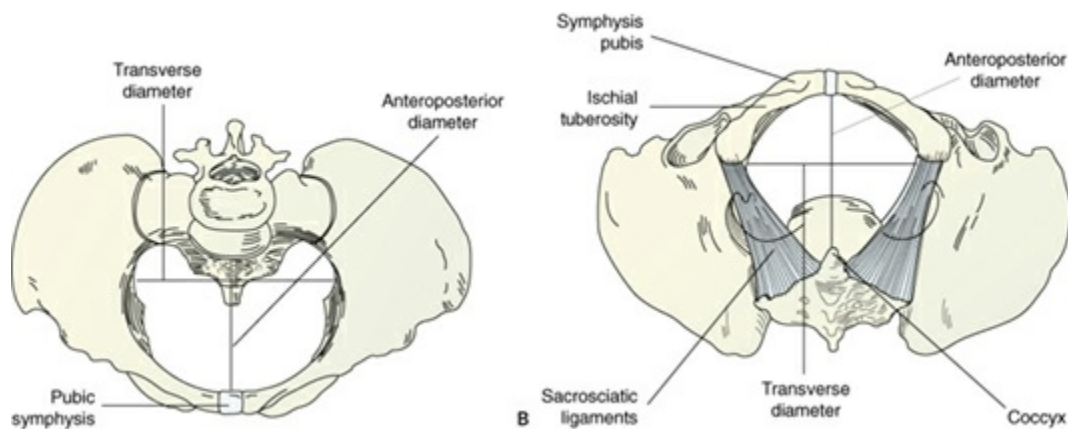

## The Components of Labor

A successful labor depends on four integrated concepts, often referred to as the four *Ps*:

1. The *passage* (a woman’s pelvis) is of adequate size and contour.
2. The *passenger* (the fetus) is of appropriate size and in an advantageous position and presentation.
3. The *powers* of labor (uterine factors) are adequate.
4. The *psyche*, or a woman’s psychological state which may either encourage or inhibit labor. This can be based on her past life experiences as well as her present psychological state.

### THE PASSAGE

The passage refers to the route a fetus must travel from the uterus through the cervix and vagina to the external perineum (Fig. 15.1).

**Figure 15.1** Views of the pelvic inlet and outlet: (A) the pelvic inlet, (B) the pelvic outlet.

In most instances, if a disproportion between fetus and pelvis occurs, the pelvis is the structure at fault. If the fetus is the cause of the disproportion, it is often not because the fetal head is too large but because it is presenting to the birth canal at less than its narrowest diameter. Keep this in mind when discussing with parents why an infant may not be able to be born vaginally. It can be upsetting for parents to learn that a child cannot be born vaginally because the mother’s pelvis is too small. It can be much more upsetting to think their infant’s head is too large because it implies something may be seriously wrong with their baby (and that is rarely true). Avoiding this type of negative

thought helps promote good parent–child bonding.

## **THE PASSENGER**

The passenger is the fetus. The body part of the fetus that has the widest diameter is the head, so this is the part least likely to be able to pass through the pelvic ring. Whether a fetal skull can pass depends on both its structure (bones, fontanelles, and suture lines) and its alignment with the pelvis.

### **Structure of the Fetal Skull**

The cranium, the uppermost portion of the skull, is composed of eight bones. The four superior bones—the frontal (actually two fused bones), the two parietal, and the occipital—are the bones important in childbirth. The other four bones of the skull (sphenoid, ethmoid, and two temporal bones) lie at the base of the cranium and so are of little significance in childbirth because they are never presenting parts ([Fig. 15.2](#)).

**Figure 15.2** The fetal skull: (A) the lateral view, (B) the vertex view.

Fontanelle spaces compress during birth to aid in molding of the fetal head. Their presence can be assessed manually through the cervix after the cervix has dilated during labor. Palpating for fontanelle spaces during a pelvic examination helps to establish the position of the fetal head and whether it is in a favorable position for birth.

### Diameters of the Fetal Skull

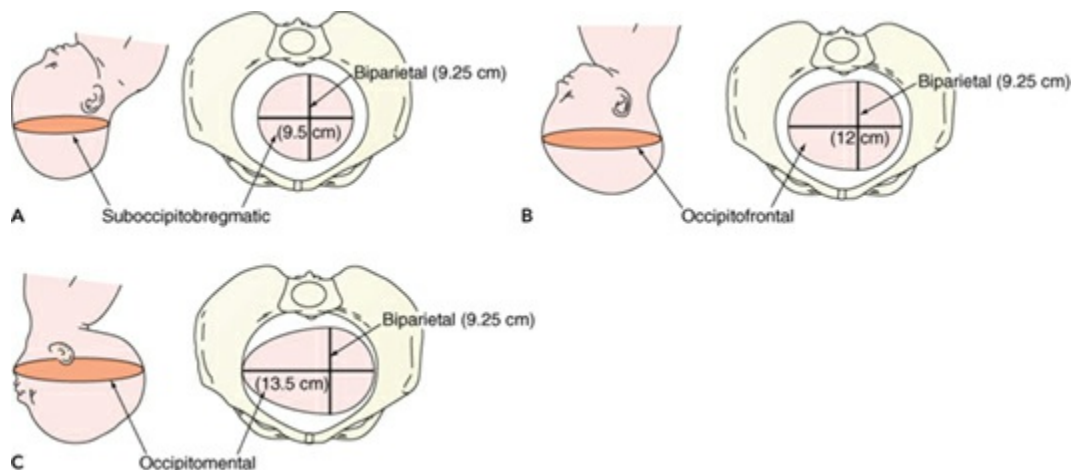

The shape of a fetal skull causes it to be wider in its anteroposterior diameter than in its transverse diameter. To fit through the inlet of the birth canal best, a fetus must present the smaller diameter (the transverse diameter) of the head to the smaller diameter of the maternal pelvis (the diagonal conjugate); otherwise, progress can be halted and vaginal birth may not be possible. The diameters of the fetal skull vary depending on where the measurement is taken (Fig. 15.2A).

- The smallest diameter of the fetal skull is the biparietal diameter or the transverse diameter, which measures about 9.25 cm.
- The smallest anteroposterior diameter is the suboccipitobregmatic measurement (approximately 9.5 cm) and is measured from the inferior aspect of the occiput to the center of the anterior fontanelle.
- The occipitofrontal diameter, measured from the occipital prominence to the bridge of the nose, is approximately 12 cm.
- The occipitontal diameter, which is the widest anteroposterior diameter (approximately 13.5 cm), is measured from the posterior fontanelle to the chin.

The anteroposterior diameter of the pelvis, a space approximately 11 cm wide, is the narrowest diameter at the pelvic inlet, and so the best presentation for birth is when the fetus presents a biparietal diameter (the narrowest fetal head diameter) to this (see [Fig. 15.2B](#)). At the outlet, the fetus must rotate to present this narrowest fetal head diameter (the biparietal diameter) to the maternal transverse diameter, a space, again, approximately 11 cm wide.

- If a fetus presents one of the anteroposterior diameters of the skull to the anteroposterior diameter of the inlet, engagement, or the settling of the fetal head into the pelvis, may not occur.
- If the fetus does not rotate, leaving the anteroposterior diameter of the skull presenting to the transverse diameter of the outlet, an arrest of progress may occur.

Which anteroposterior diameter that presents to the birth canal is determined not only by rotation but also by the degree of flexion of the fetal head ([Fig. 15.3](#)).

**Figure 15.3** (A) Complete flexion allows the smallest anteroposterior diameter of the head to enter the pelvis. (B) Moderate flexion causes a larger diameter to enter. (C) Poor flexion forces the largest diameter against the pelvic brim so the head is too large to enter the pelvis.

- In full flexion, the fetal head flexes so sharply that the chin rests on the chest, and the smallest anteroposterior diameter, the suboccipitobregmatic, presents to the

birth canal.

- If the head is held in moderate flexion, the occipitofrontal diameter presents.
- In poor flexion (the head is hyperextended), the largest diameter (the occipitomenal) will present.

It follows that full head flexion is an important aspect of labor because a fetal head presenting a diameter of 9.5 cm will fit through a pelvis much more readily than if the diameter is 12.0 or 13.5 cm.

## Molding

**Molding** is overlapping of skull bones along the suture lines, which causes a change in the shape of the fetal skull to one long and narrow, a shape that facilitates passage through the rigid pelvis. Molding is caused by the force of uterine contractions as the vertex of the head is pressed against the not yet dilated cervix. The overlapping that occurs in the sagittal suture line and, generally, the coronal suture line can be easily palpated on the newborn skull. Parents can be reassured that molding only lasts a day or two and will not be a permanent condition. There is little molding when the brow is the presenting part (described later) because frontal bones are fused. No skull molding occurs when a fetus is breech because the buttocks, not the head, present first. Babies born by cesarean birth when there is no preprocedure labor also typically have no molding.

## Fetal Presentation and Position

Other factors that play a part in whether a fetus is properly aligned in the pelvis and is in the best position to be born are fetal attitude, fetal lie, fetal presentation, and fetal position.

### Fetal Attitude

**Attitude** describes the degree of flexion a fetus assumes during labor or the relation of the fetal parts to each other (Fig. 15.4).

**Figure 15.4** (A) The fetus in full flexion presents the smallest anteroposterior diameter (suboccipitobregmatic) of the skull to the inlet in this good attitude (vertex presentation). (B) The fetus is not as well flexed (military attitude) and presents the occipitofrontal diameter to the inlet (sinciput presentation). (C) The fetus in partial extension (brow presentation). (D) The fetus in complete extension presents a wide (occipitomentale) diameter (face presentation).

- A fetus in *good* attitude is in complete flexion: The spinal column is bowed forward, the head is flexed forward so much that the chin touches the sternum, the arms are flexed and folded on the chest, the thighs are flexed onto the abdomen, and the calves are pressed against the posterior aspect of the thighs (see Fig. 15.4A). This usual “fetal position” is advantageous for birth because it helps a fetus present the smallest anteroposterior diameter of the skull to the

pelvis and also because it puts the whole body into an ovoid shape, occupying the smallest space possible.

- A fetus is in *moderate* flexion if the chin is not touching the chest but is in an alert or “military position” (see [Fig. 15.4B](#)). This position causes the next widest anteroposterior diameter, the occipitofrontal diameter, to present to the birth canal. A fair number of fetuses assume a military position early in labor. This does not usually interfere with labor, however, because later mechanisms of labor (descent and flexion) force the fetal head to fully flex.
- A fetus in partial extension presents the “brow” of the head to the birth canal (see [Fig. 15.4C](#)).
- If a fetus is in complete extension, the back is arched and the neck is extended, presenting the occipitomenal diameter of the head to the birth canal (a face presentation; see [Fig. 15.4D](#)). This unusual position usually presents too wide a skull diameter to the birth canal for vaginal birth. Such a position may occur in an otherwise healthy fetus or may be an indication there is less than the usual amount of amniotic fluid present (oligohydramnios), which is not allowing the fetus adequate movement space. It also may reflect a neurologic abnormality in the fetus causing spasticity.

## Fetal Lie

**Lie** is the relationship between the long (cephalocaudal) axis of the fetal body and the long (cephalocaudal) axis of a woman’s body—in other words, whether the fetus is lying in a horizontal (transverse) or a vertical (longitudinal) position. Approximately 96% of fetuses assume a longitudinal lie (with their long axis parallel to the long axis of the woman) ([Ferreira, Borowski, Czuba, et al., 2015](#)).

Longitudinal lies are further classified as cephalic, which means the fetal head will be the first part to contact the cervix, or breech, with a foot or the buttocks as the first portion to contact the cervix.

## Fetal Presentation

Fetal presentation denotes the body part that will first contact the cervix or be born first and is determined by the combination of fetal lie and the degree of fetal flexion (attitude).

### Cephalic Presentation

A **cephalic presentation** is the most frequent type of presentation, occurring as often as 96% of the time. With this type of presentation, the fetal head is the body part that first contacts the cervix. The four types of cephalic presentation (vertex, brow, face, and mentum) are described in [Table 15.1](#). The vertex is the ideal presenting part because the skull bones are capable of effectively molding to accommodate the cervix. This exact fit may actually aid in cervical dilatation as well as prevent complications such as a

prolapsed cord (a portion of the cord passes between the presenting part and the cervix and enters the vagina before the fetus).

**TABLE 15.1 TYPES OF CEPHALIC PRESENTATIONS**

Type	Lie	Attitude	Description
Vertex	Longitudinal	Good (full flexion)	The head is sharply flexed, making the parietal bones or the space between the fontanelles (the vertex) the presenting part. This is the most common presentation and allows the suboccipitobregmatic diameter to present to the cervix.
Brow	Longitudinal	Moderate (military)	Because the head is only moderately flexed, the brow or sinciput becomes the presenting part.
Face	Longitudinal	Poor	The fetus has extended the head to make the face the presenting part. From this position, extreme edema and distortion of the face may occur.
Mentum	Longitudinal	Very poor	The fetus has completely hyperextended the head to present the chin, causing the presenting diameter (the occipitomenal) to be so wide that vaginal birth may not be possible.

During labor, the area of the fetal skull that contacts the cervix often becomes edematous from the continued pressure against it. This edema is called a *caput succedaneum*. In the newborn, what was the point of presentation can be analyzed from the location of the caput.

### Breech Presentation

A **breech presentation** means either the buttocks or the feet are the first body parts that will contact the cervix. Breech presentations occur in approximately 4% of births and are affected by fetal attitude the same as vertex presentations (Ferreira et al., 2015).

- A good attitude brings the fetal knees up against the fetal abdomen.
- A poor attitude means the knees and legs are extended.

Breech presentation can cause a difficult birth, with the presenting point influencing the degree of difficulty. Three types of breech presentation (complete, frank, and footling) are possible and described in Table 15.2.

**TABLE 15.2 TYPES OF BREECH PRESENTATIONS**

Type	Lie	Attitude	Description
Complete	Longitudinal	Good (full	The fetus has the thighs tightly flexed on

flexion)

the abdomen; both the buttocks and the tightly flexed feet present to the cervix.

Frank      Longitudinal   Moderate

Attitude is moderate because the hips are flexed, but the knees are extended to rest on the chest. The buttocks alone present to the cervix.

Footling      Longitudinal   Poor

Neither the thighs nor lower legs are flexed. If one foot presents, it is a single-footling breech; if both present, it is a double-footling breech.

### Shoulder Presentation

In a transverse lie, a fetus lies horizontally in the pelvis so the longest fetal axis is perpendicular to that of the mother. The presenting part is usually one of the shoulders (acromion process), an iliac crest, a hand, or an elbow (Fig. 15.5). The usual contour of the mother's abdomen at term may appear fuller side to side rather than top to bottom.

**Figure 15.5** A transverse or shoulder presentation.

Fewer than 1% of fetuses lie transversely. This presentation may be caused by pelvic contractions, in which the horizontal space is greater than the vertical space or by the presence of a placenta previa (the placenta is located low in the uterus, obscuring some of the vertical space). It also can be caused by relaxed abdominal walls from grand multiparity, which allow the unsupported uterus to fall forward (Ferreira et al., 2015).

If an infant is preterm and smaller than usual, an attempt to turn the fetus to a horizontal lie (external fetal version) may be made. Most infants in a transverse lie must be born by cesarean birth, however, because they can neither be turned nor born vaginally due to this “wedged” position. Discovering a shoulder presentation during labor is an important assessment because it almost always identifies a birth position that puts both mother and child in jeopardy unless skilled healthcare personnel are available

to complete a cesarean birth.

## Fetal Position

**Fetal position** is the relationship of the presenting part to a specific quadrant and side of a woman's pelvis. For convenience, the maternal pelvis is divided into four quadrants according to the mother's right and left: (a) right anterior, (b) left anterior, (c) right posterior, and (d) left posterior. Four parts of a fetus are typically chosen as landmarks to describe the relationship of the presenting part to one of the pelvic quadrants.

- In a vertex presentation, the occiput (O) is the chosen point.
- In a face presentation, it is the chin (mentum [M]).
- In a breech presentation, it is the sacrum (Sa).
- In a shoulder presentation, it is the scapula or the acromion process (A).

Position is indicated by an abbreviation of three letters. The middle letter denotes the fetal landmark (O for occiput, M for mentum, Sa for sacrum, and A for acromion process). The first letter defines whether the landmark is pointing to the mother's right (R) or left (L). The last letter defines whether the landmark points anteriorly (A), posteriorly (P), or transversely (T).

If the occiput of a fetus points to the left anterior quadrant in a vertex position, for example, this is a left occipitoanterior (LOA) position. If the occiput points to the right posterior quadrant, the position is right occipitoposterior (ROP). LOA is the most common fetal position, and right occipitoanterior (ROA) is the second most frequent.

[Box 15.2](#) summarizes possible positions. Six common positions in cephalic presentations are illustrated in [Figure 15.6](#).

**Figure 15.6** The fetal position. All are vertex presentations. A, anterior; L, left; O, occiput; P, posterior; R, right; T, transverse.

**BOX 15.2**

**Examples of Possible Fetal Positions**

Vertex Presentation (Occiput)	Breech Presentation (Sacrum)	Shoulder Presentation (Acromion Process)
LOA, left occipitoanterior	LSaA, left sacroanterior	LAA, left scapuloanterior
LOP, left occipitoposterior	LSaP, left sacroposterior	LAP, left scapuloposterior
LOT, left occipitotransverse	LSaT, left sacrotransverse	RAA, right scapuloanterior
ROA, right occipitoanterior	RSaA, right sacroanterior	RAP, right scapuloposterior
ROP, right occipitoposterior	RSaP, right sacroposterior	
ROT, right occipitotransverse	RSaT, right sacrotransverse	

Position is important because it can influence both the process and efficiency of labor. Typically, a fetus is born fastest from an ROA or LOA position. Labor can be considerably extended if the position is posterior (ROP or LOP) and may be more painful for a woman because the rotation of the fetal head puts pressure on sacral nerves. Encouraging a woman to rest in a Sims position on the same side as the fetal spine or use a hands and knees position may encourage rotation from an occipitoposterior to an occipitoanterior position prior to and during labor (Simkin, 2010).

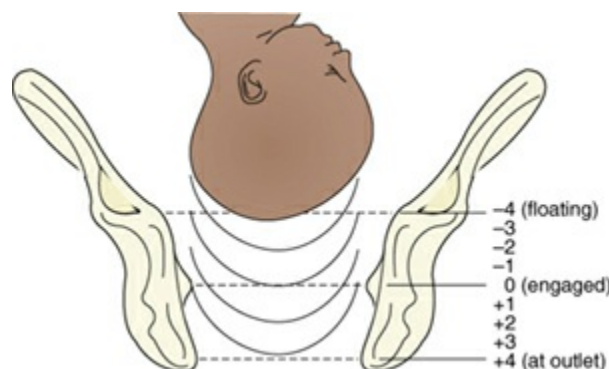

## Engagement

**Engagement** refers to the settling of the presenting part of a fetus far enough into the pelvis that it rests at the level of the ischial spines, the midpoint of the pelvis. Descent to this point means the widest part of the fetus (the presenting skull diameter in a cephalic presentation, or the intertrochanteric diameter in a breech presentation) has passed through the pelvis or the pelvic inlet has been proven adequate for birth. In a primipara, nonengagement of the head at the beginning of labor suggests that a possible complication such as an abnormal presentation or position, abnormality of the fetal head, or cephalopelvic disproportion exists. In multiparas, engagement may or may not be present at the beginning of labor. The degree of engagement is established by a vaginal and cervical examination.

- A presenting part that is not engaged is said to be “floating.”
- One that is descending but has not yet reached the ischial spines may be referred to as “dipping.”

## Station

**Station** refers to the relationship of the presenting part of the fetus to the level of the ischial spines (Fig. 15.7).

**Figure 15.7** The station (anteroposterior view). The station, or degree of engagement, of the fetal head is designated by centimeters above or below the ischial spines. At  $-4$  station, the head is “floating.” At  $0$  station, the head is “engaged.” At  $+4$  station, the head is “at outlet.”

- When the presenting fetal part is at the level of the ischial spines, it is at a 0 station (synonymous with engagement).
- If the presenting part is above the spines, the distance is measured and described as minus stations, which range from  $-1$  to  $-4$  cm.
- If the presenting part is below the ischial spines, the distance is stated as plus stations ( $+1$  to  $+4$  cm).
- At a  $+3$  or  $+4$  station, the presenting part is at the perineum and can be seen if the vulva is separated (i.e., it is crowning).

### *QSEN Checkpoint Question 15.1*

#### **TEAMWORK & COLLABORATION**

The nurse is collaborating with Celeste Bailey's obstetrician and is planning possible interventions in light of fetal position. Which of the following fetal positions is considered ideal and is most conducive to a birth that requires few interventions by the obstetrician?

- Right occipitoanterior with full flexion
- Left transverse anterior in moderate flexion
- Right occipitoposterior with no flexion
- Left sacroanterior with full flexion

*Look in [Appendix A](#) for the best answer and rationale.*

### **Mechanisms (Cardinal Movements) of Labor**

Effective passage of a fetus through the birth canal involves not only position and presentation but also a number of different position changes in order to keep the smallest diameter of the fetal head (in cephalic presentations) always presenting to the smallest diameter of the pelvis. These position changes are termed the **cardinal movements of labor**: descent, flexion, internal rotation, extension, external rotation, and expulsion ([Fig. 15.8](#)).

**Figure 15.8** The mechanism of normal labor and cardinal positions of the fetus from a left occipitoanterior position.

**Descent**

Descent is the downward movement of the biparietal diameter of the fetal head within the pelvic inlet. Full descent occurs when the fetal head protrudes beyond the dilated cervix and touches the posterior vaginal floor. Descent occurs because of pressure on the fetus by the uterine fundus. As the pressure of the fetal head presses on the sacral nerves at the pelvic floor, the mother will experience the typical “pushing sensation,”

which occurs with labor. As a woman contracts her abdominal muscles with pushing, this aids descent.

### Flexion

As descent is completed and the fetal head touches the pelvic floor, the head bends forward onto the chest, causing the smallest anteroposterior diameter (the suboccipitobregmatic diameter) to present to the birth canal. Flexion is also aided by abdominal muscle contraction during pushing.

### Internal Rotation

During descent, the biparietal diameter of the fetal skull was aligned to fit through the anteroposterior diameter of the mother's pelvis. As the head flexes at the end of descent, the occiput rotates so the head is brought into the best relationship to the outlet of the pelvis, or the anteroposterior diameter is now in the anteroposterior plane of the pelvis. This movement brings the shoulders, coming next, into the optimal position to enter the inlet, or puts the widest diameter of the shoulders (a transverse one) in line with the wide transverse diameter of the inlet.

### Extension

As the occiput of the fetal head is born, the back of the neck stops beneath the pubic arch and acts as a pivot for the rest of the head. The head extends, and the foremost parts of the head, the face and chin, are born.

### External Rotation

In external rotation, almost immediately after the head of the infant is born, the head rotates a final time (from the anteroposterior position it assumed to enter the outlet) back to the diagonal or transverse position of the early part of labor. This brings the after coming shoulders into an anteroposterior position, which is best for entering the outlet. The anterior shoulder is born first, assisted perhaps by downward flexion of the infant's head.

### Expulsion

Once the shoulders are born, the rest of the baby is born easily and smoothly because of its smaller size. This movement, called expulsion, is the end of the pelvic division of labor. For a view of the complete birth sequence, see [Figure 15.9](#).

**6:00 AM** Early in labor, a mother-to-be is supported by her husband and her sister.

**9:00 AM** The nurse checks the fetal monitor and documents fetal and maternal status.

**10:00 AM** The doctor makes a final check of cervical dilatation and says it's time to push.

**11:15 AM** She pushes from an alternative position, using a support bar.

**10:30 AM** The mother pushes in the dorsal recumbent position with her coach.

**Figure 15.9** A day in the life of a new family.

## THE POWERS OF LABOR

The third important requirement for a successful labor is effective powers of labor. This is the force supplied by the fundus of the uterus and implemented by uterine contractions, which causes cervical dilatation and then expulsion of the fetus from the uterus. After full dilatation of the cervix, the primary power is supplemented by use of a secondary power source, the abdominal muscles. It is important for women to understand that they should not bear down with their abdominal muscles to push until

the cervix is fully dilated. Doing so impedes the primary force and could cause fetal and cervical damage.

### Uterine Contractions

During pregnancy, the uterus begins to contract and relax periodically as if it is rehearsing for labor (Braxton Hicks contractions, or false labor). These contractions are usually mild but can be so strong that a woman mistakes them for true labor. As a rule, even if a woman thinks what she is feeling cannot be true labor, she needs to phone or e-mail her primary care provider to have the contractions further evaluated in case she is mistaking preterm labor for practice contractions. The mark of Braxton Hicks contractions is that they are usually irregular and are painful but do not cause cervical dilation. In contrast, effective uterine contractions have rhythmicity, a progressive increase in length and intensity, and accompany dilatation of the cervix. These differences between false and true labor are summarized in [Table 15.3](#). Contractions are assessed according to frequency, duration, and strength.

**TABLE 15.3 DIFFERENTIATING BETWEEN TRUE AND FALSE LABOR CONTRACTIONS**

<b>False Contractions</b>	<b>True Contractions</b>
Begin and remain irregular	Begin irregularly but become regular and predictable
Felt first abdominally and remain confined to the abdomen and groin	Felt first in lower back and sweep around to the abdomen in a wave
Often disappear with ambulation or sleep	Continue no matter what the woman’s level of activity
Do not increase in duration, frequency, or intensity	Increase in duration, frequency, and intensity
Do not achieve cervical dilatation	Achieve cervical dilatation

### Origins

Like cardiac contractions, labor contractions begin at a “pacemaker” point located in the uterine myometrium near one of the uterotubal junctions. Each contraction begins at that point and then sweeps down over the uterus as a wave. After a short rest period, another contraction is initiated and the downward sweep begins again.

In early labor, the uterotubal pacemaker may not operate in a synchronous manner. This makes contractions sometimes strong, sometimes weak, and somewhat irregular. This mild incoordination of early labor improves after a few hours as the pacemaker becomes more attuned to calcium concentrations in the myometrium and begins to function effectively.

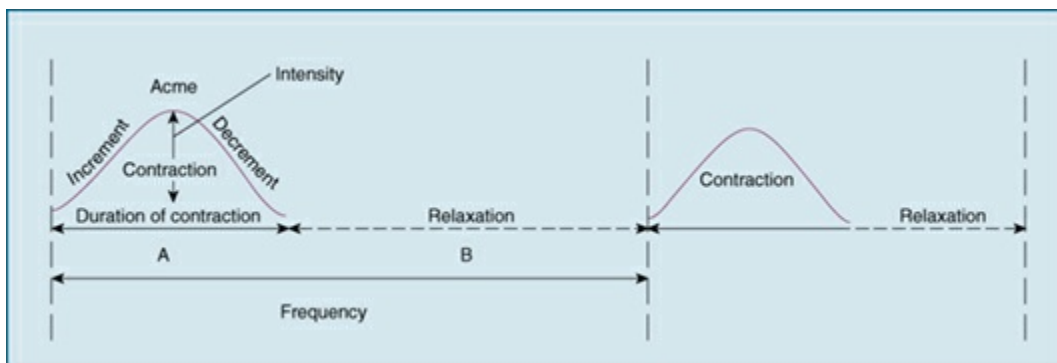

In some women, contractions appear to originate in the lower uterine segment rather

than in the fundus. These are reversed and ineffective and may actually cause tightening rather than dilatation of the cervix. It is difficult to tell from palpation that contractions are being initiated in a reverse pattern. It can be suspected, however, if the woman tells you she feels pain in her lower abdomen before the contraction is readily palpated at the fundus. It is truly revealed only when apparently strong uterine contractions do not cause cervical dilatation.

Some women seem to have additional pacemaker sites in other portions of the uterus. If this is so, contractions can be uncoordinated. Uncoordinated contractions may slow labor and can lead to failure to progress and fetal distress because they may not allow for adequate placental filling. All of these possibilities make evaluating the rate, intensity, and pattern of uterine contractions an important nursing responsibility.

## Phases

A contraction consists of three phases: the increment, when the intensity of the contraction increases; the acme, when the contraction is at its strongest; and the decrement, when the intensity decreases (Fig. 15.10). Between contractions, the uterus relaxes. As labor progresses, the relaxation intervals decrease from 10 minutes early in labor to only 2 to 3 minutes. The duration of contractions also changes, increasing from 20 to 30 seconds at the beginning to a range of 60 to 70 seconds by the end of the first stage (López Bernal & Norwitz, 2012).

**Figure 15.10** The interval and duration of uterine contractions. The frequency of contractions is the time from the beginning of one contraction to the beginning of the next. It consists of two parts: **(A)** the duration of the contraction and **(B)** the period of relaxation. The broken line indicates an indeterminate period because the relaxation time **(B)** is usually of longer duration than the actual contraction **(A)**.

## Contour Changes

As labor contractions progress and become regular and strong, the uterus gradually differentiates itself into two distinct functioning areas: an upper portion, which thickens, and a lower segment, which becomes thin-walled, supple, and passive so the fetus can be pushed out of the uterus easily. The contour of the overall uterus also changes from a

round, ovoid structure to an elongated one with a vertical diameter markedly greater than the horizontal diameter. This lengthening straightens the body of the fetus, bringing it into better alignment with the cervix and pelvis. The elongation of the uterus can cause pressure against the diaphragm and causes the often expressed sensation that a uterus is “taking control” of a woman’s body.

## Cervical Changes

Even more marked than the changes in the body of the uterus are two changes that occur in the cervix: effacement and dilatation.

### Effacement

**Effacement** is shortening and thinning of the cervical canal. All during pregnancy, the canal is approximately 1 to 2 cm long. During labor, the longitudinal traction from the contracting uterus shortens the cervix so much that the cervix virtually disappears (Fig. 15.11).

**Figure 15.11** Effacement and dilation of the cervix. **(A)** The beginning of labor. **(B)** Effacement is beginning; dilation is not apparent yet. **(C)** Effacement is almost complete. **(D)** After complete effacement, dilation proceeds rapidly.

In primiparas, effacement is accomplished before dilatation begins. Be sure to inform women of both effacement and dilation following a pelvic examination. If a woman is told at noon, for example, she is 3 cm dilated and then at 4 pm, she is told she is still 3 cm dilated, it is a discouraging report because it seems as if absolutely nothing has happened in 4 hours. Effacement, however, will have been occurring; telling her about this can be the encouragement she needs to continue breathing or working with contractions.

In multiparas, dilatation may proceed before effacement is complete. Effacement must occur by the end of dilatation, however, before the fetus can be safely pushed through the cervical canal; otherwise, cervical tearing can result.

## Dilatation

**Dilatation** refers to the enlargement or widening of the cervical canal from an opening a few millimeters wide to one large enough (approximately 10 cm) to permit passage of a fetus (see [Fig. 15.11](#)).

Dilatation occurs first because uterine contractions gradually increase the diameter of the cervical canal lumen by pulling the cervix up over the presenting part of the fetus. Secondly, the fluid-filled membranes push ahead of the fetus and serve as an opening wedge. If they are ruptured, the presenting part will serve this same function, although maybe not as effectively.

As dilatation begins, there is an increase in the amount of vaginal secretions (show) because minute capillaries in the cervix rupture and the last of the mucus plug that has sealed the cervix since early pregnancy is released.

### *QSEN Checkpoint Question 15.2*

#### **QUALITY IMPROVEMENT**

Celeste Bailey didn't recognize for over an hour that she was in labor. During her prenatal education, Celeste should have been taught to recognize which sign of true labor?

- Sudden loss of energy from epinephrine release
- "Nagging" but constant pain in the lower back
- Urinary urgency from increased bladder pressure
- "Show" or release of the cervical mucus plug

*Look in [Appendix A](#) for the best answer and rationale.*

## **THE PSYCHE**

The fourth “P,” or a woman’s psychological outlook, refers to the psychological state or feelings a woman brings into labor. For many women, this is a feeling of apprehension or fright. For almost everyone, it includes a sense of excitement or awe.

Women who manage best in labor typically are those who have a strong sense of self-esteem and a meaningful support person with them. These factors allow women to feel in control of sensations and circumstances they have never experienced before and which may not be what they pictured (Hodnett, Gates, Hofmeyr, et al., 2013). Women without adequate support can have a labor experience so frightening and stressful that they develop symptoms of posttraumatic stress disorder (PTSD) (Beck, 2016).

Encourage women to ask questions at prenatal visits and to attend preparation for childbirth classes so they are as well prepared for labor as possible. Encourage them after birth to talk about and share their experience because a “debriefing time” can be an important way to help them appreciate everything that happened and integrate the experience into their total life.

### *QSEN Checkpoint Question 15.3*

#### **EVIDENCE-BASED PRACTICE**

Labor and birth can be such overwhelming events that between 1% and 6% of women develop PTSD after childbirth. “Hotspots” are moments of extreme distress that strongly influence the development of PTSD. To find what are the hotspots in labor, researchers asked 675 women who experienced a difficult or traumatic birth to complete a questionnaire describing their labor and birth experience. Of the women, 67% reported at least one hotspot during birth and 52.9% had reexperiencing anxiety of these hotspots. Women were more likely to have PTSD if hotspots involved fear and lack of control or if the hotspots concerned interpersonal difficulties or maternal complications compared to complications with the baby (Greenfield, Jomeen, & Glover, 2016).

Based on the previous study, which statement by Celeste would cause the most concern for the nurse that labor could be becoming traumatic for Celeste?

- a. “I’m feeling as if I’m losing a grasp on things.”
- b. “I wish my husband was able to be here.”
- c. “Pushing is harder to do than I thought it would be.”
- d. “I wish this didn’t hurt so much.”

*Look in Appendix A for the best answer and rationale.*

## **The Stages of Labor**

Labor is traditionally divided into three stages:

- The first stage of dilatation, which begins with the initiation of true labor contractions and ends when the cervix is fully dilated
- The second stage, extending from the time of full dilatation until the infant is

born

- The third or placental stage, lasting from the time the infant is born until after the delivery of the placenta
- The first 1 to 4 hours after birth of the placenta is sometimes termed the “fourth stage” to emphasize the importance of close maternal observation needed at this time.

## THE FIRST STAGE

The first stage, which takes about 12 hours to complete, is divided into three segments: a latent, an active, and a transition phase. Traditionally the Freidman’s curve, an algorithm for determining normal labor progress, has been utilized in labor settings everywhere. However, new research is discovering that a normal labor can actually take a great deal longer than previously thought (Zhang, Landy, Branch, et al., 2010).

### The Latent Phase

The latent or early phase begins at the onset of regularly perceived uterine contractions and ends when rapid cervical dilatation begins. Contractions during this phase are mild and short, lasting 20 to 40 seconds. Cervical effacement occurs, and the cervix dilates minimally. A birthing parent who is multiparous usually progresses more quickly than a nullipara. A woman who enters labor with a “nonripe” cervix will probably have a longer than average latent phase. If a woman wants analgesia at this point, she shouldn’t be denied of it, but analgesia given too early in labor is a factor that tends to prolong this phase.

In a woman who is psychologically prepared for labor and who does not tense at each tightening sensation in her abdomen, latent phase contractions cause only minimal discomfort and can be managed by controlled breathing. During this phase, encourage women to continue to walk about and make preparations for birth, such as doing last-minute packing for her stay at the hospital or birthing center, preparing older children for her departure and the upcoming birth, or giving instructions to the person who will take care of them while she is away. If desired, she could begin alternative methods of pain relief such as aromatherapy, distraction, or acupressure (Steel, Adams, & Sibbritt, et al., 2014). If the woman should come to a birthing setting this early, encourage her to continue to be active and to use any nonpharmacotherapeutic measures she finds effective.

### The Active Phase

During the active phase of labor, cervical dilatation occurs more rapidly. Contractions grow stronger, lasting 40 to 60 seconds, and occur approximately every 3 to 5 minutes. Show (increased vaginal secretions) and perhaps spontaneous rupture of the membranes may occur during this time. Encourage women to be active participants in labor by keeping active and assuming whatever position is most comfortable for them during this

time, except flat on their back (Iravani, Janghorbani, Zarean, et al., 2015).

This phase can be difficult for a woman because contractions grow so much stronger and last so much longer than they did in the latent phase that she begins to experience true discomfort. It is also both an exciting and a frightening time because it is obvious something dramatic is definitely happening. In a few hours, a woman will have a new baby. Her life will never be the same again.

### The Transition Phase

During the **transition** phase, contractions reach their peak of intensity, occurring every 2 to 3 minutes with a duration of 60 to 70 seconds, and a maximum cervical dilatation of 8 to 10 cm occurs. If it has not previously occurred, show will occur as the last of the mucus plug from the cervix is released. If the membranes have not previously ruptured, they will usually rupture at full dilatation (10 cm). By the end of this phase, both full dilatation (10 cm) and complete cervical effacement (obliteration of the cervix) have occurred.

During this phase, a woman may experience intense discomfort that is so strong, it might be accompanied by nausea and vomiting. She may also experience a feeling of loss of control, anxiety, panic, and/or irritability. Because of the intensity and duration of the contractions, it may seem as though labor has taken charge of her. A few minutes before, she may have enjoyed having her forehead wiped with a cool cloth or her back rubbed. Now, she may knock a partner's hand away from her. Her focus turns entirely inward to the task of birthing her baby. As a woman reaches the end of this stage at 10 cm of dilatation, unless she has been administered epidural anesthesia, a new sensation, the irresistible urge to push, usually begins.

#### *What If... 15.1*

**Celeste tells the nurse she is certain her labor is going wrong because it has lasted over 6 hours. Is this an unusually long time for a first stage of labor for a woman having her first child? Would she be comforted by learning the usual length?**

## THE SECOND STAGE

The second stage of labor is the time span from full dilatation and cervical effacement to birth of the infant. A woman typically feels contractions change from the characteristic crescendo–decrescendo pattern to an uncontrollable urge to push or bear down with each contraction as if to move her bowels. She may experience momentary nausea or vomiting because pressure is no longer exerted on her stomach as the fetus descends into the pelvis. She pushes with such force that she perspires and the blood vessels in her neck become distended.

The fetus begins descent and, as the fetal head touches the internal perineum to

begin internal rotation, her perineum begins to bulge and appear tense. The anus may become everted, and stool may be expelled. As the fetal head pushes against the vaginal introitus, this opens and the fetal scalp appears at the opening to the vagina and enlarges from the size of a dime, to a quarter, then a half-dollar. This is termed **crowning**.

It takes a few contractions of this new type for a woman to realize everything is all right, just different, and to appreciate it feels better and less frightening, to push with contractions. As she concentrates on pushing, she may become unaware of the conversation in the room. Pain may disappear as all of her energy and thoughts are directed toward giving birth. As the fetal head is pushed out of the birth canal, it extends and then rotates to bring the shoulders into the best line with the pelvis. The body of the baby is then born.

## THE THIRD STAGE

The third stage of labor, the placental stage, begins with the birth of the infant and ends with the delivery of the placenta. Two separate phases are involved: *placental separation* and *placental expulsion*.

After the birth of the infant, the uterus can be palpated as a firm, round mass just below the level of the umbilicus. After a few minutes of rest, uterine contractions begin again, and the organ assumes a discoid shape. It retains this new shape until the placenta has separated, approximately 5 minutes after the birth of the infant.

### Placental Separation

As the uterus contracts down on an almost empty interior, there is such a disproportion between the placenta and the contracting wall of the uterus that folding and separation of the placenta occur. Active bleeding on the maternal surface of the placenta begins with separation, which helps to separate the placenta still further by pushing it away from its attachment site. As separation is completed, the placenta sinks to the lower uterine segment or the upper vagina.

The placenta has loosened and is ready to deliver when:

- There is lengthening of the umbilical cord.
- A sudden gush of vaginal blood occurs.
- The placenta is visible at the vaginal opening.
- The uterus contracts and feels firm again.

If the placenta separates first at its center and lastly at its edges, it tends to fold on itself like an umbrella and presents at the vaginal opening with the fetal surface evident. Approximately 80% of placentas separate and present in this way. Appearing shiny and glistening from the fetal membranes, this is called a *Schultze* presentation. If, however, the placenta separates first at its edges, it slides along the uterine surface and presents at the vagina with the maternal surface evident. It looks raw, red, and irregular, with the ridges or cotyledons that separate blood collection spaces evident; this is called a *Duncan* presentation. Although there is no difference in the outcome, record which way

the placenta presented. A simple trick of remembering the presentations is remembering that, if the placenta appears shiny, it is a Schultze presentation. If it looks “dirty” (the irregular maternal surface shows), it is a Duncan presentation (Fig. 15.12).

**Figure 15.12** The fetal (A) and maternal (B) surfaces of the placenta. (Photos by Joe Mitchell.)

This stage can take anywhere from 1 to 30 minutes and still be considered normal. Because bleeding occurs as the placenta separates, before the uterus contracts sufficiently to seal maternal capillaries, there is a blood loss of about 300 to 500 ml, not a great amount in relation to the extra blood volume that was formed during pregnancy.

### Placental Expulsion

Once separation has occurred, the placenta delivers either by the natural bearing-down effort of the mother or by gentle pressure on the contracted uterine fundus by the primary healthcare provider (a Credé maneuver). Pressure should never be applied to a uterus in a noncontracted state because doing so could cause the uterus to evert (turn inside out), accompanied by massive hemorrhage (Bienstock et al., 2015). If the placenta does not deliver spontaneously, it can be removed manually. It needs to be inspected after delivery to be certain it is intact and part of it was not retained (which could prevent the uterus from fully contracting and lead to postpartal hemorrhage). In recognition of cultural preferences, be certain to ask if a woman wants to take home the placenta because this can be a strong cultural tradition you don't want to break (Box 15.3).

It is important for women to understand what is happening to them during labor so they can make informed decisions as to their care. If a woman is not proficient in English, make arrangements to locate an interpreter. If she is hearing challenged, it is the healthcare facility's responsibility to provide an interpreter for her so she can receive adequate explanations of her progress. Remember, whether a woman enjoys being touched or not is in part culturally determined. Assess early in a woman's labor whether she might benefit from such caring measures as having her hand held or her back rubbed or if she wants this only from her support person.

For most healthcare providers in the United States, a placenta has little importance or meaning after its work of fetal oxygenation is done. Worldwide, however, the placenta has continuing importance. Based on this, ask women if they want to take it home with them. In a number of Asian and Native American cultures, it is important to bury the placenta to ensure the child will continue to be healthy. In some parts of China, the placenta is cooked then ground into a powder and eaten to ensure the continued health of the mother (M. F. Moore, 2016). Be certain when supplying placentas to women to take home that you respect standard infection precautions and hospital policy.

Some women choose to have a cord blood sample withdrawn from the cord to be banked for stem cell transplantation in the future. In some major health centers, women may be asked to donate a placental blood sample for a community stem cell banking program (Sun, Yue, He, et al., 2016).

#### ***QSEN Checkpoint Question 15.4***

##### **PATIENT-CENTERED CARE**

Celeste is anxious for her placenta to deliver so she can move to a rocking chair and help relieve her back pain. To best facilitate Celeste's wishes, which action is best?

- Tug gently on the umbilical cord until the placenta comes loose.
- Ask Celeste to continue hard pushing as she did to birth her baby.
- Push on the lax fundus of her uterus to cause the placenta to loosen.
- Assure her that a placenta loosens quickly so the waiting time will not be long.

*Look in Appendix A for the best answer and rationale.*

## **Maternal and Fetal Responses to Labor**

Labor is a local process that involves the abdomen and reproductive organs, but because

it is such an intense process, it has systemic physiologic effects on both a woman and her fetus. Its intensity is so great that almost all body systems are affected by it.

## THE MATERNAL PHYSIOLOGIC EFFECTS AND PSYCHOLOGICAL RESPONSES

Pregnancy has effects on many systems of the birthing parent. During labor, there are yet further effects which may require the nurse to deliver specific care to their patient. Knowing and recognizing what is normal and what is not normal can help to ensure safe provision of care (Table 15.4).

**TABLE 15.4** PHYSIOLOGICAL EFFECTS OF LABOR

System	Response	Recommended Nursing Action
Cardiovascular system	<ul style="list-style-type: none"> <li>• Cardiac output increases 40%–50% from prelabor levels.</li> <li>• Blood loss at birth is 300–500 ml on average.</li> <li>• Blood pressure may rise with pain response and, due to work of the system during contractions, by an average systolic rise of 15 mmHg per contraction. Epidural anesthesia may cause hypotension.</li> </ul>	<ul style="list-style-type: none"> <li>• Monitor closely for hemorrhage.</li> <li>• Monitor for signs of pathology with hypertensive episodes. Ensure that patients are well hydrated prior to epidural administration. This usually involves an IV fluid bolus (see Chapter 16).</li> </ul>
Hematopoietic system	<ul style="list-style-type: none"> <li>• During labor, WBCs increase to a level of 25,000–30,000 cells/mm<sup>3</sup> compared to 5,000–10,000 cell/mm<sup>3</sup>.</li> </ul>	<ul style="list-style-type: none"> <li>• Continue to monitor for any signs of infection.</li> </ul>
Respiratory system	<ul style="list-style-type: none"> <li>• Increased respiratory rate to respond to increased cardiovascular parameters</li> <li>• Total oxygen needs</li> </ul>	<ul style="list-style-type: none"> <li>• Monitor for any signs of hyperventilation. If hyperventilation occurs, rebreathing into a paper bag can be helpful.</li> <li>• If needed, use appropriately patterned breathing to regulate respiratory rate.</li> </ul>

	increase 100% during the second stage of labor.	
Temperature regulation	<ul style="list-style-type: none"> <li>• Temperature may increase up to (1°F).</li> <li>• Diaphoresis occurs with accompanying evaporation to cool and limit excessive warming.</li> </ul>	<ul style="list-style-type: none"> <li>• Monitor for any signs of infection.</li> <li>• Offer cool washcloths for the patient's forehead for comfort if needed.</li> </ul>
Fluid balance	<ul style="list-style-type: none"> <li>• Insensible water loss increases during labor due to diaphoresis and the increase in rate and depth of respirations.</li> </ul>	<ul style="list-style-type: none"> <li>• Encourage women to sip fluid during labor the same as they would if they were exercising to keep hydrated.</li> <li>• If a woman is nauseated by labor, encourage sips of fluid, ice chips, or hard candy to supply some extra fluid.</li> </ul>
Urinary system	<ul style="list-style-type: none"> <li>• Pressure of the fetal head as it descends in the birth canal against the anterior bladder reduces bladder tone or the ability of the bladder to sense filling.</li> </ul>	<ul style="list-style-type: none"> <li>• Ask the birthing parent to void approximately every 2 hours during labor to avoid overfilling because overfilling can decrease postpartal bladder tone.</li> </ul>
Musculoskeletal system	<ul style="list-style-type: none"> <li>• During pregnancy, <i>relaxin</i> is secreted from the ovaries causing the cartilage between joints to be more flexible. This allows the joints of the pelvis to be able to open as much as 2 cm in labor to allow for fetal passage.</li> </ul>	<ul style="list-style-type: none"> <li>• Monitor for appropriate mobility and be mindful of fall risks.</li> </ul>
Gastrointestinal (GI) system	<ul style="list-style-type: none"> <li>• Blood shunts to life-sustaining organs causing the GI system to become fairly inactive during labor.</li> </ul>	<ul style="list-style-type: none"> <li>• Although many hospital protocols dictate that women who present in labor should not partake of oral nutrition, there is little evidence to support this restrictive practice.</li> </ul>

	<ul style="list-style-type: none"> <li>• Digestive and emptying time of the stomach becomes lengthened.</li> <li>• Some women experience a loose bowel movement as contractions grow strong.</li> </ul>	
Neurologic and sensory response	<ul style="list-style-type: none"> <li>• Increased pain</li> <li>• Increased respiratory rate</li> </ul>	<ul style="list-style-type: none"> <li>• Where pain registers is important in appreciating why epidural anesthesia is effective. For early labor, the anesthetic block needs to suppress the lower thoracic synapses; for birth, it needs to block sacral nerves.</li> <li>• Discuss nonpharmacologic pain techniques if the patient does not desire medication.</li> </ul>
Psychological responses	<ul style="list-style-type: none"> <li>• Labor can lead to emotional distress because it is not only painful and fatiguing but it also represents the beginning of a major life change for a woman and her partner.</li> </ul>	<ul style="list-style-type: none"> <li>• Offer expeditious care to the patient.</li> <li>• Continue to encourage her process of labor.</li> <li>• Prior to birth, a woman can investigate the services of a doula.</li> <li>• A <b>doula</b> is an individual with specialized training who provides physical, emotional, and psychological support to laboring parents. A doula does not perform clinical tasks. However, the simple gift of presence has been shown to reduce the need for analgesia and anesthesia requests, shorten labor times, and increase satisfaction with the birth experience.</li> </ul>

## The Response to Pain

Cultural factors can strongly influence a woman's experience and satisfaction with labor. In the past, American women were accustomed to expecting hospital procedures and a medical model of care; based on this, they followed instructions with few questions. Today, women are encouraged to help plan their care. In addition, every woman responds to cultural cues in some way. This makes her response to pain, her

choice of nourishment, her preferred birthing position, the proximity and involvement of a support person, and customs related to the immediate postpartal period highly individualized.

To make labor a positive experience, be prepared to adapt care to the woman's specific needs. If a woman has traditions that run counter to hospital protocols, address these differences and make arrangements to accommodate her desires, beliefs, or customs, if possible, such as advocating for special foods to eat, ballroom dancing in order to remain upright, or saving the placenta for the mother to take home.

### **The Response to Fatigue**

By the time the date of birth approaches, a woman is generally tired from the normal discomforts of pregnancy and has not slept well for the past month (Nazik & Eryilmaz, 2014). For example, a side-lying position caused backache; when she turned onto her back, her fetus kicked and wakened her; when she turned back to her side, her back ached again. Sleep hunger from this type of discomfort can make it difficult for a woman to perceive situations clearly or to adjust rapidly to new situations. It can make a small deficiency such as a wrinkled sheet appear as a major threatening discrepancy in her care. It can make the process of labor loom as an overwhelming, unendurable experience unless she has competent people with her to offer support, reassurance, and comfort.

### **The Response to Fear**

Women appreciate a review of the labor process early in labor as a reminder that childbirth is not a strange, bewildering event but a predictable and well-documented one. Being taken by surprise—labor moving faster or slower than the woman thought it would or contractions harder and longer than she remembers from last time—can lead a woman to feel out of control and increase the level of pain she experiences. This sense of lack of control combined with pain may cause her to begin to worry for her infant and may make her afraid she will not meet her own behavioral expectations. Explain and repeat as necessary that labor is predictable but also variable. Contractions last a certain length and reach a certain intensity but always have a rest period in between so she can have a break from pain. Fear of labor this way releases adrenaline, and adrenaline interferes with oxytocin release and so can limit the effectiveness of uterine contractions (Rouhe, Samelo-Aro, & Toivanen, 2015).

## **FETAL RESPONSES TO LABOR**

The pressure and circulatory changes that occur with contractions not only affect the mother but also can cause detectable physiologic changes in the fetus as well.

### **The Neurologic System**

Uterine contractions exert pressure on the fetal head, so the same response that is

involved with any instance of increased intracranial pressure occurs. The fetal heart rate (FHR) decreases by as much as 5 beats/min during a contraction, as soon as contraction strength reaches 40 mmHg; although not measurable, fetal blood pressure also rises. The decrease in FHR appears on a fetal heart monitor as a normal or early deceleration pattern.

### The Cardiovascular System

A sufficiently mature fetus is unaffected by the continual variations of heart rate that occur with labor contractions. During a contraction, as the arteries of the uterus become sharply constricted, and the filling of cotyledons almost completely halts, the amount of nutrients, including oxygen, exchanged during this time is greatly reduced, causing a slight but inconsequential fetal hypoxia. The increase in blood pressure caused by increased intracranial pressure raises blood pressure and keeps circulation from falling below normal for the duration of a contraction.

### The Integumentary System

The pressure involved in the birth process is often reflected in minimal petechiae or ecchymotic areas on a fetus (particularly the presenting part). There may also be edema of the presenting part (caput succedaneum) from this pressure.

### The Musculoskeletal System

The force of uterine contractions tends to push a fetus into a position of full flexion or with the head bent forward, which is the most advantageous position for birth.

### The Respiratory System

The process of labor appears to aid in the maturation of surfactant production by alveoli in the fetal lung. Both the pressure applied to the chest from contractions and passage through the birth canal help to clear the respiratory tract of lung fluid. For this reason, an infant born vaginally is usually able to establish respirations more easily than a fetus born by cesarean birth.

## Measuring Progress in Labor

A woman's progress in labor is recorded on a labor record (a Partogram) devised by the World Health Organization, or a like form on which vital signs, FHR, cervical dilation, descent of the fetal head, urine tests, and any drugs administered can be recorded.

Remember, when using such forms, how much and what type of analgesia a woman receives in labor can influence the length of labor. Because "norms" on such a record refer to averages, an individual woman's labor can vary greatly from the ideal projected course of labor and still be normal for that woman.

After each cervical examination, cervical dilatation and **fetal descent** (which may be

referred to as “moulding”) are plotted on the graph. The pattern of cervical dilatation usually plots as a rising S-shaped curve. You may need to remind women that assessments of cervical dilation are subjective, so one examiner may report a different finding from another (Archie & Roman, 2013). At the end of the latent phase of the first stage of labor, cervical dilatation is 3 to 4 cm. As a woman enters the active phase of the first stage, cervical dilation proceeds at a minimum of 1 cm/hr, or about 7 additional hours to reach full dilation (10 cm). The form shows an “alert” line, which marks when 4 hours has passed. Four hours beyond that, an “action” line advises a primary care provider that cervical dilation is taking longer than usual and that an intervention may be necessary to make the labor safe and effective. Maintaining an ongoing record and alerting the care provider that the alert line or action line is approaching are important nursing responsibilities.

## MATERNAL DANGER SIGNS OF LABOR

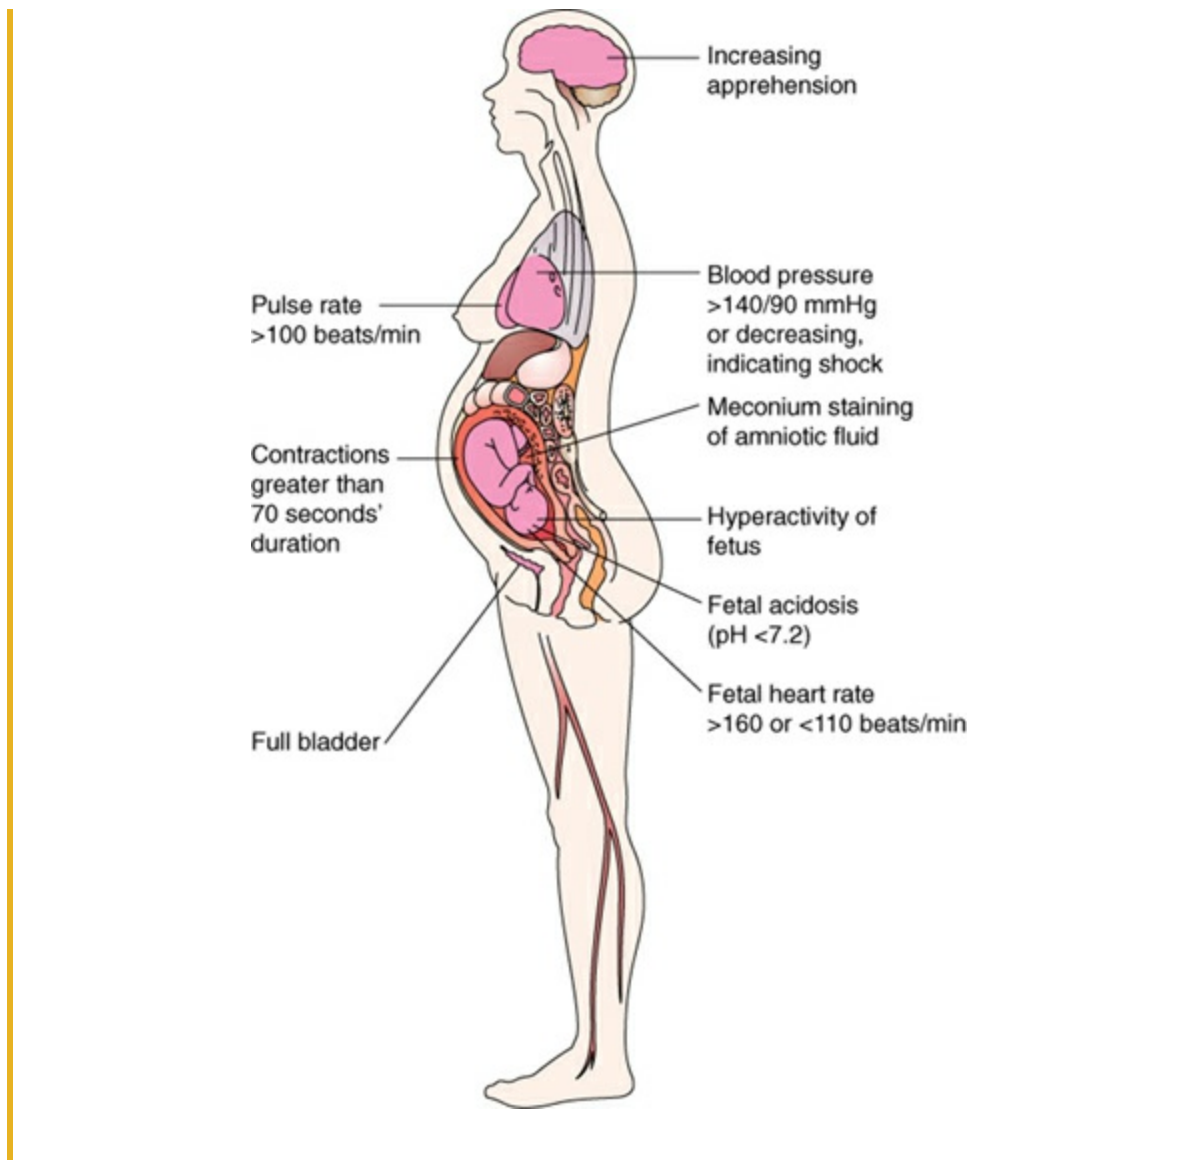

Wide variation exists among individuals in their response to labor and their pattern of labor contractions. Certain signs, however, indicate that the course of events is deviating from usual. These signs, both fetal and maternal, are described in Box 15.4. Nursing care of a woman who is experiencing these signs and so may be developing a complication during labor or birth is addressed in Chapter 23. In addition to problems of cervical dilation or contractions, other symptoms suggest augmentation or intervention of labor are necessary.

### BOX 15.4

#### Nursing Care Planning Using Assessment

##### ASSESSING FOR DANGER SIGNS OF LABOR

### High or Low Blood Pressure

Normally, a woman's blood pressure rises slightly in the second (pelvic) stage of labor because of her pushing effort. A systolic pressure greater than 140 mmHg and a diastolic pressure greater than 90 mmHg, or an increase in the systolic pressure of more than 30 mmHg or in the diastolic pressure of more than 15 mmHg (the basic criteria for gestational hypertension), should be reported. Just as important to report is a falling blood pressure because it may be the first sign of intrauterine hemorrhage, although a falling blood pressure from hemorrhage is often associated with other clinical signs of hypovolemic shock, such as apprehension, increased pulse rate, and pallor.

### Abnormal Pulse

Most women during pregnancy have a pulse rate of 70 to 80 beats/min. This rate normally increases slightly during the second stage of labor because of the exertion involved. A maternal pulse rate greater than 100 beats/min during labor is unusual and

should be reported because it may be another indication of hemorrhage.

### **Inadequate or Prolonged Contractions**

Uterine contractions normally become more frequent, intense, and longer as labor progresses. If they become less frequent, less intense, or shorter in duration, this may indicate uterine exhaustion (inertia). This problem may be correctable but needs augmentation or other interventions to accomplish this.

Observe also if there is a period of relaxation between contractions so the intervillous spaces of the uterus can fill and maintain an adequate supply of oxygen and nutrients for the fetus. As a rule, uterine contractions lasting longer than 70 seconds are becoming long enough to compromise fetal well-being because this interferes with adequate uterine artery filling.

### **Abnormal Lower Abdominal Contour**

If a woman has a full bladder during labor, a round bulge appears on her lower anterior abdomen. This is a danger signal for two reasons: First, the bladder may be injured by the pressure of the fetal head pressing against it; and second, the pressure of the full bladder may not allow the fetal head to descend. To avoid a full bladder, ask women to try to void about every 2 hours during labor.

### **Increasing Apprehension**

Warnings of psychological danger during labor are as important to consider in assessing maternal well-being as are physical signs. As she approaches the second stage of labor, a woman who is becoming increasingly apprehensive despite clear explanations of unfolding events may not be “hearing” because she has a concern that has not been met. Using an approach such as “You seem more and more concerned. Could you tell me what is worrying you?” may be helpful. Increasing apprehension also needs to be investigated for physical reasons because it can be a sign of oxygen deprivation or internal hemorrhage.

## **FETAL DANGER SIGNS OF LABOR**

As well as observing for a woman’s danger signs of pregnancy, observing fetal danger signs is equally important. These fetal danger signs include the following.

### **High or Low Fetal Heart Rate**

As a rule, an FHR of more than 160 beats/min (fetal tachycardia) or less than 110 beats/min (fetal bradycardia) is a sign of possible fetal distress. An equally important sign is a late or variable deceleration pattern revealed on a fetal monitor (described later in this chapter). Frequent monitoring by a fetoscope, Doppler, or a monitor is necessary to detect these changes as they first occur.

## Meconium Staining

This is not always a sign of fetal distress but is highly correlated with its occurrence. Meconium staining, a green color in the amniotic fluid, reveals the fetus has had a loss of rectal sphincter control, allowing meconium to pass into the amniotic fluid. It may indicate a fetus has or is experiencing hypoxia, which stimulates the vagal reflex and leads to increased bowel motility. Although meconium staining may be usual in a breech presentation because pressure on the buttocks causes meconium loss, it should always be reported immediately even with breech presentations so its cause can be investigated.

## Hyperactivity

Ordinarily, a fetus remains quiet and barely moves during labor. Fetal hyperactivity may be a subtle sign that hypoxia is occurring because frantic motion is a common reaction to the need for oxygen.

## Low Oxygen Saturation

Oxygen saturation in a fetus is normally 40% to 70%. A fetus can be assessed for this by a catheter inserted next to the cheek (under 40% oxygenation needs further assessment). If fetal blood is obtained by scalp puncture, the finding of acidosis (blood pH lower than 7.2) suggests fetal well-being is becoming compromised and that further investigation is also necessary.

### *QSEN Checkpoint Question 15.5*

#### **SAFETY**

Suppose Celeste is having long and hard uterine contractions. What length of contraction would the nurse report as indicative of a potential safety risk?

- Any length of contraction over 30 seconds
- A contraction over 70 seconds in length
- A contraction that peaks at 20 seconds
- A contraction that appears intensely painful

*Look in [Appendix A](#) for the best answer and rationale.*

## Maternal and Fetal Assessments During Labor

Women are invariably nervous when they arrive at a hospital or birth center. Nursing assessment is important to detect how they are managing physically and emotionally to this intense event in their life.

## THE IMMEDIATE ASSESSMENT OF A WOMAN IN FIRST STAGE OF LABOR

A number of immediate assessment measures are necessary to safeguard maternal and fetal health when a woman first arrives at a birthing facility. After she and her support person are oriented to the area, focus on obtaining this vital assessment data.

### **The Initial Interview and Physical Examination**

Information about the woman's pregnancy can be gained from her prenatal record electronically on admission or if a paper copy has been forwarded to the birth setting beforehand. Additional important data that needs to be obtained includes a description of her labor thus far, her general physical condition, and her preparedness and plans for labor and birth. This amount of information is scant but helps to establish whether the woman is in active labor and needs immediate preparation for birth or whether she has arrived at the birthing setting at an early stage of labor and therefore will benefit most from paced interventions.

Ask about the following:

- Her baby's expected date of birth (EDB)
- When her contractions began
- Amount and character of any show
- Whether rupture of membranes has occurred
- Any known drug allergies
- If she uses any recreational or prescription drugs (women addicted to opioids need special precautions before analgesia is administered for pain management; their newborn may need special care to prevent neonatal abstinence syndrome from opioid withdrawal)
- Past pregnancy and present pregnancy history if her prenatal record is not available. It is important to note the route of delivery with any prior births as well as any complications which may have occurred.
- Her birth plan or what individualized measures she thinks will create a memorable experience for her such as whether she wants analgesia or who she would like to cut the umbilical cord

Assess the following:

- Vital signs: temperature, pulse, respirations, and blood pressure (assess between contractions for comfort and accuracy)
- Nature of her contractions (frequency, duration, and intensity)
- Her rating of pain on a 10-point scale
- What she has done to be prepared for labor such as learning breathing exercises
- Urine specimen for protein and glucose
- Position and presentation of her fetus

It is important to document fetal presentation and position at the beginning of labor because these help predict if the presentation of a body part other than the vertex could be putting a fetus at risk or leading to the possibility labor will be longer than usual because fetal descent will be less effective, causing ineffective dilatation of the cervix. A different presentation could also lead to early rupture of membranes, increasing the

possibility of infection, fetal anoxia from cord prolapse, and meconium staining, all of which can lead to cesarean birth or respiratory distress at birth (Barber, Lundsberg, Belanger, et al., 2011).

## **THE DETAILED ASSESSMENT DURING THE FIRST STAGE OF LABOR**

If the woman is in active labor, the history taken on arrival may be the only history obtained until after her baby is born. If birth is not imminent, both a more extensive history and a physical examination can be obtained.

### **The History**

Performing a detailed interview of a woman in labor can be difficult because of the constant interruptions labor contractions cause. Be patient until a contraction ends so you don't interrupt any form of controlled breathing a woman is using. Remember, the longest contraction is rarely more than 60 seconds. If a woman concentrates so intently on a breathing exercise, she completely forgets a question asked just before a contraction, repeat the question as the contraction subsides, as if it had not been asked before, or as if it is no trouble to ask it again.

### **Current Pregnancy History**

Important information needed for a complete history includes documentation of gravida and parity status, a description of this pregnancy (e.g., intended or not, place and pattern of prenatal care, adequacy of nutrition, whether any complications such as spotting, falls, hypertension of pregnancy, infection, alcohol or drug ingestion occurred during pregnancy), plans for labor (e.g., Does she want to have the baby naturally? Will she use breathing exercises? Will her support person be able to remain with her continuously?), and plans for child care (e.g., Will she breastfeed? Has she chosen a primary healthcare provider for the baby? If she's having a boy, does she want him circumcised?).

### **Past Pregnancy History**

Document prior pregnancies, abortions, or miscarriages, including number, dates, types of birth, any complications, and outcomes, including health, sex, and birth weights of previous children.

### **Past Health History**

Document any previous surgeries (abdominal surgical adhesions might interfere with fetal passage), heart disease or diabetes (special precautions will be required during labor and birth), anemia (blood loss at birth may be more important than usual), tuberculosis (she'll need testing after birth to be certain healed lung lesions weren't

reactivated by birth), kidney disease or hypertension (blood pressure must be monitored even more carefully than usual), or if she has ever had a sexually transmitted infection such as herpes (the infant may be exposed to the disease by vaginal contact if the disease is active). Determine also whether a woman's lifestyle places her at high risk for prescription or nonprescription drug abuse or HIV exposure.

### Family Medical History

Ask if any family member has a condition that could be inherited such as a cognitive challenge, heart disease, blood dyscrasia, diabetes, kidney disease, allergies, seizures, hearing loss, or malignant hyperthermia (a dominantly inherited disorder that causes a dangerous increase in temperature in response to certain anesthetics). If any of these are present, adequate preparation can then be made for a child who might have special needs at birth.

### The Physical Examination

After history taking, a woman needs a physical examination, including a pelvic examination, to confirm her general health, the presentation and position of the fetus, and the stage of cervical dilatation. In order to have an HIV test, a woman must sign additional informed consent over and above her usual health facility consent.

The physical assessment during labor begins, as does all physical assessments, with the woman's overall appearance: Does she appear tired? Pale? Ill? Frightened? Are there signs of edema or dehydration? Does she have open lesions anywhere? Be prepared to adapt further examination techniques with regard to a woman's stage of labor, frequency of contractions, and labor progression.

Be certain to palpate for enlargement of neck lymph nodes to detect the possibility of a respiratory infection. Inspect the mucous membrane of her mouth and the conjunctiva of her eyes for color to see if paleness suggests anemia. Examine her teeth for caries or abscesses because an oral infection might account for a postpartal fever. Examine the outer and inner surfaces of her lips carefully to detect herpes lesions (pinpoint vesicles on an erythematous base). Report to her primary care provider if herpetic lesions are present anywhere because, although oral lesions are invariably a type 1 herpes virus (common cold sores), type 2 (genital) herpes virus needs to be identified because this can be lethal to newborns; a woman's obstetric healthcare provider may suggest that the woman with oral herpes lesions take isolation precautions such as not kissing her newborn until the lesions crust.

Auscultate the woman's lungs to be certain they are clear of rales. Listen for normal heart sounds and rhythms as well. Many pregnant women at term have a grade 2 to 3 systolic ejection murmur because of the extra volume of blood that must cross their heart valves. Document if this is noticeable. Next, inspect and palpate her breasts. Are they free of cysts and lumps? Mark the chart of a woman who has a palpable mass in her breasts for reexamination after labor and birth. This is probably an enlarged milk

gland but needs further evaluation to be certain it is not something more serious such as a breast malignancy.

## Abdominal and Lower Leg Assessment

Assessing a woman's abdomen is important to estimate fetal size by fundal height (which should be at the level of the xiphoid process at term). Palpate and percuss the bladder area (over the symphysis pubis) to detect a full bladder. Assess for abdominal scars to reveal previous abdominal or pelvic surgery that could have left adhesions.

Finally, inspect lower extremities for skin turgor to assess hydration and also for edema and varicose veins. Women with large varicosities are more prone to thrombophlebitis after birth than other women. Severe edema suggests hypertension of pregnancy. A blood pressure 140/90 mmHg or higher can confirm this.

## Determining Fetal Position, Presentation, and Lie

Four methods can be used to determine if the fetus is in an optimal position for birth:

- Determining the place on the woman's abdomen where fetal heart tones are heard strongest
- Abdominal inspection and palpation, called Leopold maneuvers
- Vaginal examination
- Sonography

## Leopold Maneuvers

**Leopold maneuvers** are a systematic method of observation and palpation to determine fetal presentation and position and are done as part of a physical examination. Steps for this are described in [Box 15.5](#).

### BOX 15.5

#### Nursing Care Planning Using Procedures

#### LEOPOLD MANEUVERS

**Purpose:** Systematically observe and palpate the abdomen to determine fetal presentation and position.

Procedure	Principle
1. Explain the procedure and instruct the woman to void to empty her bladder.	1. Explanation reduces anxiety and enhances cooperation. An empty bladder promotes comfort and allows for more productive palpation because fetal contour will not be obscured by a distended bladder.
2. Wash your hands using warm water.	2. Hand washing prevents the spread of

Provide privacy.

3. Position the woman supine with knees slightly flexed. Place a small pillow or rolled towel under her left side.
4. Observe the woman's abdomen as to which is the longest diameter and where fetal movement is apparent.
5. First maneuver: Stand at the foot of the woman, facing her, and place both hands flat on her abdomen. Palpate the superior surface of the fundus. Determine consistency, shape, and mobility.

6. Second maneuver: Face the woman, hold the left hand stationary on the left side of the uterus while you palpate with the right hand on the opposite side of the uterus from top to bottom. Repeat palpation using the opposite side.

possible infection. Using warm water aids in patient comfort and prevents tightening of abdominal muscles during palpation.

3. Flexing the knees relaxes the abdominal muscles. Using a pillow or towel tilts the uterus off the vena cava, preventing supine hypotension syndrome.
4. The longest diameter (axis) is the length of the fetus. The location of activity most likely reflects the position of the feet.
5. This maneuver determines whether the fetal head or breech is in the fundus. A head feels more firm than a breech, is round and hard, and moves independently of the body (the breech feels softer and moves only in conjunction with the body).

6. This maneuver locates the back of the fetus. The fetal back feels like a smooth, hard, and resistant surface; the knees and elbows of the fetus on the opposite side feel more like a number of angular bumps or nodules.

7. Third maneuver: Gently grasp the lower portion of the abdomen just above the symphysis pubis between the thumb and fingers and try to press the thumb and finger together. Determine any movement and whether the part feels firm or soft.

7. This maneuver determines which part of the fetus is at the inlet and its mobility. If the presenting part moves upward so your fingers and thumb can be pressed together, the presenting part is not engaged (not firmly settled into the pelvis). If the part is firm, it is the head; if soft, then it is the breech.

8. Fourth maneuver: Place fingers on both sides of the uterus approximately 2 in. above the inguinal ligaments, pressing downward and inward in the direction of the birth canal. Allow fingers to be carried downward.

8. This maneuver is only done if the fetus is in a cephalic presentation because it determines fetal attitude and degree of fetal extension into the pelvis. The fingers of one hand will slide along the uterine contour and meet no obstruction, indicating the back of the fetal neck. The other hand will meet an obstruction an inch or so above the ligament—this is the fetal brow. The position of the fetal brow should correspond to the side of the uterus that contained the elbows and knees of the fetus. If the fetus is in a poor attitude, the examining fingers will meet an obstruction on the same side as the fetal back; that is, the fingers will touch the hyperextended head. If the brow is very easily palpated (as if it lies just under the

skin), the fetus is probably in a posterior position (the occiput is pointing toward the woman's back).

## The Vaginal Examination

A vaginal examination is necessary to determine the extent of cervical softening, effacement, and dilatation and to confirm the fetal presentation, position, and degree of descent. These are traditionally done by the primary care provider but, if not available, can be done by a nurse skilled in the technique. Responsibilities for helping with a vaginal examination during labor are shown in [Box 15.6](#).

### BOX 15.6

#### Nursing Care Planning Using Procedures

#### ASSISTING WITH A VAGINAL EXAMINATION

**Purpose:** Determine cervical readiness for labor and fetal position and presentation.

Procedure	Principle
1. Wash your hands and explain the procedure to the patient. Provide privacy.	1. Hand washing helps prevent the spread of microorganisms. Explanations ensure patient cooperation and compliance. Privacy enhances self-esteem.
2. Assemble equipment, including sterile examining gloves, sterile lubricant, and gauze squares. Ask the woman to turn onto her back with knees flexed (a dorsal recumbent position).	2. Organization and planning improve efficiency. Positioning in this manner allows for good visualization of the perineum. Use of a sterile glove prevents contamination of the birth canal.
3. Discard one drop of clean lubricating solution and drop an ample supply on tips of gloved fingers of examiner.	3. Discarding the first drop of lubricant ensures quantity used will not be contaminated.
4. The examiner places a hand on the outer edges of the woman's vulva and spread her labia while inspecting for lesions. Help look for red, irritated mucous membranes; open, ulcerated sores; and clustered, pinpoint vesicles.	4. Presence of any lesions may indicate an infection and may possibly preclude vaginal birth.
5. Note any fluid escaping from the vagina that could be amniotic fluid, in addition to the presence of the	5. Amniotic fluid implies membranes have ruptured and the umbilical cord may have prolapsed. Bleeding may be

umbilical cord or bleeding.

6. If there is no bleeding or cord visible, the examiner stabilizes the uterus by placing a hand on the woman's abdomen and then introducing the index and middle fingers of the other hand into the vagina, directing them toward the posterior vaginal wall.
7. The examiner touches the cervix with gloved fingers to assess:
  - a. Cervical consistency, position, and rate if *firm* or *soft*.
  - b. Extent of dilatation and whether an anterior rim or lip of cervix is present.

- c. Estimate the degree of effacement.
    - d. Estimate whether membranes are intact.

a sign of placenta previa. *Vaginal examinations should not be continued if a possible placenta previa exists.*

6. The posterior vaginal wall is less sensitive than the anterior wall.
7. a. The cervix feels like a circular rim of tissue around a center depression. If firm, it feels similar to the tip of a nose; if soft, it is as pliable as an earlobe.
  - b. An index finger averages about 1 cm; a middle finger about 1.5 cm. If they can both enter the cervix, the cervix is dilated 2.5–3 cm. If there would be room for double the width of two fingers, the dilatation is about 5–6 cm. When the space is four times the width of two fingertips, dilatation is complete at 10 cm.
  - c. Effacement is estimated in a percentage depending on thickness. A cervix before labor is 2–2.5 cm thick. If it is only 1 cm thick, it is 50% effaced. If it is tissue paper thin, it is 100% effaced. With a 100% effaced cervix, dilatation is difficult to feel because the edges of the cervix are so thin.
  - d. The membranes (with a slight amount of amniotic fluid in front of the presenting part) assume the shape of a watch crystal. With a contraction, they bulge forward, become prominent, and can be felt much more readily.

- |  |   |
|--|---|
| <p>8. Next, the examiner locates the ischial spines, identifies the presenting part, and rates the station of the fetus.</p>   | <p>8. Ischial spines are palpated as notches at the 4 and 8 o'clock positions of the pelvic outlet. Station is the number of centimeters above or below the spines the presenting fetal part has reached. Identifying the presenting part confirms findings obtained with Leopold maneuvers. The vertex has a hard, smooth feel. Fetal hair may be palpable but massed together and wet, and it may be difficult to appreciate through gloves. Palpating the two fontanelles, one diamond-shaped and one triangular, helps identification. Buttocks feel softer and give under fingertip pressure. Identifying the anus may be possible because the sphincter action will "trap" an examining finger.</p> |
| <p>9. Next is establishment of the fetal position.</p>   | <p>9. The fontanelle palpated is invariably the posterior one because the fetus maintains a flexed position, presenting the posterior not the anterior fontanelle. If it points toward an anterior quadrant, the position is ROA or LOA. In a breech presentation, the anus can serve as a marker for position.</p>   |
| <p>10. Upon withdrawal of the examining hand, help wipe the perineum front to back to remove secretions or examining lubricant. Help patient return to side or sit up.</p> | <p>10. Wiping front to back prevents moving rectal contamination forward to the vagina. Side lying or sitting helps prevent supine hypotension syndrome.</p>  |
| <p>11. Document procedure, assessment findings, and how patient tolerated procedure.</p>   | <p>11. Documentation provides a means for communication and evaluation of care and patient outcomes.</p>  |

Vaginal examinations are best done between contractions. Although more of the fetal skull can be palpated during a contraction because the cervix retracts more at that time, an examination during a contraction is more uncomfortable and rarely is justified by the additional amount of information gained. A palpation of membranes during a contraction, when they are under pressure, also can cause them to rupture.

Women are anxious to have frequent reports during labor to reassure them that everything is progressing well, but vaginal exams should be kept to a minimum to prevent infection. The woman's primary care provider will tell a woman immediately after an examination about her progress. If giving a progress report, remember that most women are aware of the word dilatation but not effacement. Just saying, "No further dilatation," therefore, is a depressing report. "You're not dilated a lot more, but a lot of thinning is happening and that's just as important" is the same report given in a positive manner. After a vaginal examination, plot the new degree of dilatation and descent of the presenting part on a labor progress graph, as described earlier.

Vaginal examinations should not be done in the presence of fresh bleeding because fresh bleeding may indicate that a placenta previa (implantation of the placenta so low in the uterus that it is encroaching on the cervical os) is present. Performing a vaginal examination in this instance might tear the placenta and cause hemorrhage, resulting in danger to both the mother and fetus. Make certain a primary care provider knows about the fresh bleeding before attempting a vaginal examination.

Women from cultures where female circumcision is allowed may have tightened or obstructed vaginal openings from scarring, which can make a vaginal exam painful. Note this because it also indicates a woman may need a cesarean birth to prevent perineal tearing if her vagina cannot dilate adequately.

## **Sonography**

Although not routine, sonography may be used to determine the diameters of the fetal skull and to determine presentation, position, flexion, and degree of descent of a fetus at the beginning of labor. This is usually done by a portable unit, but if it's necessary for a woman to be transported to another department to have this done, be certain someone accompanies her, so, if labor should become more active, she can be returned quickly to the labor or birth service for needed care.

## **Assessing Rupture of Membranes**

One out of every four labors begins with spontaneous rupture of the fetal membranes. When this occurs, a woman feels a sudden gush or a slow trickle of amniotic fluid from her vagina. This is a startling sensation for most women because it feels as if she has lost bladder control. She may feel embarrassed before she realizes the warm fluid on her perineum and legs is not urine but an unexpected announcement that labor is beginning. If the fluid expelled was only a small amount, there may be a question as to whether the membranes have ruptured.

A sterile vaginal examination using a sterile speculum usually reveals whether amniotic fluid is present in the vagina. After vaginal secretions are obtained with a sterile, cotton-tipped applicator, test them with a strip of Nitrazine paper. Vaginal secretions are usually acid; amniotic fluid, in contrast, is alkaline. If amniotic fluid has passed through the vagina recently, the pH of the vaginal fluid will probably be alkaline

(greater than 6.5) when tested by Nitrazine paper (appears blue-green or gray to deep blue). A false blue reading may occur in a woman with intact membranes who has a heavy, bloody show because blood is also alkaline. An additional test that can be done is a fern test (examination of vaginal secretions under a microscope). Because of its high estrogen content, amniotic fluid will show a fern pattern (see [Chapter 5, Fig. 5.13A](#)) when dried and examined in this way; urine will not.

If the woman’s membranes ruptured at home, ask her to describe the color of the amniotic fluid, the amount, the odor, and the approximate time of rupture. Amniotic fluid should be clear as water. Yellow-stained fluid suggests a blood incompatibility between the mother and fetus (the amniotic fluid is bilirubin stained from the breakdown of red blood cells). Green fluid suggests meconium staining. Although meconium staining is normal in breech births because of compression of the buttocks, in a vertex presentation, it may indicate fetal anoxia. Either way, a fetus with meconium staining needs immediate assessment. After birth, the infant continues to need close assessment at birth to rule out possible meconium aspiration ([Lee, Romero, Lee, et al., 2016](#)). If the fluid is malodorous, there could be an infection. If membranes rupture during labor, assess FHR immediately to be certain the umbilical cord hasn’t prolapsed and is now being compressed against the cervix by the fetal head. The time of rupture is important because the potential time clock for an infection begins with ruptured membranes. It’s preferable if the baby is born within 24 hours of rupture to reduce the risk of infection.

### Assessment of Pelvic Adequacy

Evaluating pelvic adequacy using internal conjugate and ischial tuberosity diameters is generally done during pregnancy either manually or by sonogram, so, by weeks 32 to 36 of pregnancy, a primary care provider can be alerted that cephalopelvic disproportion could occur. Because the diameters obtained during pregnancy have not changed, they are not retaken if already obtained.

### Vital Signs

Vital signs are taken at the beginning and then periodically during labor, as summarized in [Table 15.5](#).

**TABLE 15.5 TYPICAL TIME INTERVALS FOR NURSING INTERVENTIONS DURING THE FIRST STAGE OF LABOR**

Intervention	Assessment	Latent Phase (0–3 cm)	Active Phase (4–7 cm)	Transition Phase (8–10 cm)
	on Admission			
<i>Assess and Record</i>				
Temperature	X	q4h (unless membranes are	q4h (unless membranes are	q4h (unless membranes are

		ruptured, then q2h)	ruptured, then q2h)	ruptured, then q2h)
Pulse	X	q30–60 min	q30–60 min	q15–30 min
Respirations	X	q30–60 min	q30–60 min	q15–30 min
Blood pressure	X	q30–60 min	q30–60 min	q15–30 min
Voiding	X	q2h	q2h	q2h
Fetal heart rate	X	q30–60 min	q15–30 min	q15–30 min
Contractions	X	q30–60 min	q15–30 min	q10–15 min
Perineum	X	q30–60 min	q30 min	q15 min
<i>Provide</i>				
Ambulation and change of position	X	Continuously; question if membranes rupture	Continuously; question if membranes rupture	Continuously
Support	X	Continuously	Continuously	Continuously

## Temperature

Temperature is usually obtained every 4 hours during labor. Report a temperature greater than 99°F (37.2°C) because it may indicate the development of infection. Unless there are accompanying symptoms, however, temperature elevation in a woman who has taken little fluid by mouth usually reflects dehydration (urge her to drink at least sips of water to maintain hydration). After rupture of the membranes, temperature should be taken every 2 hours because the possibility for infection markedly increases after that time.

## Pulse and Respiration

The pulse and respiration rate should be measured and recorded at the same time intervals as temperature. A woman's pulse may be rapid on admission because she is nervous and anxious. After she has become better acquainted with her surroundings and has been assured everything is going well, her pulse usually falls in a range between 70 and 80 beats/min. A persistent pulse rate of more than 100 beats/min could be tachycardia from dehydration or hemorrhage and so needs investigation. Respiratory rate during labor is usually 18 to 20 breaths/min. Do not count respirations during contractions because women tend to breathe rapidly from pain. Conversely, if a woman is using controlled breathing to decrease pain in labor, her respiration rate during contractions can be abnormally slow.

Observe for hyperventilation (rapid, deep respirations) because prolonged hyperventilation can cause a “blowing off” of carbon dioxide and accompanying symptoms of dizziness and tingling of hands and feet. Rebreathing into a paper bag and reassurance the feeling is normal help to reverse this process.

## Blood Pressure

Blood pressure is usually measured and recorded every 4 hours as well. As with pulse and respirations, measure blood pressure between contractions, both for a woman’s comfort and for accuracy, because maternal blood pressure tends to rise 5 to 15 mmHg during a contraction. An increase in blood pressure at other times is potentially dangerous because it may indicate the development of hypertension of pregnancy. A decrease in blood pressure or a decrease in the pulse pressure (the difference between the systolic and diastolic pressures) may indicate hemorrhage. If a woman received an analgesic agent (such as meperidine), which tends to cause hypotension, check her blood pressure approximately 15 minutes after administration to be certain extreme hypotension did not occur.

## Laboratory Analysis

Most women have some preliminary laboratory studies done in early labor.

### Blood

Blood is drawn for hemoglobin and hematocrit, a serologic test for syphilis (Venereal Disease Research Laboratory [VDRL] test), hepatitis B antibodies, and blood typing to determine whether a blood incompatibility is likely to exist in the newborn and what type of blood will need to be supplied if the woman should have an acute blood loss. If a woman gives permission for HIV testing, blood for this will be drawn as well.

### Urine

Obtain a clean-catch urine specimen and test it at the point of care for protein and glucose, then send it to the laboratory for a complete urinalysis. If a woman reports any symptoms that suggest a urinary tract infection such as burning on urination, blood in urine, extreme frequency, or flank pain, obtain a clean-catch specimen for culture. A woman in labor is able to void most easily if she is allowed to use a bathroom. However, if a woman has ruptured membranes, check whether she should ambulate to a bathroom until it is confirmed the fetal head is well engaged so gravity does not cause a prolapsed cord. Use a bedpan or receptacle placed on a commode to collect any material passed from the vagina so this can be assessed as well.

## The Assessment of Uterine Contractions

Depending on the hospital or birthing center policy, most women are monitored by an

external contraction monitor for about 20 minutes in early labor. The monitor is then removed, and contractions are assessed intermittently by Doppler because extensive electronic monitoring has not shown to lower fetal mortality with low-risk women, can limit mobility, and can lead to an increase in cesarean birth (Cox & King, 2015). The use of internal fetal monitoring is reserved for high-risk pregnancies and is described in Chapter 24.

### Length of Contractions

To determine the length of a contraction with a monitor in place, simply observe the rhythm strip and, using the time line, count the number of seconds the contraction lasted. To determine the beginning of a contraction without a monitor, rest a hand on a woman's abdomen at the fundus of the uterus very gently until you sense the gradual tensing and upward rising of the fundus that accompanies a contraction (Fig. 15.13). Time the duration of the contraction from the moment the uterus first tenses until it has relaxed again. It is possible to palpate this tensing approximately 5 seconds before the woman is able to feel the contraction because contractions become palpable when the intrauterine pressure reaches approximately 20 mmHg. However, the pain of a contraction is not usually felt until pressure reaches approximately 25 mmHg.

**Figure 15.13** Contractions can be assessed by very gently placing a hand over the fundus of the uterus.

### Intensity of Contractions

The intensity of a contraction refers to its strength. On a monitor, this is the height of the waveform. If you are assessing manually, rate a contraction according to:

- Mild, if the uterus does not feel more than minimally tense

- Moderate, if the uterus feels firm
- Strong, if the uterus feels as hard as a wooden board or you are unable to indent the uterus with your fingertips at the peak of the contraction

After estimating either the intensity or duration of a contraction, recheck the fundus at the conclusion of the contraction to be certain it does relax and becomes soft to the touch again. This demonstrates that the uterus is not in continuous contraction but is providing a relaxation time, during which placental blood vessels can fill to supply the fetus with adequate oxygen.

## Frequency of Contractions

Lastly, time the frequency of contractions or how often they are occurring. Frequency is timed from the beginning of one contraction to the beginning of the next (see [Fig. 15.10](#)).

Use as light a touch as possible on a woman's abdomen while evaluating contractions or estimating their strength manually. Otherwise, the uterine fundus can become tender if it has to push against the extra weight of a hand with each contraction, creating unnecessary discomfort for a woman in labor.

### *What If . . . 15.2*

**Celeste Bailey refuses to have any electronic fetal monitoring. Would this worry the nurse? Would the nurse try to convince her she needs this?**

## THE INITIAL FETAL ASSESSMENT

Although fairly passive in labor, a fetus is subjected to extreme pressure by uterine contractions and passage through the birth canal, so it is important to ascertain that the FHR remains within normal limits despite these pressures.

### Auscultation of Fetal Heart Sounds

Fetal heart sounds are transmitted best through the convex portion of a fetus because that is the part that lies in closest contact with the uterine wall.

- In a vertex or breech presentation, fetal heart sounds are usually best heard through the fetal back.
- In a face presentation, the back becomes concave so the sounds are best heard through the more convex thorax.
- In breech presentations, fetal heart sounds are heard most clearly high in the uterus, at a woman's umbilicus or above.
- In cephalic presentations, they are heard loudest low in a woman's abdomen.
- In an ROA position, sounds are heard best in the right lower quadrant.
- In an LOA position, sounds are heard best in the left lower quadrant.
- In posterior positions (LOP or ROP), heart sounds may be loudest at a woman's

side.

Figure 15.14 illustrates where fetal heart sounds radiate best from various fetal positions.

**Figure 15.14** Locating fetal heart sounds by fetal position: (A) Left occipitoanterior (LOA), (B) right occipitoanterior (ROA), (C) left occipitoposterior (LOP), (D) right occipitoposterior, and (E) left sacroanterior (LSaA).

Hearing fetal heart sounds in these positions not only confirms that the fetus is responding well to labor but also provides confirmatory information about fetal position. Conversely, recognizing fetal position aids in locating fetal heart sounds.

As a rule, determine the FHR every 30 minutes during beginning latent labor, every 15 minutes during active first stage labor, and every 5 minutes during the second stage of labor. This can be done by inspecting an FHR monitoring strip or by periodic auscultation by a fetoscope (a modified stethoscope attached to a headpiece), a Pinard stethoscope (a hollow tube that directs sound into the ear), or a Doppler unit (which uses ultrasound waves that bounce off the fetal heart to produce echoes or clicking noises, which reflect the fetal heartbeat [Fig. 15.15]) as labor progresses.

**Figure 15.15** (A) Auscultation of the fetal heartbeat using a fetoscope. (Beth Van Trees/Shutterstock.com) (B) A Doppler ultrasound device can be used to monitor fetal heart rate intermittently in low-risk labor. (COLLATERAL/Shutterstock.com) (C) A nurse-midwife using a Pinard stethoscope. (Capifrutta/Shutterstock.com)

## ELECTRONIC MONITORING

The use of fetal monitors in labor has provoked one of the biggest controversies in modern obstetric health care as their use moved from routine use in the mid-1970s for all women in labor to today when they are used judiciously to prevent intrusion on the childbirth experience and to prevent needless discomfort and distraction to the mother. Monitors are set with automatic alarms that trigger if an FHR goes below 110 beats/min or above about 170 beats/min and so may ring many times if a woman is active in labor. This causes their use to result in unnecessary cesarean births as well as frightened parents (which could adversely affect early parent–infant bonding).

Monitoring does offer advantages from a healthcare provider’s standpoint because observing the FHR on a monitor is quicker than listening with a Doppler and yields information on not only the rate but also on how the FHR responds to a forceful contraction. Use of monitors for a short-term initial assessment followed by intermittent manual monitoring is a compromise solution.

Be certain to inform parents that the FHR can vary greatly during labor so they’re not surprised when they see this and also that a monitor is only an aid and should not be the focus of their attention. Otherwise, a couple can become so focused on a monitor screen or paper strip that they lose the ability to concentrate on previously learned relaxation and breathing techniques. When giving care, be sure not to focus solely on

the equipment, continue to communicate to the couple, not the machine, and offer support to the woman and her partner as needed.

### Initial Electronic Monitoring

Electronic monitoring is noninvasive, easily applied, and does not require cervical dilatation or fetal descent before it can be used, so it can be introduced at any time during labor. The presence and duration of uterine contractions is gained by means of a pressure transducer or tocodynamometer (*toko* is Greek for “contraction”) strapped to the woman’s abdomen or held in place by stockinette (Fig. 15.16).

**Figure 15.16** External electronic monitoring in place. Two devices (a transducer for the uterus and an ultrasound sensor for the fetus) are strapped to the woman’s abdomen. (busayamol/Shutterstock.com)

Place the transducer snugly over the uterine fundus or the area where contractions are most easily felt. The transducer works to convert the pressure originated by the contraction into an electronic signal that is then recorded on graph paper.

The FHR is monitored with the use of an ultrasonic sensor or monitor (see Fig. 15.16) also strapped against a woman’s abdomen at the level of the fetal chest. The small Doppler unit converts fetal heart movements into audible beeping sounds and also records them on graph paper.

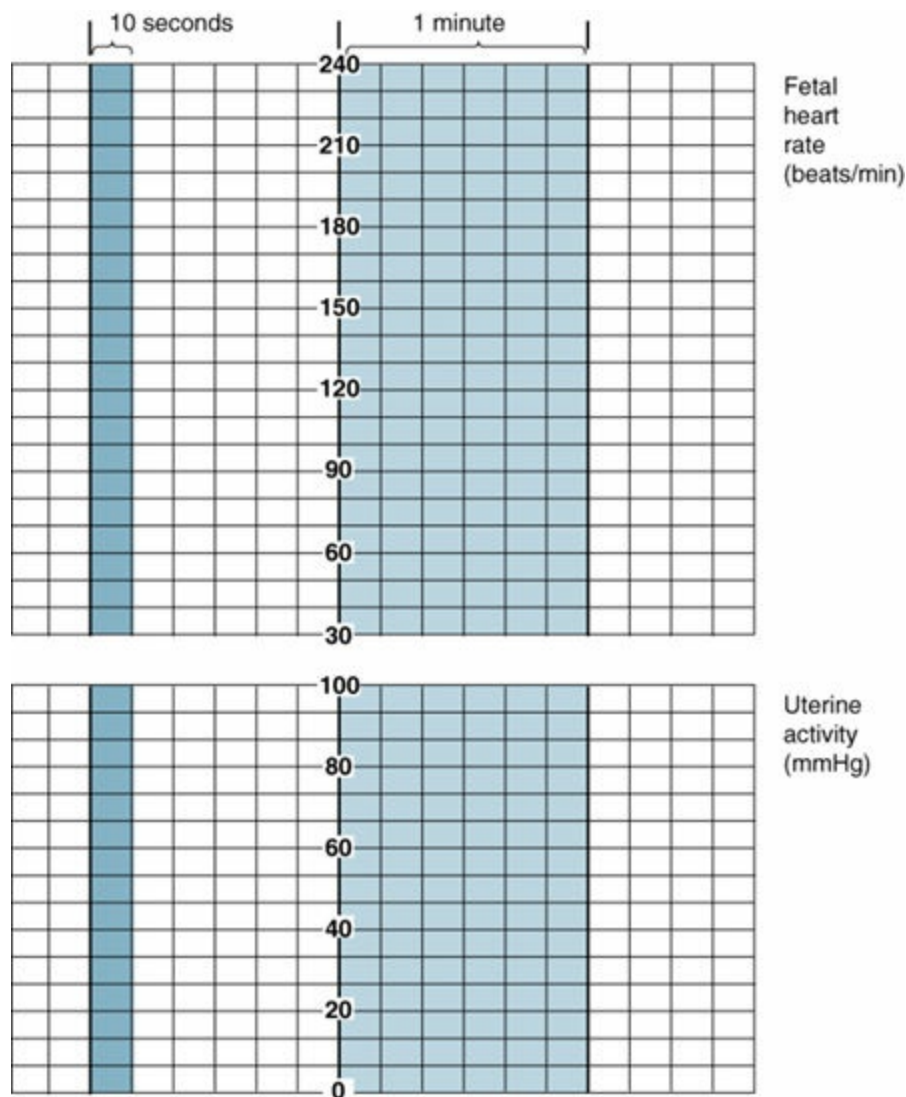

A woman who is worried something will happen to her child during labor can find it reassuring to listen to the regular beeping sound of an undistressed fetal heartbeat from a fetal heart transducer. Many women ask for and can have a short graph tracing to save for their baby book.

A disadvantage is the woman may feel discomfort from the straps holding the monitors in place, and the snugness of the sensor head may limit her ability to breathe deeply. If a woman changes her position (and she should change position often during labor), the sensor often needs to be repositioned. Remind a woman that the fetal heart signal may stop when she changes position so she does not think by the silence that her baby’s heart has stopped beating.

Urge women not to lie on their backs for monitoring but to rest on their side, sit in a chair, or bend forward over the foot of the bed or a birthing ball or rail so the likelihood of supine hypotension syndrome is not increased.

## FETAL HEART RATE AND UTERINE CONTRACTION RECORDS

Labor monitors trace both the FHR and the duration and interval of uterine contractions onto an oscilloscope screen and produce a permanent record on paper rolls (Fig. 15.17). Uterine contraction information is recorded on the bottom half of the paper, whereas FHR is recorded on the top half. Time can be calculated by counting the number of bold vertical lines on the paper (the space between two bold lines represents 60 seconds).

**Figure 15.17** A paper strip for recording electronic fetal monitoring data.

## FETAL HEART RATE PARAMETERS

Assessing and interpreting FHR patterns involves evaluating three parameters: the baseline rate, variabilities in the baseline rate, and periodic changes in the rate (acceleration and deceleration) ([American Congress of Obstetricians and Gynecologists \[ACOG\], 2009](#)).

## The Baseline Fetal Heart Rate

A baseline FHR is determined by analyzing the pace of fetal heartbeats recorded in a minimum of 2 minutes obtained between contractions. A normal rate is 110 to 160 beats/min.

## Variability

FHR variability or the difference between the highest and lowest heart rates shown on a strip is one of the most reliable indicators of fetal well-being. Variability is reflected on an FHR tracing as a slight irregularity or “jitter” to the wave. The degree of baseline variability increases (5 to 15 beats/min) when a fetus moves; it slows if a fetus sleeps. If no variability is present, it indicates the natural pacemaker activity of the fetal heart (effects of the sympathetic and parasympathetic nervous systems) may be affected. This may occur as a response to narcotics or barbiturates administered to a woman in labor, but the possibility of fetal hypoxia and acidosis must also be considered and investigated. Very immature fetuses show diminished baseline variability because of a reduced nervous system response to stimulation and immature cardiac node function.

Variability should be recorded as:

- Absent: No amplitude range is detectable.
- Minimal: Amplitude range is detectable but is 5 beats/min or fewer.
- Moderate (normal): Amplitude range is 6 to 25 beats/min.
- Marked: Amplitude range is greater than 25 beats/min.

Other patterns in the baseline rate that can be detected include fetal bradycardia (FHR is lower than 110 beats/min for 10 minutes) and fetal tachycardia (FHR is faster than 160 beats/min for a 10-minute period).

## Periodic Changes

Periodic changes or fluctuations in FHR occur in response to contractions and fetal movement and are described in terms of *accelerations* or *decelerations*. Periodic changes are short-term changes in rate other than baseline; they last from a few seconds to 1 or 2 minutes.

### Accelerations

Nonperiodic accelerations are temporary normal increases in FHR caused by fetal movement, a change in maternal position, or administration of an analgesic.

- An acceleration is a visually apparent abrupt increase (onset to peak in less than 30 seconds) in the FHR.
- At 32 weeks of gestation and beyond, an acceleration has a peak of 15 beats/min or more above baseline with a duration of 15 seconds or more but less than 2 minutes from onset to return.
- Before 32 weeks of gestation, an acceleration has a peak of 10 beats/min or more above baseline, with a duration of 10 seconds or more but less than 2 minutes

from onset to return.

- Prolonged acceleration lasts 2 minutes or more but less than 10 minutes in duration.
- If an acceleration lasts 10 minutes or longer, it is a baseline change or a new baseline is established.

## Decelerations

Decelerations are visually apparent, usually symmetrical, periodic decreases in FHR resulting from pressure on the fetal head during contractions as parasympathetic stimulation in response to vagal nerve compression brings about a slowing of FHR. Early deceleration follows the pattern of the contraction, beginning when the contraction begins and ending when the contraction ends. However, the waveform of the FHR change is the inverse of the contraction waveform, or the lowest point of the deceleration occurs with the peak of the contraction (a mirror image of the contraction). The rate rarely falls below 100 beats/min, and it returns quickly to between 110 and 160 beats/min at the end of the contraction (Fig. 15.18).

**Figure 15.18** Early fetal heart rate deceleration (the time between 2 and 4 seconds) follows the pattern of the contraction starting when the contraction begins and ending when the contraction subsides. This is a normal pattern of a healthy fetus.

Early decelerations normally occur late in labor, when the head has descended fairly low; they are viewed as innocent. If they occur early in labor, before the head has fully descended, the head compression causing the waveform change could be the result of cephalopelvic disproportion and is a cause to investigate.

## Late Decelerations

Late decelerations are those in which the onset, nadir, and recovery of the deceleration occur after the beginning, peak, and ending of the contraction, respectively (Fig. 15.19). This is an ominous pattern in labor because it suggests uteroplacental insufficiency or decreased blood flow through the intervillous spaces of the uterus during uterine contractions. This pattern may occur with marked hypertonia or increased uterine tone. Immediately change the woman's position from supine if she is lying down to lateral to relieve pressure on the vena cava and supply more blood to the uterus and fetus. Intravenous fluid or oxygen may be prescribed. Prepare for a prompt cesarean birth of

the infant if the late decelerations persist or if FHR variability becomes abnormal (absent or decreased).

**Figure 15.19** Late deceleration (the time between 20 and 22 seconds) occurs after the peak of a contraction and continues beyond the end of the contraction. This is an ominous pattern in labor because it suggests the fetus is growing short of oxygen. The prolonged deceleration (between 26 and 31 seconds) is also ominous.

### Prolonged Decelerations

Prolonged decelerations are decelerations that are a decrease from the FHR baseline of 15 beats/min or more and last longer than 2 to 3 minutes but less than 10 minutes. They generally reflect an isolated occurrence, but they may signify a significant event, such as cord compression or maternal hypotension. For this reason, they must be reported and documented. If a deceleration lasts longer than 10 minutes, it is considered a baseline change.

### Variable Decelerations

The pattern of variable decelerations refers to decelerations that occur at unpredictable times in relation to contractions. They may indicate compression of the cord, which can be an ominous development in terms of fetal well-being (Fig. 15.20). Cord compression may be occurring because of a prolapsed cord, but it most often occurs because the fetus is simply lying on the cord. It tends to occur more frequently after rupture of the membranes than when membranes are intact, or with oligohydramnios (the presence of less than a normal amount of amniotic fluid), such as occurs in postterm pregnancy or with intrauterine growth restriction. As a first step, change the woman's position from supine to lateral if she is not already lying on her side. If a prolapsed cord is diagnosed as the cause of the variable decelerations, oxygen will be prescribed as well as changing her position to a knee-to-chest one to help relieve pressure on the cord. Because a prolapsed cord is a potential serious complication of labor, nursing care and outcomes are further discussed in Chapter 23.

**Figure 15.20** A fetal heart rate (FHR) showing variable and prolonged decelerations. Note the abrupt drop in FHR in both types of decelerations. The variable decelerations return to baseline more quickly than the prolonged deceleration at 26 to 31 minutes, however.

### The Sinusoidal Pattern

In a fetus who is severely anemic or hypoxic, central nervous system control of heart pacing may be so impaired that the FHR pattern resembles a smooth, frequently undulating wave with a cycle frequency of 3 to 5 per minute and persisting 20 minutes or more. Although the cause of this pattern is poorly understood, it is recognized to be as ominous as a late deceleration or variable deceleration pattern and so needs to be reported. For unknown reasons, on occasion, especially after administration of a narcotic to the mother, a *pseudosinusoidal* or false sinusoidal pattern may appear. These are usually transient, resolve spontaneously without intervention, and are associated with a good fetal outcome. The pattern may show some variability and perhaps an FHR acceleration. Identifying these is equally important so they can be differentiated from a true sinusoidal pattern.

FHR baseline, variability, and patterns are categorized from 1 to 3 to help establish if a deviation is serious. Knowing these helps you to understand why interventions are initiated at certain points (Table 15.6).

**TABLE 15.6 THE AMERICAN CONGRESS OF OBSTETRICIANS AND GYNECOLOGISTS CATEGORIES OF FETAL HEART RATE MONITORING**

Category	Importance	Recommended Action
Category I	FHR factors (baseline and variability) are normal.	Continue routine monitoring; no specific action needed.
Category II	FHR factors are indeterminate.	Continue surveillance and reevaluation.
Category III	FHR tracings are abnormal.	Prompt evaluation is required. Expedite action to determine the cause and resolve the situation is required. This may include but is not limited to provision of maternal oxygen, change in maternal

position, discontinuation of labor stimulation, treatment of maternal hypotension, and treatment of tachysystole with FHR changes. If category III tracing does not resolve with these measures, birth should be undertaken.

FHR, fetal heart rate.

From American Congress of Obstetricians and Gynecologists. (2009). ACOG Practice Bulletin No. 106: Intrapartum fetal heart rate monitoring: Nomenclature, interpretation, and general management principle. *Obstetrics & Gynecology*, 114(1), 193–200.

### **QSEN Checkpoint Question 15.6**

#### **INFORMATICS**

The nurse assesses Celeste Bailey’s uterine contractions and the FHR. Which of the following would the nurse document as a late deceleration?

- The FHR began increasing 45 seconds after the contraction was over.
- The FHR decreased in rate 30 seconds after the start of a contraction.
- The FHR decreased in strength after the 10th consecutive contraction.
- A decrease in FHR occurs but is totally unrelated to timing of contractions.

*Look in [Appendix A](#) for the best answer and rationale.*

## **The Care of a Woman During the First Stage of Labor**

Labor and birth are natural processes, so the average woman should be able to complete labor and birth without assistance from medical interventions. Nurses can be instrumental in keeping labor as free of unnecessary interventions as possible so it remains not only safe but also a joyful and memorable experience ([Association of Women’s Health, Obstetric and Neonatal Nurses \[AWHONN\], 2011](#)). Six major concepts that make labor and birth as natural as possible include the following:

- Labor should begin on its own, not be artificially induced.
- Women should be able to move about freely throughout labor, not be confined to bed.
- Women should receive continuous support from a caring support person during labor.
- No interventions such as intravenous fluid should be used routinely.
- Women should be allowed to assume a nonsupine position such as upright and side lying for birth.
- Mother and baby should be housed together after the birth, with unlimited opportunity for breastfeeding

Because the first stage of labor begins with the start of uterine contractions and takes hours to complete, most women have been having labor contractions for hours before they arrive at a birthing center or hospital. This means, most likely, that they have been experiencing pain and relying on their own or their partner’s judgment that everything is

going well for a long time. One of their chief needs when they arrive at a birthing setting, therefore, is reassurance their judgment has been correct—everything is going well and the exhaustion and increasing pain they feel is part of usual labor.

## Nursing Diagnoses and Related Interventions

**Nursing Diagnosis:** Powerlessness related to duration of labor

**Outcome Evaluation:** Patient voices she feels in control of happenings, expresses preferences for positions and techniques to control pain, asks questions about her progress, and states feelings about what is happening.

After admission, care during the first stage of labor centers on helping a woman feel confident in her ability to control pain and maintain physiologic stability in the face of it. At first, it is exciting for a woman to feel labor contractions. They are little more than menstrual cramps and project a “this-is-really-happening” sensation. Soon, however, if a woman is not concentrating on controlled breathing, the contractions become biting in their intensity. Despite the fact she is becoming more and more uncomfortable, however, nothing seems to be happening. This can cause a couple to begin to worry something is going wrong—to think because the 9 months are over, that victory should be near, yet it is eluding them. Give couples frequent progress reports during labor, so they do not become discouraged or fearful this way at this seeming lack of progress (Box 15.7).

### BOX 15.7

#### Nursing Care Planning Tips for Effective Communication

Celeste Bailey is having a great deal of back pain as well as strong uterine contractions.

*Tip:* Be prepared to repeat instructions as necessary to prevent a woman from becoming confused. Women in labor may be enduring so much pain and are under so much stress that they don’t hear or process instructions well. Gently repeat the instructions without reminding them they were previously given the information. A reminder is not therapeutic because it can lower self-esteem and a sense of self-control.

**Nurse:** You don’t look very comfortable, Mrs. Bailey. Would you feel better if you sat in the rocking chair rather than stay in bed?

**Celeste:** Can I do that?

**Nurse:** You can use any position comfortable for you.

**Celeste:** Can I walk over to the window?

**Nurse:** Whatever is most comfortable.

**Celeste:** Thank you. You're very understanding.

*Help Empower Women.* Most women want to feel in control of what is happening to them during labor in order to be able to face this big an event in their life. They accomplish this by stating their preferences, breathing with contractions, and changing their position to the one that makes them most comfortable. In contrast, some women handle the stress of labor by becoming extremely passive and quiet. Still others feel a need to show their emotions by shouting or crying. Help each woman express her feelings in her own way or in the way that works best for her.

Part of the way women react to labor is culturally influenced. Don't stereotype women, however, by studying a list of how a typical Hispanic, Middle Eastern, or Asian woman is most apt to react in labor. Instead, ask each woman what will make her feel most comfortable and able to feel in control. A list of expected behaviors may not apply to some women at all.

*Respect Contraction Time.* Do not interrupt a woman who is in the middle of breathing exercises during labor to perform a procedure or ask questions because, once her concentration is disrupted, she will feel the pain of the contraction and, if she has been successfully using breathing exercises to reduce pain, suddenly feeling the full force of a contraction can be extremely frightening. She tenses and the pain becomes worse, causing her to doubt her ability to breathe constructively in the face of the next contraction. Instead of interrupting, allow her to finish breathing with her contraction, then ask questions or announce what procedure needs to be done next. (See [Chapter 16](#) for a discussion of pain management techniques during labor.)

*Promote Change of Positions.* Because the bed is the main piece of furniture in a birthing room, many women assume they are expected to lie quietly in bed during labor. In early labor, however, a woman should be out of bed walking or sitting in a chair, kneeling, squatting, on all fours, or in whatever position she prefers because active movement can shorten the beginning stage of labor (Jones, 2015) (Fig. 15.21). Ballroom dancing or swaying with her partner to music they have brought with them can be a helpful activity. Soaking in a tub of warm water (98.6°F [37°C]) or taking a warm shower with the water directed on the abdomen both feel relaxing and so may also help. Water tubs give a woman buoyancy and so make it easier for her to change position. Remember, they also can make a woman feel drowsy, so never leave a woman alone in a tub. Be certain the tub is kept clean of feces so a vaginal examination can be done with the woman in the tub without worry of vaginal contamination.

**Figure 15.21** Finding a comfortable position during early labor is important. Here, a nurse assists a woman with walking during labor.

The exception to being active in labor is a woman whose membranes have ruptured in early labor. She should lie on her side until it is established the FHR is stable or she has had a vaginal examination by her primary care provider.

If a woman receives medication for pain such as a narcotic, she may need to remain in bed for about 15 minutes afterward to avoid a fall if she should become dizzy from the medication. While she is in bed, encourage her to lie on her left side so the heavy uterus tips forward, away from the vena cava, allowing free blood return from the lower extremities and adequate placental filling and circulation. Most women are comfortable in this position and adjust to it readily. Position the chair for the support person facing her so she doesn't keep turning onto her back to talk. Many institutions have protocols which do not allow women to be ambulatory after the administration of narcotics.

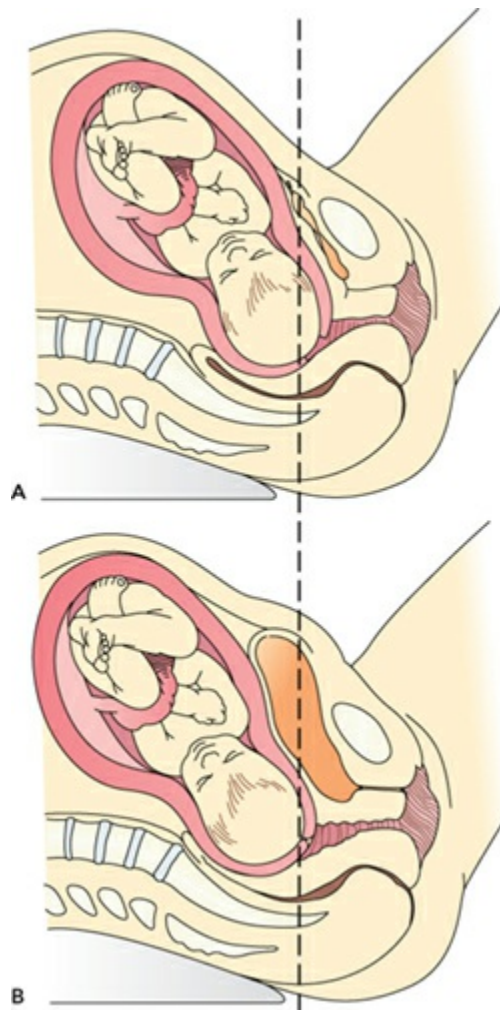

Some women have practiced breathing exercises in a supine position while at

home and may need additional coaching to do them in a sitting or dancing position. If a woman feels she must lie on her back during a contraction to make her breathing exercises effective, place a folded towel under her left hip to tilt her uterus to the side. Remind her to return to her side or sit up between contractions.

*Help With Fetal Alignment.* A baby's birth is easiest from an ROA or LOA position because a fetus that presents in an LOP or ROP position needs to rotate into an anterior position to be born. Either squatting or an "all fours" position may help the fetus turn and shorten labor. A birthing sling, or rebozo, is a long piece of fabric that can be slipped under a woman's back as she lies supine or over the abdomen if she is in a hands-and-knees position (Cohen & Thomas, 2015). A support person uses the sling to gently rock the mother's abdomen, a technique which is advocated as also helping a fetus move into good alignment with the pelvis. It is difficult to find evidence-based practice that birthing slings accomplish this, so they should be used with caution until their worth is more firmly established. There is little need for them with the fetus who is already in good alignment.

*Promote Voiding and Provide Bladder Care.* A full bladder or bowel can impede fetal descent, so encourage a woman to void, if possible, at least every 2 to 4 hours during labor. The way a full bladder can impede descent of a fetus is illustrated in Figure 15.22. The reason you need to remind a woman to void during labor is because she may mistakenly interpret the discomfort of a full bladder as part of the sensations of labor. You can assess for a full bladder by percussion (an empty bladder sounds dull; a full one sounds resonant). If a woman cannot void and the bladder becomes distended, she may need to be catheterized. Catheterizing a woman in labor is uncomfortable for her and difficult for you: The vulva is edematous from the pressure of the fetal presenting part, stretching the urethral canal downward and making the urethra difficult to locate. For best results, use a small catheter (No. 12 to 14F) and insert it between contractions. Use extremely careful aseptic technique to avoid introducing any microorganisms that might result in a urinary tract infection.

**Figure 15.22** The effect of a full bladder on fetal descent. **(A)** The bladder is empty. **(B)** A full bladder impedes fetal progress.

**Nursing Diagnosis:** Risk for ineffective breathing pattern related to breathing exercises

**Outcome Evaluation:** Patient's respiratory rate returns to normal limits after a contraction; skin is her usual color, cool, and dry. No reports of light-headedness or tingling/numbness in extremities.

Hyperventilation (an accelerated rate of respiration) occurs when a woman exhales more deeply than she inhales. As a result, extra carbon dioxide is blown off and respiratory alkalosis results. This can occur when a woman is practicing breathing exercises in preparation for labor, but it is most apt to occur during actual labor. The woman feels lightheaded and may have tingling or numbness in her toes and fingertips. If allowed to progress, hyperventilation can lead to loss of consciousness.

The best way to manage hyperventilation is to prevent it. Be certain that when a woman is breathing rapidly, she ends all breathing sessions with a long cleansing breath to help restore carbon dioxide balance. If hyperventilation begins, ask her to

breathe in and out into a paper bag, so she rebreathes the carbon dioxide she has exhaled. If a paper bag is unavailable, a woman can use her cupped hands or those of her partner.

**Nursing Diagnosis:** Anxiety related to stress of labor

**Outcome Evaluation:** Patient states she feels in control of her situation; she and her support person express confidence in their ability to weather this extraordinary event in their life.

Labor is such an intense process it creates a high level of emotional stress for both the woman and her support person. Ability to tolerate stress (to cope adequately) depends on a person's perception of the event, the support people available, and past experience in using coping mechanisms. Ways to reduce stress in labor, therefore, center on helping a woman to perceive labor clearly, providing opportunities for her partner to provide support, and helping her gain confidence that she can manage this event.

*Offer Support.* Support needs to come from healthcare personnel as well as a woman's individual support person. There is no substitute for personal touch and contact as a way to provide support during labor (unless she's a person who doesn't like to be touched). Patting an arm while telling a woman she is progressing in labor, brushing away a wisp of hair from her forehead, and wiping her forehead with a cool cloth are indispensable methods of conveying support and produce several benefits.

Effective support can make the difference in helping a woman feel able to continue with labor. In addition, a woman who is touched, who experiences the warmth and friendliness of human contact during labor—a time when she is physically dependent—may handle her newborn (who is also physically dependent and undergoing an adjustment not unlike the one she has just gone through) more warmly and affectionately.

*Respect and Promote the Support Person.* Be certain to admit a woman's support person to the birthing area along with the woman and encourage him or her to remain with the woman throughout the birth because having someone familiar with her during labor helps to counteract the sensation everything is new and unexpected. Acquaint the support person with the physical layout of the birthing room and point out where supplies such as towels, washcloths, and ice chips are stored, so he or she can get them as necessary. Be certain that all healthcare personnel are aware of whom the support person is and the importance of making him or her feel welcome.

If the support person will be acting as a labor coach, ask whether he or she has attended a prepared childbirth class and exactly how the support person wants to help the woman manage the pain of contractions. If a support person is hesitant to give coaching instructions, it's better to review techniques than to take over. Offer praise not only for the woman but also for the support person as well because watching a birth is often as totally a new experience for this person as for the woman. Relieve the

support person as necessary, so he or she can take a break and get something to eat or visit with older children (Fig. 15.23). If older children will view the birth, be certain they are oriented and have a child care provider to entertain them during the long hours of labor.

**Figure 15.23** Encouraging a support person so he can continue to give support is an important nursing role. (© Barbara Proud.)

In addition to having a support person, many women choose a doula or an expert support person to be with them in labor. Having such a person present frees the woman's partner to enjoy the birth rather than feel occupied with coaching instructions. Extensive research on the subject of doula care has demonstrated that rates of oxytocin augmentation, the need for epidural anesthesia, and cesarean birth rates can be reduced through doula support. Additionally, mothers tend to be more satisfied with the birth experience regardless of outcomes (Hodnett et al., 2013).

*Support a Woman's Pain Management Needs.* Many women plan on using nonpharmacologic pain relief measures such as hydrotherapy (soaking in a tub of warm water or taking a warm shower), position changes, or acupuncture during labor; ask if the woman has planned any of these and what you could do to help her make these effective (Chaillet, Belaid, Crochetière, et al., 2014). Other women want pharmacologic help in labor. Support whichever decision a woman has made coming into labor as well as any change she decides on as labor progresses (see Chapter 16 for a discussion of common nonpharmacologic as well as pharmacologic measures for labor).

Some healthcare providers are reluctant to suggest to a woman that pharmacologic pain relief is available as this might influence her to accept an analgesic rather than continue to use nonpharmacologic methods. Part of being in control, however, is knowing your options and feeling free to elect the one most appropriate at that time. Because pain is subjective, only the woman knows how much pain she can endure and whether she needs some supplemental help to make

childbirth the experience she planned.

### *What If... 15.3*

**Celeste's doula and Celeste's teenage sister disagree on whether Celeste needs medication for pain during labor. Whose suggestion would the nurse pay the most attention to? How could the nurse resolve the issue?**

**Nursing Diagnosis:** Risk for fluid volume deficit related to prolonged lack of oral intake and diaphoresis from the effort of labor

**Outcome Evaluation:** Patient drinks at least one glass of selected beverage every hour, states she does not feel thirsty; voids at least 30 ml/hr every 2 to 4 hours.

Women need to remain well hydrated during labor, so urge them to drink at least a glass of fluid every hour. Sucking on ice chips, popsicles, or lollipops can help supply additional fluid. Some women need isotonic sports drinks to prevent secondary uterine inertia (a cessation of labor contractions) as well as to combat generalized dehydration and exhaustion. Even with an adequate fluid intake, a woman's mouth and lips can become uncomfortably dry because of mouth breathing. Applying lip balm to prevent or relieve this discomfort can be helpful.

## The Care of a Woman During the Second Stage of Labor

The second stage of labor is the time from full cervical dilatation to birth of the newborn. Even women who have taken childbirth education classes and who believe they are well prepared for any length or type of contractions are surprised at the intensity of the pushing sensation they feel in this stage of labor. Because the feeling to push becomes so strong, some women react to this by growing argumentative and angry, or by crying and screaming. Other women react by tensing their abdominal muscles and trying to resist pushing, thus making the sensation even more painful and frightening. If the woman has not received an epidural for pain management, she should push with contractions and rest in between. In the past, women were told to hold their breath while they did this. Holding the breath for a prolonged time, however, impairs blood return from the vena cava (a Valsalva maneuver), so this should be discouraged. Instead, encourage women to assume any position that is comfortable for them and breathe any way that is natural for them, except by holding their breath while they push (Vaziri, Arzhe, Asadi, et al., 2016) (Box 15.8).

### BOX 15.8

#### Nursing Care Planning to Empower a Family

**Q.** Celeste asks you, “How will I know when I should begin to push with labor?”

**A.** After full cervical dilatation, the baby’s head descends in the pelvis to the level of the pelvic floor. When this happens, you’ll realize a strong feeling you have to push as if you need to move your bowels. Don’t push before that; wait for the natural signal. Pushing is a great moment in labor because as you push (remember not to hold your breath), you no longer feel pain, just a wonderful awareness your baby is about to be born.

A support person plays a vital role during this time because all of the preparations done up to this point may still not be enough to sustain a woman during these final contractions unless she feels well supported. This participation also creates an important sharing time later after the birth and can give a couple a sense of family for the first time.

Women also need to have an experienced healthcare person with them as they enter this stage of labor to reassure them that the change in contractions is normal and to give knowledgeable support everything is all right. [Box 15.9](#) shows an interprofessional care map illustrating both nursing and team planning for labor.

#### BOX 15.9

#### Nursing Care Planning

### AN INTERPROFESSIONAL CARE MAP FOR A WOMAN DURING LABOR AND BIRTH

Celeste Bailey is a 26-year-old woman you admit to a birthing room. She tells you she wants to have her baby “naturally,” without any analgesia or anesthesia. Her husband, a long distance truck driver, is on his way home but hasn’t arrived as of yet. Her teenage sister is with her. She states she has no idea how to coach her except to pray. As you finish assessing contractions, Celeste grips her abdomen, screams, and shouts, “I’m breathing just like I’m supposed to do! Why does this hurt so bad?”

**Family Assessment:** Patient lives with husband in fixed rent housing project. Finances rated as “horrible.” She says, “If you want to be rich, don’t marry a truck driver.” Her sister and parents live nearby.

**Patient Assessment:** Gravida 1, para 0. Contractions of moderate intensity, 45 seconds in duration, 3 minutes apart. Cervix dilated 3 cm, 60% effaced. Membranes intact. Fetal heart rate (FHR), 148 beats/min; fetus in right occipitoanterior (ROA) position. Attended childbirth education classes but appears to be using breathing exercises ineffectively without her coach. Brought a red rose to use as a focusing object. Has not voided for past 4 hours.

**Nursing Diagnosis:** Pain related to uterine contractions and pressure on pelvic structures from labor

**Outcome Criteria:** Patient manages her discomfort in labor with nonpharmacologic methods, identifies additional pain relief measures if needed, responds to questions and instructions; states labor and birth were a positive experience for her.

<b>Team Member Responsible</b>	<b>Assessment</b>	<b>Intervention</b>	<b>Rationale</b>	<b>Expected Outcome</b>
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Inspect the patient's suprapubic area and palpate for bladder distention because she has not voided for 4 hours.	Encourage patient to void every 2 hours.	A full bladder contributes to the patient's discomfort and impedes fetal descent, possibly prolonging labor.	Patient has no signs of bladder distention and voids every 2 hours during labor.
Nurse	Assess level of pain from uterine contractions and pelvic pressure by both verbal and nonverbal indicators; use 1–10 pain score.	Review and observe breathing patterns with patient and teenage sister to be certain she is obtaining maximum relief.	Pain is a subjective symptom, so only the patient can determine her degree of pain or what is most helpful to relieve it.	Patient rates her level of pain from labor contractions as good to tolerable. Teenage sister offers effective support.
<i>Teamwork and Collaboration</i>				
Nurse/primary care provider	Ask sister if she will serve as labor coach until husband arrives. Determine if a nurse anesthetist is available in case the patient changes mind about analgesia because husband is not with her.	Demonstrate to sister how to serve as coach. Consult with nurse anesthetist about patient's wish to not receive any pharmacologic pain relief.	Respecting patient's wishes is a prime mode of encouraging self-efficacy. A support person can play a major role in making labor a tolerable experience.	Sister serves as effective labor coach. Pain management team supports patient's wish for no pharmacologic interventions but will be prepared to administer pain relief if patient's wishes change or an emergency

should change the patient's goal.

*Procedures/Medications for Quality Improvement*

Nurse	Assess what particular care measures, if any, patient desires during labor such as walking or using a water tub.	Establish a birth plan with patient so all staff members can be aware of her individual preferences.	Respecting a patient's choice helps to maintain self-esteem and a feeling of control.	Patient expresses her preferences during labor.
-------	--	--	---	---

*Nutrition*

Nurse	Assess when patient last ate. Ask about preferences for fluid during labor.	Provide patient with ice chips, hard candy, or other fluid as desired.	Ice chips or hard candy can relieve mouth dryness from breathing exercises, and fluid is important to prevent dehydration.	Patient states she has no mouth discomfort and does not feel hungry; drinks at least a glass of fluid every hour.
-------	---	--	--	---

*Patient-Centered Care*

Nurse	Assess what patient knows about the usual process and time intervals of labor.	Provide information to supplement patient's knowledge of labor; update patient frequently on labor progress.	Frequent updates about patient's progress help to alleviate anxiety.	Patient states she understands the process of usual labor and indicates progress reports are helpful.
-------	--	--	--	---

*Psychosocial/Spiritual/Emotional Needs*

Nurse	Assess if physical environment seems conducive to	Provide a comfortable environment. Encourage patient to	A comfortable environment aids in relaxation and minimizes	Patient reports environment is comfortable and she feels secure. She assumes a
-------	---	---	--	--

labor.	assume different positions and to change them regularly. Respect the need for focusing during contractions.	distractions. Position changes promote fetal descent. Interrupting focusing can lessen effectiveness of the technique.	variety of positions during labor as desired. She expresses she is able to use a rose for focus during contractions unimpaired by healthcare providers.
--------	---	--	---

*Informatics for Seamless Healthcare Planning*

Nurse	Assess how patient evaluates her labor experience.	Help patient voice her satisfaction or dissatisfaction with her labor experience.	Reviewing a possibly traumatic experience helps put it into perspective among life events.	Patient states labor and birth were, at worst, a tolerable experience and, at best, a highlight of her life.
-------	--	---	--	--

A general timetable for second-stage care is shown in [Table 15.7](#). Be certain to assess fetal heart sounds at the beginning of the second stage to be certain the start of the baby’s passage into the birth canal is not occluding the cord and interfering with fetal circulation. Assisting a woman into whatever position she feels will be most effective for pushing (e.g., squatting, sitting upright, leaning forward against her partner) is important to help align the fetal presenting part with the cervix, increase the pelvic diameters, and use the fetal weight to help descent so that a prolonged second stage does not occur. A danger of a prolonged second stage is chorioamnionitis (membrane infection), an increased rate of cesarean birth, and future urinary incontinence ([Stephansson, Sandström, Petersson, et al., 2016](#)).

## PREPARING THE PLACE OF BIRTH

For a multipara, convert a birthing room into a birth room by opening the sterile packs of supplies on waiting tables when the cervix has dilated. Be certain drapes and materials used for birth are sterile so no microorganisms can be accidentally introduced into the uterus. A table arranged with equipment such as sponges, drapes, scissors, basins, clamps, vaginal packing, and sterile gowns, gloves, and towels can be left, if covered, for up to 8 hours.

A birthing bed is “broken” or the foot folded down to allow the primary care provider ready access to support a crowning newborn head. Be certain that once a bed is broken, someone remains continuously at the foot of the bed so if the fetus is born suddenly, the head and body can be supported and born safely. Some providers do not choose to “break the bed” and instead will accommodate the woman in the birthing position of her choice, whether this be side-lying, hands and knees, standing or on a birthing stool.

To provide for baby care, open the partition at the end of the room to reveal the “baby island,” or newborn care area. Such areas include a radiant heat warmer, equipment for suction and resuscitation, and supplies for eye care and identification of the newborn. Turn on the radiant heat warmer in advance, so the bottom mattress is pleasantly warm to the touch at the time of birth. Place sterile towels and a blanket on the warmer so they will also be warm when used to dry and cover the infant to help prevent hypothermia.

## POSITIONING FOR BIRTH

Women can choose a variety of positions for birth. In the past, a lithotomy position was the preferred position for birth because it offers a clear view of the perineum, but it is no longer a position of choice as a woman lying flat on her back may slow, not help, fetal descent, and lying longer than 1 hour in a lithotomy position can lead to intense pelvic congestion and possibly thrombophlebitis. More effective birth positions include the lateral or Sims position, a dorsal recumbent position (on the back with knees flexed), semi-sitting, or squatting. Using these positions plus warm compresses to the perineum place less tension on the perineum and result in fewer perineal tears ([Vaziri, Farahmand,](#)

Samsami, et al., 2014).

## **The Water Birth**

Women may not only use a warm water tub for labor comfort and relaxation but also to give birth under water. The increased buoyancy they feel from the water helps them change positions easily; a sitting posture helps with fetal descent (Impey & Child, 2012).

As women begin to push with contractions, they also often move their bowels so the water can become contaminated with feces. Keep the bath water as free as possible by lifting any feces out with a plastic scoop so, if the infant is born in the tub, he or she will be born into as clean an environment as possible.

The baby is born underwater and then immediately brought to the surface for a first breath. A potential difficulty is contamination of the bath water with feces, which could lead to uterine infection or aspiration of contaminated bath water by a newborn, which could lead to pneumonia. Newborns, however, have a dive reflex, which alerts them not to breathe while under water, so this is not usually a problem. A dive reflex may not be operative if the baby's head is brought to the surface before the entire baby is born so the timing of this is important. Maternal chilling when a woman leaves the water is another factor to consider and prevent. Yet another concern is that a short umbilical cord could tear as the baby is brought to the surface. To help prevent this, limit the amount of water in the tub to about 12 in.

Be certain tubs are cleaned with the agency-designated solution at the finish of labor so it will be clean for the next couple.

## **PROMOTING EFFECTIVE SECOND-STAGE PUSHING**

For the most effective pushing during the second stage of labor, a woman should wait to feel the urge to push even though a pelvic exam has revealed she is fully dilated (Lemos, Amorim, Dornelas de Andrade, et al., 2015). Pushing is usually best done from a semi-Fowler's position with legs raised against the abdomen, squatting, or on all fours rather than lying flat to allow gravity to aid the effort (Fig. 15.24). Make sure the woman pushes with contractions and rests between them. She can use short pushes or long, sustained ones, whichever feels more comfortable. Holding the breath during a contraction could cause a Valsalva maneuver or temporarily impede blood return to her heart because of increased intrathoracic pressure, which could then also interfere with blood supply to the uterus. To prevent her from holding her breath during pushing, urge her to grunt or breathe out during a pushing effort (as tennis players do).

**Figure 15.24** Positions for pushing during second stage labor: (A) squatting with support person, (B) on all fours, and (C) on all fours with chest support. (© Barbara Proud.)

If there is a reason such as a nuchal cord (cord located around the baby’s neck), which must be removed before the infant is fully born, it may be necessary to prevent a woman from pushing immediately after delivery of the fetal head. To help her do this, ask her to pant with contractions. Because it is difficult to push effectively when she is using her diaphragm for panting, this limits pushing. Remember, however, that pushing is involuntary. Regardless of how much a woman wants to cooperate, stopping this overwhelming urge to push is almost beyond her power. Demonstrating panting with her may be most effective. Be sure she is inhaling adequately with panting. Otherwise, she might hyperventilate and become light-headed. Have her take deep cleansing breaths between contractions to prevent this.

### **PERINEAL CLEANING AND MASSAGE**

Massaging the perineum as the fetal head enlarges the vaginal opening helps to keep it supple and prevent tearing. To remove vaginal or rectal secretions and prepare the cleanest environment for the birth of the baby, the care provider may clean the perineum with a warmed antiseptic such as Iodaphor (cold solution causes cramping) and then rinse the area with sterile water. If assisting with this, always clean from the vagina outward (so microorganisms are moved away from the vagina, not toward it), using a clean compress for each stroke. Be certain to include a wide area (vulva, upper inner thighs, pubis, and anus). [Figure 15.25](#) shows a typical pattern for cleaning.

**Figure 15.25** The pattern for cleaning the perineum before birth. Cleaning from the birth canal outward moves bacteria away from, not into, the vagina. Numbers refer to the steps of the procedure.

## THE BIRTH

As soon as the head of a fetus is prominent (approximately 8 cm across) at the vaginal opening, one technique to help the fetus achieve extension and allow the smallest head diameter to present is for the care provider to place a sterile towel over the rectum and press forward on the fetal chin while the other hand presses downward on the occiput (a Ritgen maneuver) (Fig. 15.26). This maneuver, however, is often unnecessary as babies tend to be born easily without this assistance. Pressure should never be applied to the fundus of the uterus to effect birth because uterine rupture could occur.

**Figure 15.26** The Ritgen maneuver. The *arrow* shows direction of pressure.

The woman is asked to continue pushing until the occiput of the fetal head is firmly at the pubic arch. The head is then gently born between contractions if possible. This helps to prevent the head from being expelled too rapidly, creating a major pressure change in the skull, which might then rupture cerebral blood vessels. It also reduces the

possibility of a perineal tear. A woman who has not had anesthesia experiences the birth of the head as a flash of pain or a burning sensation, as if someone had momentarily poured hot water on her perineum.

Immediately after birth of the baby's head, the primary care provider passes his or her fingers around the newborn's neck to determine whether a loop of umbilical cord is encircling the neck. It is not uncommon for a single loop of cord to be positioned this way (termed a nuchal cord). If such a loop is felt, it is gently loosened and drawn down over the fetal head. If it is too tightly coiled to allow this, it is clamped and cut before the shoulders are born. Otherwise, it could tear and interfere with the fetal oxygen supply.

After expulsion of the fetal head, external rotation occurs (a woman can feel this happening by gently touching the head if she wants to). Gentle pressure is then exerted downward on the side of the infant's head by the primary care provider so the anterior shoulder is born. Slight upward pressure on the side of the head allows the anterior shoulder to nestle against the symphysis pubis and the posterior shoulder to be born. The remainder of the body then slides free without any further difficulty.

A child is considered born when the whole body is born. This is the time that should be noted and recorded as the time of birth, which is a nursing responsibility (most primary care providers regard it as their responsibility or pleasure to announce the sex of the infant). The newborn is immediately laid on the mother's naked abdomen and covered with a warmed blanket and cap to conserve heat and encourage mother–infant bonding (E. R. Moore, Anderson, Bergman, et al., 2012). With this, the second stage of labor is complete (Fig. 15.27).

**Figure 15.27** A child is considered born when the whole body is born.  
(© Barbara Proud.)

## CUTTING AND CLAMPING THE CORD

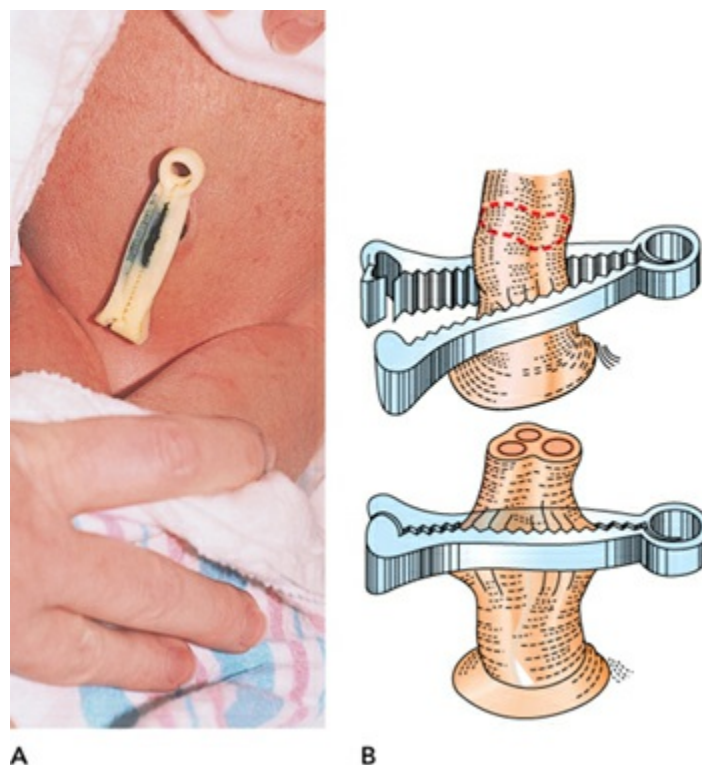

Cutting the cord is part of the stimulus that initiates a first breath or marks the newborn's most important transition into the outside world, the establishment of independent respirations. The timing of cord clamping, however, varies depending on

the parent's preference and the maturity of the infant.

The umbilical cord continues to pulsate for a few minutes after birth and then the pulsation ceases. Delaying cutting (also called physiologic clamping) until pulsation ceases and maintaining the infant at a uterine level allows as much as 100 ml more of blood to pass from the placenta into the fetus than if the infant were held in a superior position or the cord was immediately cut. Delaying cutting, therefore, helps ensure an adequate red blood cell and white cell count in the newborn (Popat, Robledo, Sebastian, et al., 2016). The timing of cord clamping, however, is individualized because late clamping of the cord this way could cause overinfusion with placental blood and the possibility of polycythemia and hyperbilirubinemia in a susceptible newborn, a particular concern if the infant is preterm.

Before cutting, the cord is clamped with two hemostats placed 8 to 10 in. from the infant's umbilicus. The woman's partner or support person may then have the privilege of cutting the cord between the hemostats. A cord blood sample is often obtained to provide a ready source of infant blood if blood typing or other emergency measures, such as establishing whether fetal acidosis was present, needs to be done. Blood may also be taken for cord blood banking so the family has stem cells available if needed in the future.

The vessels in the cord are then counted to be certain three are present and an umbilical clamp is applied to replace the forceps (Fig. 15.28). Some umbilical clamps in hospitals have an alarm attached that will ring if the infant is taken further than set hospital boundaries, a precaution against newborn abduction.

**Figure 15.28** (A) An umbilical clamp applied to the cord. (© Caroline

Brown, RNC, MS, DEd.) (B) Placing clamp and locking the clamp.

## INTRODUCING THE INFANT

After the cord is cut, it is time for the new parents to spend quality time with their newborn. The infant can remain on the mother's abdomen for skin-to-skin contact. If the woman's partner or support person wants to hold the infant, dry the infant well with a warmed towel, wrap him or her in a sterile blanket, and cover the head with a wrapped towel or cap. Be certain to handle newborns gently but firmly as they are slippery from amniotic fluid and vernix.

Most newborns receive prophylactic eye ointment against the possibility of a chlamydia infection. Don't administer this until after the parents have had this chance to see their infant for the first time (and the infant has had a chance to see them) (see [Chapter 18](#) for continuing infant care such as weighing and measuring). This initial contact is also the optimal time for a mother to begin breastfeeding because an infant seems to be hungry at birth and sucking at the breasts stimulates the release of endogenous oxytocin, encouraging uterine contraction and involution, or the return of the uterus to its prepregnant state ([World Health Organization, 2014](#)).

## The Care of a Woman During the Third and Fourth Stages of Labor

The third stage of labor is the time from the birth of the baby until the placenta is delivered. For most women, this is a time of great excitement because the infant has been born, but this can also be a time of feeling anticlimactic because the infant has finally arrived after being anticipated for so long a time.

## THE DELIVERY OF THE PLACENTA

The placenta will deliver spontaneously following most births ([Begley, Gyte, Devane, et al., 2015](#)). Although this is true in most cases, up to 30 minutes is considered normal. After delivery, the placenta is inspected to be certain it is intact without gross abnormalities and that no cotyledons remain in the uterus. Normally, a placenta is one sixth the weight of the infant. If it is unusually large or small, you may be asked to weigh it.

After the placenta inspection, if the mother's uterus has not contracted firmly on its own, the primary care provider will massage the fundus to urge it to contract. Oxytocin (Pitocin 10 units) may be prescribed to be administered intramuscularly (IM) or per 1,000 ml fluid intravenously (IV) to also help contraction ([Karch, 2013](#)). If excessive bleeding with poor uterine contraction remains, an injection of carboprost tromethamine (Hemabate) or methylergonovine maleate (Methergine) is yet another solution to increase uterine contraction and to guard against hemorrhage. It is important to know prior to the second stage whether a woman has a contraindication to either of these

drugs such as asthma or hypertension.

The administration of these drugs is a nursing responsibility in most healthcare facilities. Because Pitocin causes hypertension by vasoconstriction, be certain to obtain a baseline blood pressure measurement before administration. Question the use of such a drug if the woman had an elevated blood pressure during pregnancy that is still present.

The fourth stage of labor includes the first few hours after birth (discussed in [Chapter 17](#)). It signals the beginning of dramatic changes because it marks the beginning of both a new life and a new family.

## THE PERINEAL INSPECTION

To be certain a woman's perineum did not tear from the pressure of the fetal head, the perineum is carefully inspected after birth. About 3% of women do have a small tear extending backward from the vagina. Perineal tears are rated grade 1 to grade 4, grade 1 being minimal and grade 4 extending to and including the rectum (see [Chapter 25](#) for grading definitions and care).

Most are small enough that no suturing is needed ([Dudley, Kettle, & Ismail, 2013](#)). If a tear is large enough to require suturing, a woman usually has enough natural perineal anesthesia from pressure of the fetal head or enough effect from epidural anesthesia, she will not feel pain from the suturing. If she does have pain, a local anesthetic can be given to make the process pain-free.

## THE IMMEDIATE POSTPARTUM ASSESSMENT AND NURSING CARE

This is the beginning of the postpartal period or the fourth stage of labor. Because the uterus may be so exhausted from labor that it cannot maintain contraction, there is a high risk for hemorrhage during this time (it is the most dangerous time of birth for the mother). Obtain vital signs (pulse, respirations, and blood pressure) every 15 minutes for the first hour and then according to agency policy or the woman's condition. Pulse and respirations may be fairly rapid immediately after birth (80 to 90 beats/min and 20 to 24 breaths/min), and blood pressure may be slightly elevated due to exertion and excitement of the moment or recent oxytocin administration. Wash the perineum with the agency-designated solution and apply a perineal pad. Palpate a woman's fundus for size, consistency, and position and observe the amount and characteristics of lochia each time you record vital signs.

Return the birthing bed to its original position. Offer a clean gown and a warmed blanket because a woman often experiences chills and a shaking sensation 10 to 15 minutes after birth. This may be due to the low temperature of a birthing room but may also be a result of the sudden release of pressure on pelvic nerves or of excess epinephrine production during labor. In any event, it is a normal phenomenon but can be frightening to the mother if she associates the chills with fever or infection and worry

she will be ill at a time when she most wants to be well to care for her new child. You can reassure her this is a transitory sensation, is very common, and passes quickly. Continuing assessments are discussed in [Chapter 17](#) with care of a postpartal family.

## **The Woman With Unique Concerns in Labor**

### **THE WOMAN WITHOUT A SUPPORT PERSON**

Some women choose to labor without their partner—the usual support person—during labor. Other times, a partner is not available due to work or other commitments. Such women then ask a family member or close friend to act as their support person. A woman who brings no support person with her needs a supportive nurse to remain with her continuously during labor.

A woman whose acceptance of her pregnancy was slow to develop due to lack of adequate support people may not have completed the psychological tasks of pregnancy by the time she is in labor. This could make her more apprehensive about being alone and being asked to begin a new life role. Increased assessment of parent–child bonding may be necessary in the immediate postpartal period to be certain her loneliness does not affect her relationship with her child.

### **THE WOMAN WHO WILL BE PLACING HER BABY FOR ADOPTION**

Even if a woman has decided to place her baby for adoption during pregnancy, she needs to be an active participant in her labor and the baby’s birth and be allowed to hold her child afterward unless she chooses otherwise. Each state has a set number of days in which a mother must decide whether she wants to keep her baby or decide on adoption. Although this decision may have seemed easier to make during pregnancy, once a woman holds the baby in her arms, the prospect of giving up the child may be more painful than she realized. Offer support no matter what decision she eventually makes; also offer support as to whether she wants to hold the child or begin breastfeeding. Be certain you do not offer influencing advice because the woman is the only person who knows whether keeping this child will be right for her or for the child in the future.

### **THE WOMAN WITH CULTURAL CONCERNS**

A number of women from countries where female genital cutting is part of her culture may have difficulty with a successful second stage of labor because their perineum has so much scar tissue that their vagina cannot dilate adequately for a fetal head to pass. They may need an episiotomy or defibulation (discussed in [Chapter 24](#)) to avoid extensive perineal tearing.

### **THE WOMAN WHO IS MORBIDLY OBESE**

The incidence of women who are morbidly obese seen in birth settings is growing

yearly (Perlow, Jones, & Ozimek, 2015). Care of women with a high body mass index (BMI) requires a number of special interventions in labor and birth.

On admission, a woman may be unusually fatigued from her efforts to keep active in early labor. Because many overweight women have elevated blood pressure, be certain to assess this on admission (but then repeat it about 15 minutes later when she is more rested to be certain an elevated pressure was not from anxiety). Assess her ankles carefully for edema because this is common from overworked circulation in her lower extremities. Fetal heart sounds may be difficult to auscultate in women who are obese. Electronic monitors may not have straps long enough to hold the sensors snugly in place, so they may have to be handheld or attached by wrapped gauze or stockinette.

It's important for all women to remain active in labor. Be certain to respect modesty of all sized women while helping her change from a soiled gown to a clean one or that she is adequately covered if she plans to walk in the birthing center or hospital hallway.

Women who are morbidly obese tend to have infants with larger than usual shoulders (macrosomia), which can slow or even halt fetal descent. Be certain to particularly monitor the length of the second stage of labor (the average time is 1 hour; 2 hours is time for care providers to be alerted that a complication may be occurring) because this is when the lack of descent becomes most apparent.

Be aware that a birthing bed is narrow in relation to her body when she holds her newborn and begins breastfeeding after birth. Praise her for her work well done in giving birth. Birth is such a dramatic experience that it may be the motivation that allows her to improve her own health in the year to come so she can enter a second pregnancy in better health.

#### *What If . . . 15.4*

**The nurse is interested in exploring one of the 2020 National Health Goals related to labor and birth (see [Box 15.1](#)). Most government-sponsored money for nursing research is allotted based on these goals. What would be a possible research topic to explore pertinent to these goals that would be applicable to Celeste and her family and that would also advance evidence-based practice?**

### Unfolding Patient Stories: Carla Hernandez • Part 2

Remember **Carla Hernandez**, a 32-year-old gravida 2, para 1, who you met in [Chapter 6](#). She is at 39 5/7 weeks gestation when her husband brings her to the hospital. How does the nurse determine that she is in active labor? If she is in labor, how will the nurse monitor the progress of labor? What nursing assessments are done to identify the signs of potential complications during labor? What questions would the nurse ask Carla to identify symptoms of potential complications of labor? What nursing interventions can assist

the couple's ability to cope with pain and stress experienced during labor?

Care for Carla and other patients in a realistic virtual environment: *vSim for Nursing* ([thepoint.lww.com/vSimMaternityPed](http://thepoint.lww.com/vSimMaternityPed)). Practice documenting these patients' care in DocuCare ([thepoint.lww.com/DocuCareEHR](http://thepoint.lww.com/DocuCareEHR)).

## KEY POINTS FOR REVIEW

- Labor is the series of events by which uterine contractions expel a fetus and placenta from a woman's body.
- The exact reason why labor begins is unknown. It most likely occurs because of an interplay between fetal and uterine factors that registers as progesterone withdrawal.
- Effective labor depends on interactions between the passage, the passenger, the power of contractions, and a woman's psychological readiness.
- Labor is an almost overwhelming experience because it involves intense sensations and emotions never felt before. Urge women to bring a support person with them to help cope with the experience. Orient and explain what is happening to this person as well as the woman in labor.
- The fetal presentation (the fetal body part that will initially contact the cervix), the position (the relationship of the fetal presenting part to a specific quadrant of the woman's pelvis), and the lie (whether the fetus is presenting the head or breech to the birth canal) are important determinants of the success of labor.
- The first stage of labor lasts from the onset of cervical dilatation until dilatation is complete (10 cm). The second stage extends from the time of full dilatation until the infant is born. A third or placental stage lasts from the time the infant is born until after delivery of the placenta. A fourth stage comprises the first few hours after birth.
- Danger signs of labor include an abnormal FHR, meconium staining of amniotic fluid, abnormal maternal pulse or blood pressure, inadequate or prolonged contractions, development of an abnormal lower abdomen contour, or increasing apprehension.
- Monitoring of uterine contractions and FHR is an important nursing responsibility. Fetal bradycardia, tachycardia, and FHR variability are important observations to make.
- Interventions such as keeping a woman active during labor and promoting voiding help to strengthen contractions and make labor more effective.
- Offering psychological support is crucial to maternal well-being and helps in planning nursing care that not only meets QSEN competencies but also best meets the family's total needs.
- Pushing during the second stage of labor should be guided by the woman's need to push. Urge her to breathe out while pushing, if possible.
- The placental stage follows birth and consists of both placental separation and expulsion. Observe for excessive bleeding during this time. Do not pull on the cord to hasten separation because this can lead to uterine inversion.

- A fetus is in potential danger when the membranes rupture because of the possibility of cord prolapse. Always assess FHR at this point to safeguard the fetus.
- A woman is at potential risk for hemorrhage throughout labor because of the possibility that the placenta could dislodge. Following birth, hemorrhage remains a possibility. Assess for vaginal bleeding and vital signs during both times to be certain this is not occurring.

### CRITICAL THINKING CARE STUDY

Gail Taylor is an obese-appearing 16-year-old whom you meet as she is admitted to your labor service. Her cervix is fully effaced, 10 cm dilated, and she is pushing. Her mother tells you she didn't know Gail was pregnant because she's been living at her boyfriend's apartment for 8 months. She didn't realize she was in labor until an hour ago when she dropped by the apartment and found the living room set up for a home birth. She pulled Gail into her car and drove her to the hospital, which took over an hour because of early morning freeway traffic. Gail's mother tells you the boyfriend (a 20-year-old college student) is waiting downstairs in the parking lot; she threatened she'd charge him with rape if he came any further inside than the front door of the hospital. Gail received no prenatal care or preparation for labor; when you ask her if she's happy she's having a baby, her mother interrupts and says, "I don't want her to even see it. We'll give it away for adoption."

1. This is a family with a multitude of problems. Did the mother make a good decision when she brought Gail to the hospital in her car rather than dial for emergency help if she was worried about her? Which would have been the best place for Gail to give birth: at an apartment arranged for home birth or in a car on a busy freeway?
2. Gail is automatically a high-risk patient because of her age. What other factors make her high risk?
3. Gail's mother seems to be making decisions for everyone here. Does she have any right to make an adoption decision for Gail?

## The Nursing Role in Providing Comfort During Labor and Birth

*Jonny Baranca is a primipara in early labor whom you admit to a birthing unit. Her cervix is 3 cm dilated. She tells you her sister had epidural anesthesia that completely obliterated her pain in labor for the birth of her baby 3 months ago. Based on her sister's experience, Jonny expected to be given epidural anesthesia as soon as she arrived at the hospital as she "is in early labor." Her physician, however, asked her to wait until she is 4 cm dilated. When you enter her room, you find her lying on her back in a birthing bed, crying. Her husband shouts his "wife deserves better care than this."*

*The previous chapter discussed the process of labor and birth and nursing care responsibilities. This chapter adds information to your knowledge base about how to promote comfort during labor. Effective pain management in labor can change labor from an experience so negative it can result in a posttraumatic stress syndrome to a positive, forward-moving experience.*

**Was the information Jonny received from her sister realistic? What are some immediate interventions you could do to help Jonny better cope with her pain?**

### KEY TERMS

**analgesia**  
**anesthesia**  
**doula**  
**endorphins**  
**epidural anesthesia**  
**pain**  
**pressure anesthesia**  
**pudendal nerve block**  
**reflexology**

### OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe the physiologic basis of contractions during labor and how nonpharmacologic therapies, as well as analgesia and anesthesia, can be used to promote a woman's comfort during labor and birth.
2. Identify 2020 National Health Goals related to comfort and drug-free pain management measures effective in childbirth that nurses can help the nation achieve.
3. Assess the degree and type of discomfort a woman is experiencing during labor and birth, including her ability to cope with pain effectively and the maternal and fetal impact of pain management, including side effects and safety.
4. Formulate nursing diagnoses related to the effect of pain or pain management during labor and birth.
5. Establish expected outcomes to meet the needs of a woman experiencing discomfort during labor and birth and manage seamless transitions across differing healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement common complementary and pharmacologic measures for pain management during labor and birth.
8. Evaluate expected outcomes for effectiveness and achievement of care.
9. Integrate knowledge of pain management during labor and birth with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

---

Concerns about the discomfort and pain that accompany labor and birth can dominate a pregnant woman's or couple's thoughts during pregnancy; these can become particularly strong as the baby's due date approaches. As discussed in [Chapter 14](#), prepared childbirth classes provide couples with an opportunity to learn and practice a variety of pain management techniques, such as breathing patterns, to help reduce pain in labor.

Often, however, the labor experience is so intense it becomes overwhelming, so administration of an analgesic or a regional anesthetic may be necessary to reduce discomfort sufficiently to allow a woman to regain control over herself and use breathing patterns. If the use of regional anesthesia makes labor a satisfying, positive experience, the intervention can ultimately promote the entire family's health. Some women, however, may feel they have let down themselves, a partner, or childbirth educator by asking for anesthesia; if this happens, asking for pain medication can make labor a negative experience.

Much has been written in nursing literature about using the neutral term *contraction* or other alternative reference instead of *labor pain* to keep from reminding a woman contractions are painful. The theory is a sound one, not only because a woman is experiencing a *contracting* sensation but also because calling it *pain* could magnify fear and tension; tension, in turn, magnifies pain. Remember, however, renaming it will not change its basic nature. Discomfort accompanies labor regardless of what term is used for it. Fortunately, many nursing interventions can help reduce pain, so labor is as fulfilling and rewarding an experience as a woman hoped it would be.

Making labor and birth a memorable experience for families is so important that 2020 National Health Goals have been established to address this topic. These are shown in [Box 16.1](#).

### BOX 16.1

#### Nursing Care Planning Based on 2020 National Health Goals

Because administration of either analgesia or anesthesia during labor can prolong labor and can possibly increase the number of instruments used or risk for cesarean birth, several 2020 National Health Goals are related to the types of pain relief used in labor. Examples include:

- Reduce the maternal mortality rate to no more than 11.4 deaths per 100,000 live births from a baseline of 12.7 per 100,000.
- Reduce the fetal/newborn death rate during the perinatal period (28 weeks of gestation to 7 days after birth) to no more than 5.9 per 1,000 live births from a baseline of 6.6 per 1,000 live births ([U.S. Department of Health and Human Services, 2010](#); see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these goals by educating women about the advantages of preparing for childbirth, helping them to use breathing patterns or other complementary and alternative therapies and techniques during labor so they need a minimum of analgesia and anesthesia, and conscientiously monitoring women who receive analgesics and anesthesia.

### *Nursing Process Overview*

#### FOR PAIN RELIEF DURING LABOR AND CHILDBIRTH

##### ASSESSMENT

**Pain**, the sensation of discomfort, is a subjective, personal symptom; it is what the experiencing person says it is and present when the experiencing person says it is present ([McCaffery, 1972](#)). It is unique to each individual, so a woman is the only person who can describe or know the extent of her pain. To assess the amount of discomfort a woman is having in labor, listen carefully to not only what she says but also how she rates her discomfort level on a pain assessment scale. Also look for subtle signs such as facial tenseness, flushing or paleness, hands clenched in fists,

rapid breathing, or rapid pulse rate.

### **NURSING DIAGNOSIS**

Although pain related to labor contractions is the most obvious nursing diagnosis applicable to labor, it is not the only relevant one because pain can create other problems for the laboring woman that can negatively affect the childbirth experience. If not resolved, these problems can intensify pain. Some women, for example, may become more concerned with their reaction to the pain than to the pain itself. Because of this, applicable nursing diagnoses might include:

- Pain related to labor contractions
- Powerlessness related to the duration and intensity of labor
- Anxiety related to lack of knowledge about “normal” labor process
- Risk for situational low self-esteem related to ineffectiveness of prepared childbirth breathing exercises
- Decisional conflict related to use of analgesia or anesthesia during labor

### **OUTCOME IDENTIFICATION AND PLANNING**

When developing realistic outcomes and planning interventions to manage discomfort during labor, consider the woman’s perceptions about childbirth, her past childbirth experiences (if any), and the amount and type of childbirth preparation she and her partner have made. For example, if a woman is using breathing exercises well, expecting she will need medication late in labor is probably not realistic. However, if a woman has not made any preparation as to how she will manage labor contractions, expecting that no medication will be used might be inappropriate.

Be aware that pharmacologic agents used during labor and birth may pose risks for both the woman, such as hypotension, as well as the fetus or neonate, such as bradycardia or respiratory issues at birth. Therefore, when considering use of pharmacologic intervention, the benefit to the woman and the fetus must outweigh the risks of medication use. In addition, a decision to use analgesia or anesthesia may also affect family functioning if the method chosen limits the partner’s participation in the birth. Contrarily, the use of a pharmacologic agent may be what a woman could most benefit from, particularly if she has a history of sexual trauma (Nerum, Halvorsen, Straume, et al., 2013).

### **IMPLEMENTATION**

Keeping a woman and her support person informed about their options and how they differ as labor progresses is important. For instance, simply knowing that birth is getting closer can make the next few contractions easier to withstand. Supporting and encouraging a woman to use methods of complementary and alternative therapies for pain management, such as a birthing ball, ambulation, relaxation, and breathing techniques, also are helpful. Offering analgesia or assisting with anesthesia administration during labor or birth requires nursing judgment and a caring presence to help one woman accept analgesia when she needs it and to encourage another to experience childbirth without pharmacologic intervention when that is what she

desires.

### **OUTCOME EVALUATION**

Evaluations are ongoing and typically must occur within a short time frame.

Examples of short-term expected outcomes that would indicate successful achievement during labor are:

- Patient states pain during labor is within a tolerable level for her.
- Couple reports they feel control throughout the labor process.
- Patient and fetus remain physiologically stable with use of pharmacologic interventions.
- Patient verbalizes satisfaction with current pain control measures.

A long-term evaluation should reveal a woman found labor and birth to be an experience not only endurable but also that it allowed her to grow in self-esteem and the family to grow through a shared experience. Asking a woman to describe her labor experience afterward in relation to pain not only aids an evaluation of whether pain management was adequate but also helps her work through this emotional period of life and integrate it into her previous experiences as well.

## **Experience of Pain During Childbirth**

Pain accompanies labor contractions for several different reasons and manifests itself in different ways for each woman ([Box 16.2](#)).

BOX 16.2

### **Nursing Care Planning Using Assessment**

#### **ASSESSING A WOMAN FOR SYMPTOMS OF PAIN DURING LABOR AND CHILDBIRTH**

## ETIOLOGY OF PAIN DURING LABOR AND BIRTH

Normally, contractions of involuntary muscles, such as the heart, stomach, and intestine, do not cause pain. This concept makes uterine contractions unique because they do cause pain. Several explanations exist for why this happens. During contractions, blood vessels constrict, reducing the blood supply to uterine and cervical cells, resulting in anoxia to muscle fibers. This anoxia can cause pain in the same way blockage of the cardiac arteries causes the pain of a heart attack. As labor progresses and contractions become longer and more intense, the ischemia to cells increases, the anoxia increases, and the pain intensifies.

Pain also probably results from stretching of the cervix and perineum. This phenomenon is the same as the intestinal pain that results when accumulating gas stretches the intestines. At the end of the transitional phase in labor, when stretching of

the cervix is complete and the woman feels she has to push, pain from the contractions often disappears as long as the woman is pushing, until the fetal presenting part causes a final stretching of the perineum.

Additional discomfort in labor may stem from the pressure of the fetal presenting part on tissues, including pressure on surrounding organs, such as the bladder, the urethra, and the lower colon. In addition to these factors, cultural expectations effect how pain is perceived (Box 16.3). All these factors make nursing support, in addition to a doula or a partner, important as it can have a positive influence on pain relief in all situations of labor.

### BOX 16.3

#### Nursing Care Planning to Respect Cultural Diversity

Some women believe their expected role during labor is to be stoic and nonverbal even in the face of intense pain. Others believe expressing their discomfort by screaming or verbalizing their discomfort is what is expected. If a woman is not proficient in English, it may be particularly difficult for her to describe her level of discomfort and that she needs some assistance. Assess each woman individually to determine not only what level of comfort she feels is right for her during labor but also the manner in which she feels most able to express discomfort. Assessing individuals in this way rather than relying on a list of “typical” ways Hispanic women, Asian women, and so forth, react to pain achieves better individual care. Because of Americanization, a woman’s surname or her appearance may be not be indicative at all of how she wants to manage pain.

The amount of analgesia women desire or will accept is dependent both on the situation and her culture. In a culture in which birth is seen as a “natural” process or if a woman has attended a class to prepare for birth, the less analgesia is generally desired. Any woman who has an effective support person with her generally needs less pharmacologic pain relief than one who does not.

## PHYSIOLOGY OF PAIN

Pain is a basic protective mechanism that alerts a person that something threatening is happening somewhere in the body. The Melzack–Wall gate control theory of pain (Melzack & Wall, 1965), the most widely accepted theory of pain response, proposes pain can be halted at three points:

- The peripheral end terminals
- The synapse points in the dorsal horn of the spinal cord
- The point at which the impulse is interpreted as pain in the brain cortex

Pain in peripheral terminals is automatically reduced by the production of **endorphins** and enkephalins, naturally occurring opiates that limit transmission of pain from the end terminals. Pain can be reduced further at these end points by mechanically

irritating nerve fibers through an action such as rubbing the skin, which blocks nerve transmission.

A major way to block spinal cord neurotransmitters (i.e., never allowing the pain impulse to cross to a spinal nerve) is by the administration of pain medications. In addition, the brain cortex can be distracted from sensing impulses as pain by such techniques as imagery, thought stopping, and perhaps aromatherapy or yoga.

Sensory impulses of pain from the uterus and cervix synapse at the spinal column at the level of T10 through L1, whereas motor impulses register higher in the cord at T5 through T10. Anesthetic pain relief measures for the first stage of labor, therefore, are designed to stop pain by blocking the lower sensory sites, but not the upper motor sites, so strong contractions can continue.

Sensory impulses from the perineum, which is involved in the second stage of labor, are carried by the pudendal nerve to join the spinal column at S2, S3, and S4. When the perineum is initiating the pain, anesthetic pain relief must block these lower receptor sites. This is an important point to remember when talking to a woman in labor about pain relief. Some interventions relieve pain for both the first and second stages of labor, whereas others work for one stage but not both.

## **PERCEPTION OF PAIN**

The amount of discomfort a woman experiences during contractions differs according to her expectations of and preparation for labor; the length of her labor; the position of her fetus; the presence of fear, anxiety, worry, body image, and self-efficacy; and the availability of meaningful people around her to offer support (Fig. 16.1). As a rule, women who believe they can control their situation (have self-efficacy) are more apt to report a satisfactory birth experience than those who do not feel in control (Howarth, Swain, & Treharne, 2011).

**Figure 16.1** The discomfort a woman experiences during childbirth is related to the amount of support she receives from her family and healthcare providers. Here, the woman's support person uses the palm of his hand to apply counter pressure to her lower back, helping to ease back pain.

Fetal position is a physical variable that influences the degree of pain a woman experiences. If the fetus is in an occiput posterior position, the woman often reports intense or nagging back pain, even between contractions, much more than if a fetus is in an occipitoanterior position (Impey & Child, 2012).

Pain is perceived differently by different individuals because of psychosocial, physiologic, and cultural responses. The body's ability to produce and maintain endorphins may influence a person's overall pain threshold and the amount of pain a person perceives at any given time. Women who come into the labor experience believing the pain will be horrible are usually surprised afterward to realize the agony they expected never materialized. However, women who thought pain would be minimal can be overwhelmed by its intensity. Unrealistic expectations of labor pain can make a woman so tense during labor her pain feels worse than it would have if she had

been relaxed. A woman cannot relax simply because she is instructed to do so by another person, however. Some additional interventions must be used.

## Comfort and Nonpharmacologic Pain Relief Measures

The pattern of interventions to promote comfort and manage pain in labor has swung from a philosophy of no intervention (none given because pain in labor was expected), to a philosophy that drug intervention was always required (excessive amounts were given), to the modern approach of empowering women and their partners with information so they can choose how to best relieve pain during labor within the limits of medical safety.

Nurses play a key role in educating women and their support persons about the numerous comfort and pain relief strategies available and making sure certain couples understand the choices available to them along with the benefits and risks (L. Jones, Othman, Dowswell, et al., 2012). Throughout their decision-making process, couples need support for their choices so they can feel confident in the method they choose.

### SUPPORT FROM A DOULA OR COACH

Although, historically, women have always attended other women in childbirth, in the past 45 years or so, the father or partner of a woman's child has traditionally served as her chief support person in labor. Some partners or fathers, however, find it difficult to serve as effective coaches because they are so emotionally involved in the birth. Some women prefer to ask a sister, mother, or friend to serve as a coach.

A **doula** is a woman who is experienced in childbirth and postpartum support. These support persons (who may hold certificates as birth or postpartum doulas) provide physical, emotional, and informational support prenatally, during labor and birth, and even at home in the postnatal period. Having an effective doula can increase a woman's self-esteem, speed the labor process, and improve breastfeeding success as well as decrease rates of oxytocin augmentation, epidural anesthesia, cesarean birth, and postpartum complications (Hodnett, Gates, Hormeyr, et al., 2013).

#### *QSEN Checkpoint Question 16.1*

#### **PATIENT-CENTERED CARE**

Jonny Baranca is having a painful labor. She asks the nurse if she should have hired a doula. The nurse identifies which answer as best?

- “Definitely. Doulas time contractions and perform many tasks, taking the burden off you.”
- “Maybe. Doulas are good at telling you if you are doing everything correctly.”
- “That’s an individual choice, but a doula can serve as an important support person.”

d. “No. A second person giving advice is apt to cause conflict.”

*Look in Appendix A for the best answer and rationale.*

## COMPLEMENTARY AND ALTERNATIVE THERAPIES

Complementary and alternative therapies for pain relief involve nonpharmacologic measures that may be used either as a woman’s total pain management program or to complement pharmacologic interventions. Most of these interventions are based on the gate control theory concept that distraction can be effective at preventing the brain from processing pain sensations coming into the cortex. Many of the same techniques may help the descent of a fetus. These may include the use of acupressure, position changes, imagery, and other relaxation techniques.

### Relaxation

The technique of relaxation, as discussed in [Chapter 14](#), is taught in most preparation for childbirth classes but can be taught in early labor as well. Relaxation keeps the abdominal wall from becoming tense, allowing the uterus to rise with contractions without pressing against the hard abdominal wall. It also serves as a distraction technique because, while concentrating on relaxing, a woman cannot concentrate on pain. Asking a woman to bring favorite music or aromatherapy with her to enjoy in the birthing room, although not evidence based, can help with relaxation. Remember, no aromatic candles should be used because of nearby oxygen outlets.

### Focusing and Imagery

Concentrating intently on an object is another method of distraction, or another method of keeping sensory input from reaching the cortex of the brain ([Smith, Levett, Collins, et al., 2011](#)). For this technique, a woman uses a photograph of someone important to her or some setting she finds appealing such as a beautiful sunset. She concentrates on the photo during contractions (focusing). A woman can also concentrate on a mental image, such as waves rolling onto a beach (imagery), or chant a word or phrase such as the new baby’s name during contractions, all of which help prevent her from concentrating on the pain of contractions. If a woman has never used these techniques before, she may question how effective they are. Urge her to try one of them at least for a few contractions before she dismisses them entirely, as evidence supports their efficacy ([Hodnett et al., 2013](#)). Do not ask questions or talk while a woman is using focusing, imagery, or chanting because that is apt to break her concentration and let the sensation of pain break through.

### *QSEN Checkpoint Question 16.2*

#### EVIDENCE-BASED PRACTICE

To investigate if listening to music can help women feel less pain and anxiety in

labor, researchers assigned 30 primiparas expected to have normal spontaneous births to either an experimental group that received routine labor care or a control group that received routine care plus music therapy. Both women and their nurses assessed the degree of pain experienced during labor. Results of the study revealed women who listened to music had significantly lower pain during the latent phase of labor (Simavli, Gumus, Kaygusuz, et al., 2014).

Based on this study, which statement by Jonny represents the best way to use music therapy in labor?

- a. “I’ve brought techno music to play during the second stage so I can push to a rhythm.”
- b. “I’ll need distraction most just before I have to push. I’ll save my music until then.”
- c. “I know music probably won’t make a difference but I’ll enjoy listening to it anyway.”
- d. “I brought some romantic music to play during early labor to help me relax.”

---

*Look in Appendix A for the best answer and rationale.*

---

## Spirituality

For many women, prayer may be the first measure they use to relieve a stress they are facing (Abbaspoor, Moghaddam-Banaem, Ahmadi, et al., 2014). Provide uninterrupted time as needed. Women may bring helpful worship objects such as a Bible or Qur’an into their birthing setting to use during prayer. Remember, these are sacred objects; be careful when changing sheets that you do not accidentally throw such important objects away or let them fall to the floor.

## Breathing Techniques

Breathing patterns are taught in most preparation for childbirth classes and are well documented to decrease pain in labor (Dick-Read & Gaskin, 2013). They are largely distraction techniques because a woman concentrating on slow-paced breathing cannot concentrate on pain. Breathing strategies can be taught to a woman in labor if she is not familiar with their advantages before labor (see Chapter 14). Stay with her until she appreciates how useful slow-paced breathing can be and feels comfortable using this technique independently.

## Herbal Preparations

Several herbal preparations have traditionally been used to reduce pain with dysmenorrhea or labor, although there is little evidence-based support for their effectiveness. Examples include chamomile tea for its relaxing properties; raspberry leaf tea (women freeze it into ice cubes to suck on), which is thought to strengthen uterine contractions; skullcap; and catnip, which are thought to help with pain. Black cohosh (squawroot), an herb that induces uterine contractions, is not recommended because of

the risk of acute toxic effects such as cerebrovascular accident to the mother or fetus (Ulbricht & Windsor, 2015).

## Aromatherapy and Essential Oils

Aromatherapy is the use of aromatic oils to complement emotional and physical well-being. Their use is based on the principle that the sense of smell plays a significant role in overall health. When an essential oil is inhaled, its molecules are transported via the olfactory system to the limbic system in the brain. The brain then responds to particular aromas with emotional responses such as relaxation. These oils should not be applied directly to the skin to avoid irritation but are used in a mister so they are inhaled and then carried throughout the body. The oils may be able to penetrate cell walls and transport nutrients or oxygen to the inside of cells. The effects of aromatherapy can range from reducing postcesarean incisional pain to reducing anxiety in the first stage of labor (Fakari, Tabatabaeichehr, Kamali, et al., 2015; Metawie, Amasha, Abdraboo, et al., 2015; Roozbahani, Attarha, Akbari Torkestani, et al., 2015). The evidence regarding the efficacy of aromatherapy continues to be studied with mixed results.

### *QSEN Checkpoint Question 16.3*

#### INFORMATICS

The nurse offers to teach Jonny controlled breathing to help with pain management until she can receive her epidural. Which instruction by the nurse would be best?

- “Lie on your back and breathe in slowly while repeating, ‘I can do this.’”
- “Hold your breath as long as you possibly can before exhaling.”
- “Breathe in as slowly as you can and then breathe out just as slowly.”
- “Pant rapidly as this best lifts your abdominal wall off your expanding uterus.”

*Look in Appendix A for the best answer and rationale.*

## Heat or Cold Application

The application of heat and cold has always been used for pain relief after injuries such as minor burns or strained muscles. It is only lately that their use has been investigated as effective ways to help relieve the pain of labor. Women who are having back pain may find the application of heat to the lower back by a heating pad, instant hot pack, or warm moist compress extremely comforting. Heat applied to the perineum is proven to provide the dual benefits of soothing and softening the perineum and decreasing the risk of perineal tears (Aasheim, Nilsen, Lukasse, et al., 2011). Caution women if they are going to heat pads in a microwave to test the temperature of the pad on the forearm before applying it to their perineum. **Pressure anesthesia** (pressure to an area of the body that interferes with pain receptors) can dull sensation and, with an overheated pack, patients could sustain a perineal burn without realizing it.

Women who become warm from the exertion of labor find a cool washcloth to the forehead, chest, or back of the neck comforting. Sucking on ice chips to relieve mouth dryness is also refreshing. Immediately following birth, an ice pack applied to the perineum feels soothing, and it helps reduce edema and swelling. Cultural differences exist with preference to heat and cold. This may be evident in dietary choices or compress application (Goyal, 2016). It is imperative that nurses provide care that is culturally competent and respectful of the practices of their patients.

### **Bathing or Hydrotherapy**

Standing under a warm shower or soaking in a tub of warm water, jet hydrotherapy tub, or whirlpool is another way to apply heat to help reduce the pain of labor (Fig. 16.2) (Harper, 2014). The temperature of water used should be 37°C to prevent hyperthermia of the woman and also the newborn at birth.

**Figure 16.2** A woman in labor enjoys the soothing effects of a warm water bath.

Remind women that plastic or porcelain tubs are slippery, so they should ask for

help stepping into and out of them. Do not leave women unsupervised in a tub as they could slip and have difficulty getting their head above water. A support person can join the woman in a tub or shower if she wishes and can continue with back massage or other measures she finds soothing. Timing of contractions, auscultation of fetal heart rate, and vaginal examinations can all be done without the woman needing to leave the water. The birth environment, including the use of hydrotherapy in labor, can help support physiologic birth (Stark, Remyse, & Zwelling, 2016).

## Therapeutic Touch and Massage

In a classic work, Krieger (1990) defined therapeutic touch as the laying on of hands to redirect energy fields that lead to pain. It is based on the concept that everyone's body contains energy fields that, when plentiful, lead to health or, when in low supply, result in illness.

*Effleurage*, the technique of gentle abdominal massage often taught with Lamaze in preparation for childbirth classes is a classic example of therapeutic touch (see Chapter 14, Fig. 14.8). *Reiki* can also promote healing. The term Reiki consists of two Japanese words: *rei*, which means "God's wisdom or the higher power," and *ki*, which means "life force energy." So Reiki is actually "spiritually guided life force energy." The technique includes "laying on of hands" and is based on the theory that an unseen "life force energy" flows through us and is what causes us to be alive (Rakestraw, 2010). If one's life force energy is low, then a person is more likely to get sick or feel stress. If it is high, a person is more capable of being happy and healthy.

Although the effectiveness of therapeutic touch is not well documented, both touch and massage probably work to relieve pain by increasing the release of endorphins. Both techniques may also work because they serve as forms of distraction. Many women find massage, especially of the lower back or feet, helpful in the first and second stages of labor (L. Jones et al., 2012; Smith et al., 2012).

### QSEN Checkpoint Question 16.4

#### SAFETY

Jonny asks the nurse if she could safely use warm water tub bathing during labor.

Which answer by the nurse would be best?

- "No. The chilling that sometimes results can lead to hypothermia."
- "Yes, as long as your membranes are not ruptured."
- "No. This technique will separate you from your partner."
- "Yes, as long as you know warm water has no significant effect."

Look in Appendix A for the best answer and rationale.

## Yoga and Meditation

Yoga, a term derived from the Sanskrit word for "union," describes a series of exercises

that were originally designed to bring people closer to a divine power. It offers a significant variety of proven health benefits, including increasing the efficiency of the heart, slowing the respiratory rate, improving fitness, lowering blood pressure, promoting relaxation, reducing stress, and allaying anxiety. Exercises consist of deep breathing exercises, body postures to stretch and strengthen muscles, and meditation to focus the mind and relax the body. It may be helpful in reducing the pain of labor through its ability to relax the body and possibly through the release of endorphins. Mothers who engage in yoga prenatally have been shown to have a greater sense of self-efficacy and may experience fewer episodes of antenatal depression ([Battle, Uebelacker, Magee, et al., 2015](#); [Schwartz, Toohill, Creedy, et al., 2015](#)).

Meditation is a self-directed practice for relaxing the body and calming the mind. Mindfulness-based stress reduction (MBSR), an 8-week intervention program developed by Dr. John Kabat Zinn for patients dealing with issues of chronic pain, is based on the cultivation of intentional awareness of experiences in the present moment. Transcendental meditation (TM) is a simple, natural, and effortless activity done while resting comfortably with the eyes closed. Using one of these techniques, an individual experiences a state of deep rest that can change physical and emotional responses to stress ([Chan, 2016](#)). Women can meditate in any position. Do not interrupt a woman using meditation as a pain relief technique if at all possible in order to not break her concentration.

## Reflexology

**Reflexology** is the practice of stimulating the hands, feet, and ears as a form of therapy ([Smith, Levett, Collins, et al., 2012](#)). Professional reflexologists apply pressure to specific areas of the hands, feet, and ears to alleviate common ailments such as headache, back pain, sinus colds, and stress. The theory behind reflexology holds that the body is divided into 10 zones that run in longitudinal lines from the top of the head to the tips of the toes. Each of the body's organs and glands is linked to corresponding areas of the hands and feet. Application of pressure to a specific area aims to restore energy to the body and improve the overall condition. The point that corresponds to the uterus is located on the inside ankle about halfway between the ankle bone (malleolus) and the heel. Massaging this area is believed to begin labor or hurry labor, thus creating less pain.

## Hypnosis

Hypnosis is yet another method that can be used for pain relief in labor. A woman who wants to use this modality needs to meet with her hypnotherapist during pregnancy. At these visits, she is evaluated for and conditioned for susceptibility to hypnotic suggestion. Close to her last weeks of pregnancy, she is given a posthypnotic suggestion that she will experience a reduction in or absence of pain during labor. Fully awake and able to participate in labor, the woman who is susceptible to hypnotic suggestion may

find this may provide a very satisfactory and drug-free method of pain relief (Streibert, Reinhard, Yuan, et al., 2015). A woman who wants to use this system but began labor before the posthypnotic suggestion was given may be very disappointed to find herself in labor without the help she envisioned. Some hypnotists may visit during labor or supply the suggestion over the telephone so a woman can still use the method. Further research is needed to determine the effectiveness of the effects of hypnosis on pain relief in labor (Madden, Middleton, Cyna, et al., 2016).

### **Biofeedback**

Biofeedback is based on the belief that people have control and can regulate internal events such as heart rate and pain responses. Women who are interested in using biofeedback for pain relief in labor must attend several sessions during pregnancy to condition themselves to regulate their pain response. During these sessions, a biofeedback apparatus is used to measure muscle tone or the woman's ability to relax. Evidence is continuing to emerge that shows biofeedback is an effective method for reducing the pain of labor (Janula & Mahipal, 2015).

### **Transcutaneous Electrical Nerve Stimulation**

Transcutaneous electrical nerve stimulation (TENS) works to relieve pain by applying counterirritation to nociceptors (Santana, Gallo, Ferreira, et al., 2016). When two pairs of electrodes are attached to a woman's back to coincide with the T10 through L1 nerve pathways, low-intensity electrical stimulation is given continuously or is applied by the woman herself as a contraction begins. This stimulation blocks the afferent fibers, preventing pain from traveling to the spinal cord synapses from the uterus. As labor and descent progress, the electrodes are moved to stimulate the S2 through S4 level. High-intensity stimulation is generally needed to control the pain at this stage.

TENS can be as effective as epidural anesthesia for pain relief in labor, although some women object to being "tied down" to the equipment. Women with extreme back pain may benefit most from a TENS unit because this type of pain is difficult to relieve with controlled breathing exercises (Santana et al., 2016). This method may not only reduce the need for epidural anesthesia but also postpone the use of pharmacologic agents (Santana et al., 2016). TENS is further discussed in Chapter 24 as it applies to postoperative pain of a cesarean birth.

### **Intracutaneous Nerve Stimulation**

Intracutaneous nerve stimulation (INS) is a technique of counterirritation involving the intradermal injection of sterile water or saline along the borders of the sacrum to relieve low back pain during labor (Derry, Straube, Moore, et al., 2012). Although some women find the technique helpful, there is little evidence as to its effectiveness; other women prefer to bear back pain or relieve it by massage rather than submit to injections.

## Acupuncture and Acupressure

Acupuncture is based on the concept that illness results from an imbalance of energy. To correct the imbalance, needles are inserted into the skin at designated susceptible body points (*tsubos*) located along meridians that course throughout the body to supply the organs of the body with energy. Activation of these points (which are not necessarily near the affected organ) results in a release of endorphins, which makes this system helpful, especially in the first stage of labor (Ozgoli, Mobarakabadi, Heshmat, et al., 2016). Acupuncture may also decrease the duration of labor (Asadi, Maharlouei, Khalili, et al., 2015).

Acupressure is the application of pressure or massage at these same points. It seems to be most effective for low back pain. A common point used for women in labor is Co4 (*Hoku* or *Hegu* point), which is located between the first finger and thumb on the back of the hand. Women may report their contractions feel lighter when a support person holds and squeezes their hand because the support person is accidentally triggering this point. Acupressure can reduce maternal anxiety as well as the length of labor when specific pressure points are used (Akbarzadeh, Masoudi, Zare, et al., 2015).

### *What If... 16.1*

**The nurse had met Jonny during pregnancy and discovered she did not attend any preparation for childbirth classes because she planned to rely totally on epidural anesthesia for pain relief. Would the nurse have supported her plan? Now that she is in early labor, what are some complementary and alternative therapies the nurse could teach her to use while she waits for anesthesia?**

## PHARMACOLOGIC MEASURES FOR PAIN RELIEF DURING LABOR

The discovery of ether and chloroform in the 1800s led to the determination that childbirth could be managed relatively pain free. Unfortunately, this goal was achieved by means of complete anesthesia or unconsciousness for the woman during labor and birth. Women, afterward, had difficulty believing the birth was over and that the infant was their child.

This led to an era (late 1960s to the 1980s) in which women refused pharmacologic pain relief in labor and depended entirely on prepared childbirth measures such as breathing patterns. Since the advent of epidural anesthesia, women now have more options regarding how much or what kind of pain relief they want in labor (Anim-Somuah, Smyth, & Jones, 2011).

Pharmacologic management of pain during labor and birth includes **analgesia**, which reduces or decreases awareness of pain, and **anesthesia**, which causes partial or complete loss of pain sensation. For the best results, be certain women are included in

the selection of these methods and understand any fetal effects or maternal side effects that might occur.

Virtually all medications given during labor cross the placenta and have some effect on the fetus, which makes it important to do regular assessments of maternal and fetal responses to the administration of systemic medication. However, labor should not test a woman to the limit of her endurance because both analgesia and anesthesia are available. Be sure to caution women not to take acetylsalicylic acid (aspirin) for pain in labor as aspirin interferes with blood coagulation, increasing the risk for bleeding in the newborn or herself. In addition, the manufacturers of pain relief patches such as Salonpas, Absorbine Jr., and Icy Hot caution women not to use these in labor because of the potentially teratogenic effect of the menthol ingredient.

The best approach to pain management for women in labor is to always aid any pharmacologic intervention with a complementary or alternative therapy measure. For example, an intramuscular analgesic can be linked with breathing exercises to make both more effective.

### Goals of Pharmacologic Pain Management During Labor

The ideal or goal of medications used during labor is to relax a woman and relieve her discomfort and yet have minimal systemic effects on uterine contractions, her pushing effort, or the fetus (Box 16.4). Whether a drug affects a fetus depends on its ability to cross the placenta and that depends on its molecular weight. Drugs with a molecular weight of less than 600 Da cross very readily; drugs with a molecular weight of more than 1,000 Da cross poorly. Drugs with highly charged molecules or molecules strongly bound to protein also tend to cross more slowly than others. Fat-soluble drugs cross the easiest.

#### BOX 16.4

#### Nursing Care Planning Based on Family Teaching

**Q.** Jonny asks you, “Can I choose what medicine I want to use in labor for pain or do I have to do whatever my doctor says?”

**A.** A number of helpful rules about pain in labor are:

- You have the right to choose how much pharmacologic pain relief you want to use.
- It’s best if analgesia and anesthesia are begun after labor is well established, although this should be balanced against the need for pain relief.
- Any drug used should provide maximum relief for you and have minimal effect on your fetus.
- Constant fetal and maternal monitoring should be available, although periodic monitoring is acceptable.
- Any medicine given should not interfere with the ability of your uterus to contract

during labor or interfere with contraction after labor to prevent uterine hemorrhage.

If a drug causes a systemic response, such as hypotension in a woman, it can result in a decreased oxygen ( $PO_2$ ) gradient across the placenta, causing the indirect result of fetal hypoxia. If a drug causes confusion or disorientation, a woman may be unable to work effectively with contractions, thus prolonging labor and increasing discomfort for her. A preterm fetus, which has an immature liver and is unable to metabolize or inactivate drugs, is generally more affected by drugs than a term fetus. If a medication causes changes in a fetus, such as a decreased heart rate or central nervous system (CNS) depression, it may be difficult for the newborn infant to initiate respirations at birth, severely compromising the infant in the important first minutes of life. In addition, if a drug reduces or eliminates the bearing down reflex, a woman may have difficulty pushing effectively, which may prolong the second stage and increase the risk for a cesarean birth.

Lastly, because pain is a subjective sensation, some women are most aware of pain early in labor, whereas some report the second stage of labor as the most difficult. The point at which pain medication is needed, therefore, differs from one individual to another and should be given at whatever point an individual woman feels she needs it. When labor is in the active phase of the first stage, medication to relieve discomfort tends to speed labor progress because, with the pain gone, a woman can relax and work with, not against, her contractions. In contrast, at the second stage, epidural anesthesia or a drug that disorients a woman can slow progress and may result in more instrumentation or cesarean births. For all these reasons, no perfect analgesic agent exists for labor or birth that has no effect on labor, the mother, or the fetus.

### **Preparation for Medication Administration**

The type of medication used during labor varies among different healthcare providers and also changes based on new research as the effectiveness and safety of new drugs for use during labor are tested. To be safe, follow The Joint Commission's *2016 National Patient Safety Goals* ([The Joint Commission, 2016](#)) and remember the criteria a drug must fulfill to be used in pregnancy at any point. Never give a drug to a pregnant woman unless you know the benefit outweighs the risk for both of your patients: the mother and the fetus. Be certain to ask about allergies to all medications before administering them during labor as women in distress from pain can be too distracted to mention this unless directly asked.

Prepare a woman for the type of agent prescribed, how it will be administered with an explanation such as "You'll need to lie on your side" as well as what she can expect to happen after administration ("I'll be taking your blood pressure frequently"). Women in labor are under a lot of stress. That can make experiencing surprising body sensations from a drug without preparation about the effects that may occur so frightening it can defeat their individual coping ability and any relaxation potential associated with it.

## Opioid (Narcotic) Analgesics

*Narcotics* may be given during labor because of their potent effect, but all drugs in this category cause maternal respiratory depression as well as fetal CNS depression to some extent and so should be used cautiously (Brimdyr, Cadwell, Widström, et al., 2015).

Timing the administration of narcotics during labor is especially important as, if given too early (before 3 cm cervical dilatation), they tend to slow labor. If given close to birth, because the fetal liver takes 2 to 3 hours to activate a drug, the effect will not be registered in the fetus for 2 to 3 hours after birth. For this reason, narcotics are preferably given when the mother is more than 3 hours away from birth. This allows the peak action of the drug in the fetus to have passed by the time of birth so the newborn breathes easily.

It can be puzzling to see a sleepy baby born to a woman who was given butorphanol tartrate 2 hours before birth, for example, and an alert baby delivered to a woman who had the same drug within 1 hour of birth. In the second instance, the peak action or peak effect has not yet occurred in the infant. This newborn needs careful assessment for the next 4 hours until the drug does reach its peak.

Common opioid analgesics used in labor traditionally include butorphanol tartrate (Stadol), morphine sulfate, nalbuphine (Nubain), meperidine (Demerol), and fentanyl (Sublimaze). None of these drugs completely eliminate the pain of contractions, but they do reduce pain sensation to a level where other nonpharmacologic methods of pain relief can begin to be effective. They all begin to work 15 to 30 minutes after intramuscular administration or about 5 minutes after intravenous (IV) administration. A drawback to all these opioids is they may cause nausea and vomiting in some women. These effects appear to be dose-related (Armstrong & Fernando, 2016). They also produce a feeling of euphoria, so women often report they feel as if they are “floating”; because of this sensation, they may feel they have lost control or are unable to breathe effectively with contractions. Routes of administration and common side effects are shown in Table 16.1.

**TABLE 16.1 ANALGESICS AND ANESTHETICS COMMONLY USED IN LABOR AND BIRTH**

Type	Drug	Method of Administration	Effect on Mother	Effect on Labor Progress	Effect on Fetus/Neonate
Narcotic analgesic	Butorphanol tartrate (Stadol)	Intramuscular or intravenous	Effective analgesic; withdrawal symptoms if woman is opiate dependent	Possible slowing of labor if given early	Respiratory depression

	Nalbuphine (Nubain)	Intramuscular or intravenous	Effective analgesic; slowing of respiratory rate	Mild maternal sedation	Res
	Morphine sulfate	Intrathecal prior to epidural anesthesia	Pruritus; effective analgesia	Possible slowing of labor contractions	Son
	Fentanyl (Sublimaze)	Intravenous	Hypotension; respiratory depression	Slowing of labor if given early	Ma
Lumbar epidural block	Local anesthetic	Injected by anesthesiologist or nurse anesthetist at L3–L4 for first stage of labor; with continuous block, anesthesia will last through birth; fentanyl or morphine possibly added to cerebral spinal fluid first	Rapid onset in minutes lasting 60– 90 min; loss of pain perception for labor contractions and birth; possible maternal hypotension	Slowing of labor if given too early; pushing feeling is obliterated, resulting in possible prolonged second stage	Ma
	Bupivacaine (Marcaine)				
	Ropivacaine (Naropin)				
Pudendal block	Local anesthetic	Administered just before birth for perineal anesthesia; injected through vagina	Rapid anesthesia of perineum	None apparent	Non
	Lidocaine (Xylocaine)				a

Local infiltration of perineum	Local anesthetic  Lidocaine (Xylocaine)	Injected just before episiotomy incision	Anesthesia of perineum almost immediately	None apparent	Not a
General anesthetic	Thiopental sodium	Intravenous by anesthesiologist or nurse-anesthetist	Rapid anesthesia; also rapid recovery	Forceps required because abdominal pushing is no longer possible	Res in b v c n s d

Because of the fetal effects, whenever a narcotic is given during labor, a narcotic antagonist such as naloxone hydrochloride (Narcan) should be available for administration to the infant at birth if needed (Box 16.5). Carefully observe any infant who received naloxone hydrochloride in the immediate postpartum period because the infant's respirations may become severely depressed again when the drug's effect wears off (Karch, 2013). If severe infant respiratory depression is anticipated, naloxone hydrochloride can be given to a woman just before birth. It readily crosses the placenta and, because it interferes with or competes for narcotic binding sites, may increase the chance for spontaneous respiratory activity in the newborn.

## BOX 16.5

### Nursing Care Planning Based on Responsibility for Pharmacology

#### NALOXONE HYDROCHLORIDE (NARCAN)

**Action:** Naloxone hydrochloride is a narcotic antagonist that counteracts the effect of narcotic analgesics (Karch, 2013). It is used to counteract respiratory depression in newborns when a woman has received a narcotic analgesic during labor.

**Pregnancy Risk Category:** B

**Dosage:** 0.01 mg/kg, administered either intravenously via umbilical vein, subcutaneously, or intramuscularly; repeated at 2- to 3-minute intervals until a response is obtained

**Possible Adverse Effects:** Hypotension, hypertension, tachycardia, diaphoresis, tremulousness

**Nursing Implications**

- Anticipate the need for newborn resuscitative measures including the use of naloxone hydrochloride; have resuscitative equipment and emergency drugs readily available.
- If no intravenous access is available, prepare for possible administration via endotracheal tube.
- If no response is seen after two or three doses, question whether the respiratory depression is caused by maternal narcotic administration.
- Continuously monitor all vital signs for changes.
- Remember that the pain-relieving effect of a narcotic will be reversed as the narcotic is cleared from the baby's system; assess for pain in the neonate if a narcotic was given for pain relief.

### *What If... 16.2*

**Jonny receives no narcotics during labor, yet her newborn is born very sleepy. Would the nurse administer naloxone hydrochloride? Would asking Jonny if she uses recreational drugs be warranted in order to discover the cause of newborn respiratory depression?**

## **Additional Drugs**

Additional drugs, such as tranquilizers, may be administered during labor to reduce anxiety or potentiate the action of a narcotic. An example of such a drug is hydroxyzine hydrochloride (Vistaril). These drugs do not relieve pain, so the woman in labor needs pain management measures in addition to these drugs.

## **Nitrous Oxide**

Nitrous oxide inhalation has been widely used in Europe for effective pain relief in labor. In the United States, it is beginning to be used more prevalently. In the past, this method had resulted in adverse neonatal outcomes such as brain cell apoptosis leading to developmental impairment. There was also concern about caregiver and maternal exposure. Over the past decade, nitrous oxide has made a comeback in the United States. Research by [Rooks \(2011\)](#) has shown that in appropriate doses ( $\leq 50\%$  blend with oxygen) and with a proper and now standard delivery system, nitrous oxide can be safe for mother, fetus, neonate, and caregivers. It does not affect the pattern or intensity of contractions and does not interfere with normal labor. Apgar scores in neonates whose mothers used nitrous oxide do not significantly differ from those who used other forms of pharmacologic pain relief, or no analgesia ([Likis, Andrews, Collins, et al., 2014](#)).

## **Regional (Local) Anesthesia**

*Regional anesthesia* is the injection of a local anesthetic such as chlorprocaine (Nesacaine) or bupivacaine (Marcaine) to block specific nerve pathways (Anim-Somuah et al., 2011). This achieves pain relief by blocking sodium and potassium transport in the nerve membrane, thereby stabilizing the nerve in a polarized resting state so the nerve is unable to conduct sensations.

Various regional anesthetic injection sites are shown in Figure 16.3. Any woman with a bleeding defect, such as those that may occur with preeclampsia, need to be assessed carefully before regional anesthesia is administered to prevent bleeding at the injection site.

**Figure 16.3** Anatomy of the spinal canal and sites of injection for regional anesthesia.

Regional anesthetics have the potential to result in fetal bradycardia. This is not due to the transmission of the drug from maternal to fetal circulation but rather secondary to the effects of maternal hypotension following administration of the medication. This may resolve spontaneously, with position change or with the administration of additional medication (Mohta, Aggarwal, Sethi, et al., 2016). The effects of epidurals on breastfeeding show mixed and contradictory results in the literature (French, Cong, & Chung, 2016).

Most importantly, regional anesthesia is able to completely eliminate pain yet allow a woman to be completely awake and aware of what is happening during birth. It can make pushing with second stage labor more difficult, but it does not depress uterine tone, so the uterus remains capable of optimal contraction after birth, thereby helping to prevent postpartal hemorrhage.

In the rare event an infant is born with symptoms of toxicity from a regional anesthetic, an exchange transfusion at birth will remove the anesthetic from the infant's

bloodstream. Gastric lavage also will remove a great deal of anesthetic because anesthetics have a strong affinity for acid media, such as stomach acid.

## Epidural Anesthesia

The nerves in the spinal cord are protected by several tissue layers.

- The *pia mater* is the membrane adhering to the nerve fibers.
- Surrounding this is the *cerebrospinal fluid* (CSF).
- Next comes the arachnoid membrane and, outside that, the *dura mater*.
- Outside the *dura mater* is a vacant space (the *epidural space*).
- Beyond it is the *ligamentum flavum*, yet another protective shield for the vulnerable spinal cord (see [Fig. 16.3](#)).

An anesthetic agent introduced into the CSF in the subarachnoid space is *spinal injection* or *spinal anesthesia*. An anesthetic agent placed just inside the *ligamentum flavum* in the epidural space is called **epidural anesthesia**. Anesthetic agents placed in the epidural space at the L4–L5, L3–L4, or L2–L3 interspace block not only spinal nerve roots in the space but also the sympathetic nerve fibers that travel with them. Therefore, these blocks can provide pain relief during both labor and birth. Because a woman no longer experiences pain, the release of catecholamines (epinephrine) with a  $\beta$ -blocking effect from a pain response is decreased, making this a very effective pain relief measure for labor ([Impey & Child, 2012](#)).

Epidural blocks are suitable for almost all women. They are advantageous for women with heart disease, pulmonary disease, diabetes, and sometimes severe gestational hypertension because they make labor virtually pain free and thereby reduce stress from the discomfort of labor. Because the woman does not feel contractions, her physical energy is preserved. Epidural blocks are acceptable for use in preterm labor because the drug has scant effect on a fetus and allows for a controlled and gentle birth with lessened trauma to an immature fetal skull. Because the woman receives no systemic medication, the infant responds more quickly after birth than if systemic narcotic analgesics were used.

The chief concern with epidural anesthesia is its tendency to cause hypotension because of its blocking effect on the sympathetic nerve fibers in the epidural space. This blocking leads to decreased peripheral resistance in the woman's circulatory system. Decreased peripheral resistance causes blood to flow freely into peripheral vessels, and a pseudohypovolemia develops, which registers as hypotension. This risk can be reduced by being certain a woman is well hydrated with 500 to 1,000 ml of IV fluid, such as Ringer's lactate, before the anesthetic is administered. Ringer's lactate is preferable to a glucose solution because too much maternal glucose can cause hyperglycemia with rebound hypoglycemia in the newborn. Be certain a woman does not lie supine after an epidural block but remains on her side to help prevent supine hypotension syndrome.

If hypotension should occur, raising the woman's legs and administering oxygen and additional IV fluid along with an antihypotensive agent such as ephedrine to elevate

blood pressure may be necessary to stabilize cardiovascular status. This is an emergency because if the woman is severely hypotensive, blood is shunted away from the uterus and leads to poor perfusion of the placenta, eventually causing fetal distress.

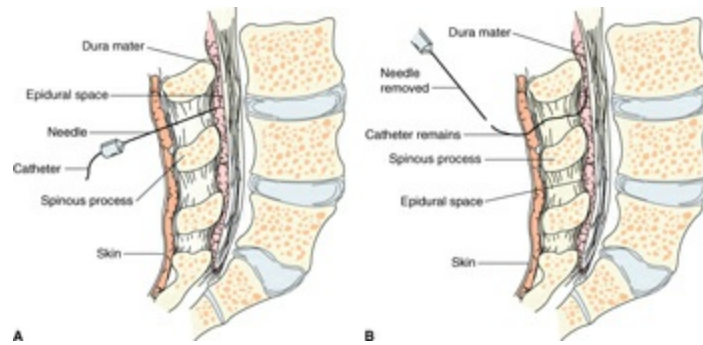

A disadvantage of epidural anesthesia is that the bearing down reflex may be reduced or absent, making it difficult for a woman to push effectively. This may delay fetal descent, thus prolonging the second stage of labor and leading to an increased number of instrument-assisted births (Schrock & Harraway-Smith, 2012). A second stage delay this way occurs primarily when the fetus is in an occipitoposterior position. Changing the woman's position (e.g., to all fours) to help fetal rotation can be helpful to aid descent. For both of these situations, allowing an epidural to wear off by the second stage of labor so that a woman can push with contractions is another option. If this is unsuccessful, an oxytocin IV to help strengthen contractions can be administered. Many women are understandably overwhelmed and disappointed if the epidural is allowed to wear off; the excellent pain control they had may make the return of contraction pain seem extreme. Encouragement and use of nonpharmacologic methods will be critical nursing interventions at this time.

In rare instances, the anesthetic enters the woman's blood circulation instead of settling into the epidural space. Drowsiness, a metallic taste on the tongue, slurred speech, blurred vision, unconsciousness, and seizure, which may lead to cardiac arrest, are alerts this has happened and, again, is an emergency situation. The woman needs oxygen and an anticonvulsant, such as diazepam (Valium) or thiopental sodium (Pentothal) IV, followed by the prompt birth of the fetus to protect the health of the woman and the fetus.

### Technique for Administration

Epidural blocks are usually delayed until a woman's cervix is dilated 3 to 5 cm as earlier administration may slow the first stage of labor. Be certain an infusion of Ringer's lactate solution is begun preprocedure and that equipment for blood pressure monitoring is in place and functioning. Help position the woman on her side on her birthing bed. If she curves her back outward, this increases the intravertebral spaces and allows easier access to the injection site.

An epidural block may consist of only an anesthetic injection into the epidural space or a combined method where a low-dose anesthetic is injected into the epidural space and a small dose of an analgesic such as fentanyl is also injected into the CSF space. This combination of drugs and technique is advantageous because it results in a "walking" or "mobile" block, which produces anesthesia up to the level of the umbilicus in 10 to 15 minutes that will last for approximately 40 minutes to 2 hours (Schrock & Harraway-Smith, 2012). Its second advantage is that it allows a woman to move about and walk while anesthesia is in effect. A catheter is left in place attached to a syringe to allow for repeated injections without further injection pain (Fig. 16.4).

**Figure 16.4** Epidural anesthesia. **(A)** A needle is inserted into the epidural space. **(B)** A catheter is threaded into the space; the needle is then removed. The catheter allows medication to be administered intermittently or continuously to relieve pain during labor and childbirth.

Assess a woman’s pulse and blood pressure following the injection. Observe for toxic symptoms of hypotension, slurred speech, and rapid pulse, which would occur if the anesthetic was accidentally placed into a blood vessel and not the hollow epidural space. Be certain to review agency policy regarding catheter care before caring for a person with a catheter in place to prevent infection at the site. Proper gowning is encouraged prior to administration for colonization reduction (Siddiqui, Davies, McGeer, et al., 2014).

An epidural block provides anesthesia for uterine contractions but not perineal relaxation. Close to birth, if the woman sits up and an additional dose of anesthesia is added to the catheter, perineal anesthesia will result as well. Leaving the lower anesthesia for late in labor this way is thought to allow for better internal rotation of the fetal head because the perineal muscle is not lax, creating a lessened need for forceps for rotation.

### Aftercare for the Woman With an Epidural Anesthesia

Following anesthetic administration, be certain a woman lies on her side, or if on her back, she should place a firm towel under her left hip to avoid hypotension from poor blood return to the heart. To keep her free from discomfort during the duration of labor, anesthetic can be continually infused by an infusion pump, or other doses of anesthetic, termed “top-ups,” can be added at intervals. Both techniques are equal in their effect on length of labor, although continuous administration may result in more cesarean births because of difficulty pushing and fetal descent (Siddiqui et al., 2014).

Each time, before an additional top-up dose is administered, ask the woman to say out loud a phrase such as “I can do it” three times. If she is unable to do this, question the dose; lack of fine motor coordination and slurred speech can indicate a slowly occurring toxic reaction.

Yet another technique used to maintain epidural anesthesia is self-administration or patient-controlled epidural analgesia (PCEA). With this technique, following a lockout

period when no more anesthetic can be administered to avoid overdosing, an analgesic mixture is delivered whenever the patient presses a button on a PCEA pump (Jokinen, Weibel, Afshari, et al., 2015). This method of administration is advantageous because less anesthetic is required compared with continuous epidural infusion (CEI) and can give the woman a feeling of empowerment as she controls her own pain management.

A nurse should be in continuous attendance as long as epidural anesthesia is being used. When recording vital signs, be aware epidural anesthesia can cause a temporary elevation in temperature, which is not serious unless it rises above 101°F (Sultan, David, Fernando, et al., 2016).

Possible complications that can occur from epidural blocks include hypotension, pruritus (especially if morphine was used), urinary retention, nausea and vomiting, and, rarely, a postpartal dural puncture headache (PDPH) (because the subarachnoid space was entered for the analgesic injection).

To detect if hypotension is occurring, continuously monitor blood pressure for the first 20 minutes after each new injection of anesthetic. Continue to periodically monitor blood pressure throughout the time the anesthetic is in effect to be certain the woman's systolic pressure does not fall to less than 100 mmHg or decrease by 20 mmHg or more in a hypertensive woman. A drop greater than this could be life-threatening to a fetus unless prompt and effective corrective measures are taken, such as repositioning and administering an antihypotensive agent (e.g., ephedrine) to ensure the fetal outcome will not be compromised.

After an epidural block, a woman loses sensation of bladder filling. Remind her to void every 2 hours, monitor intake and output, and observe and palpate for bladder distention to avoid overfilling, especially if labor is prolonged. Be aware of the standards and policies of the healthcare agency related to who may add additional anesthesia or remove the catheter. To assess after birth whether the anesthesia is wearing off, touch a woman's leg and ask if she can feel your touch. Ask her to raise her knees and observe whether she can do this easily. Even after feeling in her legs returns, walking may be difficult for her. Be certain to stay with the woman the first time she is out of bed following regional block anesthesia to prevent her from falling.

## Spinal (Subarachnoid) Anesthesia

Spinal anesthesia is not used frequently in preference to epidural blocks, but it may be used in an emergency or for a cesarean birth because the administration technique is simpler than that of an epidural and can be accomplished more rapidly.

Before spinal anesthesia, as a guard against hypotension, an IV fluid such as Ringer's lactate solution is usually begun to ensure good hydration. Be certain the fluid is infusing well before the anesthesia is administered.

For spinal anesthesia, a local anesthetic agent such as bupivacaine (Marcaine) is injected using lumbar puncture technique into the subarachnoid space (into the CSF) at the L3 and L4 interspace. A narcotic agonist such as morphine or fentanyl may be added for additional pain relief. For administration, the woman is usually asked to sit on the

side of the bed with legs dangling and head bent. Ask her to bend her head forward so her back curves and the intravertebral spaces open. Be sure either you or her support person steadies her in this sitting position because she is very “front heavy” as a result of her pregnancy and could easily fall forward if not well supported.

After injection, the anesthetic normally rises to the level of T10. Anesthesia up to the umbilicus and including both legs will be achieved. Spinal anesthetic agents may be “loaded” or “weighted” with glucose to make them heavier than CSF. This helps prevent them from rising too high in the spinal canal and interfering with the motor control of the uterus or with respiratory muscles (Drasner & Larson, 2011).

Following the anesthetic injection, if the woman was sitting, the anesthesiologist will ask the woman to lie down. It’s important a woman lies down at this time because if she continues to sit upright, the anesthetic will not rise high enough in the canal to achieve pain relief. She must not lie down before this time, however, or the anesthetic could rise too high in the canal. Lying with a pillow under the head is another method to help ensure the anesthesia will be confined to the lower spinal canal.

As mentioned, hypotension from sympathetic blockage in the lower extremities may occur immediately after spinal anesthetic administration. This leads to vasodilation and a decrease in central blood pressure. If hypotension occurs, placental blood perfusion can be compromised. Turn the woman to her left side to reduce vena cava compression. Expect the anesthesiologist to quickly increase the rate of IV fluid administration to increase blood volume; ephedrine to increase blood pressure and oxygen also may be administered. Never place a woman in a Trendelenburg position (head lower than her body) to help restore blood pressure after spinal anesthesia. This could make the anesthetic rise high in her spinal column, causing uterine or respiratory function to cease. A late complication of spinal anesthesia is a PDPH or “spinal headache.” This occurs because of CSF leakage from the needle insertion site and also possibly from the irritation of a small amount of air that entered at the injection site. It has been demonstrated that the type of needle used may be a significant factor in whether or not a woman will have a spinal headache (Genç, Sahin, Maral, et al., 2016). The shift in pressure of the CSF causes strain on the cerebral meninges, initiating the pain. The incidence of such headaches is reduced if a woman is well hydrated before injection. If a headache occurs, the postpartum woman can be encouraged to drink a large quantity of fluid because a high fluid intake rapidly provides replacement of spinal fluid.

A spinal headache can be relieved by the administration of hydrocortisone to reduce inflammation (Hanling, Lagrew, Colmenar, et al., 2016). Having the woman lie flat and administering an analgesic also helps. Some women find a cold cloth applied to their forehead helpful. If a headache is incapacitating, it can be treated with a blood patch technique. For this, 10 to 20 ml of blood is withdrawn from an accessible vein and then immediately injected into the epidural space over the spinal injection site. The injected blood clots and seals off any further leakage of CSF (Hanling et al., 2016).

### ***QSEN Checkpoint Question 16.5***

## TEAMWORK & COLLABORATION

Jonny has chosen to have epidural anesthesia, and the nurse has consequently informed the anesthesiologist. What are two risks that are potentially associated with this form of anesthesia?

- a. Hypotension and a prolonged second stage of labor can occur.
- b. Severe headache and peripheral cyanosis can occur.
- c. Women have increased back pain and abrupt transitions between stages of labor.
- d. Maternal hypertension and a reduced red blood cell count can occur.

*Look in [Appendix A](#) for the best answer and rationale.*

## MEDICATION FOR PAIN RELIEF DURING BIRTH

Stretching of the perineum causes pain that occurs during the birth. The simplest form of relief for this type of pain is the natural pressure anesthesia that results from the fetal head pressing against the stretched perineum. This natural anesthesia is often adequate to allow the fetal head to be born with only momentary pain, which, although intense and hot, occurs suddenly and is over quickly. Often, after the hours of hard contractions a woman has come through, this flash of pain seems insignificant. For some women, however, additional medication is needed to reduce the pain of birth.

### Local Anesthetics

Local anesthesia reduces the ability of local nerve fibers to conduct pain.

#### Local Infiltration

Local infiltration is the injection of an anesthetic such as lidocaine (Xylocaine) into the superficial nerves of the perineum along the vulva. The effect lasts for approximately 1 hour, allowing for a less painful birth and suturing of an episiotomy (a cut to enlarge the vagina opening; discussed in [Chapter 24](#)).

#### Pudendal Nerve Block

A **pudendal nerve block** is the injection of a local anesthetic such as bupivacaine (Marcaine) through the vagina to anesthetize the pudendal nerve. It is used for a woman who has not had an epidural to provide a pain-free birth and, if the woman should have an episiotomy, painless surgical suturing and repair. Although a pudendal nerve block is local, assess the fetal heart rate and the mother's blood pressure immediately after the injection to be certain maternal hypotension does not occur.

### General Anesthesia

General anesthesia is never preferred for childbirth because it carries the dangers of

hypoxia and possible inhalation of vomitus during administration. Because it is used so rarely, you probably will not see this used; if it is used, there are special precautions you need to be aware of. Pregnant women are particularly prone to gastric reflux and aspiration because of increased stomach pressure from the weight of the full uterus beneath it. The gastroesophageal valve at the top of the stomach also may be displaced and possibly functioning improperly. Despite these risks, general anesthesia may be necessary in emergency situations, such as if the placenta loosens before the fetus is born (placental abruption), spinal anesthesia is contraindicated, or an immediate cesarean birth is required.

For complete and rapid anesthesia during childbirth, thiopental sodium (Pentothal), a short-acting barbiturate, is usually the drug of choice. It causes rapid induction of anesthesia and, because it has a short half-life, allows for good uterine contraction afterward and so prevents postpartal hemorrhage. All women who receive a general anesthetic, however, must be observed closely in the postpartal period for uterine relaxation and the risk of uterine atony and postpartal hemorrhage.

For the procedure, after induction with thiopental sodium, the woman is intubated, and anesthesia is then maintained by administration of nitrous oxide and oxygen. Thiopental sodium crosses the placenta rapidly, so an infant born to a woman anesthetized by this method may be slow to respond at birth and may need resuscitation.

Some women comment that their throat feels raw or sore after general anesthesia administration; this is from the insertion and maintenance of an endotracheal tube. Using an anesthetic throat spray or gargle, sipping cold liquids, or sucking on ice chips (as soon as this is safe after general anesthesia) can help to relieve the discomfort.

## Preparation for the Safe Administration of General Anesthesia

To ensure safe general anesthesia administration, an anesthesiologist or nurse anesthetist needs a minimum of six drugs readily available:

- Ephedrine to use in the event blood pressure falls
- Atropine sulfate to dry oral and respiratory secretions to prevent aspiration
- Thiopental sodium (Pentothal) for rapid induction
- Succinylcholine (Anectine) to achieve laryngeal relaxation for intubation
- Diazepam (Valium) to control seizures, a possible reaction to anesthetics
- Isoproterenol (Isuprel) to reduce bronchospasm, should aspiration occur

In addition to these medications, an adult laryngoscope, an endotracheal tube, a breathing bag with a source of 100% oxygen, and a suction catheter and suction source should be at hand.

## Aspiration of Vomitus

There is a danger of vomiting with a general anesthetic; this can be fatal if a woman's airway becomes occluded by foreign matter. In addition, stomach contents have an acid pH that can cause chemical pneumonitis and secondary infection of the respiratory tract.

Some anesthesiologists may prescribe IV ranitidine (Zantac) or an oral antacid such as sodium citrate to be given before general anesthesia is administered to reduce the level of acid in stomach contents should aspiration occur. Metoclopramide (Reglan) increases gastric emptying and may also be prescribed.

For general anesthesia administration, the woman is asked to lie on her back with a wedge under her left hip to displace the uterus from the vena cava. To reduce the occurrence of hypotension and to establish a line for emergency medications, IV fluid administration is begun. The woman is then given a rapid-induction IV agent, followed by intubation with a cuffed endotracheal tube.

The moments of induction of general anesthesia before the endotracheal tube is safely in place are critical ones for the anesthesiologist. Respect his or her need to concentrate by not talking until the task is achieved.

If aspiration of vomitus should occur following administration, prompt attention is essential. The anesthesiologist suctions the woman's trachea to remove as much foreign material as possible. The woman is intubated, if she was not previously, and given 100% oxygen. IV isoproterenol to reduce bronchospasm and a corticosteroid to reduce inflammation may be given. Positive-pressure ventilation may be initiated. Blood gas analysis and a chest X-ray usually are obtained to determine how much aeration the woman is still capable of achieving.

The woman may receive mechanical ventilation until her overall clinical condition improves, as shown by X-ray films and blood gas concentrations. She may be critically ill at the time of aspiration and, after the cesarean birth, often will be transferred to an intensive care unit for the special care she needs to survive this emergency.

### **QSEN Checkpoint Question 16.6**

#### **QUALITY IMPROVEMENT**

There is no reason to think Jonny will need a general anesthetic. But if she did, what type of drug would the nurse want to ensure is readily available on a birthing unit to help minimize the risk of aspiration of vomitus?

- a. An anticonvulsant such as diazepam (Valium)
- b. A nerve relaxant such as phenobarbital
- c. Metoclopramide (Reglan) to speed gastric emptying
- d. Oxytocin to increase the effectiveness of labor

*Look in [Appendix A](#) for the best answer and rationale.*

## **Nursing Diagnoses and Related Interventions**

**Nursing Diagnosis:** Anxiety related to more pain than expected from labor contractions

**Outcome Evaluation:** Patient identifies beginning and end of contractions, expresses confidence rather than confusion about ongoing process, states she feels less anxious, and is able to concentrate on controlled breathing.

In addition to causing local discomfort, pain can evoke a general stress response (fight-or-flight syndrome). This releases epinephrine, which causes peripheral and uterine vasoconstriction. This can increase the degree of pain experienced because of the resulting increase in tissue anoxia. Reducing anxiety through relaxation techniques such as spaced breathing exercises or through administration of medication to reduce anxiety can reduce vasoconstriction and help reduce pain.

**Reduce Anxiety With Explanations of the Labor Process.** Planning with women their options for pain relief during labor should begin prenatally (Box 16.6).

## BOX 16.6

### Nursing Care Planning to Empower a Family

#### PAIN RELIEF DURING LABOR

**Q.** Jonny tells you, “I know my friends have told me pain during labor would be horrible, but what can I do so I won’t hurt so much?”

**A.** Here are some common suggestions to help with pain relief:

- Ask your primary healthcare provider early in pregnancy about pain management options for labor. The options your care provider suggests may actually influence your decision as to whether this is the optimal care provider for you.
- Attend childbirth preparation classes during pregnancy and conscientiously practice breathing or other relaxation exercises. These measures can be adequate all by themselves; if not, they may complement pharmacologic methods of pain relief.
- Make a birth plan detailing what position you choose for labor and other options you want to use. This helps give you a greater sense of control in the face of pain.
- Be certain a support person will be with you during labor. Name a second person or investigate using a doula if you are uncertain whether your usual support person will be available or can fill this role.
- Late in pregnancy, if you are still concerned, let your primary healthcare provider know. In addition to medication for pain relief during labor, medication to reduce anxiety is also available.
- On admission to the hospital, let the medical and nursing staff know you are concerned so they can work with you to find satisfactory pain management.
- The most commonly used options today are oral, intramuscular, or intravenous administration of narcotics or injection of regional anesthesia by epidural block. Ask questions about any method suggested if necessary so you’re aware of action and side effects.

- Be aware the choice of receiving analgesia or anesthesia is yours. However, if a complication occurs, be ready to compromise in the interest of safety for yourself and your child.

During labor, use a standard method of pain assessment, such as asking a woman to rate her pain level on a scale of 1 to 10 or show her a paper with a line marked 1 to 10 if she's more visually oriented, so she can rate her pain. Based on her response, evaluate whether pain relief is adequate and effective.

Introduce natural methods based on the gate control theory of pain relief such as massage or imagery. Be sure to offer careful explanations of what is happening or what will happen during labor because this can help alleviate anxiety and thereby reduce some discomfort.

Be certain to explain the characteristics of contractions (e.g., labor contractions are rhythmic and come and go repeatedly) and reinstruct as necessary. Do not assume a woman is aware of this simply because she is experiencing the contractions. Her pain may be so intense and the intensity so unexpected that she is unaware of any relief between contractions ([Box 16.7](#)).

#### BOX 16.7

#### Nursing Care Planning Tips for Effective Communication

Jonny stated early in labor that she didn't want to use any medication for pain relief. As soon as her contractions became 30 seconds in length, however, she requested some analgesia. Her physician prescribed intramuscular butorphanol tartrate (Stadol). Her contractions are now 40 seconds in duration and only moderately strong. She looks increasingly uncomfortable with each contraction.

*Tip:* Ask the patient to rate her pain on a scale of 1 to 10 rather than just asking how she feels. Assess whether she has a clear understanding of the nature of labor contractions to make it easier for her to manage them. Because women in labor are under stress, they may not hear instructions when they are given.

**Nurse:** How are you feeling, Jonny? Is there anything I can do for you?

**Jonny:** I need something stronger for pain.

**Nurse:** On a scale of 1 to 10, with 1 being little pain and 10 being the worst pain ever, how would you rate the pain you're having?

**Jonny:** Two, but I know it'll be 10 in another half hour when my contractions get so strong that they're constant.

**Nurse:** I can assist you with relaxation techniques to lessen your discomfort. Contractions aren't constant and resting in-between contractions is helpful.

This on/off effect of labor contractions differentiates the pain from that of a

toothache or headache, which is continuous. Sometimes, just knowing this can help a woman tolerate the pain even as it increases in intensity.

Do not assume a woman knows such things like when membranes rupture it is painless, that a pink-stained show is normal, or that contractions change in character during labor. A woman having her first child may not know these things. A woman having her second child may not remember what her labor was like the last time, or she may find this time so different (even if it is well within usual limits) she is frightened by it. Be certain to give explanations to a woman's partner or support person as well because it's hard to support someone when you need support yourself. Unless the support person's anxiety and fear are relieved, he or she may start to convey anxiety back to the woman in labor rather than help her relax.

**Nursing Diagnosis:** Ineffective coping related to combination of uterine contractions and anxiety

**Outcome Evaluation** Patient demonstrates effective coping by expressing confidence in her ability to maintain active participation during labor, using continued breathing techniques, expressing the need to change position, and verbalizing confidence in healthcare providers.

*Help the Woman Identify Coping Strategies.* Because pain is not a new phenomenon for a woman of childbearing age, it can be helpful to ask her to recall methods she usually uses to combat pain or anxiety, such as meditation or applying a cool cloth. Associating labor pain with usual circumstances can go a long way toward helping her collect her resources and decide on a workable pain relief strategy. **Box 16.8** shows an interprofessional care map illustrating both nursing and team planning for helping reduce anxiety to manage discomfort during labor.

## BOX 16.8

### Nursing Care Planning

#### AN INTERPROFESSIONAL CARE MAP FOR A WOMAN REQUIRING COMFORT MEASURES DURING LABOR AND BIRTH

Jonny Baranca is a primipara in early labor whom you admit to a birthing unit. Her contractions are 7 minutes apart, and her cervix is 3 cm dilated. She tells you her sister had epidural anesthesia that completely obliterated her pain in labor for the birth of her baby 3 months ago. Based on her sister's experience, Jonny expected to be given epidural anesthesia as soon as she arrived at the hospital. As she is in early labor, her physician asked her to wait until she is 4 cm dilated. When you enter her room, you find her lying on her back in a birthing bed, crying from pain. Her husband shouts at you that his "wife deserves better care than this."

**Family Assessment:** Gravida 1, para 0; accompanied by husband who will act as support person and coach. Patient works as clerk in clothing store; husband is

physical education major at local university.

**Patient Assessment:** Contractions are of moderate intensity, every 6 to 7 minutes, with a duration of 35 seconds. Cervix dilated 3 cm, 80% effaced, –1 station. Membranes intact. Fetal heart rate (FHR), 148 beats/min; fetus in right occiput anterior (ROA) position. Attended childbirth education classes but did not practice breathing exercises. Last meal: 3 hours ago; last voided, 2 hours ago.

**Nursing Diagnosis:** Pain related to effects of uterine contractions and pressure on pelvic structures

**Outcome Criteria:** Patient confirms discomfort is controlled (pain is a 3 or less on a 1 to 10 pain scale) with either nonpharmacologic or pharmacologic methods; responds to questions and instructions; identifies need for additional pain relief measures if required.

Team Member Responsible	Assessment	Intervention	Rationale	Expected Outcome
<i>Activities of Daily Living, Including Safety</i>				
Nurse	Assess what birth plan the woman wants to follow. Inspect her suprapubic area and palpate for bladder distention.	Remind patient she does not need to remain in bed. Encourage her to void every 2 hours.	Ambulation can increase comfort and progress. A full bladder contributes to discomfort and may impede fetal descent, possibly prolonging labor.	Patient ambulates in early labor. Has no signs of bladder distention; voids every 2 hours during labor.
<i>Teamwork and Collaboration</i>				
Nurse/primary healthcare provider	Locate the on-call healthcare provider to provide anesthetic pain relief when patient reaches 4 cm dilation.	Notify nurse-anesthetist concerning patient's wish to receive an epidural block as soon as possible.	Respecting patient's wishes is a prime method of encouraging self-efficacy.	Pain management team supports patient's wish for pharmacologic intervention; encourages nonpharmacologic measures until epidural anesthetic is appropriate.

*Procedures/Medications for Quality Improvement*

Nurse	Assess how patient's husband views his role in labor. Assess if patient will try controlled breathing exercises learned in preparation for labor class.	Refresh controlled breathing and imagery with support of husband. Allow husband occasional breaks. Stay with the patient during this time to provide support.	A support person increases satisfaction with labor; controlled breathing and imagery can be learned during labor.	Support person helps patient with imagery and controlled breathing. Patient allows healthcare providers to substitute for husband so husband can take occasional breaks.
-------	---	---	---	--

*Nutrition*

Nurse	Determine what patient would like to eat or drink while in labor.	Provide patient with a beverage at least every hour; food as desired.	Fluid maintains hydration; ice chips or hard candy can relieve mouth dryness from breathing exercises.	Patient states she has no mouth discomfort from breathing; drinks fluid every hour.
-------	---	---	--	---

*Patient-Centered Care*

Nurse/nurse anesthetist	Assess if patient still desires epidural anesthesia for pain management.	Provide information on epidural anesthesia as needed; update the couple on labor progress.	Frequent updates on progress help alleviate anxiety and fears that may exacerbate pain.	Couple confirms they are certain epidural anesthesia is their method of choice; receive frequent updates on labor progress.
-------------------------	--	--	---	---

*Psychosocial/Spiritual/Emotional Needs*

Nurse	Assess level of patient's pain by verbal, pain scale, and nonverbal indicators. Use 1 to 10 scale and	Support patient in her ability to manage pain until her epidural can be given.	Praise can instill a sense of control and motivation to continue to use alternative	Patient rates her level of pain from labor contractions not above 3 on a 1 to 10 scale.
-------	---	--	---	---

	evaluate response to techniques used.		methods of pain control.	
Nurse	Assess what nonpharmacologic measures (such as music, touch, environmental calm) patient thinks would help complement epidural block and aid comfort.	Provide a comfortable environment: clean sheets, cool washcloth to forehead, closed room door. Refrain from intervening with patient during a contraction.	A comfortable environment aids in relaxation, promoting effective coping. Interrupting the patient's breathing can make the technique ineffective as a pain relief measure.	Patient reports she feels environment is comfortable and complements other pain relief measures.

---

*Informatics for Seamless Healthcare Planning*

---

Nurse	Ask patient and husband to evaluate their labor experience.	Review with patient pain relief measures used and determine which were most effective.	Reviewing a possibly traumatic experience helps to put it into perspective among life events.	Patient and support person state labor and birth were, at worst, a tolerable experience and, at best, a highlight of their lives.
-------	---	--	---	---

---

***Provide Comfort Measures.*** Usually, anyone can tolerate a little discomfort from a backache, being thirsty, having dry lips, or having a leg cramp. However, few people can tolerate having all of these discomforts simultaneously or feeling even one of them while experiencing a labor contraction.

Assist the woman's support person to provide the usual comfort measures that are helpful for anyone with pain, such as reassurance, massage, or a change in position. For dry lips, ice chips to suck on, moistening the lips with a wet cloth, or using a moisturizing jelly or balm can be helpful. A cool cloth to wipe perspiration from the forehead, neck, and chest can keep a woman from feeling overheated.

A woman's sheets and clothing may wrinkle rapidly and stick to her skin if she is perspiring. The waterproof pad under her buttocks will become soiled with vaginal

secretions and will begin to feel hot and sticky. Never apply sanitary pads in labor because, although they absorb vaginal secretions well, they also tend to slip out of place, possibly carrying pathogens from the rectal area forward to the vaginal opening. Instead, change waterproof pads frequently. At least halfway through the first stage of labor, or more frequently as indicated by the woman's condition, change her sheets, offer her a clean gown, and ask if she'd like to bathe or take a shower. These measures can help her feel clean and refreshed, with a ready-to-go-again feeling.

Think of comfort measures for the woman's support person as well. Is the chair by the side of the bed comfortable? Does he or she need to stretch or take a beverage or bathroom break? Could you serve as the coach while the support person makes some phone calls? Breaks such as these allow a partner to come back rested and ready to give support again.

**Nursing Diagnosis:** Pain related to labor contractions

**Outcome Evaluation:** Patient states pain is reduced to a tolerable level with techniques used so she is able to handle or "work with" contractions and demonstrates ability to listen and respond to questions and instructions.

***Assist the Woman With Prepared Childbirth Method.*** Depending on the type of childbirth preparation a woman and her support person have had, the method used may include breathing exercises, distraction by focusing on an external object, acupuncture, therapeutic touch, music therapy, guided imagery, self-hypnosis, or a combination of these methods. The use of biofeedback is not well documented in labor but may also be effective.

Even though a woman conscientiously practiced breathing or focusing in a relaxed, fun setting of an antepartal class, the discomfort and stress of labor may make it easy for her to forget what she learned. As necessary, review previously learned breathing techniques with her. Urge her to begin using these early in labor, before contractions become strong, so she gains confidence that they can be effective at diminishing pain. If a woman has had no prior training in breathing exercises, sit with her and teach her a simple breathing pattern, so she can begin to utilize this to relieve some of her pain.

Massage is another pain relief method that can be taught to a woman and her support person during labor. This may be especially useful if a woman is experiencing back pain because rubbing or massaging the sacral area often alleviates that. Firm massage on her shoulders can provide a relaxing distraction from the sensation of internal pressure and pain.

***Encourage Comfortable Positioning.*** An upright position, sitting, walking, or swaying with a partner may be most comfortable for a woman in early labor and aids contractions and descent through gravity (see [Chapter 15](#)). If a woman wants to walk and has no support person, walk with her as she may need support during a

contraction. Leaning forward against a birthing ball or pelvic rocking between contractions may relieve tense back muscles. If a woman must remain in bed because of a situation such as her membranes have ruptured and the fetal head is not engaged, urge her to keep active within the limits of bed rest and especially not to lie on her back to avoid supine hypotension syndrome. Move bedclothes or monitor leads, if any are attached, as needed to allow her to be able to turn and remain active.

Position changes during the second stage of labor help fetal descent and may shorten labor. Urge a woman to sit, stand, kneel on hands and knees, lie in a lateral recumbent position, squat, or use whatever position she prefers (see [Chapter 15](#)). Keep in mind that maintaining these positions often requires assistance from one or two support people to keep an unbalanced woman from falling.

***Provide Pharmacologic Pain Relief.*** Helping a woman decide if and when medication for pain relief should be used requires an in-depth understanding of the available drugs, their effects on the mother and the fetus, and their mechanism and duration of action. It also requires sympathetic listening and counseling skills. Many women come into labor wishing to avoid drugs entirely. Once in labor, they may change their minds but hesitate to say so, especially if their partners also believe a birth without the use of drugs is ideal. Other women come into labor asking to receive something immediately to avoid experiencing any pain. In both instances, provide information about the use of drugs and their ultimate effects. Maintain a supportive presence to help a woman make the best decision for herself and her baby. Some women require analgesia or anesthesia because of a complication. Helping these women and their support persons understand why the medication is necessary calls for equal care and skill. As a rule, record a baseline fetal heart rate and maternal blood pressure and pulse before administering medication; reassess 15 minutes later for fetal and maternal safety.

### *What If... 16.3*

**Jonny, who is still in early labor, tells the nurse if she can't have an epidural immediately, she wants a general anesthesia. If she can't have that, she will leave the hospital. Her physician has said she cannot justify a general anesthesia for uncomplicated labor. The nurse finds Jonny crying because her doctor won't give her anything for pain. How would the nurse handle this situation?**

## **The Woman With Unique Needs**

### **THE MORBIDLY OBESE WOMAN**

Morbidly obese women may have more difficulty using some nonpharmacologic

measures for pain relief than other women. For example, be certain a portable birthing tub (looks like a child's plastic pool) will be sturdy enough to support her weight as she leans against the side. Check to be certain the labor room shower is wide enough if she wishes to use warm water sprays for pain management. Remember, birthing beds are not very wide; be cautious when you ask her to turn that she has adequate space to do that. Straddling a chair and leaning against the back may be unsafe if the chair is not strong enough to support her weight.

Analgesic administration may also pose a problem as a usual dose may not be as effective in extremely obese women. Question doses for women who might need a larger amount so they can achieve pain relief. Anesthetic administration may also cause concern as it may be more difficult for an anesthetist to identify the L3–L4 intravertebral space for injection. Although women who are classified as obese do have higher risk of labor complications, they are also at greater risk for procedures such as induction of labor, resulting in cesarean birth (Kerrigan, Kingdon, & Cheyne, 2015).

## **THE WOMAN WITH CULTURAL CONCERNS**

Because of cultural traditions, some women are very opposed to the use of analgesia or anesthesia in labor. Be certain to respect this concern by aiding women in any way possible to use the methods they have chosen for pain control and to not interrupt distraction techniques such as controlled breathing, meditation, or chanting. Mark a nursing care plan as to the woman's preference so other team members don't suggest analgesia. Caution other team members as well to remain quiet while the baby is born if there is a special prayer a partner or the woman wants to say at this time (Goyal, 2016).

In many cultures, childbearing is a woman's field of expertise so male partners may have large gaps of knowledge about what is expected of them during birth. Be certain to explain the purpose of procedures and assist the partner to help with breathing exercises, warming hot pads, making tea, or other comfort measures if the partner wants to help in other ways.

If analgesia or anesthesia becomes necessary because of an unanticipated emergency, talk to the woman and her partner afterward to be certain they understand why the additional pain management method was necessary. Stress that the overriding aim of labor is a healthy mother and healthy baby; using analgesia or anesthesia or using none at all is only different means to achieve that end.

## **THE WOMAN WITH SUBSTANCE USE DISORDER**

The incidence of women who suffer from substance use disorder, and particularly opioid use is rising, so the number of women seen in labor with these concerns is also increasing. Include a question on the use of recreational and prescription drugs when history taking at a woman's admittance to a birthing center. Concern about their baby's health, the possibility of overdosing from an analgesic administered to them during labor, or their newborn acquiring neonatal abstinence syndrome from opioid withdrawal

all encourage women to answer a question about illicit drug use honestly. Women addicted to prescription drugs may not realize they are using more of a drug than is healthy for them or their fetus and so may not mention this unless asked directly.

If a woman states she uses illicit drugs, ask what drug she uses and when was the last time she used to prevent administering an analgesic overdose. Be certain the anesthetist who will administer a regional block has this same information. Marijuana is a drug frequently smoked at the beginning of labor by users because it offers such a relaxed feeling. There is little evidence that marijuana has immediate effects on a newborn, but it is important to be cautious because a marijuana user may also be a polysubstance user. A woman needs to alert her primary healthcare provider she used it as an alternative pain measure. Cocaine is also a frequent choice for women beginning labor because, again, it has such a euphoric effect. Cocaine use during pregnancy is associated with loosening of the placenta (placenta abruption) so a woman who has taken this drug needs to be observed closely for signs of poor fetal circulation, such as a decreasing heart rate ([Oliveira, Bersusa, dos Santos, et al., 2016](#)).

Women who consistently use opioids may not receive the same pain relief from an analgesic such as butorphanol tartrate (Stadol) as nonusers, so be prepared to suggest alternative measures of pain relief as well. Their newborn may need special care at birth as many newborns of consistent users are small for gestational age and need observation for opioid withdrawal or neonatal abstinence signs ([H. E. Jones, Deppen, Hudak, et al., 2015](#)).

Many women who are addicted to opioids are identified during pregnancy and prescribed methadone or buprenorphine to substitute for their drug of addiction. Methadone has the same effect on a newborn as all opioids, so it is equally important that these women identify themselves in labor so their newborn can be closely monitored. Although buprenorphine has similar effects on neonates as methadone, some studies show that there are fewer instances of neonatal abstinence syndrome ([Noormohammadi, Forinash, Yancey, et al., 2016](#)).

A typical prescription drug abused by women is hydrocodone-acetaminophen as this is frequently prescribed for chronic pain such as carpal tunnel syndrome or back pain. The half-life of this drug is about 2 hours in addicted women ([Kokki, Franco, Raatikainen, et al., 2012](#)). It appears to have little effect on newborns; however, because the compound contains an adult dosage of acetaminophen, the newborn needs to be observed for both withdrawal and liver effects.

## **THE WOMAN WHO USES TOBACCO**

Women who smoke cigarettes typically turn to them when they are stressed, so it may be very difficult for a tobacco user to go without a cigarette if her labor lasts more than 4 hours (and labor typically does). A woman needs to ask her primary healthcare provider if she could use nicotine gum or a patch during labor; nicotine is a pregnancy category C drug, so she needs to alert the team that she is a tobacco user as her infant may have a low birth weight and may need special care ([Mei-Dan, Walfisch, Weisz, et](#)

al., 2015). Women who use tobacco in pregnancy are at risk for having a neonate with low birth weight, very low birthweight, small for gestational age, preterm, and stillbirth (Inamdar, Croucher, Chokhandre, et al., 2015).

### *What If... 16.4*

**The nurse is particularly interested in exploring one of the 2020 National Health Goals with respect to analgesia in labor (see Box 16.1). What would be a possible research topic to explore pertinent to this goal that would be applicable to Jonny Baranca's family and that would also advance evidence-based practice?**

## **KEY POINTS FOR REVIEW**

- Pain in labor occurs because of anoxia to uterine cells, stretching of the cervix and perineum, and pressure of the presenting part of the fetus on maternal tissues.
- Each person perceives pain differently. Only a woman herself can describe the type or extent of her pain.
- Usually, the better prepared a woman is for childbirth and the more effective her support person is, the less there is a need for analgesia and anesthesia.
- Encourage complementary and alternative therapies such as reducing anxiety, providing changes in position, increasing knowledge, supporting prepared childbirth exercises, and prescribed analgesics or anesthesia as these help in planning/implementing nursing care that not only meets QSEN competencies but also best meets a family's total needs.
- Be certain to ask about allergies to medications before administering them. Women under stress from pain may be too concerned to mention this unless directly asked.
- Women may lose their ability to use controlled breathing after systemic opioid administration because of a light-headed feeling. They may need additional support during this time to be able to continue with a breathing technique until this feeling passes and the analgesic agent begins to have an effect.
- Regional anesthesia, such as epidural anesthesia, is extremely effective at relieving labor pain. Be certain the woman is well hydrated with IV fluid and her blood pressure is within normal limits before assisting with administration of the anesthetic agent.
- Remind all women to lie on their side or place a firm towel under their right hip while in labor to help avoid supine hypotension. During general anesthesia administration, if a woman must lie supine, position a wedge under her right buttock to help prevent hypotension. If hypotension should occur after epidural anesthesia administration, elevating a woman's legs and administering an antihypotensive agent such as ephedrine are emergency measures to help relieve hypotension.
- If an opioid analgesic is used, naloxone hydrochloride (Narcan) must be available to

use for possible newborn resuscitation.

- General anesthesia is not administered for an uncomplicated labor because it has risks for both the mother and the infant, but it may still be used in an emergency.

### CRITICAL THINKING CARE STUDY

Bailey is a 32-year-old gravida 1, para 0 woman in active labor. She is 6 cm dilated, 40% effaced, and having moderate- to strong-intensity contractions. She has brought some rock-and-roll music with her to play during labor. Her support person is her apartment roommate Cheryl rather than her boyfriend because he “hates hospitals.”

1. What is the chance an apartment roommate will make as good a support person in labor for Bailey as the father of her baby? Should she have insisted he come to be with her?
2. Bailey has brought music that is not at all relaxing. It is loud and boisterous. Should you suggest she play music you supply with sounds of the ocean to help her relax?
3. Bailey is using controlled breathing and you hear her roommate say “push” with each contraction as well. What additional information do you need to know if her support person is giving her good advice in labor?

## Nursing Care of a Postpartal Family

*As the nurse working on a postpartum unit, you care for Leana Cooper, who gave birth to a healthy 8-lb 2-oz baby girl 6 hours ago. She is on maternity leave from her job as a court reporter. Her husband, Mike, plans to take a week off from work to help take care of the baby.*

*Leana has not voided since she gave birth. Although her baby latches well, Leana is worried she's not getting enough breast milk. She tells you, "I haven't smoked in 9 months. Can't wait to go home so I can light up." Mike pulls you aside and says, "Sometimes, I see my wife crying for no reason. Why does she get so upset over little things? Isn't she as happy as I am?"*

*Previous chapters discussed caring for the pregnant woman and her family during the antepartal and intrapartal periods. This chapter adds information about caring for a postpartal woman and family. Nurses are able to play major roles in assessment, promotion of comfort, and education during this period as they help a new family adjust to the many physiologic and psychological changes that occur during this period.*

**What additional postpartal healthcare teaching does the Cooper family need?**

### KEY TERMS

**afterpains**  
**attachment**  
**bonding**  
**chloasma**  
**colostrum**  
**diastasis recti**  
**en face position**  
**engorgement**  
**engrossment**  
**Homans sign**  
**Kegel exercises**  
**lactogenesis**  
**letting-go phase**

**linea nigra**  
**lochia**  
**relaxin**  
**rooming-in**  
**striae gravidarum**  
**taking-hold phase**  
**taking-in phase**  
**uterine atony**

## OBJECTIVES

**After mastering the contents of this chapter, you should be able to:**

1. Describe the psychological and physiologic changes that occur in a postpartal woman and her family.
2. Identify 2020 National Health Goals related to the postpartal period that nurses can help the nation achieve.
3. Assess the physiologic and psychological changes of the postpartal woman and her family.
4. Formulate nursing diagnoses related to physiologic and psychological transitions of the postpartal period.
5. Develop expected outcomes for a postpartal woman and family related to the changes during this period as well as manage seamless transitions across differing healthcare settings.
6. Using the nursing process, plan nursing care that includes the six competencies of Quality & Safety Education for Nurses (QSEN): Patient-Centered Care, Teamwork & Collaboration, Evidence-Based Practice (EBP), Quality Improvement (QI), Safety, and Informatics.
7. Implement nursing care to aid the progression of physiologic and psychological transitions occurring in a postpartal woman and family.
8. Evaluate outcome criteria for achievement and effectiveness of care.
9. Integrate knowledge of postpartal women and families with the interplay of nursing process, the six competencies of QSEN, and Family Nursing to promote quality maternal and child health nursing care.

---

The postpartal period, or *puerperium* (from the Latin *puer*, for “child,” and *parere*, for “to bring forth”), refers to the 6-week period after childbirth. It is a time of maternal changes that are both retrogressive (involution of the uterus and vagina) and progressive (production of milk for lactation, restoration of the normal menstrual cycle, and beginning of a parenting role). Protecting a woman’s health as these changes occur is important for preserving her future childbearing function and for ensuring she is

physically well enough to incorporate her new child into her family (Souza, Gülmezoglu, Vogel, et al., 2013). The period is often termed the *fourth trimester of pregnancy*.

The physical care a woman receives during the postpartal period can influence her future health. The physical care of the postpartum mother involves providing comfort and relief from any discomfort from delivery, such as the use of sitz baths and cool compresses to soothe the perineal area. Mothers may often experience temporary difficulty in passing stool in the early postpartum period. This can be addressed with the use of stool softeners and encouraging fluid intake and a high-fiber diet. The emotional support she receives can influence the emotional health of her child and family so much that it can be felt into the next generation (Newton, 2012). Box 17.1 shows 2020 National Health Goals related to the postpartal period that nurses can help the nation achieve.

### BOX 17.1

#### Nursing Care Planning Based on 2020 National Health Goals

The postpartal period is an extremely important one because of the possibility of uterine hemorrhage and because it is the optimal period for parent–child bonding. The 2020 National Health Goals that involve this time period include:

- Reduce the maternal mortality rate to no more than 11.4/100,000 live births from a baseline of 12.7/100,000.
- Increase to at least 82% the proportion of mothers who breastfeed their babies in the early postpartum period from a baseline of 74% and increase the proportion of mothers who still breastfeed at 6 months to 60.6% from a baseline of 43.5%.
- Increase the proportion of worksite lactation support programs to 38% from a baseline of 25%.
- Reduce the proportion of breastfed newborns who receive supplemental formula in the first 2 days from 24% to 14%.
- Increase the proportion of live births that occur in facilities that provide care for lactating mothers and their babies from 2.9% to 8.1%.
- Reduce postpartum relapse of smoking among women who quit smoking during pregnancy (developmental).
- Increase the proportion of women who used contraception to plan their pregnancy (developmental) (U.S. Department of Health and Human Services, 2010; see [www.healthypeople.gov](http://www.healthypeople.gov)).

Nurses can help the nation achieve these goals by maintaining close observation in the immediate postpartal period to detect maternal hemorrhage, encouraging and supporting women as they begin breastfeeding, and ensuring women receive reproductive life planning information if desired.

## FOR A POSTPARTAL WOMAN AND FAMILY

### ASSESSMENT

During the puerperium, assessment of a woman is accomplished by health interview; awareness of her prenatal, natal, and medical history; physical examination; and analysis of laboratory data. It is important to ensure that physical changes, such as uterine involution, are occurring by evaluating uterine size and consistency and the amount of lochia flow.

Assessment of a woman's psychological adjustment begins with her reaction to her baby at birth (Was she disappointed or happy with the appearance of her baby? Is she glad to be through with the pregnancy or still longing to be back in it?) and continues with every contact made with the family during and after a hospital stay. Assess the extent and quality of the woman's interaction with her child (Does she hold and talk to the infant?), her overall mood (Do you observe her crying? Does she have long periods of staring into space or not talking?), and her ability to begin infant care and self-care. A woman who feels good about herself, even though she is exhausted from childbirth, usually will try to maintain her appearance. If she is depressed, however, she probably has little energy to do things such as comb her hair or worry about her appearance and may not want to interact with her newborn.

### NURSING DIAGNOSIS

Nursing diagnoses during the postpartal period are often "risk for" diagnoses and concerned with a family's ability to accept and bond with a new child or with physiologic considerations. Examples include:

- Health-seeking behaviors related to care of newborn
- Fear related to lack of preparation for child care
- Risk for deficient fluid volume related to postpartal hemorrhage
- Risk for altered family coping related to an additional family member
- Risk for complications in human lactation/breastfeeding
- Uncertainty regarding the infant's well-being if there are congenital anomalies

### OUTCOME IDENTIFICATION AND PLANNING

Be certain that outcomes established during this time are realistic in light of a woman's changed life pattern, support from family, and cultural preferences. Most postpartal families remain in the hospital for a relatively short time, only 48 to 72 hours. The postpartum stay in an alternative birth center can be as short as 4 hours. That means outcomes must be devised that can be accomplished and evaluated during this short period of patient contact. If an outcome cannot be evaluated within this short time frame, follow-up home care, ambulatory visits, or phone calls may be necessary.

When planning care in the postpartal period, try to arrange procedures to allow optimal time for family–infant interaction and yet provide adequate time for a woman to rest to prevent exhaustion because this can improve her coping ability and plans

for self-care. Nurses can become active in promoting and incorporating the Ten Steps for a Baby-Friendly Initiative strategies (Box 17.2) postpartum to promote breastfeeding and infant-maternal bonding, such as immediate skin-to-skin contact after birth and rooming-in of mom and baby (Baby-Friendly USA, n.d.).

## BOX 17.2

### U.S. Baby Friendly Hospital Initiative *Baby-Friendly Ten Steps*

1. Have a written breastfeeding policy that is routinely communicated to all health care staff.
2. Train all health care staff in the skills necessary to implement this policy.
3. Inform all pregnant women about the benefits and management of breastfeeding.
4. Help mothers initiate breastfeeding within one hour of birth.
5. Show mothers how to breastfeed and how to maintain lactation, even if they are separated from their infants.
6. Give newborn infants no food or drink other than breast-milk, unless medically indicated.
7. Practice “rooming in”—allow mothers and infants to remain together 24 hours a day.
8. Encourage breastfeeding on demand.
9. Give no pacifiers or artificial nipples to breastfeeding infants.
10. Foster the establishment of breastfeeding support groups and refer mothers to them on discharge from the hospital or birth center.

Reprinted with permission from Baby-Friendly USA. (n.d.). *Ten steps to successful breastfeeding*. Retrieved from <http://www.babyfriendlyusa.org/about-us/baby-friendly-hospital-initiative/the-ten-steps>

After adequate instruction and assurance that mom and baby are healthy, a woman should be prepared to monitor her own health after she returns home.

Planning should also include ample time for health teaching such as care of the newborn and the need for flexibility in care because the parents do not yet know what their new life will be like or how tired they will become after being awakened frequently during the night. Brainstorming with the parents—practicing to produce at least three different methods of reaching a particular goal—is excellent practice for parenting because giving advice only solves an immediate problem; helping parents learn good problem-solving techniques improves their ability to handle the many challenges that will arise with childrearing. Refer patients and their partners to helpful websites and other resources when appropriate (see Chapter 9).

### **IMPLEMENTATION**

All interventions in the postpartal period should be family-centered, to enhance family functioning and bonding, and geared toward increasing a woman’s self-esteem, allowing her to view herself as a new mother and helping her view her new

infant as part of her family.

### **OUTCOME EVALUATION**

If a woman fails to make an adequate adjustment to her new life changes, she may have difficulty integrating an infant into the family. This could affect a child's physical and mental health, self-esteem, and ability to form a sense of trust.

Evaluation in the postpartal period, then, involves not only being certain a woman and her baby are safe but also that the woman knows how to maintain her own and her infant's health. Such follow-up evaluation can be done by telephone, during home visits, or during postpartal and well-child assessments. Examples of expected outcomes include:

- The parents spontaneously verbalize at least one positive comment about their child's characteristics before hospital discharge.
- The patient states she believes she will be able to manage newborn care with the support of her significant other.
- The patient's lochial flow is no more than one saturated perineal pad (50 ml) every 3 hours.
- The patient states she is tired but feels able to manage her newborn and family care.
- Physical interaction and holding of the infant appears appropriate and responsive to the infant's needs.

## **Psychological Changes of the Postpartal Period**

The postpartum period is a time of transition, during which a couple gives up concepts such as "childless" or "parents of one" and moves to not only trying out their new role but also determining whether they "fit" their new role. Nurses can help couples acknowledge the extent of the change so that they can gain closure on their previous lifestyle. Opening channels for communication, anticipating new needs, and highlighting potential gains that will occur because of the change are important actions.

### **BEHAVIORAL ADJUSTMENT: PHASES OF THE PUERPERIUM**

In her classic work on maternal behavior, Reva Rubin, a nurse, divided the puerperium into three separate phases (Rubin, 1984). The first of these is the **taking-in phase**, or the time when the new parents review their pregnancy and the labor and birth. The subsequent phases, called the taking-hold and letting-go phases, are times of renewed action and forward movement. At the time these phases of the puerperium were identified, women were hospitalized for 5 to 7 days after childbirth and moved in a paced manner from one step to the next. Today, with a stay in a healthcare facility as short as a few hours, women appear to move through these phases much more quickly and may even experience two different phases at once.

## Taking-In Phase

The taking-in phase is largely a time of reflection. During this 1- to 3-day period, a woman is largely passive. She prefers having a nurse attend to her needs and make decisions for her rather than do these things herself. This dependence results partly from her physical discomfort because of afterpains or hemorrhoids, partly from her uncertainty in caring for her newborn, and partly from the exhaustion that follows childbirth.

As part of thinking and pondering about her new role, the woman usually wants to talk about her pregnancy, especially about her labor and birth. She holds her new child with a sense of wonder and asks: Is birth really over? Could this child really have been inside me? She wants to rest to regain her physical strength and experience a calm atmosphere around her to quiet and contain her swirling thoughts. Encouraging her to talk about the birth is an important way to help her integrate the experience into her total life experiences (Box 17.3).

### BOX 17.3

#### Nursing Care Planning Tips for Effective Communication

Leana Cooper gave birth to a boy 6 hours ago. You want to assess her for postpartal pain, so you enter her hospital room. She is wearing a hospital gown and sitting in the chair by her bed.

*Tip:* Use therapeutic communication that encourages women to elaborate on their story and avoid any communication that discourages storytelling. Most women are interested in discussing their labor and birth experience in the days immediately after birth as a part of a “taking-in” phase. Repeating the story of how worried they were when labor started, how much pain they had, or how scared they were when their membranes broke helps them put these sensations into perspective and integrate them into their life experiences. Once you have talked about what concerns them most, they’ll then be more able to discuss and assess their pain.

**Nurse:** How are you feeling, Mrs. Cooper?

**Mrs. Cooper:** Like I’m still rushing around. I called my husband as soon as my water broke. He hit a truck on the way home, though, and afterward, his car wouldn’t start. I tried to call—

**Nurse:** Do you have any pain?

**Mrs. Cooper:** Just some afterpain. Next, I tried to call my mother, but she couldn’t come over because she didn’t have a car. My neighbor—

**Nurse:** Go on.

**Mrs. Cooper:** He said he’d drive me but then discovered his wife had his car keys.

**Nurse:** Keep going. It sounds as if you have a lot to get off your mind. Can I do anything to assist or help?

**Mrs. Cooper:** The whole thing was terrifying. I can't believe I didn't have my baby in the middle of the freeway!

If the birth experience did not go as planned, such as a surprise cesarean delivery or the infant needing specialized care in the neonatal intensive care unit (NICU), encourage the mother to express her feelings regarding the difference from the anticipated birth plan. Being able to acknowledge and articulate her feelings that her preconceived birth plan did not occur as intended is a healthy way to release any negative emotions. Discuss with the mother the possible medical reasons why the birth was different than expected. The birth plan often changes to ensure the safety of the newborn and mother. This will help the mother absorb the new reality and be able to understand the importance of the need to make the necessary changes at birth for her own health and the health of her newborn.

### **Taking-Hold Phase**

After a time of passive dependence, a woman begins to initiate action (the **taking-hold phase**). She prefers to get her own washcloth or to make her own decisions. Women who give birth without any anesthesia may reach this second phase in a matter of hours after birth.

#### *Concept Mastery Alert*

Taking-hold is a time of initiation of action and greater independence as evidenced by performing self-care.

During the taking-in period, a woman may have been too tired to care for her child. Now, she begins to take a stronger interest in her infant and begins maternal role behaviors. As a rule, it is usually best to give a woman a brief demonstration of baby care and then allow her to care for her child herself—with watchful guidance—as she enters this phase.

Although a woman's actions suggest greater independence during this time, she often still feels insecure about her ability to care for her new child. She needs praise for the things she does well, such as supporting the baby's head or beginning breastfeeding, to give her confidence. This positive reinforcement begins in the healthcare facility and continues after discharge, at home and at postpartum and well-baby visits.

Do not rush a woman through the phase of taking-in or prevent her from taking hold when she reaches this point. For many young mothers, learning to make decisions about their child's welfare is one of the most difficult phases of motherhood. It helps if a woman has practice in making such decisions in a sheltered setting, such as a hospital, rather than first taking on that level of responsibility after she is home alone. First-time mothers may need additional guidance and time during this phase compared to multigravida moms, but not always, as in the case of a multigravida mom who is

learning to care for twins.

### Letting-Go Phase

In this third phase (the **letting-go phase**), a woman finally redefines her new role. She gives up the fantasized image of her child and accepts the real one; she gives up her old role of being childless or the mother of only one or two (or however many children she had before this birth). This process requires some grief work and readjustment of relationships, similar to what occurred during pregnancy. It is extended and continues during the child's growing years. A woman who has reached this phase is well into her new role ([Box 17.4](#)).

BOX 17.4

#### Nursing Care Planning to Respect Cultural Diversity

In the United States, the postpartal period is generally regarded as a time of wellness; early ambulation and eating a varied diet are encouraged. In other cultures, the period after childbirth is regarded primarily as a time of rest. Cultural differences include restricting certain foods, reducing activity levels, or both; taboos and rituals to guard the health of the baby are not uncommon. Assessing women in the postpartal period for cultural variations of these types is important because such variation can explain why a woman might be reluctant to ambulate or why she leaves a lunch uneaten although she said she was hungry.

#### *QSEN Checkpoint Question 17.1*

##### **PATIENT-CENTERED CARE**

Leana Cooper has expressed that she is excited to “get to know” her new baby. The nurse determines which of the following actions will support Leana’s transition into a postpartal taking-hold phase?

- Tell her that she did well in labor and that it was “all worth it.”
- Encourage her to take as much time as she needs to recover from her labor.
- Help her to give her new baby a bath.
- Encourage her and her husband to choose their baby’s name as soon as possible.

*Look in [Appendix A](#) for the best answer and rationale.*

### **DEVELOPMENT OF PARENTAL ATTACHMENT, BONDING, AND POSITIVE FAMILY RELATIONSHIPS**

During pregnancy, almost every woman worries about her ability to be a “good” mother, and this concern does not evaporate as soon as the baby is born. Some women are able to recognize a newborn’s needs immediately and to give care with confident

understanding right from the start. More often, however, a woman enters into a relationship with her newborn tentatively and with qualms and conflicts that must be addressed before the relationship can be meaningful. Another factor is the infant's inherent personality. Some infants are calm and others are easily excitable. Learning the infant's cues and personality takes time and patience. This is because parental love is only partly instinctive. A major portion develops gradually, in stages such as planning the pregnancy, hearing the pregnancy confirmed, feeling the child move in utero, birthing, touching the baby, and, finally, giving total care to the child.

When a woman has successfully linked with her newborn, it is termed **attachment** or **bonding**. Although a woman carried the child inside her for 9 months, she often approaches her newborn not as someone she loves but more as she would approach a stranger. The first time she holds the infant, she may touch only the blanket. If she unfolds the blanket to examine the baby or count the fingers or toes, she may use only her fingertips for touch (Fig. 17.1). Skin-to-skin contact soon after birth facilitates the early attachment and binding phase. This should ideally occur within the first hour of any birth, even cesarean deliveries, as soon as the mother and baby are stable and last until completion of the first breastfeeding (Moore, Bergman, Anderson, et al., 2016).

**Figure 17.1** A mom and dad begin interaction with their newborn immediately after birth: a very special moment in their life. (© Kathy Sloane.)

Gradually, as a woman holds her child more, she begins to express more warmth, touching the child with the palm of her hand rather than with her fingertips. She smooths the baby's hair, brushes a cheek, plays with toes, and lets the baby's fingers clasp hers. Soon, she feels comfortable enough to press her cheek against the baby's or kiss the infant's nose; she has successfully bonded or become a mother tending to her child. Looking directly at her newborn's face, with direct eye contact (termed an **en face**

**position**), is a sign a woman is beginning effective attachment. Many fathers can be observed staring at a newborn for long intervals in this same way. Often termed **engrossment**, this action alerts caregivers to how actively the father, as well as the mother, is beginning bonding (Fig. 17.2). The length of time parents take to bond with a child depends on the circumstances of the pregnancy and birth, the wellness and ability of the child to meet the parents' expectations, reciprocal actions by the newborn, and the opportunities the parents have to interact with the child. When pregnancy or newborn complications lead to separation of the mother from her newborn, it places the woman at greater risk for developing posttraumatic stress disorder and interferes with the usual process of bonding (Dale-Hewitt, Slade, Wright, et al., 2012). Guided, supportive interactions, such as pointing out positive parental behaviors and infant responses, enhance positive parent–infant interaction. Helping parents sort out their feelings about being a mother or father and about their new responsibilities through anticipatory guidance also strengthens parent–infant bonding. Facilitating early skin-to-skin bonding between infant and mother has shown to improve breastfeeding durations and outcomes and the emotional stability of both infant and mother (Moore et al., 2016).

### **QSEN Checkpoint Question 17.2**

#### **QUALITY IMPROVEMENT**

The nurse observes Leana Cooper holding her newborn. Which position would best reassure the nurse that interventions aimed at promoting bonding have been successful?

- a. She looks directly at her infant's face and talks to him.
- b. She holds the infant over her shoulder and gently burps him.
- c. She sits in a rocking chair and slowly rocks her new infant.
- d. She lies in bed and places the infant on her stomach.

## Rooming-In

The more time a woman has to spend with her baby, the sooner she can become better acquainted with her child, feel more confident in her ability to care for her baby, and more likely form a sound mother–child relationship (Elliott-Carter & Harper, 2012). In order to qualify as “baby friendly,” a hospital must provide “**rooming-in**,” or space to keep the infant with the parents (Smith, Moorem, & Peters, 2012).

Rooming-in occurs when the infant remains in the woman’s room and the mother and child are together 23 out of 24 hours a day. With both complete and partial rooming-in (infant spends time in newborn nursery), the father and siblings can hold the infant when they visit. In many settings, the father can stay overnight in the mother’s room.

## Sibling Visitation

Separation from children is often as painful for a mother as it is for her children. Waiting at home, separated from their mother and listening only to telephone reports of what a new brother or sister looks like, can be very difficult for older children. They may picture the new baby as much older than he or she actually is. “He is eating well” may produce an image of a child sitting at a table using a fork and spoon. “He weighs 8 pounds” can be meaningless information. A chance to visit the hospital and see the new baby and their mother reduces feelings that their mother cares more about the new baby than about them. The visit can help to relieve some of the impact of separation and also help to make the baby a part of the family (Fig. 17.3). Assess to be certain siblings are free of contagious diseases such as upper respiratory tract illnesses or recent exposure to chickenpox before they visit. Then, have them wash their hands and, if they choose, hold or touch the newborn with parental assistance.

**Figure 17.3** Sibling visiting is important to bring a family together.

Encourage the success of a family visit by evaluating if the mother would like to take her pain medication before the visit. If she had a cesarean delivery, protecting her abdomen with padding can decrease anxiety of the siblings about the condition of their mother.

You may need to caution a woman that the opinions of a new brother or sister expressed by her older children may not be complimentary; for example, this baby with little hair may not be their idea of a “pretty baby.” If they thought the new baby would be big enough to play with, they may not agree that he is a “big baby.”

## **MATERNAL CONCERNS AND FEELINGS IN THE POSTPARTAL PERIOD**

Traditionally, it is assumed the bulk of a woman’s concerns in the postpartal period center on the care of her new infant. As a result, classes in the postpartal period have traditionally focused on teaching how to breastfeed and bathe infants. Many women, however, are not as concerned about infant care as they are about their adjustment to a new role change.

Typical issues identified by postpartal women that they would like to hear discussed are breast soreness; regaining their figure; regulating the demands of a job, housework, their partner, and their children; coping with emotional tension and sibling jealousy; and how to combat fatigue.

### **Abandonment**

Many mothers, if given the opportunity, admit to feeling abandoned and less important after giving birth than they did during pregnancy or labor. Only hours before, after all, they were the center of attention, with everyone asking about their health and well-being. Now, suddenly, the baby is everyone's chief interest. Relatives ask about the baby's health; the gifts are all for the baby. Even a woman's primary healthcare provider, who has made her feel so important for the last 9 months, may ask during a visit, "How's that healthy 8-pound boy?" Comments such as this can make a woman experience a sensation very close to jealousy. And how can a good mother be jealous of her own baby?

You can help a woman move past these feelings by verbalizing the problem: "How things have changed! Everyone's asking about the baby today and not about you, aren't they?" These are reassuring words for a woman and help her realize that, although uncomfortable, the feeling she is experiencing is normal.

When a newborn comes home, a father or partner may express much the same feelings as he or she feels resentful of the time the mother spends with the infant. Examination of these competitive feelings can help a couple realize that parenthood involves some compromise in favor of the baby's interests. Making infant care a shared responsibility can help alleviate these feelings and make both partners feel equally involved in the baby's care. You can help parents or partners move past this competitive stage by pointing out positive parenting behaviors, positive self-care behaviors, and the warm infant response to their behaviors.

### **Disappointment**

Another common feeling parents or partners may experience is disappointment in the baby. All during pregnancy, they pictured a chubby-cheeked, curly-haired, smiling girl or boy. They may have instead a thinner baby, without any hair, who seems to cry constantly, or may have a congenital condition. This can make it difficult to feel positive immediately toward a child who does not meet their expectations. It can cause parents to remember their adolescence, when they felt gangly and unattractive, or to experience feelings of inadequacy all over again.

You can never change the sex, size, or look of a child, but in the short time you care for a postpartal family, it is possible for a key person such as a nurse to tip a scale toward acceptance or at least help a person involved to take a clearer look at his or her situation and begin to cope with the new circumstances. As an example, handle the child warmly, to show you find the infant satisfactory or even special. Comment on the child's good points, such as long fingers, lovely eyes, and healthy appetite. Be aware, however, that, culturally, some groups are fearful for the baby if these types of comments are made because they could draw evil influences toward the child.

### **Postpartal Blues**

During the postpartal period, as many as 50% of women experience some feelings of

overwhelming sadness or “baby blues” (Baselice & Lawson, 2012). They may burst into tears easily or feel let down and irritable. This phenomenon may be caused by hormonal changes, particularly the decrease in estrogen and progesterone that occurred with delivery of the placenta. Breastfeeding has been shown to help elevate baby blues and counteract the effects of the hormonal drop that occurs after childbirth. For some women, it may be a response to dependence and low self-esteem caused by exhaustion, being away from home, physical discomfort, and the tension engendered by assuming a new role, especially if a woman is not receiving support from her partner. In addition to crying, the syndrome is evidenced by feelings of inadequacy, mood lability, anorexia, and sleep disturbance.

Anticipatory guidance and individualized support from healthcare personnel are important to help the parents understand that this unexpected response is normal. Be certain support persons also receive assurance of this type, or they can think the woman is unhappy with them or the new baby or is keeping some terrible news about the baby secret.

Give the woman a chance to verbalize her feelings and make as many decisions as she wants to help her gain a sense of control and move past this strange postpartal emotion.

Remember, however, not all postpartal women you see crying are doing so because they have baby blues. Perhaps problems at home have become overwhelming. A partner may have been laid off from a job just at this time when they most need money. One of her parents may be ill, or her house may have been damaged by a disaster such as a flood. Encouraging women to talk about their postpartal feelings helps to differentiate between problems that can be handled best with discussion and concerned understanding and those that should be referred to a social service department or a community health agency for additional support.

Women are at greater risk (19% to 48%) for moderate to severe depression after childbirth requiring formal counseling, especially if they are economically stressed or have a comorbid condition such as diabetes (Farr, Dietz, Williams, et al., 2011). Severe psychosis also can occur in women during this time (Heron, Gilbert, Dolman, et al., 2012). Because these are deeper level concerns, postpartal depression beyond the scope of “baby blues” and psychosis are discussed in Chapter 25. If a mother appears to have a level of depression that is beyond baby blues and/or has a history of previous postpartal depression (PPD), closer observation and referral is indicated immediately.

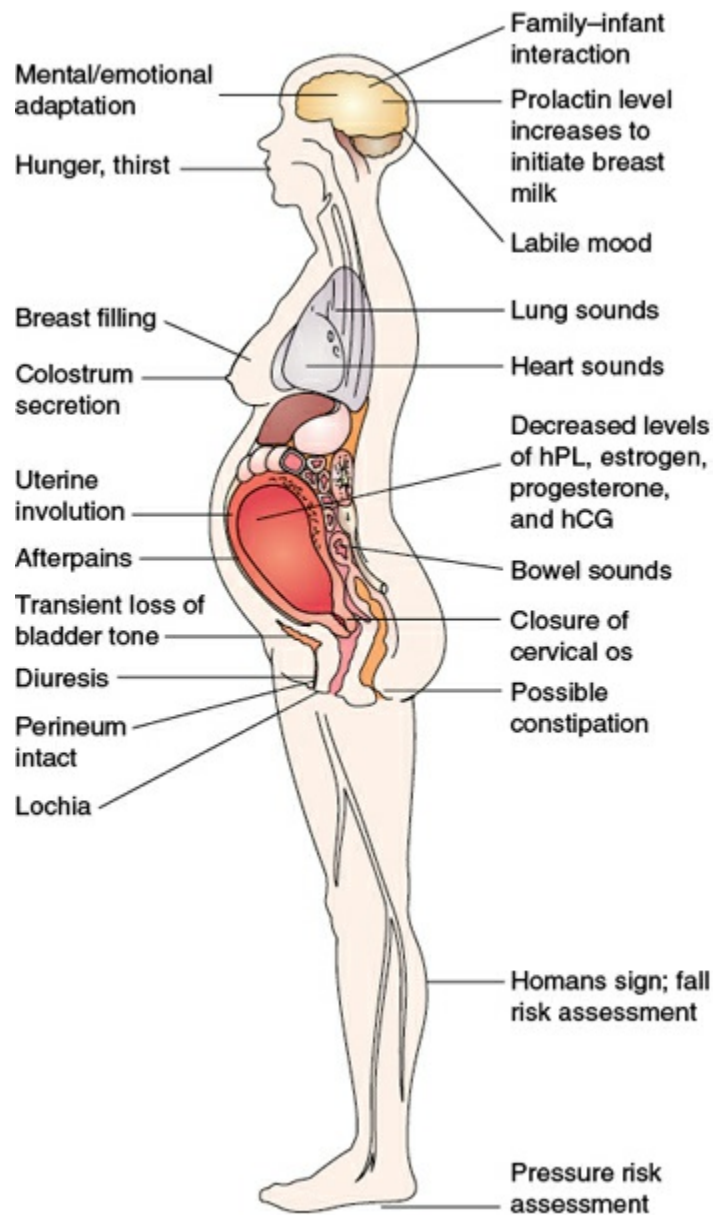

## Physiologic Changes of the Postpartal Period

Retrogressive physiologic changes that occur during the postpartal period include those related specifically to the reproductive system as well as other systemic changes (Box 17.5).

### BOX 17.5

**ASSESSING THE POSTPARTAL WOMAN**

**REPRODUCTIVE SYSTEM CHANGES**

Involution is the process whereby the reproductive organs return to their nonpregnant state. A woman is in danger of hemorrhage from the denuded surface of the uterus until involution is complete (Katz, 2012).

**The Uterus**

Involution of the uterus involves two processes. First, the area where the placenta was implanted is sealed off to prevent bleeding. Second, the organ is reduced to its

approximate pregestational size.

The sealing of the placenta site is accomplished by rapid contraction of the uterus immediately after delivery of the placenta. This contraction pinches the blood vessels entering the 7-cm-wide area left denuded by the placenta and halts bleeding. With time, thrombi form within the uterine sinuses and permanently seal the area. Eventually, endometrial tissue undermines the site and obliterates the organized thrombi, covering and healing the area so completely the process leaves no scar tissue within the uterus so does not compromise future implantation sites.

The same contraction process reduces the bulk of the uterus. Devoid of the placenta and the membranes, the walls of the uterus thicken and contract, gradually reducing the uterus from a container large enough to hold a full-term fetus to one the size of a grapefruit, a phenomenon that can be compared with a rubber band that has been stretched for many months and now is regaining its normal contour. None of the rubber band is destroyed; the shape is simply altered. For this reason, the postpartal period, like pregnancy, is not a period of illness, of necrosing cells being evacuated, but primarily a period of healthy change (Edmonds, 2012).

Immediately after birth, the uterus weighs about 1,000 g. At the end of the first week, it weighs 500 g. By the time involution is complete (6 weeks), it weighs approximately 50 g, similar to its prepregnancy weight. Because uterine contraction begins immediately after placental delivery, the fundus of the uterus is palpable through the abdominal wall, halfway between the umbilicus and the symphysis pubis, within a few minutes after birth. One hour later, it will rise to the level of the umbilicus, where it remains for approximately the next 24 hours. From then on, it decreases by one fingerbreadth, or 1 cm, per day; for example, on the first postpartal day, it will be palpable 1 cm below the umbilicus. In the average woman, by the ninth or tenth day, the uterus will have contracted so much that it is withdrawn into the pelvis and can no longer be detected by abdominal palpation (Fig. 17.4).

**Figure 17.4** Uterine involution. The uterus decreases in size at a predictable rate during the postpartal period. After 10 days, it recedes under the pubic bone and is no longer palpable.

The uterus of a breastfeeding mother may contract even more quickly because oxytocin, which is released with breastfeeding, stimulates uterine contractions. Breastfeeding alone, however, is not sufficient to protect against postpartum hemorrhage.

The fundus is normally located in the midline of the abdomen. Occasionally, it can be felt slightly to the right because the bulk of the sigmoid colon forced it to that side during pregnancy and it tends to remain in that position. Assess fundal height shortly after a woman has emptied her bladder for most accurate results because a full bladder can keep the uterus from contracting, pushing it upward and increasing the risk of excess bleeding and blood clot formation in the uterus.

Involution will occur most dependably in a woman who is well nourished and who ambulates early after birth as gravity may play a role. Involution may be delayed by a condition such as the birth of multiple fetuses, hydramnios, exhaustion from prolonged labor, grand multiparity, or physiologic effects of excessive analgesia. Contraction may be ineffective if there is retained placenta or membranes ([Samanta, Roy, Mistri, et al., 2013](#)).

An estimation of the consistency of the postpartal uterus is as important as measurement of its height. A well-contracted fundus feels so firm it can be compared with a grapefruit in both size and tenseness. Whenever the fundus feels boggy (soft or

flabby), it is not as contracted as it should be, despite its position in the abdomen.

The first hour after birth is potentially the most dangerous time for a woman. If her uterus should become relaxed during this time (**uterine atony**), she will lose blood very rapidly because no permanent thrombi have yet formed at the placental site.

In some women, contraction of the uterus after birth causes intermittent cramping termed **afterpains**, similar to that accompanying a menstrual period. Afterpains tend to be noticed most by multiparas than by primiparas and by women who have given birth to large babies or multiple births. In these situations, the uterus must contract more forcefully to regain its prepregnancy size. These sensations are noticed most intensely with breastfeeding, when the infant's sucking causes a release of oxytocin from the posterior pituitary, increasing the strength of the contractions.

## Lochia

The separation of the placenta and membranes occurs in the spongy layer or outer portion of the decidua basalis of the uterus. By the second day after birth, the layer of decidua remaining under the placental site (an area 7 cm wide) and throughout the uterus differentiates into two distinct layers. The inner layer attached to the muscular wall of the uterus remains, serving as the foundation from which a new layer of endometrium will be formed. The layer adjacent to the uterine cavity becomes necrotic and is cast off as a vaginal discharge similar to a menstrual flow. This flow, consisting of blood, fragments of decidua, white blood cells, mucus, and some bacteria, is termed **lochia** (Chi, Bapir, Lee, et al., 2010).

The portion of the uterus where the placenta was not attached is so fully cleansed by this sloughing process it will be in a reproductive state in about 3 weeks' time; it takes approximately 6 weeks (the entire postpartal period) for the placental implantation site to be healed.
